5694. What wood is used chiefly for brown malt?—  
 Hazelwood, ordinary faggots kept for some time.

5695. Are any woods excluded?—No.

5696. When you say hazelwood you mean merely  
 ordinary underwood, faggotted?—Yes, it is a different  
 class of malt altogether.

5697. (Chairman.) And the beer has a different class  
 of flavour?—Absolutely. I do not know of any way  
 of drying pale malt with wood.

5698. (Sir William Church.) I am wanting to see  
 whether the flavour of brown malt is added by the  
 fuel or by the methods in which the malt is made?—  
 No, by the fuel solely.

5699. The flavour of it is produced by the fuel?—  
 Certainly.

5700. Therefore the flavour of the pale malt to a  
 certain extent is produced by the fumes of the anthra-  
 cite coal or the coke?—I should say so certainly.

5701. Do you exclude fir for instance from the wood  
 you burn?—Yes, we use nothing else but hazelwood.

5702. Hazelwood is distinct from ordinary under-  
 wood?—We have to have it as we get it pretty well.

5703. You do not use particular wood? Beechwood  
 would contain a much larger amount of substances  
 like creosote than really nut wood?—Yes; we buy it  
 as well as we can.

5704. Hazel is the trade name for it, but it is an  
 underwood?—Yes, it gets a mixture of other stuffs in  
 with it.

5705. You would exclude fir?—Yes, we should; we  
 could not get it to begin with.

5706. (Chairman.) Would you object to it if you had  
 it?—I think very likely we should.

5707. (Mr. Cosmo Bonsor.) Have you ever tried it?—  
 No, I have never tried it.

5708. (Chairman.) Is there anything else that occurs  
 to you besides what you have told us?—I do not think  
 so.

5709. (Sir William Church.) You said the trade was  
 upset rather by this scare, but you would think that  
 it was improper that such an amount of arsenic should  
 be added by the fumes of coke as to produce considerably  
 more than one-twentieth grain of arsenic in a gallon  
 of beer?—I cannot think there is any arsenic in malt  
 to cause any harm.

5710. It has been shown that the beer brewed with  
 malt alone without glucose in it, one sample especially  
 contained as much as one-seventh of a grain per gallon?  
 —There may in some cases be a very bad piece of coal  
 or coke which may produce that, but I do not think  
 generally it can happen so. There is no devilry of any  
 sort or description in the manufacture of malt, every-  
 body tries as far as I know to produce the best article  
 he can. There is no trick in the trade.

5711. But no one was aware until quite recently  
 that the use of gas coke opened up this?—It has been  
 always used and in some places nothing else. In the  
 North and Midlands they never used anything else for  
 years. In Burton where they make the finest malt, and  
 are supposed to make the finest beer, they never used  
 anything else for years.

5712. I believe they used oven coke a good deal at  
 one time?—And gas coke, too.

5713. Gas coke was not so abundant once as it is  
 now, and we have it in evidence that oven coke con-  
 tains very much less arsenic than gas coke?—I believe  
 that is so.

5714. You yourself say you would use oven coke?—I  
 should in preference.

5715. Do you think there is no danger then where

gas coke is used without any restriction?—I think an  
 inferior gas coke would be very likely detrimental. I  
 think inferior coal would be also detrimental, there  
 is no good in using it, and if you prohibit it it would  
 be a very good thing.

5716. (Chairman.) It has been suggested that gas  
 coke from one district in England was practically free  
 from arsenic, but that in another district the ordinary  
 gas coke contained a good amount of arsenic. Have  
 you experienced anything like that?—No; we use  
 nothing else but anthracite coal in our district.

5717. (Dr. Whitelegge.) In what way do you suggest  
 that a standard ought to be fixed?—As anthracite coal  
 cannot be guaranteed free from arsenic absolutely, I  
 would suggest some standard of limit which the maltster  
 may work to.

5718. A standard of anthracite coal or a standard of  
 what?—Arsenic.

5719. Arsenic in the malt or in the coal?—In the  
 malt. I do not think you can produce malt absolutely  
 free from arsenic for the very good reason that coal is  
 not absolutely free.

5720. Would you not agree that it is desirable to  
 exclude even the least trace of arsenic that can be  
 done?—I do not think it could be done.

5721. Would it be desirable?—Certainly; but I do  
 not think it can be.

5722. If there is a variety of anthracite coal free from  
 arsenic, would you agree that it is preferable to use  
 that rather than an anthracite coal containing a little  
 arsenic?—Certainly.

5723. Would there not be danger, if a standard were  
 introduced, of suggestion that it was immaterial whether  
 the arsenic below that minimum were excluded or not?  
 —No; I do not think so.

5724. Do you think it is necessary for maltsters who  
 use anthracite coal to examine for arsenic?—I do not  
 think it is, if you ask me, although we do it now.

5725. If there were a standard, what would you pro-  
 pose the maltster should do? Test his malt from time  
 to time?—We do that now.

5726. But not to give any special attention to the  
 coal?—No, certainly not; he might have it analysed to  
 start with.

5727. Have you any suggestion to make as to the  
 amount of arsenic that should be specified on a standard  
 if any were specified?—I could not say that, but I think  
 you can produce malt if dried by good anthracite coal,  
 practically free from arsenic. I do not think you can  
 guarantee it—that is my point.

5728. What would be the object of the standard—to  
 enable the maltster to give a certificate that the arsenic  
 did not exceed a given standard?—Precisely.

5729. (Sir William Hart-Dyke.) You mean you can  
 guarantee the standard, but you have a difficulty to  
 guarantee an absolute freedom from arsenic?—We are  
 advised that we cannot get it absolutely free.

5730. (Mr. Cosmo Bonsor.) If some public authority  
 were to settle the standard, do you think every maltster  
 could keep practically below it?—Yes; that is what I  
 think should be done—that is my point.

5731. (Chairman.) Your own chemists could test it  
 and keep it out at the right time?—I think so. We  
 continue to have our malts analysed for arsenic from  
 time to time, and we endeavour to keep within that  
 standard.

5732. (Dr. Whitelegge.) And always with negative  
 results. You told us that the malt samples had never  
 been found to contain any arsenic whatever?—I was  
 only quoting my own instance.

5733. The malt had been frequently examined and  
 you never found arsenic?—Yes, we were at it every day.  
 We are asked to guarantee malt and keep it free from  
 arsenic.

5734. (Chairman.) What quantities of malt are taken  
 in the chemist's test?—A very small proportion.

5735. Have you thought of having a still more search-  
 ing test of a larger quantity?—No.

5736. Do you think that the freedom from any trace  
 of arsenic in the samples you gave is practically suf-  
 ficient?—I think so, certainly. I do not see how you can  
 do it in any other way. In our own business we are  
 endeavouring as far as possible to work within those  
 lines.

Taylor.

25 Apr. 1901.

5737. (Sir William Church.) Do you know what quantity your analyst uses in the sample?—No, I do not.

5738. You do not know whether he examines half a pound or a pound?—I could not tell you. I should think less than half a pound.

5739. (Chairman.) The quantity tested is of very great importance?—The sample is drawn from a large

bulk of stuff, a thousand quarters of malt. We draw a sample from the bin, and an average sample is sent up to be analysed; we can do it in no other way.

5740. But the quantity the analyst actually uses would be of great importance?—I do not know what he uses, but I should think less than half a pound. It is a very small quantity.

Mr. H. A.  
Taylor.

Method of  
sampling  
malt.

Mr. CORNELIUS O'SULLIVAN, called; and Examined.

Mr. C.  
O'Sullivan.

5741. (Chairman.) You are a Fellow of the Royal Society?—Yes.

5742. And you undertake the scientific and chemical work for Messrs. Bass and Co.?—Yes, at Burton-on-Trent.

5743. You have some information to give us on certain points we are enquiring into?—Information has been asked of me on the following points:—

(1) As to precautions which in your Burton experience have, in view of recent events, been considered necessary or desirable, to guard against the introduction of arsenic into beer, by any ingredient (sugars, malts, etc.).

(2) How far, in your experience, it has been found practicable to eliminate risk of introduction of minute quantities of arsenic into beer; and

(2a) Any other matters within the reference of the Commission.

In reply thereto I may say:

(1) When it became known, through the daily papers, about the 23rd of last November, that arsenic was found in some beers, although the source whence it was derived was clearly indicated, it was deemed desirable, as a precautionary measure, by the Burton brewers, in common, no doubt, with the brewers all over the country that every source by which arsenic could be introduced into beer should be carefully examined; and, as the sugars of different kinds, employed as malt substitutes, were the sources chiefly implicated, at least to begin with, the use of these was discontinued in most cases, at once, although examinations have since shown the precaution unnecessary; the sugars, as a rule, have been found free from arsenic, or at least practically so. Further, it was considered desirable that all beers in stock should be examined by the local staffs and by outside authorities. Burton brewers have, as a rule, competent chemists on their staff, and those who have not employ such men outside. The general results were that the beers were declared practically free from arsenic.

But when developments took place, and when the academic side of the question took the place of the practical one, it was found there was yet something to learn as to the presence of minute quantities of arsenic in beer and as to the sources thereof. It was observed that in some of the beers these minute quantities of arsenic were greater than in others. The cause of this was enquired into, and it was soon established that malts dried with a proportion of gas-coke contained much more arsenic than malts dried with a proportion of oven-coke. These facts were confirmed by outside observation. The use of these malts was at once discontinued, and as a further precautionary measure, even oven-coke was, as a rule, discarded and the cleanest anthracite alone employed. For many years Burton brewers have used little or no gas-coke, for the simple reason that it imparted a smoky disagreeable flavour to the malt, which was carried to the beer. Of course, as far as practical, they bought no such malt. But, inasmuch as outside maltsters recognised this fact care was taken by them to eliminate the flavour by selecting the gas-coke they employed so that in most cases it was impossible from the odour alone to distinguish gas-coke dried malt from any other. It appears, however, that the selection of the non-flavour giving varieties of gas-coke did not also eliminate the arsenic-containing ones. Hence, it was deemed desirable to discontinue the use of all outside malts, until they were tested and found to be practically free from arsenic.

All these precautions notwithstanding, it was still observed that all the beers were not absolutely free from arsenic, when the rigorous test was applied: quantities varying between 1.100th to 1.500th grain per gallon and practical purity were certified to by

competent authorities. I may mention, as an example, that I have had examined by a leading authority, with whom our own observations are in broad agreement, 32 samples of different beers, the products of some of the chief breweries of England, Ireland and Scotland, and of Holland, with the results that they contain quantities of arsenic trioxide, varying between 1.50th of a grain per gallon and practically nil.

The nil samples amount to 3 in the 32, and I believe two of these are part sugar beers, or beers brewed with part grits, made from flaked maize or rice.

This being the case, the cause of it and the means of obviating it had to be sought for. An examination of malt dust, i.e. the dust obtained on screening and fanning the malt after the grosser rootlets had been eliminated, showed that it contained much more arsenic than the malt itself; hence it has been decided to put up apparatus containing brushes and screens of the highest efficiency. They, I believe, will still further reduce the infinitesimal quantities of arsenic in beers, but I cannot hope that they will be, thereby, absolutely eliminated.

Hops have also been carefully examined, and although many growths have to be rejected in consequence of the large quantity of free sulphur they contain, very few samples have been found to contain arsenic, in fact, they may so far be said to be absolutely free. As, however, sulphur washes are used during their growth, as they are frequently treated with free sulphur when maturing, and as sulphur is used in the kiln fires during drying, it would not be surprising if hops, too, will on further investigation be found to supply their quota, however small, of arsenic to beers. This is also a contingency against which brewers will, of course, have to guard.

(2) I have indicated above the precautions taken which were considered desirable with the view of eliminating the risk of introducing even minute quantities of arsenic into beers and partially the results that might be expected. All the precautions taken have, I believe, led to a large diminution, but I cannot say that they have, so far, effected complete elimination in all cases.

I believe it can be shown that beer must have contained minute quantities of arsenic from time immemorial, but I believe there is no evidence that any effects, injurious to health, attributable to this quantity of arsenic, has so far been recorded. Methods for the detection of arsenic in beer are given in analysis books, but it is fairly clear that this arsenic is supposed to be introduced by accident or malicious intent.

I do not wish to deal with the methods of determination of minute quantities of arsenic. I may say, however, that I believe they are in some hands broadly satisfactory, as far as they go, but I am strongly of opinion this matter should be treated as the water commission treated the pure water question, that is, institute an enquiry into it with Governmental authority, so that practical methods may be established and uniform results insured.

(2a) Should there be any other points within the reference upon which the Commission may wish to examine me, I shall, in duty bound, be glad to give all the information within my knowledge.

5744. (Sir William Hart-Dyke.) I suppose you naturally, in common with all those connected with this trade, took great alarm when the news became known of this epidemic at Manchester?—I do not think I would admit the word "alarm." We certainly became nervous at the matter, but inasmuch as from time immemorial we have never observed any evil effects from the use of moderate quantities of beer we did not feel that as far as we were concerned, especially considering the materials we employed, there was very

much to fear, or at least that there was anything to be alarmed at.

5745. Were you in the habit of using glucose in any shape?—Yes.

5746. Could you tell the Commission in what proportions you used it?—Taking it all and all probably about 2½ per cent. upon the malt.

5747. The rest being malt?—Yes.

5748. And what steps did you take for the future security against poisoning?—We immediately examined the glucose as a preliminary step, and then, lest in the past, not having examined the glucose, any of the stock might have been brewed with arsenical material, the beers that had already been produced were carefully examined until they were declared free. That is as far as my firm is concerned, but I think I am speaking broadly for the district of Burton-on-Trent. I think it would be scarcely fair to speak only of my firm. I would have it understood I am speaking for the brewers of the district as far as it is within my knowledge.

5749. Burton brewers have competent chemists on their staff?—Yes, and the smaller brewers employ outside men.

5750. They would call them in for emergency or on occasion to do the work?—As a fact, probably two or three of the smaller brewers have certain consulting brewers and chemists in common. They fee them by the year and on the amount of analysis they do afterwards. So that they are really and practically quite safe.

5751. (Professor Thorpe.) You mean they have a retaining fee?—Yes.

5752. (Sir William Hart-Dyke.) The general results in the initial stages of your enquiries for arsenic were good?—As far as the methods of analysis at first employed were concerned, the declaration by ourselves as well as by one of the best analytical chemists in England were on the side of practical, if not absolute purity.

5753. Later you found, did you not, some change took place with further developments?—That is so.

5754. Could you tell the Commission a little more as to what steps you took then?—It was then of course necessary to discover the sources from which these minute quantities of arsenic were introduced into the beer. To begin with I may say it was very difficult to satisfy ourselves they did exist there. However, as time went on there was no difficulty in establishing the fact, and then it was necessary to determine from what source these traces were derived. The different varieties of malt employed were examined, and as a broad fact it may be stated that the malts which were imported from outside sources showed a larger quantity of arsenic than those produced in the town itself. Therefore from the effect to the cause was a very short step. Enquiry showed that most of the bought malts were dried with gas coke, or partially with gas coke, and as a rule that the malts made in the town were dried with anthracite and oven coke, anthracite being used in larger quantities probably than elsewhere. Hence it was a fair conclusion that the source of the arsenic in the malt was the coke. The brewers therefore making their own malts rejected the coke altogether, and used nothing but anthracite.

5755. (Chairman.) Formerly they had used gas coke and oven coke?—In some of the firms of Burton-on-Trent I believe gas coke was used to some extent, but I cannot say it was used to any large extent, because the flavour of gas coke beer, unless the gas coke is very carefully selected, is objectionable.

5756. (Sir William Hart-Dyke.) Smoky is it not?—Quite so.

5757. I suppose, generally speaking, as regards the breweries with which you are connected, your opinion is that if mischief were to arise it would come from the use of gas coke?—It would be very difficult to say that altogether because we have no definite experience, and we have no definite evidence as to what variation may take place in the composition of anthracite or in the composition of oven-made coke. It would be almost impracticable to answer your proposition at the present time.

5758. You think there would be greater security in the use of anthracite than in oven coke?—I do not think there is any large amount of evidence for that at the present time; I believe oven coke can be got

quite as clean as anthracite. I have found large quantities of malt made from mixtures of oven coke and anthracite quite as pure as those made from anthracite alone.

5759. Given the three species of fuel, anthracite, oven coke, and gas coke, if you are asked to eliminate from those three the most dangerous, you would eliminate gas coke?—Yes, certainly. And I think the evidence at the present time so far is against oven coke too, and is strongly favourable to anthracite, but the time at the disposal of those persons who are investigating the question has been so short that the quantity of evidence is not sufficiently great to come to any absolute decision on the point.

5760. You say for many years the Burton brewers have used little or no gas coke on account of this smoky disagreeable flavour?—That is so.

5761. You said outside malsters recognise this fact, and action was taken by them to eliminate the flavour by selecting the gas coke they employed so that in most cases it was impossible from the odour alone to distinguish gas coke dried malt from any other?—I believe that is really so.

5762. But that the selection of a known flavour-giving varieties of gas coke did not altogether eliminate the arsenic containing varieties, and therefore it was desirable to discontinue the use of all outside malts altogether?—That is so in my experience. Practically the outside malts, malts that have not been made by ourselves, are not used at the present time except in probably two cases in which the malt is found to be absolutely free, and these malts are also known to be anthracite dried malts.

5763. You have had a large number of samples of different beers tested, have you not?—Yes.

5764. You said "by a leading authority." Could you tell us more about the application of the test and give the authority?—Do you think it is necessary, sir?

5765. (Mr. Cosmo Bonsor.) Was it the Marsh test of the Reinsch test?—The Marsh test, the Berzelius Marsh. He used sulphuric acid in greater part with a little nitric acid so as to eliminate as much as possible the organic matter. I will tell you, if you wish, that it was the firm of Calvert and Thomson of Manchester.

5766. I think they have made testing for arsenic rather a special part of their business?—As far as I know Mr. William Thomson has had a great deal to do with the testing—at least I have it from hearsay that he has had a great deal to do with the testing for minute quantities of arsenic in cloth, carpets, and such things, because it is said there are some countries, for example, Norway and Sweden, where they will not allow a carpet introduced into the country containing more than 1/600th of a grain of arsenious acid to the square foot. I do not give it upon my authority; I have only heard it said.

5767. (Chairman.) Mr. William Thomson has been testing for carpet manufacturers?—That is my information; I have been so informed.

5768. How was the arsenic supposed to get into the carpets?—By the dyes, I daresay.

5769. (Sir William Hart-Dyke.) You say out of all these 32 samples, those containing none whatever were only three?—That is the report.

5770. And that two out of those three were beers in the composition of which sugar has taken a part?—That is the inference in consequence of the breweries from which they are derived.

5771. They came from breweries in which sugar is used?—Yes, where it is used as a malt substitute.

5772. From breweries in which in no case malt and hops alone are used?—That I cannot say definitely, only they are known as breweries in which sugar is used as a malt substitute.

5773-4. (Sir William Hart-Dyke.) The largest quantity found per gallon was 1/50th of a grain?—Yes, that is so.

5775. Have you taken some trouble to examine malt and malt dust or combings?—We have examined the malt dust and the malt itself; by the dust, I mean the matter still adhering to the grain after the rootlets or combings are screened out. It is capable of being detached by abrasion, and, as a fact, when even screened malt is moved about in sacks, a considerable quantity of it becomes loose and can be separated by

MR. C. G. Sullivan.  
26 Apr. 1901.

Gas coke suited for flavouring not necessarily satisfactory qua arsenic.

Arsenic in malt dust.

Mr. C. O'Sullivan.  
26 Apr. 1901.

screening and fanning. It was in the dust thus obtained I found much more arsenic than in the malt itself.

5776. When you say "dust" you are referring to the dust and rootlets, the result of the screening process?—I am referring to the dust obtained by abrasion after the rootlets have been separated.

5777. You said "examination of malt dust," that is the dust obtained on screening and fanning the malt after the grosser rootlets had been eliminated?—Yes, the grosser rootlets formed by the germination of the seed are broken off by machinery and separated by brushes and fans and by screens, and then the malt still contains matter which is capable of being removed from its coating by abrasion. That matter is the dust which I say was examined and found to contain more arsenic than the malt dust itself.

5778. (Chairman.) Was the portion of the dust containing the rootlets also examined for arsenic?—I have not examined them nor have I had them examined, but I should say that they would be as likely to contain arsenic upon their surface as the malt itself.

5779. (Sir William Hart-Dyke.) You say you decided to increase the efficiency of this process?—Yes, we are putting up, and I believe most of the maltsters in England are putting up, brushing, fanning, and screening machines, so as to attack this small quantity and eliminate as much as possible the removable dust, at a very considerable expense, too.

5780. That is your experience of the trade at present?—It is within my knowledge in certain cases, and I have it from hearsay in many others. There is no doubt that many of the maltsters in England have malt on their hands at the present time that they cannot sell, and everything is being done to eliminate the quantity or the proportion of arsenic that may be considered detrimental to the malt. That is absolutely within my experience.

5781. The presence of arsenic in malt at all or in this dust after screening has come as rather a surprise to the brewing trade and malting trade?—Absolutely as a surprise.

5782. There was no suspicion of it before?—Not a suspicion to my knowledge.

5783. (Chairman.) I gather that some maltsters have on hand malt they are not able to get quit of, is that because of arsenic?—So I am informed.

5784. Before the scare it would have passed as a matter of course as good malt?—Certainly.

5785. Do you know at all how much arsenic there was in any of that malt?—I should not like to say, but in some cases probably as much as 1/100th of a grain to the lb.

5786. (Mr. Cosmo Bonser.) What would that show in beer?—Taking 3lbs. of malt to the gallon of beer, which is a little above the average gravity, it would bring it down to 1/33rd grain per gallon.

5787. (Professor Thorpe.) That assumes it all went in?—Quite so. I should not like to assume it for the moment though.

5788. (Sir William Hart-Dyke.) Have you any other suggestions to make beyond the care with regard to screening?—I do not really see that any other is necessary. I have made experiments by carefully brushing malts that I knew were moderately contaminated, contaminated probably as high as 1/100th grain to the lb., and when these malts were properly brushed, brushed as efficiently as the machines being put up can brush it, they were practically free from arsenic. I do not mean to say that if a man took 5lbs. of it and got it down by hydrochloric acid and chlorate of potassium he might not get a mirror in the Marsh's apparatus, but for all practical purposes I am perfectly sure that malt would be free from arsenic.

5789. To your mind the real solution of the difficulty and the way to get security for the consumer of beer in the future, is to have this malt practically and thoroughly dealt with by a cleansing process?—That I believe is the practical way out of the difficulty at the present time.

5790. The fuel question is of course one of the most important elements?—As a matter of fact, there is no evidence so far that any arsenic carried into beer through the malt is derived from any other source than from the fuel. That may be taken as a fairly approved fact, I think.

5791. Would you suggest that if it were proved either through this enquiry or otherwise that gas coke is far more liable to cause the presence of arsenic in malt, it would be necessary to go so far as to forbid the use of gas coke for malting?—The difficulty in my mind would be how to prevent it, because if coke at all were used you could not put the key upon the gas houses or upon the malt houses, and it would be very difficult to prevent it going in. You would have to get a good many people to watch it to handle the matter in a practical way.

5792. But do you think that, considering all that has happened, the malting trade as a rule would use their utmost endeavour to protect the consumer of beer and are now inclined to use anthracite or oven coke as much as possible?—I am perfectly satisfied that there is no maltster in Britain who is not doing everything he knows to eliminate the traces of arsenic that his malt may contain, and that therefore if it is thoroughly impressed upon him that there is any risk of the introduction of arsenic by the use of any fuel, he will spare no trouble to eliminate that fuel. It is a very serious loss to the maltsters of this country at the present time to have the amount of malt I hear they have on their hands, and cannot sell or handle in any way unless some means is devised to eliminate a considerable quantity of the arsenic. Therefore to prevent any possibility of that loss of money in the future they would take every precaution that could be possibly taken or they could be helped to take by the scientific experts from outside.

5793. (Chairman.) The malt they have in their hands could not be purified by any rigorous process of brushing?—I think I have said I feel quite satisfied that with the systems of brushing that are being devised the larger quantity of the arsenic will be eliminated.

5794. And has that been tried, do you know, on the stock in hand they have so much trouble about?—I believe it has to some extent, but it takes a considerable time to have these brushes made and there are only a certain number of men in the country who have the apparatus for making them. Therefore it takes a considerable time before they will be in proper use. I feel inclined to think myself that, except for the stock of malt that is on hand, by the time they are erected they will be absolutely unnecessary, that the malt dried by anthracite will be sufficiently free for all practical purposes.

5795. In the public interest would you think it would be advisable to have a rule about the fuel used, that it must be arsenic free, or would you let the rule for the security of the public be, that there is not to be arsenic in the malt, or the double security that the fuel is to be arsenic free and the malt arsenic free?—As far as any security of the fuel being arsenic free is concerned, I believe it is a proposition outside the range of practical politics, so to say. It is out of the range of practicality. You get a seam of coal 100 yards in length and take blocks out of different lengths of that seam, and examine it for any one of the constituents. I have had to do it for the amount of chlorine that the seam of coal may contain, and I found that the variation was considerable. If, in the case of one constituent, I ask why not in the case of the other? I do not say it has been done for arsenic, but I have not the least hesitation in saying that what holds good for one small proportion of a thing will hold good for the other, and the seam of coal examined its whole length will not show identically the same quantity of arsenic. And I believe if it did we have no methods at the present time sufficiently accurate to determine that point to satisfy all conditions, because I maintain that colour tests, tests by comparison although right enough in their way, until one can weigh and measure—and these are only correct within certain limits—one cannot be satisfied that there is any real security with regard to accuracy.

5796. (Sir William Hart-Dyke.) With all the precautions human ingenuity can devise you think there is always a possibility of there being some arsenic in the beer that is drunk?—I should not like to say that. I think I have been able to prepare a beer that was absolutely free from arsenic, and I have plenty of beers certified to be absolutely free by even the most rigorous test.

5797. (Professor Thorpe.) Do you consider that preparation of such beer involves the same order of difficulty as making a chemically pure chemical?—Quite in that same order.

Mr. C. O'Sullivan.  
26 Apr.

Difficult prohibitions of gas coke by malt.

Arsenic malt—le to malt.

Removal of arsenic by brushing.

Distribution of arsenic coal probably very unequal.

Beer can be rendered absolutely free from arsenic.

5798. (Chairman.) Your remarks about fuel apply to anthracite. You think there may be arsenic in some specimens of anthracite, and not in others from the same bed?—That I must admit.

5799. The employment of sugar or glucose as malt substitutes was discontinued?—Yes, as far as most of the breweries in my district are concerned, it was discontinued as malt substitute. In the question of malt substitutes in contradistinction to any other use that sugar is applied to, I may say the malt substitute is intended to displace a certain quantity of the malt. It is used in the copper and boiled with the wort. That is the sugar used as a malt substitute. There is a small quantity of sugar solution-glucose or cane sugar being employed as priming, and added to beer after fermentation. This I do not include under the head of malt substitutes.

5800. What you refer to now is sugars used for priming?—Yes, glucose, and some brewers use well-crystallised sugar candy.

5801. That would just sweeten the beer?—The quantity used would be so infinitesimal that it does not enter into the question. If you take it that probably there would not be much more than  $1\frac{1}{2}$  per cent. upon the extract, in some small breweries it may go up to a great deal more than that, but in those breweries where it is really looked upon and introduced as a priming it does not exceed  $1\frac{1}{2}$  per cent.

5802. If there is any arsenic in the priming that all remains in the beer?—Yes, certainly, except it should be eliminated by the after fermentation, by the yeast taking up any portion of it.

5803. But the priming is applied to beer, the whole of which is put into barrels?—Quite so.

5804. So that it would be only by depositing in the barrel that any of the arsenic could fail to be in the beer?—That is so.

5805. You found afterwards that the giving up of the use of the sugars was not necessary?—That is my experience at the present time, the sugars on the market are practically if not absolutely free from arsenic.

5806. Would you still approve of those sugars being used in the two ways, both as malt substitutes and as priming?—I do not say I would approve, but I would have no objection.

5807. In high class beers is sugar used as priming?—Yes, certainly.

5808. And in the lighter class of beers, which I suppose were chiefly concerned in the epidemic, would there be glucose in the priming there, or in the brewing, or both?—In both.

5809. And a large quantity of it?—In the brewing, as the malt substitute.

5810. But a small quantity in the priming?—About the same as usual, I should say.

5811. In the beers you speak of when the use of the sugars was given up, was the quality of the beer sensibly altered?—I should say not really, in my own experience. I have heard some men say since they had to give up a certain small quantity they did not get the fineness of flavour, and had to use the better class of malt.

5812. And then they get the good quality in the beer?—Yes. That is putting the facts broadly.

5813. So that the use of glucose not only renders a smaller quantity of malt necessary, but allows of an inferior quality of malt being used?—I do not quite understand the question.

5814. I think you said that when they gave up the glucose, they were obliged to use a higher quality of malt?—That is so, and to displace the quantity of sugar by a quantity of malt equivalent to it.

5815. When you say a "higher quality of malt" in what respect was it of a higher quality?—That would be rather difficult to describe I must confess. Some brewers think that the malt they have to give the highest price for is the best malt. Others are satisfied if it gives a beer sufficiently good for their purposes. The question of real goodness is one of those things which it is very difficult to decide.

5816. Has the customer much to say in the matter, or the publican who sells to the customer?—I think, as a broad fact, he has pretty well everything to say on the matter. His tastes have to be very materially considered, and if they are not, he soon lets the brewers know. If one brewer, for example, in the town is sending out beer that is unsuitable to the tastes of the beer-drinking

part of the community, and the other brewer is sending out beer that is suitable, the brewer who is sending out the latter, will have the advantage in a very short time.

5817. We were told that some brewers before the scare gave up the use of glucose so as to have an all-malt beer, but that their customers did not like it so well, and they were obliged to go back and use the glucose?—That may be said, and probably it is true, but I hardly believe the point, taking it altogether. It was because the beer did not suit the customers that they had to go back to the use of glucose. I admit this fact; there is a certain luscious flavour in invert sugar, and also certain flavours in some of the glucose which are imparted to the lighter beers. When people get accustomed to these flavours they will not have anything else, so that I do not say it is quite an impossibility that a brewer going from sugar to malt may not be forced back to sugar again by the taste of his customers.

5818. That may be a perfectly healthful taste. The use of glucose does not make the beer less healthy, while making it more agreeable?—Certainly not. So long as it is a purely manufactured article, I cannot see that it is at all.

5819. Have you any analysis showing the quantity of arsenic in sugars referred to when you said that sugars as a rule have been found free from arsenic, or at least practically so?—At the time when these sugars were examined attempts to express such quantities as a 1-100th of a grain to the lb., or a 1-200th of a grain to the lb., or indeed, even 1-500th of a grain to a lb., seemed to be an absolute loss of time. It seemed to me at that time impossible to give a number when the quantity went below 1-20th of a grain to the lb. One may then form some idea that it did contain at least 1-20th, but one could not be sure of that. When, however, it went down to 1-200th or 1-300th of a grain to a lb., it was absolute guesswork, and I should say when it required, say 200 grammes or 300 grammes to establish definitely, there was some arsenic there, it may be altogether neglected, although it may have been put down as 1-300th to a lb.

5820. But you would say now 1-300th of a grain to a lb. might be measured?—A fair guess might be made at it. For example, I believe if it were put in the hands probably of three different men, and even men working upon the same lines, that one might very easily return it as 1-200th of a grain to a lb., and the other 1-300th of a grain to a lb., and the other 1-400th of a grain to a lb. I believe that is the condition of things in which the determination stand at the present time.

5821. Even by the most careful and well-skilled analysts?—I believe that is so.

5822. You have used the Marsh test, I think you said?—For the smaller quantities.

5823. Do you find it is more trustworthy for the smaller quantities than the Reinsch test?—I may say that I agree broadly with Professor Stevenson upon that point that in the hands of a man who knew how to work the Reinsch test, if the man had the concentration sufficiently right, and his copper sufficiently right, and the mode of sublimation, which is the real crux of the question, under the proper conditions, I believe he need not miss 1-200th of a grain to a gallon in beer. I am perfectly satisfied he could show crystals of arsenious acid from a beer containing 1-200th of a grain to the gallon. But when it goes beyond that, and one has to concentrate, and the amount of organic matter in the solution is great, the deposit on the copper is not so regular, and one cannot rely on it so well as in the case of dilute solutions. Hence when it goes beyond 1-200th of a grain per gallon, it is rather difficult to get copper that will yield crystals with any degree of satisfaction.

5824. We have been told that sometimes the copper keeps some of the arsenic, and the sublimation is not complete; is that consistent with your experience?—I have never tested the question really. When one considers the analysis of electrolytic copper, and sees quantities down to 1-100th per cent., one would not be surprised that if arsenic gets near copper at all under any conditions the whole of the arsenic would be given up again.

5825. Have you ever tried deposit on platinum foil by electrolytic action?—I have not.

5826. (Professor Thorpe.) The arsenic which is present in the coal, and of course incidentally in the coke, is probably associated with the sulphur and the iron?—I think most likely.

Mr. C.  
O'Sullivan.

26 Apr. 1901.

Character of  
beer may  
depend on  
local taste of  
public.

Estimation  
of minute  
quantities of  
arsenic  
largely guess-  
work.

Mr. C.  
O'Sullivan.

26 April 1901.

Form in  
which  
arsenic  
present in  
coal.

5827. That is to say, it would be present in what are called the coal brasses?—Yes, most likely, in the pyrites and the marcasite. Of course the pyrites vary very considerably in composition in the different coals. One kind would contain one variety of pyrites, and another another variety.

5828. But the pyrites itself if it were detected would be a significant thing to look for, and to avoid, so to say, in the selection of the coal?—I should say as a practical test for the suitability of the fuel required that the presence of any shining crystals or scales of pyrites would be very practical and important indication that the seam of coal, or the portion of coal that contained these traces, should be certainly rejected. I cannot say but it would be to the interest of the maltster to look for them.

5829. In the selection of any coal one might, so to say, keep off arsenic by keeping off coal brasses?—The evidence probably is not altogether quite satisfactory upon that point yet, but I believe in the main it may be taken as true. If you take a piece of coal and cut a cubic inch out of it, which appears to be all carbonaceous matter, I am not quite prepared to say that that block of coal might not contain some arsenic, but I am prepared to say that all other things being the same, coal showing the faces of either scales or crystals of pyrites are coals that will certainly yield the greater quantity of arsenic. I believe that is the point.

5830. That is what I want to get from you. But that method of selecting coal for industrial purposes is already in use?—I have heard so.

5831. The iron smelter, for example, in taking coal for his particular use will select it with the view to the avoidance of pyrites?—That is so.

5832. That presents no industrial difficulty?—No.

5833. Oven coke for the same reason I presume is less free from pyrites, because it is selected in view of a special purpose?—Quite so. There is no other possible reason that it should contain less.

5834. It has been selected for the absence of sulphur?—Yes. One of the curious things when one comes to consider the matter, is why it should contain any at all. Imagine the high temperature of the coke.

5835. It has probably been converted into other forms in a reducing atmosphere?—That is quite so.

5836. What is the difference in price between gas coke, oven coke, and anthracite?—I cannot say.

5837. Is it a factor which is at all likely to enter into the calculations of a maltster?—Certainly it must enter into the calculations of the maltster, otherwise he would not go to the trouble of using gas coke.

Price of  
malting fuel.

5838. It is not the convenience of its being on the spot?—That may have something to do with it. I am speaking without the book, but with a certain amount of knowledge on the matter. You may buy gas coke in the town in large quantities at 13s. a ton, but I think at the present time probably you would have to give for oven coke 22s. or 23s.

5839. And for anthracite in your district?—Probably 23s. or 24s. I am speaking without the book, but it is sufficient for practical purposes. You may take it broadly that gas coke is materially cheaper than oven coke, and oven coke is somewhat cheaper than anthracite.

5840. As you put it, anthracite is double the cost of gas coke?—Yes.

5841. How far does the cost really enter into the production of malt?—I am afraid upon these matters, upon the commercial aspect of the question, I have very little knowledge. I neither buy nor sell anything connected with the trade except some very small things.

5842. The object of my question was how far any restriction as to the use of fuel was going to enhance the price of malt?—I think you may put it down that it will certainly enhance the price of malt. The alterations which have taken place already have put up the price of malt considerably; that is, of the available malt.

5843. (Mr. Cosmo Bonsor.) The cost of making malt, not the cost of the malt?—Yes, and of course the price, too.

5844. (Professor Thorpe.) In view of the greater stringency of purity required?—That is so.

5845. You told the Commission you think that by the time this brushing machinery is in general use the

necessity of it will be very largely obviated?—That I believe is true.

5846. Do you rather deprecate the brushing of the malt apart from this question of arsenic?—Not at all. As a brewer I think it is most desirable.

5847. (Sir William Church.) With regard to that question, would you be in favour of this brushing being done by the brewers or by the maltsters; the last witness said he objected to the maltster brushing because he could palm off inferior malt?—I do not think the brewer would object to have the maltster do it, but I think, taking it altogether, he would prefer to have the brushing under his own control. There is one more factor in the matter. If malt travels any distance after it is brushed or screened there is yet still more dust eliminated by the abrasion of the particles.

5848. That would be a further safeguard to the public?—In consequence most of the better brewers have fans and screens immediately before the mills to handle such malts. In other words, I believe it is impossible to move the best screened malt without having a certain quantity of dust develop in the process of moving. The rubbing of the corn against each other; the passage of the corn from the stack into the hopper, and so on.

5849. You, speaking as a brewer, would agree with the last witness, a maltster, that the final polishing and brushing had better be done by the brewer than the maltster before it leaves his malting house?—Certainly, I think there is every reason for it.

5850. Can you tell me what the flavour of malt depends upon?—That is rather a big question.

5851. You heard, I think, the last witness's evidence?—To some extent. The flavour of malt depends upon many things. I have not prepared evidence on this point, but I have my opinions on the matter, and am quite willing to give them.

5852. At present, to meet the requirements of the brewer, the maltster has to allow the fumes of the fuel to pass through his malt?—I think you may take that as broadly so.

5853. Do you think that it would be possible to obtain that flavour in the malt without the presence of the fumes?—What you mean to ask me is, whether it would be possible to so far cure the malt without allowing the fumes or the vapours of the fuel to pass through it, that it would be as acceptable to the brewer for brewing purposes as it is at the present time. I cannot say that, taking it altogether, I have any reason to believe that it would not be possible to produce as good a malt, giving flavour by the passage of properly heated air without the products of combustion, as it would be by carrying the products of combustion through.

5854. So that its flavour really does not depend upon changes due to the fuel? You say you do not use gas coke because you wish to keep out a disagreeable flavour, but you obtain the flavour that you need in the other cases by the use of coal fumes?—That is why gas coke was rejected.

5855. But you are not prepared to say the other is necessary for giving the required flavour?—I should say not, certainly. I know of no flavour that, provided the air was of sufficient temperature and the amount of water in the malt when the temperature was employed was suitable, the roasting flavour could not be given to the malt with heated dry air as well as with heated dry air plus the products of combustion.

5856. (Mr. Cosmo Bonsor.) You would still want a draught?—Naturally.

5857. (Sir William Church.) And the brown malt that Brown is spoken of, which is dried by means of wood, is merely that you want a shorter and fiercer heat?—I have no experience with it, except that I see it now and then. It is offered to me, but I do not handle it. It is to give a certain sort of body flavour, and generally used in porter and stout.

5858. Still, if I might have your opinion, it might probably be because you get a shorter and fiercer heat from the wood than you do from the anthracite coal?—It seems likely, but I could not bind myself to an opinion.

5859. It appeared to me like that?—It appears so to me, too. There is no doubt that brown malt is what is known as blown, that is to say, a high temperature is applied to it while it still contains a large proportion of water, so that the water in the grain is volatilised by that temperature, and the skin of the grain blown

C. so as to be much expanded. If you get a sample of that malt, you will see that every grain of the malt is quite distended.

1901. 5860. Have you had analysed any of the combings?—No.

5861. You would not like, perhaps, to express an opinion whether they are likely to contain sufficient arsenic to be prejudicial to its use as a feeding stuff for cattle?—Under the ordinary conditions of drying, or even with use of ordinary gas coke, certainly not.

5862. You do not think that the use of the combings scattered over chaff and other things would be prejudicial to stock?—I should say not.

5863. What quantity of malt would you propose should be used as samples for testing, an ounce or a pound or what?—A good deal would depend upon the bulk to be sampled.

5864. I mean what amount should the chemist work with?—Some of them can work with as low as 10 grammes.

5865. You can imagine that malt might contain arsenic, that is to say, not be absolutely pure, and yet it would be impossible to detect the presence of that arsenic in an ounce, while it would be detected in a pound?—If it is found by examining an ounce there is the least trace, a more distinct indication can be obtained by using 1lb. or 10lbs., provided the reagents are sufficiently pure.

5866. I was asking you, rather supposing you agreed with the last witness in thinking there should be a standard laid down that there should not be more than a certain quantity of arsenic in malt?—That I should say distinctly would be a desirable thing, but it should be laid down with Governmental authority. I have in my own mind now the condition of things when the Water Commission first sat, or when the Water Commission was working. I remember as well as possible that the idea of estimating the 1-10th of a grain of ammonia to a gallon was simply scouted; a 1-10,000th of a grain per gallon now all analysts can detect. So that if we were to lay down to-day a certain standard, unless the method by which that standard was arrived at was clearly and distinctly stated, what we call the 1-100th of a grain to a gallon to-day may turn out later on to be 1-10th of a grain to a gallon. I do not know whether the authorities will agree with me, but it is my experience on the matter.

5867. Therefore you would not propose there should be any definite standard?—Not without accurate and careful investigation by competent men. I believe that these minute quantities of arsenic in all articles of food as well as in beer, malt, and so on, is a problem at the present time well worth investigation. It should be submitted to that investigation, and the results of it should be stated authoritatively. Then it would be for the doctors to say whether or not any quantity that could be determined by this method should be allowed.

5868. Given a definite amount and a definite method of working, what would be a convenient quantity of the malt to work with?—Anything between 10 and 100 grammes.

5869. (Professor Thorpe.) The amount, of course, to be taken must have some reference to the method which is used?—Quite so. That is the point I wish to accentuate. I want to point out that the method must be distinctly and definitely laid down. For example, if you take a thimble of glass and a cover glass, and introduce into the thimble copper from the Reinsch test, you will find it wants a large quantity of copper to get crystals, whereas the same amount of copper and the same amount of arsenic will give you, with the greatest ease, crystals quite distinct in a small tube. All you have to do is to diminish the size of the tube. In the one condition of things it is not obvious at all; in the other with the same quantity it is perfectly apparent.

5870. (Dr. Whitelegge.) What you said just now about standards referred more particularly to beer. did not it?—That was what I had in my mind at the time.

5871. Would you say a standard was necessary in the case of malt? The last witness proposed there should be a standard laid down by which the maltster should be guided, and which would enable him to give a certificate of freedom from arsenic?—I think that would be desirable. But if it were done in one case, I hardly think it would be necessary in the other.

5872. But you do not suggest at present what the standard should be?—

standard should be in either case?—Certainly not. Without further investigation I do not think we are in a position to deal with the matter finally; to put it in a condition that would be acceptable to the whole country.

5873. Do you make malt and buy malt?—Yes.

5874. In the case of the malt you make, how long has it been the practice to use anthracite?—Anthracite alone has been used only since the middle of December last.

5875. Did you analyse the coal used?—Certainly not.

5876. You cannot give us any figures?—No.

5877. You select the coal, I understand?—We do Anthracite select, putting it broadly; we get it from the South selected for Wales Colliery, where it is known from time immemorial to give the cleanest flavour. I do not think it value. has any reference to any other form of selection.

5878. Have you any apparatus for pneumatic malting?—No; we are putting up one, but we have not one working.

5879. When that is in use, will the anthracite coal still be exclusively used?—In regard to coal, as far as I understand, it depends whether they are going to dry in the drums or in kilns.

5880. You cannot tell us what the precise form of the apparatus will be?—I cannot tell you at the present time.

5881. In the case of the malt that is bought, do you ask for certificates?—Since the beginning of December certainly, and we examine samples before we attempt to buy.

5882. But in addition to the analysis you make, you ask for a certificate?—Certainly.

5883. (Sir William Hart-Dyke.) Certificate of purity?—Freedom from arsenic.

5884. (Dr. Whitelegge.) Entire freedom from arsenic?—They give it to you broadly; you will not get any one of them to give a certificate that it is absolutely free. But they give a certificate "practically free."

5885. Are those words used, "practically free," in the certificate?—I have not seen a certificate, but I understand that is the form of certificate that is used.

5886. (Sir William Hart-Dyke.) Will you put in the form of a certificate?—I will obtain one, and let you have it. I think it would be very much better to get this from a maltster, who may have it in a printed form in his hands.

5887. (Professor Thorpe.) I venture to think you are rather at cross-purposes in this sense. The maltster gives a certificate in good faith that a thing is free from arsenic?—Yes.

5888. What he really does is to give it to an analyst, who takes a determinate amount and tests it by a definite method, and finds no evidence of it and he gives a certificate on that finding?—That is quite true.

5889. (Dr. Whitelegge.) He gives a certificate of freedom from arsenic or practical freedom from arsenic, whatever it may be, and it is useful to us to see what it is that he represents. You will let us have a copy?—Certainly. But I think you ought to get it from a maltster.

5890. (Dr. Whitelegge.) Have you had any difficulty in obtaining certificates with the malt you receive?—Inasmuch as I do not buy the malt, from my personal knowledge I can make no definite statement on that matter.

5891. You are not aware of any?—I do not buy the malt myself. As far as I understand your question, a certificate is required; the maltsters have to certify, but the difficulty of getting a certificate of absolute purity from the maltster, I have been informed, is so great that it is almost impossible to get them from any maltsters in England.

5892. So that we must expect to find the certificate you are going to let us have will stop short of absolute purity. In your printed *précis* you mentioned that a number of samples of beer in stock were examined; can you say how far back that would carry you?—Some of these samples were the brews of January twelve months, and then they came down as far as the current brews.

5893. (Mr. Cosmo Bonser.) I think we have had pretty nearly the whole of your experience as regards malt, but have you tested the other ingredients of brewing, preservatives, and so forth?—Certainly.

Mr. C. O'Sullivan.  
26 Apr. 1901

Malt examined for arsenic before purchasing.

Form of guarantee given by maltster.

does not specify absolute freedom from arsenic.

Preservatives tested for arsenic.

Mr. C.  
O'Sullivan,  
26 Apr. 1901.

5894. They have all been tested for arsenic?—Most carefully.

5895. You mentioned hops; I presume the hops were bought before the scare was known, and you did not ask for a certificate?—Certainly not—not at that time. We do ask for a certificate that they are free or practically free from sulphur.

5896. That has been also since the scare?—No; we have been doing it for ten years. As far as we possibly can we buy no hops containing free sulphur.

5897. (Sir William Church.) Do you test for that chemically or judge by the nose?—We test for it chemically. I have not published the method, but we eliminate the crystals and practically re-crystallise the sulphur out of it, and examine it microscopically.

5898. I asked you, because we have had the question answered by others, who say they can always detect the sulphur in hops by smelling?—The sulphur they smell is not free sulphur. It is combined sulphur; the sulphur of the washes or the sulphur put on the kilns during drying.

5899. (Mr. Cosmo Bonsor.) We are all aware there are other substitutes for malts used besides sugar, like flaked malts and grits; is there any suggestion that there has been any arsenic in them?—I have never heard of it.

5900. Should you be satisfied if the same Government inquiry were to cover the question of a standard for these things as well as regards malt?—Certainly. What I have said applies to the whole of the ingredients used in the manufacture or to the product.

5901. In plain language, you think that there need be no practical traces of arsenic in beer, the word "practical" to be defined by a Government authority?—That is my meaning, but of course the great difficulty comes in on the question of "practical."

5902. But we get rid of that difficulty by throwing the responsibility on to an authority who can vary it from time to time as knowledge comes?—Quite so.

5903. (Sir William Hart-Dyke.) With regard to hops, of course the quantity of hops used is very small compared with malt in brewing?—Certainly.

(SIR WILLIAM HART-DYKE in the Chair.)

5911. (Professor Thorpe.) The Commission, I think, would like to know something more in detail as to the last matter in your *précis* to which you draw attention, namely, the question of the particular method which you would suggest as to how these standards or determinations of what I may call limiting values in the amount of arsenic in beer or in similar materials could be arrived at?—My ideas in these matters are these. The described knowledge of the method by which these minute quantities are determined so vary amongst themselves, that in the face of such a condition of things it seems to me absolutely necessary that this Commission or some authoritative part of it should see that the point is investigated, on some definite and distinct lines. As you know, you have taken up determination of one of the constituents of butter, and three or four men who had knowledge of the matter came to the conclusion how it was to be done, and when the product under consideration was to be considered right.

5912. You are alluding to an action which was taken in my capacity as head of the laboratory to agree with the analysts as to what particular factors should be taken to determine a particular point. Is that strictly analogous?—I think so.

5913. In that particular instance to which you make allusion we had to put into effect a clause in a particular Act, and it was necessary to devise certain experimental conditions to give effect to a statement in that Act. There is nothing here analogous to that?—I quite agree with that. The committee of investigation, or whatever it might be, could act in a similar way. I think it can be distinctly proved that from time immemorial beer must have contained a certain amount of arsenic, and if a man asks for beer and is supplied with an article containing this amount of arsenic, whether he knows it or not, it cannot be asserted that he did not get an article of the nature and quality demanded. That is how the matter already concerns an Act of Parliament.

5914. What is in your mind is this, that you assume that samples will be taken under the provisions of the

5904. Could you off-hand give the Commission, taking an 18 gallon cask of beer, the amount of hops used?—There is no difficulty about that at all. Taking pale ale as an example; in 18 gals. of it there is, broadly, the extract of 40 lbs. malt, the amount of hops being 24 lbs. in the same bulk.

5905. Therefore, although you indicate in your evidence the possibility of a small portion of arsenic being found in hops, yet the risk from it would be infinitesimal?—Absolutely so.

5906. And you would rather wish to confirm what has been upheld by other witnesses, that the danger of arsenical poisoning as regards hops is very remote now, if not impossible?—That is so.

5907. And the two chief points you really wish to indicate as regards malt are the very great care with regard to the material used for fuel, and the special care with regard to the cleansing of the malt afterwards?—That is so.

5908. And further, I think by the evidence you have given you do not think the question should rest altogether there, but some standard might be applied for the sake of future security?—That is my meaning.

5909. Both as regards the beer and as regards malt?—Yes, and all other foods. It would be a most grievous thing to keep the brewers of the country in the condition in which they have been for the last six months. It becomes an impracticable condition of things; everything is examined, everything has to be determined, and then there is the insecurity of the results which some ales may give; for instance, your chemist may find a 1-200th of a grain to a gallon, and another finds 1-50th. How can you explain that? These are questions that will continually crop up and keep the brewer and brewer's chemist in such a condition that life will be fairly intolerable to him.

5910. You think, therefore, that the process by which this standard should be arrived at should be determined after very careful inquiry?—That I am satisfied about. The broad lines of the investigation are very well established. They want to be carefully worked out and put into a concrete form, every definition well described, so that no man could make a mistake over a question.

Food and Drugs Act, and that the allegation will be made that inasmuch as it contained arsenic it was not of the nature, substance, and quality demanded?—Yes.

5915. And what you want is provision to be made where the line is to be drawn?—Yes. Go back upon the old samples of beer, establish the amount of arsenic they contain and determine the value of the evidence there is to show the extent, if any, of the injurious effects attributable to them. Working on these lines I maintain it is perfectly open to such a Commission to lay down standards that would be workable and available.

5916. Do you propose that this Commission should do this?—Or a Sub-Commission appointed by this Commission.

5917. Your point being that this Commission should address itself to this particular point in a clause of the Act of 1875, namely, to define when the beer is not of the nature, substance, and quality demanded, *and* the amount of arsenic which it contains?—I think that is broadly the question.

5918. How would you suggest that should be done?—I have not thought the matter out, but it seems to me such standards should go to the Government as a recommendation from this Commission, or that Government should be recommended to appoint a Special Commission of investigation of experts upon this one question alone.

5919. The reference of this Commission is very wide—it includes not only beer, but any article of food?—I know that is so.

5920. That would affect, of course, a great many interests. If the Commission set itself to work to satisfy the terms of its reference with respect to what you say it would involve a great many interests?—Naturally.

5921. What would be the constitution of the Sub-Commission which would handle this question, having regard to the occurrence of arsenic in food generally?—I cannot say anything about the large amount of labour it

C. Green. would necessitate, but when the general good has to be considered that labour must not be considered.

5922. Perhaps you would state to us in detail what kind of constitution this Sub-Commission should have?—I have nothing really in my head at the present time, but it seems to me that a Commission like the Pure Water Commission, of which you have a fair knowledge, would handle the matter with satisfaction.

5923. Should it be a Committee exclusively composed of chemical analysts?—I think broadly so, with a medical element.

5924. It should be a mixed Commission of chemists and medical men?—Yes. It is rather difficult to see where the medical men come in. If it was once granted there was a certain amount of arsenic permissible it would be for the chemist to say how much arsenic there is, and for the medical men to say whether it is injurious or not. But I say point blank, the medical men give us no evidence up to the present time that although beer must have contained arsenic from time immemorial they have been able to attribute any injurious effect from the arsenic in that beer.

5925. Your suggestion means that there should be a committee of analysts to prescribe methods for the detection and determination of the amount of arsenic in foods and in drinks, and that that commission should be associated with medical men to assist them in arriving at some defining limit as to arsenic which should be permissible?—That is not my proposition at all. My idea is that the first object would be to determine what was the nature and quality of the article under consideration from time immemorial, and if it were proved that upon the average beer, for example, did contain a certain small amount of arsenic, it should be the function of the sub-committee or sub-commission to define definitely how that quantity or proportion should be determined, and then, of course, it would be for the doctors to say, and for the Government to decide, whether it was permissible or not.

5926. But beer of the nature, substance and quality demanded would be a beer brewed from malt and hops, it may be, with or without glucose, but the malt might have been dried with arsenical coke?—Yes.

5927. That might be of the nature, substance, and quality hitherto demanded?—That is my contention; they would have to go back and determine what has been the condition of things.

5928. Is it your contention that that standard should be based on beer now discovered to have been brewed from malt containing arsenic derived from coke?—That would be one of my contentions.

5929. That we should be content with such and such an amount of arsenic?—No; that would come in a medical opinion. Observations would be made upon it to see how far that has been injurious, and how far it is likely to be injurious; there will come in the medical opinion.

5930. That is an unknown factor in our inquiry, as to how far injury to health has in times past been due to the consumption of arsenic?—I simply put it in this way, that as far as I have read in this evidence at the present time, until it was discovered some time

ago that beer was brewed from arsenical glucose, we had no evidence that any material injury was done to health by the use of beer from malt and hops alone, or with the addition of the materials that we are allowed by the Act of 1880.

5931. I think I understand what your contention is, and I express no opinion about that?—I know it is a very broad question and a very large question, and not having thought the matter out until you suggested it to me, I am not prepared to give that answer which I might if I had thought it out. But I do not think there should be any difficulty. Your contention is, that there is an Act of Parliament that helped you in the case of butter. There is an Act of Parliament in my mind to help you in this case too, and that if you were to satisfy yourself that this contamination has been present from time immemorial in this article of food, it would be for you to say within what limits it should be permissible now.

5932. (Sir William Church.) When you say from time immemorial, there would be no arsenic until coal was used for drying malt, and I presume that until comparatively speaking a short time ago the greater bulk of malt was dried with wood?—With charcoal.

5933. (Mr. Cosmo Benson.) The other Act of Parliament to which you allude, I suppose, is the Act of Parliament of 1888, which gives the Excise power to stop any deleterious matter going into the beer?—No, that is not what I have in my mind. I think Dr. Thorpe understands what I mean. He had under the Sale of Food and Drugs Act to establish a certain fact, whether the article possessed such properties as to enable it to be declared a genuine article or not. I say the same thing applies to beer. This beer has been sold as an article of food for centuries, we will say, and that it must have contained arsenic. Therefore it would be difficult to say—

5934. (Professor Thorpe.) Pardon me. It can only have contained with certainty arsenic since coal or gas coke have been used?—Coal has been used for a long time—two or three hundred years or more.

5935. (Mr. Cosmo Benson.) But you are aware of that particular clause in that Act which gives the Board of Inland Revenue absolute authority to stop deleterious articles?—That is so.

5936. I presume arsenic in large quantities is deleterious?—That is where the large quantities come in. There is no doubt the Inland Revenue have, under that portion of the Act, absolute authority to prevent the use of glucose containing what they may consider deleterious quantities of arsenic. I am not quite sure even now that if Professor Thorpe found one-thousandth of a grain to a lb. in the sugar that he would not have the power of stopping it.

5937. Or in malt?—In malt or in sugar, because it would come to the question of how far it is deleterious.

5938. (Professor Thorpe.) I have not that statutory power. What you really drive at is that we should, somehow or other, by machinery, get that statutory power?—That is so.

5939. Have you anything more to say on the broad question?—No.

Mr. C.  
O'Sullivan.

(SIR WILLIAM CHURCH in the Chair.)

SIR LAUDER BRUNTON, called; and Examined.

5940. (Sir William Church.) I believe you are a Fellow of the Royal Society, and physician to St. Bartholomew's Hospital?—I am.

5941. And you have made a particular study of therapeutics?—I have.

5941<sup>a</sup>. You studied the recent epidemic, and were a member of the Expert Committee of the Manchester Brewers' Association?—Yes.

5942. You are prepared, I think, to give the Commissioners an account of the action of arsenic upon the human system as observed during the recent epidemic?—Yes. If I may be permitted to give a short account of the general action of arsenic upon the body, I think I may be able to classify the symptoms observed in the present epidemic of arsenical poisoning so as to render it easier both to remember them and to understand the

varieties which have been described. Arsenic belongs to the same chemical group as nitrogen, which not only constitutes nearly four-fifths by volume of the atmosphere, but is an essential ingredient of all living tissues, and may be called the pivot on which all life turns. Other members of the group are phosphorus and antimony, both of which have an action very much like arsenic in many respects, and phosphorus, like nitrogen, is an important constituent of the healthy body. It is not certain whether arsenic acts by replacing nitrogen or phosphorus in the living tissues, and especially in protoplasm, which is one of the most important constituents of nerves, but it appears to have the power of altering the chemical changes or metabolism which occurs in them during life, and on which their function depend. In minute doses it appears to be beneficial, but in large doses it is poisonous, and will

Sir  
L. Brunton.

Sir  
L. Brunton.  
26 Apr. 1901.

destroy both animal or plant life, so that in large quantities it will produce in man or animals irritation and inflammation of any part of the body on which it may be applied. This application may be made directly to a part, or the arsenic may reach it through the circulation. Thus, arsenic, when it is swallowed, reaches the stomach and intestines by direct application, and by irritating them produces vomiting and purging. In the form of dust, as from wall paper, or in making artificial flowers, it may enter the eyes, nose and air passages, and, thus, it may produce conjunctivitis, nasal and respiratory catarrh, and cough; or it may be applied directly to the skin and cause irritation and eruptions upon it. If much diluted it may produce little or no local irritation of the stomach, intestines or respiratory passages, but from these it may be absorbed by the blood, and carried by the blood to every part of the body. When absorbed from the stomach and intestines it is obliged to pass through the liver before it can enter the general circulation, and consequently the largest amount of arsenic is usually found in this organ after death from arsenical poisoning. Whilst circulating in the blood it may act on the heart, muscles and nerves. But it is not carried by the blood only to these organs, for through the circulation it goes a second time to the stomach, intestines, respiratory passages and mucous membranes of the eyes and skin. By these organs it is eliminated, and during the process of elimination it may again give rise to irritation in them just as it would do if directly applied. Moreover, John Hunter, Sir Everard Home and Sir Benjamin Brodie have shown that when arsenic is applied to a wound it produces more violent and more immediate inflammation of the stomach than when the poison is administered internally, and that this inflammation of the stomach precedes any appearance of inflammation in the wound (Phil. Trans. 1812, Pt. 1, pp. 209-210). Brodie concludes that "it may be inferred that arsenic, in whatever way it is administered, does not produce its effect even on the stomach until it is carried into the blood." This conclusion is perhaps too sweeping, and not strictly true for arsenic in large doses and in a concentrated form, but it is probably quite correct when the poison is taken in moderate or small doses, and in a diluted form, as in the beer at Manchester. Whilst circulating in the blood arsenic is carried to every organ and tissue of the body, and affects markedly the nervous system and muscles, the mucous membranes and skin. It begins to be eliminated by the kidneys within a few minutes of its absorption, and is also eliminated by the mucous membranes and skin. If only small doses are taken daily the whole of the poison may probably be daily eliminated, and it may be taken for months without any harm. But if the doses are larger, less is eliminated daily than is absorbed, and it becomes stored in the body and produces symptoms of poisoning. During the process of elimination it irritates all the mucous membranes and the skin, and produces corresponding symptoms. By irritating the mucous membrane of the stomach it causes loss of appetite, nausea, vomiting and epigastric pain. In the intestine it produces colicky pains and diarrhoea. By irritating the respiratory tract it gives rise to coryza, cough, hoarseness, huskiness of the voice, oppression of the chest, retrosternal pain and bronchitis, with occasional hæmoptysis. In the eyes it causes irritation, conjunctivitis and oedema of the eyelids. In the skin it produces all sorts of eruptions, nettle-rash, redness, papules, pustules, vesicles and boils. Three of the most marked are pigmentation, herpes, and a condition to which the name of keratosis has been given in which the epidermis peels off the palms of the hands and soles of the feet in large flakes. Keratosis is probably due to the local action of arsenic upon the skin; for Ringer and Murrell found that in frogs poisoned by it the cuticle could be readily stripped from the body, and Nunn showed that this is due to softening of the protoplasm in the epidermis, so that it becomes almost completely detached from the dermis. The herpetic eruptions, as well as loss of hair, brittleness, or shedding of the nails, excessive sweating and subcutaneous oedema, however, are probably dependent rather upon the action of arsenic on the trophic or nutritive nerves of the skin to which reference will afterwards be made. During its circulation in the blood arsenic acts on the muscles of the limbs, on the muscular fibre of the heart, on the liver and other glandular organs, and especially upon the nerve trunks, although it acts, also, to a small extent on the spinal cord and brain. It thus tends to cause anemia, as well as fatty degeneration of the muscles and of the heart, so that the limbs become

feeble, and the heart so weak that death may occur from its failure. The liver also undergoes fatty change. The nervous system, and especially nerve trunks, are especially attacked by the poison. Nerve trunks usually contain fibres having three different functions, namely sensory, motor and trophic or nutritive, and all those functions are altered by the inflammation which arsenic produces in the nerve trunks. The alterations are of two kinds; first, the nerves are unable to do the things they ought to do; and, secondly, they do things they ought not to do. The sensory nerves instead of conveying definite impressions to the brain become dulled, so that the patient does not feel external objects with the same accuracy that he or she ought, and in consequence complains of numbness, and may be unable to distinguish where or what things are, and may thus, for example, be quite unable to sew, or even to write, and may drop things from the hand unwittingly, while the patient may feel as if his feet were walking on wool instead of on the floor. At the same time, the sensory nerves convey to the patient impressions for which there is no real objective ground. He may feel as if pins and needles were running into him, insects were running over him, or he may feel intense burning or pain of all sorts in various parts of the body, and both the skin and the muscles may be so abnormally tender that the slightest touch or pressure is not felt as touch or pressure, but causes the most intense suffering. On account of the weakness of the motor nerves the patient soon gets tired, and then certain muscles become so weak as to act only imperfectly, or may become completely paralysed, and not act at all. On this account the gait becomes feeble and staggering, the feet drop, the hands drop, the patient becomes unable to walk or stand, and may be even unable to feed himself, while on account of the diaphragm being weak or paralysed the respiration becomes feeble and imperfect. By stimulating the trophic or nutritive nerves, and perhaps by directly altering the tissue change of the parts themselves, arsenic may at first appear to increase nutrition, so that small quantities render animals or men taking it plumper and more active, their hair grows more thickly, and their skin appears clearer than before. But if this point be overpassed, the animals or men become thinner and wasted, the skin dry and hard, peeling off in scales, and often much pigmented. This pigmentation varies in appearance. It is sometimes slight but general, sometimes patchy, and sometimes so generally diffused and deep in colour as to make the patient appear to belong to a dark-skinned race. The peeling of the skin generally occurs in bran-like scales, but the epidermis may separate from the soles of the feet and palms of the hands in very large flakes. To this the name of "keratosis" is given. Local swellings of an oedematous or dropsical nature may occur in various parts of the body, and are particularly noticeable in the eyelids. The spinal cord may also undergo alteration, and some of the neuralgic pains, the loss or perversion of sensations of heat or cold, loss of reflexes and want of co-ordination in movement may be partly due to alteration in it, as well as to alteration in the nerve trunks. In some cases, although rarely, the brain has been found to be affected, and symptoms of melancholia or mania have occurred. The nervous ganglia of the heart may be weakened, and this, along with the feebleness of its muscular fibre, already mentioned as due to arsenic, may lead to syncope, or even to death. The nerves which regulate the contraction of blood vessels are said by Böhm to be paralysed by large doses of arsenic, so that the vessels dilate, especially those of the abdomen, and this, along with the weakness of the heart, explains the low tension of the pulse observed in severe cases during this epidemic. The blood vessels of the soles of the feet and of the palms of the hands become much dilated, so that the skin of these parts towards the outside becomes very red, and at the same time it becomes exquisitely tender and very painful. This condition is known under the name of erythro-melalgia.

5943. Do the symptoms vary with the amount of arsenic taken?—All the symptoms I have mentioned may occur in chronic arsenical poisoning, but they may not all appear in the same person or to the same extent, for their occurrence may depend upon the quantity of arsenic they have taken, upon the length of time its administration is continued, upon the form in which it is taken, and upon the personal peculiar idiosyncrasy of the person taking it. Small quantities of arsenic, such as the 50th to a 10th of a grain, may be taken by many people for months together with no apparent bad health, but, on the contrary, with better

nutrition and increased strength. In these cases it is probable that the whole of the arsenic is eliminated daily as quickly as it is taken, and that there is no storage of it within the body; but if larger quantities are taken, so that the whole is not eliminated, it will gradually accumulate, and symptoms of poisoning begin to occur, which may become very severe or fatal. Yet, if the administration of the drug be stopped before a fatal issue is reached, the poison which has already been stored up in the body is gradually excreted, and the patient may recover even when apparently at death's door. But during the process of elimination symptoms of sub-acute poisoning may occur, and the arsenic which has been stored up for awhile in the body may, in passing out through the mucous membranes of the intestine and stomach, irritate them and produce vomiting and purging, as in some of Mr. Dixon Mann's cases three weeks after the arsenic had ceased to be taken.

5944. Are some persons so constituted as to bear larger doses of arsenic than others?—The effect of arsenic can be modified by the age, strength, and constitution of the patient taking it, women usually being able to take less than men, and children very much less than either. Susceptibility to arsenic varies very considerably, and while three minims of Fowler's solution, which is a 1 per cent. solution of arsenic, and is the preparation commonly given in medicine, will sometimes cause such symptoms of intestinal irritation as will necessitate its discontinuance, other patients will take 30 minims, or even more, three times a day without any discomfort whatever. The way in which it is given alters its action, so that if five minims of Fowler's solution were given on an empty stomach three times a day it would probably produce irritation of the stomach and intestines, whereas if given when the stomach was full it would be diluted by the food and be absorbed without producing any local irritation whatever. When much diluted in the form of beer, the local action of arsenic on the stomach and intestines at the time of taking it is probably very slight, and the gastro-intestinal irritation observed during this epidemic was comparatively trivial as compared with the other symptoms, and was probably due to irritation of the mucous membrane occurring during its elimination. During the circulation of arsenic in the blood, it is not improbable that its action may be determined to one part of the body or to another by other substances taken at the same time. A well-marked instance of this kind of action is known in the case of mercury. Alcohol is well known to have a strong affinity for the nervous structures in the body, whilst that of mercury is much less. But alcohol seems to direct mercury to the nervous system, and cause it to act upon them. An example of this is given by the fact that during the preparation of an alcoholic compound of mercury, called mercuric methide, two chemists who were subjected to the fumes were poisoned by the compound, and showed signs of nervous disease, one of them becoming maniacal and dying within three months, and the other becoming idiotic, and dying after about a year's confinement in a lunatic asylum. Osler has observed that mercury taken along with alcohol seems to have more tendency to produce peripheral neuritis than if taken alone, the alcohol seeming, as it were, to direct the arsenic to the nervous system. If the statements made by some of the patients who have suffered in the present epidemic of this arsenical poisoning as to quantity of beer they have taken are correct, the amount of arsenic consumed in some cases must have been so exceedingly small as to lead one to ask whether the neuritis can be due to arsenic alone, even though its action may have been directed to the nerves by alcohol or hops, or whether some other poison besides arsenic has not been present in the beer, or whether the arsenic is not present in such a combination as to have a much more deleterious action than that of pure arsenic itself. There are difficulties in accepting the statements of some of the patients as correct, for in the case of Alice Booker, which terminated fatally, and in which Dr. Stevenson separated a weighable quantity of arsenic from the viscera, the patient only admitted having taken less than one pint per diem. It is quite possible that arsenic may be present in beer, combined with either a hydrocarbon or with a proteid, for although it is said not to unite with albumen to form an albuminate, it has been found to enter into combination with casein. At present, however, this is only a hypothesis, and Professor Hewitt and I are at present engaged in investigating the subject. It is, however, a research full of difficulties, and if we succeed in obtaining definite

results at all, it will probably not be until after the expiration of several months at the earliest.

5945. Do you know of any other facts bearing on the hypothesis you have just mentioned?—Yes. In an epidemic of arsenical poisoning at Würzburg, where the arsenic was contained in bread, only one case of paralysis was observed in 373 cases of poisoning. This extraordinary want of action on the motor nerves when taken in bread as compared with its action when taken along with alcohol in beer or wine tends to substantiate my hypothesis.

5946. Have you any doubts as to the epidemic in Manchester being due to arsenical poisoning?—I have heard doubts expressed as to whether the epidemic in Manchester was due to arsenic at all, and I confess that when I first went I thought that possibly the symptoms might be caused by organic impurities in beer, such as some of the higher alcohols, e.g., fusel oil, by albumoses, or by furfural. But an examination of the facts has convinced me that the epidemic was due entirely, or almost entirely, to arsenic. No doubt neuritis may be produced by toxins of an albuminous nature, such as occur in the body in diphtheria, in plague, and in beri beri, or are found outside the body in diseased grain, such as ergot and maize, producing ergotism and pellagra. But in the present epidemic the cases of illness were distinctly traced to beer. There was no diseased grain used in its production, no evidence of any infective disorder; in fact, there has been no evidence of the presence of anything excepting arsenic, and possibly selenium, that would produce the symptoms. These symptoms consisting in a combination of gastro-enteric irritation, peripheral neuritis, pigmentation, and eruptions of the skin, are almost characteristic of arsenical poisoning. They occurred in previous epidemics. For instance, in the one which occurred in Hyères, in which a number of persons were poisoned by arsenic in wine, the symptoms were almost identical with those of the present epidemic. In both these epidemics the symptoms may be conveniently classed in the manner adopted by MM. Vidal and Ollivier for those observed at Hyères into:—

- (1.) Digestive.
- (2.) Cutaneous.
- (3.) Nervous.

In both epidemics the digestive symptoms were not nearly so prominent as would have been expected from the well-known irritant action on the digestive canal which arsenic produces in cases of acute poisoning, and in some cases symptoms of this sort were completely absent. They seem to have been rather more marked at Hyères than at Manchester, a circumstance which one would naturally expect both from the more irritating action of wine as compared with beer on the mucous membrane of the stomach and intestine, and from the larger proportion of arsenic in the wine (0.8 gramme per litre). The digestive symptoms were alike in both epidemics, viz., loss of appetite, vomiting, abdominal pain, and diarrhoea. Retrosternal constriction or pain was noted in both, and I have mentioned it already along with cough, but at Hyères it was attributed to digestive derangement. In both epidemics the symptoms produced during absorption were slight in comparison with those which occurred during the circulation of the poison in the system and during its elimination.\* The cutaneous symptoms which occurred were of the most varied kind in both epidemics. In Hyères the forms were so manifold as to exhaust dermatological nomenclature, and they of skin were no less so in Manchester.† In both epidemics two affections of the most striking cutaneous symptoms were pigmentation of the surface generally, and separation of the epidermis from the feet and hands in such huge flakes that it seemed as if the whole skin of the soles and palms came off in one piece (keratosis). At Hyères coppery patches on the skin and an eruption the colour of burnt coffee were noticed, but the pigmentation does not appear so have been so dark or so extensive as in some of the cases at Manchester. In both epidemics the nervous

\* MM. Vidal and Ollivier say "Les ingestions répétées de doses dissimulables, mais relativement élevées, d'arsenic n'ont été suivies que d'accidents peu importants correspondant à la période d'absorption; les plus sérieux se sont montrés pendant la diffusion dans l'organisme se surtout l'élimination. Bull. de l'Acad. de Med., 1888, T. xx, p. 624.

† According to MM. Vidal and Ollivier "Si l'on voulait donner un nom adapté exactement à la forme de toutes ces éruptions il faudrait épuiser la nomenclature dermatologique actuelle. Bull. de l'Acad. de Med., 1888, xx, p. 623.

Sir  
L. Bruntton.

symptoms were the most important, and in both cases they were at first attributed to alcohol and not to arsenic.\* In both epidemics, although numbness and loss of sensation were observed, they were not such prominent symptoms as pain and tenderness, weakness and paralysis. In both pain was a most marked feature, varying in intensity from slight "pins and needles" to most intense agony; and a very striking symptom was extreme tenderness to touch or pressure, so that the patients could not bear the pressure of the bedclothes on their limbs. Extreme tenderness of the calves and other muscles of the body on pinching, as well as the redness and exceeding painfulness of the soles of the feet and palms of the hands (erythromelalgia), which were so marked in the Manchester cases, are less prominently noticed in the accounts of the Hyères epidemic. Something of the same kind seems, however, to have been present for the patients are said to have complained of pain as if dogs were gnawing their calves and the soles of their feet. In both epidemics the muscular weakness or paralysis, the difficulty in walking, the peculiar gait, and sometimes the complete inability to stand, were all alike. Both resembled each other, also, in the affections of the respiratory system; indeed, with the slight difference indicated already, the symptoms in one epidemic might stand for those of the other. In both epidemics there can be little or no doubt that the symptoms were chiefly, if not entirely, due to arsenical poisoning, for (1) there was an absence of any other sufficient cause, (2) there was sufficient arsenic to cause symptoms of poisoning, (3) the symptoms corresponded with those which have been observed in cases of chronic poisoning by arsenic taken in other ways.

5947. Then you have no doubt in your mind that the recent epidemic was due to arsenical poisoning?—When I first went to Manchester to investigate the epidemic I started with the idea that the symptoms of poisoning were probably due not to the arsenic in beer, but to some other impurity, but I soon found that the arsenical origin of the epidemic could be proved beyond a doubt. The present epidemic is certainly due to contamination of beer through glucose and invert sugar made by one particular firm, who had been supplied with sulphuric acid containing a very large quantity of arsenic. The extraordinary number of cases of peripheral neuritis which have occurred in this epidemic, together with the fact that this disease has been specially observed and described by two Manchester men, Professors Ross and Dreschfeld, naturally raises the question whether the peripheral neuritis, a disease which is commonly attributed to alcohol, is not caused in most, if not in all, cases by arsenical poisoning, and whether poisoning by arsenic may not have been going on to a greater or less extent in Manchester for many years. A good deal may be said on both sides of this question. On the one hand, it cannot be denied that peripheral neuritis may be caused by toxins, for it is found in diphtheria, where no poison except that of diphtheria has gained access to the organism, and Sidney Martin has shown that the diphtheritic toxin, apart from the bacillus, will produce neuritis in animals. But, on the other hand, although it is commonly supposed that alcohol will cause the disease, it is by no means certain that ethylic alcohol will do so, and alcoholic neuritis in spirit drinkers may possibly be due to other substances than ethylic alcohol. A remarkable observation was made to me in a letter by Sir William Gairdner. About sixteen years ago he was examining in Manchester, and went through the wards of the late Dr. Ross. He saw there several cases of peripheral neuritis, and was much astonished because he could not recollect seeing more than two cases in Glasgow in all his life. He wondered if he could have overlooked the disease, but after consideration he came to the conclusion that it did not exist in Glasgow, notwithstanding the large quantity of whisky which was drunk there, and ought to have produced the disease if it were due to alcohol as usually supposed. The fact that arsenic has now been found both in hops and malt renders it not improbable that cases of peripheral neuritis in Manchester may for years past have been due to a certain amount of contamination of beer by arsenic through hops and malt, and although it is not yet certain, it seems probable that this contamination may have arisen from the use of coal or coke containing arsenic in the process of drying.

5948. Have you anything to say with regard to the recent discovery of selenium in beer?—The recent and

remarkable discovery of selenium in beer by Professor Tannichoff imports a new factor into the question, but further information is required before any conclusion can be arrived at as to whether this substance may be partly to blame for producing neuritis, and if so, to what extent.

5949. You wish to make some observations on objections which have been raised to the practice of using glucose in brewing?—The occurrence of this epidemic has caused an outcry against the practice of using glucose and invert sugar in brewing, and a demand that only barley and hops shall be employed. But I am informed that this would render it difficult to brew the light beers similar to the German lager or Pilsener beers which have come to be so extensively drunk in this country within the last thirty years. I regard the introduction of such light beers as a benefit to the public, for it supplies a drink which can, if pure, be taken without causing the heaviness, drowsiness, stupidity and headache which so commonly follow the consumption of heavy ales.

5950. And you wish to indicate that indirectly the recent epidemic may have given a useful lesson?—Although this epidemic has done much harm, has caused great pecuniary loss to the brewers, who were not to blame, and, still worse, has caused great pain, paralysis, and, in some cases, death to the unwitting consumers of the contaminated beer, it has not been without its advantages. For it has shown how a poisonous substance may find its way into a chemical, and, through it, not only into beer, but many other substances used as food. It has shown, also, how a poison like arsenic may find its way into food in such unexpected ways as through hops and malt, and thus enforces the necessity of guarding the consumer not by placing restrictions upon manufacture, but by demanding that the manufacturer shall in the future be held responsible for the purity of the articles he sells, and that all materials for beer or foodstuffs should be sold with a guarantee of purity which should be rigorously enforced.

5951. With regard to what you say as to the action of arsenic when it is applied to wounds and external inflammations, is it not the case that arsenic coming into contact with the skin of those who are working in preparations of arsenic of itself produces very troublesome sores?—It does.

5952. Is that due to external application, and not to its having been absorbed?—No, to its local action. I have noted that it may be applied directly to the skin, and cause irritations and eruptions upon it.

5953. You say that the liver also undergoes fatty change. Of course in this epidemic there has been a mixture of alcoholic poisoning probably with arsenical poisoning?—I think in all the cases that I saw in Manchester the symptoms were mixed—partly alcoholic and partly arsenical.

5954. Would you mind telling the Commission a little more with regard to the changes that you think arsenic produces on the liver?—The liver cells undergo fatty degeneration. The substance of the cells themselves are more or less converted into fat. In cases of alcoholic degeneration you will very often find a greater enlargement of the liver than with arsenical poisoning, apparently more deposition of fat; not so much conversion of the protoplasm of the cells into fat, but an absolute deposition of fat from elsewhere.

5955. In very chronic cases of poisoning with either substance there are further alterations which you think differ in the two cases?—In the case of alcoholic poisoning one generally gets a large deposition of fibrous tissue, giving rise to hardening and afterwards to a contraction of the liver, the fat being absorbed. I do not know that this is observed to anything like the extent, or has indeed ever been observed to any extent, in cases of arsenical poisoning. Most of the observations on the action of arsenic on the liver have been made upon animals, and of course in them the poisoning is carried out quickly, and there is not the same time for observation that there is in cases of alcoholic degeneration of the liver in man.

5956. So that we really know very little with certainty with regard to the action of arsenic upon the liver when carried on for long periods of time?—Very little.

5957. Could you tell the Commission anything with regard to Dr. Dixon Mann's cases, where three weeks after the arsenic had ceased to be taken, irritation of the stomach and intestines took place?—Do you know whether any examination of the urine was made at that

Peripheral neuritis before the epidemic may have been caused by arsenic.

Food manufacturer should be responsible for purity of his product.

Effect of arsenic on the liver.

More information needed as to selenium in beer.

\* "Jusqu'en 20 mars," dit le Dr. Dubrandy, "j'avais toujours supposé que les accidents pourraient bien être d'origine alcoolique et produits par l'usage d'alcools absorbés en nature ou sous forme de vins vides pris en excès." Bull. de l'Acad. de Med., xx, p. 620.

time, whether it was really certain that arsenic was passing out of the body at that time?—I regret I cannot state definitely. These cases were described by him at a meeting of the Royal Medico-Chirurgical Society. He made the statement very positively that there were cases of arsenical poisoning, but I cannot at this moment recollect whether, during the time when the symptoms were developed, arsenic was observed in the urine or not.

5958. Would that not be a proof that arsenic was really being eliminated at that time, whereas this is only an inference from the occurrence of the purging and vomiting? Some persons are so constituted as to bear larger doses of arsenic than others?—Yes.

5959. And the effect of arsenic, as you say, can be modified by the age, strength, and constitution of the patient taking it, women usually being able to take less than men, and children very much less than either—that is, when arsenic is given medicinally?—Yes, when one knows definitely that the patient is taking arsenic, and knows the exact amount that is given.

5960. Is it generally recognised, that women can take less than men, bulk for bulk of body?—I should not say bulk for bulk. This is only a general statement of men compared with women, and not men and women as compared by body weight.

5961. Or children?—Children I do not think stand it nearly as well. Some of them do, but children, as a rule, do not bear arsenic so well as grown-up people. The intestines seem to be more irritable, and the proportionate dose is very apt to cause pain and diarrhoea.

5962. Does the susceptibility of different children vary very greatly?—Enormously, I think.

5963. Is that the only reason that you can advance for women having apparently suffered more severely than men in this epidemic?—No, I think it is that the women have really taken more beer, and that possibly the women have been supplied always with the same kind of beer—that they have gone to a public-house near at hand, so that where they have taken arsenical beer they have taken it continuously. A man moves about and perhaps drinks arsenical beer at one public-house, non-arsenical at another, and so on. So that the two reasons, I think, are that the women have actually drunk more beer than the men, and that they have drunk regularly beer containing arsenic, whereas men who have drunk a good deal may have had a mixture of beers.

5964. Do you think that the greater physical labour of the men leads to more rapid elimination of the arsenic?—That is possible, but I do not know.

5965. Have you any information to give the Commission with regard to the work that you are carrying on with Professor Hewitt which you alluded to?—We find it an exceedingly difficult problem. We have tried to obtain from beer arsenical products, but they are so exceedingly difficult to obtain, and so exceedingly difficult to settle their constitution, that we are thinking of beginning really from the other end, and of trying to obtain arsenical substances which may be possibly present in beer. For example, we think of trying to obtain arsenical ureas in which the nitrogen of the ureas should be replaced by arsenic and several other compounds of that sort. If we succeed in those we may possibly go on to try and obtain arsenical albumoses. But the substances present in beer are certainly very complex, and we have not come to any definite conclusion as yet.

5966. Have you any evidence that arsenic is present in the beer in a complex organic condition?—There is no definite evidence yet. The reason for supposing that it may be so is this, that in the case of epidemics where the arsenic has been taken in alcoholic liquids there has been much more affection of the nerves. In one case, for example, where a large number of cases occurred from arsenic taken in bread, the nerves were not nearly so much affected.

5967. That possibly may be explained by the joint action of the two bodies together, without imagining that they form a new body?—That is quite possible. As I said, it is possibly determined by the action of the alcohol.

5968. Have you any doubts as to the epidemic in Manchester being due to arsenical poisoning?—None whatever.

5969. Recognising now that it was due to that at Manchester, would you mind stating whether you think there were any reasons why the doctors at first were

slow in recognising it?—I believe that for a number of years cases of neuritis have occurred in Manchester.

5970. Would you anticipate that neuritis was the form of disease which would first attract attention in arsenical poisoning?—No. But the number of people suffering from alcoholic neuritis was supposed to be due to alcohol, and not to arsenic.

5971. That you have mentioned. I am asking whether anything has occurred to you to explain the delay of the profession generally in recognising that this disease in Manchester was due to accidental arsenical poisoning, and not to alcoholic poisoning or any other poisoning. During the early part of the epidemic, the great absence of sickness and diarrhoea amongst the people who were taking arsenical beer was noteworthy. The first symptoms that attracted attention were not gastric, which is usually the case in arsenical poisoning?—There is that, and their being familiar with cases of neuritis due as they supposed to alcohol. They therefore classed these cases, which might have otherwise attracted attention, as being due to alcohol. If I might put it in other words, their familiarity with alcoholic neuritis misled them because they attributed the neuritis always to the alcohol and to nothing else.

5972. Do you think it is a fact that alcoholic neuritis has been much more prevalent in Manchester, Liverpool, and the neighbourhood than in London and district?—I think it must be so, because it was in Manchester that the disease attracted so much attention. It was there very clearly described by Ross and Dreschfeld, whereas men in other parts of the country had not seen the cases or else had passed them over. Sir William Gairdner, of Glasgow, told me that he had been examining in the Victoria University, and was much struck with the fact that there was not only one but two or more cases of peripheral neuritis in Dr. Ross's wards. It struck him all the more because he had not seen such cases in Glasgow. On taxing his memory he could not remember more than two at the very outside in the whole of his life, and yet people in Glasgow drank enough whisky to give them alcoholic neuritis if the neuritis was due to alcohol pure and simple. Although he could not explain this prevalence of alcoholic neuritis in Manchester at the time, on learning that people had been drinking beer containing arsenic, he went over the facts, and came to the conclusion that the neuritis he had observed was probably not really alcoholic but arsenical.

5973. The profession generally in London were quite conversant with what they call alcoholic neuritis in London?—Yes, but not to the same extent.

5974. That leads you to think that it is possible that arsenical poisoning has been going on for some time?—Yes.

5975. With regard to Professor Gairdner's remark, is it not true that apparently different alcoholic drinks do produce different changes in the tissues of the body?—I think it is quite true. I once came across rather a curious observation in regard to different kinds of wine, which was made to me by the landlord of a hotel, and not by a medical man. The landlord of the hotel of Les Avants, above Montreux, told me that the people in their own valley who drank white wine all became affected with tremor, so that they were obliged to give up their occupation, whereas the people who drank red wine in the same localities did not suffer in the same way. The actual explanation of that I have not been able to find out, but it was suggested to me that the white wine was often more or less sweetened with glycerine, and that the glycerine might possibly contain arsenic, and that those people who drank white wine might be suffering from arsenical tremor brought on through taking white wine sweetened with glycerine.

5976. Is it not the case that whisky does not seem to produce the same sort of degeneration upon the internal organs that gin does?—That is quite true, I think. For example, in the liver there is one variety of diseased liver which is known under the name of "gin drinker's liver," and which appears to be more marked in the case of those who drink gin than in those who drink whisky.

5977. It is comparatively rarely found in Edinburgh and Glasgow, or Scotland generally?—Yes.

5978. So that the mere fact of alcoholic paralysis not being so prevalent in Scotland may depend upon some unknown cause, just in the same way as cirrhosis of the liver is not so common in Scotland from alcohol?—Yes.

Sir  
L. Branton.  
26 Apr. 1901.

Epidemic at first wrongly attributed to alcohol.

Greater prevalence of alcoholic neuritis in Manchester before the epidemic.

Dr. Ross & Dreschfeld were misled by the prevalence of alcoholic neuritis in Manchester at the time.

probably due to arsenic.

Glycerine in wine.

Sir  
L. Brunton.  
26 Apr. 1901.

Pure glucose  
not injurious  
in beer.

5979. Do you think there is any widespread feeling against the practice of using glucose in brewing?—I do not think so.

5980. Is glucose likely to be injurious when used in beer?—No, certainly not. It seems to me that glucose is one of the things about which you can be absolutely certain that it contains no arsenic.

5981. Do you think there would be any difference when the glucose or invert sugar was added in the copper in making the wort, or if it was added afterwards to the finished beer? There is a process which they call priming in which glucose is used?—I suppose that if it was added to the beer before fermentation some of it might be taken up by the yeast and thus removed from the beer.

5982. I mean pure glucose?—No, I do not think so.

5983. You think that pure glucose, used in brewing, if it is fermented, is perfectly wholesome?—Perfectly.

5984. And you think that the resulting liquid is equally wholesome if it is added after the fermentation has been completed?—Perfectly so. Glucose is a perfectly innocuous substance and an excellent food. The results would be different as regards the liquids. As regards the health of the person, they are both perfectly innocuous.

5985. It has been given in evidence before us by one medical man that he thought the beers brewed with glucose were not so wholesome, and more often led to vomiting and stomach troubles than those which did not contain a large quantity of glucose?—I know of no facts which would lead one to believe that. I cannot deny it, because I have not the data.

5986. You know nothing which would lead you to think that the addition of this unfermented glucose to the finished beer would be likely to cause the beer to be unwholesome?—No, except that in very large quantities sugar of any kind disagrees with some people, whether in the form of glucose or saccharose.

A Govern-  
ment Board  
of reference  
should control  
purity of  
food.

5987. Have you thought out at all in what way guarantees of purity should be rigorously enforced by the manufacturers in buying materials?—I think that practically we want in this country something corresponding to the German Gesundheitsrath, a Board of Public Health, and that such a Board should have at least one representative of various sections. One would require at least one man thoroughly acquainted with public health, and the management of public health affairs. You would want a thoroughly trained chemist; you would certainly want a bacteriologist; you would want a man to investigate the action of any poisons that might happen to turn up, a pharmacologist, and you would also want a medical man—five different representatives, and probably you would want instead of one of each, several.

5988. Several members?—Yes, several members of each section.

5989. With what bodies would this board be in relation, and how would it work?—I have not thoroughly considered the relationships of it; I have only thought that it would have to take cognizance of questions brought before it by public analysts and medical officers of health.

5990. It would be a board of reference rather than a board of action?—Yes.

5991. (Professor Thorpe.) With what Government department would it have relations?—Unless the Local Government Board were reconstituted it would come into relationship with the Local Government Board.

5992. (Mr. Cosmo Benson.) Would it be appointed by the President of the Local Government Board and discharged by him?—It might be so.

5993. (Professor Thorpe.) Take any particular case, boracic acid, on which you gave us evidence before the Committee. After taking evidence, and making such inquiries, suppose that this board came to the conclusion that the use of that particular antiseptic was injurious, what would follow on that finding?—Then instructions should be given to the medical officers of health that all cases where boracic acid was found should be prosecuted.

5994. Under what Act?—I should think the Sale of Food and Drugs Act would cover that, would it not?

5995. Not unless somebody had declared it to be a noxious and deleterious thing, and not of the nature, substance, and quality demanded?—The question whe-

ther boracic acid was a noxious thing or not would be referred to this board.

5996. If the board came to the conclusion it was, your idea is that they would recommend the Local Government Board to take action under the provisions of the Sale of Food and Drugs Act?—Yes. We must have some definite advising body to whom such questions could be referred.

5997. You have just drawn our attention to the peripheral different mode of action of different forms of commercial alcohol. You instance, for example, the difference in the mode of action of gin and whisky. I believe you have given some attention to the action of the aldehydes. Is it possible that the action may be in some way connected with the presence or absence of bodies of this character?—That I cannot tell. I thought at first it might be. When I went to Manchester I saw so clearly that it was arsenical poisoning and not connected with the aldehydes. One reason why I believe that it is not connected with the aldehydes is that in the epidemic of Hyères the symptoms resembled exactly those of the epidemic in Manchester, and the ordinary light wine of the south of France contains very little aldehydes.

5998. You quickly satisfied yourself in the case of the beer that it was due to the arsenic, because arsenic was found in relatively large quantities, and the symptoms corresponded to those produced by arsenic; but nevertheless, is it not possible that the continued ingestion of small quantities of furfuraldehyde is capable of producing peripheral neuritis?—That I cannot tell, because these are just the questions that at present there is no possibility of settling. At present the only way to settle such a question would be either to make a prolonged series of experiments upon animals, which would very likely give unsatisfactory results, and the other would be to let a number of people go on taking a kind of spirit which we know to contain aldehyde. But one point about the aldehydes is that they are present in Scotch whisky, and in Glasgow, where the whisky was taken for a length of time and in considerable quantities, and where we may assume—although, perhaps, we have no definite evidence—that all that time the people were drinking whisky containing furfural—probably they were, and did not get peripheral neuritis.

5999. Furfural would be most largely found in the newest whisky?—Yes.

6000. And it became eliminated by age?—Yes.

6000\*. To it is due the physiological effect between aged whisky and new whisky?—Yes. In Glasgow I fancy they drink a great deal of new whisky.

6001. Does Irish whisky contain more furfural than Scotch whisky?—I fancy it does, but I do not know. I believe in Ireland there used to be a great deal of Irish whisky which paid no duty, and there was no separation between the alcohol and the impurities. The whole thing was simply distilled over, and that must have contained a large quantity of furfural.

6002. In illicit-made whisky there must be a large preponderance of furfuraldehydes and other aldehydes; but the amount of illicit whisky is so small that its influence as regards neuritis would probably not be detectable?—I hope so.

6003. (Dr. Whitelegge.) I did not quite gather whether you had any reason to think that arsenic in beer was probably not in the form simply of arsenic oxide?—No, I cannot say definitely. It is a hypothesis that requires to be worked out. As I said before, the practical research necessary to answer this question is an exceedingly difficult one. It takes a lot of time, and you get a great many disappointments.

6004. Have attempts been made by yourself or other experimenters to separate out the arsenic in whatever form of combination it exists, by dialysis, or in other ways?—Not by dialysis. Dr. Hewitt is working at the thing just now, and I cannot give you the data he has. But it has been more by precipitation.

6005. You referred to the difficulty that would arise Advant in brewing light beers similar to German lager and glucose Pilsener, if glucose were disallowed? Am I right in sup- light h posing that glucose is not used in brewing those beers in Bavaria and other parts of Germany?—I believe that is quite true. It comes to be really an economic question. I only speak from hearsay. I was told that our barley contains a much larger quantity of nitrogenous substances than the foreign. That if we use malt made from British barley, without the addition of glucose to

Sir L.  
Brunton.  
26 Apr. 1901

counterbalance the extra nitrogenous matter, we are bound to have a very heavy beer, such as was prevalent some thirty years ago. There are only two alternatives, we must either add glucose, or else we must go to Germany, or some place for the lighter barley to make malt with.

6006. So that the difference arises from the difference in the English and German barley?—That is so.

6007. I did not catch what you said was the difference between the malts?—The German barley contains a smaller quantity of nitrogenous matter. There is a larger proportion of starchy matter, and if we brew with English barley we get into the beer too large a proportion of nitrogenous matter, and to counterbalance this we must put in some extra saccharine, and if this is not done the other alternative is, we must go somewhere else and get a foreign barley from which to make malt, because the foreign barleys yield a smaller proportion of nitrogenous matter and a larger proportion of saccharine.

6008. You suggested the composition of a Board to pronounce an authoritative opinion on points in connection with the sale of Food and Drugs Act, not beer in particular, but foods in general?—Everything.

6009. Would you think of such a body as exercising any control over the processes of manufacture?—No, I think they had better not. It would be a great pity to interfere with the processes of manufacture.

6010. You suggested that the manufacturer should in

future be held responsible for the purity of the article he sells. You would not think of that as a function of the body you propose?—No. The Medical Officers of Health would get specimens of various articles, or if the purchaser complained of some product being impure, it might well be submitted to such a Board, and their decision upon it would be final, instead of as at present simply involving a lawsuit.

6011. Their opinion as to the harmfulness or the reverse of a given constituent found by analysis?—Yes.

6012. You are not thinking of a Court of Appeal on the question of analyses *per se*?—No, although that might very well be combined with it.

6013. Do you think of the Board as having any executive officers, or as relying entirely for its information on the public analyst or Medical Officer of Health?—I have not worked it out in detail, and I do not think I can give any very definite opinion upon that. In my own mind I had simply thought of the medical officer of health, but in practice it might come to be advisable for the Board to have officers of its own. Instead of beginning on a large scale, and working the thing out completely, I thought of beginning on a small scale, and seeing how it would work practically.

6014. Has the Gesundheitsrath a staff of inspectors?—I am afraid I cannot tell you that just now. I regret I have not looked up that point.

Sir  
L. Branton.  
26 Apr. 1901.

## TWELFTH DAY.

WESTMINSTER PALACE HOTEL.

Saturday, 27th April, 1901.

PRESENT:

The Right Hon. LORD KELVIN (*Chairman*)

The Right Hon. Sir WILLIAM HART-DYKE,  
Sir WILLIAM CHURCH,  
Professor THORPE.

Dr. WHITELEGGE.  
Mr. COSMO BONSON.

Dr. BUCHANAN, *Secretary*.

Mr. RICHARD CHARLES GARTON, called; and Examined.

6015. (*Chairman*.) You are partner in the firm of Messrs. Garton, Hill and Co., Brewing Sugar Manufacturers, of Southampton Wharf, Battersea?—Yes.

6016. Is your produce solely used in brewing, or is it also sent out for use in various articles of confectionery?—Exclusively used in brewing.

6017. Not made for golden syrup?—No.

6018. You tell us that your firm was established in 1860; your father was the first to introduce invert sugar for use in brewing, and he worked out the process in conjunction with Dr. Letheby and Dr. Herapath?—Yes.

6019. Your firm manufactures a large percentage of the total brewing sugars made in this country?—Yes.

6020. What percentages?—Approximately 45 per cent. of that manufactured in this country.

6021. Shortly previous to the establishment of the factory by your father for the manufacture of invert sugar, had glucose been manufactured?—Yes, it had; not on a very large scale.

6022. For what purposes?—For brewing purposes.

6023. Not very much before your father took it up?—Only two or three years before.

6024. What do you mean exactly by "invert," which appears to be used in different senses?—I mean the product of the action of acid upon the cane sugar employed; the sugar is given a left-handed rotation to polarised light.

6025. Does any right-hand polarisation of the crystallisable sugar remain, or is it completely changed?—It completely turns over to the left.

6026. And the strength of the invert polarisation, is it equal to the strength of the direct polarisation of the cane sugar before the use of the acid?—The polarisation of the pure cane sugar would be upon a scale, as I understand it, plus 56; but when it is turned to the left it would give a minus 12 or 13.

6027. So that the invert rotation is much less than the original rotation in the opposite direction?—Yes; but may I be allowed to ask my head chemist, Dr. Thorne, who is here, if I am correct in the figure? I find that the change should be from the ratio plus 36 to minus 12½.

6028. Some ten years afterwards there was added to your manufacture of invert the manufacture of glucose for brewing?—Yes.

6029. You tell us that at a later stage your father became associated with Mr. Cornelius O'Sullivan, one of the pioneers of the practical work of the transformation of starch into sugars?—Yes.

6030. Had he patented processes for doing that?—He had.

6031. Patented details for the mode of application of the acid and the mode of their removal?—Yes.

6032. There was a special product, dextrin maltose, dextrin malt, the use of which arose from his work in conjunction with

Mr.  
R. C. Garton.  
27 Apr. 1901.

Mr.  
R. C. Garton.  
27 Apr. 1901.

your father. How is that distinct from glucose?—It is a transformation product between starch and glucose.

6033. It is a carbo-hydrate substance with properties intermediate between starch and glucose?—Yes.

6034. Glucose, invert and dextrin maltose are the only brewing sugars manufactured by your firm. They are all produced by the action of sulphuric acid either on cane sugar or starch?—Yes.

6035. Then various substances may be used for giving the starch?—Almost any starch-producing substance might be used for the manufacture of glucose.

Maize, sag,  
and tapioca  
flours made  
into glucose.

6036. Potato?—Potato might, but in our own case we confine ourselves to three products only, namely, prepared cornflour, sago flour, and tapioca flour.

6037. (Sir William Hart-Dyke.) Including maize?—Maize cornflour, but not raw maize. We do not use raw maize.

6038. (Sir William Church.) Nor rice?—Not in our own case. It is used in the manufacture of glucose, but not in our own specific case.

6039. (Chairman.) One of the cheapest forms of starch I suppose, is that derived from potato?—Not at the present day. It is not used in the manufacture of glucose in England at the present day. It is relatively dear as compared with other starches.

Rice and  
raw maize  
may be used.

6040. (Professor Thorpe.) I think it would conduce to clearness if you told the Commission, once and for all, what are the variety of starches used in the manufacture of glucose by all manufacturers, and what you yourselves specifically use?—I have given those which we specifically use. The other forms of starch would be rice and maize. Beyond that I do not think any other form is used.

6041. (Chairman.) Would you prefer tapioca to either rice or maize?—We ourselves do.

6042. Why?—There are certain oils and fats which are eliminated from rice and maize, which we consider to be detrimental in the manufacture of the brewing sugar.

6043. It would introduce an objectionable element, a disagreeable flavour?—Yes; it is a very disagreeable flavour at times.

6044. Would it be unwholesome in the beer?—I do not think the resulting product would be unwholesome, because of the subsequent process to remove anything of that character. But the starch of maize and tapioca flour and sago flour contains less nitrogenous matter, and is more easily worked than the other starches, hence we employ them.

6045. How is the sulphuric acid removed when it has done its work?—It is removed by the neutralisation of an alkali.

6046. What base do you use?—Chalk.

6047. No other?—We finish with a small percentage of lime.

6048. That has practically the same effect, lime and chalk?—Yes. No sulphuric acid is left in the solution in consequence.

6049. Do you find that the process of precipitation can be so complete as to leave no discoverable sulphuric acid?—I do consider so, and that is absolutely controlled by our laboratory department.

Amount of  
acid used in  
manufacture  
of invert.

6050. With respect to the manufacture of invert, do you use a definite proportion of acid?—The acids vary according to the class of sugar employed. We can use from so little as  $\frac{1}{2}$  per cent. up to  $2\frac{1}{4}$  per cent. as the maximum. I have taken out an average which we consider to be used, and that is  $1\frac{1}{2}$  per cent. of sulphuric acid.

6051. How is the percentage reckoned, by weight of sulphuric acid to weight of starch, or sugar as the case might be?—Yes.

6052. (Professor Thorpe.) Is that real sulphuric acid?—That is of the 70 per cent.

6053. (Chairman.) One and three-quarters of sulphuric acid of 70 per cent. strength to 100 by weight of sugar?—That is so.

6054. (Professor Thorpe.) One hundred by weight of raw sugar, which is not pure sugar?—Yes. It would contain some invert sugar, and some moisture, and a little ash, and some alkaline salts.

6055. What would be the average of real sugar in what you are using?—About 90 or 92 per cent.

6056. (Chairman.) Ninety per cent. of crystallisable sugar?—No, of total sugar.

6057. That includes crystallizable sugar and uncrystallizable, including molasses?—Yes.

6058. There would be a considerable proportion of crystallizable sugar, and a considerable proportion of grape sugar?—Not a considerable proportion of the latter, not exceeding 8 or 9 per cent.

6059. With regard to the manufacture of glucose?—The percentage of acids will vary to a greater degree, almost, than in the process of making invert sugar. It would go from  $4\frac{1}{2}$  per cent. in the case of American cornflour, which I described just now, up to 8 per cent. for some of the tapioca flour. It varies from  $4\frac{1}{2}$  to 8 per cent., but I see that the average taken from our books is  $5\frac{1}{2}$  per cent.

Mr.  
R. C. Garton.  
27 Apr. 1901.

6060. (Professor Thorpe.) Of the 70 per cent. acid?—Yes.

6061. (Chairman.) How do you explain that more acid is wanted for one of the substances and less for another?—Because there is contained in these starches a large percentage of fibrous matter to which the acid goes instead of carrying on its direct conversion.

6062. Is that fibrous matter nitrogenous fibrine?—Yes.

6063. Do you use pressure in the manufacture of glucose?—That is so.

6064. Without the pressure you would need a still larger quantity of acid?—Yes, a larger quantity of acid would be employed without the use of pressure.

6065. (Sir William Church.) You speak of prepared cornflour; is that other than ground?—It is a precipitated starch after being washed and dried.

6066. (Professor Thorpe.) I think perhaps it would conduce to clearness if we had it upon the notes why treatment by sulphuric acid is required in these things as a process to begin with. Take the case of cane sugar. Cane sugar is a sugar fermentable by the action of yeast. When you add yeast to cane sugar, would you tell the Commission exactly what happens?—The first action would be that the yeast would act upon the cane sugar and invert it, but the process is an exceedingly slow one, and a very difficult one to carry out because of the manner in which it weakens the yeast plant. The object of inverting sugar by acid is to bring it readily into that state. In brewing when you add your inverted cane sugar the yeast is immediately able to go about its work, and is not weakened or deteriorated by having to do inversion first.

Object  
inverting  
for brew

6067. When you act directly on cane sugar by means of yeast it requires a considerable amount of time before the true alcoholic fermentation is started?—That is so, and there is considerable danger that the alcoholic fermentation might not catch on in time to prevent the other bodies being formed.

6068. What you do by this hydrolyzing or inverting by means of sulphuric acid is that you quicken the action you would otherwise have to do with the yeast?—Putting it in my own words, we assist the yeast to take on the vinous fermentation at once.

6069. You use the word "carbo-hydrate"; would you kindly explain what you mean by the word carbo-hydrate?—Perhaps I might ask Dr. Thorne to deal with this. It is more of a chemical term.

(Dr. Thorne) (Chemist to Messrs. Garton, Hill, and Co.) The carbo-hydrates are those series of compounds in which the composition of the substance is in the proportion of the carbon and water.

6070. All sugars are carbo-hydrates?

(Dr. Thorne.) Yes.

6071. But all carbo-hydrates are not sugars?

(Dr. Thorne.) No; carbo-hydrates would include all the starches.

6072. The word carbo-hydrate is a generic term including starches, sugars, and all substances in which the ratio of the carbon to the water is as you have stated. (To the Witness.) Some of these carbo-hydrates are fermentable and some are not?—That is so. Some of the sugars in those carbo-hydrates are fermentable and some are not.

6073. In the action of sulphuric acid upon the materials that you employ for the manufacture of glucose, the various starches with associated cellulose or similar matter, cellulose itself being a carbo-hydrate, does that cellulose itself contribute in any way to the fermentation of sugars?—Yes, it does. The cellulose is

converted into a form of sugar by the action of the acid.

6074. A fermentable form of sugar?—No.

6075. Then you really get more sugar in your glucose than corresponds to the amount of starch present with which you started?—That is if you have a lot of cellulose.

6076. In maize, where you would have a large amount of associated cellulose, do you get more glucose than corresponds to the amount of starch present?—I am not able to answer the question with maize because I have not worked upon it.

6077. Take the case of second grade tapioca and sago, where the mixed foreign matter other than starch is considerable?—It is minute.

6078. But you would have a certain amount of sugar other than from the pure starch?—It would be a very small percentage indeed.

6079. What do you mean by a very small percentage?—At the most it would be half per cent.

(Dr. Thorne.) Practically none of the cellulose is converted in the ordinary way of working; at most 1 or two per cent. of the cellulose present is actually converted.

6080. What do you mean by the ordinary way of working?

(Dr. Thorne.) The commercial way of working.

6081. But of course it is theoretically convertible?

(Dr. Thorne.) But it requires longer treatment and higher pressure.

(Witness.) In the face of that subject we are quite aware of the fact that these non-fermentable bodies could be formed if the starch was left too long in contact with the acid, and that is one of the things we have to guard against to prevent these bodies being formed by the destruction of the sugar which would be formed by the conversion by the remaining acid.

6082. (Chairman.) The acid you reckon at 70 per cent. with a specific gravity of 1.6. Do you dilute it before applying it to the starch?—Yes, it is diluted to a specific gravity of 1.200.

6083. You spoke of pressure being used; what pressure do you go to?—30 lbs. pressure. The vessels are made of gunmetal.

6084. And the liquor raised to boiling point at that pressure?—The action of raising the pressure brings it up; the vessel contains steam coils.

6085. What temperature is the liquor raised to in the vessel?—275° Fahrenheit.

6086. Does so high a temperature tend to alter the fermentability of the product?—We use our acid accordingly, and the time of the operation is a big factor in that connection. As a result of the conversion I think I may say that glucose in the ordinary form contains very little matter which has been transformed from sugar into a non-fermentable carbo-hydrate.

6087. Do you use pressure in the manufacture of invert as well as of glucose?—We never put cane sugar or sugar used in the manufacture of invert into a pressure vessel.

6088. If you were to apply to cane sugar the same pressure and temperature as in the case of glucose, would not that convert some of the sugar without acid?—We should caramelise the sugar.

6089. But as a fact it would be inverted?—Yes; but there would be also destruction.

6090. Would not that be fermentable?—No.

6091. Have you studied the optic property of caramel?—I have not, personally.

6092. It is inverted, is it not?

(Dr. Thorne.) Up to a certain extent; but the action is carried much further, it does not stop at invert sugar. When you get caramelisation taking place you get a large number of other carbo-hydrates, some of which are fermentable and some are not, and the caramel is not one product, but a mixture of decomposition products.

6093. (Professor Thorpe.) The process of caramelisation is attended with the abstraction of water?—Yes.

6094. (Dr. Whittegg.) You told us that you manufactured glucose for brewers only: that meant brewers are your only customers?—They are.

6095. There is a considerable amount of glucose used

in other manufactures than brewing, is there not?—There is.

6096. That comes from the other manufacturers in England, and from foreign sources?—I think no other manufacturer in England sells other than for brewing purposes.

6097. Can you say why—is the substance required different?—I cannot explain why because I could manufacture it myself for confectionery purposes, but we do not.

6098. What you would manufacture for confectionery purposes would be different in some respects from the article you make now?—The article used for confectionery purposes is that which I have described here as dextrin maltose, that is the composition of the article which is now used in the country for confectionery purposes.

6099. Do you make dextrin maltose?—Yes, for brewers, but not for confectionery.

6100. The dextrin maltose required for confectionery is different from the brewing dextrin maltose?—No.

6101. Is the dextrin maltose you manufacture suitable for confectionery?—Yes, it could be used, so far as dextrin maltose is suitable for confectioners.

6102. It is a mere accident that all you make goes to brewers?—Clearly; we could manufacture it for the confectionery market if it were deemed necessary.

6103. But I understand you to mean there is more than that, that the article you manufacture is suitable for confectioners if confectioners come to you to buy it?—Yes; so far as it is suitable for confectionery purposes; it is almost the identical substance; it is an intermission product after the conversion of starch by acid.

6104. Confectioners use other forms of artificial sugar, do not they, besides this?—I am not quite sure on the point.

6105. Do you supply cider makers or mineral water makers?—None.

6106. Can you tell us whether they use a sugar similar to what you prepare?—I do not think they do.

6107. Potato starch is used to make glucose abroad I understand you to say?—Yes.

6108. Not in England?—On account of its price only.

6109. Would the product be different at all in appearance or properties?—No, I do not think it would be. There is a distinctive property in glucose manufactured from potato starch, and that is that it has rather a bitter flavour.

6110. (Chairman.) Do you sell dextrin maltose as a separate product different from the brewing sugars?—Yes, by name of dextrin maltose. The invert cane sugar is sold under the name of laevo saccharum. The glucose is sold by us as dextro saccharum as denoting the two forms of sugar.

6111. What kind of sulphuric acid do you use, brimstone acid is it?—We originally used brimstone acid made from Sicilian brimstone.

6112. Did you give up the use of brimstone acid?—Yes, some years ago; the object was this, that the people from whom we bought our brimstone acid represented to us that by the process of purifying sulphuric acid we could get it as pure and as free from arsenic as the brimstone acid, and we satisfied ourselves upon that point, and after considerable research by our head chemist, at that time Mr. Heron, we adopted the use of the de-arsenicated pyrites-made acid.

6113. Arsenic was the special substance to be removed by purification?—Yes, we have been well aware of the presence of arsenic in acid ever since we have been in business.

6114. In the purification of pyrites acid is there anything but arsenic to be taken out of it?—There is iron and lead and the nitrous compounds.

6115. Does lead get into the pyrites acid?—Yes.

6116. Iron comes from where?—The iron would be in the pyrites.

6117. (Professor Thorpe.) The iron would be everywhere, in the coke and the towers?—Yes; I am only able to describe the particular points that we wished to avoid in our acid. I am not conversant with the actual manufacture of the acid.

6118. (Chairman.) Iron is one of the substances to be got rid of. How does it get into the acid?

Mr.  
R. C. Garton,  
27 Apr. 1901.  
English glucose makers supply brewers principally.

Potato starch expensive.

Uses de-arsenicated pyrites acid.

Mr. R. C. Garton. (Dr. Thorne.) I think it would come mainly from the coke in the Glover towers, and so on, that the acid ran over; not in the fumes, but only after the sulphur had been turned into liquid acid by the steam and moisture.

27 Apr. 1901.

6119. (Chairman.) For the last twenty years you have always obtained your sulphuric acid from one source? (Witness.) Yes; Messrs. F. W. Berk and Co. We have always dealt with them.

6120. Do they supply brimstone acid, or have they given up the making of it?—They have given up the manufacture of brimstone acid.

6121. (Mr. Cosmo Benson.) Has the price varied much for your acid?—The price has never varied at all. We have never discussed the price with them. We pay them a good price, and we have never gone into that question since.

Supply in special tank.

6122. (Chairman.) You take care that you get the acid not contaminated on the way to your works?—We are very cautious in regard to that, because we will only allow it to be supplied in one barge kept for us alone. It is not supplied in carboys. It is supplied in a tank barge.

6123. A tank of what material?—A lead tank.

6124. (Sir William Hart-Dyke.) Belonging to the vendor?—Yes.

6125. (Chairman.) A small quantity of lead may be taken up from the tank?—Not at the gravity at which we receive it.

6126. Do you receive it at the gravity of 1·6?—Yes; our own chemist takes charge of the acid as soon as it arrives at the works. No portion of the cargo is allowed to be discharged until our own head chemist has certified he is satisfied.

6127. (Dr. Whitelocke.) How long has that system been in force?—It may be 15 years; I cannot be quite sure.

No written contract with sulphuric acid maker.

6128. (Chairman.) Have you a written contract with Messrs. Berk?—No; we have never had a written contract with them. Everything is settled verbally. It is an old, long-standing arrangement which is continually renewed and discussed from time to time as we see them.

6129. There is no chance of their forgetting that there must not be arsenic in it?—We have their definite assurance that they examine every load before it leaves their place.

6130. (Sir William Church.) Messrs. Berk and Co.'s works are on the river, are they not?—Yes, at Bow.

6131. This arrangement could not probably hold good in another factory?—No. Other manufacturers do receive it in carboys, but ours is a very special way of receiving it, and makes it exceedingly easy to detect whether the acid is right or not.

6132. (Sir William Hart-Dyke.) And you can test a large quantity at once?—Yes; a large bulk.

6133. (Chairman.) You have perfect confidence in Messrs. Berk and Co., but you think it right to keep a check of the supply?—That is in accordance with our method of working; we check everything we take into the works. I do not mean any particular reference to arsenic, but everything is taken into the laboratory as it comes into the works in the ordinary way of business.

6134. You require colourless acid?—We have always colourless acid.

6135. Do you have any B.O.V.?—No; this acid is the colour of water. I have brought a sample, if you would like to see it. (Sample exhibited.)

6136. Do you know if brown oil of vitriol is used by any glucose manufacturers?—No, it is not.

6137. You consider the colourlessness of the liquid important as security against accidents?—Yes.

At a constant price.

6138. Do you get this at a constant price?—The price has never varied. I think acid can be bought cheaper than we buy it, but we have been satisfied to pay this price, feeling that we were in good hands, and that it would be unwise to discuss any question of economy.

6139. What is the price?—42s. a ton.

6140. For delivery in large lots?—We receive it in tank barges holding about 30 tons.

6141. You have invoices in support of this statement?—Certainly.

6142. (Professor Thorpe.) If Messrs. Bostocks were paying 47s. 6d. for the same character of vitriol, they

were also paying a very good price too?—That included the carriage of carboys from Leeds to Liverpool. The carriage I expect would be a substantial item. Our carriage is a very minimum sum, because it is simply a tank journey from wharf to wharf.

6143. (Mr. Cosmo Benson.) Who does the tank-barge belong to?—Messrs. Berk.

6144. Does the price charged by Messrs. Berk vary with the market?—No; the price has been very nearly constant. I think perhaps in that we might have opened up a question, but we have always considered it was best to leave the price as it stood.

6145. Carriage to a distance would involve its being put into carboys?—It would.

6146. Would that be a source of danger?—I think it might be some source of danger that carboys might be mixed.

6147. But not with proper precaution?—No, none whatever.

6148. It would add largely to the cost?—Very largely indeed.

6149. (Professor Thorpe.) You are aware there are other methods of transmitting oil of vitriol than in carboys, even long distances?—No; I have not gone into that.

6150. You can send it in large cast-iron cylinders. It is sent by railway constantly?—Naturally it could be done, in the same way as we have ours in a tank. It is merely a tank on wheels.

6151. (Chairman.) Have you ever examined the sugar with a view to detecting impurities, if there are any?—Not before this occurrence of the outbreak in Manchester.

6152. But in this outbreak?—We have analysed a large number of samples.

6152\*. Have you found any arsenic in any of them?—It is extraordinary, seeing how very largely diffused arsenic is that the samples should be so free. I should not like to say that we have not found any arsenic, because the test is so extraordinary that you can find the minutest possible trace. I have here tubes, if the Commission would like to see them, of various quantities of arsenic that we have detected both in our acid and in other materials, but it is of such an infinitesimal and minute character that it almost might be called negligible. (The tubes were submitted to the Commission.)

Glucose ly tested arsenic.

only an infinitesimal quantity found.

6153. Is this from the sugars or some of the ingredients?—That is from the glucose, a glucose which we have made and tested by the Marsh test. The tube will show you how exceedingly free the sample was from arsenic under the severe test.

6154. Have you tested some of the raw materials?—Yes; but we find no arsenic in those. This is another tube, a glucose, which was made in the very early part of November, and represents a sample which was out at the time of the outbreak in the trade. There you see an infinitesimal spot. We have tried large numbers, and we find no trace, but I bring this one forward as showing what could be found. I think that contains about 1,000th part of a grain.

6155. In what quantity of glucose?—In a pound of glucose.

6156. That is a specimen, manufactured on the 10th of November, 1900?—Yes. In connection with that it would be interesting to see the standards. (The standards were shown to the Commission.)

6157. How do you account for the minute quantity of arsenic, in that specimen?—It might come from so many trivial causes. It might come from a tank, it might come from a little new charcoal over which it was put. Of course, we should never have found that amount under the old method of testing. That is the result of a test extending over nearly half an hour in the Marsh test. At 10 minutes that did not show any reaction at all for arsenic. I brought it up to show to the Commission how very minute it was, and the very small quantity that could be found. Here is a sample of the pyrites acid. (Sample put in.)

6158. This is the 23/3/1901, that is the 23rd March?—Yes. Here is a sample of the brimstone acid. (Sample acid not shown.)

6159. This is the 26th April?—Yes. That was a sample of brimstone acid we had from the people who manufacture our pyrites acid. We have been going into the question of brimstone acid with them. They do

free from arsenic.

Mr. Garton. not make it, but we have been discussing with them as to whether we should buy brimstone acid in the future, and that is a sample we had to see how it looked.

6160. Of Sicilian brimstone acid?—Yes.

(Dr. Thorne.) That was not their manufacture, it is only a sample they obtained for us, not their own make.

(Witness.) But they are putting themselves into a position to make brimstone acid.

6161. (Chairman.) They got this from a brimstone acid manufacturer?—Yes.

6162. (Professor Thorpe.) Was that sold to you as free from arsenic?—That is not sold to us, it is only a sample sent to us to examine.

6163. But not put forward as free from arsenic?—I anticipate by its being sent in that form that it was. Here is a sample of another delivery of our acid. That is a pyrites acid.

6164. But there is something here?—Yes, that is the result where 20 grammes of the acid has been taken and kept in the Marsh test for half an hour, and that is the only result we could get.

6165. What do you consider the colour here proves?—It may be a trace.

6166. Might it be something else?—It might be anything. It is so infinitesimal that it is impossible to say. (The standards were explained by Dr. Thorne to the Commission.)

6167. (Professor Thorpe.) On the test which you have shown us, it would be obviously a greater security to insist upon de-arsenication in the acid, whatever it be, than to take it on the assumption that it was pure because it was made from Sicilian sulphur?—That would not do at all. The proper course would be to have a guarantee that the acid was de-arsenicated, apart from what it was made from. It would be a sense of false security to think that because you bought sulphur-made acid you would therefore have arsenic-free acid. With a guarantee of de-arsenicated acid you would be perfectly safe.

6168. (Chairman.) Do you know the process that Berk and Co. follow in making the acid? Is it the same as other pyrites acid makers?—Yes, they purify the acid for our purpose by a special process.

(Dr. Thorne.) By the sulphuretted hydrogen process.

6169. (Chairman.) Do you know how much difference that makes in the cost?—I think it is absolutely nominal.

6170. Do they sell acid not so purified to those who do not demand purity?—Yes. This is a sample of their brown oil of vitriol. (Sample shown.) It has not been purified. We asked them for this sample, which we thought might be interesting. It is not de-arsenicated.

6171. The price of this is not greatly less than the price of purified acid?—The difference is very nominal indeed.

6172. Do you know what the price of this is in the market?—I cannot give it to you definitely.

6173. (Sir William Church.) Have you had your acid tested for anything else besides arsenic?—Yes, from time to time.

6174. Has any special investigation of it been made for selenium?—Yes, our chemist has tested it for selenium.

6175. Has any trace of selenium been found?—Not in the pyrites acid.

6176. In the brimstone acid?—I think he has come to the conclusion that infinitesimal traces have been discovered.

(Dr. Thorne.) Yes. I have not come across a brimstone acid absolutely free from selenium, but I have not detected it in purified de-arsenicated pyrites acid. The process of purification takes out the selenium at the same time it takes out the arsenic.

(Sir William Church.) As far as any danger from selenium comes, there appears to be less in pyrites than in brimstone acid.

(Dr. Thorne.) I should say emphatically less.

6177. (Mr. Cosmo Bonsor.) The test for selenium is a very easy one, is it not?

(Dr. Thorne.) In large quantities, not in a very fine degree.

6178. (Mr. Cosmo Bonsor.) Anything that would be likely to be injurious to health would show itself very quickly?

(Dr. Thorne.) You can test easily to one part in 200,000. I say that because the arsenic test goes to one part in seven millions.

6179. (Chairman.) Would selenium show in the colour of the deposits we have in some of those tubes?

(Dr. Thorne.) Yes, but precautions have been taken in all those tests to remove the selenium in the process.

6180. Have you found selenium can be removed?

(Dr. Thorne.) It can be removed.

6181. You found there was selenium, which had to be removed?

(Dr. Thorne.) In brimstone acid I found selenium present. In pyrites acid I found no selenium present.

6182. (Professor Thorpe.) What you mean is that you so arranged your method of testing for arsenic that it would have eliminated any selenium which had been there?—(Dr. Thorne.) Yes. In those tubes it is arsenic, and there is not a chance of there being selenium. Selenium has been tested for separately, but not in that test.

6183. (Chairman.) (To the Witness.) Would it make any difference to you if there was a statutory guarantee of purity imposed?—The purity of the article we manufacture?

6184. Either of the article you manufacture or of the sulphuric acid that you admit?—It would not make the slightest difference, because we have always acted on that necessary guarantee to the public.

6185. You have gone on without a written guarantee, but by care on your own part and the part of the makers you find it satisfactory?—Absolutely satisfactory.

6186. Then it would not disturb you if there was a satisfactory guarantee of purity to be given by the acid makers?—It would not make the slightest difference to us in our manufacture, or any other way. We should be quite prepared to carry out any recommendation that the Commission might think fit to make.

6187. Since the outbreak your firm have, in fact, adopted a form of guarantee for purity?—Yes. Immediately upon the outbreak we issued a guarantee, the form of which I have brought, and which is now in use.

6188. "We certify that the delivery to which the enclosed invoice relates is perfectly free from arsenic or other deleterious ingredients"?—That is the notice.

6189. (Professor Thorpe.) Who signs that guarantee?—One of the partners, every day.

6190. Does the chemist take part in the guarantee?—We receive his report before the guarantees are signed. He sends down his report to the partners on his samples, and we sign the guarantees then and there.

6191. Would there be any difficulty in making him jointly responsible for the guarantee?—Not the slightest difficulty in the world. He is practically now responsible, because we should not sign the guarantee without we had his authority to do it.

6192. But it would be desirable for statutory purposes that the name of the tester should go on the guarantee form?—That would not make the slightest difference to us; it could be very readily carried out.

6193. (Dr. Whitelegge.) Messrs. Berk and Co. are chemical manufacturers in general?—Yes.

6194. They make other things than sulphuric acid?—Not at these works.

6195. Do they make sulphuric acid for other purposes?—Yes, for manure purposes.

6196. And largely for those other purposes?—I am not able to say the extent of their manufacture. Their chief works, I think, for other chemical manufactures are at Swansea.

6197. But at the same works at which the sulphuric acid for your purposes are made, other sulphuric acid is made?—I believe it is.

6198. (Chairman.) You have made no change in your mode of action in respect of the supply of acid since this scare?—We have made no change in our methods at all. It was considered the proper course to pursue to go on just as we have been working.

6199. (Dr. Whitelegge.) Is there not rather a difference implied in your statement, that since the outbreak every material has been specifically tested for arsenic?—That is the only difference. The method has always been that a sample of the acid is taken directly the barge arrives. It is placed in the laboratory. That

Mr. R. C. Garton.

27 Apr. 1901.

Guarantee of purity of sulphuric acid or of manufactured article advisable.

Greater stringency in testing acid for arsenic recently

Mr.  
C. Garton.  
7 Apr. 1901.

has been always the case. Now the only alteration is that we test each of those samples specifically for arsenic.

6200. That was not done before the outbreak?—Not every sample, but they were constantly being tested.

6201. Constantly being tested for arsenic?—Yes. In fact, it had been tested at quite a recent period before the scare. That was not done because we feared that the manufacturer was selling us an inferior article, but merely in our common way of business as a check.

6202. (Professor Thorpe.) Of course, this certificate that you give necessarily has reference to a particular method of testing?—Yes.

6203. And also to a particular amount of material which is used in the testing?—Yes.

Official  
standard for  
arsenic  
should be  
prescribed.

6204. Therefore it only indicates a particular standard of delicacy?—As applied to ourselves, yes. In that respect it would be most desirable that some common form of working should be adopted.

6205. What would you suggest as to how that common form of certificate should be arrived at so that all certificates might have equal value? Have you any suggestions to offer to the Commission as to how that could be attained?—Seeing that analytical chemists from all parts are constantly testing these samples, to my mind the best way would be to arrive at a common understanding by some conference.

6206. A conference arranged between whom?—Between those chemists and the officials.

6207. What officials?—The Government officials.

6208. (Mr. Cosmo Bonsor.) You would be quite satisfied if a Government Department was the reference?—Absolutely satisfied.

6209. (Professor Thorpe.) Are you speaking of brewers' materials or of things in general which may contain arsenic?—I am speaking of brewing materials.

might be  
done by In-  
and  
Revenue in  
the case of  
brewing  
materials.

6210. Would it satisfy you, for example, as a manufacturer of brewing sugars, if the Excise authorities were to take charge of a small departmental committee to fix the methods and generally prescribe the form of certificate under which all manufacturers of brewing sugar should work?—I think it would be most admirable. It would get rid of a great deal of trouble and the harassing that is now going on. In fact, I consider that it is absolutely necessary that some common form of guarantee should be arrived at.

6211. I may point out to you, of course, that the matter is rather far-reaching, because it does not merely concern the Excise authorities immediately, but it concerns, of course, public analysts who are not under the Excise remotely?—Yes.

with aid of  
Committee  
of chemists.

6212. Therefore you must have a rather wider organization to take the whole thing into consideration?—That is why I made the proposition that the general body of chemists should be consulted as to the method to be adopted.

6213. That is rather a large order, is it not?—I think you could get representatives from the chemical societies.

6214. You mean that you would like to see a committee formed in which all the interests, say the Excise authorities, yourselves as manufacturers?—I think you might eliminate us from the conference.

6215. Would not the maltsters, for example, be concerned?—I think not. I think they would be perfectly satisfied if a common form was adopted.

6216. Then your idea is that a committee of chemists and persons concerned with the testing of brewing materials and also of the testing of finished beer as the public takes it, should draw up regulations with a view to determining methods for standards of purity?—I do think so.

6217. Supposing a committee had come to some arrangement defining the methods, and, therefore, controlling the degree of delicacy, what could they do further; to whom would they report; what further action is contemplated?—I do not quite understand.

6218. This Commission, for example, might appoint a small sub-committee or recommend the formation of a small sub-committee to take up that particular aspect of the question. They might make certain findings. What would be the subsequent action? How would they become operative?—You mean to say how would they be received.

6219. Who would deal with them?—Which department of the Government?

Mr.  
R. C. Garton.  
27 Apr. 1901.

6220. Yes?—I suppose the laboratories are not to be thought of. I do not know that I can make a suggestion.

6221. (Mr. Cosmo Bonsor.) You are aware of the two Acts of Parliament, the Sale of Food and Drugs Act, which looks after the adulteration of food generally, and also the regulations as regards the prevention of deleterious articles entering into beer which is looked after by the Excise. Either of these departments would do, would not they?—Yes, either would do, but I am quite unable to say which would be the better.

6222. (Chairman.) You have no experience of their action; you have not been attacked for adulterations nor for deleterious impurities by persons acting under instructions of either department of the Government?—No.

6223. You have no experience of such action, and cannot offer us any advice?—No, I cannot.

6224. But you are willing to accept anything that is proposed?—Yes.

6225. (Dr. Whitelegge.) Would you be equally content with administration in that sense by any local authority?—Do you suggest a County Council authority?

6226. Yes, by the county authorities or other local bodies?—I should prefer the other method.

6227. (Chairman.) Have you ever used any other than the Marsh test for arsenic?—No, we have always used the Marsh test.

6228. Have you ever used Bloxham's electrolytic test?—No.

6229. I do not know whether you or your chemist have thought of the electrolytic method?—(Dr. Thorne.) I have been intending to experiment with the electrolytic method, but really, my time has been so much taken up with this matter, and I have been so satisfied with the character of the result of the Marsh test, and the delicacy and absolute certainty of the Marsh test, that for the present I have stuck to the Marsh test. I think that the Bloxham test might possibly be a very satisfactory one, but I do not think it can exceed the satisfactory character of the Marsh test.

6230. (Chairman.) Might Bloxham's method possibly give more definite quantitative results?

(Dr. Thorne.) I do not think so.

6231. (Sir William Church.) Your firm seems always from the commencement to have from time to time tested your sulphuric acid for arsenic?—Yes.

6232. As a practical manufacturer of what is really a foodstuff do you not think it is the duty of every manufacturer of foodstuffs similar to this, to take the same precaution, and from time to time test for themselves the purity of any substance like sulphuric acid which everybody knew might be contaminated?—I think as a check upon his business he ought to do so, but the great responsibility would lie with the manufacturer who makes the acid for him in the common understanding that they work together.

Duty of  
sugar manu-  
facturer to  
check purity  
of his acid.

6233. You would say without doubt that where there is no specific contract that de-arsenicated acid is used it is the duty of the manufacturer of invert or glucose to see that the acid he uses is pure?—Yes, by a check.

6234. (Dr. Whitelegge.) If by accident arsenic found its way into sugar manufactured by you you would find it by your own tests?—Yes.

6235. Would you be able, by looking back at the record of your tests, to say whether there had been arsenic in a particular consignment?—Do you mean with regard to tests that we have made?

6236. Yes?—We have got samples of our various sugars ranging over a considerable period.

6237. Have you a record of the tests being made and the result of the tests?—For arsenic pure and simple, no; although we make our tests for arsenic and keep our laboratory book, if the things are right there is scarcely any record made. When there is anything which comes under our observation which ought to be put into our books we place it there.

Nature of  
records of  
tests made

6238. Your record is only a record of something being wrong?—Yes, in that sense.

6239. Is that so well established a practice that if there is no record you may assume with confidence it is right?—In our case distinctly.

Mr. Garton. 6240. If arsenic was found in a sample of sugar you could trace that back to a particular consignment of sulphuric acid, and if there was no record of the sulphuric acid containing arsenic then you would know that certainly there was no arsenic there?—Dependent on the fact whether the arsenic was produced by the acid.

6241. I do not mean that you trace the arsenic back to sulphuric acid, but you trace back the sulphuric acid which took part in that sugar?—Yes.

6242. You would know the sulphuric acid was free if there was no record?—Yes, and it was not answerable for any trace of arsenic that might be found.

6243. (Chairman.) Do you record in your books that tests have been made even when the results are blank?—We have never made those records.

6244. You do not say, so many tests were made and nothing found deleterious?—No; I have in my laboratory book a record that every barge of acid has been sampled and recorded.

6245. That it has been sampled and tested?—Tested in some form or other. It is placed in the laboratory for the chemist; that has been the practice for many years.

6246. So that there is no chance of an inadvertence in respect to things passing?—The acid could not be possibly taken into the works except it was passed by the chemist.

6247. (Sir William Church.) I understand you to say that although in the general course of your business you did not test every tank barge for arsenic you have been in the habit from time to time of doing so?—Constantly.

6248. And you think that that precaution should be used by all manufacturers of brewing materials, glucose and invert?—Yes; coupled with the understanding that the article is being made for the particular purpose.

6249. Still more so if it is not coupled with that understanding?—Yes.

ntage of  
s in  
ng  
6250. (Chairman.) With regard to the use of sugars in brewing what do you say?—They are in no sense adulterants or substitutes for better material. One or other of them is used by all of the best brewers in the Kingdom often without any economy, and solely for improvement of quality, and in other cases because you can obtain an equal or superior quality at less cost and trouble. So far from these products belonging to the type of adulteration, they represent the real growth of the science of brewing, and the excellence of the products go hand in hand with the increase of skill in using them. Glucose and dextrin maltose are derived from pure starch just as much as the maltose which is formed in the mash tun and by an equally pure process. They are sugars of the same type as the maltose, and in every sense as suitable for the purpose. But they have the great advantage that they can be made free from those types of nitrogenous matter found in barley malt, which constitute one of the greatest difficulties in brewing English beer, their removal necessitating prolonged storage of the beer and the employment of much hop. It thus puts a definite material in the hands of the scientific brewer by which he can obtain complete control over the article produced. With regard to invert sugar, it is a far more expensive article for the brewer than the cane sugar itself, and the whole manufacture is for the purpose of giving him a more readily fermentable sugar than cane sugar, which cannot be employed without materially weakening the yeast. So important are these properties that all modern ale requires their use. As compared with malt, there is no economy in the use of invert, as a pound of extract obtained from invert is about the same cost as that obtained from malt, and yet three-quarters of the total production of my firm consists of this substance. It is for the results of the brewing, and not for lessening the cost of the materials, that it is employed.

6251. (Sir William Hart-Dyke.) I suppose you could tell the Commission whether the occurrence of this great scare has made any practical difference in the trade?—On the contrary. It has not diminished the use of sugar, but in the particular district where the outbreak took place it has largely increased it.

6252. With regard to your own trade. I do not want to ask you anything inquisitorial, but generally speaking, as regards your own trade, have you found any alteration in it since this scare occurred?—No diminution.

6253. You referred to the use of these materials, glucose and invert sugar, as being used for brewers for improvement of quality, and you make some comparison between their use and that of malt later on, where you state that there were certain difficulties with regard to brewing with malt which are got over by this quicker process. With regard to malt: is it not a fact that in the English barley growing districts in bad seasons, when the barley grown is not of very good quality, sugar has been very largely used?—Yes; that is to enable the brewer to use that quality of barley.

6254. That is to say to supply the saccharine matter which is absent in the barley?—Yes.

6255. In a season where a very good sample of barley is grown in this country there is naturally more of the barley used for malting purposes minus this addition which is otherwise necessary?—The sugar is not so necessary when a good quality of barley can be produced.

6256. You are aware that in debates in the House of Commons on this question of malting and the use of substitutes, it has been said by leading brewers in the House of Commons that if they were forced to use nothing but barley they would have to go to the foreigner so as to get the very best article when a good sample is not grown in this country?—Yes. I confirm that absolutely as a brewer. I consider that unless a true sense of the position is quickly ascertained, one of the most serious blows to the farmer is now about to take place. This recent agitation on behalf of the pure beer movement, resuscitated because of the arsenic scare, has carried the whole history of the use of these brewing materials into a new phase, and if this Pure Beer Bill were passed, I have no hesitation whatever in saying that the British barley grower is practically doomed. I will give you a specific instance which will emphasise all I have said. In anticipation of what is going to happen in connection with this Bill, a brewing friend of mine in the North, who has never used foreign barley at all, has this week purchased 10,000 quarters, which he is going to use in the place of English barley. That has only to be accentuated throughout the country, and I think the last stage of the British farmer will be very much worse than the first.

6257. Are you an agriculturist yourself?—In a small way.

6258. I suppose so long as your trade lives and thrives you would be rather in favour of the use of malt, generally speaking, for beer?—I am taking it from a scientific point of view, and also from the point of view that I am a brewer in a very considerable way.

6259. You urge that one of the difficulties with regard to the malt brewing is the prolonged storage that is necessary?—True.

6260. Surely you are aware that beer brewed from malt and hops is a very popular beverage in this country?—I am not inclined to accept that theory. I think a good deal of political agitation has been raised on the subject, but I have my doubts as to whether it is the popular beverage.

6261. You have your doubts?—Very strongly.

6262. You would not urge that the necessity of storage was a great difficulty in the use of malt and hops?—I think you cannot produce even with lengthened storage the quality of beer which the ordinary public require to-day; malt and hops alone would not produce it; you would have to re-educate the consumer to malt and hop beer.

6263. You think that when once the consumer is initiated in what you consider the merits of beer brewed under the system you advocate, he would not go back again to the other?—It will take a very long time to get him back to the old malt and hops.

6264. You are aware that evidence has again and again been given before this Commission that by common care in malting, beer brewed from malt can be made absolutely secure?—That is the fault I have to find with the manufacturer who brought about this trouble—that even with common care his sugar need not have contained any arsenic.

6265. In either case, as regards the consumer, you wish to urge upon the Commission that it is really a question of common care whether brewing from malt or brewing from glucose?—Yes; the whole question of arsenic in these materials is quite new to us all.

6266. (Chairman.) Is there not an economy in the use of invert, to save the cost of malt?—There is no economy in the use of invert sugar.

Mr.  
R. C. Garton.  
27 Apr. 1901.

No economy  
in use of  
invert sugar.

Mr.  
C. Garton.  
7 Apr. 1901.

has been always the case. Now the only alteration is that we test each of those samples specifically for arsenic.

6200. That was not done before the outbreak?—Not every sample, but they were constantly being tested.

6201. Constantly being tested for arsenic?—Yes. In fact, it had been tested at quite a recent period before the scare. That was not done because we feared that the manufacturer was selling us an inferior article, but merely in our common way of business as a check.

6202. (Professor Thorpe.) Of course, this certificate that you give necessarily has reference to a particular method of testing?—Yes.

6203. And also to a particular amount of material which is used in the testing?—Yes.

6204. Therefore it only indicates a particular standard of delicacy?—As applied to ourselves, yes. In that respect it would be most desirable that some common form of working should be adopted.

6205. What would you suggest as to how that common form of certificate should be arrived at so that all certificates might have equal value? Have you any suggestions to offer to the Commission as to how that could be attained?—Seeing that analytical chemists from all parts are constantly testing these samples, to my mind the best way would be to arrive at a common understanding by some conference.

6206. A conference arranged between whom?—Between those chemists and the officials.

6207. What officials?—The Government officials.

6208. (Mr. Cosmo Bonsor.) You would be quite satisfied if a Government Department was the reference?—Absolutely satisfied.

6209. (Professor Thorpe.) Are you speaking of brewers' materials or of things in general which may contain arsenic?—I am speaking of brewing materials.

6210. Would it satisfy you, for example, as a manufacturer of brewing sugars, if the Excise authorities were to take charge of a small departmental committee to fix the methods and generally prescribe the form of certificate under which all manufacturers of brewing sugar should work?—I think it would be most admirable. It would get rid of a great deal of trouble and the harassing that is now going on. In fact, I consider that it is absolutely necessary that some common form of guarantee should be arrived at.

6211. I may point out to you, of course, that the matter is rather far-reaching, because it does not merely concern the Excise authorities immediately, but it concerns, of course, public analysts who are not under the Excise remotely?—Yes.

6212. Therefore you must have a rather wider organization to take the whole thing into consideration?—That is why I made the proposition that the general body of chemists should be consulted as to the method to be adopted.

6213. That is rather a large order, is it not?—I think you could get representatives from the chemical societies.

6214. You mean that you would like to see a committee formed in which all the interests, say the Excise authorities, yourselves as manufacturers?—I think you might eliminate us from the conference.

6215. Would not the maltsters, for example, be concerned?—I think not. I think they would be perfectly satisfied if a common form was adopted.

6216. Then your idea is that a committee of chemists and persons concerned with the testing of brewing materials and also of the testing of finished beer as the public takes it, should draw up regulations with a view to determining methods for standards of purity?—I do think so.

6217. Supposing a committee had come to some arrangement defining the methods, and, therefore, connecting the degree of delicacy, what could they do further; to whom would they report; what further action is contemplated?—I do not quite understand.

6218. This Commission, for example, might appoint a small sub-committee or recommend the formation of a small sub-committee to take up that particular aspect of the question. They might make certain findings. What would be the subsequent action? How would they become operative?—You mean to say how would they be received.

6219. Who would deal with them?—Which department of the Government?

6220. Yes?—I suppose the laboratories are not to be thought of. I do not know that I can make a suggestion.

6221. (Mr. Cosmo Bonsor.) You are aware of the two Acts of Parliament, the Sale of Food and Drugs Act, which looks after the adulteration of food generally, and also the regulations as regards the prevention of deleterious articles entering into beer which is looked after by the Excise. Either of these departments would do, would not they?—Yes, either would do, but I am quite unable to say which would be the better.

6222. (Chairman.) You have no experience of their action; you have not been attacked for adulterations nor for deleterious impurities by persons acting under instructions of either department of the Government?—No.

6223. You have no experience of such action, and cannot offer us any advice?—No, I cannot.

6224. But you are willing to accept anything that is proposed?—Yes.

6225. (Dr. Whitelegge.) Would you be equally content with administration in that sense by any local authority?—Do you suggest a County Council authority?

6226. Yes, by the county authorities or other local bodies?—I should prefer the other method.

6227. (Chairman.) Have you ever used any other than the Marsh test for arsenic?—No, we have always used the Marsh test.

6228. Have you ever used Bloxham's electrolytic test?—No.

6229. I do not know whether you or your chemist have thought of the electrolytic method?—(Dr. Thorne.) I have been intending to experiment with the electrolytic method, but really, my time has been so much taken up with this matter, and I have been so satisfied with the character of the result of the Marsh test, and the delicacy and absolute certainty of the Marsh test, that for the present I have stuck to the Marsh test. I think that the Bloxham test might possibly be a very satisfactory one, but I do not think it can exceed the satisfactory character of the Marsh test.

6230. (Chairman.) Might Bloxham's method possibly give more definite quantitative results?

(Dr. Thorne.) I do not think so.

6231. (Sir William Church.) Your firm seems always from the commencement to have from time to time tested your sulphuric acid for arsenic?—Yes.

6232. As a practical manufacturer of what is really a foodstuff do you not think it is the duty of every manufacturer of foodstuffs similar to this, to take the same precaution, and from time to time test for themselves the purity of any substance like sulphuric acid which everybody knew might be contaminated?—I think as a check upon his business he ought to do so, but the great responsibility would lie with the manufacturer who makes the acid for him in the common understanding that they work together.

6233. You would say without doubt that where there is no specific contract that de-arsenicated acid is used it is the duty of the manufacturer of invert or glucose to see that the acid he uses is pure?—Yes, by a check.

6234. (Dr. Whitelegge.) If by accident arsenic found its way into sugar manufactured by you you would find it by your own tests?—Yes.

6251. (Sir William Hart-Dyke.) I suppose you could tell the Commission whether the occurrence of this great scare has made any practical difference in the trade?—On the contrary. It has not diminished the use of sugar, but in the particular district where the outbreak took place it has largely increased it.

6252. With regard to your own trade. I do not want to ask you anything inquisitorial, but generally speaking, as regards your own trade, have you found any alteration in it since this scare occurred?—No diminution.

6253. You referred to the use of these materials, glucose and invert sugar, as being used for brewers for improvement of quality, and you make some comparison between their use and that of malt later on, where you state that there were certain difficulties with regard to brewing with malt which are got over by this quicker process. With regard to malt: is it not a fact that in the English barley growing districts in bad seasons, when the barley grown is not of very good quality, sugar has been very largely used?—Yes; that is to enable the brewer to use that quality of barley.

6254. That is to say to supply the saccharine matter which is absent in the barley?—Yes.

6255. In a season where a very good sample of barley is grown in this country there is naturally more of the barley used for malting purposes minus this addition which is otherwise necessary?—The sugar is not so necessary when a good quality of barley can be produced.

6256. You are aware that in debates in the House of Commons on this question of malting and the use of substitutes, it has been said by leading brewers in the House of Commons that if they were forced to use nothing but barley they would have to go to the foreigner so as to get the very best article when a good sample is not grown in this country?—Yes. I confirm that absolutely as a brewer. I consider that unless a true sense of the position is quickly ascertained, one of the most serious blows to the farmer is now about to take place. This recent agitation on behalf of the pure beer movement, resuscitated because of the arsenic scare, has carried the whole history of the use of these brewing materials into a new phase, and if this Pure Beer Bill were passed, I have no hesitation whatever in saying that the British barley grower is practically doomed. I will give you a specific instance which will emphasise all I have said. In anticipation of what is going to happen in connection with this Bill, a brewing friend of mine in the North, who has never used foreign barley at all, has this week purchased 10,000 quarters, which he is going to use in the place of English barley. That has only to be accentuated throughout the country, and I think the last stage of the British farmer will be very much worse than the first.

6257. Are you an agriculturist yourself?—In a small way.

6258. I suppose so long as your trade lives and thrives you would be rather in favour of the use of malt, generally speaking, for beer?—I am taking it from a scientific point of view, and also from the point of view that I am a brewer in a very considerable way.

6259. You urge that one of the difficulties with regard to the malt brewing is the prolonged storage that is necessary?—True.

6260. Surely you are aware that beer brewed from malt and hops is a very popular beverage in this country?—I am not inclined to accept that theory. I think a good deal of political agitation has been raised on the subject, but I have my doubts as to whether it is the popular beverage.

6261. You have your doubts?—Very strongly.

6262. You would not urge that the necessity of storage was a great difficulty in the use of malt and hops?—I think you cannot produce even with lengthened storage the quality of beer which the ordinary public require to-day; malt and hops alone would not produce it; you would have to re-educate the consumer to malt and hop beer.

6263. You think that when once the consumer is initiated in what you consider the merits of beer brewed under the system you advocate, he would not go back again to the other?—It will take a very long time to get him back to the old malt and hops.

6264. You are aware that evidence has again and again been given before this Commission that by common care in malting, beer brewed from malt can be made absolutely secure?—That is the fault I have to find with the manufacturer who brought about this trouble—that even with common care his sugar need not have contained any arsenic.

6265. In either case, as regards the consumer, you wish to urge upon the Commission that it is really a question of common care whether brewing from malt or brewing from glucose?—Yes; the whole question of arsenic in these materials is quite new to us all.

6266. (Chairman.) Is there not an economy in the use of invert, to save the cost of malt?—There is no economy in the use of invert sugar.

Mr.  
R. C. Garton,  
27 Apr. 1901.

No economy  
in use of  
invert sugar.

Mr. R. C. Garton. 6267. Why should it be used?—Because it produces a better result than all malt alone.

6268. So that you consider that the buyer would be inclined rather to take beer not certified to be malt and hops alone?—I think he would if he were left alone.

6269. (Sir William Church.) To put it another way—you say that both, looked at from the scientific aspect and also from the practical aspect as a brewer, that a better quality of beer can be produced by a certain quantity of invert sugar and glucose being used than without it?—Emphatically.

6270. Do you think that if a large percentage of glucose or invert sugar is added it might impart any unwholesome property to the beer?—No, it would not. I say this distinctly, that if you use too large a percentage you do not get a beer, you get that which is more inclined to be a wine.

6271. Do you think it makes any difference in the wholesomeness of the finished beer whether you use a large proportion of glucose or invert sugar before the fermentation of the beer, or whether you add it afterwards?—I do not think it makes any difference, because the sugar in itself is perfectly pure and wholesome; in one case it is split up into the carbonic acid gas and the alcohol, and in the other case it may be that some of the sugar remains in the beer unsplit up, which the fermentation continues to split up as it goes along.

6272. May we take it as your opinion that it is not for lessening the cost of materials that brewing sugars are employed?—It is not.

6273. (Sir William Hart-Dyke.) I suppose that what I may call the more modern process of brewing without storage, although the materials are more expensive, yet the beer is brewed in one month and drunk the next month. Given the demand for it, the brewers would not lose much as against the old storage method?—There is an economy, I grant, in the fact that you can get your beer into condition earlier, but there is no economy in the first cost of the material.

6274. (Mr. Cosmo Bonsor.) You mentioned a friend

of yours in the North who bought 10,000 quarters of foreign barley. Was that since the Budget statement of the Chancellor of the Exchequer?—It was this week.

6275. Possibly it may have something to do with using the foreign malt to replace glucose and invert sugar?—I have it from his own mouth that it was in anticipation of the fact that he will probably be called upon to produce a so-called pure beer by English barley malt, and he will have to buy foreign to supplant it.

6276. It was not the tax on the glucose or the sugar that was frightening him?—No; because he promised me he will continue to use my sugar notwithstanding the price.

6277. (Dr. Whitledge.) In your own brewery you use glucose and invert sugar?—No; we do not use glucose.

6278. Only invert sugar?—Yes.

6279. What is the maximum proportion?—20 per cent.

6280. (Chairman.) Going back to the barley—Why is it not possible to fulfil the condition of nothing but malt and hops without introducing foreign barley?—The English barleys are so unripe and contain so much nitrogenous and albuminous matter that it is perfectly impossible to get the clarifying effect upon them without you have what is generally called more sun in your mash-tun.

6281. So that brewers are obliged to get barley from more sunny climes than our own to make a good result if it is to be an all-malt beer?—That is so.

6282. (Mr. Cosmo Bonsor.) As a brewer, there is no difficulty in getting beer free from arsenic?—No. Practically free, commercially free.

6283. You see no difficulty, either as a manufacturer of this glucose or as a brewer?—None whatever.

6284. Leaving the test of what is commercially free to a Government authority?—Distinctly.

6285. (Chairman.) In case the Commission would like to see the process of your manufacture, would it be convenient to you to allow us to come?—Distinctly, at any time.

Dr. NATHAN RAW, Medical Superintendent of the Mill Road Infirmary, Liverpool, called; and Examined.

Dr. N. Raw. 6286. (Chairman.) You are Medical Superintendent of the Mill Road Infirmary, Liverpool?—Yes.

6287. And consulting physician to the West Derby Union Workhouse?—Yes.

Epidemic in Liverpool less extensive than in Manchester. 6288. The recent epidemic of arsenical poisoning does not seem to have been so extensive in Liverpool as in Manchester?—No.

6289. You have put in a statement as to the number of patients admitted?—During the last three years, out of 12,623 patients admitted into Mill Road Infirmary under my care, there have been 225 cases of peripheral neuritis, of which number 153 have presented symptoms which might be attributed to arsenic. Of these 225 cases of peripheral neuritis 51 died, the apparent cause of death being general asthenia, with cardiac failure in most of the cases. As bearing on the question as to when the arsenical contamination of beer commenced, the statistics of this infirmary are of great value, and recent disclosures have proved that my suggestion that the poisoning commenced in May last is probably correct.

Statistics of peripheral neuritis at Mill Road Infirmary. The following table shows the number of cases of neuritis admitted into Mill Road Infirmary during the last three and a-half years:—

	1898.	1899.	1900.	1901 to April 22.
January	3	8	—	13
February	1	1	5	7
March	1	8	1	2
April	—	1	2	1
May	3	4	7	—
June	2	3	11	—
July	4	—	12	—
August	1	3	17	—
September	3	2	25	—
October	2	2	22	—
November	3	1	16	—
December	3	1	25	—
Total	26	34	143	23

6290. Your table shows that during the years 1898 to 1899 the number of cases of neuritis average thirty for the year, but a sudden increase was first noticed in the beginning of June?—Yes.

6291. Which steadily increased to the end of 1900?—Yes. In fact, the cases continued to appear until almost the middle of January; then they suddenly ceased, and I have not had a case for over nine weeks.

6292. Reviewing the epidemic as a whole, and after careful observation, what have you concluded?—Reviewing the epidemic as a whole, and after very careful observation, I have noticed the cases to be divided into two important classes: (1) The acute.—Of these I have only seen 17 cases. They occurred late in the epidemic, about the beginning of December, and presented a totally different set of symptoms from those of the more advanced or chronic cases. These cases had the appearance of having been suddenly and acutely poisoned with a large dose of arsenic. The symptoms, although acute for a few days, soon passed off, and the patients made a rapid recovery, and in all cases were discharged recovered. (2) The Chronic Cases.—These formed by far the greatest number, and on admission presented the usual symptoms of peripheral neuritis, and had the appearance of some slow and chronic form of poisoning attributed at that time to alcohol. Although I have been in the habit of seeing cases of alcoholic neuritis for the last fifteen years, I had not noticed any difference in the character of the symptoms in patients admitted into this infirmary until the beginning of August, when a few of the patients showed well-marked general pigmentation of the skin, which, for want of a better diagnosis, was attributed to Addison's Disease. During the next three months six cases were diagnosed as Addison's Disease, although it was felt at the time that the cases were not typical of that affection. Of these six cases three died, and on post mortem examination no evidences whatever were found to confirm the diagnosis of Addison's Disease; on the contrary, the cause of death seemed to be alcoholic neuritis. It was not until the paper of Dr. Reynolds appeared at the end of November that my attention was directed to arsenic, and then, of course, the epidemic was explained, and steps at once taken to prevent its

Mr. R. C. Garton. 27 Apr. 1901.

Proportion of invert sugar used at his Brewery.

Towards end of epidemic symptoms of acute arsenical poisoning.

Earlier case resembled alcoholic neuritis.

Pigmentation simulating Addison's disease.

*Raw.* spread. With regard to the cause of alcoholic neuritis I am convinced, from a very careful observation of a very large number of cases, that beer and porter are the general drinks consumed, by far the greater number being due to beer alone; but I have certainly seen cases of undoubted alcoholic neuritis in which the patients have only taken brandy or whisky. With regard to this point my experience whilst in charge of a large Scotch hospital for four years is of interest, as during the whole of that time I only saw four cases of peripheral alcoholic neuritis, and it is well known that the popular drink in Scotland is whisky. I believe also that the serious lesions are caused by the continual drinking of moderate quantities every day for prolonged periods, rather than to sudden outbursts where large quantities are taken and rapidly excreted.

6293. (*Chairman.*) What are the serious lesions to which you refer?—The paralytic symptoms.

6294. It is probable now that these lesions were due to arsenic?—The recent cases undoubtedly must have been accelerated by arsenic. The great majority of cases of ordinary alcoholic neuritis occur amongst women of the poorer classes, and in Liverpool it is the custom for these women to congregate in each other's houses and send for cheap beer during the whole of the day. By consuming it off the premises they get what is called "the long pull," which means that they get a good deal more beer than they ask for. I mention this because when a patient says she has taken a pint of beer a day, one can safely assume double that amount. I understand that in Liverpool this practice of giving the "long pull" has now been abolished.

6295. (*Sir William Church.*) Did the acute cases show traces of any pigmentation?—Not at all. In none of the acute cases was any pigmentation seen.

6296. With regard to the "long pull," do you mean that when they send to the public-houses for a pint they get two?—They get between  $1\frac{1}{2}$  and 2 pints, if the beer is consumed off the premises. But if they consume the beer in the public-house they get the measure they ask for.

6297. When they send a jug they get a double pull?—Yes, which is generally half as much again or a little more.

6298. (*Chairman.*) 50 or 60 per cent. above the quantity they ask for?—Yes.

6299. They pay for a pint and get nearly two?—Yes.

6300. If drunk on the premises they get only the pint?—Yes.

6301. (*Dr. Whitelegge.*) Can you say how many of the 145 cases noted in your table as occurring in 1900 proved fatal?—Seventeen.

6302. (*Chairman.*) In the other cases would the cure be complete or is the constitution broken for life?—In some of the cases the paralysis apparently is permanent; paralysis of the legs and paralysis of the arms.

6303. (*Sir William Church.*) One has not had time yet to say whether it will be permanent. You will admit that paralysis from peripheral neuritis and paralysis arising from other causes, diphtheria, for instance, sometimes takes many months before it improves, and still more months before recovery is complete, but in most cases eventually becomes complete?—In most of them they certainly do, but some of them are very inveterate at present. Some of them have been under treatment for more than a year.

6304. (*Chairman.*) You use the expression "ordinary alcoholic neuritis"; do you consider that now should be modified in the light of later knowledge?—I certainly think that arsenic accentuates the symptoms of alcohol in producing neuritis to a very marked extent, but I am not at all convinced that you cannot have alcoholic neuritis without arsenic at all.

6305. The peripheral symptoms and paralytic symptoms?—Yes.

6306. (*Dr. Whitelegge.*) You mentioned three fatal cases attributable to Addison's Disease, which now you think probably were due to arsenic?—Undoubtedly they were.

6307. How would these cases appear in the Registrar-General's returns? Does the certificate of Addison's Disease remain?—Yes.

6308. (*Sir William Hart-Dyke.*) Would you rather wish to suggest to the Commission there is peripheral neuritis that may exist from pure alcoholic excess?—Yes.

6309. And there may be a disease where that exists, 4576.

but very much accentuated and increased in its intensity by the presence of arsenic?—That is my opinion. *Dr. N. Raw.*

6310. There are two types as it were. The type you were aware of before this scare existed, that is to say alcoholic poisoning?—Yes.

6311. But you have discovered since this scare that the mischief which may accrue to a patient from drinking too much alcohol may be accentuated enormously increased by the addition of small quantities of arsenic?—small Enormously so. The presence of arsenic will produce very serious symptoms if in the presence of alcohol, arsenic.

6312. Would you inform the Commission if these same forms of paralysis may arise from arsenic without any alcohol at all?—Yes, they may.

6313. (*Chairman.*) With regard to the amount of arsenic in beer, what have you to say?—In some of the samples of beer examined by the Public Analyst of Liverpool as much as  $1\frac{1}{2}$  grains of arsenic to the gallon was found. This, of course, was an extreme amount, and the general adulteration varied from one-thirtieth grain to one-tenth grain of arsenic per gallon.

In one particular case of acute arsenical poisoning a man who had previously been a teetotaler for six months drank forty-two pints of beer in two days. On the second day afterwards he was seized with all the symptoms of acute poisoning, and on admission to hospital was very seriously ill. On examination of his urine arsenic was found in large quantity. The symptoms passed off rapidly, and within a fortnight he left the hospital quite cured. This is an example of a large amount of arsenic having been taken into the system in a short period of time, but in the great majority of the cases small quantities of arsenic had been taken spread over a prolonged period. In many cases patients would only admit to having taken small quantities of alcoholic liquors. The symptoms and appearance have been so ably and fully described by various observers that it is not necessary to refer to them here, but I have observed a few interesting points which, so far, have not to my knowledge been recorded.

6314. (*Sir William Church.*) In the case of this man who drank 42 pints of beer in two days, the symptoms of beer were gastro-intestinal?—Yes, and sensory symptoms drunk by too, very marked. Those were his chief symptoms. patients.

6315. But not followed by any permanent paralysis?—Not by any paralysis. His chief symptoms were extreme pain in his hands and feet.

6316. (*Dr. Whitelegge.*) Were those met with in the acute cases?—Yes, always.

6317. (*Chairman.*) Did the paralysis come after the Neuritis two days drinking?—He had no paralysis. He had extreme pain in the superficial nerves, but he has quite paralysis recovered.

6318. He had acute pain, neuritis, but not paralysis?—Yes, and no paralysis.

6319. Not many cases were met with taking small quantities of alcoholic liquors?—Beer and stout. Some from small of the patients had certainly only taken two pints of beer a day and two bottles of stout a day for some months.

6320. Two bottles of stout would be about two pints, or a little more?—Yes.

6321. Did those patients who said they had only taken small quantities show signs of arsenical poisoning?—Yes; that was during the arsenic epidemic.

6322. (*Dr. Whitelegge.*) Were the cases which you have associated with very small consumption of beer severe cases or slight?—Some of them very severe.

6323. You are not inclined to affirm any direct connection between the amount used and the severity of the symptoms, without regard to the personal equation of course?—I do not think it has any bearing at all, taking into account the length of time they take the small quantities.

6324. (*Chairman.*) Assuming that it was true they had taken only a small quantity, the effect seems to have been accumulative with regard to arsenic?—Yes, and I think that is the important point.

6325. With respect to pigmentation?—Two kinds Arsenical of pigmentation are met with in arsenical poisoning pigmentation—one, which is a general darkening of the whole of two kinds, surface of the body, does not desquamate. This appears slowly and disappears very slowly. The other form is one in which the skin becomes dark in colour rapidly, especially attacking the flexures, the breast,

Dr. N. Rose.  
27 Apr. 1901.

and the front of the abdomen. The epidermis desquamates freely, and can be pulled off, leaving a normally coloured skin underneath. The first variety of pigmentation was met with in the earlier part of the epidemic; the second class only towards the end of the epidemic; and to my mind it seemed to suggest some rather serious increase of the contamination of beer.

6326. (Chairman.) Might it not be that they have been under the influence of contaminated beer longer? It might have been but I could not answer that for certain.

Return of  
symptoms  
though no  
fresh arsenic  
taken.

6327. Have you noticed any relapse?—I have noticed in two cases under my care at present a complete relapse of all the symptoms. The patients were apparently well; pain had disappeared, and the desquamation of the skin had been complete when, without any warning, a fresh attack of neuritis developed, as acute as before, with a general discolouration and desquamation of the skin.

6328. (Chairman.) Without more drinking?—Certainly. They had been in hospital all the time.

6329. (Dr. Whitelegge.) They were not taking iodide?—No.

6330. (Sir William Church.) In connection with these cases, did you make any examination of the urine during that time?—In both these cases arsenic was found in the urine shortly after admission.

6331. I mean at the time they relapsed?—No.

6332. Was it examined?—It was examined, but nothing was found.

6333. (Chairman.) No arsenic was found in the urine at the time of the relapse?—No.

6334. (Professor Thorpe.) With respect to the statement of this particular form of pigmentation you described which only occurred towards the end of the epidemic, and in your mind suggested some serious increase in the contamination of beer, what period of time do you mean of the epidemic?—Towards the last six weeks of the epidemic.

6335. What particular date would that be?—About the second week in December. We did not notice any desquamation of any case until the second week in December.

Arsenic in  
urine.

6336. (Chairman.) Have you found arsenic in the urine in any cases?—I have been able to find arsenic in the urine in six cases out of 34 examined, but in no case was I able to find it after ten days from admission. I think Professor Dixon Mann has found it much later than that.

6337. (Sir William Church.) I ask with regard to these two cases. Dr. Dixon Mann has had certain cases in which there was a sort of relapse, but unfortunately in his case the urine was not examined?—Both mine were at once, and nothing was found.

6338. (Chairman.) What tests did you make?—I used the Reinsch test.

6339. With a considerable quantity of the urine?—I took 20 ounces of urine and evaporated it down to four slowly.

6340. So that that would be a very sensitive test?—I think that is the best test for urine.

Beer the  
common  
cause of  
alcoholic  
neuritis,  
spirits  
rarely.

6341. With regard to the cause of peripheral neuritis in general?—With regard to the cause of peripheral neuritis in general, I am of opinion that beer and porter are by far the commonest causes of the disease, yet I have seen undoubted cases caused by spirit-drinking. It is extremely difficult to get a reliable history of drinking from many patients, but I have had undoubted cases where the disease was produced purely by spirits. I have also seen cases of peripheral neuritis caused by the medicinal administration of arsenic in disease; these symptoms, however, have quickly passed off on the cessation of the drug.

6342. In the peripheral neuritis that you allude to now as resulting from spirits and not beer, was there paralysis?—Yes, marked paralysis.

6343. So that there is always paralysis in what you call peripheral neuritis?—Generally, yes.

Keratosis  
common at  
end of  
epidemic.

6344. (Sir William Church.) With regard to this desquamation, did none of your cases present symptoms of keratosis?—Yes, large numbers.

6345. Did not any of the earlier cases present it?—No.

6346. Only the late ones?—Yes.

6347. So that there was no crust coming away

from your early cases?—No; there was nothing to distinguish the early cases from the ordinary cases we have seen for years.

6348. (Chairman.) What are your general conclusions?—After a careful observation of the epidemic I have come to the conclusion that the sensory symptoms are more pronounced in arsenical neuritis than in ordinary alcoholic neuritis, and, although very severe at first, they soon pass away. The motor symptoms tend more quickly to recovery under treatment than the purely alcoholic cases, and most of my patients have completely recovered, although a few are making little progress. When one considers the enormous number of people who have been drinking this beer, which has in some cases in Liverpool contained 1½ grains of arsenic to the gallon, one is bound to think that some people are more susceptible to arsenic than others, as only a very small proportion has been attacked. It is apparent, too, that arsenic is a cumulative poison to some extent. It would seem also that the action of arsenic in the system is more virulent in the presence of alcohol than when given alone. So far as Liverpool is concerned the epidemic is at an end, and I have not had a new case of arsenical poisoning during the last nine weeks. It is just possible that with greater care in the manufacture of beer alcoholic neuritis may become much less frequent, and I have noticed that since the epidemic of arsenical poisoning in Liverpool the amount of alcoholism has very much decreased, a state of matters which I sincerely hope will continue.

Individuals  
susceptible  
to arsenic

Decrease  
"alcoholism"  
in Liverpool  
since the  
epidemic.

6349. Does that result from less excess in drinking?—I think so. I think it has given the community a great fright—at least we have noticed that in admissions to the hospital.

6350. (Dr. Whitelegge.) You say that the amount of alcoholism has decreased very much?—Yes.

6351. On what ground do you come to that conclusion?—On the admissions to the hospital. My hospital is confined entirely to the very poor, and the ordinary admissions suffering from alcohol are certainly very much less than they were.

6352. Including the remote effects from alcoholism?—Yes; general diseases which are produced by alcohol or accelerated by alcohol.

6353. For instance cirrhosis and ascites?—We have not noticed that so much, but ordinary delirium tremens, and things of that sort.

6354. You are thinking of groups of diseases in which there is already time for any recent causation to have made itself clear?—Yes. I do not know what the ultimate effect will be.

6355. Do you now regard alcoholic neuritis as existing apart from arsenic?—In my opinion, certainly.

6356. And with regard to the alcoholic neuritis which may exist apart from arsenic, do you attribute that to beer and porter rather than spirits?—In the majority of cases certainly.

6357. So that if arsenic were eliminated entirely from malt liquors, alcoholic neuritis would be a reality?—I think so, if taken in excess.

6358. And connected with malt liquors rather than with spirits?—Yes, if taken in excess.

6359. You told us of cases in which relapse occurred. Can you say at what interval the relapse occurred?—Ten weeks.

6360. (Sir William Church.) That leads me to ask one other question. If you think that alcoholic neuritis is more frequently produced by beer drinking than spirit-drinking why has there been such a large proportion of cases to the population in Liverpool and its neighbourhood, Manchester and Salford, than in London, which is a beer-drinking population?—In Liverpool and Manchester I think a very large amount of beer is consumed as compared with spirits.

6361. I am speaking of before beer was thought to be contaminated, in years gone by?—I cannot explain that.

6362. You would not like to express an opinion that the population there drink even more beer than in London?—No; I do not know at all.

6363. (Chairman.) Do you not think that some of the now known causes may have existed occasionally to a considerable degree in old times; that is to say, that some of those cases which are so closely analogous to the arsenical poisoning in their symptoms may have been due to unsuspected arsenic in the beer?—It is

quite possible that some of the symptoms may have been produced by very small quantities of arsenic spread over prolonged periods, but, of course, recently undoubtedly the arsenic has been in very large quantities, and so accentuated the symptoms.

6364. (*Dr. Whitelegge.*) Can you give us the proportion of the sexes in these cases?—I have the proportion as regards 132 cases, and I sent them to Dr. Buchanan, for his report to the Local Government Board.

WEST DERRY UNION INFIRMARY, LIVERPOOL.—Age and Sex of Peripheral Neuritis Cases.

	Under 10.	20.	30.	40.	50.	60.	70 and upwards.	All ages.
Males	—	5	12	17	6	3	—	43
Females	1	7	39	29	10	3	—	89
Total	1	12	51	46	16	6	—	132

6365. (*Chairman.*) Have you any evidence as to the number of deaths from the epidemic in the Manchester and Liverpool district, or the number under your own cognisance?—I have had 17 during the epidemic, and I have had 51 cases which have ended fatally out of the total number of cases. The 17 undoubtedly died from arsenical poisoning.

6366. (*Professor Thorpe.*) During this epidemic?—Yes.

6367. (*Chairman.*) Does anything else occur to you to tell us?—Bearing on the question which you yourself suggested, I have had four years' experience in charge of one of the large Scotch hospitals, and your remarks are certainly very important, because I saw only four cases of neuritis there out of 10,000 admissions. Beer was taken in very small quantities.

6368. That is a much smaller proportion than in Liverpool and Manchester before this large outbreak?—Extremely small.

Mr. GEORGE E. DAVIS, called; and Examined.

6380. (*Chairman.*) You are chemical engineer and consulting chemist of the Manchester Technical Laboratory?—Yes.

6381. You have given us a statement, for which we are very much obliged to you, which will appear in our report?—Yes.

(*The following is the statement:*)—

In order to thoroughly understand the present position of the sulphuric acid industry it is necessary to go back to the year 1870, when the trade was of much smaller dimensions than it is to-day.

In that year the manufacturers of sulphuric acid might well have been divided into two classes:—

(1) Those who manufactured the acid for their own uses, such as the alkali makers and the makers of phosphatic manures, and

(2) Those who manufactured the acid for sale to ordinary customers.

In the first class, but little other than Spanish pyrites was employed, and the two kinds of this ore mostly used were Mason's and Tharsis. At that time or soon after, the Rio Tinto mines were offering cargoes, but as the acid makers had become used to the manipulation of the Mason and Tharsis ores the Rio Tinto ore did not find much favour.

Moreover it was freely stated that the Tinto ore contained more arsenic than either Mason's or the Tharsis, and the influence of this upon the extraction of the copper that these pyrites contained was so uncertain that most vitriol makers preferred to use pyrites they did not know something of, rather than change to a source of which so little was known.

Then, again, this period was one in which a transition was being effected from an old method of working to a new. In the old method the kilns and chambers formed the whole of the vitriol plant, with in some cases a small steam tower at the end of them to prevent large escapes of gas into the atmosphere. In the new method (which was then so new that practically only a few of the alkali and manure makers had adopted it), a Gay-Lussac tower at the end of the chambers, absorbed

6369. There was a larger proportion of neuritis than in Scotland before this outbreak?—Very much smaller percentage in Scotland, because they generally take 27 Apr. 1901. whisky.

6370. And that was before the time of this outbreak?—Yes; I am referring now to seven years ago.

6371. (*Dr. Whitelegge.*) Where was that?—Dundee Royal Infirmary.

6372. Would the class of population make any material difference? The one is a Poor-law infirmary and the other a general infirmary?—The class of the population was almost the same, the working class.

6373. (*Sir William Church.*) Could you inform the Commission whether, in your opinion, beyond paralysis different sorts of alcoholic drinks appear to have rather different effects upon the human body?—In my opinion the neuritis which is caused by spirits is rather more paralytic in nature.

6374. Quite apart from neuritis, are there any other effects produced on the human body which are attributed to alcohol, and which differ a good deal in different parts of the kingdom? Perhaps you have never been much in London?—No, I have not.

6375. Are you aware that so-called gin-drinkers' liver which used to be attributed to the use principally of gin is found in Scotland?—Yes; I do not know how frequently, but it is fairly common there. The other lesions you find in the body are just as common in Scotland as in England, in my experience.

6376. Your experience is contrary to that of a great many others with regard to cirrhosis of the liver, hob-nail liver, gin-drinkers' liver. It used to be very uncommon in Edinburgh years ago?—I do not know.

6377. (*Professor Thorpe.*) Is the gin-drinkers' liver common in Liverpool?—Not very common. I saw more gin-drinkers' liver in Scotland than in Liverpool.

6378. (*Dr. Whitelegge.*) Contracted liver?—Yes.

6379. You have met with this in Scotland in association with whisky?—Yes; in many cases.

Cirrhosis of liver common there.

in strong sulphuric acid the nitrous fumes that formerly went into the atmosphere, and this acid was employed in another tower, called the Glover tower, to furnish nitrous fumes, that were led into the chambers with a flow of gas from the pyrites kilns. This tower was placed between the pyrites kilns and the first sulphuric acid chamber.

In 1871, in a works in South-East Lancashire with which I was connected, the new method was employed, and Mason's ore was used as the raw material.

This Mason's ore in 1871 contained 0.42 per cent of arsenic, and the sulphuric acid made from it contained at 140° Tw. or 1.7 sp. gr.:—4.3 grms. per litre of  $As_2O_3$ —3.2 grms. per litre of As, or 0.19 per cent. As.

Upon going to St. Helens in 1874 the two works to which I was attached worked on the old system. Tharsis ore was burned here which contained 0.32 per cent. arsenic.

In these works there were no Glover towers, but a long and large iron flue intervened between the pyrites kilns and the vitriol chambers. In this flue a large quantity of the arsenic was condensed as  $As_2O_3$ , and this was removed about once in six months. The deposit in this flue was very arsenical, as it contained over 54 per cent. of arsenic trioxide as well as some antimony and bismuth.

The acid made in these works contained:—2.26 grms. per litre of  $As_2O_3$ —1.72 grms. per litre of As.—0.11 per cent. of As.

In another factory in the same town burning Tharsis ore (in 1875) the heat from the burning pyrites was utilised for concentrating the chamber acid by passing the flames over its surface, in a pan at the end of the pyrites burners, between them and the leaden chambers. In this case there was no flue in which the arsenic could deposit, and the sulphuric acid consequently contained more arsenic than usual, but not much more.

It was 2.66 grms. per litre  $As_2O_3$ —2.02 grms. per litre As—0.12 per cent. As.

In what was the new system of working in 1870-7 the Glover tower placed between the pyrites kilns and the first leaden chamber acted practically as a washer and

Mr. G. E. Davis.

Mr.  
G. E. Davis.  
27 Apr. 1901.

scrubbed the major portion of the arsenic from the gases by means of the vitriol that was showered down it. This is precisely the method of working to-day, and when the whole of the acid made in the establishment is poured down the Glover tower, the acid issuing from the tower contains the whole of the arsenic volatilised from the burning pyrites. The tower itself, however, does not wash out the whole of the arsenic from the gases; some arsenic goes forward into the first chambers of a series. But as this acid eventually finds its way down the Glover tower, it will be evident that the total arsenic is found in the outflow from the tower.

Arsenic in  
Glover tower  
acid and in  
chamber  
acid.

During some investigations relating to the distribution of arsenic in a sulphuric acid plant, which I made in 1872, it was found that when the acid running from the Glover tower contained 4.3 grammes per litre of arsenious acid, the acid in the first chamber contained 1.6 grammes per litre, 0.3 grammes per litre in the second chamber, and mere traces in the last two chambers.

Of course it will be seen that if acid is taken out of the chambers without passing down the Glover tower, it will not be charged with its normal average amount of arsenic, and the acid running from the tower will then be more highly charged with arsenic owing to the smaller volume, and in such cases the percentage of arsenic is very high.

In one case that came under my notice the hot acid from the Glover tower contained 18.0 grms. per litre of arsenious acid when Rio Tinto pyrites was being used.

In the seventies, small quantities of coal pyrites (called "brasses") were burned, but the quantity was insignificant in works of the first class.

Arsenic in  
different  
pyrites ores.

To-day the chief source of pyrites material is the Rio Tinto. This ore contains 0.40 per cent. of arsenic, and is very regular in its composition. Tharsis pyrites is burned still to a certain extent, Mason's to a very small extent, and there are several other mines sending their products to this country and known by various trade names, such as "Seville," "Santa Rosa," "Norwegian," etc.

Seville ore is very arseniferous; it contains 0.9 per cent. of As.

Santa Rosa is still more arseniferous, and often contains as much as 2.24 per cent. of As.

Sulphuric acid made in 1897 from Rio Tinto pyrites under my superintendence contained:—4.8 grms. per litre of  $\text{As}_2\text{O}_3$  = 3.6 grms. per litre of As. = 0.21 per cent. As.

Norwegian ores are very variable in their composition. Some are free from arsenic, other varieties contain arsenic and copper, while some kinds contain so much selenium as to unfit them for many industrial purposes.

I may now pass to the second class of manufacturers, who, in 1870-80, manufactured the acid for sale to ordinary customers.

At this time, say 1871, most of the acid sold was rectified, water-white, vitriol of a sp. gr. of 1.840 or 1.64° Tw. Even when the acid was required by the consumer to be employed in the diluted state, he as a rule preferred the rectified acid, and to dilute it with water to his requirements. The two kinds in the market then were known as brimstone acid and pyrites acid. The brimstone acid makers used Sicilian brimstone, and the contracts were nearly universally made for "Sicilian brimstone," "Best Thirds," and it was from this quality that the whole of the "brimstone" acid was made in those days. At this time, 1871, and perhaps a few years before, sulphuric acid began to be made from spent oxide of iron. The refuse from gas works, and this was by many people regarded as a very fair substitute for brimstone acid in many cases. It had at that time no special designation, and at times it was not altogether free from arsenic. It had, however, a ready sale as it was a clean good acid, and for sulphate of ammonia making gave a good grey sulphate, which pyrites acid would not do.

Acid from  
Sicilian  
brimstone,

from spent  
oxide.

From 1871 to 1877 the manufacture of sulphuric acid from spent oxide underwent considerable expansion, and the acid was a serious competitor with brimstone acid, so much so that the makers of brimstone acid went about to their customers decrying the acid made from "gas works refuse," as they called it; and several of them instructed their customers that such acid was not "brimstone" acid, and therefore ought to be classed with pyrites acid, which was lower in price.

This state of affairs was put before me in 1878 by a

firm then making about 80 tons per week of sulphuric acid from spent oxide, and I advised them that although most of the acid made from spent oxide was every bit as good as that made from "best thirds Sicilian brimstone," yet by no stretch of the imagination could it be "brimstone acid," and I advised that it should be called "sulphur acid," as spent oxide from gas works contains its sulphur in the free state. So it was called sulphur acid in many places, to distinguish it from brimstone acid on the one hand and pyrites acid on the other. Some works have called it oxide acid, and both these designations mean the same thing.

The extension of the manufacture of acid from spent oxide continued until the year 1886, when spent oxide became scarce, and its price tended upwards.

This set some manufacturers thinking that if the arsenic could be extracted from the vitriol during manufacture, lower grades of pyrites (that is ores containing more impurities, notably arsenic) could be profitably dealt with. These ores are those already mentioned such as the Seville and Santa Rosa. This was effected on a very large scale, and in 1887 began a movement which has not only had a serious effect upon the "sulphur" acid trade, but has nearly civilised "Brimstone" acid out of existence.

I have examined many samples of genuine brimstone acid and found them always arsenic free.

I have also examined many samples of sulphur acid made from spent oxide, and while they have been generally free from arsenic, many samples have been found to contain arsenic, but in traces only, often very minute traces.

I have also examined a very large number of samples of pyrites acids, but the results already given will sufficiently indicate their arsenic contents.

The arsenic existing in pyrites is found there as metalloïd arsenicum in combination with some heavy metal, generally copper, iron or nickel. When such a pyrites is burned in a current of air some of the arsenic is oxidised and volatilises; 70 to 80 per cent. of the arsenic leaves the pyrites on combustion. It has already been shown that when a long and cool flue intervenes between the pyrites kilns and the leaden chambers, some of the arsenious acid condenses therein, but still a large quantity passes on and finds its way into the acid of the chambers.

Under the modern system of working the interposition of the Glover tower between the pyrites kilns and the leaden chambers causes a very large proportion of the arsenic to be absorbed in the vitriol that is run down it, and this amount is kept out of the leaden chambers, so that the acid drawn from the chambers is much less arsenical than the Glover tower acid. It is certainly less arsenical than it would be if the Glover tower had not been interposed.

The vitriol running from the Glover tower is very hot, generally, 300° F. to 320° F., and usually of a sp. gr. of 1.75 or 1.50° Tw. At this temperature and strength a litre will dissolve about 60 grammes of arsenious oxide, or equal about 2.58 per cent. by weight of metalloïd arsenic. When, however, this arsenical acid is cooled down to the ordinary atmospheric temperature the greater portion of the arsenious acid crystallises out, and a saturated solution containing about 10 grammes per litre of arsenious acid is supernatant. This is equal to 0.57 per cent. by weight of arsenious acid, or 0.43 per cent. of metalloïd arsenic.

I have seen it stated in print during the past few months that a vitriol of commerce was found to contain 1.8 per cent. of arsenic, or four times as much as the above figures show an acid can hold in solution. This can be accounted for by the fact that the arsenious acid which crystallises out during cooling has not been allowed to settle out before sale.

There is also a further explanation. The arsenic existing in sulphuric acid made by the modern method occurs in two forms: arsenious acid and arsenic acid. The arsenic acid is more soluble in sulphuric acid than the former is.

The foregoing experiences show that it would not be difficult to so arrange the apparatus that from 70 per cent. to 80 per cent. of the arsenic contained in very arsenical sulphuric acid would be eliminated by cooling and subsidence. No invention would be required, but simply the application of known facts.

In all the works where pyrites vitriol is "de-arsenicated" the operation is performed by diluting the vitriol

Mr.  
G. E. Davis.

fr. with water and precipitating the arsenic as sulphide by  
Davis. contact with sulphuretted hydrogen gas.

1901. When the sulphuric acid is sufficiently diluted and kept cool it is possible to eliminate the whole of the arsenic, if the operation is properly conducted. Such acid is even better than acid made from brimstone for many purposes, as the sulphuretted hydrogen gas also purges the acid of its nitrous contents, which are very detrimental in some processes, such as the manufacture of aerated waters and the preparation of some colouring matters.

Irregularity of working cannot, however, be thoroughly guarded against in the de-arsenication of pyrites acid without much care in the supervision of the operations. The precipitate of arsenious sulphide is a very bulky one, and much sulphuric acid is entangled with it. It would not pay to lose this, and so the precipitate is washed and sometimes heated to facilitate the subsidence of the arsenious sulphide. During any process of heating some arsenious sulphide and also some antimony that accompanies the arsenic is redissolved, and if this solution is mixed with the bulk of the de-arsenicated acid arsenic will be found in the so-called purified acid.

There is one other point that deserves to be mentioned. The more arsenic in the raw acid the greater will be the bulk of the arsenious sulphide precipitate necessarily be, and consequently the greater trouble in the manipulations. When an acid maker sells two qualities of acid, viz., an arsenical acid and a de-arsenicated acid, it is to his interest to concentrate as much arsenic as possible into his common or arsenicated acid, say the Glover tower acid, so as to have less in his chamber acid to precipitate. In such a case the untreated acid would contain far more arsenic than the average acid of a maker who did not de-arsenicate at all. For some purposes perhaps this would not matter, but it is not a step in the right direction.

In 1878 I carried out a series of experiments for a firm, with which I was then connected, of eliminating the arsenic by means of a stream of hydrochloric acid gas, but it was found that it was only the arsenious acid that was eliminated. The arsenic present as arsenic acid still remained, and the process was discontinued as an imperfect one.

When arsenical sulphuric acid is used for the preparation of other acids the arsenic generally contaminates them. In 1876 a sample of phosphoric acid sent to me for analysis contained 2.6 grammes per litre of arsenious acid, and a sample of liquid muriatic acid recently examined contained 1.12 grammes of arsenious acid per litre. This last acid was made with sulphuric acid, the produce of Rio Tinto pyrites.

6382. (Chairman.) With respect to some of the chief points of your statement, we understand formerly the vitriol plant consisted essentially of kilns for burning the pyrites and chambers for making the acid, with the long flue to the kilns, in which a good deal of the arsenic condensed?—That was so.

6383. The introduction of the Glover tower in connection with the Gay-Lussac tower meant that in between the kilns and the chambers a washing tower was interposed?—Yes; that was called the Glover tower. It was for the purpose of boiling down the acid from the chambers. The acid was weak as it came from the chambers, and contained a great deal of water, and formerly, prior to 1870, it used to be boiled down in leaden pans, but the Glover tower was an invention to boil down this acid by means of the waste heat coming from the pyrites.

6384. The washing in this tower is done by sulphuric acid, which is continuously passed back from the chambers?—Yes.

6385. The washing in the tower takes up a large proportion of the arsenic?—Yes.

6386. In which of the substances concerned is the arsenic taken up?—The arsenious acid is in the state of vapour carried along with the sulphurous acid from the sulphur of the pyrites and the arsenious acid being a solid substance, whilst the other is a gas, the vitriol poured down this tower washes out the arsenic.

6387. Where does the arsenic washed out go?—Into the sulphuric acid.

6388. The Glover tower acid is thus highly arsenical?—It is.

6389. While chamber acid is much less arsenical?—

6390. And the amount of the arsenic diminishes from chamber to chamber?—Yes.

6391. The effect of the Glover tower has been on the one hand to enable pyrites acid from the chambers to be comparatively free from arsenic?—Yes, about one-third of the quantity that exists in the tower acid.

6392. On the other hand, it has caused the production of a commercial sulphuric acid from the Glover tower, which is much more arsenical than was made previously?—Yes.

6393. Are the acids from the chambers and from the Glover tower about equally strong as regards sulphuric acid?—Yes, about an equal strength of real sulphuric acid, or to be more exact, the chamber acid contains about 70 per cent. of sulphuric acid while the Glover tower acid contains 80 per cent.

6394. The cheaper and more arsenical ores, such as Seville and the Santa Rosa, are coming into the market as well as the Rio Tinto ore; formerly it was Rio Tinto?—Nearly entirely; but now the Rio Tinto are putting up their price, and the world will be now searched for ores, perhaps not quite so pure.

6395. The Rio Tinto ore was a sulphuret of copper?—Yes, and iron.

6396. Which the most, iron pyrites or copper pyrites?—The iron pyrites, a bi-sulphide of iron.

6397. Is there much earthy or rocky matter along with this ore, or does the pyrites come out nearly free from earthy matter?—There is not very much impurity in the ore. I think the full amount of sulphur it can hold theoretically is 52 per cent., whereas it contains from 49 to 50.

6398. Which contains?—The ore contains from 49 to 50 in practice, and it can only hold 52 theoretically, so that it is very nearly pure pyrites.

6399. When very arsenical ores are used, the manufacturer makes both arsenical and non-arsenical acid?—Generally.

6400. And he has a special reason for trying to get as much arsenic as possible into his Glover tower acid?—Yes, when he de-arsenicates.

6401. Does he de-arsenicate the Glover tower acid generally?—Not if he can help it, because it contains too much arsenic.

6402. Why does not he?—When the sulphuretted hydrogen is passed through this strong acid, there is so much sulphide of arsenic that perhaps two-thirds of the settling-tanks would be filled with this material, and he would be only able to draw off from these tanks about one-third of the acid he treated.

6403. What remains in the mud, has that to be got out?—Yes. And that is why he would rather not treat this strong acid.

6404. He could purify the whole of it?—Yes.

6405. Is it an expensive process?—Much more expensive than treating the chamber acid only.

6406. Treating the chamber acid to purify the arsenic is not a very expensive process?—No, because there is a small quantity of arsenic in it.

6407. It makes a very small difference on the price of the finished product to purify it from arsenic?—I think I have read some of the evidence, but I think it chamber is minimised rather. It does cost a few shillings per acid ton.

6408. Two or three shillings?—It might go up to 5s.

6409. 5s. out of 45s. perhaps?—Yes. It would vary, perhaps, from 1s. to 5s., according to the amount of arsenic that is present in the acid.

6410. What do they do with the Glover tower acid—sell it?—It is sold to these people, to whom arsenic is no damage, such as the manure makers.

6411. Is arsenic no damage to them?—I have not followed the question out.

6412. Would not putting so much arsenic into the manure make it liable to get into the roots, or even into the plants?—I have not followed that subject out.

6413. The arsenic found in the refuse of the Glover tower acid is not a product of any value?—No, not at present. It has been tried to utilise it, and I think one or two manufacturers do in a small way, but I don't think there is any great use for the whole of it.

6414. It is sulphide of arsenic?—Yes, it is.

Mr.  
G. E. Davis.  
27 Apr. 1901.

Ores coming into the markets increasingly arsenical.

Tower acid not in practice de-arsenicated.

Cost of de-arsenicating chamber acid.

Mr. G. E. Davis. 6415. Arsenium and sulphur?—Yes.

6416. It would be a dangerous thing to throw out?—It is very insoluble. I do not think it would do much harm on an ordinary waste heap.

6417. Could you get quit of it in a rubbish heap?—Yes, in the ordinary rubbish heap of the works, which is a mixture of everything.

6418. The Glover tower acid when hot can dissolve about six times more arsenious oxide than when cold; is that so?—Yes.

6419. Hence when we have been told of a commercial acid in which a deposit of crystallised arsenious oxide was found, we may infer that the amount of arsenic might have been materially diminished by simply cooling and decanting?—That is so.

6420. And such acid may be sold without a special note that it contains arsenic?—Yes; I do not think any note is made as a rule in selling acids, whether it contains arsenic in any greater or less degree.

6421. That would be highly poisonous if, by chance, a few drops of the sulphuric acid was used in medicine and various ways?—Very poisonous indeed. It ought not to be used for food.

6422. Do you know whether sulphuric acid is used in any acidulated drops or other confectionery?—I think vegetable acids are used for that, citric and tartaric.

6423. Is sulphuric acid ever used for cheapness; it is as wholesome as any other if it is not too strong?—I do not think it is used because there is a peculiar taste about the vegetable acids. On the other hand citric and tartaric acid are both made with sulphuric acid as a basis, and the arsenic in sulphuric acid would probably get into the citric or tartaric.

6424. Would you approve of allowing what you call Glover tower acid to be sold at all without a notice that, although called sulphuric acid, it contained a large amount of arsenic?—I think so. I think it should be used for certain purposes. I think caution should be exercised by the people who are going to use it.

6425. It does seem rather dangerous to sell a sulphuric acid without note or comment, a liquid containing as much arsenic in solution?—It is dangerous for food stuffs.

6426. Cooling the sulphuric acid from the Glover tower process would not remove much of the arsenic which is present as arsenic acid?—No; it would remove none that was present as arsenic acid.

6427. It would remove crystals of arsenious acid?—Yes.

6428. How is the de-arsenication of chamber acid effected? Is that by the aid of sulphuretted hydrogen?—Yes, that is how it is done at present.

6429. Diluting and precipitating. Is there any other substance required to precipitate it?—No.

6430. You simply dilute the acid and precipitate by sulphuretted hydrogen gas?—Yes.

6431. Must the acid be diluted?—Yes, because arsenic is not wholly precipitated without you reach a certain degree of dilution; in the strong acid precipitation does not take place.

6432. The result is completely arsenic-free acid, but considerably diluted with water?—Yes.

6433. Is it not rather an expensive process to dilute the acid, precipitate the arsenic, and afterwards strengthen the acid?—No. It only costs, I should think, on an average, something like 3s. 6d. a ton.

6434. Does that include the re-strengthening of the acid?—Yes.

6435. Is it possible in this way to produce a completely arsenic-free acid?—It is.

6436. Can arsenic-free in this sense mean that no arsenic could be found by any test in a quantity such as an ounce of acid?—Yes; it could be entirely precipitated from it.

6437. With regard to arsenic in brimstone acid and spent oxide acid, have you found brimstone acid made from Sicilian sulphur uniformly arsenic-free?—Always; when I have been able to prove to my own satisfaction that the acid has been really made from Sicilian brimstone it has been always free from arsenic.

6438. Have you ever found any arsenic whatever in sulphuric acid made from Sicilian sulphur?—No, I have not.

Sulphuric acid super-saturated with arsenic,

may be sold without declaration.

Citric and tartaric acids liable to be arsenical.

Arsenic acid in sulphuric acid.

Arsenic can be completely removed from chamber acid.

6439. Have you tested a great many samples?—A great many.

6440. We have been told that it is sometimes found in acid made from Sicilian brimstone?—I have found arsenic in acid which has been sold as brimstone a.c.d., but which afterwards I found out had been made from something else.

6441. What else?—The spent oxide from a gas works, and coal pyrites.

6442. Spent oxide gives you sulphur?—Yes.

6443. But mixed with some other impurities?—The first sample I ever tested of spent oxide acid contained traces of arsenic, and I followed the whole question up, and I found it was due to hydrochloric acid containing arsenic having been used to prepare the oxide of iron that went into the gas works in the first place.

6444. How much sulphur is there in the spent oxide supplied for this purpose?—It varies from 40 to 55 per cent.

6445. Which may have been contaminated by arsenic in the way you described?—Yes, sometimes.

6446. The arsenic is introduced through impure hydrochloric acid, but by using pure hydrochloric acid in the process the spent oxide sulphur would be free from arsenic?—Yes, quite free.

6447. That is a by-product from the gas works?—It is.

6448. Is any process of de-arsenication carried out at any works which produce brimstone acid or spent oxide acid?—No; it is not necessary.

6449. It is generally considered that the sulphuric acid which is produced, whether from brimstone or spent oxide, is arsenic-free?—It is generally free enough for all practical purposes.

6450. But you say that in a specimen which was called brimstone acid you found arsenic, and traced that back to spent oxide?—Yes.

6451. Then spent oxide without a special test for its purity does not give security against arsenic in the final product?—No; but the quantity is very small, mere traces. It does contain sometimes arsenic.

6452. When sulphuric acid containing arsenic is used for the preparation of other acids, the acid generally contaminates them?—Generally it does.

6453. In what cases may arsenical acid be used for the preparation of other acids?—Some years ago it was very largely used in making phosphoric acid; it is used in making acetic acid. All these things are matters of history; they are mostly detailed in "Gmelin's Handbook of Chemistry." The arsenic is found in these acids on account of pyrites sulphuric acid having been used for the preparation of these other acids. It is mentioned in Gmelin's handbook that acetic acid has been found in Germany to contain arsenic, which was traced to pyrites acid, and the quantity I found some years ago in phosphoric acid was rather large.

6454. Derived from arsenical sulphuric acid?—Yes.

6455. That is an enormous quantity that you found in 1876, 2.6 grammes of arsenious acid per litre?—Yes, and that was being sold at that time for sugar refining.

6456. The phosphoric acid was used for sugar refining?—Yes. The juice was treated with lime and the excess of lime was taken out by phosphoric acid.

6457. Was there any poisoning by the sugar so produced discovered?—I daresay in those years it would be put down to neuritis.

6458. With regard to the sugar that was treated by impure phosphoric acid, were there tests known to have been made?—I do not think so.

6459. You found a sample of phosphoric acid ready to be used for purifying sugar?—Yes.

6460. Containing as much as 2.6 grammes per litre?—Yes.

6461. That is a  $\frac{1}{4}$  per cent. by weight?—Yes. In 1876 a sample of phosphoric acid sent to me for analysis contained 2.6 grammes per litre, of arsenious acid.

6462. Of arsenious acid per litre of phosphoric acid?—Yes.

6463. (Professor Thorpe.) Do you really mean that?—Yes.

6464. Was it a solution of phosphoric acid?—Yes. In those years it was sold as a liquid concentrated to 140 Twaddle, 1.7 specific gravity.

Mr. G. E. Davis. 27 Apr. 1901. Sicilian brimstone acid always free from arsenic.

Origin of arsenic in spent oxide acid.

Arsenic in acetic acid.

in phosphoric acid used for sugar refining.

6465. Phosphoric acid is now usually sold in a solid condition, is not it?—Not for manufacturing purposes. It is for finer chemicals, the glacial, but this was made by treating phosphate of lime with sulphuric acid made from the copper pyrites and then boiling down the liquid resulting from that, after separating the sulphate of lime. One works used to turn out about 20 tons a week.

6466. (Chairman.) You found recently a sample of liquid muriatic acid containing 1·12 grammes of arsenious acid per litre?—Yes.

6467. This last acid was made with sulphuric acid, produced with Rio Tinto pyrites?—Yes, and that is a very good average sample.

6468. (Sir William Church.) You say that by a process of cooling the Glover tower acid you would get rid of a good deal of the arsenious acid, but the arsenic acid would not be affected by that?—It is about one-third of the total quantity present there as arsenic acid, and if this acid is worked over these towers several times some of this arsenic, as arsenious acid, might separate out in the tanks by crystallisation, but the arsenic acid does not crystallise out. So that if it goes over the tower two or three times, pumped in at the top, and running out at the bottom, although a great deal of arsenious acid is separated out, the arsenic acid is continually increasing, so that that accounts, I think, for some of the acid one has read of in the papers being so strongly charged with arsenic. It was stated at the coroners' inquest that there was 1·8 grammes per litre in some of the acid, and that is a great deal more arsenic than ordinary acid will hold in solution. The only way to account for that is that it was present there as arsenic acid to a great extent, which does not separate out by crystallisation.

6469. (Chairman.) Does arsenic acid escape some of the tests that are applied?—It might do, but I do not think it does as a rule. The fact is, that when you pass sulphuretted hydrogen through a solution of vitriol containing arsenious acid and arsenic acid, the arsenious acid is converted into sulphide first, and the arsenic acid that is there does not form a sulphide until a considerable time. First of all, it has to be reduced by the sulphuretted hydrogen going through it to the state of arsenious acid, and then the arsenious acid is converted into sulphide, and that forms a very good practical test when one is de-arsenicating acid, because the sulphuretted hydrogen saturates the solution, and if, after standing a few hours, you find the acid no longer smells of sulphuretted hydrogen you know you have not passed enough through, and that some of the arsenic acid that is there perhaps has not been thrown down.

6470. The precipitation of sulphuretted hydrogen, if conducted long enough, will throw down all the arsenic acid after the arsenious acid?—Yes.

6471. First, the arsenious acid, and then given a continuation of the process, the whole arsenic acid will be thrown down?—It will.

6472. (Professor Thorpe.) What do you precisely understand by brimstone acid?—Acid made from Sicilian brimstone.

6473. Would you not understand by brimstone acid, acid made from spent oxide?—Certainly not.

6474. Although, of course, in the spent oxide it is a sulphur from which the stuff is produced?—Yes; but I make a distinction between sulphur and brimstone; brimstone is the native article, sulphur is a manufactured substance.

6475. Is that distinction always recognised in the trade?—It was in those early days.

6476. Is it now?—I would not like to say now. I have not had anything to do with the brimstone trade for 10 or 12 years; but I should not think it was.

6477. It would not be right for a manufacturer to designate as brimstone acid an acid made from sulphur which may be contained in spent oxide?—Certainly not. I should say it was quite a wrong thing to do.

6478. And you think in making that assertion you

would be supported by the general opinion of the trade?—I think so.

6479. Taking brimstone acid in your sense, can you tell the Commission the relative proportion of brimstone acid to pyrites acid made in this country?—No, I could not without getting statistics, and those are very difficult to get just now, because many manufacturers make the pyrites acid for their own use, and nobody but themselves have the statistics. It could be only got by taking the total quantity of pyrites coming into this country, and then supposing it was all used for one purpose.

6480. I presume all the pyrites that comes into this country from those sources, at all events, you have mentioned, is used in the manufacture of oil of vitriol?—I think so; but the bulk of it is used up again in the works where it is produced. It does not go outside to customers at all.

6481. I am quite aware of that. A large quantity is used in the alkali trade and in the manure trade?—Yes.

6482. Therefore it does not go into general consumption?—No.

6483. Would you call acid made from recovered sulphur brimstone acid?—No; I should call that recovered sulphur acid.

6484. Is that a term recognised in the trade?—Yes, it is always sold as sulphur, and generally recovered sulphur. The acid that was made in those years when brimstone acid was being made to be sold to consumers was always specified in the contracts that it should be Sicilian brimstone, best thirds. There were several qualities of brimstone, firsts, seconds, and thirds. Thirds were divided into one or two grades again. The first was too expensive to make vitriol of, and the second quality was considered to be so, but the best thirds, that is, the first grade of the third quality, was always selected for brimstone making; so that it was a very definite thing in those years. It was best thirds, and the whole of the brimstone acid in those days were made from that quality.

6485. (Chairman.) Did the firsts and seconds contain sometimes arsenic?—No.

6486. The best thirds was better quality than the first and seconds?—There was more rock with the third, which they would not have in the first and second quality. The first and second quality was generally 99·9 per cent. of sulphur, but the best thirds was 95 to 97.

6487. In Germany is the acid made chiefly from German brimstone acid or chiefly from pyrites?—Chiefly from pyrites.

6488. Is there much brimstone acid made in Germany?—I do not think so.

6489. Is it easy to get arsenic-free acid in Germany?—Yes, there are de-arsenicating plants working in Germany.

6490. But ordinary German pyrites acid is as liable to contain arsenic, and contains as much arsenic as English made pyrites acid?—Quite so. They have methods of taking it out with sulphuretted hydrogen in much the same way as we have.

6491. They have a Glover tower?—Yes.

6492. And your remarks about the Glover tower and the difficulty of purifying the Glover tower applies equally to the German mode of manufacture?—Yes.

6493. (Dr. Whitelegge.) At the end of your report you mentioned a large proportion of arsenic being contained in hydrochloric acid; is that general?—Yes, that is very general.

6494. Is hydrochloric acid used much in the preparation of food substances?—It is used a little. In the making of dextrin and even glucose it is quite permissible to use hydrochloric acid.

6495. And when hydrochloric acid is used it is necessary to take the same precautions against the presence of arsenic as in the case of sulphuric acid?—That is so.

Mr.  
G. E. Davis.

acid.

(Sir William Church in the chair.)

Mr.  
G. E. Davis.  
27 Apr. 1901.

Hydrochloric  
acid for food  
purposes  
should be  
cylinder acid.

Selenium in  
sulphuric  
acid.

Sulphuric  
acid from  
recovered  
sulphur,  
contains no  
sensible  
quantity of  
arsenic.

6496. (Dr. Whitledge.) Are those precautions generally taken?—There is another circumstance, if you will allow me. Hydrochloric acid, that is used for food stuffs, as a rule is what is called cylinder acid; that is, it is not made in the ordinary way from pyrites. It is made from brimstone acid in the first place, in cylinders, and in much smaller quantities. Perhaps only two or three tons a week would be made in a cylinder, whereas you would make 150 tons a week in the ordinary furnaces. There is more care taken, and the price is about two or three times that of what is made in the large way, so that when a man wants to use hydrochloric acid for food stuffs he generally buys what is called cylinder acid.

6497. Which would contain a little arsenic?—It would not be contaminated with arsenic if it were made from brimstone acid. The difficulty is in the buyer finding out that it contains arsenic without testing it. That is why I think the onus of the acid being pure should be put upon him. He goes about to the cheapest market to buy as cheaply as he can, and he does not know until it is too late that an acid he is buying is made from pyrites instead of brimstone. He would know it if he were testing the substance he was buying.

6498. You mention that the Norwegian ore occasionally contains selenium?—Yes.

6499. Can you tell us anything about the presence of selenium in sulphuric acid?—It is present sometimes in small quantities, very small quantities indeed. It generally shows itself by volatilising into the hydrochloric acid when hydrochloric acid is made from it. Otherwise you do not find its presence very marked. It has a peculiar property of turning the hydrochloric acid after a time red, and a deposit forms in the carboys in which it is put of a blood-red colour, which people, as a rule, who are not chemists, fancy is iron. I have known of a good many carboys of acid having been returned to the makers with this deposit in the bottom, with the information that they could not use it because of the iron in it. That iron has been found to be selenium.

6500. In the sulphuric acid would it make itself felt?—No.

6501. (Professor Thorpe.) Has it not a power of turning sulphuric acid a particular colour?—It may have, but that colour is always masked by impurities in the sulphuric acid. In a large works the sulphuric acid is almost always brought into contact with some organic substance, and instead of getting a clear acid it is generally brown from the presence of organic matter.

6502. (Dr. Whitledge.) Would selenium be only found in acid from Norwegian ores?—Yes, in any considerable quantity.

6503. Is much of the sulphuric acid on the market prepared from Norwegian ore?—Not much. It is a very difficult ore to work, and, therefore, it has not found much favour.

6504. So that in general one would not expect to find selenium in any sulphuric acid?—Not in a quantity to do any damage.

6505. Can you say anything as to the proportion in which selenium would be present as a maximum in the Norwegian ore?—No; I have never determined the quantity.

6506. (Professor Thorpe.) To come back to where I left off. You told us that sulphuric acid made from recovered sulphur would be known in the trade as sulphur acid?—Yes.

6507. Recovered sulphur may contain a little arsenic, may it not?—I do not think it is likely when made by the Chance process. It is all made from sulphuretted hydrogen volatilised by means of carbonic acid.

6508. You think that recovered sulphur would not contain any sensible quantity of arsenic?—Not any sensible quantity. The acid from it would be quite as good as if made from brimstone, but it is not brimstone acid for all that.

6509. The introduction of the Glover tower has effected considerable economy in the manufacture of sulphuric acid?—Yes.

6510. It has done that, I presume, by employing the heat of the gases as they come from the kilns in concentrating the oil of vitriol?—That is so.

6511. In order that that heat may be in a maximum quantity it is necessary that these gases must be delivered as promptly as possible from the kiln into the Glover tower?—Yes.

6512. Therefore there is no intermediate cooling process which would allow of the deposition of the arsenious oxide?—No, we always try to make the flue as short as possible.

6513. In the old-fashioned system there was time given for a deposit of the arsenic?—Yes.

6514. In the old-fashioned method of making oil of vitriol there was a less chance of any large quantity of arsenious oxide getting into the oil of vitriol?—Yes; it used to settle in the cooling flue, and was taken out generally twice a year. The plant was stopped for cleaning the long flue out. We used to clean out in one particular flue I remember three or four cart-loads of arsenic at a time.

6515. Therefore the effect of this economy has been to bring about the possibility of a larger introduction of arsenious oxide into the acid?—Yes.

6516. But as the method is at present worked, that arsenious oxide is largely concentrated in the Glover tower?—Yes.

6517. These acids of which we read in the newspapers, and which have been connected with the formation of arsenical glucose, were they, in your opinion, probably Glover acids?—They must have been direct from the Glover tower.

6518. And therefore must have contained the maximum possible contents of arsenic?—Yes. I have never seen such samples myself in the whole of my experience.

6519. (Sir William Church.) You saw examples of the acid that had been used?—No, but I have seen the results.

6520. You are judging from the analysis?—Yes. I have never seen such results.

6521. Is it common to get actual deposit of arsenic as a sediment from Glover tower acid?—Yes, it is, in the works themselves, but not in customers' tanks outside.

6522. To be sent out?—No.

6523. (Professor Thorpe.) If you object to give an answer to this question you will say so; but do you think it would be a proper thing for any oil of vitriol maker to send Glover acids to persons calling themselves sugar refiners?—Not if they knew they were sugar refiners; or for the preparation of food of any kind.

6524. It has been suggested to us that it would be desirable to prescribe that whenever sulphuric acid is used for food purposes it should be brimstone acid; do you think that is necessary?—No, I do not think that is necessary at all.

6525. You believe that the methods of de-arsenicating oil of vitriol are so effective that purified oil of vitriol could be obtained with certainty?—Yes.

Mr.  
G. E. Davis.  
27 Apr. 1901.

Concentration  
of arsenic in  
Glover  
tower.

De-arsenicated  
acid suitable  
for food  
purposes

## THIRTEENTH DAY.

AT WESTMINSTER PALACE HOTEL.

Friday, 3rd May, 1901.

PRESENT :

The Right Hon. LORD KELVIN (in the Chair).

The Right Hon. SIR WILLIAM HART-DYKE.  
SIR WILLIAM CHURCH.  
Professor THORPE.

Dr. WHITELEGGE.  
Mr. COSMO BONSOR.

Dr. BUCHANAN, *Secretary*.

SIR HENRY W. PRIMROSE, K.C.B., C.S.I., called; and Examined.

W. 6525.\* (Chairman.) You are the Chairman of the  
Board of Inland Revenue?—Yes.

of 6526. Your Board possesses considerable powers over  
breweries?—We do.

in 6527. These powers have been given in one respect  
for the protection of the Revenue?—Speaking generally, I think we may say so.

6528. But not merely for the protection of the Revenue?—The powers given us under the Act of 1888 go rather beyond that; otherwise I should say they were confined wholly to the protection of the Revenue.

6529. The Revenue is derived from the sale of certain objects?—That is so.

6530. It might be presumed that the Government in getting Revenue from the sale of objects would itself as far as possible guarantee the healthfulness of those objects by the sale of which it makes money?—I am not quite sure that that has been the view of the Government.

6531. Does it seem to you right that the view of the Government should if necessary be altered so as to adopt that conclusion?—That is a large question of policy. As regards the actual fact I do not myself read the law as implying that hitherto we, as representing the Government, are responsible for the wholesomeness of the taxed article.

6532. There is a Revenue Act, or Acts, which might conceivably be utilised for the protection of public health?—That is so, certainly.

6533. If it could not be conceivably so utilised, would not the Act need amendment?—If it was desired to impose more direct responsibility upon the Department no doubt the law would have to be altered.

6534. But is it not right that the contingency of making money from the public by selling poisons, or injurious ingredients, should be provided against?—I think it may be provided against in another way: by making the persons who sell the article responsible, rather than by making the Government responsible who merely take a tax upon the article.

6535. To secure that no article liable to tax shall pass without taxation it is necessary to analyse some of the products?—Yes.

6536. Ought not the law to be that in analysing those products care is taken—not merely may be taken, but shall be taken—that the products are not injurious? There is an opportunity of testing; in fact, there is an obligation to chemically test the articles on which the tax is leviable?—Yes.

6537. Is it right that the articles should pass through the hands of an analyst of the Revenue and pay tax and yet be poisonous?—The analyses required to test for purposes of health, I take it, is different from the analyses required for the test for the purposes of Revenue. Therefore it would be an additional duty imposed if we had to test for soundness of condition.

6538. Is not that a duty that is owed to the public from whom the money is taken?—I should not like to express an opinion upon that.

6539. The Act is framed so that it can be conceivably utilised for the protection of public health?—Yes.

6540. Is it not right that as far as that is conceivable or possible in the Act it ought practically to be done?—I think a great deal would depend upon what was proposed. I should say it would not be of practical advantage to make the Department primarily responsible, because I think it would interfere very seriously with the convenience of the trade. Everything would be sent up to one central laboratory, which would have to be considerably enlarged if they were to analyse very closely and carefully the whole of the produce of the breweries from the point of view of public health, and the analyses would probably be very considerably delayed by them. In the meantime very much of the produce would have gone into consumption, or may have gone into consumption. I should say myself that that is a duty which would be better entrusted to the various localities. The mere fact that the article is taxed ought not necessarily to make any great difference as compared with articles that are not taxed. The locality is responsible for all articles of food and drink that are sold, and I think it would be better to leave to them that responsibility with regard to beer in the same way.

6541. And not to include any protection of the public against poison in the analyses that are made for protection of the Revenue?—I think it would add very largely to the business of the Central Government Laboratory, and I think it would be a pity to make the Central Government Laboratory primarily responsible for that investigation. I think its proper function is rather that of a court of appeal or referee in disputed cases.

6542. Has in fact the clause in the 1888 Act as to noxious ingredients been acted on?—No, not as regards noxious ingredients; it has been acted upon once as regards a material or substance which was considered to be injurious to the Revenue, namely, saccharine. As soon as the Act was passed a notice was published in the "Gazette" prohibiting the use of saccharin. Perhaps I may hand in a copy of that prohibition. It says that the "use of the said extract or product is calculated to affect prejudicially the interest of the Revenue." And thereupon the use of it was prohibited. That is the only order that has been issued under the Act of 1888; and in no case has any order been issued prohibiting the use of a substance on the ground of its being noxious or deleterious.

6543. (Sir William Hart-Dyke.) As regards health?—Yes.

6544. (Chairman.) So that I may take it your answer to the question: Has the clause in 1888 Act as to noxious ingredients been acted upon, is No?—Yes, the answer would be no.

6545. Without reservation?—Yes.

6546. Can you give a synopsis of the powers which are actually possessed under the Act of 1888 and of the powers of the Board of Inland Revenue under any other Acts which may bear on the protection of the

Sir H. W.  
Primrose.

Objections to making Board of Inland Revenue primarily responsible for purity of beer.

Under 1888 Act Saccharine prohibited for revenue reasons.

but no ingredients on ground of risk to health.

Sir H. W.  
Primrose.

3 May 1901.

Powers of  
Excise at  
brewery.

public health?—I have a note here of those of the powers which might possibly be utilised for the protection of the public health; it by no means includes all our powers, but includes, I believe, all those germane to this Inquiry. Our first Act is the Act of 1830; an Act which substituted a beer duty for the malt duty, 43 and 44 Victoria, Chapter 20. Under that Act every brewer of beer for sale is required to take out a licence and to make entry of his premises, and we have power to visit the premises at any time. Under Section 26 we are empowered to take samples of any worts, beer, or materials for brewing in the possession of the brewer. That is the material provision as regards this Inquiry, that we have power to take sample at any time of practically anything in the brewery. Then we come to an Act of 1885, which amended the Act of 1830 to a certain extent, and that gives us certain powers over the use of sugar by brewers, and it requires that they shall keep a sugar store, and that they are prohibited from receiving sugar unless accompanied by an invoice from the seller containing the particulars thereof. The Commissioners of Inland Revenue are empowered to require by a notice served upon the brewer that an account of all sugar received shall be kept; and upon the notice being made the brewery is required to deliver to the officer of Inland Revenue all the invoices relating to the sugar subsequently received. Perhaps I had better put off until later saying exactly what we have done under these different clauses. I will for the moment merely go through what our powers are. Under another section of that same Act a brewer of beer for sale is prohibited from adulterating beer or adding any matter or thing thereto, except finings for the purpose of clarification, or other matter or things sanctioned by the Commissioners of Inland Revenue. The only other important provision is that in the Act of 1830 to which reference has been already made, and which enables us to prohibit the use in brewing of any substance or liquor of a noxious or detrimental nature, or which, being a chemical or artificial extract or product, may affect prejudicially the interest of the Revenue. That is a short statement, I think, of the powers that might be useful in connection with this Inquiry.

6547. The sampling and examination of materials in works is permitted?—Yes.

Object of  
sampling by  
Excise  
Officers.

6548. Is it practised as a rule or only in cases of appeal?—That is practised regularly. I think I may say there are two main objects; one is to check the brewing value of materials, especially of any new materials. Supposing any new material is introduced as a material for brewing, we should have to estimate its value for brewing purposes, and assign it a value relatively to malt—malt on one side or sugar on the other.

6549. (Mr. Cosmo Bonser.) As regards its product?—Yes.

6550. (Chairman.) That is done regularly in every brewery?—That would not be done merely for the purpose of checking brewing materials but only when there was some special reason. That perhaps would come under the second object for which we take samples of materials and wort, viz., to check the returns of the brewers and of our own officers of the results of the brewing. Where there is any suspicion as to the correctness of such returns samples of materials and wort would be specially taken. For instance, if we found that the produce of a brewery was habitually less or more than what would have been expected from the materials entered, because I may mention that the brewer before he begins to brew has to enter the whole of the materials that he proposes to use in that brewing—although we do not charge on that we use that as a means of testing the correctness of the results of the brewing on which we do make the charge—if it were found that the results of brewings were suspiciously large or suspiciously small, then we should take special samples. Otherwise we merely follow a prescribed course. Our officers are told to take samples at certain stated intervals, not regularly, but from time to time, and to send them up to the laboratory for testing. There is another occasion upon which samples must be taken of the wort, and that is, if before our officer has taken an account of the wort the fermentation has begun, then a sample is taken in order to determine what the original gravity was, because the gravity would have changed owing to fermentation having begun. Speaking quite generally, the principal object I should say of taking samples is

to check the returns made by the brewers and by our own officers upon which the duty is assessed.

6551. And that is done practically from day to day, even when no question arises?—Yes, that is being constantly done.

6552. With regard to the receipt and storage of sugar, by sugar is meant what?—Sugar and all its equivalents, legally everything that is not malt and corn is sugar.

6553. Cane sugar, if it was in the brewery, would be included?—Yes.

6554. Glucose would be included?—Yes.

6555. And inverts?—Yes. Under Section 7 of the Act of 1835 we have very considerable powers, but as a matter of fact we have not found it necessary to enforce them in all respects. We practically content ourselves as regards sugar with requiring that brewers should keep any sugar that they have in sugar store. It is not to be in any other part of the brewery. There have been one or two occasions upon which we have served the notice upon the brewer to deliver his invoices, but none of recent years, and I think only two or three times since the Act was passed. It is only where we have not been satisfied with the condition of things, and where there has been some suspicion that a brewer has been using sugar improperly. As regards adulteration or additions to beer, I may perhaps point out that that refers to finished beer. In the manufacture of the beer the law practically permits the use of any material capable of being used in brewing. All that we have to do is to value the material relatively to malt or sugar. The Act was passed in 1885, I believe, because it was found that we required greater powers in order to prevent the addition of sugar or sugar solutions to beer after it was finished.

6556. That is what is called priming?—Yes, in order to regulate that. Our policy has been not to object to additions that do not affect the gravity of the beer, or the apparent gravity of the beer. Provided the substances that have been submitted to us do not appear to alter the gravity of the beer after it is finished, or to alter the apparent gravity of the beer, we should not object to them provided they were wholesome. If there was anything submitted to us that was obviously unwholesome we should object to that, but in no instance has any substance been submitted to us for addition to beer that we had to object to on the ground of its being unwholesome. Additions are made for three purposes. First, for fining or clarifying the beer, for that isinglass or some other similar substance is commonly used. Then there is the priming, which is intended to give a certain life and briskness to the beer before it goes out. Mainly sugar solution is used for that, if not entirely. We have had one or two instances of things in the way of frothing powders to give a head to beer, but most of those have been refused. I believe Bradley's powder is allowed, otherwise we have refused several.

6557. Refused on what ground?—For instance, last year we had a case before us of some stuff called stoutine. That was intended to give a head to beer, but in the advertisement it also claimed that it practically enabled the brewer to diminish his gravity by four degrees.

6558. What does that mean in relation to alcoholic strength?—That would not necessarily affect the alcoholic strength, but it would affect the amount of duty chargeable.

6559. The duty is charged according to the gravity?—The original gravity of the worts before fermentation.

6560. Is there any taking of specific gravity of the finished beer?—No, unless in the case of any suspicion that the gravity has been increased. Supposing sugar were added after we had taken the gravity, and the dip of wort, then we might test the finished beer, but in the ordinary course of things we merely test the original gravity of the wort before fermentation, and assess the duty on that, and do not again test the beer.

6561. Adding sugar as priming would add to the Duty specific gravity of the finished beer?—Yes, to a small changed degree, and of course duty is charged upon so much priming sugar as they put into the priming.

6562. Duty is charged on the priming?—Yes.

6563. Is the charge on the same principle as if the priming ultimately became fermented?—It is charged on the same principle as if it had been put into the original wort.

Sir H. W.  
Primrose.

System of  
sampling.

6564. So that priming is charged as a fermentable material?—Yes.

6565. And it does add to the alcoholic strength after the beer has been kept for a little time?—I suppose it would very slightly.

6566. It gives some degree of briskness to the beer, and in so doing must add to the alcohol?—Yes.

6567. (*Professor Thorpe.*) That is indicated by a term frequently used here, "the after-fermentation." There is always an after-fermentation, and that of course acts upon the added sugar?—Yes.

6568. (*Chairman.*) Would you kindly give us the titles and dates of the Acts?—The Act of 1830 is the Act 43 and 44 Victoria, Chapter 20; 48 and 49 is 1885; 51 and 52 is 1888. Just to finish on that point of the additions to beer, there is one other object in the additions, and that is what they call preservatives. Certain things have been sanctioned for that purpose, such as bisulphate of lime, sulphate of lime, salicylic acid, and carbonate of potash. I think that represents practically the whole of them.

6569. I suppose the effect of these substances is to keep the beer from going sour?—Yes.

6570. Is salicylic acid admitted to be useful in that respect?—I believe brewers consider it is so. I am not competent to speak on that, I am not a chemist.

6571. Is that prohibited?—No, it is allowed.

6572. The question of the health of the drinker of the beer in respect of salicylic acid has not appeared?—No.

6573. None of the other substances that you mentioned are considered as adulterations?—No, because they have been allowed by the Commissioners of Inland Revenue.

6574. What is adulteration in the sense in which the word is used in the Act?—I suppose any addition really would be adulteration, but it ceases to be adulteration if the substance added is approved by the Commissioners. That I take to be the state of the law.

6575. We were told by one of the public analysts who gave evidence that he would consider glucose as an adulteration in golden syrup. That does not come under the Inland Revenue, I presume?—No.

6576. The question what was adulteration and what defines adulteration necessarily arises when you meet with the word in the Act?—We should consider the addition of water, for instance, an adulteration. It is dilution, but I think it might fall within the legal meaning of adulteration.

6577. The addition of water to whisky by a publican, is that adulteration of the whisky?—I think that might perhaps be adulteration within the meaning of the section.

6578. And the publican would be liable to be fined for getting money under false pretences?—A publican is prohibited under the Sale of Food and Drugs Act from selling whisky below a certain strength, or any spirit. Whisky 25 per cent. under proof is the minimum at which a publican may sell. He could put water to that extent.

6579. But if he puts in more water he is cheating?—He could be prosecuted under the Sale of Food and Drugs Act.

6580. But not in virtue of the adulteration being deleterious to health?—No, as being a fraud upon the purchaser.

6581. Not letting the buyer have his money's worth?—Yes.

6582. (*Professor Thorpe.*) I think also it is not in that case the Revenue who prosecutes him, but the public authority?—It is. We have never taken action I am told on Revenue ground.

6583. (*Chairman.*) With regard to the prohibition of substances under the Act of 1888, that is for two purposes; (1) to secure the Revenue, and (2) to protect the public against noxious ingredients?—Yes.

6584. Can you suggest any really practical method of utilising that provision of the Act of 1888 so far as public health is concerned? Other authorities must be responsible also, but can you suggest any useful mode of taking advantage of that provision of the Act by the Board of Inland Revenue?—We considered carefully whether in connection with this particular epidemic and this particular incident of the arsenical poisoning of beer we could usefully exercise the powers

that are given us by the Act of 1888, and we came, on the whole, to the conclusion that it would be extremely difficult. In the first place, the substances that have produced the epidemic were not noxious or detrimental in their own nature. It was owing to the accidental introduction into them of a deleterious substance.

6585. But one of the substances was arsenic?—That is so; and, of course, we could prohibit the use of arsenic. But it would be almost absurd to prohibit the use of arsenic. The question is, could we have prohibited the use of glucose or invert sugar containing arsenic? That was the point we considered. As a matter of law we are advised that it would be conceivably possible, but as a matter of practice it seemed to us that it would be very difficult to enforce the prohibition, for the reason that no Excise officers could possibly state whether or not the article was or was not contaminated with arsenic. It would have involved sampling every consignment of invert sugar or glucose that was received at a brewery, sending it up to London to be tested, and then reporting whether it was free or not. To be of practical use it would have been desirable that a brewer should not have been allowed to use it until it had been certified as free, and we came to the conclusion that that section would not really meet this particular case. A suggestion was made which I think is a practical one and might be useful, and in which we could very well assist, that the law should provide that no brewer should receive into his brewery any of the substances without a certificate that they had been submitted to a particular test, the test being one that should be prescribed by a suitable authority, either by the Government Laboratory or other authority, and that then we could aid in seeing that that provision of the law was enforced. Under this power we have in the Act of 1885, we could see the invoices and certificates and occasionally test the samples to see that the certificates were really valid.

6586. But suppose you put the question of deleteriousness to health practically on the same footing as the question of the revenue. Of course, it would be impossible to send samples of every consignment to the London Central Laboratory as you have explained, but that is not done either for the protection of revenue. You do not send samples of every substance to the Government Laboratory in London for the sake of protecting the revenue, but it is only in a case where your inspectors are not satisfied, and think that some of the substances used must be tested?—Yes. A certain number are dealt with at local laboratories, but the majority are sent to London. We deal with some samples at the local chemical stations, but we have not a great many of them, and the majority are sent to London. My point is that if we were testing in matters of health it would mean a far larger number of samples than are necessary for the purpose of revenue. It would never be safe for us to assume that things were going right.

6587. A small proportion of all the material comes to London and is tested for the sake of the revenue?—Yes.

6588. But not hitherto for the protection against deleterious ingredients?—No.

6589. Would there be any real difficulty in ordering that every sample that is sent for test to the Central Laboratory in respect to duty should also be tested in respect to healthiness. That would add somewhat to the work of the laboratory, but it would not be an enormous expense to test specimens that you have already in hand and are testing partially, simply making the test somewhat more comprehensive and including a test against arsenic, which we now know to be a substance that beer is liable to contain?—If it was limited to testing for one particular poison like arsenic I imagine that would not very seriously affect us. But then comes the question, can you limit it to one thing? Nobody suspected the presence of arsenic a year ago, and a year hence something else may be found.

6590. Of course it would be impossible to exact a full chemical analysis of every product, but it would not add greatly to the labour at present incurred to test for a substance we now know to have entered considerably and injuriously into the beer on which the duty is paid?—I am not really qualified to speak on that, and I should suggest that the Commission might perhaps take evidence on that from Dr. Thorpe, the Principal of the Laboratory. He could tell you at once.

6591. We hope to do that and have his advice upon the matter, but in the meantime we may take it you do not see any constitutional or legal difficulty in extend-

purity of  
brewing in-  
gredients  
should  
involve  
penalty.

6656. I suppose some of the samples of beer were found to contain arsenic?—Nearly all of those that were submitted for destruction. There were cases, or certainly one case, in which a considerable quantity of beer was destroyed, and we did not discover any arsenic in it. Their chemist had discovered arsenic, but the Government laboratory did not.

6657. Where arsenic was found in a large quantity, were the local authorities informed?—No; because, as I explained, the examination that we made was in respect to the beers which were condemned by the brewers themselves.

6658. (Professor Thorpe.) They were all beers lodged for rebate in consequence of containing arsenic, or of being brewed from materials which were known to contain arsenic?—Yes.

6659. (Dr. Whittegg.) The enquiry did not proceed beyond samples taken from breweries by reason of being known to contain arsenic, and proposed for destruction and rebate?—Yes.

6660. You mentioned the circular issued by the Local Government Board to the local authorities?—Yes.

6661. That was issued by the Local Government Board on the advice of the Board of Inland Revenue?—No; I should not like to say that.

6662. At all events, it was issued by the Local Government Board?—Yes.

6663. Has the Board of Inland Revenue ever issued any instructions in connection with the arsenic in beer?—No.

6664. You suggested, I think, that the local authorities ought to be primarily responsible for dealing with the sources of danger to public health?—Yes.

6665. You are thinking of the finished beer?—Yes.

6666. And the finished beer in the hands of the retailers?—Yes.

6667. Were you contemplating further powers for the local authorities to deal with the beer before it reaches the retailers?—I see no reason why they should not be allowed to have samples at any stage of manufacture.

6668. Irrespective of locality?—Yes; within their own area. The local authority should have power, if it was thought necessary, to watch over the manufacture of beer, as well as over the distribution of it.

6669. You are aware, of course, that no such power exists now?—I know.

6670. Would you extend that suggestion to the manufacture of beer ingredients?—That is a point I do not feel I am competent to speak about. It is quite conceivable that it might be a desirable thing to do.

6671. You suggested further that the brewer should be required to obtain a certificate of purity of the ingredients, as a measure of protection?—I think that would be a good thing.

6672. What would happen if such a certificate were given inaccurately? What machinery would there be for enforcing the accuracy of such a certificate?—None, as things are now. I am contemplating legislation.

6673. But assuming there was legislation requiring a certificate, and, as you further suggest, a certificate in prescribed terms, have you thought what machinery ought to be brought into operation, assuming an inaccurate certificate to be given?—I assume that penalties would be imposed. We did sketch out the sort of provisions that might be put into the law. No doubt there would have to be heavy penalties attached to the giver of the certificate.

6674. I understood you to say it would not be convenient, at all events to the Board of Inland Revenue, to undertake any extensive duty of analysis of samples, and I think you further told us that the brewer ought not to be compelled to make analysis. The local authorities, as the matter stands at present, would not be on the brewers' premises, and some sort of provision would seem to be necessary for action in case of the certificate being wrong?—No doubt. What might be done, and I think perhaps would not be a bad thing to do, would be at the same time to give powers of inspection of the manufactories where these glucoses and so on are made. There are not a great many of them. They would be the people who give the certificate, and therefore it might be well to place them under some sort of observation, giving power to enter their premises.

6675. If the local authorities had power to enter on the brewers' premises, would they not have the great

advantage which at present the Board of Inland Revenue officers have, and the local authority's officers have not, of testing from a large bulk?—Yes.

6676. If samples are taken from the brewery, is there not the great advantage that the samples can be taken from a large bulk?—Yes.

6677. As matters stand, and without the local authority having power of entry to the brewery, or manufactory, are we not placed at a great disadvantage, first by not being able to test in bulk, and secondly, in the case of beer, by the very large bulk of the individual sample they have to take from the retailer?—No doubt that would be so.

6678. You said it would be a very difficult task for the Board of Inland Revenue to undertake extensive sampling for the protection of public health, but it would be possible if their duty were limited to one item such as arsenic?—Yes.

6679. Of course the same difficulty of volume of work would apply equally if that were done by the local authorities?—No doubt.

6680. What is attempted under the Sale of Food and Drugs Act is not to cover the whole ground, but to test by infrequent sampling, probably not one in a thousand of any given food substances?—That is so.

6681. So that as matters stand, if it is difficult for the Board of Inland Revenue to contemplate an extensive sampling of ingredients in bulk or food in bulk, it is almost impossible for the local authorities?—I think it would be much less difficult for the local authority. They would only have to deal with the breweries within their own area, and they would not have to deal with such an immense number of samples as we should have.

6682. You mention certain substances as having been approved by the Board of Inland Revenue, and certain others having been observed. I did not quite understand your answer to the Chairman to be final as to the consideration of health in that approval or refusal. Have considerations of health entered into the decision?—Yes, to this extent, that if any of those substances had been thought to be dangerous to health in the quantities that they would be used, we could have refused. That I have no doubt about.

6683. Under the powers of the Act of 1883?—No; rather under the Act of 1885, because these are things that are added. They come under this: "The brewer is prohibited from adding any matter or thing to beer except finings for the purpose of clarification or other matters or things sanctioned by the Commissioners of the Inland Revenue." When they want to add to finished beer something for the purpose of priming or preserving, they have to submit the substances they propose to use to us, to know if we should object. We should object strongly, I think, to anything which could be regarded as undoubtedly dangerous to health.

6684. Then the fact that you do take public health considerations into account in a decision under that head does not depend in any way on the reading of this doubtful point in the 1883 Act?—No; that is quite independent of the 1883 Act.

6685. Has your view of the 1883 Act in that respect always been the same?—Always.

6686. I think you were a member of the Committee on Beer Materials?—I was.

6687. In the report of the Committee there is one paragraph: "Moreover the Treasury are empowered to prohibit the use in the manufacture of beer of any substances or liquor of a noxious or detrimental nature. It is the duty of the chemist employed in the Government laboratory to keep a vigilant watch in this respect over all beer brewed and sold, and they have ample opportunities for so doing; but it has never in practice been found necessary for them to prohibit the use of any material by reason of its detrimental nature, the prohibition of saccharine in 1883 having been due solely to reasons affecting revenue." In that paragraph are we to understand that the "noxious or detrimental" are held to apply mainly to revenue considerations?—I think not. I think the intention was to indicate that if in the course of their examination of material the Board of Inland Revenue had come across things clearly noxious or detrimental in their nature, they had opportunities of observing them, and could have prohibited them. I think it is intended to reassure the public mind as to their not being noxious or detrimental substances used.

H. W. 6688. Although an examination has been made, none have ever been found?—Yes.

6689. I see Mr. Bannister, in his report to that Committee, says:—"The samples of beer and wort that came to us were not examined except for the original gravity. The samples of beer and wort that came up to us are divided into two classes, some for the determination of original gravity just for the purpose of checking brewers' returns, but others are actually examined for the purpose of seeing whether they contain any deleterious ingredient. That work is constantly going on." That would apply, then, to the wholesomeness and absence of poisonous ingredients?—Yes. I do not understand in our laboratory that we have made exhaustive analyses with the view of looking for such a thing as arsenic, for instance. I am not a chemist myself, but I understand in analysing you do not find a thing unless you look for it, and I do not believe the laboratory has assiduously looked for such elements as arsenic. But if there had been anything very serious there would be an opportunity to find it. I think that is all Mr. Bannister meant.

6690. Having found that arsenic was present in beer, and in the glucose from which some of that beer was made, the difficulty that the Board of Inland Revenue felt was that the arsenic was not a substance added as such, but was merely an ingredient of the beer ingredient?—It was a pure accident. In speaking as regards our action last December and January, we know a great deal more about the thing now than we did then. Even then it appeared more or less an accident. We knew it was not distributed over the whole country, but limited to a certain part of the country, and now it appears it was limited to the product of one factory.

6691. (Professor Thorpe.) I think I should like to bring out one or two points which I daresay Sir Henry Primrose would wish to make clear to the Commission. You told us that you thought it was no necessary duty of the Excise authorities, because they took a tax off what was a food or drink, that they should necessarily be responsible for its quality or purity?—That is my view.

6692. There is no logical necessity imposed upon it by virtue of that accident?—No.

6693. It is a fact, is it not, that the Excise takes a revenue off a number of proprietary articles, as they are called?—Yes; patent medicines.

6694. But it undertakes no responsibility as to the character of those things?—Certainly not.

6695. The Revenue authorities, speaking generally, do handle, for fiscal purposes, considerable quantities of food, the Customs for example?—Yes.

6696. They take duty off such things as dried fruits, chocolate, liqueurs, wines, but in levying the duty on those things they are not in any way answerable, nor do they take any responsibility for their quality?—That is so.

6697. (Dr. Whitelegge.) Nor, I presume, is there any paragraph like this we have been discussing in the 1888 Act, applicable to patent medicines or other substances?—The 1888 Act would apply to the patent medicines. It does not specially mention beer. What it really says is, "on any article liable to a duty of

Excise," therefore it would include the patent medicines.

6698. (Professor Thorpe.) But with respect to the intention of the 1888 Act, the difficulty we had in considering the application of it, I believe, must be that the substance which was to be prohibited was in its very essence and in its very nature detrimental—that it was not accidental detrimental contamination, but it was like cocculus indicus, or grains of paradise, or quassia, that is things which were of their essence and nature detrimental?—That is the view which has always been acted upon, and held at Somerset House.

6699. With respect to the question which Mr. Cosmo Benson put to you, as to the willingness of the Excise authorities to consider favourably an application for the return from the publican of the spoilt beer or from the traders, there is in the Customs procedure a somewhat analogous case as regards tobacco which is not marketable—offal tobacco, for example?—Yes.

6700. There the Customs will receive and repay the duty on that on the ground that it is not of any commercial importance?—Yes.

6701. And this idea that possibly the Excise might do something similar in the case of unusable beer?—Yes, that is a very parallel case.

6702. In the answer you gave to Dr. Whitelegge respecting the action which we might take in superintending, or even that the local authorities might take in superintending, the output of the glucose and invert works, there would be a difficulty, would there not, that a considerable quantity of similar material is imported?—Yes.

6703. Therefore the character of that material could only be guaranteed on the certificate?—That is so.

6704. In the case of imported glucose, the local authority or the Excise would have no means whatever of controlling the manufacture of these things?—No, that would have to be done on the certificate.

6705. It would rather lead to complications to have two methods of supervising the genuineness or character of the same product?—Yes; I think it would.

6706. (Sir William Hart Dyke.) With regard to administration, may we gather that with regard to guaranteeing the public against a catastrophe such as lately happened, you could easily collect certificates of purity, if such were demanded? It would not bring any extra stress of work on your department to do that?—No, I think it would be quite simple.

6707. But if we endeavoured to press you further, and if the guarantee of purity by test is to be demanded of each ingredient entering the brewery, to place this on your Department would be beyond the scope of your duties, and cause a dislocation of the work of your Department?—That is my view.

6708. And, therefore, whether Parliamentary action be thought necessary or not, in any case you think the onus of protecting the public in future should be thrown on the Local Government Board?—I think that would be consistent. They are already responsible for non-exciseable food and drinks, and I do not see why there should be any great difference made as regards the exciseable.

52 accurately determined.

Dr. J. C.  
Brown.

Dr. J. C.  
Brown,  
3 May 1901.

Add to these:—

- 16 additional samples approximately estimated to contain between one-half grain and one grain per gallon.
- 23 additional samples approximately estimated to contain between one-fifth to one-half grain per gallon.
- 23 additional samples approximately estimated to contain between one-tenth to one-fifth grain per gallon.
- 26 additional samples approximately estimated to contain between one-twentieth to one-tenth grain per gallon.
- 21 distinct traces, but under one-twentieth grain per gallon.
- 116 detectable but negligible traces.
- 593 none detectable in half-a-pint.

Total 890 samples of beer.

The larger quantities were all before 6th December.)

During February 1901, a total of 133 additional samples of beer were analysed:—

- 7 contained about one-tenth grain per gallon, or more than one-twentieth grain per gallon.
- 14 contained very distinct traces of arsenic.

[All the above 21 samples were from the County area.]

- 112 contained such very minute traces that they were considered genuine. Of these genuine samples

68 were from County area.

34 " " City of Liverpool.

10 " " small Boroughs.

Dr. J. C.  
Brown,  
3 May 19

#### Malt.

Forty-eight samples of malt from private sources in malt, have been analysed during three months. All except six contained arsenic in quantities varying from a minute trace up to a quarter of a grain per lb.

The six samples of malt free from arsenic had all been brushed after they came from the kiln.

Six additional samples of malt have been analysed in March. These show a great improvement. The largest quantity is .04, or 1.25th grain per lb., and two contain only the minutest trace—practically nothing.

#### Yeast.

Nineteen samples of yeast were analysed, all of which (except one) contained a distinct trace of arsenic in yeast, The quantity in each was too small to be determined, but the average quantity in the 18 samples was found to be .015, or 1.67th grain per lb. They included British and foreign pressed yeast and balm from a brewery.

Latterly 14 additional samples of yeast have been analysed, all of which except two contained similar quantities of arsenic.

#### Sulphuric Acid.

I have analysed six samples of brown oil of vitriol in Nichol obtained from Messrs. Bostocks. sulphuric acid.

The first is most instructive, received on 27th November, 1900. When received it was clear and brown, but it was supersaturated with arsenic. It contained 2.6 per cent. of arsenious oxide. On standing in a cool place for some weeks, with occasional disturbance, it gradually deposited crystals on the sides and bottom of the bottle, and when the clear decanted acid was analysed on the 17th January, 1901, it contained only 1.12 per cent. arsenious oxide, the rest having been deposited in the form of prisms, presumably rhombic. When these crystals were placed under the microscope, moist with oil of vitriol as they were, and a drop of water was added to dilute the oil of vitriol, the crystals cleaved into octohedra with flat sides, while some dissolved in the hot acid. On leaving the crystals in the liquid they gradually grew, especially on the flat sides, and in two hours they were large and perfect octohedra.

Photographs show the three stages, though much less perfectly than they were seen under the microscope.

Other samples analysed in 1901 contained:—

- 1.92 per cent. of arsenic, including crystals deposited.
  - 2.36 per cent. " " " "
  - 2.24 per cent. " " " "
  - 2.5 per cent. " " " "
- per cent., of which 1.9 was in the clear acid and deposited.

The arsenic in each case was purified and weighed precisely, and the quantity of arsenious sulphide weighed from 11.32 grammes of acid has been dissolved and reprecipitated and preserved in a bottle for exhibition.

All selenium was removed, as well as other impurities, before weighing the arsenic. Selenium Nicholson acid.

Every sample of acid contained selenium, but only in very small quantities. The average was probably about .006 per cent.

One sample contained a quantity which when weighed was .0046 per cent., another .0044 per cent., and others smaller quantities.

If the selenium was present as selenious acid about 22lb. selenium or 40lb. selenious acid must have been delivered to Bostock's from 1st April to the end of October.

Selenium occurs in vitriol chambers chiefly as element reduced by the sulphurous acid of the flues, and Glover towers. The small quantity dissolved in the vitriol is probably selenious acid, and it is removed by the same process which removes arsenic industrially.

J. C. Beer made from partly-cleaned malt contained 1-30th grain arsenic per gallon.

6710. You have also some general observations on arsenic in beer?—The City of Liverpool was completely cleared of beer made from Bostock's sugar before 18th December, and in the County of Lancaster only a few samples here and there were found after that date. But still arsenic did not disappear from the beer sold even by perfectly reliable houses, whose beer was made from no other materials than malt and hops. It became necessary to trace the source of these smaller quantities of arsenic. The barrels, vats, pipes, and other plant of the breweries had been cleaned, and were found to be quite free from arsenic. Hops and finings and other incidental materials were found to be free from arsenic. Yeast was found to be always very slightly arsenical. In some instances yeast was obtained specially from a very large brewer in the Midlands brewing solely from malt and hops, and still the beer made with it was arsenical. A sample of that yeast was found to be as highly arsenical as Liverpool yeast which had been in contact with some of Bostock's sugar. Beer from the brewery before being fined, and before the last proportion of hops was added, was found to be more arsenical than the finished beer. This is, usually the case when the quantity of arsenic is small, but yeast and hops do not appreciably purify more highly arsenical beer. Very large quantities of arsenic break down the yeast cells. In slight cases the yeast and the hop residues from which the beer was drained off were found to contain some arsenic, even when the finished clarified beer, as sold, contained practically none. Hops were found to be free from arsenic, the exceedingly minute trace suspected in one case being too small to be identified. The arsenic was in all cases investigated clearly traced to the malt. The malt used was found to contain more arsenic than the finished beer made from it. A sample of beer made from good malt which had been dried with the best fuel was found to contain as much as 1-12th grain of arsenic per gallon before racking. This whole brew was destroyed. Another sample was made from very similar malt, but not analysed until it was ready for sale, and it contained only 1-70th grain per gallon.

Origin of Arsenic in Malt.—Barley for malting was obtained from the ship and from the quay, and from the storehouse before malting, and was found to be free. Malt from Scotch barley, English, Asia Minor, North and South America, and other places always contained arsenic. This arsenic was traced to the fuel.

The quantity of arsenic in malt from good fuel was usually 1-15th grain per lb.

The best quality of malt was dried with the best fuel, as follows:—

Anthracite which contained only	·0075	arsenic per cent.
Coke which contained only	·0035	" "
and	·0025	" "

But this was a very exceptional quality of oven coke, limited in quantity, and it is probable that not very much malt is prepared with such pure fuel as this. Some of the malt dried with this fuel was found to contain ·084, or 1-12th grain of arsenic per lb. The same malt after cleaning (brushing and screening) contained only ·0126, or 1-80th grain per lb.

Other samples were found to contain less arsenic after screening than before, but not so small a quantity as should be; after a single brushing they contained only a distinct trace, while after three brushings the arsenic was almost a vanishing quantity, although arsenic could still be identified from 1lb. of malt.

Malt Dust.—All the samples of dust from the malt screens contained a quantity of arsenic.

Washings of Malt.—Malt, when washed, yielded at once practically all its arsenic to the washing water. The method is not available, however, for cleaning.

Recent Improvements in some Malts.—In the present year, after malsters had been warned to brush their malt, figures which were obtained from malt as sold were:—

·056, or 1-18th grain per lb., and  
·045, equal to 1-22nd grain per lb.

After brushing this was greatly reduced; after triple brushing the quantity could not be estimated. It is probable that most of the beer against which prosecutions have been instituted in the County area since the middle of January have been cases of beer contaminated by malt.

Dr. J. C. Brown,  
3 May 1901.

Instances of Particularly Arsenical Malt.—The following figures have been obtained by precise determination in the case of malt dried with inferior fuel:—

1 sample of malt gave 1-9th grain arsenic per lb.

1	"	"	"	1-7th	"	"	"
1	"	"	"	1-6th	"	"	"
1	"	"	"	1-6th	"	"	"
1	contained as much as	1-4th	"	"	"	"	"

Beer which we are credibly informed was made from some of the above arsenical malts contained 1-5th grain of arsenic per gallon, a serious quantity. I understand the beer was destroyed.

Screening without brushing is not sufficient to remove all the arsenic, because it adheres to the skin of the malt.

But more perfect brushing would undoubtedly remove all but a negligible quantity.

After one brushing some of the above malts came down to 1-25th grain per lb.

6711. (Professor Thorpe.) You have had the opportunity of analysing a considerable number of samples of brown oil of vitriol which you obtained from Messrs. Bostock and which you have reason to suppose were of Messrs. Nicholson's manufacture?—I do not know or whose manufacture except from the evidence that was given at the inquests. At the inquests I heard it given in evidence that it was of Nicholson's manufacture, but that all came from Bostock's.

6712. How did you obtain them?—Generally the medical officer of health sent one of his subordinates for them to Messrs. Bostock; one was given to me by Messrs. Bostock themselves.

6713. By what authority did the medical officer of health get into Messrs. Bostock's factory and take the samples?—By Dr. Hope's authority.

6714. Is there any statutory power vested in Dr. Hope?—No, he had no power to go if they had refused to admit him. But they did not; they were perfectly willing to give any facility.

6715. It was simply an act of grace on their part that you got samples through Dr. Hope?—Entirely, except in one instance, and in one instance it was by the permission of the official liquidator. That was the last sample I got.

6716. You give the details of the analysis of the oil of vitriol that you made; speaking generally they were practically saturated solutions of arsenious acid in oil of vitriol?—They were all super-saturated solutions. There was more arsenic than the sulphuric acid could hold permanently. When the arsenic was first dissolved it was in warm acid, which can hold a larger quantity, but some time after I got it, almost immediately after, it began to deposit solid arsenious oxide on the sides and bottom of the bottle, and that process of approaching to equilibrium went on for many months. I do not think all the arsenic that should come out in solid is out yet. It is gradually being produced. Here is a portion of the acid. (Sample put in.) When that stands a little the acid will be clear and brown. That was quite clear when I got it.

6717-8. (Chairman.) Was the brown oil of vitriol supposed to be intended for use in making glucose?—It was actually used for making glucose.

6719. I thought they always had it clear?—It is not necessary to be clear. There is no harm in it being brown provided there is no arsenic in it. There may be arsenic in it while it is clear, and there may be no arsenic although it is brown.

6720. But it is much less guaranteeable being pure if it is brown than if it is clear as water?—I think no more nor less guarantee whatever.

6721. There is more guarantee if it is clear than if it is brown?—I think not.

6722. We were told by one witness that sulphuric acid ought to be clear as it was a great addition to the guarantee against impurities?—There is a fallacy in that which I will point out. What he no doubt meant was that if the acid has been purified by various processes so as to take out the arsenic, then it will be

Super-saturated with arsenic.

Colour of acid no relation to arsenic.

Dr. J. C.  
Brown.  
3 May 1901

clearer, and that is true; but it may be made clear without any arsenic being removed, so that the mere clearness is no guarantee whatever.

6723. And the brown colouring matter of the brown oil of vitriol may be quite innocuous?—Certainly. Brown oil of vitriol of the old kind made from Sicilian sulphur contains practically no arsenic.

6724. And what is the material that gives it the brown colour?—Traces of organic matter; dust from the air, coal smoke in the process of burning, straw—anything.

6725. (Professor Thorpe.) A very small quantity of organic matter will serve to tinge the oil of vitriol and make it very brown?—Very small indeed, a minute particle of sugar will tinge a whole Winchester of acid.

6726. Does your knowledge of sulphuric acid manufacture enable you to give the Commission any information as to the probable origin of this sulphuric acid?—Yes.

6727. From what particular part of the manufacture has the sulphuric acid been probably derived?—I have not the slightest doubt that it was Glover tower acid.

6728. Why do you say you have no doubt it was Glover tower acid?—Because I do not know anywhere else it could get such a quantity of arsenious acid in it.

6729. (Chairman.) What are we to understand is the substance which makes this as thick as mud and with a large deposit?—Crystals of arsenious oxide.

6730. This has come from the acid by simply leaving it to itself?—Yes, and it has deposited some of the arsenic which there was in excess of what it could retain permanently.

6731. Did Bostock's people use that?—They used it before the crystals appeared, I expect.

6732. It takes some time after it cools before the crystals appear?—Yes. Arsenic is a very slow substance chemically and physically, and evidently it does not come out of super-saturated solution for a very long time indeed, because the first sample that I received had been in the works for certainly a fortnight, probably much more, and I did not observe any crystals until some time after.

6733. Several weeks?—It begun to deposit perhaps within a week, but it had not completed the deposition two months afterwards.

6734. (Professor Thorpe.) Would not that circumstance rather indicate that the arsenious oxide was in some chemical combination with the sulphuric acid?—There is a compound known of  $\text{SO}_3$  with arsenious oxide, and I believe this is not that, although I have not absolutely proved it. My evidence, so far as it goes, is two-fold. First I tried to get away as much as I could of the adhering sulphuric acid from the crystals without using water or altering in any way the composition, and then there was very little sulphuric acid remaining to be got on analysis, not enough to account for the compound  $\text{SO}_3 \cdot \text{As}_2\text{O}_3$ . The second piece of evidence is this. Here is a photograph of the original crystals which are prisms in the best sample I have been able to obtain. You may not be able to repeat that on the crystals I have handed in, but this is one sample which was particularly fortunate. On treating the microscopic slide, of which that is a photograph, with very little water, allowing it to pass below the cover, on the slide, as the water reached the acid crystals and diluted the acid—of course, a little heat was developed—a part of the arsenic dissolved, but the majority of the crystals underwent cleavage into imperfect octohedral crystals. Here is another photograph showing that stage. (Photograph put in.) It is not so good as it is in the microscope, because they are a little shaken, but you will see there the remains of some prisms that have cleaved into octohedra with flattened sides. Leaving that under the microscope and watching it, the imperfect octohedra began to grow, and they grow particularly on the flattened sides, so that in the course of an hour or two they are larger and perfect octohedral crystals. Here is a photograph of a more advanced stage, showing the perfect octohedra. (Photograph shown.)

6735. (Professor Thorpe.) That fact throws no light upon the nature of the arsenic in the solution?—No, except by inference.

6736. What you are illustrating is the well-known fact that arsenious oxide is dimorphic?—Yes, but I was using that as evidence that the crystals that come out

are not the compound, but the arsenious oxide crystals in the labile form.

6737. In addition to arsenic you also found that the sulphuric acid you examined contained minute quantities of selenium?—Yes.

6738. And the amount you set down on the average is about '005 per cent.?—Yes.

6739. How did you estimate that amount?—I boiled the sulphuric acid with hydrochloric acid in order to convert any conceivable selenic acid into selenious acid, and I then passed sulphurous acid gas, and got a precipitate of elementary selenium, which I collected. I think I treated it with a little ammonium carbonate, and ultimately, when pure and dried, I weighed it.

6740. You have no doubt in your own mind of the identity of what you weighed as selenium?—None whatever. I proved that it was selenium.

6741. How did you prove it was selenium?—On other portions, not the portion I actually weighed, I converted into selenic acid, reduced it to selenious acid, then I converted into selenium sulphide, in some cases purifying that by ammonium carbonate and by sulphide of carbon.

6742. Did you find selenium also in the sulphuric acid which had been used?—Yes, but not in the elementary state. I also performed a colour test, which is not perhaps of much value, but I did perform the colour test with codeine.

6743. In this particular case?—On some of it.

6744. But you do not attach any importance to that?—I do not.

6745. You are aware, of course, that a large number of substances will give precisely the same colour?—Yes.

6746. Even arsenic acid itself?—But having heard of this being used, I used it for what it is worth.

6747. Do you think it is of no value?—I do not think it is of any value, but I have no doubt about the selenium.

6748. Did you make any search for selenium in the sugars?—Yes.

6749. Did you find it?—It was not a very perfect search: it was an afterthought; I did not find any.

6750. You did not find it in any of the sugars?—I do not think I found selenium in any sugar. I certainly failed to find it in any beer. I also added a small quantity of selenious acid to sugar and to beer, and afterwards analysed it, and I found that.

6751. What was the amount that you did add?—'01 grain selenium added as selenious acid per pound, equal to '00014 per cent.

6752. Do you wish the Commission to believe then that had selenium been present to the extent you indicate, you would have been able to find it in the sugar you examined?—I think I should. I do not wish to be too positive about that because, as I said, my examination for selenium was not a crucial one. I did not work it out so perfectly as I should have done had I tackled it earlier. For instance, I am not prepared to go into a witness box and declare upon oath that there is never any selenium in the sugar.

6753. The sugars that you did actually examine, apart from the synthetic experiment you made, were those Bostock's sugars?—In all cases.

6754. But did they contain arsenic?—Large quantities of arsenic. The figures of the quantities of arsenic in those Bostock's sugars I have handed in, and I feel quite convinced that there was not so much as '01 grain of selenium per pound.

6755. Selenious acid or selenium?—Selenium in any form calculated as elementary selenium.

6756. Have you anything to tell the Commission beyond what is here in your précis, which you hand in, as to the modes in which arsenic finds its way into beer?—There are two sources, the arsenical glucose and the arsenical malt. I have nothing to add to that.

6757. Now we come to the method of testing. You state at some length your modes of testing, both qualitatively and quantitatively, for arsenic. Perhaps you would explain in detail to the Commission what you have to say on that point?—It is a rule in my laboratory that any analyses of a substance in such a condition that it may come into court, shall be analysed by two different hands, generally one under my super-

vision, or Mr. Williams, my chief assistant and colleague's supervision, and one by another skilled chemist, working quite independently, and further, if possible, by two different methods, so that not only do we have two independent analyses, but the check that two different methods afford to prevent the possibility of an error slipping through. In the case of the arsenic in the beer, those two methods were, first a purely qualitative test which gives, carefully performed, a pretty good general idea of quantity within certain wide limits. The qualitative test is to take a small quantity, not 200 or 250 cubic centimetres, but 30 cubic centimetres, or 50 cubic centimetres, in a small flask; add 10 per cent of its bulk of pure hydrochloric acid, which has been tested and found absolutely free from arsenic, and add a piece of thin electrolytic copper foil about 5-16ths of an inch square; boil vigorously on a sand bath for half an hour; pour off the beer, and note the appearance of the copper. If it is not thickly coated, return the beer to the flask and boil for another half an hour, and again pour off and examine the copper. If the copper is now thoroughly coated it is removed, washed and dried, but if there is only a slight coating, a slight tarnish, it is returned to the flask and the boiling continued with the beer for another hour, that is two hours altogether, then removed, washed and dried. If the copper has been removed before the whole of the arsenic has been deposited, which often happens, a second piece of copper is added and boiled for an hour, or whatever time may be necessary, until you are satisfied that all the arsenic obtainable in that way has been removed upon the copper. The reason for not continuing with the same copper is that when the deposit becomes thick it is apt to scale off either in the flask or later, when it has been transferred to a tube. The dry copper is then rolled into a cylindrical form and introduced into a clean dry tube of hard glass, 3-32nds of an inch diameter internally, or about that, about 2½ inches long, previously warmed in a flame. The end of the tube containing the copper roll is very cautiously heated, holding it first about an inch above one of the flames of a Bunsen rose burner, turned very low, and when the arsenic has left the copper, it is driven slightly up the tube to a clean part by holding the tube rather nearer the flame. During the sublimation the tube is held nearly horizontally. That is an ordinary method of examination, and it is only made very precise for the purpose of getting an approximation to a rough quantitative idea.

6758. In other words it is the Reinsch method, of which you have given us so full details of the way you carry it out?—Precisely.

6759. Having in this way got some rough idea of the quantity, how do you proceed to more accurately estimate the quantity?—I then take another portion, much larger, a litre or a litre and a half, or 2 litres if possible of the beer, and analyse it by Fresenius's well-known method, with a slight deviation, for an object that I will mention. It is evaporated first in a large porcelain dish on a sand bath to about 250 cubic centimetres. The dish is then transferred to a boiling water bath, 75 c.c. of pure concentrated hydrochloric acid added, and then 2 grams at a time of potassium chlorate, with constant stirring until a thin yellow liquid is formed, and then a further 2 grams of potassium chlorate is added, and it is allowed to cool. When it is cool it is filtered, washed and evaporated, so as to get off the whole of the chlorine or chlorine compound that is evolved. Again it is allowed to cool, and saturated with sulphur dioxide to reduce the arsenic to the arsenious acid. The sulphur dioxide is evaporated off, and then the hot solution is treated with sulphuretted hydrogen, heated in a water bath ultimately to nearly expel the sulphuretted hydrogen. It may be necessary to continue passing the sulphuretted hydrogen gas for hours, or it may be all finished generally in an hour. In this case an hour is enough, I think. Then the precipitate is filtered and washed to free it from chloride, which is very important; and it is digested at this stage with a hot mixture of 2 volumes of 5 per cent. solution of ammonium carbonate with 1 volume of 10 per cent. solution of ammonium hydrate, the liquid being poured repeatedly through the filter. This is for the purpose of dissolving at this stage the arsenious sulphide, and getting rid at once of any antimony or lead, or metals of that kind that might be present as impurities. The usual way is to leave that till later. I find it better to get that done at this stage. Then the solution is evaporated to dryness, the residue moistened with fuming nitric acid free

from chlorine; the solution is evaporated to dryness, and the yellow residue moistened with concentrated sulphuric acid and heated in a water bath for an hour. To the thick black solution thus formed a few small pieces of Swedish filter paper are added to render the mass pasty—this is taken from Fresenius—transferred to an air bath, and heated to 160° centigrade, taking great care that the heat never exceeds 170°, until the mass is friable and yields a colourless solution. That is a process of charring, which effectually reduces arsenic acid to arsenious acid. The residue is then extracted with hydrochloric acid dilute. The residue is filtered and washed with water containing hydrochloric acid, and then precipitated in hot solution with the sulphuretted hydrogen again. It is warmed in a water bath to expel the excess of sulphuretted hydrogen. The precipitate is washed, dried and digested on the filter paper with bi-sulphide of carbon in a small beaker, that is to remove sulphur that may be present as sulphur, and then is dried and digested with about 15 cubic centimetres of a hot mixture of ammonium carbonate and ammonium hydrate as before. This solution is filtered and evaporated to dryness in an accurately weighed porcelain dish or capsule, carefully dried at fully 100° until the weight is constant. The precipitate is now probably pure arsenious sulphide. If it is not, it is re-dissolved and the whole purified again, and re-precipitated. In good hands that is seldom necessary. If it is necessary I find generally that the weighing after and the weighing before the second purification gives exactly the same figure.

6760. Would you kindly explain why you think it necessary in the case of beer to make use of the same drastic method of breaking up the organic matter, that you would do in an ordinary toxicological enquiry. In the first place, perhaps you might tell the Commission how far you think there is any direct evidence of the formation of any combination of organic matter in beer?—Those are two quite different questions.

6761. Perhaps it would be better to begin with the direct evidence as to the possible occurrence of any organic combination of arsenic in beer?—There is a little ambiguity in the phrase "organic combination." I will divide that into two parts if you will allow me. In December last I thought it was quite a possible thing that there might be some compound of arsenic other than arsenious oxide. Medical men were expressing considerable doubts whether the poisoning that took place was due to arsenious acid, and whether there might not be a more poisonous compound not known. I therefore took a large quantity of a certain barrel of implicated beer and distilled it, once into an acid dish, and once into an alkaline flask, and examined both of these for arsenic, but I found nothing, and I am satisfied that there is no very volatile compound of arsenic present in beer. There is no cacodyle or homologue of cacodyle. Moreover, the odour of beer would be offensive if these were present, and I am quite sure that they are not. Also, I did not feel the necessity that medical men felt for supposing that there was some extra poisonous body, because I account for all they feel difficulty about in another way. First, the large quantity of liquid very easily absorbed brings the arsenic quickly into the circulation, and it all acts or gets an opportunity of acting, whereas where they administer arsenic in the ordinary way, or particularly when arsenic is administered as a poison, a portion of that, and sometimes a very considerable portion, never gets into the circulation; it passes out through the faeces in all probability. And secondly, it is perfectly clear to me now that on the whole the quantity of arsenic present in beer has been very generally and very greatly understated, so that the quantities that have been drunk have been much greater than medical men suppose. I think those two things may account for all that they find a difficulty about.

Dr. J. C.  
Brown.  
3 May 1901.

Question  
of combina-  
tion of  
arsenic with  
organic  
matter of  
beer.

Amount  
of arsenic  
in beer  
often under  
stated.

6762. (Chairman.) There was more arsenic than the analysis had shown?—Yes; as a rule, and considerably more than the medical men have been told, or that they have gathered has been present.

6763. (Sir William Hart Dyke.) Do you mean analysed since this epidemic or previous to this epidemic?—Since this epidemic. Before the epidemic they did not suppose there was any arsenic in beer. It was exceedingly difficult to convince them that there was.

6764. (Chairman.) Do you think that probably before the epidemic there has been a deleterious amount of arsenic in many beers?—Undoubtedly.

6765. (Professor Thorpe.) What is your evidence for

Beer  
arsenic  
before the  
epidemic.

Dr. J. C. Brown.  
3 May 1901.] that. You say you are undoubtedly of opinion that there was a considerable quantity of arsenic in beer before the epidemic manifested itself. Is that what I gathered you to say?—Yes, in some beer.

No arsenic  
in brewing  
plant.

6766. What is the evidence you have of that?—That is a somewhat long story. In the course of the examination of the implicated beer several brewers asked various chemists, including myself, to help them to get the arsenic entirely eliminated from their works, and for that purpose they brought samples of the beer before it was finished, at various stages, from the vats, and I found that the arsenic did not disappear so quickly as I thought it ought to disappear after the use of Bostock's sugar was discontinued. We thought that it might be arsenic adhering to the vats and various pipes, and other portions of the plant. That was carefully investigated. I had shavings taken off the vats and every imaginable thing examined, with the result that we found that all the arsenic had been completely cleaned out of the plant; there was nothing left there. Then we tried all the materials, and we found arsenic in yeast.

6767. (Chairman.) In yeast that had been used before the epidemic?—In the yeast that was being used after Bostock's sugar was discontinued.

6768. That was a continuation of the yeast that had been used during the time of Bostock's sugar?—At first it was. Then they discontinued their own yeast, and sent to a brewery in the Midlands for a fresh supply of yeast and brewed from that, and still arsenic was found in the product. I then asked for a specimen of the yeast as it came from the Midland Brewery, which was one that used no sugar of any kind, brewed solely from malt and hops, and I found as much arsenic there as in the yeast that had come from beer that had been in contact with Bostock's sugar. They were no better for getting fresh yeast than by using their own. We pursued the search for the source of the arsenic, and very soon found that the source was malt. Of course, we then stopped the malt and told the medical officer. However, he did not require to take any steps, for the maltsters, who were very concerned about this, came down by the next train with specimens of their barley and their fuel. Of course, we had to forbid the use of the arsenicated malt. The result of the investigation and the efforts of the maltsters was this. I will give you the result of the examination of typically good fuel. Anthracite, which contained only .0075 of arsenious oxide per cent, and coke, which contained only .0035 and .0025 of arsenious oxide per cent, was used with certain samples of malt, and the malt dried with that fuel, which is the very best fuel in England, contained .064 grains of arsenic per pound—1-12th of a grain per pound on the surface of the malt. That was what some of the best beer was being brewed with.

6769. Was that malt which had already been brushed and screened?—No; that had neither been brushed nor screened.

Improvement  
on brushing.

6770. Would it be brushed and screened before being used by the brewer, or might he ignore that?—Not in that case. I will tell you the result of brushing. The same malt, after being brushed and screened, contained only 1-80th of a grain per pound, which was of little consequence; and when it had undergone the process of brushing three times we could hardly detect—we could just detect it—but we could hardly detect the arsenic at all. I should say here that when the malt is crushed up and mashed, and the arsenic extracted from that, you do not get the whole; some of the arsenic so combines with the organic matter that you cannot practically get it out unless you destroy the whole of the malt, which is a very slow and tedious process, and quite unnecessary, because, if the malt is left entire and washed well with water containing a small quantity of alkaline carbonate, the arsenic dissolves quite readily, and we get practically the whole easily in that way, and then estimates of the quantity were obtained in that way.

6771. Would the washing not bring it out from the crushed malt?—Not entirely. From the crushed malt you do not get it all out entirely by the water. Some is lost by adhering to the solid matter of the malt.

6772. (Professor Thorpe.) What you mean to say is this in effect:—that when great care such as you have mentioned is taken in the preparation of malts from fuels which are reasonably free from arsenic, nevertheless arsenic can be found in the malt?—Yes.

6773. And you infer from that, that inasmuch as malt of even worse character as regards arsenication must have been previously used, therefore beer containing

arsenic must have been in vogue prior to the epidemic?—Yes, but I am more precise than that.

6774. What more evidence is there, then, as to the amount?—In the course of examination of other samples of beer that we condemned for containing arsenic concerning which the brewers declared, and with truth, I believe, that the beer was brewed entirely from malt and hops, we asked for samples of the malt, and we obtained the following figures from different samples: 1-9th of a grain of arsenic per pound; 1-7th of a grain of arsenic per pound; 1-6th of a grain of arsenic per pound; another one 1-6th of a grain of arsenic per pound; and one contained as much as 1-4th of a grain of arsenic per pound.

6775. (Sir William Church.) Were those unbrushed malts?—Yes, as they came from the maltsters, and as they were being used by the brewer, and beer which we were credibly informed was made from two of these arsenical malts contained as much as 1-5th of a grain of arsenic per gallon. Of course, that beer was condemned, and it was all destroyed, but if it had not been interfered with that would all have been sold with a guarantee, probably, that it was made from nothing but malt and hops; and if that was occurring several weeks after the scare was made public, of course there is no doubt it was happening several weeks and years before the scare.

6776. (Professor Thorpe.) Do you wish the Commission to believe that beer brewed from malt and hops under normal conditions contains as much as 1-5th of a grain per gallon of arsenious oxide?—Yes, it did sometimes.

6777. Do you think it is a common occurrence with beer?—I should think not; I should think it is a very uncommon occurrence, but if malt is dried with gas coke, as it sometimes is, then I should think it was very likely to occur in such malt unless it were carefully brushed.

6778. Have you reason to believe that evil consequences would result from drinking beer containing as large a quantity as one-fifth of a grain of arsenic?—Medical men say that serious consequences occur from drinking much less.

6779. Is there any evidence of the occurrence of anything approaching in character this epidemic during the last forty or fifty years when that character of beer must have been in vogue?—That is a medical question which I am not qualified to go into, but there is undoubtedly a considerable impression arising in the minds of medical men that some of the symptoms of what they call peripheral neuritis that had been observed before the epidemic may have been due—I only say may—to arsenic in beer, which has come from other sources than sugar.

6780. But this character of beer that you are mentioning is the universal type of beer; it is the beer which has been brewed all over the country?—It is very seldom, I hope, made from malt which has been dried with gas coke.

6781. (Sir William Hart Dyke.) Did you discover what fuel had been applied to this malt?—I was not, malt of course, able to arrive at that. The maltster was naturally very reticent about that; but I have no doubt whatever that it was gas coke; and I may say that he has since then discarded his process. He has also changed his fuel, brushed the malt, and has reduced the quantity to what may perfectly well be neglected. In the present year, after maltsters had been warned to brush their malt, figures were obtained showing 1-18th of a grain of arsenic per lb., 1-22 of a grain of arsenic per lb., 1-80th of a grain of arsenic per lb., and during the last month the quantity is so minute that I sometimes cannot identify it from a pound of malt.

6782. (Professor Thorpe.) Does this finish all that you have to say as to the evidence that there may have been a considerable quantity of arsenical beer in existence prior to the epidemic?—Of slightly arsenical beer.

6783. I do not quite understand why peripheral neuritis, then, under those circumstances should not have been more widespread than it apparently has been?—May I point out first that the quantity of beer containing so much as from 1-10th to 1-5th of a grain has undoubtedly been a very small proportion of the total made; secondly, that a considerable number of maltsters did brush their malt before the epidemic; thirdly, that many brewers brush their malt somewhat after it comes from the maltsters. All those lessen the risk; fourthly, the number of people drink-

Brown.  
May 1901.

ing a very large quantity of beer is quite limited. You have to have a coincidence of five things before you have the probability of neuritis.

6784. I must point out to you that these coincidences are just as likely to happen in Bristol, Plymouth, Southampton, London, or anywhere you like where large quantities of beer are drunk?—Then I would next point out to you that medical men say there has been a considerable prevalence of slight peripheral neuritis in the North of England as compared with the districts round London and Scotland. In places where beer has been drunk in large quantities, three gallons of beer a day, you have had peripheral neuritis, and the question with them is whether that has not arisen from this imperfect malt.

6785. (Chairman.) Are there differences between the northern districts and the districts round London? Are there more cases of excess of beer drinking in the North than in the South?—I do not know that. It is very difficult to find out how much beer a person drinks. He is very unwilling to tell.

6786. Are there differences between the malts in the northern districts and the malts in the southern districts? Do you see any reason for supposing that there were more cases of arsenic in the northern district malts than in the southern district malts?—I have no means of knowing that, because I have had no experience of the southern malts; but I have had some amount of evidence of what has been sold in the North and in the Midlands.

ination  
enic  
organic  
r of

6787. (Professor Thorpe.) To bring you back to the point which we somewhat departed from, you told us how you eliminated in your mind the possibility of the occurrence of cacodyl or anything analogous to cacodyl as a form of organic combination of arsenic. But you said, apart from that, you had reason to believe that the arsenic was in some form of combination with the organic matter, because you had to destroy that combination by the method you have told us. What is your evidence for that?—My supposition does not go further than that the arsenious oxide itself is combined with organic matter, and is held back and prevented from being precipitated much in the same way that iron is held back by organic matter, sugar and so on, from being precipitated by ammonia. It is not necessary to suppose, although it may be true, that the arsenic is combined with organic matter in the same way as iron is combined in ferrocyanide. It is quite enough that the arsenic should be, as arsenic, combined with organic matter in some way that prevents precipitation. I do not know further than that.

6788. That is a surmise?—No; I do not surmise; there is something more than that.

6789. But you surmise to that extent, viz., that there is some agency, which you call organic matter, which keeps the arsenic up and prevents it from being thrown down by the ordinary tests which chemists apply for its discovery?—I do not surmise that. That is a fact which I find by experiment.

uction  
enic  
r of  
neces-  
f all  
ic is  
pre-  
d by  
uretted  
gen.

6790. Perhaps you will explain to us, then, how you find it?—Here is an example of the evidence, four analyses for comparison. First, an arsenical beer that I know all about is taken. One litre of the beer is concentrated, is acidulated, heated and precipitated by sulphuretted hydrogen, the gas being passed until the laboratory is closed for the day. It is allowed to stand all night, and then it is not quite clear in the morning. Then the beer is filtered, and the precipitate is examined. The filtrate is again heated and treated for nearly a day with sulphuretted hydrogen and filtered. The beer filtrate from the arsenic deposit is again treated with sulphuretted hydrogen and the following day that is filtered, and the precipitate examined. The filtrate is so treated for a third and a fourth time, with a precipitate in each case more or less, and each precipitate has the arsenic estimated in it. Finally, the filtrate is oxidised to destroy the organic matter, and the arsenic is estimated by precipitating as sulphide distilling with hydrochloric acid and weighing finally as sulphide. The first precipitate yielded '001 gramme of arsenious sulphide.

6791. When you say the arsenic is volatilised by distilling with hydrochloric acid, do you mean you treat an impure sulphide with hydrochloric acid and distil it?—Yes.

6792. That is all you do?—I treat it as nearly as I can by the Somerset House method.

6793. I should like to know exactly what you do?—For my present purpose it is not necessary to say, I think, how I do it. I get so much arsenic by any reliable way I do not lay stress upon the method there. It is the previous part that I lay the stress upon.

6794. Pardon me, this is very essential. You get an impure sulphide of arsenic which you purify in the manner you described, but not fully described. I should like to know exactly what you do?—I was only trying to save time. I will take the first precipitate.

6795. Cannot you shortly describe what you do with these arsenical precipitates? They are all of the same character?—The precipitate was washed, slightly dried in the water oven for an hour or two; the filter with the precipitate was placed in a distilling flask, and strong hydrochloric acid added with ferric chloride and ferrous sulphate, and was then distilled into water; a further quantity of hydrochloric acid was added and distilled again; and this was repeated until there was no arsenic left.

6796. That is all I wanted. I merely wanted to get certain additional details which you have now given, which you did not give before?—I did not think it was necessary. That was finally obtained as arsenious sulphide and purified, dried, and weighed.

6797. Will you tell us shortly what was the effect—that you did not recover all the arsenic that you knew to be there?—The first precipitation with sulphuretted hydrogen yielded '001; the second yielded '0005; the third yielded no arsenic; the fourth no arsenic; and there was left in the filtrate, and recovered after destroying the organic matter, '0055, making a total of '007 of arsenious sulphide, which corresponds to '39 grain of arsenious oxide per gallon.

6798. What was known to be there?—I am coming to that. In the second experiment a similar course was pursued, except that after the fifth precipitation a good deal more hydrochloric acid was added before passing the sulphuretted hydrogen, and a good deal of the sixth precipitate was obtained. There was a seventh precipitate obtained before the final filtrate was taken for the destruction of organic matter. The result was that the first precipitate yielded '001 as before. It may be a coincidence, but it is a remarkable one. The second one yielded '002, much more than the previous one. The third, fourth, fifth, sixth, and seventh yielded no arsenic, and there remained recoverable after destruction of the organic matter '004, which brings up the total to '007, as in the first experiment.

6799. (Sir William Church.) Were those the same beers?—The same beer.

6800. (Professor Thorpe.) Does that mean that when you pass successively sulphuretted hydrogen and allow the liquid to stand, and filter it, you get the arsenious sulphide down little by little?—No.

6801. Yes, you do. Some of the arsenic remains in solution; but notwithstanding your arsenious sulphide is coming down little by little?—No; it only comes down in the first and second precipitations. It does not come down in the third, fourth, fifth, sixth, and seventh days' passing of gas, and the great bulk of it remains in the final filtrate.

6802. (Chairman.) So that you get four by your final process, whereas the previous process only gave three?—Yes, making a total of seven milligrammes.

6803. That was all you could get out?—Yes, in the second experiment. In the first experiment we got '0055 by the last process, and only '0015 by the other. In the third experiment another litre of the same beer, first destroying the organic matter, gave the whole precipitate at the first passing of the gas in a much shorter time, and it amounted to '007, the same total as before.

6804. In this last case you oxidised the organic matter in the beginning?—Yes, and then you get the whole of it at once. In the fourth experiment pure beer was taken, and '0052 gramme of arsenious oxide added to a litre of the beer. The organic matter was not destroyed; it was acidulated, heated, and the gas passed direct, and the whole of the arsenic was obtained in the first precipitate. That is the sort of evidence I have that the arsenious oxide is compounded to some extent with the organic matter so that it is not precipitated.

6805. (Professor Thorpe.) Is what you wish us to believe that when you add, we will say, arsenious oxide to finished beer, you can by the ordinary well-known methods recover it?—I hesitate to take the word

Dr. J. C.  
Brown.  
May 1901.

Pure beer after addition of arsenic behaves differently to beer brewed with arsenic.

Dr. J. C.  
Brown.

3 May 1901.

"well-known methods." I say they are all well-known methods.

6806. Your method?—The simple method without destruction of organic matter.

6807. You recovered it by your method straight away?—I recovered it by simple precipitation as if the organic matter was not there.

6808. When, however, the arsenic was brewed with the beer you could not recover it?—That is so; not nearly the whole of it. It may have been due to the brewing or to long keeping, or it may have been due to other substances that they add. It may be the sulphite, or it may be any conceivable thing; but as a matter of fact the beer which was brewed and treated in various ways—we do not know how—and that was sold, did not yield more than a fraction, and a varying fraction, of the arsenic known to be there, until the organic matter was destroyed.

6809. You say somewhere or other in your *précis* that the fact, namely, that you cannot recover the arsenic from the beer, has been known to you for 25 years?—I did not say beer. I said organic matter.

6810. I understood you to say that the fact that you could not recover the arsenic from beer has been known to you for 25 years?—I did not intend to say beer, but from the organic matter containing arsenic.

6811. (Chairman.) You distinguish between arsenious acid added to the beer in one experiment and arsenious acid that has somehow or other got into it in the brewing or manufacture?—What I mean by that is exactly this, that the finding of all the arsenic from a mixture which anybody makes with pure beer for comparison is no argument in favour of the idea that you get all the arsenic by the same method from what you call Bostock's beer. The importance of that lies in this, that the various gentlemen who have applied various processes, with what I believe to be incorrect results, have generally used the argument that they have compared the results with the quantities added by themselves, but they have added those quantities to beer already brewed, and that is the fallacy. They are not justified in assuming that the results are correct when that is all their evidence.

6812. (Professor Thorpe.) If it is shown to you that no matter whether the arsenious oxide is added to the finished beer, or whether it is added to the wort, and the beer is brewed, and the results are the same—supposing that is proved to you, what becomes of the supposition that there is some combination formed in the process of fermentation?—That evidence is not crucial enough. It does not disprove the fact that you do not get nearly all your arsenic from Bostock's beer, whatever the reason may be. If you can make beer to which you add arsenic and can get the whole of the arsenic, it does not prove that I get all the arsenic from Bostock's beer, or that you would get all the arsenic from Bostock's beer.

6813. It proves that both of us ought to?—No, I do not think it does. It proves that something happens in Bostock's beers that does not happen in others.

6814. (Sir William Church.) You have said that "when sulphuretted hydrogen is passed into acidulated arsenical beer, whether concentrated or not, only a portion of the arsenic is precipitated; this is a colloid precipitate which does not coagulate well, and it is very difficult to filter. An unknown but large proportion remains in the beer. This has been known to me for 25 years." That is, I think, what Dr. Thorpe was alluding to?—I do not mean beer specially. It is badly worded. What I meant there was that as applied to the presence of arsenic in organic matter generally, and not specifically beer, that fact has been known. I did not actually think of beer 25 years ago. If I had I should have known that.

6815. But this peculiarity of the precipitated sulphide has been known to you for 25 years?—Yes, that peculiarity of the sulphide of arsenic and the fact that you could not get it from organic matter without destroying the organic matter, has been well known to me and others for more than 25 years.

6816. (Chairman.) Instead of the words "arsenical beer" in this statement, you would substitute acidulated vegetable or animal organic matter containing arsenic?—Yes.

6817. This statement will be correct then?—Yes, if you make that correction it is strictly right.

6818. When sulphuretted hydrogen is passed into

acidulated organic liquid matter containing arsenic, whether concentrated or not, only a portion of the arsenic is precipitated. This is colloid precipitate, which does not coagulate well, and it is very difficult to filter. An unknown but large proportion remains in the beer. This has been known to me for 25 years?—There, if you put "remains in the liquid," take out the word "beer;" then it will be right.

6819. "An unknown but large proportion remains in the liquid?"—That will then be quite right.

6820. (Dr. Whitelegge.) That would not be strictly true of arsenic newly added?—In the case of this test that I made I was surprised to find that I did get the whole of the arsenic down. It had not in the short time, I suppose, under the circumstances compounded itself in such a way that it was held back. It is a very slow thing. It does not compound itself quickly, and does not come out of the compound quickly.

6821. The proposition would relate not quite strictly to all arsenic present in organic liquid, but to arsenic that has had time to assume some change?—Some unknown change. I do not know what the change is.

6822. (Sir William Church.) I understood you to say to Dr. Thorpe that the fact of his being able to recover the whole of his arsenic from beer brewed from arsenical materials would not satisfy you that in another case of a beer brewed with different arsenicated materials you would be able to do it?—The experiment he alluded to is a very important one and a very interesting one.

6823. But it would not be to you conclusive that the same would occur under all circumstances?—No number of negatives of course can disprove my positive, and it is not my positive alone. These four experiments I have just alluded to are typical, and they were very carefully done by undoubtedly correct methods.

6824. Had you any further experience of the same sort?—Yes, there are some others which are not quite in a fit condition to be sent up here in the shape of figures. When I got sufficient evidence I did not go further for myself. I am quite satisfied, but if the further details will be of more satisfaction to you I can send you more from another strength of beer.

6825. You have had other details which confirm in your own mind that opinion?—Yes, I had further evidence which is of some importance. I have some dishes here which I should have produced before. These dishes show the amount got in the different precipitations.

6826. (Chairman.) What is the yellow matter we see?—That is the sulphide of arsenic. This dish shows a precipitate which was before the Courts, and, I think, will be again. That corresponds to 1.5th of a grain per gallon.

6827. (Dr. Whitelegge.) These actual samples were not weighed?—That was a sample I weighed in the porcelain. It was carefully dried and weighed fresh from the desiccator.

6828. (Chairman.) How did you weigh this precipitate, because we here see it a hard coating on the porcelain?—The dish is carefully dried in a desiccator, taken from a desiccator and weighed, and that stuff is got into it and weighed again.

6829. The weight of the dish is taken, and after that it is weighed with this precipitate?—Yes.

6830. What is the actual weight of this precipitate, 1.354 R.D.?—That weighs .006 gramme. That was from 1,500 grammes, a litre and a half of beer. What I wanted to say about that is this, that other gentlemen working by mirrors and other guessing methods, call that 1.30th of a grain, 1.15th of a grain, 1.40th of a grain, and Somerset House return it 1.30th of a grain.

6831. (Chairman.) And you find it to be 1.5th of a grain?—I find that amount which corresponds to 1.5th of a grain per gallon. That is an actual case, and it was that which led me to go into all these details. There is a corroboration of the substantial correctness of the figure 1.5th of a grain per gallon, in the fact that I was subsequently informed that the brewer of the beer was supplied with malt by the same maltster who supplied the two samples in which I have already mentioned we found 1.6th and 1.9th grain arsenious oxide respectively, and which corresponded with 1.5th of a grain arsenious oxide in the beer which was brewed solely from them and hops.

6832. (Dr. Whitelegge.) Would you say that whilst the other methods of analysis may omit some arsenic,

Dr. J. C.  
Brown.

3 May 1901

Divergence of results obtained by different analysts applying different methods to beer.

in the way you perform the experiment there cannot be an over-statement?—That is an under-statement, because I lose a little. In comparing the two methods I find such figures as these, '35 instead of '39 grains per gallon. I lose, therefore, a small fraction like that. What I say is, that when I get that, and produce it, and weigh it absolutely pure, there is at least that amount, there cannot be less, unless I have arsenic in my materials. I wish to state to the Commission the precautions I take to prevent error from the materials employed. First, every batch of every re-agent is tested, every Winchester quart, or every bottle of hydrochloric acid, is carefully tested, and if there is the slightest trace the bottle is rejected and not allowed to enter the place. Secondly, blank experiments are made with the same quantities of exactly the same ingredients that were employed upon that beer, in that experiment, using pure beer in the same quantity, with the result that we get a blank dish, no weighable quantity of anything. There is a third corroboration of that, that with the same ingredients we have estimated much smaller quantities of arsenic in both beer and malt, and have found quantities as low as 1-70th and 1-80th, and less. Now, if the impurities came from the ingredients, we should never find so small a quantity as 1-70th, it would be impossible. We should find the same quantities of impurity every time. Therefore, I think the evidence is absolute that at least that amount of arsenic was present there.

6833. (Chairman.) What are the weights of the first and second precipitate in experiment A?—001 gramme is the weight of the amount precipitated on the porcelain there.

6834. One milligramme on the porcelain?—Yes. You have the figures down.

6835. I wanted to know the weight on the porcelain?—001 gramme on that porcelain from a litre of the beer.

6836. On the second porcelain, what is the actual weight?—002.

6837. Then on the third, fourth and fifth we have nothing?—Nothing.

6838. And nothing was shown in weighing?—No.

6839. On the sixth we see nothing?—That is after the addition of more hydrochloric acid, and the further precipitation of sulphur and organic matter, and there is no arsenic on the porcelain.

6840. And no addition to the weight of the porcelain?—None.

6841. And the seventh of experiment A. was that still with further hydrochloric acid?—That is simply the filtrate from the sixth, and there is nothing there.

6842. Now the final precipitate?—004 gramme.

6843. The weight of this precipitate then is four milligrammes?—Yes. They are the figures I gave you before, dish A is the second experiment, and then I gave you the calculation into grains per gallon, which was '39. It is the same for B. I have the B dishes if you would like to see them, they correspond to the first experiment which I mentioned.

6844. Can you tell us the smallest quantity of precipitate on the porcelain that you can weigh?—I do not think I can, because it depends on the balance. I have a balance that I could employ if I wish to do it, that would give 1-10th of a milligramme or less; but I do not think it necessary to use that.

6845. What is the weight of the porcelain itself?—It varies, say, 19 grammes for a large precipitate, and five grammes for a small one.

6846. And you can weigh 1-10th milligramme on 19 grammes?—I should think one might do so, but I never did it. I do not trace the fractions of a milligramme beyond a half or a quarter. I should not trace my ordinary work to the 1-10th of a milligramme, but it can be done when desirable.

6847. Have you any case in which the precipitate is visible, and yet not perceptible on your balance in this experiment?—No yellow precipitate.

6848. If it is visible at all you would be able to weigh it in the balance?—Yes, in that experiment.

6849. Do you think there is any case in which you could weigh it in the balance, and yet it is not perceptible to the eye?—Not the arsenious sulphide; I can see as little as I can weigh; but I think I ought to say here that in official work there is always the check of

the Reinsch test. I will give you a very important example. In some of the evidence that has been given before you, I learn that you were a little concerned about a certain preliminary report that I had made regarding a sample, calling it a "small quantity" in one case, and saying merely "arsenic" in another. When I came to the figures I did not get quite so much from the sample that was recorded provisionally as simply arsenic, as I got from the sample which was recorded as a small quantity, and I was not quite satisfied with the result, because it did not quite agree with the Reinsch indications, which indicated rather a larger quantity from the one recorded as simply arsenic; and I repeated the analysis, so that by the time the case came into Court I was able to prove a larger quantity. Some had been lost in the first estimation. There is an illustration of the use of the second process as a check.

6850. What do you call the second process?—The Reinsch test.

6851. What you stated as to the necessity for oxidising away the organic matter, does that apply to the Reinsch test as well as to the precipitation test?—Not nearly so much. I think we do not quite get all the arsenic down by the Reinsch test, but we get a very much more nearly total quantity than we do from the Marsh, or by simple precipitation by sulphuretted hydrogen.

6852. The precipitation by sulphuretted hydrogen is surer than either of the other two tests?—For quantitative purposes, provided the organic matter has been first destroyed, otherwise it may be worse.

6853. So that the Reinsch test is not so much affected by the peculiar organic affinities you have discovered?—Not if you boil long enough; but the one hour generally employed is often not sufficient unless your object is to fail to get small quantities of arsenic.

6854. What about the organic affinity you have discussed, and the Marsh test? Will it vitiate the Marsh test?—I have five objections to the Marsh test, of which that is one.

6855. You consider that the Marsh test is in this respect worse than the Reinsch test?—Immensely so. Twenty years ago it was my duty, along with another very careful and reliable chemist, to investigate a series of murders by arsenic in which there were many victims. In one case of a child there was a very small quantity of arsenic. We applied the Reinsch method and we applied the Marsh method. The quantity was far too small for weighing, and we failed to get evidence we could use for judicial purposes by the Marsh test. But we got perfectly clear and unmistakable evidence by the Reinsch method, and on that we gave evidence in Court. I instance that as a crucial test made under circumstances of a strong feeling of responsibility. Since that time we have never relied upon the Marsh test where there is organic matter.

6856. On that occasion, did you use the method of oxidising the organic matter?—Not in that one particular body, because the quantity was much too small. In the case of other bodies at the same trial we did. We used very much the method I have described, but we went further, and instead of stopping with that yellow precipitate, we oxidised it and converted it into arsenic acid, and precipitated it as arsenate of silver, which gave a further link in the chain of evidence. I do not go so far as that in beer analyses for two reasons. First, we have got our confirmation by the octahedral crystals from the Reinsch test, and that is confirmation qualitatively, and the yellow precipitate in that test is an exceedingly good one to show to a magistrate, or to this Commission. Here are the crystals. (Tube shown.) You see there the crystals obtained by the Reinsch method from an ounce of beer (No. 858), and there is another tube containing the crystals from an ounce of beer. This is the porcelain dish 858. I certified 1-10th, and I found 1-9th really, and there is the arsenic in the form of sulphide. I have handed you the rough tube containing only a portion of the crystals from an ounce of the beer. You could not possibly produce those crystals in such quantity from an ounce of beer if there was not at least 1-10th. Two other gentlemen found 1-80th and 1-100th of a grain. Somerset House certified 1-100th, Dr. Stevenson estimating it, of course, not precisely, can easily distinguish between 1-100th and 1-10th by the Reinsch test; he applied both Reinsch and Marsh tests, and he says that from these he makes it to be '17 of a grain per gallon. In a letter to me, he says he believes that these esti-

Tests for arsenic in beer compared.

Divergence of results of different analysts using different methods.

Dr. J. C.  
Brown.

3 May 1901

mates of his are correct within 20 per cent. If you take 20 per cent. off that, you still have 1-7th of a grain per gallon against my 1-9th.

6857. So that that agrees with your 1-9th?—He makes it a little more than my 1-9th. Then to Mr. E. W. T. Jones, a very careful public analyst at Wolverhampton, I sent a small quantity only, and using 50 cc. in Reinsch's method he also says there is at least 1-7th; so that there is Stevenson by Marsh and Reinsch, and Jones by Reinsch alone, and myself, and I think five of my assistants, each separately getting over 1-9th by Reinsch's test, and there is finally my precise estimate in that dish of 1-9th.

6858. How much was the amount weighed on this dish, No. 858?—003 of a gramme from a litre and a half.

6859. In this case it was just one precipitation. You had taken your proper precaution of oxidation beforehand?—Yes. That was my final method at that time.

6860. (Sir William Church.) Going back to what Dr. Thorpe was asking you, is the slow deposit of arsenious acid from sulphuric acid a well known and a regularly recognised fact?—Not until last year. No one has ever seen, as far as I can ascertain, anything like such a quantity of arsenic in sulphuric acid before. The largest that people are acquainted with is about 1-5th of that.

6861. (Dr. Whitelegge.) Even in Glover tower acid?—My 2-6 per cent. sample is called the record, I think.

6862. (Sir William Church.) You think it is quite possible that when Messrs. Bostock had this acid delivered to them there was nothing peculiar in its appearance?—There was nothing when it was delivered to them, and there was nothing when I got it from them first on the 27th November last. It would not have attracted attention then as being anything out of the way. If it did deposit, it would not be seen in the carboys.

6863. With regard to the malts you spoke of, are you well acquainted with malt from different parts of the country?—I have examined malts from different parts of the country.

6864. I ought rather to say, with the process of malting?—I know something about it.

6865. We have had it stated in evidence before us here that the south country maltsters almost all use anthracite coal?—Then their beer will be undoubtedly purer.

6866. The London beers have not been found to have arsenic?—That accounts for it, but at the same time as I have shown you even in anthracite there is more arsenic than will now be passed, and it can be removed in the same way as the arsenic from worse fuel, viz., by brushing and polishing the malt.

6867. I suppose that care taken in the selection of the coal would almost do it?—I do not think you will find any anthracite quite free from arsenic. What I examined was about the minimum you will find; it was a very good anthracite indeed. There is always a little pyrites, and it comes from the pyrites. Of course, we are now much more critical than we should have been before.

6868. Is it not the case that gas coke is apt to give a disagreeable flavour to the malt, so that you cannot use a very large quantity of it?—I am told that the public will have the fuel dried malt, and will not have beer made from malt dried by hot air and not by fuel, either coke or anthracite. That is what brewers and maltsters alike tell me.

6869. It has been given in evidence before us that if you use gas coke exclusively for your fire below the malt, it gives a disagreeable flavour, and that you cannot very well use pure gas coke?—I hope that is true, but I have not come across that fact.

6870. That might account for a very variable amount, according to the proportion of gas coke which was mixed with oven coke?—Certainly.

6871. You would agree with the evidence given before us that oven coke is less likely to contain arsenic than gas coke?—Yes, the figures I gave you were for oven coke, and they were from a very special quality of oven coke, that is limited in quantity and used only by the best maltsters, but even there there is a trace of arsenic which requires to be brushed off. I insist upon brushing now, and the maltsters are rapidly adopting the brushing process.

6872. I think I understood you to say in one specimen

of malt you examined there was 1-12th of a grain per pound before brushing, and that after brushing thoroughly there was only 1-80th of a grain per pound?—Yes; after the third brushing there was 1-80th of a grain.

6873. That points to the fact that screening and brushing, if carried out thoroughly, will almost entirely remove the contamination of arsenic?—Quite so. Screening alone is not enough, but screening and brushing is enough.

6874. You say here that it is absolutely essential, as I suppose we should all agree, that the Legislature should provide some simple and efficient means of fixing the standard of arsenic and other things, and unless that is done there will be a great deal of useless litigation and want of uniformity. For practical purposes, what quantity of beer do you think should be taken for examination?—I ask now for a Winchester half-gallon, and I like to employ for the quantitative process a litre and a half, that is about one third of a gallon.

6875. So that a Winchester half-gallon gives you about 4½ to 5 litres?—It is over 2 litres.

6876. A sample has to be divided into three parts, so that a larger quantity would be required?—They now ask for a gallon and a half, but where they cannot well get that for various reasons, they take a gallon, and we can do with the gallon. One part goes to the vendor, one is retained by the inspector for production in Court, and one comes to the analyst, and from that one-third of a gallon I can do all that is necessary, but with the smaller quantities of arsenic I like more if I can get it.

6877. Do you think that is sufficient almost for practical purposes?—Half a gallon is ample for practical purposes.

6878. (Chairman.) Do you evaporate it down?—For the quantitative analysis I evaporate it down to a quarter of a litre, 250 cc. or thereabouts. That is the concentration of from four to six parts. For the Reinsch's test it is far better not to evaporate at all, and to take a smaller quantity, because in that way you get a more delicate distinction between a small and a large proportion of arsenic in the beer. Moreover, it is objectionable, on the whole, to take the 200 cc. that the Brewers' Committee advised; it is undesirable for the administration of the Act to take that quantity. It is far better to take 50, because every particle of the beer must come in contact with the copper. The copper does not extract arsenic from a portion of the beer a little distance away from it. It must be in contact. There is no attraction like the magnet for iron. It takes far longer, and there is more chance of underestimating if you have a larger quantity of the beer. Their method was employed for their purposes, because they wanted to fail to find a small quantity, which would be passed as not worth bothering about. But the public analyst ought to be more precise than that.

6879. (Sir William Church.) I should like to know your opinion of what has been stated before us by some witnesses that the Reinsch test acts better in beer than it does in water, that is, that the arsenic is deposited more rapidly on the copper in a solution of beer than it is in water?—I do not find that. I can believe that the arsenic may begin to be deposited earlier in the beer in some circumstances, but the later portions of it will not be deposited so quickly, and probably will not be deposited at all. You fail probably to find the whole. Certainly it does not come down so well at the finish.

6880. (Chairman.) In respect to the quantity used, surely the Reinsch test would not lose any sensibility by using double or treble quantities of the beer boiled?—It is apt to do so if you do not boil sufficiently long.

6881. I think your answer confounds two distinct ideas. One is getting all the arsenic out of the beer, and another is getting as much as the beer can show on the copper. If you take a gallon of beer and boil it according to the Reinsch with a piece of copper of a given size, you would get rather more on the copper than if you only take 50cc. ?—Yes, but you do not want to get so much as that.

6882. You want the test to be as sensitive as possible?—If you get a large quantity which is a small fraction of the whole, from a large quantity of beer, that is not so good a result as getting nearly the whole of the arsenic from a smaller quantity of beer.

6883. Then for that purpose the test should be continued, a first piece of copper and a second?—Yes, and

Dr. J. C.  
Brown.

3 May 1901

Need for official standard as regards arsenic in beer

Quantity of beer required for purpose of F. and Acts.

Degree of delicacy of Expert Committee's test

Reinsch test in water or beer compared.

Quantity of beer needed for Reinsch test.

Nicholson acid super-saturated with arsenic.

Arsenic in anthracite,

And in coke.

J. C. a third, fourth, and fifth, until you have exhausted the arsenic in the beer.

6884. Is that is done there is reason for the smaller quantity?—If that is done the larger quantity will be no disadvantage, but when to save time you do not do that, the smaller quantity is better.

6885. If you are not going to take all the arsenic out of the beer by the Reinsch test, then the larger the quantity of beer used the better?—Yes.

6886. So that it would be better to use 100cc. than 20?—Yes, but not if you are going to make it an approximately quantitative process. If you are going to guess the quantity it is better to take the small quantity.

6887. That is to say if you continue it until you take it all out of the beer?—That is what I meant.

6888. But then, on the other hand, the quantities you get out will be too small to be perceptible. If you want to make a really exhaustive test you should take a large quantity and continue it. Every part of the beer comes in contact with the copper?—Yes, but I can find a real 1-100th of a grain per gallon by 50cc., and that is delicate enough.

6889-90. I am simply questioning the idea that under any circumstances a smaller quantity is more favourable for the Reinsch test?—I do not wish to press it. I prefer 50 now, having worked with 200 for two or three months. I prefer the 50 as the result of experience, when I wish an approximately quantitative result, not otherwise.

6891. Do you know what others use?—200.

6892. Others do use the larger quantity?—Yes, and I have come by experience to prefer the 50; the reason being this, that we get more certainly the whole of the quantity out, and a man who is in a little hurry and does not take a second piece of copper will miss some of the arsenic in the 200, and I will get the whole from 50, and the whole from 50 is better than a fraction from 200.

6893. But nobody, as a rule, continues the test until he has secured that the whole is out?—I think he ought to.

6894. That is an important point, but it is not done according to the rule that has been given as having been resolved upon by the experts who reported for the brewers?—I know, but they did not wish to find very small quantities. That is why I mentioned it here, and I think it is important, because the whole value of the test beyond their particular object is getting as nearly as possible the whole out of a certain fixed quantity of the beer. We do not want to get a large, but unknown, fraction of the whole, but as nearly as possible the whole.

6895. Then, I understand and see the rightness of your view. When you get, too, such small quantities that there is a great difficulty in weighing them, then clearly a larger quantity of the material gives you a surer result?—Yes, but for my weighing process I do not use Reinsch at all. For my weighing process I use the extraction by Fresenius method destroying the organic matter, and for that purpose I want as large a quantity as possible.

6896. (Dr. Whitledge.) You found selenium in Nicholson's acid?—Yes, in all the samples I found it.

6897. Did you notice anything peculiar about the colour that suggested selenium?—No.

6898. It is not necessary then for a characteristic colour to be assumed when selenium is present?—No, because the selenium is there as selenious acid, and that is not coloured. It is selenium element that is coloured, or the sulphide. I am glad you mention that, because I have brought up an interesting specimen of selenium. (Specimen shown.) That is a specimen of selenium got at the Glover tower.

6899. (Sir William Church.) Is this from Bostock's acid?—No, that is from a good works. I did not know before that selenium was got at the Glover towers, but I am told it is skimmed off the acid.

6900. (Dr. Whitledge.) As an ordinary source of selenium?—No, it is not yet utilised, I believe. It is elementary selenium.

6901. As a fruitful source of selenium?—It varies with different ores. It is not found in the flues of some works. I have always failed to get any in the flues, but it is got in the Glover towers. As the fumes go up in the presence of plenty of sulphur di-oxide, the

sulphur di-oxide reduces any selenious acid to the elementary form, and the dilute acid coming down washes that solid selenium out, and it floats on the acid at the bottom. A little is also got in the chambers, but much less than at the towers.

6902. Then one would expect to find selenium ordinarily in sulphuric acid unless it has been removed by purification?—In some sulphuric acid, not in all. The acid is spontaneously purified by the sulphur di-oxide in the Glover tower, and the process of purification is merely perfecting in another tower what has been already begun.

6903. And the purification intended to remove arsenic would at the same time remove any remaining selenium?—There are several methods of removing arsenic, but the best one will also remove selenium.

6904. What method is that?—Treatment with sulphuretted hydrogen in a tower, like the Gay-Lussac tower.

6905. That removes the selenium?—Yes.

6906. Have you any reason to think that analytic results from the same barrel of beer may be affected by whether a sample was taken from the upper or the lower part?—You are thinking of a piece of evidence that was given by some other analyst to Dr. Sergeant, and I cannot go so far as he did. But there is this foundation for it that I have found very clearly, that there is relatively much less arsenic in cases of slight contamination, after the beer has been racked and the finings added than there is in the original vat in which it has been brewed. The quantity is less when the beer is finished. I have traced that to the small quantities of solid matter, finings, yeast, and other things that are more highly arsenicated than the liquid. I have come upon the further fact two or three times, that that same beer which was better after it was racked than when it was in the vat has apparently lost almost the whole of its arsenic some weeks afterwards when it has been sold in the public-house—I chanced to follow the same beer—and I can only attribute that change to the settlement of minute solid particles of the yeast, malt, and finings. They throw a handful of hops into the barrel, and when that settles it takes a little out. When the quantity of arsenic is large I have found the arsenic in the hops and sediment, but I could not make out that it was greater in the solid matter than in the liquid, and therefore did not sensibly purify the beer. No doubt it is a means of purification, when the quantity is sufficiently small, and that is partly how I account for malt slightly arsenicated yielding absolutely free beer.

6907. (Chairman.) Is there not a danger in the casks? Will not it go on depositing until there is a considerable quantity in the casks?—Every cask that goes back to the brewery is carefully purified by water, soda and steam successively, and there is not a trace of arsenic left after these processes. I have tried that. I have a sample I should have put in before, when speaking of Bostock's acid. A quantity of liquid sulphuric acid equal to the total liquid in that bottle yielded the amount of arsenious sulphide which is in that bottle. (Specimen shown.)

6908. What is the liquid?—It is water, but it shows the bulk of the 11 grammes of acid that I took, and the precipitate there is the sulphide of arsenic obtained from it.

6909. This selenium I see is marked as being from the Glover tower?—Yes.

6910. Where was it found?—It was skimmed off the acid at the bottom of the tower.

6911. Skimmed as the scum off the acid?—Yes. Bostock's acid we believe to be the acid from the bottom of the Glover tower. That is the selenium skimmed off similar acid from another works.

6912. In these other works, did that selenium get into the acid in large quantities?—It could not be perceived. I failed to find it.

6913. Although it existed in that scum to skim it off, there was not enough in the acid to show at all?—The sulphur di-oxide in the Glover tower precipitates it all as elementary selenium, and it is skimmed off in that form, and never goes out. Besides, nobody ought to sell Glover tower acid.

6914. What is done with the Glover tower acid?—It is used up again for other purposes of purification.

6915. (Dr. Whitledge.) You told us just now of the divergent results obtained in the analysis of one par-

Dr. J. C.

Brown.

3 May 1901.

Purification of sulphuric acid from arsenic will also remove selenium.

Beer may lose arsenic on keeping

is selenium  
minium  
have

*Dr. J. C. Brown.* ticular sample; that you obtained 1-9th, and Dr. Stevenson something which, after allowance, came to 1-7th, and other results were widely different?—Mr. Jones also got 1-7th.

6916. And Somerset House only found 1-100th?—Yes.

6917. Do you regard those results as satisfactory for the purpose of a court of justice?—They are unsatisfactory, but I think there would have been a conviction; my dishes would have persuaded the magistrate, I believe.

6918. But as a matter of fact, different methods were adopted, and they led to divergent results, which divergent results would have been before the court who had to decide?—They would have been before the court.

6919. In the light of that experience and others of the same kind, would you say there ought to be some agreement as to the uniform method of analysis?—To a certain extent there ought to be an agreement, and I should be perfectly satisfied with the destruction of the organic matter before starting the process of estimating and an absolute weighing of the arsenic in some form.

6920. You would be in favour of as much uniformity as possible, but you regard the preliminary destruction of the organic matter as essential in any satisfactory method?—Yes; there are two or three methods after that, and I would be content with any of them. One man might be more expert with one, and another with another.

6921. You speak of some samples as showing such very minute traces as to be considered "genuine." What sort of a standard have you in mind?—I should not like to say that any beer containing less than 1-100th of a grain per gallon was other than genuine.

6922. You would return a beer containing less than 1-100th as genuine?—Yes, I think so.

6923. In an official certificate?—I think so.

6924. Would the medical officer of health or whoever receives that certificate understand from that that it was absolutely free?—None of the medical officers that I have to do with would, because I have told them it does not always mean that.

6925. I think one of them drew the conclusion that it was entirely free. When you use the term genuine, you do not mean it to be inferred it is entirely free from arsenic?—I mean that it is practically free.

6926. You have a reservation; you do not mean absolutely free?—No; there is no beer in which I could not get a couple of crystals if I evaporated down a sufficient number of gallons.

6927. Did you advise the authorities by whom the samples are taken as to the selection of samples and the quantity of samples?—Yes, sometimes; it is my duty to advise them.

6928. The Corporation of Liverpool and the county authority of Lancashire?—Yes; but they are not obliged to follow my advice.

6929. You are consulted?—Yes. When I was first appointed, 29½ years ago, the Corporation of Liverpool through the Health Committee told me to advise and instruct the inspectors, and that is still my duty, but since Dr. Hope became Chief Inspector—when he was

made Medical Officer of Health he was made Chief Inspector—he has required much less advice.

6930. But you do confer with Dr. Hope?—Yes, by telephone nearly every day. The county authorities, when they appointed me in 1875, also clearly instructed me to advise the superintendents, and particularly to tell them in each case, whether the certificate was such as to indicate clearly an offence or not. That is still my duty.

6931. If you became aware of any danger to public health arising out of such a matter as arsenic in beer it would rest with you to advise that samples be taken?—It would not be my official duty to do it, but I should be expected to do it, and I should certainly do it.

6932. Have you received instructions from the Local Government Board of any kind?—Not from the Local Government Board.

6933. You make an annual and quarterly report to the Local Government Board?—I make a statutory quarterly report to every authority for which I act, and a copy of that has to be made out by their office and sent to the Local Government Board.

6934. So that you have no official communication with the Local Government Board?—Not directly. But they send me a copy of their annual reports, and get copies of my quarterly reports.

6935. Are you in official relation with the Government laboratory?—No.

6936. And neither from the Government laboratory nor the Local Government Board have you received any official instructions?—No. I should prefer not to receive instructions from them. We have had private communications, and comparing of notes occasionally for mutual benefit, which has been very useful. There are a number of details in the reports that have been handed to you by Dr. Sergeant and Dr. Hope which are not quite correct, partly through clerical errors, no doubt, and partly because my first returns were made upon the very rough qualitative estimation not intended to be for the purposes of the Act: "a small quantity," and that sort of phrase was used. It was after the first quarterly report, before I had better estimates, and therefore the medical officers have not in all cases got the better estimates. I have prepared clear details of the whole for the different authorities, which you might like to have, and which may be more reliable than what you received from them. (Document handed in.)

6937. (Sir William Church.) Shall we be able to identify these with the tables we have already got?—I think so. I have put them in such a form as would do that. In addition, there is the Borough of Preston, which they do not know about; there is the Borough of Blackburn, for which Mr. Collingwood Williams acts; and there is the Borough of Barrow-in-Furness, for which he also acts. The Borough of Bootle, for which we both act, had all its beers so purified by the action of the city authorities that they never found any arsenical beer. (Documents put in.)

6938. (Chairman.) I understand you have some suggestions to make to us as to administrative questions, which you will send to Dr. Buchanan for incorporation as an Appendix?—Yes. (See Appendix No. 15, p. 362.)

Destruction of organic matter should be essential to any official test for arsenic in beer.

A public analyst advises as to selection of samples under F. and D. Acts.

Analyst no instructions from Local Government Board.

and not in relation with Government Laboratory.

*Dr. J. C. Brown.* 3 May 1901.

## FOURTEENTH DAY.

AT WESTMINSTER PALACE HOTEL.

Saturday, 4th May, 1901.

PRESENT :

The Right Hon. LORD KELVIN (*Chairman*).Sir WILLIAM CHURCH.  
The Right Hon. Sir WILLIAM HART-DYKE.Dr. WHITELEGGE.  
Mr. COSMO BONSOR.Dr. BUCHANAN, *Secretary*.

Mr. THOMAS WATSON LOVIBOND; called and Examined.

W. and. 1901. 6939. (*Chairman*.) You have held the position of managing director to the Newcastle Breweries for 11 or 12 years?—Yes.

6940. Is that a large trade?—Yes, a very large business; involving nearly two millions of money and two hundred thousand barrels a year turnover.

6941. You were chairman during two years, 1899 and 1900, of the Country Brewers' Society?—Yes, I vacated the chair in December last.

6942. And you are Fellow of the Institute of Chemistry, and worked formerly under Dr. Graham in University College, London?—Yes.

6943. You have practised and supervised in brewing operations for thirty-eight years, and are acquainted with the manufacture of every class of beer?—Yes.

6944. I understand, with the great experience you have thus had, you wish to endorse what has been told us about the desirability of using sugars and other adjuncts in brewing?—Fully; I look upon them as a practical necessity for modern brewing—an absolute necessity.

6945. Is it your opinion that these adjuncts are an advantage to the brewer?—If the adjuncts are properly chosen they improve the quality of the beer, and in some cases effect economy, but not so much in all cases.

6946. But you consider they improve the quality?—If they are properly chosen—decidedly.

6947. An incidental advantage is the shortening of the time needed to brew?—That is my own experience. I have been able at Newcastle to turn out good light beers in very much less time than was the custom of the trade formerly, under a fortnight a great deal of our beers, and three weeks the longest, and of course the advantages to me are considerable. I have been able to make a cellaring accommodation serve now for three times the trade it served for twelve years ago.

6948. In your view and the view of your Society, if adjuncts were prohibited, more foreign barley would have to be used?—Unquestionably. Foreign barley is the one substitute that we can look to in the absence of what are commonly called adjuncts. English barley, except the very finest, is not fitted for use entirely by itself.

6949. The British barley grower, we understand in your view, would not benefit by the prohibition of brewing sugars?—I do not think he would.

6950. Speaking on behalf of the trade, you would welcome any recommendation which would safeguard the public against any possible contamination of beer—for instance, by arsenic?—Certainly I would—any recommendation which would safeguard the public would protect the brewer as well.

6951. Whether introduced in the malt or by brewing sugars?—Wherever it comes from, if it can be safeguarded it will be a protection to us as well as to the public.

6952. Can you tell us how many brewers there are in England and Wales apart from publican brewers?—I cannot give you any figures later than September, 1899,

and in that year there were about 6,796 brewers altogether, and a large proportion of those, very nearly 5,000, were practically publican brewers; so that the brewers of any importance were only some 1,800. Of those 300 are small, the general result being that there are only some 1,400 brewers of any importance.

6953. Brewers other than publicans?—Yes, in England, and of those very nearly half are members of our Society. My reason for wishing to state this is that statements are being constantly made, and Mr. Chaplin himself in the House made a similar statement, to the effect that the great majority of the brewing trade do not use adjuncts, and that, of course, was intended to convey the impression that the use of adjuncts is in the minority in quantity, whereas it is only in the minority in number of brewers. The 5,000 publican brewers, who, of course, are a very large proportion in number, only use 3·8 per cent. of the total brewing materials used in the Kingdom. They are a perfectly insignificant minority, and do not in any way represent the brewing trade.

6954. Do the publican brewers use brewing sugars?—To a very small extent.

6955. (*Mr. Cosmo Bonsor*.) Those are the Excise statistics?—Yes. I have put in fuller papers in sending my proof to Dr. Buchanan, but they are public figures. There is nothing at all that cannot be got at in the ordinary way.

6956. (*Chairman*.) How many brewers to your knowledge use no malt adjuncts?—I could not say that. You may safely take it that a great proportion of publican brewers, the small brewers, use none, but of the balance, the important brewers, I should say there are very few indeed who use none, but I could not give you figures.

6957. Are any of the publican brewers members of the Country Brewers' Society?—No, they would scarcely be eligible. The Country Brewers' Society is supposed to represent the wholesale brewing trade of the country, not including Burton or London, and one or two other important districts, such as Manchester, where they have their own large and important societies, independent of the Country Brewers'.

6958. Can you give us a statement of the action taken by the Country Brewers' Society with regard to arsenic in beer since November 24th, 1900?—Yes. I give that statement with a view to showing that the Country Brewers' Society was as active as possible in facing this difficulty, and in warning its members of the danger that had arisen very unexpectedly. The first intimation was on the 24th November, when I saw two paragraphs in the North Country papers to the effect that there had been arsenical poisoning on the western side of the Northern part of England. I sent those paragraphs at once to the secretary. At that time I was chairman. The secretary, on the 23rd November, interviewed a reporter from the "Daily Telegraph," and on the same day a meeting of the Parliamentary Committee of the Society was held, and on the following day, the 29th November, a letter from the secretary appeared in the "Times," asking the public to

Mr. T. W. Lovibond.  
4 May 1901.

Many brewers use no adjuncts to malt, but their output is small.

Action by Country Brewers' Society on discovery of arsenic in beer.

Mr. T. W.  
Loribond.

4 May 1901.

suspend their judgment until the facts were better known. On the same day a circular was issued to the members of the Society, warning them that no sugars should be used in brewing unless they had been examined for arsenic. That circular is, I believe, the first circular of any public nature which was issued to any large number of the brewing trade on this subject. I believe that it was issued simultaneously with Messrs. Bostock's telegram to their own customers, but it was issued prior to Messrs. Bostock's circular in which the explained more fully, and asked that their materials should not be used. On the 30th another meeting of the Parliamentary Committee was held, and another paragraph was issued intended to allay alarm. On the 3rd December the matter was considered by the General Committee of the Society, and the steps taken up to that time by the Parliamentary Committee were approved. On the 13th December the General Committee met again, received a further report from the scientific advisers, and ordered that another circular, marked "C," advising examination for arsenic of all descriptions of glucoses, invert sugars, priming sugars, and caramels, and urging that facilities should be given to local authorities, should be sent to the members. On the 19th December a circular, marked "D," was issued to the members of the Society, quoting Mr. Estcourt's warning as to the presence of arsenic in malt, and again advising care. On the 21st December copies of the report (marked "E" in my papers) of the Commission of Experts appointed by the Manchester Brewers' Association (Appendix 5), and of Dr. Dr. Dupré's letter to the "Times" of December 21st, were issued to the members of the Society. On the 9th January, 1901, the Parliamentary Committee met and again discussed the matter. On the 23rd January, at a meeting of the General Committee, the advisers reported additional facts, and certain points were referred to the General Purposes Sub-Committee for inquiry. On the 7th February the General Purposes Sub-Committee met. On the 15th February they again met, and the General Committee met and received a report from the Sub-Committee, and the further circular, marked "G," dated February 15th, asking for particulars of any proceedings which were being threatened against members, was issued to the members. We have also distributed Dr. Buchanan's report to the Local Government Board. Extracts have been issued to all members.

6959. The Society kept a close watch on the developments of the subject?—I think you may take that—probably the closest of any public body connected with the trade.

6960. Who are the scientific advisers of the Society?—Dr. Moritz and Dr. Morris.

6961. Dr. Buchanan informs us that he was in error in saying in a foot-note to his report to the Local Government Board that a circular sent to the members of the Country Brewers' Society cautioned them against Bostock's sugar, the fact really being that members were cautioned against the use of any brewing sugars which had not been first examined for arsenic, and that he would like this put right?—Yes. Our first circular was issued on the 29th November, and it did not mention Messrs. Bostock's name. At that time Messrs. Bostock's name was scarcely public property, and we did not desire to mention any firm by name. But we did issue that circular six days before the issue of the Manchester expert's report.

6962. Dr. Buchanan states that he has informed the Brewers' Society that this would be corrected in any further issue of his report?—I shall be very much obliged. We should be glad that this slight inaccuracy in the report should be corrected so as to set the Society quite straight before this Commission and before the public generally.

6963. In respect to action taken with regard to arsenic by your own firm?—I think on that subject I had better perhaps tell you exactly what I have done. As soon as our fears were aroused by the knowledge of what was taking place elsewhere, I had analyses made in my own laboratory by our head brewer, who himself is a perfectly competent chemist, for arsenic, of all our materials and all our products—very carefully done indeed; and the result was that we found no arsenic whatever existing in any one of these materials or products excepting in one instance. In that instance the amount of arsenic found was definitely perceptible, but it was exceedingly small; it would not be more than 1-20th of a milligramme of arsenic in 5 grammes of the dust.

6964. (Sir William Hart Dyke.) Malt dust?—Yes, but I must explain what kind of dust. The substance in which we found this minute trace of arsenic was not the malt culms—or combings as they are called in some parts—that is to say the rootlets of the growing barley. In that we found none, but the dust in which we did find a trace was the very fine dust which is rubbed off the malt, and which is exhausted from the malt before grinding by means of a fan, and carried to a chamber. In 5 grammes of that dust we found 1-20th of a milligramme of arsenic or something under. I need hardly point out that that dust is a very miscellaneous sort of substance. It is partly soil, partly spores of all kinds of organisms, and tiny bits of the skin or husk of the malt. It is a very mixed product which in our case does not go into the beer at all. It is extracted by the malt fan and removed before the malt is ground. One material of which I had my doubts was very carefully examined, and that is the coke we use for drying the malt. We do not use anthracite coal in the North of England, the freight being very heavy; it is costly. We use coke, and it has been the practice with my company to use the best oven coke we can get. It is the Mickley Coal Company's coke, and we did not find after many examinations of this coke that there was any arsenic present. It is a very high-class coke, an oven coke and not a gas coke. Gas coke is more or less a suspicious subject. It is a coke I never would have used and never have used.

6965. (Sir William Hart Dyke.) Did you ever use gas coke?—Gas coke probably still is used in some parts of the country, but I have never used it because I know the risk and dangers of it.

6966. (Chairman.) Did you know the risk of arsenic in coke before this recent epidemic?—As a chemist I knew it perfectly well; as a practical brewer it had never been brought before me in such a way as to make me think it necessary to search for arsenic.

6967. The malt to which you referred as having found a very small trace of arsenic in the dust was malt made by yourselves?—Yes.

6968. Do you make all your own malt?—Not quite. We buy probably 1-5th of our consumption.

6969. Have you tested any of the malt you bought for arsenic?—Since the trouble in November last we have only bought malt from a firm in Newcastle, and their malt has been tested and found as satisfactory as our own. Their practice is the same as ours. They use a high-class oven coke for drying.

6970. Have you tried more than once to find whether there is any arsenic in the rootlets?—Yes, several times, and we have not found arsenic in the rootlets. I ought to explain that in the process of aspirating the real *bond fide* dust to which I have referred, the rootlets are left in a very much cleaner condition than they would be if the malt was screened as a whole. The screening and grinding are conducted in one operation, the small dust is aspirated out by the fan, but the malt culms are dropped through the breeze of the fan, and are gathered in a separate place, clear of the fine dust.

6971. Is the clearing away of the fine dust done after the rootlets have been knocked off?—After they have been knocked off, but at the same time as the whole malt, culms, dust, and everything are dropping down towards the mill.

6972. You draw away the fine dust?—Yes, by a fan.

6973. And the fan would not carry the rootlets away?—No, the rootlets go in one direction, the malt in another, and the dust in another.

6974. We understand from the statement we have before us that you can and do produce beer in which no arsenic can be detected in a half litre?—Quite so. We have attempted many of our experiments on the full half litre instead of on the 200cc. recommended by the committee of experts who reported to the Manchester brewers.

6975. By what test?—By the Reinsch test.

6976. How much copper have you used, and how long a time for boiling?—The quantity of copper is not essential; we use a small piece something under an inch square.

6977. Each side was coated?—There would be two sides, arsenic free copper gauze, and the time would be somewhere near an hour.

Mr. T. W.  
Loribond.

4 May 1901.

N.A. arsenic found in malt culms.

but present in malt dust.

Oven coke used in the maltings.

Screening separates malt culm and dust.

No arsenic detected in half a litre of their beer.

Action by  
Newcastle  
Brewery  
Company.

6978. Have you ever put in fresh copper and continued the boiling for another hour?—Yes; we have done that; we have carried on some of our experiments for a very long time, two or three hours with the view of seeing if that would give a different result, but we have not found arsenic.

6979. Have you found arsenic in any case?—In no case at all except in the case of this fine malt dust.

6980. In the case of the malt dust you perform the test in the same way by boiling?—No, that would not be conducted in the same way; that would be digested with nitric acid and sulphuric acid, and then the product washed out and treated by the Marsh test.

6981. In the case of malt, what quantity has been found free from arsenic by Marsh or Reinsch tests?—We have taken from 5 to 10 grammes; generally 5 grammes, but some of our experiments have been done on 10.

6982. What adjuncts do you use in your brewery?—I have not used glucose for a good many years. The adjuncts I have used and am now using are inverted cane sugar and maize grits.

6983. The maize grits are converted by the aid of sulphuric acid?—No. On that point I may mention that for many years I inverted my own cane sugar by the aid of sulphuric acid. Not with any view of avoiding arsenic, but with the view to keep an exceedingly unpleasant and difficult material to handle like vitriol out of the brewery. I some years ago adopted the process of inverting the cane sugar by means of yeast, a simple and admirable process which inverts cane sugar in exactly the same way as acid, but in which the agent employed is brewers' yeast. That has been my method for some years past. In the case of the maize grits, there the conversion is the purely natural diastatic conversion in which the agent is the diastase of malt and the product made is not the glucose of sugar manufacturers, like Bostock's and others, which is mainly dextrose, but it is the natural substances always obtained in the mash tun, viz., dextrin and maltose.

6984. Does that give the same result in brewing as inverts prepared from sugar?—It is not to be compared with invert prepared from sugar, because the products are different, but it is to be compared with the glucose, mainly dextrose, made from grain such as rice or maize. But whereas the glucose manufacturer produces an article mainly dextrose, easily fermentable, the conversion by means of diastase produces a wort composed of maltose and dextrin, which are the natural substances produced by diastatic conversion of malt itself.

6985. With respect to the brewing the beer, is it nearly the same whether you take the glucose or invert made by sulphuric acid, or whether you take invert made in the manner you have described?—No, the results are widely different. In the case of grain, more particularly maize grain—I do not say quite the same of rice—but in the case of maize the results by our mode of conversion are vastly superior to the results obtained from acid made glucose.

6986. In what respect superior?—In respect of fullness of the resulting beer, and in flavour. I think those are the two main points. The beer is fuller, and the flavour is better.

6987. In respect to alcoholic result is it the same?—I should think theoretically you would get a little more alcohol from the sugar makers' glucose than you would from the corresponding quantity of grain. I think there would be a little difference inasmuch as the dextrose of the sugar maker is a more fermentable substance than the mixed sugars that are produced by the diastatic mode of conversion in the mash tun.

6988. What you call the "diastatic mode" is conversion by yeast?—No, I mean a mash tun conversion. Diastase is a soluble ferment, to use a simple expression, which is produced naturally. In barley malt that diastase has a convertive power which acts not alone on the starch and sugar materials of which the malt consists, but on all other starch or sugar materials presented to it under proper conditions, and we make use of this diastatic power. I think I ought to explain that the yeast conversion which is in your mind, and to which I referred just now, is a totally different thing. That is not a conversion of starch into malt sugars, which is the mash tun process, but a conversion of cane sugar into invert sugar which is not a mash tun process. The latter is done outside the mash tun, and there is no connection between the two processes.

6989. (Sir William Hart Dyke.) It is added afterwards?—Yes, the invert sugar is added in the copper after the mashing.

6990. After that process is over?—Yes.

6991. (Chairman.) How do you conduct the inversion of cane sugar by yeast?—It is a question of temperature. The cane sugar is first dissolved in boiling water. The hot sugar solution is cooled down to the proper temperature, the temperature of maximum invertive power or activity of the yeast, a proper proportion of yeast is added, and it is a mere question of time for the yeast to effect the complete inversion of the cane sugar into invert sugar.

6992. If that process was allowed to continue, alcoholic fermentation would take place?—No. The temperature at which it is done is not a suitable temperature for fermentation. In fact the yeast which is used for inverting the sugar is killed so far as its fermentative or alcoholic producing power is concerned.

6993. You do not first treat the yeast in any way?—No.

6994. At what temperature do you conduct this inversion process by yeast?—About 130 to 135 F.

6995. And the fermenting temperature is much lower?—Yes, from 54 to 75 F. in this country. It would not go on at the higher temperature of 130.

6996. You use the word with reference to the maize, "maize grits"; how is that produced?—That is produced mainly in America by purely mechanical means. The maize grain is decorticated, and then run through machines, and attacked by means of knives, which cut out the germ of the grain, and the germ of the grain is that part which contains nearly all the oily matter of the maize, most of the albuminous matter, and practically all that portion of the albuminous matter that is soluble. The remainder is ground between rollers into pieces about the size of large pin heads. The fine starch dust which arises in the process is carefully taken out and used for other purposes, and the grits sent to us consist of nothing but the pin head size bits of the starchy matter of the grain.

6997. And contains none of the oily matter?—Practically none of the oil, and practically none of the soluble albuminoids.

6998. (Mr. Cosmo Benson.) There is no chemical used in the process?—No, it is entirely mechanical.

6999. (Chairman.) Does that separate entirely the germinating portion of the maize from the remainder?—Yes, it separates the germ entirely.

7000. Would it be correct to describe maize grits as starch?—A very pure form of starch indeed, considering it has not been purified by any manufacture.

7001. You get it so pure it gives no disagreeable flavours?—No, and our flavours are improved, which could not be said of many forms of raw grain.

7002. Is it by fans that the maize is separated into two parts?—I have never been through an American mill, but I should think it was rather done by screens than fans; it is bound to be done by screens. Fans would not give the clean dust-free product we require.

7003. Do you buy any of your adjuncts beside the maize grits?—That comes from America.

7004. Have you had occasion to require any guarantee with reference to the quality of the maize grits?—No, we buy by sample, and if it comes according to sample we are perfectly satisfied. From the point of view of arsenic I do not consider there is the least necessity to require a guarantee as regards maize grits. We have examined them, but we did not expect to find, and then did not find any, arsenic.

7005. Do you buy any other adjunct?—Nothing but cane sugar. That also is an article which I believe is above suspicion—unless it is treated with arsenicated acid.

7006. We are to understand then in your own brewery you have never used sulphuric acid?—Yes, some years ago, but I gave it up.

7007. And you never use it now?—No, and have not done so for some years.

7008. Did you give it up for anything deleterious, or only from inconvenience?—I gave it up because I looked upon it as a dangerous and unpleasant material to handle—a splash in the eye will deprive a man of his eyesight. I had two or three accidents; I gave it up because I found a better method.

Mr. T. W. Lowboud.  
4 May 1901.

Inversion of cane sugar by yeast.

Preparation of maize grits.

no arsenic found in

Objection to use of sulphuric acid in a brewery.

Mr. T. W.  
Lowbend.

4 May 1901.

7009. The method you practise you found also fairly economical?—More economical than acid, because my yeast costs me nothing, and my acid did cost something, although it is a cheap substance.

7010. So that you use what you find and believe to be a safer and better process, and yet not a more costly process?—More economical, in fact.

7011. In the general way you still approve of the use of what are called brewers' sugars?—Certainly.

7012. Although you do not use them yourself?—I have no fault to find with them. Other brewers find them useful, and I know they are useful. They come under the general principle of useful adjuncts. In my opinion glucose is not so useful an adjunct as invert sugar, but that is a matter of opinion in which some brewers differ from me, and they find glucose a useful material, and it is one of that class which I consider essential materials to be used for modern brewing.

7013. You would rather not use sulphuric acid yourself, but if the users of brewers' sugar find it advantageous you do not disapprove?—Not at all, because the brewers' sugar makers remove the vitriol.

7014. And they take upon themselves the arrangements to prevent inconveniences from such a dangerous material?—Yes, and they ought to take upon themselves the risk.

7015. It must be found economical by them, and by some brewers to use sulphuric acid in that way?—Yes, it is economical, undoubtedly. The acid process is practically the only one available for manufacturers who manufacture on a very large scale. I do not think the yeast process would be practicable, or applicable to the enormous scale of the sugar manufacturer.

7016. You have some remarks to make with regard to the tied house system in relation to the epidemic?—I should like to point out that much as the tied-house system may be abused, I believe that in this case it has been a very great deal of assistance throughout this trouble in the Manchester and North-Western district. If it had not been for the absolute power of control which the brewer has over his tenant and customer in the matter of his stocks and so on, instead of these beers being promptly condemned, and carted back to the brewery, and taken out of consumption, as they were throughout practically the whole of the district, the licensees would have had to be dealt with individually. You would have been dealing with a class of men ignorant to a very large extent of the risks they were running and, as has been shown in two or three isolated cases, you would have found objections and difficulties on the part of some licensees to having the beer condemned in a wholesale way. I suggest that the tied-house system enabled the large brewers, like my friend Mr. Groves' firm, to insist upon the prompt and immediate withdrawal of these beers from consumption, and their prompt destruction.

7017. (Sir William Hart Dyke.) You describe two systems, your own and the one more generally used, in each case making adjuncts; in your case by the use of yeast and in the other through the medium of sulphuric acid?—Yes. They only apply as I think I explained to cane sugar. They do not apply to grain conversion. As far as the results are concerned they are identical. It is a mere question of method and time.

7018. Did you adopt this method you have described so well to us, the yeast system, on account of its cheapness, or had you a hidden dread that a catastrophe might happen through the use of a material which might contain arsenic?—I looked upon it as a great advantage to get rid of a dangerous substance like vitriol. I had one or two small accidents from careless men and I did not want to have the responsibility of blinding a man or injuring a man, and I was only too glad to find a process which enabled me to achieve the same result without the use of vitriol.

7019. Apart from avoiding arsenic it was a dangerous stuff to meddle with, and you thought the other process was equally cheap and secure, and would suit you?—In the use of vitriol I was always careful to use good vitriol because I know perfectly well, as most of us do know, that the common vitriol produced for manurial manufacturing purposes, contains a great amount of arsenic, and is totally unfit for our use.

7020. You say by the use of malt adjuncts you are enabled to produce a better beer in from 2 to 3 weeks time instead of an inferior article from all malt in about double the time. I want you to tell the Commission something in regard to this newer system—it may not

be called a modern system because it has been going on for a good many years—of brewing through adjuncts instead of the older system by malt. Has this system grown up on account of a change in the taste of the public?—I think you may say that since 1880 the use of malt adjuncts has created a taste for lighter, cleaner beers. The natural result of using these materials was the production of a lighter and cleaner beer that hit the public taste, and that change has been gradually going on for the last 22 years with the result that there is far more of this light clean beer brewed now than there was then, and also with the result that the heavier beers of our fathers' days are brewed far less. They are not so wholesome, there is no question about it, and to me they are not so palatable.

7021. I think you rather criticised the quality of some of the home-grown barley, and I suppose you would wish the Commission to understand that in your trade, apart from the reasons you have just given for the change in the system of brewing, there have been difficulties as regards the qualities of English malt. In some years there is a great difference in English barley, and where an inferior barley is used, adjuncts have to be employed to supply the saccharine matter which is absent?—It is necessary to make some distinction between the various parts of the kingdom. Take Norfolk and Suffolk, where in ordinary good seasons very fine barleys are grown.

7022. Lincolnshire?—Some of the Lincolnshire chalk districts produce very fine barley. There are many districts which produce the very best barley England can grow, and that means as good barley as can be grown anywhere else; but there are other districts, notably my own district, Northumberland and Durham, where our barleys are coarse in nature, coarse in composition, and coarse in their skin, and where it is only in favourable years when we have a favourable harvest time without much wet and so on, that we can use our barleys to any considerable extent. This year I have only bought about a thousand quarters of local barleys; a rival of mine in the trade who is doing an almost equally large business, told his shareholders that he had bought one parcel this season and could not buy any more. Last harvest was an unfavourable one. Other harvests I buy some thousands of quarters of the local barley.

7023. Providing you could get a good sample you have no objection to any home-grown barley?—No; the quality of our malting barleys must be above a certain standard; if the barleys are below that standard it must go for grinding, it is not good enough for us.

7024. (Chairman.) Do you buy much foreign barley?—Yes, a great deal.

7025. You find it necessary?—Yes.

7026. (Sir William Hart Dyke.) You have had 38 years' experience of brewing, and having had a thorough knowledge of chemistry as well, you have been able to go very thoroughly into the causes of this late epidemic?—I think as thoroughly as any other brewer in the kingdom.

7027. As regards your examination of the malt and malt test, you only malt a certain percentage of the malt you use?—70 or 80 per cent. is made at home.

7028. And the balance of course you buy?—Yes.

7029. Will you tell the Commission where you are in the habit of purchasing your malt?—What I call our ordinary malts, that is for the manufacture of ordinary mild beers, are bought generally either from a maltster in Newcastle, a friend and neighbour of our own, or from another old friend and comparative neighbour at Berwick-on-Tweed, where the same class of barley is malted. But if we have to buy fine malts for pale ales we generally go to Newark or some other place where we can get malt made from fine Lincolnshire chalk land barleys or good Norfolk barleys.

7030. When you went through this testing process of the materials you were using, did you test the purchased malt?—At that time we were only buying from one maker, our Newcastle friend, and his malt was tested with the same result as our own.

7031. Both classes were therefore tested, home-made and that which you purchased?—Yes.

7032. Have you ever used gas coke?—No; my knowledge tells me that gas coke is an unfit substance for use for the purpose. It is liable to be too sulphurous, and malting that of course means the danger of arsenic.

Mr. T. W.  
Lowbend.

4 May 1901.

Light beer prepared with adjunct preferred by public.

Variations in quality of English barley.

Tied house system facilitated withdrawal of arsenical beer from publicans.

7033. Your knowledge of chemistry gave you a whole some dread of gas coke?—Yes.

7034. Can you tell us from what you have read, whether you would consider there was a twofold possibility of danger as regards malt in respect to the use of the fuel, and in not cleaning the malt properly?—I should not think there is any material danger from not cleaning malt properly provided that the malt has been dried with proper fuel. I look upon the exceedingly minute quantity of arsenic which I have found in our own refuse dust as so immaterial that, although we do and have for very many years taken the pains to remove this dust, I do not think that the risk of arsenical poisoning from it is at all worth consideration. That was not our reason for removing the dust. Our reason was to remove from the malt and consequently from the mash tun and the finished beer, all, or as nearly all as possible, of the spores, germs and other organisms in the suspended condition which, if they get through into the beer, would do it harm.

7035. You think the primary cause of mischief and danger lies in the fuel?—Where arsenic can be found in malt, or beer made from malt alone, I think it is quite clear that the source must be the fuel. I know of no other source of any determinable quantity.

7036. The process of cleaning is a double process, screening and brushing, and there is a fan whereby this dust is separated?—That is so.

7037. Therefore there is a double cleansing process going on at the same time?—That is so, and that is done in most large breweries more or less perfectly according to the age of their machinery. The newest machinery will be naturally the most perfect. For many years past brewers have been devoting their serious attention to the thorough cleaning of their malt before it is ground.

7038. The only trace of arsenic you were able to find was in this dust?—This refuse dust.

7039. In a brewery where this cleaning process was carried on, badly and without proper care, this separating process might not take place?—That is quite clear. In the dust we only found 1·20th milligramme in 5 grammes. I do not know what percentage the dust is in weight to the whole of the malt, but probably not 1·10th per cent., so that you have to apply a very big factor before you can bring that quantity of arsenic into relation with the malt itself or to a pint of beer.

7040. I am pressing you on this point on the question of feeding of stock. You are aware, are you not, that large quantities of what is called "malt dust" is used for feeding stock. Is this malt dust that you said in your case is carried to a chamber elsewhere, ever used for the feeding of stock?—No, there is no nutritive power in it at all. It is dirt, dust, and filth of all kinds in a dry or powder form. What is commonly called "malt dust" is not dust at all in the sense I have been using the word "malt dust." Malt dust or malt culms or malt combings is the rootlets of the growing barley which are brittle after the malt is dried and which are knocked off and separated, and we, like all other brewers, sell that for the purpose of feeding stock, sheep more particularly. That I have found to be free from arsenic as far as our brewery is concerned.

7041. Are you aware that evidence has been given before this Commission whereby a very large quantity of arsenic has been found in what a witness termed "malt dust" which had been accumulating for many months in a kiln? I suppose under no circumstances such dust as that could be used for the purpose of feeding stock?—I would not like to say it could not be used for the feeding of stock, but I should say that the malt combings which accumulate underneath the tiles would be a very poor food and very unlikely to be used for the purpose. Where arsenic has been found in these malt combings or rootlets I think you will find that that will be concurrently with the use of an inferior fuel. If an arsenical fuel is used for drying the malt you will find more arsenic in proportion in the rootlets than you will in the malt, because arsenic comes up with the products of combustion from the fire, and the arsenic is deposited upon the malt as it goes through, and it will naturally, in proportion to the weight of the substance, be deposited in larger quantity on the rootlet than upon the grain which is large and comparatively heavy.

7042. (Mr. Cosmo Bonser.) I should like to ask a question with regard to the difficulties that this Com-

mission is in on the question of different samples having been analysed for arsenic, and of different chemists giving absolutely different results. We have had extremely variable replies to the same sample, varying from 1·5th to 1·50th, and, as a practical brewer, I was going to ask you whether you would think it possible that the difference in the sample being drawn from the top of the cask or the bottom of the cask might make some difference?—No, not in the case of the beer. I should say it would make no difference.

7043. I presume you use finings?—Yes, for most of our beer.

7044. What acid do you use for dissolving the isinglass?—Sulphurous acid.

7045. Not sour beer?—No.

7046. Those finings would fall, I presume, to the bottom of the cask?—Yes.

7047. Would not they collect a certain amount of arsenic or any impurity?—They collect all mechanical impurities, of course, and I am not prepared to say that they might not collect arsenical impurity. I do not think so, because I should look for the arsenic in solution. But I am not prepared to say it does not. On that subject of the differing results from different chemists may I point out that the determination of exceedingly minute quantities of arsenic is a very delicate one. It is not one that can be reduced to terms of an ordinary balance; you cannot get it out and weigh it like you can lime or anything of that kind. And these very minute quantities are reported upon the basis of certain appearances in the Reinsch or Marsh tubes, and a good deal depends on the personal equation of the analyst. I look upon it as very desirable that there should be some kind of exposition of a standard method to be devised by a committee of the very best and most accomplished chemists connected with the higher chemistry and our trade—a standard method applicable to beer and the other substances used in our business by which the appreciable quantity of arsenic which shall be considered objectionable shall be found, and so the product or the beer condemned.

7048. You would be prepared to accept one of the Government Departments to name that standard?—I should have far more confidence in a recommendation made by the Government Department in conjunction with a committee of experts outside the Department.

7049. I expect no Government Department would name a standard of that description without such a thorough investigation?—Then I would have perfect confidence in it.

7050. What is in my mind is that you may set a standard to-day which may be absolutely and totally inapplicable ten years hence. To-day's knowledge may be varied by something which may happen, and consequently you will want some Government Department from time to time to readjust the standard if necessary?—Under these circumstances I would have every confidence in a recommendation made by the proper Government Department.

7051. (Dr. Whitledge.) In issuing your circular to the members of the Country Brewers' Society on November 29th, did you suggest any particular test or standard?—No, that is not our business. I do not think the society is competent to make such a recommendation; we merely advised that they must not for their own safety use glucose and sugars without having them analysed.

7052. In your own case you have examined not only the beer, but all the ingredients, and only in one case, that of malt dust, you found arsenic?—That is so.

7053. Are we to understand that all the rest were absolutely free from arsenic?—Absolutely.

7054. No trace?—No trace.

7055. Were those results confirmed by the scientific advisers of whom you spoke?—No, I did not think it necessary to send my material to London or to incur any very great expense. I am a Fellow of the Institute of Chemistry myself, and my head brewer is at least as competent a chemist as I am—I should say much more so—and we considered ourselves quite capable of doing it at home.

7056. Had Dr. Moritz and Dr. Morris been advising the society before this recent arsenic question?—Generally for years. Dr. Moritz has been our adviser for a great many years; Dr. Morris only more recently, when he joined Dr. Moritz.

7057. In the case of the malt you buy, is that brushed

Loribond.

4 May 1901.

All malt at  
his brewery  
is brushed.

No guarantee  
as to fuel  
demanded in  
case of  
bought malt.

Guarantees  
of purity  
have only  
doubtful  
value.

Little  
demand for  
all-malt light  
beer brewed  
as in  
Germany.

before delivery to you or after?—I should say in the case of what I buy in Newcastle it is brushed, because they have a perfectly appointed malting, and they are very smart people. What I buy in one or two places I think probably will not be brushed, but run over a screen, but I cannot say with certainty. It will depend on the enterprise and perfection with which the maltster carries out his malting process.

7058. If it reaches you without being brushed, would it be brushed?—Yes; whatever is done to it beforehand.

7059. In bought malt, do you make any stipulation as to the fuel to be used?—No, I have never made a stipulation.

7060. Is it within your knowledge what fuel is used by the maltsters from whom you buy?—No. I simply confine myself to people in whom I have confidence, whose samples come up to the mark, and of whom I have some personal knowledge.

7061. The society are prepared to accept any precautions that seem necessary in order to prevent the risk of arsenic?—Yes. I feel sure that the society and the trade as a whole would cheerfully accept any reasonable precautions that did not involve the prohibition of the reasonable substitutes we have learned to use in the last 40 years.

7062. What sort of precautions are you thinking of—guarantees or analysis?—I do not think a guarantee is of much use. A general guarantee is practically a useless thing. A particular guarantee—that is, a guarantee with every delivery, is such a difficult and such a costly thing, that I think it would be not observed. It seems to me that the precautions that are required are to make the manufacturer of each material, whether it be beer or whether it be sugar, responsible for the quality of his substance.

7063. Make him legally responsible?—Certainly.

7064. Would you regard it as necessary for a brewer to analyse every malt he receives for arsenic in particular?—I certainly should now.

7065. Habitually and regularly?—Yes. After our experience of November, if a brewer does not take some steps to protect himself against arsenical contamination, accidental though it might be, he is not doing his duty to himself or customers.

7066. (Sir William Hart Dyke.) Would you have a penalty for not doing so, or would you place the penalty upon the result?—I think the state of the law itself is quite sufficient. People have been already fined very handsome sums for negligence in this respect. There is one very prominent instance in Northamptonshire and I sympathise very warmly with the result, where a board of directors and the brewer were heavily fined for not taking proper precautions.

7067. (Sir William Church.) I should like you to inform the Commission why light beers like German, Bavarian beers cannot be brewed in this country from malt and hops alone?—I am not prepared to say they cannot be; as a matter of fact, there are two or three breweries in this country where they do more or less successfully produce such beers. Tennants, of Glasgow, produce a very good lager, as do the Tottenham Brewery in London, all from malt and hops, I believe. The reason why one does not produce the light German lager beer in this country is mainly that there is no great demand for it.

7068. In Germany the use of sugar in those light beers is forbidden?—Only in certain parts of Germany. There are parts of Germany where maize is largely used, and other parts where malt alone is used. In Bavaria, I believe, the law is very strict.

7069. It is not a matter of difference in the preparation of the malt?—Do you mean the difference in the production of the character of the beer?

7070. Yes?—There is a difference in the preparation of the malt and the mode of drying, but the essential difference is in the mode of mashing or preparing the worts. They are prepared there in a totally different way to ours; the worts are boiled, and we dare not do anything of that kind, and the result is they get a more dextrinous wort than we do, which means a less fermentable wort. The result is, although they use light gravities, they get comparatively more fullness in their beer on account of using these less fermentable materials.

7071. You would not agree with another witness who told the Commission that he thought that cylinder dried malt was used for these light beers, and would not be applicable for our general brewing purposes in England?—I do not know what he meant by the expression "cylinder dried malt." The essential difference between German and English malt, as far as drying is concerned, is that the English malt is dried by the direct products of combustion of the coke or anthracite coal being passed through the kilns and through the malt, and our experience is that if we substitute for that the German system, where the products of combustion are passed through metal tubes and the heated air from those metal tubes is used as a drying medium, we do not get the same character and flavour of malt as when we use the direct products of combustion. If by cylinder dried malt he meant a process by which hot air without the products of combustion were passed through cylinders, then I say the difference is a very material one, and the hot air process is not applicable to our English malts. It has been tried many times, and dropped.

7072. So that in your opinion roasting malt, if I might use such a term, without the direct contact of the fumes, would not produce a malt suitable for brewing beer to the English taste?—No, it would not. It has been tried many times and I do not know of any instance where it has been successfully maintained.

7073. (Chairman.) Is it a flavour conferred by the fumes that is wanted?—Yes. It is too complicated a thing to explain. We do not know why the differences arise but we do know that we get flavour from the malt that is dried direct from coke and from coal different from that which is dried by heated air. Empyreumatic products may account for it to some extent.

7074. Would the peat-reck flavour esteemed in Scotland for whisky do for beer?—No, I do not think so. I do not know of any instance, and I do not think there is an instance where brewers' malt has been dried by means of peat, and I should like to point out that the peat-reck would be far too powerful a flavour to make it applicable. Whisky is distilled and the peat-reck in the whisky is only that portion of it which comes over in the still.

7075. Is the flavour from oven coke the same as the flavour from anthracite?—Yes, practically; they are both fairly pure forms of carbon and as long as they are sulphur-free they are practically the same thing.

7076. (Sir William Church.) I think I understood you to say that the main object in brushing the malt was to get rid of impurities of all sorts, but especially of the spores of organisms. Are these organisms which have survived the heating kilns? Is not malt exposed to a temperature sufficiently high to kill organisms?—The drying process is not sufficiently high in temperature to destroy those organisms which are in the stage of suspended activity. If you will take the living organism, living under moist conditions, and put him into a kiln. I think you would inevitably kill him. But if you take an organism in a dried and inactive condition, I do not suppose the heat of the kiln would destroy it. Boiling water will not always destroy it.

7077. What is the heat that malt is exposed to?—160° to 210° F. We can only get as high as 210. Some tell me they get to 220, but I have my doubts. If we get much higher than 210 we impart too much colour to the malt. The malt begins to caramellise, and we cannot get the pale colour and the delicate flavour essential to fine beers.

7078. But the malt for porter is dried at a greater temperature?—Yes, that is done at a much higher temperature direct over fires at a very high temperature indeed.

7079. (Chairman.) For porter could not the process be carried on entirely in cylinders without exposing the malt at all to the fumes of the fire?—The proportion of black malt used makes it immaterial whether it is dried by the direct products of combustion or heated air; the actual process is that a malt, after being malted and grown on the floor, is dried on a kiln in the ordinary way to a fair condition of dryness, but to be converted to black malt it is taken shortly before it is required for use to revolving cylinders and there it is roasted like coffee over a glowing hot fire and almost touching.

Mr. T. W.  
Loribond.

Mr. THOMAS EARP, called; and Examined.

7080. (Chairman.) You are a partner in the firm of Messrs. Gilstrap and Earp, maltsters, in Newark-on-Trent?—I am.

7081. You have represented Newark-on-Trent in Parliament, I believe?—I did.

7082. You have been connected with malting for over 50 years?—Yes.

7083. During which time gas coke, oven coke, and coal have been used as fuel for drying and curing malt?—That is so.

7084. Have you found strong reason to prefer one or other of these three kinds of fuel?—Not reasons of sufficient strength to create a very great preference until the recent difficulties arose. We have also found that coal gave us less flavour which might be regarded as objectionable, less sulphur flavour, that is to say; but beyond that there has been no reason for giving it manifest preference.

7085. The coal must have been anthracite, not bituminous?—Yes.

7086. And you found anthracite preferable in respect of flavour than gas coke or oven coke?—Yes, that gave a much cleaner flavour.

7087. The difference being that there is more sulphur in the gas coke than in the oven coke?—In the gas coke especially.

7088. You tell us that you have never heard of any injury arising from the use of malt until the discovery of the effects of using glucose, that then enquiries were instituted which led to a suspicion that malt might contribute arsenic to beer, but that before this epidemic you had no suspicion malt could introduce arsenic?—That is so.

7089. Did your firm take any steps when as a result of this arsenical poisoning suspicion was directed to malt?—We instantly turned our attention to using coal exclusively. We took steps to shorten, to some extent, the period of exposure of the malt to the fumes; we endeavoured to exercise greater care in the treating of the malt on the kilns, so as to detach entirely every particle of the rootlet. We also tried the effect of brushing to some extent.

7090. Had you not done so much brushing before?—We had not; that was always left to the brewer. He was considered so far interested that our aim was to deliver the malt in a fair condition from a commercial point of view, and if brewers had special fancies for extra cleanliness we expected them to exercise their own care.

7091. You merely took the rootlets off by screening?—We merely took the rootlets off.

7092. Your firm submitted samples of malt and subsequently of cokes and coals for analysis?—We did.

7093. With what result?—I do not know whether the Commissioners would like me just to go through these particulars; I should be glad to do so.

7094. Perhaps you will kindly give us a statement of the results in respect to the analysis of malts?—I will just mention these figures and endeavour to do so in such a manner as to show how we have dealt with the difficulty. In the first place the impregnation of barley by various fuels in the process of sweating became a question with us.

7095. That is the first process?—Yes, the first process to which barley is subjected. We generally sweat it on the kiln, for 24 hours, and then after it has had time to cool, say a fortnight, we steep it, and we have always found since we established this enquiry that any impregnation which barley received, being absolutely free from any taint previously to sweating, was lost at about the sixth day of the growth of the barley on the floors. That no doubt is partly the result of the washing and sparging of the grain when it gets into steep. After the growth has gone at a temperature of from 50 to 60 and whilst the barley is yet green, say after the 4th or 5th day, we found no trace whatever of impregnation by arsenic.

7096. Did you find some impregnation of arsenic from the primary kilning?—Yes; but we consider that is lost in the process of flooring the malt.

7097. Washed out in the steeping do you mean?—Yes. Also lost in the agitation, turning and working of the barley, but, I think, most is washed off in the steeping.

4576.

7098. The next process in which there is exposure to fuel is the drying and kilning in the malting?—That is so.

7099. Did you find arsenic introduced by the kiln drying?—Yes. We find in the various coals we have used an average anthracite gave one-seventieth grain of arsenic per lb. of coal. The same coal being used for various malts, we have found an average of 1/350th of a grain of arsenic per lb. of the malt. That is by the Marsh test.

7100. (Sir William Church.) There would be a variation in that from 1/50th to 1/100th?—Yes, in the coal. Now I come to the oven coke, which we find to give at the rate of 1/30th of a grain per lb. of the coke. And we find that the arsenic in malt corresponds very closely with that given by coal; 1/300th as against 1/350th of a grain per lb. of malt. Hence we conclude that oven coke is not an entirely unsafe coke to use. Gas coke gave different results. In what we have tried of gas coke it has been tried in combination with coal and this combined fuel has given us 1/200th of a grain per lb. of arsenic in malt. A sample of the gas coke alone contained 1/14th grain per pound. We have practically discontinued the use of both coals and we are relying on anthracite coal. These experiments have been made for direction in our own manufacture.

7101. (Chairman.) You did not find the oven coke sufficiently free from arsenic to allow you to use it with confidence?—Not so completely so as in the case of coal.

7102. And you have resolved now to use coal only?—Yes; we are using only coal.

7103. But oven coke you find compared favourably with gas coke?—Yes.

7104. Have you turned your attention to the question of extra cleaning and screening?—Yes.

7105. Are you entirely satisfied that the mischief already done is not to be entirely eradicated by any process of cleaning or screening?—When once done we do not find that by any means we can absolutely cleanse the grain.

7106. So that you look upon the use of any coal that contributes arsenic to the malt as involving a danger not to be overcome by any attention to the malt afterwards, such as brushing and screening?—My contention is that it is impossible to get it absolutely free, but one naturally concludes that as malt has been used from time immemorial, and apparently without danger or injury, it may be so used in the future if we only knew the exact point at which danger may come in. For that we are looking to the Commission to give us some information which may be valuable to us in endeavouring to avert any further catastrophe.

7107. (Sir William Church.) When you say from "time immemorial," can you tell me when charcoal ceased to be used?—A great deal of South country malt was dried with charcoal?—Charcoal has been used quite up to within 150 years ago. I spoke of malt as having fuel, been used from time immemorial, not coke.

7108. I thought you were using that as an argument of the fuel being free from arsenic?—The freedom of danger has existed since the discontinuance of the use of charcoal.

7109. That is not such a very great number of years ago, at all events in many maltings?—The great bulk of the malt has been produced by means of coal and coke drying for the last 200 years anyhow. No doubt charcoal is used, and I believe that peat has been used in old days.

7110. But 200 years ago would the bulk of the malt dried in the South of England or the Midlands be dried with coke or coal?—In the South of England coal I should think mainly. The nearer you come to the coal producing country the more coal is resorted to, and the earlier it was resorted to. But after the discovery of gas and the distribution of malting throughout the country, the various maltsters naturally relied on the nearest source of supply, which was a gas works. They were in ignorance of any danger arising from the use of it, and they simply used it—in fact, no danger was discovered and no injury apparently resulted.

7111. We have had a good deal of evidence that, comparatively speaking, few maltsters used gas coke because of gas coke giving a nasty taste to the malt?—That is

Mr. T. Earp.

4 May 1901.

Oven coke renders malt less arsenical than gas coke

Arsenic cannot be removed by brushing &c.

Use of charcoal as malting fuel.

Mr.  
T. Eorp.

4 May 1901.

the objection to it, but nevertheless it has been used and no doubt is largely used.

7112. Mixed I suppose with other coke or coal?—In some cases that would be so.

7113. (Chairman.) You have modified to some extent the period occupied in drying and curing malt?—We have been able to do that to some extent. During the last 15 or 20 years we have been generally using four days for the drying of malt, but in olden times, when I first knew the trade at all events, we never went beyond three days. The necessity for extending the time I think was brought about by the altered character of the beer preferred, and the use of sugar I think had something also to do with it. Malt has been made rather differently in order to work with sugar where it was thought desirable to use it. We used to make a more diastastic malt than we have made of late years, and in those days the three days' drying worked very well, but when less diastastic malt had to be produced we found a great advantage in slower drying in the first part of the process. In both cases we have had to use greater heat for curing and finishing.

7114. (Mr. Cosmo Benson.) Would the slower drying process give a larger increase of bulk?—Not necessarily. The quick drying in the old days would have the effect of promoting the growth of the acrospire in consequence of the malt being put on the kiln at a rather greater heat and forced a little, and the result was you got a greater bulk of lighter malt. Malt has been made heavier since the Malt Duty days.

7115. (Chairman.) Why made heavier?—I think it is the result of the better processes of brewing employed. More chemical knowledge being developed, the raw material has no doubt been used with greater care and with greater economy. To do that the extract producing properties of the malt have been increased.

7116. Have you tried some experiments in drying which might lead to some alteration in the construction of the drying kiln?—We have done that, but I am sorry to say we have lamentably failed to arrive at much advantage at present. We have tried also the effect of drying with gas, but that has been simply experimentally on a small scale.

7117. Producer gas or common gas?—Common gas. We have passed it through a burner recommended to us by Mr. Sugg; we get it as pure as possible and still we find a slight trace of arsenic, although it was but slight.

7118. As small as you have sometimes with anthracite?—Yes, quite as small as we have found with anthracite; I almost think rather smaller.

7119. So that you would consider gas a safer fuel than even anthracite coal in respect to arsenic?—I do not know that I could go as far as to say that, but as a matter of experiment we satisfied ourselves that we have a resource in the event of our being driven to it.

7120. Gas from different gas works made with different coals would be very different in quality?—That would be so. We are not without hope that the Mond gas which is now under examination very carefully, might possibly discover something very economical and effectual.

7121. You have not as yet had any opportunity of trying it?—No.

7122. It might be a great advantage if such gas could be supplied through a large district?—It might be of very great advantage, and we think it would. I am in correspondence with an electrician, a very old friend of mine, who is making some experiments with regard to the possibility of employing electric heat for drying, and if we had the Electric Power Companies sending heat direct from our coal pits into our kilns it would be a great triumph.

7123. Would the flavour from electric heat satisfy the customers of the brewers?—There is no reason why it should not I think.

7124. I am afraid if the flavour is wanted from the fumes of coal it would not be found there when electric heat is used?—We have brewing friends who contend that that flavour is not wanted. They are satisfied with a brewing material free from that.

7125. Have you yourself made any trials or otherwise had experience of drying the malt without allowing the fumes to have access to it at all?—Only experimentally. I tried it in a drum on one or two occasions long before the malting drums were in practical use,

but I was never satisfied with the flavour myself. One has been used to working up to a certain flavour. In fact, I have generally trusted my own palate to tell me what the flavour should be, and I think if malt had been as poisonous as some people suppose I should have been a dead man a long time ago.

7126. Have you ever tried a hot iron floor, non-perforated, to dry the malt on?—We have not tried that on a large scale, but we have put plates down just to try the experiment, and I am inclined to think that that may be a very advisable thing to try thoroughly.

7127. That would entirely eliminate arsenic from the malt so far as the drying in the kiln is concerned?—If malt is not allowed to have contact with the fumes from the coke or coal, that no doubt would be a very excellent plan.

7128. Would there be any great expense or difficulty in altering your present malt houses so as to dry without access to the fumes?—It would not be worth any consideration at all. We should simply substitute an iron tile not perforated for a perforated tile.

7129. Would that be easily done?—Easily done.

7130. You have not tried that on a large scale?—No.

7131. That would entirely get over the difficulty, and you could take whatever fuel is cheapest?—It would no doubt necessitate a modification in the system of turning. It would create the necessity for some structural alteration. We should be obliged to have machine turning in that case, because the plates would otherwise get so hot that they would char the malt.

7132. These technical matters are of great importance, but it might be easy to get over that by proper plates and air going between them?—I am quite satisfied myself there are no difficulties which might not be got over. It will largely depend on the disposition of the public to accept any decision which this Commission arrives at, and if the decision of the Commission permits the continued recourse to practices which have prevailed so long with great care against the accident of another Bostock difficulty, then intervention would not be necessitated. But if intervention and adaptation be necessitated, I am quite satisfied the difficulty can be overcome and a suitable article for brewing from can be obtained.

7133. Does the turning to which you refer on the drying plates have any effect whatever in keeping down the temperature of the plates? Suppose the turning is not practised, then certain grains of malt would remain longer in contact with the plates, and they might be burnt, the hotter the surface, the place would become.

7134. Do you think the iron plate itself would become come charred?—The longer the malt remained undisturbed, the longer the malt remained undisturbed?—Yes.

7135. Is the turning done by a man walking about over it?—Yes.

7136. He walks amongst the fumes?—Yes.

7137. Can he work a great many hours doing that, or is he obliged to come away pretty quickly so as not to be injured by the fumes?—They generally open all the windows of the malt kiln when they are turning, and let in all the fresh air they can. It is a process which they carry out very rapidly. They do not often leave their work before they have done it. On a kiln of say 30 quarters, you would get two or three men; on a 60-quarter kiln perhaps four or five men. They very soon turn it over, and with the windows opened no injury appears to be sustained.

7138. I have walked over a kiln on one occasion in which anthracite coal was used, and I perceived a very decided curious acrid odour from the fuel, but that does not give an injurious flavour to the malt?—Not at all.

7139. Do you attribute the flavour of malt to any Fumes benefit got from the fumes of the anthracite coal or necessary the coke?—No; I think it is simply the effect of the heat and air.

7140. So that any difference between drying inside a cylinder and upon a flat floor must be due to an influence of the heat on each grain which is different according to the air it meets in one way or the other?—I think so.

7141. So that if air was driven through the cylinders it might probably have the same effect that it has at present on the ordinary malting floor with open windows?—I think it might.

Experiments  
with coal  
gas in place  
of fuel.

Mr.  
T. Eorp.  
4 May 1901

Experi-  
mental malt-  
ing without  
access of  
fumes to  
grains.

901. 7142. It seems a very important matter, and if it is comparatively simple to get rid of the admission of the fumes to the malt, the very great difficulty spoken of in respect to arsenic would be entirely done away with?—I think any direction which went so far as to be a general order on that subject would be a danger, but I think experiments should be encouraged. The circumstances of the time will bring about the experiments. We have waited until we have finished our work for the season, when there are several things we, as a firm, shall try, and no doubt our neighbours will do the same.

7143. I hope you and your fellow-workers in the same field will make good experiments. This Commission cannot determine what is the best way of drying malt, but I think after what we all know now, and nobody knew a year ago, great efforts should be made to improve the mode of drying and, if possible, to get malt with the proper flavour without any access from the fumes of the fire whatever. We are encouraged to hope that from what you have said you do not think it will be a great difficulty, and not as one of the witnesses has said, entail enormous expenditure?—The suggestion made by yourself would not be an expensive matter; I mean to try iron plates not perforated. That could be done very simply. If it had not been for the question of the weight of carrying that out we should ourselves have tried it, but we thought it would not do to load the kiln with any additional weight. It might bring damage to the men.

7144. Thin iron,  $\frac{1}{4}$ th or 1-16th of an inch, would not add much to the weight?—I do not think sheet iron is what we shall want. I think we shall want cast metal plates; I think they would do the work better.

7145. I might suggest an experiment on the floors after suitable modification, and if you find you can get the malt properly dried and a proper flavour in that way, the process might be extended so as to suit even the fumes of bituminous coal?—Quite so.

7146. For twenty years past you have had your own laboratory, and employed a chemist in your business?—That is so.

7147. In face of the importance of the crisis through which we have been passing, you have resorted more especially to professional chemists in London and in Manchester for tests?—Yes.

7148. And for advice independently of the work done on your premises?—Yes. That has led to the formation of our determination to stick to coal until something better, at all events, was found out. It has not carried us much beyond that.

7149. You feel public spirited enough to say that you and your brother maltsters may be relied upon to co-operate in efforts to secure any advantages arising from ascertained possibilities of improvement?—That is the feeling I believe of the whole of the trade.

7150. (Sir William Hart Dyke.) With regard to this question of the non-perforated floor, I suppose it has not been really tried on a large scale, or sufficiently tried by maltsters for you to be able to form a very decided opinion?—No. I will tell you what has happened in a particular case. We had a little old kiln at one time with a quaint old-fashioned cast-iron tile, with slits instead of round perforations, and in process of time when it came into our possession we found that it had been somewhat neglected, and the little slits were all filled up with the broken corn and so on. I saw the heap of malt that was made in the kiln, and I was astonished at the excellence of it. It was made from very nice barley. Undoubtedly it had been practically like an iron floor, because the interstices had been closed up by neglect. Some old maltster had worked it for a time, and the turning of the grain was perpetually cutting certain corns, and the farina in a soft state had worked into the interstices.

7151. (Mr. Cosmo Bonsor.) No draught went through it?—Very little, indeed; and very decent malt was made.

7152. (Chairman.) That malt that you say was so good was made without any access to the fumes?—Yes, by accident, and it convinced me there was a possibility of making good malt in that way.

7153. You are sure the fumes had no access to that malt?—I would not say they had literally no access, but I mean to say there would be hardly any.

7154. And the malt was certainly good?—Yes, it was

good. We have of course been going quite in the opposite direction lately, in that we have been getting very expensive floors, German wire floors. I have no doubt Mr. Bonsor knows all about them, and their cost. They consist of wide of triangular shape, and the upper side of the triangle is the floor, and there is an admission of the air very freely from below where the angle exists. The floors are very open, indeed. When you are underneath them and the malt is off, the light is hardly impeded; they are so very open. We have been working in that direction entirely under the belief that it was a very great advantage; if we had suspected arsenic would show itself we might have gone less in that direction.

7155. (Mr. Cosmo Bonsor.) You have always considered that draught is necessary?—Very much draught.

7156. (Sir William Hart Dyke.) From below?—Yes.

7157. It is the same with hop drying?—Everything has been made conducive to that in all our schemes.

7158. The plan just suggested would be a direct reversal?—Direct reversal.

7159. You have not really had a proof of what the effect on the malting would be beyond this one instance you know of where it was a partial stopping?—No.

7160. It was not complete?—No.

7161. You are aware the heat would get through in a different way through these little cracks that were stopped up than through sheet iron a quarter of an inch thick; the process would be almost revolutionising the system where you have had a thorough draught from below?—Yes. The hot air would be excluded.

7162. (Chairman.) The fact that good malt was made in the case of the happy accident to which you refer, might perhaps point to as good a result as that happy accident which led to the invention of roast pig?—Yes.

7163. On the other hand if air must go through the malt in a way it would not do if it was placed in an unperforated floor might not a double floor be used, one a continuous iron plate, or possible tile plate to take the heat of the fire, and a well perforated floor such as that you have described for the grain to lie upon, a few inches above it, so that there would be ample circulation of hot air from below through the grating and iron cloth on which the malt rests?—I think it would be quite well worth trying.

7164. The main thing is to try whether or not the chemicals in the fumes are wanted, or whether hot air properly circulated through the malt on a flat perforated floor would suffice without the chemicals of the fumes?—Quite so.

7165. It would be a very different thing from turning it in cylinders, which I understand is the only process hitherto employed for drying the malts without access to the fumes?—That is so; I know of none other.

7166. I believe I have been told that some of the fine German lager beers are made from malts which have been dried in cylinders, without access to the fumes. I do not know whether that is correct?—I believe that is correct, but it is a different class of beer. Its treatment and methods of fermentation are different altogether. I do not know whether the difference in the beer might not be accounted for in that way. It is not the beer, I think, that the Englishman would care for.

7167. (Sir William Hart Dyke.) It is quite evident, is it not, that experiments in all directions will now be made, apart altogether from what this Commission may precisely seek to have adopted; you and others in your trade will be using all your experience in every direction to try and get security?—We have been doing it all our lives in one direction or another.

7168. You have been also cleaning your malt more than you have done previously, and it is assisting your customers?—Yes, we have done a good deal of that.

7169. As regards the purity and the protection of the public, those who drink beer, you would wish the liability to rest on the seller of the finished product?—There is no getting away from that, I think.

7170. You think that would be just and right?—Yes.

7171. You state here you considered you have reached a position in your manufacture which gives practical purity. With regard to that I suppose the security you consider to be behind you in that regard is really the fuel?—Yes. The employment of coal and the shortening of time. The three points are the adoption of coal, the slight shortening of the time of exposure,

and the extra treating and screening keeping it clear of rootlets.

7172. You wish us to infer, do you not, that the real protection is good fuel, anthracite coal, because I think you have said in your evidence that it is impossible, take what care you may, and use what you may, to get all the arsenic out of malt when it has been conveyed there by fumes?—That is so.

7173. Therefore your real security is the fuel?—That is our sheet anchor now.

7174. And that is the use of anthracite coal?—Yes.

7175. (Mr. Cosmo Bonser.) You used to dry on tiles, I think?—We did largely.

7176. (Chairman.) Perforated tiles?—Yes, earthenware tiles.

7177. (Mr. Cosmo Bonser.) You discontinued the earthenware tiles because the holes got blocked up and you did not get sufficient draught?—They were much more liable to block.

7178. And you did not get sufficient draught through your places?—That is so.

7179. You took the wire flooring from your kilns practically after the Ware system, and the idea of the Ware system of kiln was to get as near as possible to a chimney as could be devised?—That is so.

7180. And that is practically the kind of kiln you have at the present moment?—Yes.

7181. Consequently it would be more or less of a retrograde movement to go back to anything in the form of a closed chamber?—It would be that, undoubtedly, so far as pre-conceived ideas are concerned. The only question is as to whether the new conditions and new requirements do not necessitate even what appears to be a retrograde movement sometimes. We may have departed from the right whilst thinking we were going away from the wrong.

7182. I presume that the experiments you have had on your malt show that it is practically free from arsenic at the present moment?—Practically, at present, free. We have no complaint from day to day, and, moreover, there is a cessation of all the excitements and the deaths. If we had never had the Bostock misfortune I should not have the honour of appearing before the Commission at this moment.

7183. You would be prepared, I presume, to give to the brewer a guarantee of practical purity?—I do not say absolute purity?—Yes, practical purity—we are giving that.

7184. And you would be prepared to accept a standard of what is practical purity from one of the large Government Departments?—That is what we very much require. Nothing would please the trade generally more than to know what is expected of them, and what they may safely do, and I am sure they will do it.

7185. (Dr. Whitledge.) Can you tell us the exact terms of the certificate which you give of practical purity from arsenic?—I am afraid I could not remember. We have not adopted one particular formula. We

have varied it according to the exigencies of the case and the exactions of our friends. Some are content with simply a very thin guarantee; others are very exacting, and want something very safe. We have generally gone on these lines, and we have found it pretty generally accepted too, that we will guarantee that no malt shall leave our premises without our being satisfied that it is practically free from impurity.

7186. In speaking of arsenic derived from coal, you gave us figures showing arsenic in malt to the extent of 1-400th, 1-300th, and 1-350th?—Yes.

7187. Would you be prepared to give the certificate of the sort you named in connection with the samples containing, say, 1-300th?—Specifying?

7188. No; according to the examples you gave us, malt, in the preparation of which coal has been used, may contain 1-400th or 1-300th. Would you regard that as a sample of malt to which a certificate in the general terms you described would be appropriate?—Yes.

7189. You would not expect the brewer to understand your certificate to mean that there was not a trace of arsenic, even 1-300th of a grain to the lb.?—No, we should not expect that. There are so many uncertainties and there are so many difficulties even with regard to the purity of the particular material used in making the tests.

7190. (Sir William Church.) Who do you think ought to do the final brushing of the malt, the maltster or the brewer?—I hope that nothing will occur to place an obligation to do the final brushing in the malt kiln. We should want to extend our kilns very much, and we should have no end of difficulty if we had all that to do. Of course it is not an impossibility, and I fancy in some breweries there are machines which allow a certain amount of brushing to be done before the malt reaches the rollers. I think that is a safeguard to some extent, and that might be assisted by a little fan.

7191. I was not so much enquiring as to the way in which it should be done. We have had evidence before us—one brewer, if not more, said that he thought the final brushing was best done in the brewery, because they can judge better a sample of malt before it has had this final brushing than after it has. He went so far as to say that an inferior quality of malt well brushed might pass as a good sample?—I think the brewer may be trusted to find out that.

7192. You told us you had in your employment a chemist for 20 years. I presume that his business was really only to examine your materials for trade purposes. He did not examine them for accidental contaminations?—No, but in order to ascertain whether we were complying with the requirements of the chemistry of brewing.

7193. Whether your proportion of maltose was right or that sort of thing?—Quite so.

7194. You never examined for arsenic?—No.

7195. Or any other accidental impurity?—No, we never suspected anything deleterious.

Mr.  
T. Earp.

Mr. LAWRENCE BRIANT, called; and Examined.

Mr.  
L. Briant.

7196. (Chairman.) You are a brewers' analyst, and have been in practice as such for 22 years?—Yes.

7197. I believe you are also the author of a book on brewing?—Yes. I am the author of a *Laboratory Text Book for Brewers*, which has gone through two editions, and I think I may claim to have an intimate knowledge of brewing operations and of the materials which are used therein. Since the end of November last I have examined a large number of beers and the materials with which they are brewed for the presence of arsenic, the number so examined being considerably over 2,500.

7198. I believe you have been requested by the Chemical Manufacturing Section of the Brewery Traders' Association to make enquiries on their behalf into the presence of arsenic in their manufactures, and the precautions which are taken to prevent such contaminations?—Yes, and with that object I have visited the works of the firms connected with that Association, which, whilst not including absolutely the whole of the firms which supply brewers with preservatives, etc., is certainly representative. I have made enquiries into the methods of working, and though it is obvious that in some cases special processes are employed, the de-

tails of which the manufacturer does not care to disclose, yet every facility has been afforded to me for obtaining information upon all points bearing upon the questions at issue. I have also collected from my brewery clients a number of samples of preservatives, caramels, etc., which have been supplied to them prior to the end of November last, that is to say, before the possibility of arsenical poisoning by beer was realised. So that I have examined samples both from manufacturers and supplied direct to me through brewers. These latter samples represent, therefore, the normal output of such firms prior to any alterations which might have been made in their manufacture after the discovery that arsenic had been found in beer.

7199. What method of analysis did you adopt?—I have used the Marsh method, except at the commencement, when I used the Reinsch test. The Reinsch test, of course, is not as satisfactory in some respects as the Marsh, but it had the great advantage of being very simple and quickly performed, and at the commencement of the difficulty which occurred it was necessary to get through a large number of samples. Lately I have used the Marsh test almost exclusively. I have tried the Gutzeit test, and I have rejected it.

Mr.  
L. Briant.

By the Marsh test I am able to detect with ease the presence of 01 milligramme of arsenious oxide.

7200. In how much material?—In 50 grammes of material. When I speak of substances as free from arsenic I mean that no arsenic can be found by a test of the delicacy above named when operating upon about 50 grammes of the substance under examination. The substances into which I have made a special enquiry are:—(1) Hardening materials; (2) antiseptics; (3) finings; (4) caramelised preparations; (5) yeast foods. In considering the liability of the substances which I have specially examined to introduce contamination, it is necessary to recognise the relatively small quantities which are employed by brewers. Taking the maximum amount of ingredients used in ordinary brewing operations, it will be found that with most substances used the actual quantity introduced into a gallon of beer is extremely small, so that a very gross contamination of this material would be necessary to introduce any perceptible amount of arsenic into the beer.

7201. Can you give the Commission a list of the firms or companies invited to give samples of the various materials?—I can give you a list of the names. This particular manufacturing Section includes the majority of the chemical manufacturers who supply brewers with material. It does not absolutely include the whole, but for the purpose of preparing evidence for this Commission, I thought it best to secure samples from the whole of the manufacturers who supply brewers with chemicals.

7202. What are the hardening materials?—Hardening materials are used by brewers for the purpose of raising the mineral matter in their waters to certain standards. The amounts of hardening material added necessarily vary according to the character of the beer which is required, but the maximum amounts generally added are as follows:—

Sulphate of lime - - -	50 grains per gallon.
Sulphate of magnesia - - -	10 " " "
Chloride of calcium - - -	20 " " "
Chloride of sodium - - -	50 " " "
Potassium sulphate or chloride -	15 " " "
Kainit - - -	50 " " "

7203. What is kainit?—Kainit is a natural deposit supposed to have been derived from evaporation of an inland sea. It is obtained from mines in Stettin, in Germany. It is mined out of the ground. The coarser varieties of kainit are, I believe, used as a manure. The finer varieties are used for hardening purposes. In some cases they are purified first of all. In other cases they are used without any treatment. Kainit consists essentially of a mixture of potassium sulphate, magnesium sulphate, and sodium chloride.

7204. Are the quantities of the different substances given in this table the quantities of the substances habitually added?—Not the whole of them.

7205. One or the other?—One or the other.

7206. Something of all?—No, not exactly. It entirely depends upon the character of the beer. In some cases chloride of sodium alone would be used. In other cases kainit alone would be used. In other cases a mixture of sulphate of lime and sulphate of magnesia would be used, but in any case the total amount of hardening materials added would seldom exceed 50 grains per gallon.

7207. Is something of hardening material essential?—For certain classes of beer with certain waters.

7208. Is that to please the taste of the consumers?—Yes.

7209. Not to make the beer keep?—It does render the stability of the beer higher, undoubtedly. In Burton, the district from whence the most celebrated pale ales of this country come, the water naturally contains a large quantity of sulphate of lime, and a moderate quantity of magnesia salts. If we wish to brew a pale ale of Burton character in a district other than Burton we add to our water supply the salts which are deficient in that supply; that is to say, we add sulphate of lime and sulphate of magnesia.

7210. And does that make a perceptible difference in the flavour of the beer?—It makes a very great difference in the flavour of the beer. In fact, we cannot pro-

duce a high-class bitter beer without the presence of sulphate of lime.

7211. We shall be very much obliged if you will hand in a list of the persons or firms from whom you received samples, and whose works you visited?—Yes, I will do so.\* May I explain that the firms whose works I have visited do not by any means exhaust the firms from whom I have received samples. A number of samples have been received direct from my brewery clients; in fact immediately the possibility of the access of arsenic to beer was realised, practically the whole of my clients in the United Kingdom sent to me the whole of their materials, necessarily including their hardening materials and preservatives; so that I have, in that indirect method, analysed practically the whole of the preservatives, hardening materials, yeast, foods, and other materials which have been produced by English manufacturers.

7212. Sulphate of lime is added in the form of Calcium gypsum?—As a rule in the form of gypsum. In a few cases, in place of gypsum, an article called precipitated sulphate of lime is employed. It is employed in place of gypsum because gypsum is rather slowly soluble. When precipitated sulphate of lime is employed it dissolves almost immediately, hence it is sometimes used. Precipitated sulphate of lime is made by suspending chalk, or whiting, which is a purified form of chalk, in water, and adding to it sulphuric acid. The sulphuric acid decomposes the chalk and produces sulphate of lime, which deposits from the liquid. That sulphate of lime is washed, and is then supplied to the brewer, usually in the form of a paste, in which form it is very easily soluble, and is in many ways preferable to ordinary gypsum.

7213. Is it dissolved in the beer?—It is dissolved in the water with which the beer is brewed, and is carried forward into the beer.

7214. Then it is sparingly soluble?—Gypsum itself dissolves rather slowly, being soluble to the extent of a little over 100 grains per gallon.

7215. (Mr. Cosmo Bonser.) When gypsum is put into water the water takes up exactly the amount of gypsum that it can contain?—Undoubtedly, no more.

7216. Gypsum is a Derby spar, which practically makes the same water as the Trent, the waters used in Burton beers?—Yes.

7217. The spring rises in gypsum?—Yes. The gypsum which is added is mined out of the same districts from which the Burton waters are obtained, and instead of drawing our water from Burton we bring the gypsum to the water.

7218. (Chairman.) Is there a saturated solution of gypsum? Do you put in as much gypsum as the water will dissolve?—Not quite.

7219. It is not saturated?—It is not saturated. There are objections to complete saturation. We find that if we saturate our water with sulphate of lime the beers do not clarify as quickly as they otherwise would, or as quickly as we desire for the present class of trade.

7220. Do you also use common salt?—Yes, it is used. Salt, usually in the brewing of mild beers, not in bitter beers. The ordinary bar salt of commerce is that form of salt which is usually employed, just the same salt as we use on our tables.

7221. Other sulphates or chlorides are also used?—They are not frequently used; they are sometimes used.

7222. Is that for obtaining various flavours in beer?—For hardening.

7223. And also for flavouring?—Certainly. In certain districts certain particular flavours are desired. In certain districts waters containing large quantities of chlorides produce the desired flavour of beer. In other districts waters containing large quantities of sulphates produce the required flavour of beer. The brewer seeks to treat his water so as to produce a beer suitable to the particular district which he is supplying.

7224. Did you discover any arsenic in any of these substances?—I have discovered arsenic in a few of

\* Note by Witness.—This is the list referred to:—Boake, Roberts, A., and Co., Ltd.; Burgoyne, Burbridge, and Co.; Cafferata and Co.; Clowes, Walker, Limited; Collett, J. M., and Co.; Gillman and Spencer, Limited; Hallams, Limited; Kendall, F., and Son; Malto-Peptide Co.; Prentice Brothers; Vanguard Manufacturing Co.; Von Heyden's Chemical Co.

Mr.  
L. Brient.  
4 May 1901.

Mr.  
L. Brient.  
4 May 1901.

Kainit may be arsenical, but should not introduce material quantity of arsenic into beer.

the materials, but the amount has been extremely small. The largest amount of arsenic which I have found in any material has been in kainit. In that material I have found, approximately, '02 milligramme in 50 grammes of the material, that is to say, '0028 grain in a pound of kainit.

7225. That is grains of arsenious oxide, not so much arsenium?—Not the metal, but the oxide. Assuming that 50 grains of this material were present in a gallon of beer—and that is a very large amount, the maximum which would be present—then even if a material of the maximum impurity which I have examined were used, only '00002 grain of arsenic per gallon could be introduced into the beer. The amount introduced is so small that it is practically negligible.

Epsom salts.

7226. The other materials mentioned under this heading contain no arsenic, or less than the above-named amount?—Yes, I have found a small amount of arsenic in some samples of commercial Epsom salts. The amount of Epsom salts which a brewer uses is very small. I have never found more than '01 milligramme of arsenic in Epsom salts, and, calculated out, based on the amount which an ordinary brewer uses, it comes to the fifth place of decimals; and when we remember that Epsom salts are used in very large quantities, without particular danger to ourselves, medicinally, one cannot think that the use of three or four grains per gallon of Epsom salts can be of much matter when one is in the habit of taking  $\frac{1}{2}$  ounce of Epsom salts.

7227. (Mr. Cosmo Bonsor.) Do you recommend Epsom salts to be used in beer?—I do not, personally.

7228. (Chairman.) Is it according to the taste of the consumers in certain districts that Epsom salts is added to the beer?—It is derived from this, that a certain small amount of magnesium salts is undoubtedly present in some of the Burton waters, and brewers who are endeavouring to produce beers of Burton type perhaps too slavishly copy all the ingredients which are present in the Burton water.

Kainit.

7229. If kainit is a natural earth and occasionally contains arsenic, may not particular masses of kainit be notably arsenical?—That is possible. I can only say I have examined, I believe, about 28 samples of kainit drawn from breweries all over the kingdom, and I have not found any arsenic in 25 out of the 28. But in three I have found arsenic. The largest amount of arsenic which I have found in any of those is, as I have stated, '02 milligramme, in 50 grammes, equal to '0028 grain per lb., an amount which, I think, is quite negligible.

7230. Is kainit used by a great many brewers?—A considerable number of brewers are using kainit.

7231. Do the brewers get it chiefly direct from Germany, or do they buy it from sellers of chemical materials in England?—Most usually from sellers of chemical materials.

Preservatives used in beer.

7232. What do you say as to antiseptics?—The greater proportion of preservatives used in beer consist of preparations of sulphites, the active agent being, of course, the sulphurous acid (sulphur dioxide) contained in the sulphite. In addition to sulphites, small quantities of salicylic acid are sometimes employed. The quantities in which preservatives are added are quite small, and may, I think, be fairly taken to be as follows: calcium, sodium, or potassium sulphite are used at the rate, usually, of one ounce per barrel of beer. This is equivalent to about 12 grains per gallon. In a few and quite exceptional cases, as much as  $1\frac{1}{2}$  ounces per barrel may be used. Of liquid sulphites bisulphite of lime is that most generally used, and is the oldest preservative. It was used before any of the solid sulphites were introduced. The amount of that employed varies very considerably indeed, but generally lies between 6 and 10 fluid ounces per barrel; this is equivalent to about the same actual addition as of solid sulphites. Other special forms of liquid sulphites are supplied to brewers, and of those from 2 to 4 ounces per barrel are added, which are really equivalent to the same amount that I have above named of solid sulphites. Salicylic acid is used to the extent of  $\frac{1}{2}$  or  $\frac{1}{4}$ , or, in exceptional cases,  $\frac{2}{3}$  of an ounce per barrel, usually half an ounce per barrel, that is, to the extent of 6 grains per gallon. So that it is quite clear, in view of the very small quantities of these materials which are added to beer as preservatives, the very grossest contamination must have taken place to introduce any appreciable amount of

Sulphites.

Salicylic acid.

arsenic into beer. All these preservatives, so far as I have been able to ascertain, have been made with every reasonable care, and from commercially pure chemicals.

7233. I believe you have some information to give us with regard to sulphuric acid in this connection?—Sulphites, the basis of practically the whole of the preservatives supplied to brewers, are produced, of course, by the aid of sulphurous acid, and sulphurous acid is made by one of three methods. First, by the burning of sulphur; second, by heating sulphuric acid with sulphur; and third, by heating coke or charcoal with sulphuric acid. All of the makers of sulphites in England use one of these three methods. In every case of the factories which I have visited, the resulting gases are passed through a washer or scrubber before they are led into the saturation vessel, the vessel in which the sulphite is prepared. I found from direct experiments, a number of which I have made in my laboratory, and on a larger scale in the works, that if arsenic were present in the original acid it is entirely separated when the gases pass through the washer. In fact, the arsenic, if present, is held back in the washing vessel. Every manufacturer, so far as I have been able to ascertain, uses a washer for his gases, and therefore every manufacturer practically secures himself against any arsenic being carried forward into his products. The arsenic which is present in any preservatives, if it is present, is therefore not derived from the sulphurous acid. As a matter of fact, the sulphuric acid which is used in making sulphurous acid is, so far as I can ascertain, and has been, of very good quality indeed. In most cases it has been pure to the fourth place of decimals. I found on examining the books of some manufacturers whose works I have visited, that they have consistently, not lately, but for two or three years past, made examinations of the acid which they have employed, that they have tested for arsenic in the acid, and that they have only used acid which has been reasonably—I will not say absolutely—free from arsenic. The largest amount of arsenic which I have found in any of the sulphites has been '02 milligramme per 50 grammes, that is equivalent to '0028 grain per lb. As only about 12 grains of such a preparation is used in a gallon of beer, the actual amount of arsenic introduced would not exceed, in the worst sample which I have examined, '000004 grain per gallon; in fact,  $\frac{1}{200000}$  grain, which is, of course, quite negligible.

7234. That we may consider as quite negligible?—I think so.

7235. In the case of a beer likely to go sour, might not a much larger quantity of bisulphite or other preservative be added?—It is unlikely. The amounts which I have given you are the maximum. A very large number of brewers do not use as large an amount as I have stated, that is to say, 1oz. per barrel of solid, and 6 to 10oz. of liquid sulphite. It is most unlikely that in any considerable number of cases larger quantities of sulphite than that given would be used. As a matter of fact, if larger quantities were used they would communicate a flavour to the beer, and would render it objectionable. The public taste would not permit larger quantities to be employed.

7236. (Sir William Church.) Is boracic acid ever used as a preservative?—I have made enquiries as to that from practically every manufacturer in England, and they all deny that boracic acid has ever been sold by them as a preservative for beer.

7237. (Mr. Cosmo Bonsor.) Salicylic acid is very little used?—Very little.

7238. It is used more for cleansing vessels and casks than for beer?—It may be used for that purpose. The amount of salicylic acid used is very small. The main preservative relied upon by brewers is some form of sulphite.

7239. I take it that in mentioning salicylic acid you mention it because it has been supplied to brewers, but it does not necessarily mean that it has gone into the beer?—No, but it is sometimes added direct to beer.

7240. It is more used for cleansing purposes, for getting rid of bad yeast that has impregnated wood in any form than for any other purpose?—Yes, it is a most powerful disinfectant, and for that purpose is most useful in destroying infection which may have occurred in wooden vessels. It is supplied to brewers, though it is not the main preservative upon which brewers rely.

7241. The principal preservative is bisulphite of lime?—Yes.

Mr.  
L. Brient.  
4 May 1901.

Manufacture of sulphurous acid and its freedom from arsenic.

Boracic acid not added to beer.

Salicylic acid seldom.

Mr.  
Briant.  
ay, 1901.

7242. (Sir William Church.) With regard to salicylic acid being used for disinfecting and cleansing purposes, what has led brewers to use it for that purpose? It is not so powerful a germicide as many other things which are known?—No, not so powerful, for instance, as mercury, but we should be afraid to use a mercury salt in the interior of a fermenting vessel which was subsequently to be filled with beer.

7243. That is the very reason I asked you the question. It is used as being a germicide, and as one that is not poisonous?—Certainly.

7244. Except in very large doses?—Yes, that is the point. We wish to disinfect our vessels, which are subsequently to be filled with beer, and although we may wash the preservatives off we could not ensure that every trace of preservative was removed; therefore, though we all admit that mercury is one of the most powerful germicides, its use would be inadmissible and inappropriate for cleansing vessels which are to be subsequently filled with beer.

7245. (Chairman.) Is carbolic acid used in any cleansing?—It is not used in any vessels which are to be filled with beer or wort. Carbolic acid may be used on the floors but not added to the beer. The smallest quantity would absolutely ruin the flavour of the beer.

7246. Besides preservatives, there are what are called finings. Have you anything to say about these?—Finings are made from isinglass, the swimming bladder of the sturgeon, and the commoner sorts are made from soles' skins. Some very fine samples are made from gelatine. The finings are, as we technically term it, "cut," that is, semi-dissolved by treatment by means of an acid. The acid employed for cutting or dissolving finings in very many cases is sulphurous acid. In some cases tartaric acid is added, as well as sulphurous acid. Sulphurous acid, as I have previously mentioned, is practically arsenic free, and the use of sulphurous acid is therefore not open to any objection. Tartaric acid is used in the preparation of some finings, and tartaric acid undoubtedly does, in some commercial samples, contain traces of arsenic. There is no doubt that it is an extremely difficult thing to get commercial tartaric acid which is absolutely arsenic free by the very rigid test to which we subject materials at the present time. For that reason personally I think it would be wise to reject the use of tartaric acid entirely from the preparation of finings. This is, however, only my own individual opinion. It is quite easy to make finings without their employment, in fact, in my opinion better finings can be made without the use of tartaric acid than with. Assuming that tartaric acid has been used, and assuming that it has been used in the proportion of 1 lb. of tartaric acid to every 7 lbs. of isinglass, together with 1 gallon of sulphurous acid of 5 per cent. strength, these materials would be sufficient to make a hoghead of finings. Before the hoghead of finings was used, it would be diluted with either water or beer, with an equal bulk, making two hogheads of finings, and then of that diluted material one pint to one quart would be added to each barrel of the beer. Taking the maximum amount of one quart and the quantity of tartaric acid used as that which I have named, the amount of tartaric acid introduced would not be more than 15 grains per gallon of finings, whilst the amount of sulphurous acid would be approximately half that. I have examined a considerable number of samples of finings for arsenic, and I have found a minute trace of arsenic in two of them. The worst sample that I examined contained arsenic to the amount of '016 milligrammes per 100 c.c., equivalent, that is, to '011 grains per gallon. Assuming these finings, which are the very worst that I have come across, to have been used in the maximum amount mentioned, the amount of arsenic which could be introduced into a gallon of beer would be '00007 grains per gallon. It is quite clear that whilst a very minute amount of arsenic, quite a negligible amount, might be introduced by the use of tartaric acid, the amount which would be so introduced would be nothing compared with the amount which must be commonly taken in the ordinary baking powders of commerce, most of which are prepared with tartaric acid. The amount of tartaric acid present in those must be enormously greater than can be present in beer.

7247. What is the largest amount of arsenic that you have found in tartaric acid?—I have not examined a very large number of tartaric acids. I have examined the finished products in most cases. But I have a few samples of tartaric acid which I have examined. I have one sample of tartaric acid which contained approxi-

mately one-fiftieth of a grain of arsenic per lb. of tartaric acid.

7248. Is that the greatest amount?—I have one further sample which contained one-thirtieth of a grain of arsenic per lb. Those are the largest amounts. The amount of tartaric acid used by a brewer in the preparation of his finings is, of course, very small indeed.

7249. The arsenic so introduced would be negligible in beer?—Absolutely negligible. At least I gather that as regards when you come to 1/10,000th of a grain per gallon it is negligible.

7250. Why should you use tartaric acid? Is it not more expensive than sulphurous acid?—It is not a question of expense, it is a question of convenience, and of quickness in cutting. Tartaric acid is found to cut finings to make them ready for use more rapidly than sulphurous acid, and for that reason perhaps has been used. The most practical brewers are of opinion that very rapidly prepared finings are not always the best finings, and that a slower method of preparation will often give a really more efficient article, and a great number of brewers now from choice prefer the sulphurous acid-made finings.

7251. How is the tartaric acid applied?—It is dissolved in water, and applied to the isinglass?—The isinglass is first of all washed, and soaked in cold water until it swells up. We then add the tartaric acid, which may be previously dissolved, or, in some cases, has not been previously dissolved, and a certain amount of 5 per cent. solution of sulphurous acid, that is, if we are using tartaric acid and sulphurous acid. The isinglass is allowed to remain in this acid solution, and slowly cuts, as we term it, that is to say, becomes disintegrated. Whether it truly dissolves or not is a question which is much disputed. It forms a sort of jelly-like mass.

7252. But is it not a jelly-like mass when it is moistened with water?—No, it is not the same form at all. It swells up into a solid jelly mass, but on cutting with finings it breaks down into a liquid, through which very minute particles of gelatine or isinglass are suffused in a state of semi-solution. We believe it is not true solution.

7253. If you filtered that through an ordinary filter, or blotting paper, would the isinglass be kept back?—Yes.

7254. As it is, it remains suspended in the water?—Yes. When we add that to the beer, then the yeast and other matters suspended in the beer attach themselves to the finings, and agglomerate into one solid mass, and fall through the beer and fine the beer, rendering it quite clear.

7255. Is the beer poured off, or is the sediment removed from it?—It depends upon the class of trade done. For the London mild beer the finings are worked out of the top of the cask, out of the bung hole. The finings are added to the beer, and the gas in the beer buoys up the finings, and they work out of the bung hole. The consequence is, you get a cask of absolutely brilliant beer. In the provinces generally the finings are allowed to work downwards instead of upwards and remain deposited at the bottom of the cask.

Outside London sediment after fining remains in cask.

7256. How is the beer cleared?—Is it drawn off with a syphon or just left?—In an ordinary cask the tap hole is an inch or so above the bottom of the cask, and in that way the finings and the deposit are not disturbed.

7257. So that the beer is left on the lees, as it were, and drawn off gently from the top from above?—Yes, except in the London trade, when the finings are worked out.

7258. (Mr. Cosmo Bonsor.) London finings are never made with tartaric acid?—No.

7259. They are made with sour beer?—Yes.

7260. In the case where the finings work through the top, the isinglass is cut with sour beer?—Almost invariably.

7261. (Sir William Church.) That is to say, with acetic acid. Why is acetic acid not used for finings?—Sour beer, of course, consists of a mixture of acetic and lactic acids. Brewers are of opinion that the most effective finings are those made with sour beer.

7262. (Mr. Cosmo Bonsor.) It is a quick process?—Yes.

7263. (Chairman.) Is not sour beer dangerous?—That is the reason why such finings are not so much used with stock beers as they are with beers which are consumed very quickly.

Mr.  
L. Briant.  
4 May 1901.

be cut  
arsenic  
tartaric acid.

out of  
found  
tartaric

Mr.  
L. Briant.

4 May 1901.

7264. The sour beer does not leave a bad flavour?—No, the amount introduced is so small.

7265. (Mr. Cosmo Bonser.) In examining finings under a microscope they are practically all small particles?—Yes, in a very minute state of subdivision.

7266. The fining of beer with isinglass dissolved in acid is quite a different process to what fining wine by eggs is?—Quite a different process.

7267. (Chairman.) What do the finings do? Is it the gelatinous matter that causes the material that you wish to take out to stick to itself?—The finings, which are in a state of semi-solution, when they are added to the beer, are thrown out of solution and pass downwards or upwards through the beer, according to the method of fining, carrying with them any matters which are suspended in the beer, leaving the beer brilliant.

Manufacture  
of caramel.

7268. What about caramel?—Most caramels are made from glucose. In many cases liquid glucose is used for this purpose, sometimes solid. American and sometimes German glucose is employed. Some caramels are made from cane sugar, not from glucose. All the manufacturers of caramel from whom I have made enquiries deny that inferior glucose is in any case used by them. They inform me that it is necessary for their purposes to use a thoroughly high quality glucose, and such glucose they always buy. The amount of caramel added in the case of black beers may, in exceptional cases, be as much as 8 per cent. or 10 per cent., but usually it does not exceed 6 per cent.

Proportion  
of caramel  
used in beer.

7269. Eight per cent. to the volume measure?—Of the amount of materials employed.

7270. So that there would be 8 or 10 volumes of caramel to 92 or 90 volumes of beer?—No, to 90 volumes of malt and other sugar. Ten per cent. is the expression of the equivalent in what we term a grist of materials used for producing the beer.

7271. The caramels are to be used in brewing?—Yes.

7272. And put in before the brewing is completed?—put in at the commencement of the brewing?—After the wort is drawn off from the malt into the copper. The amount of caramel used in some cases is as high as 8 or 10 per cent.

7273. Eight per cent. of the wort?—Eight per cent. of the materials used for producing the wort. Supposing you have a grist of 50 quarters of malt, 8 per cent. of 50 quarters would be equivalent to 4 quarters of caramel.

7274. Then there is a great mass of water over and above that—the materials are put into water?—The caramel is generally added to the copper, and is not added to the mash tun at all. After the malt is exhausted in the mash tun the amount of caramel which is deemed necessary is added to the copper.

7275. (Mr. Cosmo Bonser.) Take a 50 quarter grist; 40 quarters of malt, 8 cwt. of sugar, 8 cwt. of caramel would make a 50 quarter brew?—That is so.

7275a. That, I take it, is the material with which the beer is commenced?—That is so.

7276. The malt is put into the mash tun, water is added to the malt; the product that comes from the mash tun is pumped into the copper, where the hops and the caramel and the sugar are added?—That is so.

7277. (Chairman.) I do not see the percentage yet. What does the 8 per cent. refer to?—It is 8 per cent. of the excise brewing.

7278. I am afraid I do not understand, and I would like to know what it means?—I will be very pleased to work out an exact example for you.\*

7279. How is caramel prepared?—Caramel is prepared from glucose, sometimes from cane sugar, and is prepared by heating, by "caramelising," as we term it.

7280. It is prepared in the purification of sugar, when it is conducted at a certain temperature?—Cara-

mel is not a by-product of the purification of sugar. It is specially prepared.

7281. But does it not also occur in the preparation of sugar by some of the older processes?—There is no doubt that the exposure of sugar solution to a high temperature, as used to occur before vacuum pans were used, did produce a certain amount of colouring of the sugar.

7282. That was not done by design, but now you make caramel by design?—Yes.

7283. How is the caramel used?—The caramel used by brewers is either a thick viscid liquid, which will only just pour, which has a specific gravity of about 1.500, or in the solid form, more usually in the liquid form. The solid form is about one-fifth stronger than the liquid. The whole of the caramels that I have been found in able to obtain have been tested for arsenic, and I have found no arsenic in any caramel of English manufacture. I have found arsenic in two samples of German manufacture, in no case exceeding one-hundredth of a grain per lb.

Arsonic  
found in  
German  
caramel.

7284. My questions with regard to the percentage were absolutely necessary in order to understand how much arsenic one-hundredth of a grain per pound of caramel could introduce?—Just so. Assuming that in the production of a black beer caramel was used to the maximum extent, then not more than 4oz. of caramel could be used, and taking the very worst example of caramel which I have ever examined, the caramel could not introduce more than 1-400th grain of arsenic per gallon to the beer. But such a caramel as I have mentioned (the German-made caramel containing arsenic) would not be used by a brewer. Every brewer would reject it.

7285. Reject it now. But had caramels ever been tested before for arsenic?—I think not.

7286. Is there any knowledge of sulphuric acid having been used in the manufacture of caramel?—Sulphuric acids are not used in the manufacture of caramel. Caramel is made by heating glucose, or cane sugar, either by itself, or sometimes by the addition of ammonia salts, such as carbonate of ammonia or carbonate of potash—that is by the addition of alkali, but not of an acid, to sugar or to glucose.

7287. Going beyond beer, to which this Commission is not limited, it becomes a very important question to know whether caramel is liable to be contaminated with arsenic. The caramels that you have examined, which have been made for beer, are the same as the caramels that are used for general food?—I believe that many of the caramels which are supplied to brewers are also supplied to the public.

7288. They are largely used?—They are very largely used, of course, for colouring purposes.

7289. Is there any risk of what are called yeast foods becoming contaminated with arsenic?—There are two sorts of yeast foods used, yeast foods which consist practically of phosphates and yeast foods which consist of nitrogenous matters. The yeast foods which consist of phosphates do, in one or two cases, contain minute traces of arsenic. The amount is very small, but they do, undoubtedly, contain it. I believe that is derived from the phosphates themselves, for so far as I have been able to ascertain it is extremely difficult at the present time to get any phosphate of commerce which is absolutely free from traces of arsenic. Almost the whole of the phosphates of commerce I believe contain minute traces of arsenic. Therefore, yeast foods which are made with phosphates are liable to contain a very small trace of arsenic. But when one considers the amount of yeast food which is used it becomes apparent that the danger of poisoning is nil, because the amount of phosphatic yeast food which is employed is not more than 1lb. to thirty barrels of wort or beer. The yeast food is added during the fermentation. The yeast food does not consist entirely of phosphates, but of a mixture of phosphates and such substances as malt, pea or bean flour. In two samples of phosphatic food I have found traces of arsenic. The largest amount found has been .02 milligrammes, which is a very small amount; and in view of the very small quantity of such food which is added to the beer I think the amount is quite negligible.

Yeast food

Phosphate  
may contain  
arsenic,  
but this  
proportion  
in beer very  
small.

\* Example.—A 20 quarter brew of black beer might consist of 15 quarters pale malt, 2 quarters of black malt, 1 quarter of amber or crystal malt, 2 quarters of sugar; total, 20 quarters. Now, 2 cwt. of caramel is approximately equal in colouring power to 1 quarter of black malt. If, therefore, one-half of the black malt were replaced by caramel, we should use 2 cwt. (= 1 quarter of black malt), and should speak of the proportion of caramel as 5 per cent. in the total grist.

7290. Are the words "yeast food" technical words in breweries?—The liquid or wort extracted from the malt in which yeast grows is sometimes deficient in certain of the constituents which the yeast requires for its nutriment. Being deficient we add to that wort a food.

Yeast food

7291. A food for the yeast to draw upon?—Yes. Just in the same way that we might add to the ground certain manures for supplying the plants with their food, so we sometimes add food for the yeast plant. Those foods are either phosphatic or nitrogenous. In the case of phosphate yeast foods, minute traces of arsenic have been found, but so minute as to be practically negligible, remembering that only about 1lb. of phosphatic yeast food is added to thirty barrels, or 900 gallons, of beer.

7292. Since the epidemic, brewers have demanded the phosphatic yeast foods to be free from arsenic?—Absolutely arsenic free. There are also nitrogenous yeast foods. These are made in some cases from malt rootlets, in others from some nitrogenous material, the source of which I do not know. The nitrogenous foods made from malt rootlets are made entirely from malt rootlets which have been dried with anthracite coal, and have always been so made because it was found that the flavour was injured if rootlets were used from malt which have been dried with gas coke. The malt culms which have been used have been always practically free from arsenic, and inasmuch as the amount of yeast food added is only about 1lb. to twenty or thirty barrels, sometimes considerably less, it is quite clear that the amount of arsenic introduced is perfectly negligible.

7293. (Dr. Whitelegge.) Is not a considerable quantity

of arsenic found sometimes in sodium phosphate?—That is so.

7294. I have an example before me which was found to contain .072 per cent., or five grains of arsenious oxide per lb. That is a much larger quantity than you have met with?—Much larger.

7295. So that on that basis a material increment of arsenic might occur in the beer?—Undoubtedly. It is very difficult to get phosphates which are absolutely free from arsenic at present.

7296. (Chairman.) Is that because of sulphuric acid having been used in the preparation of the phosphates?—Yes, I believe so.

7297. In general, are the firms which you have visited taking precautions as regards arsenic?—They are taking every precaution which they are able to take. In every case they have chemists who test the products which they make. The whole of the materials as they come into the works are carefully tested before they are accepted, and every precaution which can be taken is now being taken.

7298. Are they asked to guarantee their products as arsenic free?—Almost invariably.

7299. And do they do so?—They do so.

Mr.  
L. Brant.

1 May 1901.

Manufacturers of brewers' chemicals now taking precautions to exclude arsenic.

and guarantee their chemicals to be arsenic-free.

## FIFTEENTH DAY.

WESTMINSTER PALACE HOTEL.

Friday, 10th May, 1901.

PRESENT:

Sir WILLIAM CHURCH (in the Chair).

Prof. THORPE.

Dr. WHITELEGGE.

Mr. COSMO Bonsor.

Dr. BUCHANAN, Secretary.

Mr. EDWARD WILLIAMSON, called; and Examined.

7300. (Chairman.) You are the Secretary of Bostock's and Co., Ltd., I believe?—I was the Secretary of the late Company.

1901. 7301. They are now in liquidation?—That is so.

7302. And you are desirous, I think, of putting in a statement to the Commission?—Yes. In view of this action which we have entered against Messrs. Nicholson; perhaps it would be better if I were allowed to hand in a written statement. If questions were asked they might lead in some way to a prejudice of the case pending.

7303. This, I believe, is your written statement?—Yes; and with your permission I will hand it in.

7304. Since it was printed, I think, your statement has received some manuscript corrections?—Yes; that is, slight alterations.

7305. And you are therefore content that this as it now stands should go in to the Commission?—Yes.

7306. The Commission do not propose to in any way cross-examine you upon your statement, but there are a few questions bearing upon it which we wish to ask you. We understand that there is a considerable amount of glucose and invert sugar which is contaminated with arsenic still in possession of the liquidators?—Yes; that is so.

7307. Besides that which was left on your hands, I understand that some is what has been returned to you from the brewers whom you had supplied?—Yes; that is so.

7308. Could you give the Commission any idea as to how much there is?—At present I think we have about 700 tons.

4676.

7309. (Prof. Thorpe.) Do you refer to both glucose and invert?—Yes.

7310. (Chairman.) Has any been disposed of since it was found to be contaminated?—About 100 tons altogether.

7311. In what way?—We have disposed of it for textile purposes to calico printers who use it, to tanners and curriers, and we have sold it to various drysalers as middlemen. We have, however, stated on the invoice that it was contaminated with arsenic and unfit for food and drink purposes. We thought at the time we might sell it on those lines.

7312. (Professor Thorpe.) Have you sold both invert and glucose?—No, glucose only.

7313. (Chairman.) With no other safeguard except your statement that it was contaminated with arsenic?—That is the only safeguard.

7314. The sale was made on behalf of the liquidators, I suppose?—Yes, principally, the liquidators were not appointed until the 1st of April, and that was on account of the Official Receiver.

7315. Do you know whether the liquidators propose to take steps to sell it in the same way or in any other way?—That is their intention.

7316. Is there no way by which the public could be more safeguarded from accident? We know some of your sugar was used by children to make toffy, and with bad results?—We were not aware of that.

7317. They took it from a brewer, and they might in the same way take it from a leather-dresser's store?—If you think it necessary, or can suggest any other method

Mr. E. Williamson.

10 May 1901.

Sale of arsenical glucose as such.

Mr. E. Williamson. of safeguarding the public, I have no doubt it will be done.

10 May 1901. 7318. It is not for the Commission to suggest; I ask you whether you would make any suggestion on the point?—I really do not know what other safeguard we could adopt; that is, if it is intended to be sold at all. Of course, it could be destroyed.

7319. 700 tons of poisonous substance I suggest to you is a very dangerous thing?—Yes, if there is any chance of it getting into a food product it would be dangerous.

7320. Is there any way in which it could be stained so that nobody should think of using it for food? Is there any means by which it could be made disagreeable to the taste?—If you did that you might render it useless for textile purposes; that is the only thing which occurs to me.

7321. (Prof. Thorpe.) It is quite conceivable to make it repulsive by the addition of small quantities of material which would not affect its use for commercial purposes as you suggest, but would entirely prohibit it from being used as food?—If that can be done, I have no doubt it will be done.

7322. (Chairman.) I do not think it is for the Commission to suggest that, but I think it is a part of the Commissioners' duty to suggest that this substance should not be parted with by Messrs. Bostock, or by the liquidators, except with such precautions as are necessary to guard against accident from its use?—Yes, that is a matter which I will put before the liquidators for their consideration before they dispose of any more.

No action by M.O.H. regarding Bostock's arsenical sugars. 7323. (Dr. Whitelegge.) Has the Medical Officer of Health for Garston been consulted about this stock?—He has not.

7324. He has taken no action in the matter?—No.

7325. (Chairman.) I put this before you. I think before this substance is parted with the Commission

ought to be informed as to what steps it is proposed to take?—Very good, sir; I will see that you are informed.

7326. I think you received a letter from the Commission, dated 19th Feb., in which the Commission stated that they would be obliged if you would inform them at an early date of any proposals which may be made for disposing of the sugars in question?—Yes, that is so.

7327. And you acknowledged the receipt of that letter, writing, for Messrs. Bostock, "We beg to acknowledge the receipt of your favour of yesterday's date, re our stock of contaminated sugars, which we will bear in mind"?—Yes.

7328. Notwithstanding this, we have at no time received any information from you that any was disposed of?—That appears to have been overlooked. It has been in many people's hands since that date. We went into voluntary liquidation, then into the Official Receiver's hands, and now the firm has gone into compulsory liquidation, and in that way the communication appears to have been overlooked.

7329. It is a very important thing to be overlooked; our letter was addressed to the liquidators?—Yes.

7330. Whether they are compulsory liquidators or not, it was addressed to the liquidators?—I believe at that time it was in the hands of the Official Receiver, and that letter was handed to him.

7331. Perhaps you will take all steps necessary to ensure that there are no other omissions?—I will. I will undertake to.

7332. And you will keep the Commission informed of the destination of any of your invert sugars or glucoses if disposed of, and what precautions have been taken, or what precautions you intend to take, and what is the destination of any which is disposed of?—I will see that this is done.

Mr. E. G. FRANCIS, called; and Examined.

Mr. E. G. Francis. 7333. (Chairman.) I believe you are manager of the Manbré Saccharine Company?—Yes, and also director.

7334. You have occupied the position of manager for 23 years, I think?—That is so.

7335. During the first two years of that period the works were in Booth Street, Spitalfields, and the rest of the time at Fulham Palace Road, Hammersmith?—Yes.

7336. During the whole of that time the sulphuric acid used in the works has been supplied by Messrs. James Gibbs and Company, Limited, of Victoria Docks, with the exception of a few weeks in 1892?—That is so.

7337. Has there been any difference in the acid during those years?—Until the end of 1891 the acid was made from brimstone, but after that it was made for a period from pyrites, followed by an interval of three years, during which it was made from brimstone, and since then from pyrites.

Pyrites acid commercially represented as being made from brimstone. 7338. What was the cause of your changing the source of your acid?—It was clearly understood that the acid which we used should be made from brimstone, and towards the end of 1891 the manager of Gibbs and Company called upon me, and said he was very sorry, but he could not supply me any longer with brimstone-made acid as the demand for that acid has declined so much that it did not pay to make it. He proposed to substitute an acid made from pyrites, which he guaranteed should be equally as pure as the brimstone-made acid. In fact, he said that he might have sent me that acid without my knowing anything about it, it was so pure. But he, knowing that I had this predilection for brimstone-made acid, thought it only fair to tell me he was about to discontinue its manufacture.

7339. You did not accede to that, I believe?—I was very nervous about using that acid, because I quite realised the tainted source from which it was made, and I preferred, if possible, to continue to use the brimstone-made acid. In the end I was obliged to leave Gibbs and Company because the manager said he could not supply me with any other kind of acid than that made from pyrites. Accordingly, I ultimately got a supply from Messrs. Wallace and Company, who undertook to give me the acid I wanted.

7340. You subsequently found out that Messrs. Wallace and Company were not supplying brimstone acid?—Yes, in a few weeks' time the same manager of

Gibbs and Company called upon me, and said that he presumed the acid we had been using was satisfactory since we left them, or he would probably have heard from me. He said he thought it only fair to state that the acid which Wallace and Company were supplying to us was bought from him, the manager of Gibbs and Company, and sold to us as brimstone acid. On learning this I lost confidence in Wallace and Co., and accordingly went back to Gibbs. I had more confidence in Gibbs and Company than Wallace, especially after that incident.

7341. Did you ever find that the acid that you got through Messrs. Wallace contained any arsenic?—No, it was quite as pure as the acid we used before.

7342. Had you any guarantee, when you went back to Messrs. Gibbs? Did you ask them to give you a guarantee as to the purity of their acid?—No, I was satisfied. I have shown that I had every reason to repose the utmost confidence in Messrs. Gibbs. The manager came to me after the change, and told me frankly he could not supply brimstone-made acid, and accordingly I felt that I could have the same confidence in him as I had before.

7343. Subsequently you had some further trouble?—I was always nervous about the pyrites acid, and I pressed him to make it from brimstone if he could, and he wrote me a letter saying he was about to resume deliveries of brimstone-made acid, and for about three years from that date he supplied me with that, but there was no obligation on his part to do so. He knew of my predilection.

7344. (Chairman.) Towards the end of 1898 I believe Messrs. Gibbs and Co. intimated to you that they were going to discontinue the manufacture themselves of sulphuric acid?—Yes, they said they were about to give up making acid, but they undertook to supply me with an acid of equal quality to their own make, made by the well-known firm of Spence, Chapman, and Messell, acid just as pure as that which had been supplied by Messrs. Gibbs and Co. But I did not know the people, and I thought it would be better to have a guarantee.

7345. In that matter Gibbs and Co. were only acting as agents for Spence, Chapman and Messell?—Yes; I did not know Chapman's then, but I have known them since, and I know them to be a firm of the highest repute; but I thought it was as well to have a written guarantee that the acid should be free from arsenic.

Mr. E. Williamson.  
10 May 1901

Additional precautions promised.

Mr. E. G. Francis.

Prefers brimstone acid, but satisfied that pyrites acid is satisfactory.

E. G. 7346. With Messrs. Spencer, Chapman and Messell  
neis. you have made yearly contracts?—I have made them with  
Gibbs and Co., but I knew soon after we commenced to  
use the other acid that it was Spencer, Chapman and  
Messell's, and since then for the last three years I have  
had this guarantee that it should be free from arsenic.

7347. And the guarantee is worded as follows, I think.  
"Guaranteed free from arsenic, iron, and nitrogenous  
compounds?"—Yes, I have the contract here. I have  
also an earlier one than that. I hand you the first con-  
tract, dated 7th December, 1898. (Handed in.)

COPY.

London, E.C., 7th December, 1898.  
Contract No. 4,874.

Messrs. The Manbré Saccharine Co., Ltd.,  
Hammersmith, W.

We have this day sold to you the undermentioned  
goods:—

Quantity.—Your total requirements from 1st Decem-  
ber, 1898, until 31st December, 1899.

Goods.—Sulphuric acid, 70 per cent., guaranteed free  
from arsenic, iron and nitrogenous compounds.

Price.—Forty-two shillings and sixpence per ton.

Delivery.—As required, in vanloads delivered to your  
works in carboys.

Payment.—Monthly account, less 2½ per cent. discount.

Conditions.—Customary. Carboys to be returned  
from time to time or paid for as may be arranged.

Yours faithfully,

JAMES GIBBS AND CO.,

(Sd.) L. E. Strong,

Secretary.

7348. The guarantee in the contract for the current  
year is worded, "Guaranteed practically free from ar-  
senic"?—Yes.

7349. The one which you hand in says, "We have this  
day sold you the undermentioned goods, sulphuric acid,  
70 per cent., guaranteed free from arsenic, iron, and ni-  
trogenous compounds"?—Yes, that is so.

7350. It says, "Delivered in vanloads to your works  
in carboys"?—Yes, and the other contracts have been  
worded in the same way, except the present contract,  
which is worded slightly differently.

7351. Did you take any steps to check the deliveries  
yourself?—Yes, we tested them occasionally.

7352. And did you ever find that the substance con-  
tained arsenic?—No.

7353. Upon learning of the accidents that had hap-  
pened in Manchester, did you take any particular steps?  
—We at once examined first of all every particle of  
sugar that we had in our works also all the sugar which  
we had in the depôts, because we thought it better to  
make doubly sure that there was no possibility of any of  
our sugar being contaminated. We examined every  
pound of sugar that we had in the place, not only in the  
factory but in the various depôts, and the same with  
regard to our customers' stocks, for they had several  
hundreds of tons at that time. It was all tested.

7354. And you found none of it contaminated?—None  
at all.

7355. Therefore, in your opinion, with proper care,  
there is no risk of the invert sugar being contaminated?  
—Absolutely none whatever. In the first place, since  
this outbreak of poisoning we examine every carboy of  
acid, and although we were particular before,—of  
course, everybody else is now—we are more particular  
than ever. With a precaution of that kind, which,  
after all, is only common sense and easily done, there can  
be no possibility whatever of contamination. I should  
like to mention, while I think of it, if I may be allowed  
to do so, that I understand Mr. Garton, in his evidence,  
before you, has stated that as large a percentage of acid  
is used as 8 per cent. in the conversion of glucose. I  
think he must have been mis-reported, or that he must  
have made some error, because it is a most important  
point. We can effect our conversion with less than 2  
per cent.

7356. That is of invert sugar?—No, of glucose.

7357. What pressure do you use?—We use 60 to 65  
pounds.

7358. The amount of pressure makes a considerable  
difference?—Yes, but our process was at one time a  
4576.

patent, it is a high conversion process, and by that  
means we are enabled to use the minimum amount of  
acid, and I can state that we never exceed 2 per cent.

7359. (Professor Thorpe.) The amount of acid depends  
on the purity of the starch that you start with, does it  
not?—Of course, the purer the starch, the less acid. If  
we could use quite a pure starch we could do it with less  
than that quantity; but taking all the materials we use,  
our percentage comes out very much less than was stated  
to you by Mr. Garton.

7360. You use pure starch?—We use the purest we can  
get, but I thought it best to correct the statement of Mr.  
Garton, because it is rather misleading if people get the  
idea that an inordinate quantity of acid is used, which  
may or may not be tainted. Such a statement naturally  
adds to the degree of scare in the public mind.

7361. When Mr. Garton was giving his evidence I  
might say he was comprehending the whole of the  
trade. I believe he told us he himself used a special  
character of starch material, and as a matter of  
individual practice it is only very exceptionally that he  
used so large an amount of acid as he indicated?—I  
think it only fair to say that we at any rate have never  
exceeded 2 per cent.

7362. But in the case of making glucose direct from  
maize, is it not the practice to use a larger amount?—It  
is not made from maize direct. I draw a distinction  
between maize and maize starch.

7363. But I think glucose is made from maize directly,  
is it not?—I do not think it is made directly from maize.  
The only people who used it in that way were Johnsons'  
Saccharum Company; and they commenced by making  
it direct from the grain, but they had to abandon that  
because it was more or less of a failure.

7364. Is it a fact that when you make glucose from  
second grade tapioca, you require more acid?—In our  
particular case we never use more than two per cent.

7365. Do you exclusively use sago and tapioca?—  
No, not exclusively; we use sago, tapioca, and maize  
starch.

7366. (Mr. Cosmo Bonsor.) Do you use rice-starch?—  
No, not rice.

7367. Do you use Sarawak flour?—Yes, we use that  
too. As far as my experience goes, whatever material  
you may use I cannot see the necessity for using such  
inordinate quantities of acid as 8 per cent. I thought  
it probable that Mr. Garton had fallen into error, or  
that he had been misreported.

7368. (Chairman.) Do you wish the Commission to  
understand that you in your works use not more than  
2 per cent. of acid? Of course we know that you use  
a considerable amount of steam pressure?—Yes, we use  
probably a higher pressure than anybody else. Our  
plant was so arranged, and it was a patent under which  
we worked years ago. We have maintained that plant  
ever since. It is a high conversion, and a more rapid  
process than one at a lower temperature.

7369. What you want us to understand is that, in your  
opinion, in the manufacture of glucose there is no valid  
reason why such a high percentage of acid should be  
used?—I do. I rather want to make a point of that.

7370. (Professor Thorpe.) You have made it clear to  
us what you understand by brimstone acid?—Yes, I  
mean acid made from pure brimstone, not pyrites.

7371. Would the acid made from recovered sulphur  
be to your mind brimstone acid?—No, nothing would  
convey the idea to my mind that it was brimstone-  
made acid unless it were made from sulphur.

7372. Recovered sulphur?—I should not regard that  
as brimstone-made acid.

7373. You mean the native product then, I suppose?—  
Yes, Sicilian sulphur, uncombined with any other  
material. I should imagine, according to my simple  
understanding—though people may take different  
views, perhaps—that brimstone acid would be made  
from that source alone.

7374. Would you understand by that, acid made from  
Sicilian brimstone?—Yes, I would. I do not mean to  
say that acid as pure cannot be made from other ma-  
terial. The acid we use is made from pyrites. I have  
since the scare, especially knowing the prejudice exist-  
ing, tried to get a supply of brimstone-made acid, not  
because I think it is any better, but simply on account  
of the prejudice, if you like to call it so, which exists  
against the use of pyrites-made acid. I have tested end-  
less samples of brimstone acid, but I have never found

Mr. E. G.  
Francis.

10 May 1901.

Glucose not  
made direct  
from maize.

Brimstone  
acid should  
mean acid  
from natural  
sulphur.

Mr. E. G.  
Francis.  
10 May 1901.

acid so pure, on the whole, as the acid which I am using now, made from pyrites.

7375. In the case of brimstone acid no particular pains would be taken to free it from arsenic?—That is so. I do not think a man who gets acid made from brimstone would look at it so closely as acid made from pyrites.

Pyrites acid  
may be  
better than  
arsenic  
than brim-  
stone acid.

7376. Is it your idea that by virtue of the purification which would have to be gone through in the case of acid made from pyrites, it would be a purer product than the brimstone-made acid?—I am sure of it. Knowing as much as I do about it, and knowing that I am now dealing with a firm of repute, I feel safer in using that acid than any acid made from brimstone, assuming that we did not look into it as closely as we do. On that assumption I can see the possibility of brimstone acid containing minute traces of arsenic.

7377. (Mr. Cosmo Bonsor.) Which test do you use?—Marsh's.

7378. Entirely?—Yes.

7379. I understood you to say you were prepared to give a guarantee with your goods?—We do.

7380. A guarantee that they are absolutely free from arsenic?—We do; we state it on each invoice.

7381. Are you prepared to agree that that guarantee should be checked by a Public Department after the goods are delivered?—Yes, I believe it is checked by our customers.

7382. By the brewers or by the Public Authority?—Certainly. I should be only too pleased for it to be checked.

Form of  
guarantee by  
sugar maker.

7383. (Professor Thorpe.) But is your guarantee signed by anybody, or is it a general guarantee?—We print it now on the invoice. We used to write a letter previously to each customer, giving the guarantee, but we find that customers are satisfied with a guarantee printed on the invoice. It says, "We guarantee the above goods free from arsenic." They are satisfied with that.

7384. At your works you have a chemist, I suppose?—Yes, we have three.

7385. So you do your own testing?—Yes, all the operations are tested.

Records of  
tests kept  
since the  
epidemic.

7386. (Dr. Whitelegge.) Do you keep a record of the analyses made?—We do now. We did not before, but now we keep a record of all the tests we make.

7387. You keep a record whether the results are positive or negative?—Yes.

7388. Prior to 1891 you were aware of the danger from arsenic?—I was always aware of the danger of arsenic being in acid, especially that made from pyrites.

7389. It was a matter of common knowledge?—Yes.

7390. Was there any question of arsenic involved in that temporary change from Messrs. Gibbs to the other firm?—I was afraid of it, and preferred brimstone acid.

7391. You told us that during a period of three years, 1894-6 inclusive, a reversion was made to sulphur-made acid?—I had always a prejudice, if you like to call it so, in favour of brimstone-made acid.

7392. Can you tell us whether that intermediate change was due to any suspicion of arsenic?—No, it was not; there was no question of arsenic.

7393. You make brewing sugars, I suppose?—Yes.

7394. Glucose and invert sugar; nothing else?—Yes, and caramel.

7395. Do you supply to brewers direct?—We do.

7396. Do you supply to any other persons?—No, we deal solely with brewers, with the exception of a few tons occasionally to a dealer. But our trade is directly with brewers, you may say, almost entirely.

7397. And you have no knowledge of the sugars you make passing into other hands for industrial purposes or for making jams or syrups?—No, it would not do for making jam, because it is solid glucose; liquid glucose is used for that.

7398. You do not know of any other industrial application of it?—Only brewing.

7399. What about textile manufactures?—No, it would be too dear for them.

7400. (Chairman.) You said you did not know of any other industrial application. We have just heard from another witness that some of Bostock's invert sugars and glucose has been sold for the purpose of calico dressing?—I have never known it used for that, but I have known it used for giving a fictitious weight to leather. Our stuff is too dear for purposes of that kind. It is a commoner kind which is used for that purpose. I have not heard of any other industrial use of it.

7401. (Mr. Cosmo Bonsor.) You said just now that you made glucose, invert sugar, and caramel. Have you made any maize flakes?—Oh, yes, we have; we do make that too.

7402. Do you use any acid for the purpose?—No, none at all.

7403. Could you give, in a few words, a description of the process from maize?—Yes, we purify it to free it from germs and husk, then reduce it to grits; these grits are then gelatinised and passed through rollers, and the result is flakes. The flakes are then dried in dryers, after passing through these rollers. There is no acid used in the manufacture at all.

7404. So there is no opportunity of contamination?—There is no possibility whatever of contamination, none whatever.

7405. Would you mind our seeing one of your invoices?—Certainly. You will see that it is an invoice specifying the goods in writing in the ordinary way, and that below the specification, at the foot of the invoice, we print: "We guarantee the above goods free from arsenic."

Mr. E. G.  
Francis.  
10 May 1901.

Manufacture  
is almost  
entirely for  
brewers

too dear for  
textile pur-  
poses, &c.

No acid use  
in flaked  
maize.

MR. RUDOLF FREDERICK WAHL (Managing Director, Nord-Deutsche Kartoffel-Mehl Fabrik, Ltd., of Custrin, Prussia), called; and Examined.

Mr.  
R. F. Wahl.

7406. (Chairman.) I believe you are the Managing Director of the Nord-Deutsche Kartoffel-Mehl Fabrik, Ltd., of Custrin, Prussia?—Yes.

7407. Although the Limited Company only dates from 1901 it is a very old business, I believe?—The Company was formed in 1870, upwards of 30 years ago. Before then my father and my grandfather were manufacturers on the Rhine.

German  
farina is  
purified  
potato  
starch.

7408. You make, I believe, three principal products, purified starch or farina, dextrine, and glucose?—Yes.

7409. The first is manufactured for the purpose of making the other two?—Yes, that is so.

7410. What is the farina, dextrine and glucose which you manufacture chiefly used for?—Farina is used partly for food purposes and also in the textile, paper, and other industries. It is very largely used in Manchester, and for similar purposes all over the world.

7411. For giving body to calicoes?—For sizing and for foodstuffs. It is very largely used in making macaroni and for thickening sauces. It is very largely used for vermicelli in Spain and also in Italy for the same purpose.

7412. What is the farina, chiefly prepared from?—From potatoes.

7413. The amount which you manufacture is, I believe, very large?—Yes.

7414. Will you give the Commission some idea of the amount of farina which you annually manufacture?—It varies very much according to the crop. When the crop is abundant the sales vary accordingly; but on an average, I think about 20,000 tons of farina alone is our quantity.

7415. You estimate that the whole manufacture of the material amounts to something like 250,000 tons a year?—That is a bold guess; but taking into consideration that Germany, Holland and France are about the only countries in which farina is manufactured in large quantities, we can form an idea that this is about the correct quantity. We cannot say whether it is absolutely correct, as we have no statistics on that point.

7416. Is the term farina exclusively applied to potato starch?—Yes, I should say so. Farina is also called potato flour and potato starch.

7417. (Professor Thorpe.) Maize starch is never called farina, is it?—I have never heard it called so.

7418. (Chairman.) The preparation and purification

Mr.  
R. F. Wahl.

of farina is purely and solely by mechanical means; no chemicals are used at all, I believe?—No, no chemicals are used. We never use chemicals for it.

1901. 7419. You say you never do?—No.

7420. I suppose you have never heard the wholesomeness of farina manufactured from potatoes called in question?—Never.

7421. It is quite freed from nitrogenous matters?—Oh yes, I have brought you some samples of farina which are our products. (The witness handed samples to the Commission.)

7422. How do you make the dextrine from your farina?—By calcining with the use of acid, with a very small addition of acid.

7423. (Professor Thorpe.) What acid?—Nitric acid.

7424. (Chairman.) That is not used in any way as a foodstuff?—Never.

7425. It is required for what material?—Also for textile purposes and for mixing with colours for paper-hangers, and for coating labels, for gummed papers, and so on.

7426. It is the basis of most of the gums in use, I believe?—Yes.

7427. The commoner gums, of course?—Yes; the commoner gums.

7428. That is, comparatively speaking, a very small part of your manufacture of dextrine?—It is not so very small; we make about 5,000 or 6,000 tons of that a year; that is, of dextrine. That is also largely used all over the world; it is used in England, and goes to America, Spain, and Italy. Of course, Germany is our principal market.

7429. Your glucose is used, I suppose, almost entirely as a foodstuff?—Not entirely. I was listening to what was said before, and I may say that in Germany it is used occasionally for textile manufactures, and also for paper-making. In this country it is not so much used for the textile industry.

7430. (Mr. Cosmo Bonsor.) Do you refer to glucose?—Yes, glucose.

7431. (Chairman.) How do you make your glucose?—We make it with brimstone acid, and in the usual way, that is, with pressure. I have been hearing what was said about the percentage of acid used, and I can only say we use considerably less than that which has been stated in this room as the lowest quantity.

7432. Do you mean less than two per cent.?—Yes; considerably less.

7433. Mr. Francis said he used considerably less?—Yes, but we use less than one-half.

7434. Do you use very high pressure?—Not very high.

7435. He told us what pressure he used; do you object to telling us what pressure you use?—I do not mind saying we use two atmospheres; that is 28lbs. to the square inch. Of course, for liquid glucose less acid is used than for solid glucose.

7436. (Professor Thorpe.) All your glucose, I suppose, is made from purified potato starch?—Yes.

7437. Short of water, it is 99 per cent. of starch, with very little ash in it, I suppose?—Yes.

7438. It is a product which should be converted with a theoretical minimum quantity of acid?—That is so. You have the starch in front of you.

7439. (Chairman.) And the purer the starch the less the percentage of sulphuric acid necessary?—Yes; but it is not only purity, but consistency which is aimed at. If you boil starch which is very thin, and take three parts of water to one part of starch, you require more acid than if you have a very condensed liquid starch to deal with.

7440. Do you know what your glucose is chiefly used for in the matter of foodstuffs?—Yes; in Germany it is largely used for brewing, and also for the improvement of wines.

7441. Do you know what proportion the German brewers use the glucose in?—I could not say.

7442. Nor the wine makers?—No, I do not know anything about that.

7443. I think it is not only used in Germany for wine making, but also in France and Italy?—In France very largely, certainly.

7444. (Mr. Cosmo Bonsor.) For champagne?—No, it

cannot be used for champagne. I daresay it has been tried, but glucose is not adaptable for champagne making, but for clarets it is used to a large extent.

7445. (Professor Thorpe.) You say it is used for the improvement of wine. How does the addition of glucose improve the wine?—It is used for the improvement of inferior vintages. When there is little sun in the summer and the grapes are very sour, sugar is added to decrease the acidity of the grape, and the added sugar helps to get the alcoholic strength.

7446. (Chairman.) Its use is prohibited, I think, in Bavaria, Wurtemberg, and Baden, is it?—Yes, for brewing purposes.

7447. Why?—For political purposes. I suppose the Farmers' League has got a very strong hold, or strong representation in their Parliaments, and thus it has been brought about that it is prohibited.

7448. They have prohibited any substitute for malt in brewing, I believe?—Yes, they have prohibited any substitutes, although it is publicly known that they do use substitutes—they smuggle them in in Bavaria.

7449. Still, we do not recognise the breaking of the law here?—Well, we do not sell any to those countries for purposes for which they are prohibited.

7450. Can you, of your own knowledge, inform us that it is the law in Bavaria, Wurtemberg and Baden that no malt substitute should be used for brewing?—Yes, but that does not refer to wine. Bavaria is not a wine-growing country, but in Wurtemberg they make wine from fruit, such as apples and pears, and for cider it is very largely used.

7451. (Professor Thorpe.) There is a certain amount of wine-growing in Baden, I believe?—Yes.

7452. Is glucose used in conjunction with the wine industry in Baden?—Yes, as far as I know.

7453. (Chairman.) You inform the Commission that 10,000 tons, or not less than 10,000 tons are used in Germany alone?—Yes.

7454. For beer and wine?—Yes, quite so.

7455. Not less than 6,000 tons employed in German breweries for the years 1893 and 1899?—Yes, and the consumption is increasing.

7456. Is there by law any restriction in Germany to the amount of glucose in beer?—I should not think so.

7457. No restriction at all?—I think not.

7458. Do you know at all what is the average amount added to the malt?—I could not say.

7459. You say in common with rice, which is largely used in Germany, its use is recognised and regulated. I thought you might be able to tell us what the regulation was?—It is simply regulated by the excise duty which is paid on glucose in beer making. The brewers have to pay.

7460. The Government in Germany reckon so much which pay glucose as the equivalent of so much malt, do they?—Duty on I do not know how they reckon it. I know there is a glucose duty, amounting, I think, to 8s. per 100 kilos, equal to used about 4s. per cwt. on glucose.

7461. (Dr. Whitelegge.) Do you refer to glucose used in brewing, or to glucose generally?—I refer to brewing.

7462. There is no duty on glucose as such?—No.

7463. (Mr. Cosmo Bonsor.) Could you tell us whether in those countries where glucose is forbidden to be used for brewing, beer brewed from glucose is also prohibited from being imported?—It is not prohibited from importation.

7464. So you could import beer brewed from it, though you are not allowed to brew from it?—Yes, but in their own country people drink their own beer generally.

7465. (Professor Thorpe.) I suppose importing beer into Bavaria would be something like carrying coals to Newcastle?—Yes.

7466. (Mr. Cosmo Bonsor.) It is only a question of law?—There is no restriction on that, I think.

7467. (Chairman.) Do you use sulphuric acid?—Yes.

7468. For dextrine you use nitric acid?—Yes.

7469. What is the source of your sulphuric acid?—We get it from Stettin, from one of the first chemical works in Germany. We have got it from Stettin for the last 30 years, ever since we started as a limited company.

Mr.  
R. F. Wahl.

but not  
tested by  
glucose  
makers until  
recently.

Small use of  
liquid  
German  
glucose in  
England.

Bleached  
by sul-  
phurous acid.

7470. Do you require a guarantee with it?—We always get it. I have brought five invoices as specimens for you to see, dated 1895, 1896, and 1900, all before the scare.

7471. You have yearly contracts, I believe?—Yes. These are the invoices. It is always stated to be free from arsenic, and we have got a factory—a small factory—in Baden, in the neighbourhood of Karlsruhe, where we also manufacture a small quantity of glucose. In order to be absolutely certain that we get pure sulphuric acid we get it sent from Stettin to that place, which means a journey through the whole of Germany, at a very considerable cost. This cost enhances the cost of sulphuric acid by 50 per cent. You will notice there, sir, one invoice embracing the freight, and from the note at the side you will see that the freight comes to half as much again as the sulphuric acid.

7472. Do you specify what the acid is to be?—Free from arsenic.

7473. You say here the acid is made from Sicilian brimstone?—That is so. We have been assured it is made from Sicilian brimstone.

7474. Does it mean purified acid?—It means made from sulphur imported from Sicily.

7475. At Stettin?—At Stettin.

7476. (Chairman.) You formerly did not test the acid yourself?—We did not before, but since the epidemic we test every carboy of acid that comes into our place.

7477. Have you found any of it contaminated?—No.

7478. You have not had to reject any?—No, not sulphuric acid.

7479. Do you ever test your product too?—Always, every day, we test it not only when it is finished, but also in the progress of manufacture. The tests we use are Gutzeit and Marsh.

7480. Are Messrs. Julius Franks and Ohlman your agents in this country?—Yes, for the solid glucose.

7481. And you have no objection in your trade in giving the guarantees of purity to your customers?—Certainly not.

7482. I think you heard the last witness's evidence?—Yes.

7483. Do you agree with him as to the greater purity of purified pyrites acid over brimstone acid?—I do not know so much about that, but we guard ourselves by testing every carboy, and here is the result of one of our tests. Here is the Marsh tube. We also test all the sulphuric acid we get delivered, and there is not the slightest sign on this tube, as you see. This is made with 25 grammes.

7484. Is any supervision exercised by Government, or have they any control over the materials which you use, or is that left entirely to your own judgment?—That is left to us.

7485. Do you yourself make caramel?—Yes.

7486. And what is caramel used for?—For colouring purposes, mostly for beer, vinegar, and spirits.

7487. You do not, I suppose, know whether your agents in England supply their sugars to other than brewers?—No, we do not know.

7488. Do you think that any large quantity is used for confectionery or jam-making?—The liquid glucose, yes. I have brought you a sample of that. (Sample shown.)

7489. Do you import a large quantity of liquid glucose into England?—Not very much. It comes to 500 or 600 tons in a year. It used to be much larger, but since the American competition came we cannot compete so well, because our articles are considerably dearer than others. People pay for their good quality.

7490. Is this liquid glucose much used on the Continent for making fruit syrups?—Enormously; a very much larger quantity than of dry glucose.

7491. (Professor Thorpe.) That glucose you have brought us is bleached now?—It is purified by charcoal.

7492. Is it not bleached with the use of sulphurous acid or sulphites?—To a very small extent. It runs out of the filters like this.

7493. Is there such an amount of sulphurous acid in it as precludes it from being used in brewing?—Certainly not.

7494. Are there many makers of these products in Germany?—Yes.

7495. How does your firm compare, in point of magnitude, with others?—It is by a long way the largest.

7496. Do the other firms, too, send their products to England, do you know?—Not in later years, or to a very small extent only. We know it by statistics. I understand you to be only speaking of glucose now?

7497. Yes?—Nearly all the glucose which comes to this country comes from us.

7498. Has your attention been called to some statements as to the occurrence of arsenic in German-made glucose, on the authority of Dr. Ritter?—No.

7499. You have not heard, for example, that as far back as 1878 attention was called to the occurrence of arsenic in German-made glucose?—I remember it at the time, but it has never been proved. That was at the time when our glucose and all sorts of glucoses had been examined by the Reichsgesundheitsamt, in Berlin; but it has never been followed up nor mentioned since.

7500. Not in Germany?—Not in Germany.

7501. You are not aware that the matter was substantiated, as far as the French glucoses are concerned, by Professor Clouet?—I am not aware of it.

7502. It is news to you, then, that German glucose could contain arsenic?—It is.

7503. Are your agents in Liverpool?—No, in London.

7504. Are they agents for any other makers of this material? Or are they general agents?—They may sell other glucoses—that I do not know. They are practically buyers from us, not what you call agents, people working on commission.

7505. They buy from you to resell?—Yes.

7506. They may very likely buy from other makers?—I should not think they buy from German makers, but they may buy American glucoses.

7507. Do they buy invert from you?—We do not make invert. These which I hand to you are the only glucoses we make. (Samples shown the Commission.)

7508. (Mr. Cosmo Bonsor.) You invoice to them, and not to the brewer?—We never sell to the brewer.

7509. You really do not know the brewer?—We do not.

7510. What if they make a bad debt?—That is their business.

7511. Not your business?—No.

7512. (Professor Thorpe.) What amount of water does this glucose contain?—12 to 13 per cent.

7513. Is it fairly uniform in the proportion of water which it contains?—Yes, it is made of the same strength, almost exactly the same.

7514. The process of your manufacture is such that you ensure it shall contain 12 to 13 per cent.?—Yes, it is always weighed.

7515. Do you imagine yours is dryer than English made glucose?—I should say it is about the same.

7516. The other form of glucose also contains the same amount of water?—Slightly more.

7517. The white contains slightly more?—Slightly more, but that is only a question as to how it is asked for. We make glucose for export to Australia with a considerably less quantity of water in than that.

7518. What is the amount which this sample contains?—About 15 per cent.

7519. And that which you send to Australia—how dry is that?—About 11 per cent.

7520. (Mr. Cosmo Bonsor.) You state that you have no objection to giving a guarantee with your goods to the agents?—Certainly not.

7521. And you would have no objection to the Customs, I presume, being the check upon that guarantee?—Certainly not. I am assuming that the materials used by the different chemists for testing are absolutely pure, because it has very often been found and proved that the materials are not pure. We ourselves have been trying very hard to get the purest materials possible—for example, zinc for the Marsh test. We have examined the zinc and found—I do not know whether it could be called a trace—of arsenic, but there was a

Mr.  
R. F. Wahl.

German  
glucose  
in English  
brewing

is consigned  
to agents,  
not to brew  
direct.

little white circle round the tube, even with the purest materials we could obtain over there.

1901. 7522. Has it ever come to your knowledge that saccharine has been mixed with glucose for the purpose of giving added sweetness to it?—We have never done so.

7523. Has it come to your knowledge?—It has come to my knowledge that it has been done in this country. In Germany the use of saccharine has been altogether prohibited since about twelve months ago.

7524. The use of saccharine has?—Yes, except that it can only be bought from pharmaceutical chemists; it cannot be bought in bulk. I may mention that the samples I have brought are not made up for the Commission. They are average trade samples.

7525. (Dr. Whitelegge.) Do you use only potato starch?—Only potato starch.

and 7526. And from that you make both solid and liquid glucose?—Yes.

id. 7527. Will you tell us, briefly, what is the distinction between the two?—Do you mean between the solid and the liquid?

7528. Yes?—Liquid glucose is the first stage. Liquid glucose is not boiled so far that it crystallises. It is a between product.

7529. But by further treatment liquid glucose would yield solid?—Yes, it would turn solid. Liquid glucose may turn solid afterwards if by any mistake it is carried a little too far.

7530. Liquid glucose is cheaper?—No; on the contrary, it is rather dearer, because the package is dearer. It is supplied in big casks, and they are expensive. Also, in consistency it is very thick. Here is the strongest consistency.

7531. (Professor Thorpe.) What is the actual amount of sugar in this sample?—I should say about 40 per cent.

7532. (Dr. Whitelegge.) Are both used in brewing?—The liquid form is not used in this country, to my knowledge, for brewing, but it is used largely in America. We used to ship large quantities to America in former times, before the maize glucose was invented, and I have been informed it has been used for brewers mostly.

7533. Would other kinds be used in wine?—You could not use liquid glucose in wine.

7534. The glucose used in brewing in North Germany is the solid?—It is solid.

7535. Is that used in brewing beer similar to Bavarian beer?—It is more used for the top fermentation beer.

7536. Would it not be suitable for the other?—I do not know, but I believe it would.

al 7537. Is there any Government inspection of your sent in of factory in Germany?—Oh, yes.

ture 7538. Any special inspection by reason of glucose any. being made?—No.

7539. Simply the ordinary application of a Factory Act?—That is it.

7540. You told us that you have found no arsenic in the sulphuric acid?—No.

7541. Does that mean absolute freedom from arsenic?—Absolute freedom.

7542. Not even traces have been found?—Not even traces.

7543. You limited your answer to the sulphuric acid. May we take it that in other acid arsenic has been found? Had you in mind the discovery of other kinds?—Hydrochloric and nitric. I have not examined them.

7544. You have not found arsenic in any acids?—In hydrochloric, to my knowledge, small traces of arsenic have been found.

7545. Was that supplied on a guarantee in the same way?—Only purified hydrochloric acid.

7546. It was not said to be free from arsenic?—No; because that is used for the purification and cleaning of charcoal. Will you let me say a few more words? It has been stated that potato starch, in its conversion into glucose, produces a deleterious substance called gallsin, which is an unfermentable matter. I wanted to hand in a paper to show it is untrue, and that it has been proved by eminent chemists and physiologists that it is an absolutely harmless substance. I have brought here a paper and literature dealing with this subject.

7547. (Chairman.) Do you say your manufacture is exclusively from starch of your own making?—Yes.

7548. We have heard from other makers of glucose that there is a danger in using some of these meals; invariably that you do get nitrogenous compounds which are offensive, if not dangerous?—Yes. Well, we are excluded from using anything but potato starch, on account of the very high duty in Germany on other imported starches, like tapioca, rice, and sago flour. There is a duty of about £8 or £9 a ton, which renders it prohibitive for us to use these starches.

7549. Is there not very considerable difficulty in freeing potato starch from other matters?—It is not nearly as difficult as from maize, but by careful manufacture it is made as pure as you see it there.

7550. Made pure by purely mechanical processes such as grinding and washing?—Yes, grinding and washing.

7551. If not purified, I think potato starch would when treated, give origin to a considerable amount of offensive matter?—I should think so. I do not think anybody would use potato starch for glucose making without it was cleaned. They could not very well. The potato water has to be got out of the potato first before the starch settles down.

7552. (Professor Thorpe.) What is the particular mode of treatment which enables you to get this white as compared with greyish colour?—The white is the original product, and the yellowish colour is made to people's fancy. It is simply a matter of fancy. Most people in this country prefer the yellow to the white. In Germany we sell the white. We also send white to this country, but yellow to a greater extent. The yellow is not a second quality; that is, it is the same pure quality as the white, only treated differently.

7553. But containing a slightly different percentage of water?—Slightly less. That is only a matter of detail. If they would like to have it stronger and pay a higher price we should be pleased to do it.

7554. Could you tell us whether it would be possible to determine that that was made from farina or from pure tapioca, or whether it was made from pearl starch? Would not pearl starch and farina yield identical products?—I think in pearl starch—which I understand is maize starch—you might find a small percentage of converted gluten by the aid of acid, and you would always find a trace of phosphoric acid in sugar made from maize too, as far as I know.

7555. Is there no phosphoric acid in this?—No. In my experience potato and farina starches are the purest you can have. It does not contain gluten, which maize starch does.

7556. You think it might be possible to differentiate between the various glucoses?—I never tried it. It might be possible. But I shall be pleased to let you know. I will ask our chemist to make experiments; I daresay he can let me know.\*

7557. I should personally like to know how it might be possible to detect the origin of any particular form of glucose. It would be very useful to know.

(Mr. Cosmo Bonsor.) It would be very useful to detect the origin of beer in the same way.

\* Note by Witness.—Our chemist, whom I have consulted, writes that he considers it is not possible with any claim to absolute accuracy to find out by analysis whether glucose was made from farina, maize, starch, tapioca, or sago, or any other flours.

Mr.  
R. F. Waik  
10 May 1901.

Potato starch  
contains no  
gluten.

Mr. WALTER W. BERRY, called; and Examined.

Mr. W. W.  
Berry.  
10 May 1901.

7558. (Chairman.) You have, I think, had large experience in the growing of hops?—I have grown hops all my life.

7559. On a large scale?—Fairly large, yes.

7560. (Mr. Cosmo Benson.) You do grow hops, and you also sell other growers' hops?—Yes, but I only sell the hops which I am interested in. Part of my business is my own and part of my mother's. I sell hops in my own name.

7561. You manage other people's hops?—No; I am called in for advice professionally, but I do not control any other growths but those of my own family.

7562. (Chairman.) Perhaps you will have the kindness to inform the Commission upon the systems in use in growing hops, so far as it bears upon this question. I do not think we need go into the preparation of the land, or the planting of the hops, but rather the growth of the hop each year?—Your desire, I understand, is to know in what way chemicals are used in the growth?

Hop  
insecticides,  
soft soap and  
quassia.

7563. At what time of the year do you generally commence spraying with insecticides; when do you commence washing the hops?—I shall be commencing to-morrow, so it will be fairly early in the season. It is on the appearance of certain insects that we commence to spray, to check the damage as early as possible. At the present time the vines are just shooting out of the ground, and the turnip flea has commenced to attack. The season being a late one, if the turnip fleas are persistent we get only a small quantity of bine. So we are endeavouring to check the spread of the insect. We are using a strong solution of soft soap and quassia, just to make the plant nasty, so that the insect will not eat it.

7564. Is the turnip flea the same beetle as attacks the turnip plant?—Yes.

7565. That is when the hops come out of the ground?—They attack the vines as soon as they see them.

7566. (Dr. Whitelocke.) Not later?—Yes; it is troublesome now. They do not blacken the plant as the aphid does, but they retard the growth.

7567. Will you tell us your address?—Gushmere Court, near Faversham.

7568. (Chairman.) At a later stage, when the hops get up, aphid is apt to appear?—Yes, and we spray vigorously to get rid of the aphid during the earlier stages, to keep the plant free, that it may grow freely, and to prevent the cones from getting damaged from the filth that arises from the aphid.

7569. What is used for spraying hops to get rid of aphid?—The principal ingredient is good quality soft soap. In all the washes that are used, soft soap is largely employed. Extract of quassia chip is also used to make the plant bitter, so that the young insects which we miss killing may not thrive on the plant. We find that although we kill the aphid, before it is dead, young ones are born, and we might miss the young ones. But if the plant is made bitter the little insects do not thrive on the plant. Clean quassia chip is used for that purpose, simply to make the plant bitter.

and other  
substances.

7570. Do you use anything else?—Great numbers of things are used. Many chemists are producing various things, but they are only used experimentally. I have used a wash called Spimo, which consists very largely of soft soap. There is also some quassia, and there may be some other ingredients of which I have no knowledge. But in use that is practically like my own. Not being a chemist, I cannot say what the other ingredients may be.

Paris green  
not applied to  
hops.

7571. So far as you know, chemical substances, such as Paris green, are not used?—Never used on hops; at least, I have never known it used. Paris green is only used on fruit, where altogether other kinds of insects have to be dealt with. It would be a great waste and an unnecessary expense to use Paris green in a hop garden.

7572. Is sulphur never used?—Sulphur is largely used. Dissolved sulphur is used in the wash, in quantities of about three or four pounds of dissolved sulphur to an acre of hops.

7573. Do you know what dissolved sulphur is?—Liver of sulphur.

7574. Is it dissolved with the soft soap?—No.

7575. Is it a soft soap solution?—No. What I call dissolved sulphur is this. We receive it as liver of sulphur, and that, in water, soon becomes quite liquid. But we do not attempt to dissolve ordinary sulphur ourselves.

7576. You would have a difficulty, I think?—We should have a difficulty in perfectly dissolving it, but I have assisted in some experiments to try and get it dissolved by the use of lime and acid; that is, to try and make a solution from the flowers of sulphur, but it is very difficult, and the results have not been very satisfactory.

7577. (Professor Thorpe.) You make your own solution of soft soap?—Yes; we buy soft soap by the ton and boil it, and add to that the liquor which we get from steeping quassia chip in moderately hot water for 24 hours.

7578. You never tried the effect of adding flowers of sulphur to the boiling soft soap solution, did you?—We put it in, but I have not done it for years. If we get an early attack of mildew in the hops, and when one washing has not affected it, we have tried this, but it was only done as an experiment, and we got no beneficial results.

7579. What do you think it is in the soft soap which protects the plant?—The alkali.

7580. You could use it as pure alkali just as well as in soap?—Yes. It is possible, but with the soap all the machinery works well. If you simply had alkali and water the machinery would not work well.

7581. (Chairman.) In the first attack of the aphid sulphur is very little used?—Yes. It is not used for aphid, it is only used for mould. And I would explain that, in the early days, when little was known by hop-growers of the disadvantages or advantages of sulphur, it was used carelessly. But to-day it is used carefully, and our system is to so treat the plant in its early stages as to keep it healthy, and so that the crop is clean. It is years since I have seen any quantity of mildew in the cones, and the brewers with whom we deal beg of us not to use sulphur when the cones are produced, but only in the earlier stages. It is impossible for sulphur very largely to get on to the plant at all.

to destroy  
mould.

7582. Therefore, I understand from you that it is almost impossible for any amount of sulphur to be present upon the flower of the hop?—Yes.

7583. Then it is not, as I think there is a common impression, dusted with dry preparations containing sulphur?—They are in certain instances. If a man sees his crop going he will make great effort to save it. But it is not necessary to use it in later stages.

7584. But when you get an attack of mildew when the bine is in flower, is it not the case that powders are used for sprinkling?—Yes, they are vigorously sulphured then. A man will make a great effort to avoid losing his crop, and as a last resort he will sulphur it. It used to be the system to do it always, to do it for the purposes of colour. But brewers have, and I think very wisely, declared that they will not attend so much to colour as they have done. Therefore we produce a much more natural article, and sulphur has dropped out of use.

and when  
hop is in  
flower.

7585. Still, in those cases where the burr is vigorously sulphured there might be a certain amount of sulphur powder remaining in the burr when it is gathered?—Yes, there might be in such a case, but those cases are very infrequent to what they used to be. I would like to explain the nature of the sulphur we use for this purpose. We use the best flowers of sulphur, sublimated Sicilian sulphurs. Other sulphurs it is impossible to use; they are not sufficiently light.

7586. The Kent farmer would not specify anything further than flowers of sulphur?—Yes; he would have one of two or three makes only, because such flowers of sulphur as are used for chemical purposes are not good for us, they are not sufficiently light. Hops grow ten to twenty feet high; our machine passes under the hops, and it is like a winnowing machine which winnows chaff out of corn. It winnows the sulphur into the air.

7587. The farmer would perhaps specify it should be in an extremely finely divided condition, but he does

Mr. W. W.  
Berry.

10 May 1901

Use of  
sulphur in  
hop grow

not specify that it should be of any guaranteed purity?—No; the question has never been raised until this season.

1901. 7588. Therefore, as you said, he would use Sicilian sulphur?—Yes.

used. 7589. But, so far as you know, he probably would use sulphur obtained from the refuse of gas works?—No; and for this reason. We buy sulphur for dusting the plant with, and for purposes of stimulating a plant which is flagging. We also buy what is called rolled brimstone. That is purified rock brimstone, which comes from the Mediterranean for bleaching purposes in the kilns. We have always known that it was necessary to have the purest and best quality we could get for use in the kilns, not because we had any chemical knowledge as to possibility of contamination, but because, in producing such a valuable article as good hop, we have felt it was necessary to buy the best, inasmuch as a few shillings a ton is the only difference in price between the ordinary and the best. I have only known hop farmers buy the best. The best sulphur is the Sicilian, and the firm who supply seven-tenths of the whole are Brandram Brothers. There are two or three others, whose sulphur I believe is equally good.

7590. (Professor Thorpe.) Are this firm importers of sulphur?—I do not know anything about their business, except that they have a large business in sulphur. Whether they import it or buy it of shippers, I do not know.

7591. Do they deal exclusively in sulphur?—No; they manufacture white lead, and so on.

7592. Where is their place?—At Rotherhithe. When I was called upon to give evidence, I asked those with whom I trade if they would give me information, and they replied that the sulphur and soap are absolutely free from arsenic. In one case the man replied that he believed it always had been absolutely free from arsenic.

7593. (Chairman.) As a matter of fact, probably they had never looked for it?—I was going to suggest they believed it always had been, and this year they are sampling everything they send out, and find that there is absolute freedom from arsenic.

7594. You are able, of your own knowledge, to tell us that the sulphuring of hops with powdered sulphur only occurs in exceptional years to any extent?—Yes; and in an exceptional acre in a crop. It is an expensive operation, and brewers object to it, and therefore it is not done if it can be avoided. The brewers have said, "If you have any necessity to sulphur any portion of your crop, ear-mark that, that we may know." And very great care is taken.

7595. You have a great experience of methods of gathering and curing hops?—Yes.

7596. And you have already told us that best brimstone is used on the kilns for bleaching?—Yes.

7597. Is that largely or generally used?—Yes. But the quantity of sulphur used is very small; it is only necessary to use very little. I have used 2lbs. of sulphur to a cwt. of hops. It is burnt in a pan.

7598. It is not thrown into the fire that is used at the bottom of the hop kilns?—I have seen it done in that way, but I do not adopt that plan myself; it is very wasteful, and you do not get rid of it. My plan is to have a pan into which the necessary quantity of sulphur is placed, and when the hops are first put on the kiln, full of natural moisture, this sulphur is burnt underneath it for two hours. Then there is no necessity for anything further. If you put the brimstone on the fire, it melts and all runs through on to the ashes below. When the manager of the kilns finds he is getting more heat than he wants, he puts ashes on to check the heat, and the sulphur which is not consumed he puts up, and there is constantly some sulphur. We absolutely burn out what we require to use.

7599. You take your pan away?—You cannot do that when it is burning.

7600. What fuel do you use?—We use the best Welsh anthracite. There again the best is the cheapest, because it is free from waste. We can burn 100 tons of best Welsh anthracite with less than 1 per cent. of ash.

7601. I am speaking of your own district generally?—I know of nothing being used in my district but anthracite from the best Welsh collieries. Years ago we used gas coke, but during my time never.

7602. Speaking of the district generally, gas coke is seldom used?—I have not heard of it being used in my own district, but I have heard that it is used in Worcestershire. Speaking generally, I have no knowledge of it.

7603. The fumes of the fuel pass through the hops?—Yes; hence the necessity of good anthracite coal.

7604. During all your experience, has anthracite coal been used, or do you remember the time when hop kilns were worked with charcoal?—We use a little charcoal now, but charcoal is used for hastening up the fire. For instance, if the heat is flagging, or if we get the hop discoloured by the change of wind and the draught is not regular, by putting on a few pounds of charcoal it helps to kindle the anthracite and keep the heat up steadily. A few bushels of charcoal are used in each kiln each season, but only for regulating the fire; not as coal is used, but only to assist the coal.

7605. Have you any views whether there should be any alterations made in the practice of either washing or cleaning hops or drying them?—I think not. It is impossible for any sulphur to get into the hops in any appreciable quantity. I also think that the material we use is so thoroughly pure from any contamination that it is impossible for any damage to accrue from hops. I have heard that arsenic has been found in hops, but I have also known of hundreds of samples being carefully tested by an expert without any trace of arsenic being found. I can only imagine the possibility of any trace of arsenic where a very low class of gas refuse has been used as fuel, and the fumes have left any kind of soot—what I understand as soot, or whatever it may be—in the hops. I can imagine such a case, but the system of hop growing on a large scale is such that I think contamination from arsenic is impossible.

7606. I suppose to use any gas coke would be likely to spoil the aroma of the hops, would it not?—I have no knowledge about that. I have never used gas coke. We have always been able to produce a satisfactory article, one that has given satisfaction to the consumer, by the use of the best anthracite coal. I have adopted that course, and I have never attempted to use gas coke. If coal was at famine prices and coke available we might have used it, but there has never been the necessity.

7607. As far as your knowledge goes even the small growers do not use gas coke, do they?—No. The vessels come in with coal for the large growers, and the merchants who supply us with 100 tons will supply the small growers with one or two tons. The small grower gets exactly the same article as we get. It would not be of any advantage. Even if the smaller growers wanted cheap coal it would not be of any advantage to them.

7608. In your opinion it is unnecessary to take any precautions in the manufacture of hops for the brewer, but you admit yourself that traces of arsenic have been found in hops?—I have heard so, but I do not believe it. When I say I do not believe it, I would not dispute any evidence that has been brought before the Commission, but I think I should have known if it had been conclusively proved that any hops had been found with arsenic in them. For instance, the Hop Trade Association in London do not know of any instance where arsenic has been traced to hops.

7609. It is only lately that it has been looked for?—That is so.

7610. I suppose you would be prepared to say it would be probable that in those cases in which it had been found it might have come from hops that had been sprinkled with powder for the sake of mould?—I do not think that. If it is possible at all it is from using very bad fuel. I do not think it is possible in the growth of the hop, because these heavy, dirty sulphurs could not be got up on to the hops. We only use sulphurs which are absolutely pure—like this sublimated sulphur.

7611. Arsenic is sublimated with sulphur—it is all sublimated together?—Yes, if there is any; I am not a chemist, but what I look upon as the residue would, to my mind, contain the dangerous matter, but it may not be so.

7612. You think that if there is a risk of arsenic it is from the use of improper fuel?—Yes. I think there is no risk in any other way.

Mr. W. W. Berry.

10 May 1901.

Gas coke seldom used to dry hops.

Charcoal used, mixed with coal.

Arsenic in hops.

Any arsenic in hops would come from fuel.

Mr. W. W.  
Berry.  
10 May 1901.

7613. (*Professor Thorpe.*) Does any quassia get upon the hops?—I do not say it never does, but not often. It is used in the earlier stages.

7614. There is no idea in using quassia that it also adds to the bitterness of the hops, is there?—No. You would not find a good planter wishing to improve the quality of his hops by the addition of anything.

7615. (*Chairman.*) But as a matter of fact, it is very seldom that sulphur is ever used after the burr appears?—Only in very exceptional cases. I have known a case where it has been necessary, but only where the hops have been more or less neglected in the earlier stages.

7616. (*Professor Thorpe.*) Have attempts been made to follow the same methods of using insecticides in hop growing as in grape vine growing?—Only in respect to mildew. I have always thought there was something to be learnt from the vine grower on the question of mildew, because mildew is a most serious trouble to the grower, but the insecticides, I believe, are so different. What we require for our aphids is such a simple remedy and so cheap and easy to be applied, that we do not want to learn from anyone. In the case of sulphur, however, it is different. We have endeavoured to get some information with regard to the methods of applying sulphur. But I do not know any improvement on what we now use—on the finest flowers of sulphur.

7617. In France they largely use what are called the sulpho-carbonates; that is an alkaline solution made by burning together bisulphide of carbon and soda or bisulphide of carbon and lime. It is very soluble, and a very little goes a long way. Has that to your knowledge been used in England?—Yes, I think there are two or three people who are now putting up a compound wash which is used by the smaller growers who do not want to build up the necessary plant for producing the wash such as I use. They buy a cask, or even a gallon of this particular kind of wash, which contains a dissolved sulphur. We know because of the very foul smell when the bung is taken out. It is used to a small extent, but only to a small extent. It may be that we have something to learn in that direction.

7618. Is offal tobacco extract ever used by you as an insecticide?—It would only be used very early in the season, and in very persistent attacks. Nicotine is, of course, one of the best things to use to destroy insect life, but it is very costly as compared with soft soap and quassia. Where you have a plant to manipulate the soft soap and quassia there is nothing so cheap.

7619. I am not speaking of the direct application of nicotine so much as the mere infusion of waste tobacco—what is called offal tobacco, which is cheap enough. The Customs are only too glad if you will take it away?—I have never had it offered to me, or I might have experimented with it. I have no knowledge at the present time of tobacco juice being used in hop gardens at all, but it used to be used.

7620. You are not aware that the Board of Customs gives facilities to agriculturists and people making such things as sheep washes for the use of this product?—I know that every opportunity is given in bond for dealing with this stuff. Chemists have told me that there are some fruit tree washes, and washes which are used under glass, and so on, where it is used, but I do not know of its being used in the hop garden.

7621. The use of a product like that would have the advantage of entirely preventing the possibility of the access of arsenic?—Quite so.

7622. Are foreign hops treated very much in the same way as you have described in the case of English hops?—I have never had time to travel during the hop season. I have had to attend to my own crop, and I, therefore, have absolutely no knowledge on that point.

7623. You have no knowledge of the kind of insecticide which is used in foreign countries in connection with hops?—No.

7624. What I want to get at is whether foreign hops are more liable to contain arsenic than English-grown hops?—I should be glad to hear that they were, but I should not like to say so, because I have no knowledge.

7625. (*Mr. Cosmo Benson.*) Would you tell the Commission how much on an average it costs to cultivate an acre of hops?—£50.

7626. That includes rent, rates, tithe—in fact every-

thing from the commencement up to the completion of the curing of the hops?—£50 an acre. If I get over £50 an acre for the crop there is a profit; if I get less, there is a loss. Some seasons it will cost more, and for this reason: if we grow a large crop that large crop costs a great deal more to pick and cure and get to London than a small crop at a higher price per cwt.

7627. How much of the £50 an acre would you put down to labour: have you ever divided it?—I am afraid I could not give you those figures. If it would be of interest to you I would have them looked up. Labour would be by far the largest item. I should say roughly that £30 out of the £50 would be for labour, probably a little more than that even.

7628. By the time the hop reaches maturity it is more or less an artificial product?—It is unfortunate if it is. It is never so good as when it grows naturally. We have, however, to resort to artificial means to get hops at all in bad seasons. If we did not destroy the insects, the insects would destroy the hops.

7629. I believe you grow several sorts of hops?—We grow Golding hops and Golding hops only. But the Golding hop is in three sections: there is the old Golding which hangs later on the poles than any other varieties, supposing it is healthy, but there is an early Golding hop which is practically the same hop, but it ripens somewhat earlier. That was raised from one plant which was grown in the garden and cultivated on and on. It is called the Brambling Golding, as it originated in the Parish of Brambling. It is the same hop but it ripens earlier. We have an intermediate "sport" now which we call Cobb's variety. I grow no other varieties than those three.

7630. What is the object of growing three different sorts of hops: is it for kiln purposes?—I cannot admit there are three different sorts of hops.

7631. Then three hops that come to maturity at different times?—For this reason. We have to get labour from London and elsewhere, from the large towns, and it would be impossible from a commercial point of view to house all these people for 7 or 8 days only to pick the crop while it is at its best. We desire to pick our hops during three or four weeks, and we get the earlier section of the Golding hop, and the intermediate section, and the later section by careful selection. We have got the best variety of hop now, so that it will ripen in three stages. We can pick them now in about 3 weeks.

7632. (*Dr. Whitelegg.*) Are hops always dried by exposing them to the fumes of the fuel: is there any other method in use?—No.

7633. For what purpose is the sulphur used at this stage?—I am not competent to tell you the reason why, but sulphur, to the extent of about 20 or 25 lbs. to the acre, is scattered over the plants by means of the appliances I have explained, and it has the effect of stimulating a tired plant. For instance, if from atmospheric reasons, from very great heat and drought, a plant is flagging, it, so to speak, breathes the fumes of the sulphur, which is of great assistance to it.

7634. I mean rather the sulphur used in the kilning process—the sulphur that is burnt?—The sulphur that is burnt is, I think, used for the purposes of colour. It is for bleaching purposes.

7635. Is it used with all hops?—I have known experiments made where hops have been left unsulphured, and I have known the brewers to request that you will send them a few packages of absolutely unsulphured hops; but we have never known the order to be repeated.

7636. Does it alter the hop in any other respect except in colour?—Not the slightest; but when the hop is quite green and begins to dry, the sulphur fumes passing through give the hops the desired colour.

7637. Does that affect the colour of the beer?—I think not.

7638. Is it anything but prejudice on the part of the brewer?—I should imagine it is more or less a prejudice on the part of the consumer.

7639. But if so, it is an universal prejudice?—Yes.

7640. Have you been asked for any guarantee with the hops you supply to brewers?—I understand that brewers have asked for a guarantee from the hop trade. The hop trade is so convinced that there is nothing in the hops, and that it is impossible to get anything wrong in them, that they have declined to listen to any such proposal.

Mr. W. W.  
Berry.  
10 May 1901.

Tobacco  
extract as  
insecticide  
for hops.

Brewers  
require hops  
bleached by  
sulphur.

Hop trader  
have refused  
to guarantee  
hops as free  
from arsenic

W. W. Berry. 7641. (Professor Thorpe.) Even although they use arsenical coke?—We do not know of any arsenical coke being used. We only use anthracite coal, as far as I know.

7642. But you told us that the trade might occasionally use gas coke?—I say if they did there might be a danger, but I can imagine no danger in any other direction.

7643. But there is some danger as there is in the case of malt?—Quite so.

7644. If maltsters are required to give a guarantee, why should not hop growers be required to do so?—Well!

7645. (Dr. Whitelegge.) Would hop growers be prepared to give the same sort of guarantee which has been suggested in the case of maltsters?—I think they would resent it, and say "Why should we give a guarantee, we only use these things?" If you ask me personally my own feeling, I may say that I should be prepared to guarantee my article.

7646. As free from arsenic?—Yes.

7647. You are prepared to guarantee that you use only anthracite coal and Sicilian sulphur?—Yes.

7648. And your sulphur you would be willing to give up if the brewers would consent?—I should be glad to save the expense.

7649. An earlier witness has given us the results of analyses of hops. Bearing upon an answer which you just now gave that it was unknown to the trade that small quantities of arsenic had been found in hops, we have heard from one of the witnesses who has been called before us that a number of analyses of hops have been made in which small quantities of arsenic have been found?—Indeed! I should imagine that the samples could not have come from that part of the country which I have most knowledge of.

7650. What you have told us about the treatment of hops in growth and manufacture applies generally, I suppose, to other districts besides Kent?—Yes, I think so.

7651. You have told us that in Worcestershire it probably is the practice to use coke instead of anthracite?—Excuse me, I do not think I put it in that way. When the question of arsenic was raised I heard of a sample of hops which it was suggested had been dried with gas refuse, small coke. That, I understood, was a Worcestershire sample. But I have no knowledge of coke ever being used anywhere else.

7652. Your impression is that anthracite is principally used, even in Worcestershire?—Yes.

7653. Are there any other important centres except Kent and Worcestershire?—Yes. A good many hops are grown in Hampshire and Sussex, but the process is the same. Except in but a very few cases, I am certain that nothing but the very best anthracite coal is ever used. It is so easily detected if you get any other coal. If other than Welsh coal were used a farmer would know it directly he went into his kiln from the bad smell. A farmer dare not have a bad smell to his hops. If a brewer put his nose to the hops and found there was a bad smell to them he would not buy them. Of necessity we are bound to use the best coal.

7654. I suppose the curing is done on a small scale often: a small grower would cure his own hops?—Yes. There may be a man who has one kiln; in my own case I have thirty kilns, but the process in the one kiln is exactly the same as in my thirty kilns. I think the small grower puts his hops on the market as pure as I do. He buys his coal and sulphur from the same people.

7655. And you think he may be equally trusted to buy only anthracite coal and use pure sulphur?—I think so. He would have a difficulty in getting anything else.

7656. (Chairman.) I do not think you quite appreciate the difficulty. Where would the small grower

buy his sulphur?—He would buy his sulphur one cask at a time where I buy ten tons at a time.

Mr. W. W. Berry.

7657. He would probably buy it from a small dealer?—No, I think not. This business is the business of my district, and the sulphur comes down perhaps in 50 or 100 tons at a time to the town. I get my quantity, whatever I want, and the small man gets what he wants. He cannot get anything else. It is kept in stock. What is necessary for large people is necessary for small people, and they have no option. The small people must have the same thing as we have.

7658. Then you think there would be no difficulty in a hop grower obtaining from the sulphur seller sulphur which was pure?—That is my opinion. I have asked all the men I have dealt with if they think the sulphur is pure, and they have told me that they will guarantee that everything shall be pure. They say they believe it is always pure.

7659. But do you think in the future there will be any difficulty in the hop grower obtaining from the firm from which he purchases his sulphur a guarantee of purity?—I have in my hand guarantees from the people from whom I buy, and I have already bought on that guarantee.

Hop growers' sulphur is guaranteed free from arsenic.

7660. What do they guarantee?—I have here a letter from Brandram Brothers and Co., Limited, manufacturers of white lead, and vermilion colour grinders, refiners of saltpetre, brimstone, etc., etc. They write from Rotherhithe, under date of April 15th, 1901, as follows:—"Mr. H. S. Tett, Faversham. Dear Sir,—Enclosed we beg to hand you a supply of circulars, re our sulphur products, guaranteeing same free from arsenic, for distribution amongst your customers. Should the supply be insufficient we shall be happy to send you more. Yours, very truly, Brandram Bros. and Co., Ltd." With that there is a printed notice, which is as follows:—"Notice. To Hop Growers, Chemists, and others. In consequence of the recent trouble caused by the presence of arsenic in beer, Messrs. Brandram Bros. and Co. Limited, of Rotherhithe, London, S.E., beg to state that their 'Brandram's' Pure Sublimated Flowers of Sulphur, 'Brandram's' Finest Virgin Roll Brimstone, 'Brandram's' Finest Hop Sulphur, 'Brandram's' Finest Powdered Sulphur Vivum, have been analysed by the eminent Analytical Chemists, Messrs. E. F. Teschemacher and J. Denham Smith, of 1, Aubert Park, Highbury, N., and pronounced by them to be 'free from arsenic.' That is the notice. The letter says that they guarantee their products all free from arsenic. This is from the principal firm, and I have similar letters from two or three others.

7661. So that in future you think there would be no difficulty for a hop grower getting a guarantee of the purity of the sulphur he uses if he asks for it?—That is so. The fact that that class of sulphur is being sent down to the hop districts would, I believe, make it very difficult for any man to get any other variety than that.

7662. (Dr. Whitelegge.) Would you go so far as to say that it would be wrong to use any other fuel than anthracite and possibly charcoal?—I do not know that it would be wrong, but my successes have been built up by using the very best fuel I can get. I buy the best of everything. The difference between an inferior article and the best is usually only a few shillings. I think £10 a year would make all the difference between buying the best anthracite or the second best. The railway carriage from South Wales is the same. It is only a question of prime cost on the bank, whether it comes out of No. 1 or No. 2 vein.

Anthracite of different qualities.

7663. You do not consider it right to use gas coke?—No, I do not. There is no saving in using it. If the kilns are properly constructed, and the coal is judiciously handled, best anthracite coal is as cheap as coke. The better the quality of the coal the more economical it is.

## SIXTEENTH DAY.

WESTMINSTER PALACE HOTEL.

Monday, 13th May, 1901.

PRESENT:

The Right Hon. Lord KELVIN (in the Chair).

SIR WILLIAM CHURCH.  
Prof. THORPE.Mr. COSMO BONSOR.  
Dr. WHITELEGGE.

Dr. BUCHANAN, Secretary.

Mr. HUGH BAIRD, called; and Examined.

Mr. H. Baird. 7664. (Chairman.) You are a large maltster in Scotland?—Yes.

13 May 1901 7665. Can you inform the Commission what fuel is used in your maltings?—We use nothing but anthracite coal. We have drawn it from one pit from ten to twelve years, namely, the Gartshore Pit, Stirlingshire.

Anthracite hand-picked at collieries 7666. Do you select the fuel in any way, or simply take what comes from the mines?—The fuel that is sent to us has been passed over screens and then through meshes to get it of one size. At the foot of these screens boys and women watch for any piece that they think doubtful. Then when it comes into our possession we have it all riddled before utilising it in any of our furnaces.

and riddled at maltsters. 7667. A piece looking doubtful in what respect?—Sometimes they may think a piece is not perfectly pure—a dull piece, and then it is thrown to one side.

7668. Those pieces are all rejected by you?—They do not come to us at all. They are rejected at the coal pit.

7669. What length of time is your malt kept on the kiln?—From four and a half to five days.

7670. What steps are taken to prevent accumulation of dust and deposit—the products of combustion?—All our beams and our plates are brushed down once a week, and oftener if required.

7671. And is the floor bared and swept occasionally? Below the kilns it is swept out regularly, sometimes every day, but always twice or three times a week.

7672. That is the bottom of the kiln. But what about the floor on which the malt dries?—That is cleaned every time the kiln is taken off.

7673. Every time the malt is taken off the floor and sides of the kiln are brushed?—The kiln floor is brushed clean, but I referred prior to that to the floor below the kiln, where the dust may come down through the holes on to the bottom floor.

All brewer's malt brushed. 7674. At what stages of malting, and how often, is your malt screened and brushed?—We clean our malts twice as they leave the kiln before they go into the deposit rooms, and then it is cleaned once, and sometimes twice, over the machinery before it goes to the consumer.

7675. In the case of malt going to breweries would all grades of malt receive the same amount of brushing?—All malts we send to our customers do receive the same amount of brushing.

Pneumatic malting not as satisfactory for brewers as kiln 7676. Have you had experience of pneumatic malting?—We have.

7677. Do you use it?—We have got one drum, and we work it for distillers' malt, but not for brewers' purposes, because we do not approve of it. We do not think it makes the high-class malt we require to send out to brewers.

7678. In what respect is the malt inferior?—We have found a difficulty in getting it rid of the moisture. We cannot get our malt what we call freed properly.

7679. In the pneumatic malting, is not the air drawn through several cylinders or drums which rotate?—Yes.

7680. So as to shake the malt?—The malt falls over gradually.

7681. But you find you cannot get the malt properly dried that way?—We do not dry it in a drum at all. Some people do dry it in a drum, but not in the same drums used to germinate the malt.

7682. In the pneumatic malting the drying would not necessarily take place in drums, though germination does?—I believe some drums are constructed for drying, but I have never seen them.

7683. In "pneumatic malting," as generally understood, then, the drying would be done on the same plan as ordinary kiln drying?—We do so. We dry it the same way in an open kiln.

7684. Why is it that you cannot dry it so well in drums?—We have no experience of drying malt in a drum, and from what I have heard, people do not like it.

7685. What objection do you understand is made to it?—I do not think malt can be cured unless heat passes through it, and in the pneumatic drying drum you can only pass the heat from the exterior, or through the pipes running through it, and it does not get the same amount of heat applied to it that it would get in an ordinary kiln.

7686. In the pneumatic drying drum the drum is heated, and heated air is drawn through?—Yes.

7687. We have been told there are various processes by which the malt can be kiln dried without being exposed to the fumes of the fire. We have been told that in some of the chief beer factories of Germany the malt in drying is not exposed to the fumes of the fire at all?—There are such kilns in Germany.

7688. Have you any experience or knowledge of those kilns?—I have not seen them at work.

7689. That malt makes German beer which is esteemed for some qualities?—Of course, German beer is treated in an entirely different manner to home beers; the mashing process is quite different, and, therefore, that malt, although it might suit their purposes, would not suit home-brewed beer at all.

7690. Why do you think malt that has been dried without exposure to the fumes of the fire should, if properly dried, not give as good beer?—I see no reason why it should not, if it is properly dried; but it is a question if it is properly dried.

7691. We have been told that part of the flavour that is required by the users of beer in this country depends on the exposure of the malt to the fumes of the coal, and that if the malt was not exposed to the fumes of the coal, it would be impossible to get the flavour that is liked?—You cannot get the flavour if the fumes from the fuel do not go through the malt.

Mr. H. Baird.

13 May 1901

In pneumatic malting fine drying is on the kiln.

German malt not exposed to fumes

but would suit English beer.

Flavour of fumes essential

7692. What part of the fumes is it that give the flavour?—I think it is more because on account of the fumes the heat is properly applied to the malt, and gets thoroughly through the malt.

7693. Then, if it were hot air instead of hot fumes, the result, so far as drying, would be thoroughly the same?—It might be, but I question it.

7694. Have you reason to believe that the carbonic oxide or the carbonic acid, or anything else in the fumes is essential to the flavour of the malt?—I should not like to answer that.

7695. Do you see any reason why that malt should not be kiln-dried purely by hot air, supposing the process could be carried out, and produce a malt quite as good as that produced by the present process?—I do not think it could, as far as my judgment goes.

7696. Suppose the hot air gets through it just as much as the fumes of the fire?—There is something that must come from the fuel which gives a flavour to the malt that we cannot get with hot air.

7697. Very different kinds of fuel are used. We have been told by witnesses that in some of the first-class English malt-making oven coke is used. The fumes of oven coke are very different from the fumes of anthracite?—You can get such from pure coke, and also from anthracite. In our high-dried malts we cannot get the same heat from coke to apply to the malt as from anthracite. Especially for stout brewing, we find we get heat from anthracite that gives our malt a flavour, which you might call an oatmeal flavour, which you cannot get otherwise.

7698-99. Have you ever used peat for fuel in your kilns?—Once, and once only, and we had to take the whole kiln down before we could make brewers' malt on it again. We could not get quit of the flavour.

7700. But for distillers' malt it would be suitable?—Yes. It was for a distiller we made it. His works were burnt down, and we did it for him, and the whole kiln was impregnated with peat to such an extent that we could not use it.

7701. The peat fuel is practically used largely for malt for whisky?—Entirely to give whisky the flavour.

7702. Is there any other fuel used for malt for whisky?—Yes, coke.

7703. The greater part of the whisky is made from malt dried by other fuels than peat?—I should say so, the greater part.

7704. Have you made any change in your practice in consequence of the discovery of the liability of malt to arsenic?—No.

7705. Have you had chemical tests made of your malt?—Yes, we have had them regularly made by several chemists.

7706. With what result?—They were found free, except in one case, and that gave us 1-350th of a grain per lb. of malt; the same malt at the same time was tested by three other chemists, who found it perfectly free.

7707. Have you ever had the dust that comes away in the brushing and screening examined?—No, we have not, but our combings that come from the malts were found perfectly free.

7708-9. Do the combings carry with them an outside surface that has been exposed to the fumes of the fire?—Yes.

7710. The combings are chiefly the rootlets?—Yes.

7711. Not the husk?—No husk.

7712-13. Besides the process of screening that takes away the combings, you use brushing to remove incrustation from the outside of the husks?—Yes, we have had brushes in force for about twelve years now.

7714. Have you had any chemical analyses made of the fuel that you used?—We have, and a sample of an anthracite has been declared free from arsenic.

7715. Did you have it done before this scare?—Not before.

7716. Therefore, you have made a little change in your practice in that respect?—We made a change to see if it was pure.

7717. Have you had the malt examined before brushing?—We have not. We have had it always done after it left our screens.

7718. Except in the one case, in which a very small quantity of arsenic was found, no arsenic has been

detected at all in the malts?—No, in none of our malts. I may add that we have them done every week by our own chemist, and by other chemists for arsenic. That is since the scare commenced.

7719. What tests for arsenic have been applied?—I believe the whole of them used the Marsh tests.

7720. Have you been asked to guarantee your malt free from arsenic?—We have, and have done so.

7721. For some time?—For certainly the last five months. I know our malts have been going to brewers' chemists and found all right. I do not know who the chemists were, but they were found perfectly free from arsenic.

7722. The answers to the questions which have been put to you apply to all your maltings?—My answers apply to all the malts we make ourselves. Of course, distillers' malt is not brushed or screened; it goes with the rootlets attached to it. A distiller uses the rootlets along with the malt, except in certain cases, where malts are used for making yeast, and then they have the very best that can be got.

7723. The rootlets contain a fermentable matter?—There is a certain amount of saccharine matter in them, and it can be converted to alcohol, I suppose.

7724. If the rootlets were taken off, would the malt lose some of its value for distillers?—I cannot say.

7725. But in beer the rootlets are never used?—Never.

7726. You send away the rootlets to be used for cattle feeding?—Yes; in fact, all our combings go to the Continent for feeding cattle there. We have had contracts for years for all to go to one port.

7727. What place?—They go to Denmark and Hamburg.

7728. You actually send from Scotland food for cattle to Denmark?—Yes, they buy it from us regularly.

7729. Where is your barley grown?—Nearly all in Scotland, and some in Yorkshire.

7730. You use some foreign barley?—Both foreign and home.

7731. Is the greater part of the barley you use home grown?—The larger proportion.

7732. Does the home supply sometimes fail, and necessitate your taking foreign barley?—We require to make a large quantity of malt from foreign grain for brewers' requirements.

7733. Does the foreign malt fulfil certain requirements that cannot be fulfilled by home-grown malt?—It does. The brewers hold that it brightens the beer more quickly.

7734. May we take the answers you have given as applying on the whole generally to other large malsters in Scotland?—I think so.

7735. The same system as you follow is practised by the others?—I think so. Everyone has his own system, but I think they are all very particular.

7736. (Sir William Church.) Do the distillers use very much foreign barley?—Some of our distillers use nothing but foreign barley, and others use a large proportion of home. The Highland distillers and the distilleries in the north use nearly all home barley, and they fall back on heavy foreign when they cannot get home; that was owing to the great demand for whisky a few years ago, and the great quantity of whisky distilled.

7737. You mean by the northern whiskey makers the people about Inverness, for instance?—And on the West coast, too.

7738. They use chiefly home-grown barley?—Yes.

7739. That barley must be less well harvested than the barleys of the Southern counties?—Certainly it is; but in some cases some of our northern districts in Scotland grow as fine barley as I ever saw anywhere—Cromarty, Ross-shire, and Inverness.

7740. But they are more liable to have it injured in the harvest?—It depends entirely on the weather. We have seen barley grown in the finest counties in England ruined by getting rain before we got it. Our barleys were not so ripe, and could stand up against the weather, whereas English barleys being riper would give way.

7741. You told us that the distillers, who want, of course, a very high percentage of alcohol, use home

distillers.

malt to a very great extent. We have been told that you want the foreign malt because weight for weight it contains more fermentable matter than the home malt, and less nitrogenous matter?—The northern distillers and the west coast distillers make malt whisky. The southern distillers are raw-grain distillers, and they not only use a large quantity of Indian corn converted, and they malt this light foreign barley to assist them with their converted maize. There are two distinct distillers, the grain distiller and the malt distiller.

7742. I do not know whether you could answer this question for me. I suppose that the presence of nitrogenous matter in the malt in undue proportions is not so important for the distiller, who distils his product, as for the brewer who does not?—That I could not say.

7743. (Dr. Whitelegge.) In one sample, and one only, arsenic was found in a very small proportion—1-350th you say?—Yes.

7744. Was that brushed?—Yes. It was ordinary screened malt that went from one of our malthouses. It was screened and brushed.

7745. Do you make more than one class of malt?—We do.

7746. Several classes?—Yes.

7747. Is brushing applied equally to all?—All our pale malts are brushed and screened, and have been so for fully twelve years.

7748. How long has it been the practice to pick over the fuel in the way you describe to us?—Our man has told us it has gone on ever since we got it from him.

7749. Do you stipulate for that?—Yes; we made a stipulation for nothing but pure anthracite coal, and it has to be picked over.

7750. (Chairman.) Can you give the Commission the form of guarantee that you use?—As far as my memory goes we guarantee our malts pure.

7751. (Mr. Cosmo Bonsor.) Perhaps you will send it in?—I will send a copy with pleasure; it is a stamped form. "Our malts are free from all foreign or poisonous matter." We stamp our invoices with this when requested for a guarantee.

7752. (Chairman.) That is your guarantee?—Yes.

7753. And the condition that you exact in respect to the coal, to have it hand-picked by the people at the pit mouth; have you that form?—We have not that in writing; we simply insist on nothing but pure anthracite coal being given to us. I should just like to say, of course, that we use coal in our kilns, but we use to a large extent coke in our retorts. We are large makers of black malt. Of course these are hermetically tight.

7754. The black malt is not exposed to the fumes at all?—No.

7755. The black malt is made from grain first malted in your kilns?—It is first dried at our kilns, and then converted into black malt in the cylinders or the retorts.

Form of  
guarantee  
of malt  
given.

No guarantee  
with fuel.

Black malt  
not specially  
exposed to  
fumes.

7756. But so far as the kilning is concerned there is no distinction?—No.

7757. And then you put it afterwards into the cylinder, like a coffee roaster?—Yes.

7758. In these cylinders you use whatever fuel you like?—What we can get the greatest heat from. We have not the same draught, and therefore we cannot use anthracite coal with it.

7759. (Mr. Cosmo Bonsor.) Do you kiln-dry your barley?—All our home barleys.

7760. That is kiln-dried with anthracite, and not coke?—With anthracite, and not coke.

7761. (Chairman.) In that first drying, the heat is much less than in a final kiln drying?—A great deal less.

7762-65. (Dr. Whitelegge.) Do you know anything of any method or suggestion of treating fuel with lime, or other base in such a way as to prevent it giving off arsenic?—I never heard of it.

7766. (Chairman.) I wish we could really get information of a positive kind, whether or not the exposure of the grain to the actual fumes of the fire is required to get the proper flavour. We have asked many gentlemen who know their own business well, and know the business generally, and we have got no decided answer, but merely the answer that there is a general opinion or idea that the hot air which kiln-dries the malt ought to come from the fire, if the beer is to have the desired flavour, but we have no experimental proof of that opinion at all. We had one interesting statement to the effect that in a certain particular case of kiln drying, the malt was not exposed to the fumes of the fire, and it was very good. Have you information of that kind?—There has been only one kiln recently erected in Scotland to dry malt without a direct fire, and that has been erected to make lager beer, because when they put it on the other kilns they found they wanted not to dry it so highly. I do not know the result of that.

7767. But that makes lager beer?—Yes; I question whether the malt would make Scotch beer. But I have not heard the results.

7768. There does not seem any good reason to expect that if the malt was dried with hot air at the same temperature, and to the same amount of dryness, without the fumes having come from the fire itself, the result would not be as good?—I do not think it would be as good.

7769. (Mr. Cosmo Bonsor.) Could you sell it?—I question whether I could.

7770. (Chairman.) You have never made the experiment?—I have been asked by a distiller to make malts for him when he got into trouble.

7771. (Professor Thorpe.) Is not the distinction rather of the same order as that which obtains between meat roasted at the fire and meat roasted in the oven; there is a belief on the part of some people that meat roasted in the oven has not the same flavour as when roasted before the open fire?—So I understood.

Kiln-drying  
of barley.

Flavour  
of fumes  
thought to  
be essential.

Mr. EGBERT GRANT HOOPER, called; and Examined.

Mr. E. G.  
Hooper.

7772-5. (Chairman.) You are a Fellow of the Institute of Chemistry, Fellow of the Chemical Society, and a Member of Council of the Society of Chemical Industry?—Yes.

7776. You have been an analyst for 24 years in the Government Laboratory?—That is so.

Samples of  
arsenical  
beer, on  
which rebate  
claimed,  
tested at  
Government  
Laboratory.

7777. What have you to say with regard to experience of the Government Laboratory in the question of the presence of arsenic in beer?—The question of the presence of arsenic in beer and brewing materials first presented itself officially at the Government Laboratory at the beginning of December last, when, in consequence of the discovery of arsenic in certain beers brewed in Lancashire, applications were made to the Board of Inland Revenue to permit the destruction of the contaminated liquor in the presence of Excise officials, with a view to the repayment of the duty which had been charged upon it. Samples of such beers were then forwarded to the Government Laboratory, and continued to be received for some time. In all 748 samples have been lodged, representing 28,264 barrels, the produce of 67 brewers scattered throughout 11 counties, but mainly in Lancashire, Staffordshire, and

Yorkshire. It cannot, however, be asserted that this comprises the produce of every brewer who may have used arsenicated materials, as some are known to have destroyed their beer immediately they became aware that it was contaminated, and without lodging applications for the repayment of duty. An examination of the brewers' entries of the materials used in the particular brewings, together with a determination of the exact original gravity, and a qualitative examination of the beer for arsenic, would have sufficed to substantiate the claim for drawback, but with a view of affording information to the Royal Commission, it was decided to make a more detailed examination in order to obtain some precise knowledge as to the extent to which the beer had been contaminated. The accurate estimation of the amount of arsenic in so large a number of samples would, of course, have occupied a very considerable amount of time, and it seemed unnecessary to do more than to make a selection from the produce of each brewer. In all 143 quantitative determinations of the arsenic in these beers have been made, and full particulars with reference to the origin of the samples, the dates of brewing, and the proportions of arsenic found are given in Table I., from which it may be

Mr. E.  
Hooper

Quantitative  
determinations

seen that the results are fairly representative of the whole. There is no reason to suppose that any further information as to the order of amount in which arsenic was present in the contaminated beers would have been obtained if the entire number had been quantitatively examined. It may be stated that in the Government Laboratory the estimation of minimal amounts of arsenic in metals, such as zinc, copper, and tin supplied by contractors to the Post Office, India Office, etc., is of constant occurrence, and considerable attention has been given for some years past to the subject of its accurate quantitative determination. It appeared possible that the process employed in such cases might be so adapted as to permit of the separation of small quantities of arsenic from beer and brewing materials—that is, from solutions containing a relatively large amount of organic matter, and experiments were made, to begin with, to ascertain how far the associated organic matter interfered with the accurate estimation of arsenic by the well-tried methods hitherto used. Known quantities of arsenious acid were added to wort and beer, and after concentration, the arsenic was precipitated with sulphuretted hydrogen. The sulphide of arsenic, with a varying amount of organic matter which falls out of solution in the course of the treatment, was then filtered off, and afterwards distilled with ferric chloride and hydrochloric acid. Under these circumstances the arsenic distils as arsenious chloride, accompanied only by a small amount of organic matter, from which it can be readily freed, and the arsenic is finally precipitated and weighed as arsenious sulphide.

7778. You say "a small amount of organic matter from which it can be readily freed." Will you describe to the Commission how it is freed from organic matter?—The precipitate of sulphide and of organic matter is collected on a filter paper, the filter paper is rolled up with its contents, and transferred to a small flask, where an addition of hydrochloric acid and ferric chloride is made, and, on heating, the arsenious chloride distils off, carrying over at first a trace of organic products, but only a trace. The distillate contains the whole of the arsenic. It may be necessary to redistill it to free it from the traces of organic matter carried over, but after such distillation the sulphide is precipitated with sulphuretted hydrogen, and is weighed on a Gooch capsule on a layer of asbestos. The apparatus is in the next room if the Commissioners would like to see it.

7779. You said that the distillate carries away the whole of the arsenic. Have you tested the residue to see whether or not there is some arsenic in it?—Yes; after the first distillation a second distillation is taken, and the distillate collected apart. Sulphuretted hydrogen is passed through that second distillate to see there is no arsenic. Should there be arsenic a third distillation is taken, and so on, until a distillate is obtained which contains no arsenic.

7780. But, as a rule, is all the arsenic carried off in the first distillation?—Where the quantity is small, as in any of these beers, it is so. Where the quantity is large, as in some of the experiments we have made, amounting up to 19 or 20 milligrammes instead of 2 or 3, then a third or fourth, and in some cases where the organic matter has been considerable, as where we have taken a large volume of wort to operate upon, the five or even six distillations were necessary to get over the last trace of arsenic. (The apparatus was exhibited, and explained to the Commission.) The beer having been concentrated from a litre down to about 150 cc., is acidified by the addition of hydrochloric acid; sulphuretted hydrogen gas is passed through it, and we then get the arsenic precipitated with a certain amount of organic matter. After standing for some hours it is filtered, generally the next morning, on a plate filter just covered with a filter paper, and the amount of matter which separates is of this character. This includes the arsenic and the organic matter. It is rolled up with its contents and transferred to this small flask, where hydrochloric acid and the ferric chloride solution are added, and the distillation is then commenced.

7781. The paper disappears?—It becomes more or less charred and disintegrated. The connections are all ground so as to fit tightly and no cork or rubber is in any way in contact with the hydrochloric acid which distils over, carrying with it the arsenic chloride. It meets nothing but glass on its way; the whole of the arsenic chloride is retained in the first receiver, but by way of precaution, lest any trace should escape condensation, a side delivery tube passes any vapour through a U tube containing a small quantity of water. This dis-

tillate contains the whole of the arsenic. Sulphuretted hydrogen is then passed through the solution, with the result that the arsenic is precipitated there, not quite of pure colour. This is separated and redistilled, with the result that a pure distillate of arsenious chloride is obtained, which is once more precipitated by sulphuretted hydrogen, and the pure arsenious sulphide is then filtered on to a small perforated Gooch capsule coated with a little asbestos.

7782. How is this asbestos prepared?—It is treated with hydrochloric acid washed and heated to redness.

7783. This looks like a piece of fabric?—Yes, the finely divided asbestos fibres settle in a felt-like layer.

7784. It simply results from the asbestos being allowed to settle?—Yes.

7784\*. (Professor Thorpe.) It has not merely settled but been pulled into a tight mass by the force of the pump?—Yes.

7785. (Chairman.) How is the asbestos got into that finely subdivided condition originally?—A special preparation of asbestos is sold for the purpose, but we go through it carefully, and see it is finely divided; it is shaken up with water, and a little of the water is poured on, leaving the layer of asbestos.

7786. This makes a very thorough filter?—Yes.

7787. And allows nothing of the precipitate to go through?—None whatever.

7788. Is it as thorough a filter as the best blotting-paper filter?—Yes; it is better in many respects than even the finest papers we have.

7789. As thorough in its prevention of anything going through?—That is so. It has also the advantage afterwards that, unlike paper, after being dried it is not hygroscopic; it does not take up moisture, so that you can weigh it without any danger of its increasing in weight from the absorption of water from the atmosphere.

7790. Gooch's filter, including the small Gooch capsule, and the use of the asbestos you have described, is a well-known process?—Yes.

7791. What have you to say about the validity of this method?—The validity of this method of determining the amount of arsenic in beer and brewing materials was established by the following experiments, viz.:—(1) Malt worts produced in the laboratory were examined by the process, and proved to yield no arsenic. (2) To malt wort proved to be free from arsenic, known quantities of arsenious oxide were added, and the arsenic then separated and determined. Thus: Arsenious oxide added 0.5 milligrammes, quantity found 0.56 milligrammes; arsenious oxide added 1.9 milligrammes, quantity found 2.1 milligrammes; arsenious oxide added 4.8 milligrammes, quantity found 4.9 milligrammes; arsenious oxide added 19.2 milligrammes, quantity found 18.8 milligrammes.

7792. Added to how much wort?—To either a litre, or half a litre of malt wort. To prove that beer might be concentrated directly, i.e., in the slightly acid condition, without loss of arsenic, the following experiment was made. Arsenicated beer from a brewery was divided into two portions of 900 c.c.s. each. One portion was directly evaporated, and the other was first rendered just alkaline by the addition of pure caustic soda, and then evaporated. The two experiments were otherwise conducted alike, and the arsenic estimated by the process already described. The results in the two cases were 0.21 and 0.20 grain of arsenious oxide per gallon of beer. As regards minimal quantities, it may be pointed out that quantities of arsenious sulphide not exceeding two-tenths of a milligramme are readily isolated and weighed. Two-tenths of a milligram of arsenious sulphide calculated on a litre of beer equals 0.011 grain per gallon, or one part in more than six millions, and the same weight calculated on 100 grammes of sugar or of malt equals 0.011 grain per lb., whilst one litre of beer or 100 grammes of brewing sugar or of malt does not represent the maximum quantity that it is possible to employ for analysis when using this method. Further experiments are described later in connection with the study of the influence of fermentation. For the determination of arsenic in brew- Similar ing sugars a weight of 50 or 100 grammes of the sugar is method of dissolved in 150 c.c.s. of water, acidified with hydro- testing malt. chloric acid and the arsenic precipitated with sulphuretted hydrogen, and ultimately separated and weighed in exactly the same manner as in the case of beer. In the case of malt the same process is used, the arsenic

Mr. E. G. Hooper.

13 May 1901.

The method tested with malt worts made in the laboratory.

Mr. E. G.  
Hooper.  
13 May 1901.

being removed from the malt, where unground, by heating two or three times with hot water, containing a little pure alkali, and where ground, by first mashing and then thoroughly washing the grains. The washings, or the combined wort and washings, as the case may be, are then concentrated, and treated for the separation of the arsenic by the process adopted for beer.

7793. (Chairman.) Would the alkali suffice to take the arsenic out of any grain when not ground?—There would be no difficulty whatever in taking the arsenic out.

7793a. Would it not take a long soaking before the arsenic would come out?—No. Boiling water dissolves 11 per cent. of arsenious acid, consequently the very small quantity of arsenious acid present on the malt would be readily dissolved.

7794. If on the outside of the malt?—It always is if it is unground.

7795. But if there was any arsenic inside it would not come out so readily?—No, it would be necessary to practically turn the malt into wort.

Question of  
combination  
of arsenic  
with organic  
matter of  
beer.

7795. What have you to say as to the influence of fermentative action on arsenious or arsenic oxide present in wort, with special reference to the possibility of the formation of so-called organo-arsenic derivatives and consequent failure to detect the arsenic in such compounds?—It was considered advisable that a fermentation experiment should be made on a scale sufficiently large to afford clear evidence of any formation of organo-arsenic compounds from which arsenic would fail to be separated by the process described. With a view of imitating, as far as laboratory appliances would permit, the conditions obtaining in practice, it was decided to operate upon a relatively large volume of wort containing from two to three grains of arsenious oxide per gallon. In such a case the quantities of liquid and of arsenic might be anticipated to afford an unequivocal result, and if any loss occurred in consequence of the increased difficulty of separating the last trace of arsenic from the considerable amount of organic matter accompanying the sulphide, as first precipitated and necessarily distilled with it, this would tend, not to obscure, but to increase the weight of evidence of the formation of such organo-arsenic compounds. A quantity of wort of 1060° gravity was accordingly prepared and divided into three parts. To one part (a litre) yeast was added in equal quantity to that used in the two succeeding experiments, portions of the same bulk of yeast being used in each of these cases. When fermentation was complete the liquid was concentrated without separating the yeast and the whole tested for arsenic. No arsenious sulphide was obtained, and the freedom from arsenic of both wort and yeast was thus established. To five litres of the wort 193.7 milligrammes of arsenious oxide was added and then yeast as before. Fermentation was allowed to proceed until the specific gravity of the resulting beer had been reduced to 1016°, and the whole bulk, including the yeast, was then concentrated and the arsenic determined as in previous instances. The amount of matter first separated was, of course, large, and several distillations were necessary before a distillate was obtained which contained no arsenic. Finally the pure arsenious sulphide, as weighed, equalled 190.3 milligrammes of arsenious oxide against 193.7 milligrammes added. Thus 98.2 per cent. of the arsenic present was recovered under these conditions, or, in other words, instead of 2.71 grains per gallon known to be present, 2.65 grains were actually found, and if any organo-compound of arsenic was formed, the extent to which it eluded detection amounted to no more than 0.06 grain of arsenious oxide per gallon. As a measure of the action exerted by yeast in removing arsenic from arsenicated wort the following experiment was next made. To a third portion of the wort previously tested, arsenious oxide was added to the extent of 2.51 grains per gallon. It was then fermented by the addition of the yeast already proved to be free from arsenic, and when fermentation was complete and the bulk of the yeast had deposited, the wort was syphoned off and cleared by the addition of finings. When the finings had settled, five litres of the clear beer were separated, and in this quantity the arsenic was determined as before. The arsenic found amounted to 171.9 milligrammes, against 179.8 milligrammes of arsenious oxide known to be present, correction being made for the alteration in volume due to the addition of finings. There was thus a recovery of 95.6 per cent., and diminution of arsenical contamination by the removal of the yeast formed during fermentation in this particular

No alteration  
in recover-  
able arsenic  
results from  
fermentation

case therefore did not exceed 4.4 per cent. even in a strongly contaminated beer. Expressed in grains of arsenious oxide per gallon the reduction was from 2.51 to 2.40 as an extreme result, for this determination again was made on the large quantity of five litres. It remains to be determined how far hops (with or without associated sulphur) may influence the removal of arsenic by the formation of arsenious sulphide, which may be removed either by straining through the hops in the hop-back, or by subsequent deposition on the surface of the yeast. To prove that arsenic oxide if present would be isolated by this process as readily as arsenious oxide, and that fermentation in this case also in no way interfered with the ultimate determination of the whole of the arsenic present, two further experiments were made. Known weights of arsenic oxide were fully oxidised by boiling with bromine-water, and after the excess of bromine had been boiled off, the solutions were added to wort, and the latter fermented. When fermentation had ceased, the resulting beers were concentrated, and the arsenic present in each case was determined as in the previous experiments. The results were as follows, viz. :—

EXPERIMENT I.		
Arsenic equal to)		milligrammes.
arsenious oxide)		added 3.45
		found 3.45
EXPERIMENT II.		
Arsenic equal to)		milligrammes.
arsenious oxide)		0.7
		0.8

A control experiment was carried out in this case also, and the wort and yeast used proved to be free from arsenic. It will be seen that these fermentation experiments afford little or no evidence of the formation of organo-arsenic compounds, but, on the contrary, indicate that there is either no production of compounds from which arsenic cannot be separated by the ordinary tests, or that, at the outside, such compounds are only formed to an extent that for practical purposes is quite negligible.

7796a. (Chairman.) I see you say "known weights of arsenious oxide were fully oxidised by boiling with bromine water?—Arsenious acid on being heated with an oxidising agent, such as bromine, becomes converted into arsenic acid. Arsenic acid is not immediately precipitated by sulphuretted hydrogen. In other words, it has to be reduced to the arsenious condition before sulphuretted hydrogen acts upon it with the production of arsenious sulphide. Therefore it might be contended that if arsenic acid were present in any of these brewing sugars and went through the brewing process unchanged, the process of precipitating that arsenic by means of sulphuretted hydrogen would fail so far as arsenic acid was present. We have proved, whether arsenic acid or arsenious acid be present, both are separated and determined by this process.

7797. (Chairman.) What was the composition of the wort used for fermentation in the experiment?—It was entirely malt wort.

7798. No glucose?—No glucose was added.

7799. Before it was fermented was it boiled as would be done in actual brewing with hops?—Yes, it was boiled, but no hops were used that the question might not be complicated by any action the hops might have on this particular experiment.

7800. In the experiment in which the yeast was separated, was the arsenic in the yeast estimated?—It was not.

7801. Have you any evidence as to the form in which the arsenic is present in the yeast?—None.

7802. In these experiments have bi-sulphites or other preservatives been added?—No preservatives were added.

7803. Nor phosphates?—No.

7804. Nor yeast foods?—No.

(Professor Thorpe.) Have you any reason to believe that any of these things would modify the results?—No.

7805. Assuming that the wort has been made partially with a saccharine solution such as glucose or invert, is there any reason to believe that the results would be in any way modified?—I think not.

7806. (Sir William Church.) When you added compounds of arsenic such as cacodylic acid or any of its salts, you would not recover them by this method?—

Mr. E. G.  
Hooper.  
13 May 1901.

13 May 1901.

6. Express experiments have not been made with cacodylic compounds, but it has been proved here that no cacodylic compound is formed naturally in malt wort, or if any such compound is formed, it is actually operated on by the sulphuretted hydrogen and is obtained in this process. There is no evidence, however, of the formation of any such compounds in an ordinary fermentation.

7807. That I follow and understand, but supposing that it were present, this process would not discover it, would it?—It is stated that cacodylic acid is not precipitated by sulphuretted hydrogen. If sulphur compounds are formed they appear to be either soluble in or decomposed by hydrochloric acid.

7808. But you have not performed any direct experiments for that purpose?—No.

7809. You have kindly shown the Commission all the steps of this process, which is very complete, but at the same time it does not seem to me to be a very laborious chemical process? It is simple enough?—That is so.

7810. I was going to ask whether in your opinion such a test as that could be satisfactorily worked by any competent analytical chemist?—Quite so. There is no difficulty at all about it. Every piece of chemical work demands care and accuracy. There is nothing involved about this; it requires just the usual care and accuracy which any good piece of chemical work demands.

7810a. (Chairman.) It is very much more laborious or longer than the Marsh test?—Yes. Naturally it takes a considerably longer time. This is a quantitative determination instead of a mere qualitative test.

7811. This determination would require at least two days?—No. If you are doing a number two would be finished every day. Two would be started to-day and completed to-morrow, when two further experiments would be started so that the output would be two a day.

7811. One experiment could not be completed in less than two days?—Not on the lines we have taken.

7813. The Marsh test is much more speedy?—Yes, but it is not a gravimetric test.

7814. The Marsh test still continues to be very valuable for many purposes, but in your view is not a quantitative test?—Most valuable. Of course it is used as a quantitative test as well.

of (Sir William Church.) You can get evidence of the presence of arsenic by this test when you do not get sufficient precipitate to be weighable?—Yes. If you will take the smaller of the Gooch's, you will see there is a slight yellow stain on one. We have had several illustrations where that has weighed less than 1-10th of a milligramme. We have had evidence of a smaller quantity than one could actually weigh. But I think we would generally stop at a point where we could weigh.

7815. (Chairman.) In that case what was the result obtained from?—A litre.

7816. Could the Reinsch test have given any indication whatever of arsenic in that case, the exceedingly small quantity?—I should be very doubtful about it myself, but my experience of the Reinsch test is not so considerable as that of many others.

7817. Would the Marsh test have shown anything in this small case?—It would.

7818. So that the Marsh test would show something, when the Reinsch test shows nothing?—I think so.

7819. The quantity used in the Marsh test need be very small to show it?—The common quantity used is 10 cc., but I have not found it advisable to limit it to that small quantity myself. I prefer to use up to 50 cc.

7820. Even that is only 1-20th part of the amount used in the quantitative test you have described?—That is so.

7821. Could either the Marsh or the Reinsch test be rendered sensitive for the exceedingly small quantity you speak of by applying them to a much larger quantity of liquor than 50 cc.?—Yes, I think they could.

7822. Even without concentrating the liquor?—No; I should proceed in that direction, I think.

to 7822a. (Professor Thorpe.) There is a practical difficulty in the employment of any concentrated solution by the Marsh test?—Yes, due to the frothing.

7823. When you take these highly sweetened and concentrated solutions they froth in the apparatus to an inconvenient extent, and therefore the whole froth is carried bodily forward in the gas and soils the tube?—Yes, there are limitations in the Marsh test.

7824. (Chairman.) You need to get quit of the thick gummy matters?—Certainly.

7825. Does that apply also to the Reinsch test?—Yes; as concentration proceeds in the Reinsch it is very liable to bump considerably; we have had the liquid thrown right up to the ceiling in the laboratory you were in this morning.

7826. (Dr. Whitelegge.) Nothing is done with the filtrate after the first precipitation with sulphuretted hydrogen, is it?—We always keep it over, and it has repeatedly been further examined. The gas has been again passed through it, and if any precipitate whatever falls—because organic matter will fall on standing—it has been again filtered and the precipitate distilled. But we have not found any arsenic so retained, proving that the whole is taken out at the first precipitation. But that has always stood in our quantitative experiments all night.

7827. Have you seen the evidence that Dr. Campbell Brown gave us the other day?—I saw the newspaper report.

7828. He told us that taking, not an experimental beer, but what we may call a Bostock beer in acid solution, sulphuretted hydrogen gave a precipitate?—Yes.

7829. Passing sulphuretted hydrogen through the filtrate he sometimes got a second precipitate, but passing a second, third, and fourth time gave no further precipitate. Nevertheless, on oxidising the organic matter present in the filtrate he obtained a residuum of arsenic?—I think there are some practical difficulties to meet which experience with the process is necessary. Probably Dr. Campbell Brown did not get so far. I consider it very essential that a clear filtrate should be obtained. Dr. Campbell Brown, I gather, did not succeed in getting that clear filtrate. A clear filtrate cannot be obtained readily if the solution is filtered cold, even with the use of the best paper. But if heated nearly to the boiling point, and then filtered, an absolutely bright filtrate is readily obtained. Under those circumstances there can be no danger of any arsenious sulphide failing to be obtained on the paper. I have alluded to it as being absolutely essential that a clear filtrate should be obtained.

7830. (Chairman.) Have you tested the clear filtrate for arsenic?—Yes, on several occasions, and we have never found any carried through.

7831. The first filter is an ordinary paper filter?—Yes.

7832. And you found no arsenic has come through that?—That is so.

7833. (Dr. Whitelegge.) Have you tested the filtrate by Marsh and otherwise than by sulphuretted hydrogen?—No, I have not done that.

7834. You have not adopted the particular procedure of oxidising the organic matter?—No, that would be too lengthy. The essence and advantage of this process is that it avoids the necessity for that.

7835. The suggestion I understand him to make is not so much that there is arsenious sulphide there that has not been collected but that the arsenic has not gone down?—Quite so. But our experimental evidence proves that there is no such compound as that. Arsenic is put into wort, and the latter fermented. The arsenic is then separated and found to be equal in amount to that added, thereby showing there has been no such combination of arsenious acid with organic matter as precludes the precipitation of arsenic under those circumstances.

7836. Do you think it is safe to assume any arsenic present will come down as a sulphide?—The experimental evidence establishes that.

7837. But is that entirely in accord with what Dr. Campbell Brown found, dealing with a beer made from arsenicated materials?—143 determinations have been made on Bostock's beers, and the quantities obtained show that there could be no loss because the quantities are larger than a number of other people have found.

7838. In some cases, but in other cases your method has given a smaller quantity, has not it?—You mean in a reference case?

7838a. Yes?—But the results obtained in the Govern-

Mr. E. G. Hooper.

Claims that sulphuretted hydrogen precipitates all the arsenic from beer.

Mr. E. G.  
Hooper.

13 May 1901.

ment laboratory were supported and confirmed by other evidence. I could give you the particulars if you wish them.

7839. (Sir William Church.) Your result is the result of actual weighing?—That is so.

7839a. The others were only the results of estimation?—In some cases, Dr. Campbell Brown does weigh his, but he goes through the process of destroying the whole of the organic matter.

7840. (Chairman.) Dr. Campbell Brown gave very distinct evidence to the effect that he found in the first place a precipitate by sulphuretted hydrogen; in the second place a little more precipitate. A third, fourth, and fifth gave no more arsenic. Then he oxidised, by chlorates I think, and got a residue from which he obtained rather more arsenic than he had got out in the first, second, and third put together; that is substantially his evidence, and he gave it in the most circumstantial manner. Can you suggest any explanation of that?—There are several points upon which the accuracy of his results would depend. First of all the solution must be completely saturated with sulphuretted hydrogen or the whole of the arsenic would not be precipitated, and on each fresh treatment he would get down a further precipitate with sulphuretted hydrogen. But I am inclined to think from my own experience that the explanation of his results—that is, those results of getting successive quantities, is due to an inefficient filtration. There is the extreme difficulty in obtaining a clear filtrate from a beer of this kind unless it is specially treated. I found it so myself, but it is quite possible that with efficient filtration you can get out the whole of the arsenic present. Sulphur must, of course, be first formed. If you pass sulphuretted hydrogen for only a limited time you may precipitate half the arsenic, but if you pass it long enough the whole of the arsenic is thrown down. I should not imagine Dr. Campbell Brown would pass sulphuretted hydrogen gas through his solution for a limited time, and therefore that is probably not the explanation.

7840a. (Dr. Whitelegge.) He says: "One litre of the beer is concentrated, is acidulated, and precipitated by sulphuretted hydrogen, the gas being passed until the laboratory is closed for the day," and that is repeated twice or three times and four times?—That is without any previous oxidation.

7841. This was an experiment to show that oxidation is necessary. After having removed as much as can be removed by the treatment with sulphuretted hydrogen and separation of the deposit, there remained in solution a very material amount, equal to that removed by the sulphuretted hydrogen?—Our experience is exactly the contrary to that.

7841a. That I gather, and I want to know if you can throw any light on it?—I think it is due to the filtration. He said in the notes I saw of his evidence that he failed to obtain a clear filtrate.

7842. He told us also that the discrepancy did not arise where arsenious oxide had been added to finished beer; it was only in beer brewed from arsenicated materials that he found this difficulty in getting down a very large proportion of the arsenic?—The only difference is that there had been a fermentation in between. We have made experiments on that basis, and we found no difference under such circumstances.

7843. Your artificial brewing gave results in accordance with the experiment with directly adding arsenic?—Quite so.

7844. Dr. Campbell Brown's experiments did not?—No.

7845. (Professor Thorpe.) Is there any *a priori* reason to believe that by brewing the arsenious oxide would change?—None that I am aware of.

7846. (Dr. Whitelegge.) In speaking of yeast you say: "There was thus a recovery of 95.6 per cent. and diminution of arsenical contamination by the removal of the yeast formed during fermentation in this particular case did not exceed 4.4 per cent. even in strongly contaminated beer." Would not the quantity of arsenic thus removed, if expressed as a percentage of total arsenic, be likely to be less marked in a strongly contaminated beer?—Not where the arsenic was not present to such an extent as to inhibit the growth of the yeast. Two grains to the gallon would not inhibit the growth of the yeast, so that for all practical purposes there was a normal fermentation.

7847. I was looking at it in the other way. Yeast is able to take up a small amount of arsenic. Would not

the amount of arsenic that the yeast could take away be relatively larger if the initial amount of arsenic is small?—No, I should imagine that since it had plenty of food on which to feed it would avail itself to the full and take out the larger quantity.

7848. (Professor Thorpe.) That is on the supposition that arsenic is a yeast food at all?—Exactly.

7849. (Dr. Whitelegge.) Supposing we were experimenting with yeast upon two worts, one largely arsenical and the other arsenical to a slight degree, the amount of yeast being the same in each case. If the yeast abstracted the same amount of arsenic from each wort, then the percentage of arsenic taken up by the yeast would be higher in the case of the slightly arsenical wort?—Yes, supposing it is constant throughout it would.

7850. (Professor Thorpe.) Is there any evidence to show that yeast takes up a constant amount of arsenic?—No.

7851. (Dr. Whitelegge.) You say that it did not exceed 4.4 per cent. even in the strongly contaminated beer. I should have thought the suggestion was the other way round?—I do not think so. I quite think it would take up more rather than less, the more the arsenic is present.

7852. (Sir William Church.) The stronger the contaminated beer the more chance there would be of some possible compound of arsenic being entangled in it?—Quite so. All the sediment goes down with the yeast. Not merely all the yeast has gone down, but whatever matter has fallen out of the solution in the process of brewing together with the finings has been carried down, and whatever could possibly be entangled has amounted only to this percentage. I do not contend that yeast has taken up any.

7853. (Professor Thorpe.) I should like at this stage to make clear what has been said with reference to the imputation which I gather was made by Dr. Campbell Brown that the Government Laboratory was in the habit of finding less arsenic than several analysts in police cases which had been before magistrates. That is not the case, and I should like to make that clear. Here is a paper which contains the whole of the police cases with which the Government Laboratory has been concerned, and although Mr. Hooper was not concerned in the actual cases—

7854. (Sir William Church.) My impression is that we had evidence before us that Dr. Campbell Brown and the Government Laboratory agreed in one case and differed somewhat in another.

7855. (Professor Thorpe.) That is not as I read it in the evidence. All my knowledge of what Dr. Campbell Brown said is what Dr. Whitelegge elicited from him. Dr. Whitelegge asked Dr. Campbell Brown whether there was not a certain case in which he found a relatively large quantity of arsenious oxide, in which he was corroborated by Dr. Stevenson, and in which the Government Laboratory found only a small proportion—I think 1-100th of a grain. There was a certain case which was tried at Rochdale in which the Government Laboratory found 1-30th of a grain, and in which they were independently corroborated by two other analysts. That was a beer which was brewed from malt and hops, and was proved by our own Excise officer as well as the brewer himself to be so brewed.

7856. (Chairman.) Was that a case in which Dr. Campbell Brown found as much as 1-5th of a grain of arsenic?

(Professor Thorpe.) That was a case in which he said he found as much as 1-5th of a grain. Then there was another case which was mentioned by Mr. Jones of Wolverhampton. Mr. Jones, of Wolverhampton, who described his process, which, you will remember, consisted in a modification of the Reinsch's method, in which the arsenic was removed from the beer by copper, and afterwards dissolved off the copper and distilled with ferric chloride and hydrochloric acid—in that particular sample of beer Mr. Jones found .07 grain of arsenious oxide per gallon. We found in precisely the same sample of beer .19, which is getting on for three times the amount of arsenious oxide which Mr. Jones obtained. On another occasion he found in a certain sample of beer as little as .09. In that particular case we found as much as .38, that is to say, four times as much. That I put down to the fact that the copper in Mr. Jones's process does not really abstract the whole of the arsenic from the solution, whereas, of course, by treatment

the Rochdale  
case

Whether arsenic brewed with the beer or not makes no difference to the test.

E. G. Hesper. with sulphuretted hydrogen our contention is that the whole of it is thrown down, and can be recovered by the mode which has been explained. In a third case, a sample which was received from Doncaster, and was analysed by Mr. Thomson, of Manchester, we were in substantial agreement with him. He found 1-20th of a grain; we found 1-15th of a grain. In all the other cases we have agreed substantially with the analysts. Mr. Lowe, of Chester, who analysed three samples of

beer, found only traces, and we returned the amount as about 1-100th of a grain. Mr. E. G. Hesper.

7856a. (Chairman.) Will you put in this table? (Professor Thorpe.) I think it would be convenient that that table should be put in as being an account of our work with such reference samples as have been received up to this time.

The following is the table referred to:—

REFERENCE SAMPLES of Beer for Arsenic.

No.	Place.	Analyst.	Quantity of Arsenic per gallon certified by Analyst.	Government Laboratory Report.
1	Preston	Mr. Campbell-Brown	"A certain small quantity"	An appreciable trace estimated as not exceeding $\frac{1}{16}$ th of a grain.
2	Roehdale	"	$\frac{1}{16}$ th of a grain per gallon	·033 grain $\text{As}_2\text{O}_3$ per gallon.
3	Wolverhampton	Mr. Jones	·07 grain $\text{As}_2\text{O}_3$ per gallon	·19 grain.
4	"	"	·05 grain	No evidence.
5	[Porter]	"	·09 grain	·38 grain.
6	Ruabon	"	"Contains a certain amount of arsenic."	No evidence.
7	Doncaster	Mr. Thomson (of Manchester).	Found $\frac{1}{20}$ th grain	·067 grain = $\frac{1}{15}$ th of a grain.
8	Mold	Mr. Lowe	Traces of arsenic	$\frac{1}{16}$ th of a grain.
9	"	"	"	No evidence.
10	"	"	"	No evidence.

7857. (Chairman.) You can give evidence as to the amount of arsenic contained in beers brewed from arsenicated materials based upon the examination of samples representing 28,264 barrels of beer lodged by

67 brewers on making application for repayment of duty?—Yes.

The following are the tables:—

## NOTES.

1. May possibly be due to the malt used.
2. Sugar supplied by Brewers' Invert Co. said to have been manufactured by Bostock & Co.
3. Brewer states that Bostock's sugar was in stock, and may have been used in this brewing by accident.
4. Sugar supplied by Messrs. Ince, Pickering & Co., said to have been manufactured by Bostock & Co.
5. Yeast pressings from arsenicated beer added.
6. Yeast used stated to have been found by Brewer's chemist to contain arsenic.
7. Brewer, prosecuted by local authorities for selling beer containing arsenic, stated that the contamination had been traced by his chemist and was due to the malt used.

## SUMMARY.

Month.	May.	June.	July.	August.	September.	October.	November.
Number of Samples	1	2	3	7	9	21	80
Average $As_2O_3$	12	17	38	45	33	50	42

It will be seen from the foregoing tables and the summaries annexed to them that the proportion of arsenic found varied from less than five-hundredths of a grain up to half a grain per gallon in something like three-fourths of the whole number of cases, but that as regards the remaining fourth, the quantity of arsenic ranged from half a grain to about one and three-quarter grains, with one exceptional case of three grains to the gallon. It has been already remarked that a large proportion of these contaminated beers were drawn from the counties of Lancashire, Staffordshire, and Yorkshire, but one sample was brewed at Bristol. In all but 18 instances Bostock's sugar wholly or in part had been used, either in the production of the beer or in priming. In eight out of the eighteen cases where sugar obtained from Messrs. Bostock directly had not been employed it was stated that the sugar, though supplied by another firm, had been manufactured by Bostock; in two instances it was found that the arsenic was due to the use of yeast or of yeast pressings from contaminated beer; in one instance the brewer stated that Bostock's sugar was in stock at the time, and might have been used by accident, and in the remaining seven cases it was alleged that the arsenical contamination had been traced to the malt used. As regards the period over which the arsenical contamination extended, it will be noted that the oldest sample examined was brewed on the 24th May, 1900. Beer at the present time is consumed very shortly after it is produced, and consequently, whilst there are many samples representing the November production—the date at which the contamination was detected—considerably fewer samples of beer produced at earlier dates are available. It may, however, be noted that in the one May sample the proportion of arsenious oxide per gallon was 0.12 grain, the two brewed in June contained 0.16 and 0.19 grain respectively.

7858. All of the same brewery?—No; they are from different breweries. This is regarding them merely in point of time. The three July samples all showed higher proportions of arsenic, and in one case exceeded half a grain to the gallon; in August the average of six samples is 0.45 grain per gallon, and one sample contained 0.65 grain; in September the average is slightly lower (0.33), but one sample contained rather more than one grain of arsenious oxide per gallon; in the October beers, the average is half a grain per

gallon, and of the twenty-one samples eight contained more than this—two, from different breweries, containing as much as 1.47 and 1.23 grain per gallon, respectively, though it should perhaps be pointed out that these were in both cases strong beers, the original gravities being 1.075° and 1.066° respectively. As regards the November samples, the average is 0.42 grain of arsenious oxide per gallon, but there are seven samples in which the contamination exceeds one grain, and in one exceptional case the proportion rises to three grains per gallon, the largest proportion shown by any of the samples. This exceptional amount of arsenic was found in a sample of stout (Expt. No. 75) brewed by the executors of William Astley, at Nelson, Burnley, on the 27th November. The result was confirmed by the examination of a duplicate sample, but no sample of the sugar used, which was described as Bostock's "Caramelised glucose," could be obtained. Another sample of stout produced at the same brewery (No. 74) showed the next highest amount obtained, viz., 1.73 grains per gallon. This was brewed on the 20th November, and half the quantity of sugar used in this brewing was said to be of the same consignment as was employed in the brewing of the 27th November, the other half being of a previous consignment.

7859. Was the same quantity of sugar used in each case, on the 20th and 27th November?—On the 20th November the materials used were 128 bushels of malt and 896 pounds of glucose. On 27th November the materials used were 110 bushels of malt and 672 pounds of glucose. The proportion of sugar to total materials was in the first case 18 and in the second case 16 per cent. No priming was used in the second case, but in the first case it was primed by the addition of Bostock's "porter heading."

7860. (Sir William Church.) There was not a very great amount of difference?—No; 16 and 18.

7860a. (Professor Thorpe.) The difference is probably in the priming?—That is not included.

7861. In one case the beer was primed; in the other case not?—Yes, that is so.

7861a. (Chairman.) The beer on the 27th November contained three grains per gallon, and no priming was used?—That is so.

7862. The beer brewed on the 20th November contained a smaller quantity of arsenic—1.73 grains per gallon?—Yes.

7863. Half the quantity of sugar used in this brewing was said to be of the same consignment as was employed in the brewing of the 27th November?—That is so. The much larger proportion of arsenic in the beer brewed on the 27th November therefore points to the later sugar being more highly contaminated than that delivered earlier. Two beers brewed at the same brewery on 8th October and 24th September, respectively (Nos. 73 and 72) contained arsenic equal to 0.90 and 0.52 grains of arsenious oxide per gallon, and no explanation of the exceptional degree of contamination shown by the two stouts has been found, black beers from other breweries containing less rather than more arsenic than the ales. The strength of the beer in every case has, of course, some bearing upon the quantity of arsenic present, for the original gravity of the samples analysed varied from 1.037° to, in one case, 1.080°, the arsenious oxide in the latter case (No. 128) amounting to 1.21 grain per gallon. In the case of six samples from a Birmingham brewery (Nos. 12, 126) the beer of the highest original gravity, 1.076° (No. 121) contained 1.47 grain of arsenious oxide per gallon. The remaining five samples had an original gravity of 1.063-4°; in one the arsenious oxide amounted to 1.40 grain per gallon, whilst in the other four it varied between 0.94 and 1.13 grains per gallon. Generally, however, the original gravity of the beers was much lower than those just mentioned, and in a large proportion of the whole number lay between 1.040° and 1.057° with an average of about 1.055°. After the evidence which has been given before the Commission, it is unnecessary to further prove that the serious arsenical contamination of these beers was due to certain of the sugars employed in their production. The results of the examination of such sugars are given in Tables III. and V., and, as bearing upon the proportion of arsenic found in the beers, it is only necessary here to allude to the very varying proportions in which sugar was employed. The highest proportions of sugar to malt and grain used were 50 per cent. and 47 per cent. respectively, of the total brewing materials, and in neither case did the arsenious oxide ex-

Mr. E. G. Hooper.  
13 May 1901.

Greatest amount of arsenic found in any of the beers.

Highest ratio of sugar to malt in arsenical beers on which rebate claimed.

Mr. E. G.  
Hooper.  
13 May 1901

ceed 0.60 grain per gallon, but such proportions of sugar were exceptional. The lowest proportions of sugar were less than 1 per cent., and in two out of three of these the arsenic found in the beer was 0.05 grain of arsenious oxide per gallon, though in the third case (Expt. No. 67) it amounted to 0.22 grain per gallon. The average proportion of sugar used in the production of these beers was 8 per cent., and in the two beers showing the highest degree of contamination the proportions were 16 per cent. and 18 per cent. respectively. In many cases, however, the sugar employed was obtained from more than one firm, and no evidence has been obtained at the Government Laboratory that the brewing sugars generally in use during the past year were contaminated with arsenic. No sample of malt known to have been used in the production of these beers has been obtained, but the proportion of arsenic found in malts in use in various parts of the country between June and November I refer to later.

Arsenic in  
Non-Bostock  
beer.

7864. (Dr. Whitledge.) In Table I. in some instances there is nothing said about sugar. Does that mean that no sugar was used, or that the information is not available?—In the production of all of these beers sugar was used.

7865. In Note 7 to that table: "It was alleged that the contamination was traced by the brewers' chemist to the malt," and I see by the table that in that case the amount of arsenic found was 0.34 grains per gallon. May we take that as well authenticated?—We can only state the facts. These particular beers were brewed in January of this year.

7866. At all events, the glucose in that instance was from a source we had not had associated with arsenic so far?—That is so.

7867. I suppose, as a matter of fact, if one went carefully through this table looking, not to date of brewing, but to locality of the breweries, the quantities of arsenic would be found to vary a great deal—for instance, the Birmingham results vary a good deal?—The greater number of these happened to be strong beers. I emphasised that point. Obviously the proportion of material in a strong beer is greater than in a weaker beer, and you might reasonably expect if part of that material is arsenical you would get a larger arsenical content.

7868. Bearing in mind those local differences, are we quite on safe ground in assuming from the figures you give us that there was a general increase in arsenical

contamination month by month?—It seems to me there was certainly an increase of arsenical contamination up to July. After July the increase was not very considerable. Although there are a large number of cases where more than a grain per gallon was shown, if you work it out on the total number of samples the percentage is pretty much the same. From July to November a fairly steady average is obtained—33 to 50—but there are an increasing number of instances of the higher quantities—that is, above a grain per gallon. In September there was one, in October two cases, in November there were seven cases, with one at 0.94. But as a percentage on the total number of samples examined the difference was not great—that is, the percentage of those over one grain was 11, 13, and 10 for the three months I have given you. So that one must make allowance for the larger number of samples when one fixes one's eyes on the larger quantities found.

7869. (Chairman.) You have evidence as to the amount of arsenic contained in brewing materials, based on the examination of samples forwarded to the Government Laboratory by Excise officials?—Among the samples sent for examination in connection with the arsenicated beers there were three unfermented sugar solutions which were found to contain arsenic equal to 7.99, 8.14, and 2.62 grains of arsenious oxide per gallon. These were priming solutions prepared on the 23rd, the 28th, and the 24th November respectively, the first two from invert sugar and "fluid" sugar respectively, both manufactured by Bostock and Company, and the third, which was described as "black priming solution," from equal quantities of Bostock's invert sugar and of caramel from a maker whose name could not be ascertained. The calculated proportions in grains of arsenious oxide per pound of sugar used were 1.66, 1.74, and 1.09 respectively, the last being calculated on the invert sugar alone. Three samples of invert sugar and one sample of solid glucose, all stated to be of Bostock's manufacture, were also sent for examination in connection with the applications for repayment of duty on the destroyed beer. The three samples of invert sugar were found to contain arsenic equal to 2.04, 1.83, and 1.67 grains of arsenious oxide per pound respectively, whilst the quantity in the solid glucose was 1.99 grains per pound. Samples of solid and liquid caramel used in brewings of arsenical porter and stout were found to be free from arsenic, and it was stated that these were not obtained from Messrs. Bostock. All these results are embodied in Table III.

Mr. E. G.  
Hooper.

\* Kept over at Brewery from November (unused).

G. 7870. You have also evidence as to the amount of arsenic contained in brewing materials based upon the examination of samples forwarded to the Government Laboratory by Excise officials for the determination of brewing value?—The sugars we have already dealt with were directly connected with the arsenical beers alluded to in Table I. The samples I am now going to allude to were sent up previous to the detection of arsenic in beer, and were forwarded from various parts of the country by Revenue officials. As regards the samples of brewing materials forwarded by Excise officers to the laboratory, it may be stated that as a rule these samples are preserved for three months after receipt, and at the end of that time, unless otherwise ordered, are destroyed, storage for a longer period being impossible on account of the large number and variety of articles received for examination. On the discovery of the arsenical contamination of beer all the brewing materials in store or under examination were placed aside to be tested for arsenic, and 164 samples of sugar with 48 samples of malt have since

been examined. The sugars included samples taken at breweries in each of the months from June to November, and the total was made up of 64 glucoses and 40 invert and priming sugars. Of these six samples of glucose and two invert sugars were found to contain arsenic. These samples are classified in Table IV. In four instances the proportion of arsenic was found to be larger than that in the sugars obtained for examination in connection with the arsenicated beers, particulars of which have been already given. All the arsenicated samples were drawn from the North of England, and with one exception were probably of Bostock's manufacture, whilst only a small proportion of arsenic was found in this excepted instance. The full particulars as to these contaminated sugars are shown in Table V, whilst in Table VI, a list of places is given from which the non-arsenicated sugars were drawn. Fourteen samples of glucose and six samples of invert sugar taken from breweries during March of this year were all found to be free from arsenic.

Mr. E. G.  
Hooper.

Meaning of "freedom from arsenic" when applied to sugars.

7871. (Chairman.) What does "free from arsenic" mean at the Government Laboratory? Does it mean free from arsenic which can be separated and weighed from a litre of beer or from 100 grammes of sugar, or do you apply a qualitative test as well?—It means such a quantity of arsenic as is not shown by the Marsh test when tested upon 20 grammes of sugar.

7872. The test from 100 grammes of sugar would be analogous to the test from a litre of beer?—It would.

7873. If it has been declared free from arsenic by the Marsh test on 20 grammes of sugar?—That is so.

and to beer.

7874. And as regards beer, when has that been declared arsenic free?—When the Marsh test showed no reaction for arsenic with not less than 50 cc.

7875. Can you say how much arsenic there might be in a gallon of beer escaping that test?—There is no evidence that there is any.

7876. If there was 1-100th of a grain of arsenic per gallon would it be shown?—Readily.

7877. 1-200th?—Then it becomes doubtful.

Maximum amount of sugar which might be used in beer

7878. (Professor Thorpe.) What amount of sugar could there conceivably be in a litre of beer, used in the fermentation or in the priming?—Taking 1,080°, which is very strong beer, 20 grammes per 100 c.c. or 200 grammes per litre, supposing the whole of the gravity to be due to sugar.

7879. Assuming that the beer had a mean density of 1,055°, what is the maximum amount of sugar that could be used in the formation of that beer?—1,771 lb. per gallon.

7880. How much would that be in a litre?—Roundly, it would be 142 grammes of sugar per litre of beer at 1,055 gravity.

Quantities of arsenic found in malt.

7880a. (Chairman.) With regard to malt taken from breweries during the months from June to November of last year, you say that all but six afforded evidence of the presence of arsenic, but the highest proportion of arsenic was only 0.05 grain of arsenious oxide per pound of malt?—That is so.

7881. In 22 samples the arsenious oxide per pound of malt lay between 0.05 and 0.02 of a grain?—Yes.

7881a. And that in 19 cases, whilst still showing traces, the quantity was less than 0.02 per pound of malt?—That is so.

7882. Of the malt samples received during the month of March three contained from .05 to .02 of a grain of arsenious oxide per pound, five contained traces amounting to less than .02 grain per pound, and one only was quite free from arsenic?—That is so.

7883. (Professor Thorpe.) Can you tell the Commission how much arsenic there would have been in a litre of beer if the whole of that beer had been brewed from malt, and the amount of arsenious oxide in the malt used was the maximum? You found .06 of a grain per pound of malt. How arsenicated would that beer be, assuming that the whole of the arsenic went in?—16 of a grain per gallon if the whole of the arsenic present in the malt to the extent of .05 grain per pound had gone into the beer.

7884. Are you quite right there?—I think so. It is below what has been said by Dr. Campbell Brown, for instance, to have been found in an all-malt beer.

7885. How much malt goes to a gallon of beer, roughly speaking?—2.33 lb. I said .16, but it is really .116.

7886. (Chairman.) 2.33 times .05 is .12 nearly?—Yes, .116 exactly.

7887. You have evidence as to the presence or otherwise of selenium in brewing sugars obtained at various times during the past ten months?—In view of the possibility that brewing sugars prepared or treated with sulphuric acid might possibly contain selenium, it was felt to be necessary that search should be made for this substance. The samples of solid sugar and of prepared sugar solutions which had been used in the preparation of beers proved to be arsenicated were first examined. These samples were received directly from the breweries, and full particulars as to the description of sugar, arsenical content, date of sampling, etc., have been given in Table III. In no case was any selenium found to be present in the sugar or sugar solution. The sugars enumerated in Table V. were next examined, and were also found to be free from selenium. These samples include all the sugars found to be arsenicated of those sent for examination by Excise officials throughout the United Kingdom between June and November last. Finally, a selection of the non-arsenicated sugars forwarded for examination from various parts of the country between June and March last were tested for selenium, but in these samples also no selenium could be detected. It should perhaps be stated that when traces of selenious acid were added to glucose or invert sugar the presence of selenium was readily demonstrated. No evidence of the presence of selenium in brewing sugars—glucose or invert—has therefore been obtained at the Government Laboratory.

7888. You have evidence also as to the presence or absence of arsenic in imported brewing sugars?—The samples of brewing sugars obtained from various parts of the country, and classified in Tables V. and VI. probably represent with a very considerable degree of completeness the whole of the sugars, whether of home or foreign manufacture, in common use by brewers in the United Kingdom. To render the investigation even more thorough, however, samples of brewing sugars were taken by the Customs authorities from importations extending over a month. One hundred and seventy-seven samples in all were received, consisting of solid and liquid glucose, caramel and syrups, described as "molasses." These samples were received from the United States of America, Germany, Belgium, Holland, and Canada. With two exceptions, all these samples were found to be free from arsenic. The two samples in which evidence of arsenic was obtained consisted of liquid glucose, imported, at London and Hull, respectively, in both cases from Stettin. The amount of arsenic was small. The exact quantities in the two instances are .02 and .01 grain per pound respectively.

7889. Were these samples from Belgium, Holland, and Canada made in those places?—We cannot say. We only know that they were imported from there. Certain marks are on the packages, which, on investigation, might possibly lead to some information being obtained, if the Commission deem it of importance.

7889a. (Professor Thorpe.) The Customs will have no information?—No.

Mr. E. Hooper.  
13 May 1901.

Amount of malt which may be in all malt beer.

No evidence of selenium in Boston sugars.

or in other sugars.

Arsenic in German glucose.

G. 7890. In the case of Holland and Belgium, for instance, it might be German glucose which came down the Rhine?—I think so.

1901. 7891. (Chairman.) Are these imported sugars all glucose?—They were glucose, caramel, and other sugars, which are imported according to the Customs regulations, as molasses, that is to say, they are of the character of treacle.

7892. With regard to the evidence of the presence or absence of arsenic in beer supplied by Government contractors for Army and Navy use, have you anything to say on that?—All samples of beer supplied under Government contracts which have been submitted for analysis since December last have been examined for arsenic. Forty-six samples of this class have been received, and 45 of these were found to be free from arsenic, whilst one War Office sample contained about one-hundredth of a grain of arsenious oxide per gallon (·011 grains), and was so reported.

7893. Do you, as a matter of routine, have beer intended for Army and Navy use sent to you for examination?—Not quite as a matter of routine, but samples come frequently at rather irregular intervals, taken as those in charge of the contracts, or the inspecting officers, deem necessary.

7894. To test for quality?—Yes.

7895. And for freedom from noxious substances?—That has been included.

7896. Did you ever test them for arsenic before the recent outbreak?—No.

7897. (Professor Thorpe.) These beers for the Government service, whether for the Army or Navy, are tendered according to the specification of gravity, etc., and it is your duty to see how far the beers conform to the specification?—Yes.

7898. As a matter of fact we have under consideration now the revision of the terms of the specification, in view of this scare?—Yes.

7899. (Dr. Whitelegge.) In the event of any mischief

being associated with beers supplied for the Army or the Navy, would samples come to the Government Laboratory for examination?—We have had one case of vinegar some three or four years ago. There was a case of poisoning at Portsmouth. They did not know what was the cause, but vinegar was stated to have caused the illness of 17 men. I directed it should be searched, for second group metals, which include lead, arsenic, and copper, and we readily found arsenic in fairly considerable quantity. Samples of the vinegar were afterwards sent as received direct from the vinegar manufacturer, and those samples of vinegar were found to be quite free from arsenic. That is the only case we have had.

7900. (Chairman.) Was there any explanation of how the arsenic got into the vinegar in that special case?—The military officials had an inquiry, but it was never published, and we are not acquainted with the result arrived at.

7901. How much arsenic did you find?—A very large amount; 230 grains, if I remember rightly, but I should like to refresh my memory.

7902. (Chairman.) That could not be a mere accident?—No, it was malicious.

Mr. E. G. Hooper.  
13 May 1901.  
Arsenic in vinegar at Portsmouth.

7903. (Dr. Whitelegge.) There has been no recent occurrence of illness amongst troops or sailors attributed to beer, which has come to your notice?—None whatever.

7904. Was not there something of the kind last year amongst volunteers in camp somewhere?—I have a faint recollection of having seen something, but I am afraid I cannot recall the exact particulars.

7905. If there had been arsenic found you would have known of it?—Yes.

7906. (Chairman.) If we have any further questions to ask on any of the evidence which will be before us in print, we may perhaps wish to see you again?—I shall be quite prepared to attend.

Added maliciously.

## SEVENTEENTH DAY.

Tuesday, 21st May, 1901.

PRESENT:

The Right Hon. Lord KELVIN (in the Chair).

Sir WILLIAM CHURCH.  
Professor THORPE.

Mr. COSMO BONSOR.  
Dr. WHITELEGGE.

Dr. BUCHANAN, Secretary.

Mr. OTTO HEHNER, called; and Examined.

mer. 1901. 7907. (Chairman.) You are public analyst for Nottinghamshire, West Sussex, the Isle of Wight, and the boroughs of Derby and Ryde?—Yes.

7908. And past President of the Society of Public Analysts and Chairman of the London section of the Society of Chemical Industry?—Yes.

7909. You have given considerable attention to the question of arsenic in ingredients of food and in commercial products?—I have.

7910. Will you kindly tell the Commission what you have found?—I have analysed a very great number of samples of beer from different parts of the country, also malts and chemicals which are used in the manufacture of beer, and, as a general experience, I may say, that it is exceedingly rare that I find a sample of beer which is totally devoid of arsenic. The same thing applies to malt. I doubt whether I ever found a single sample of malt which is totally free from arsenic. I would draw from that the conclusion that whilst the present system of malting and brewing is in practice, it is impossible to expect a beer to be quite free from arsenic.

7911. You speak of the present system of malting; but what characteristic of the present system do you refer to?—To the system of malting where the fumes of coal come in contact with the malt. Of course, on the Continent, malting is largely on an entirely different system of drying from what is in this country, and a system which is not, under present circumstances, applicable in England.

7912. Why should it not be applicable in England?—Because it would mean the reconstruction of all the malting ovens, which is rather a large order at the present time. I think gradually there might be a change unless meantime other means are found to retain the arsenic in coal. I have every hope that partly by careful selection of the fuel and partly by chemical treatment of the fuel, arsenic will be kept out of malt much more than hitherto has been the case. Already, as far as my experience goes, most maltsters are exceedingly careful in the selection of their fuel, which was not the case a few months ago, and methods are being tried with the intention, and, I think, with every hope, of retaining the arsenic in the coal. It is a very curious fact that in the burning of the coal or arsenic.

Mr. O. Hehner.  
21 May 1901.

How arsenic in beer may be reduced.

Treatment of malting fuel in order to fix the arsenic.

Mr.  
O. Hehner.  
21 May 1901.

coke, the arsenic does not entirely, or only to a small proportion, volatilise. One would imagine that arsenic was volatile at the high temperature of a furnace with a reducing agent present, but as a matter of fact the bulk of the arsenic remains in the ash, and I believe it is practicable or probable that the rest of the arsenic can be also retained. Therefore I say under the present conditions of malting I think you cannot expect freedom until some change has been brought about either in the mode of drying or in the mode of combustion.

Most of  
arsenic in  
coal remains  
in the ash.

7913. Have you ever analysed the ash of various kinds of coal for arsenic?—Yes. I have never found one free. I have made quantitative determinations of the proportion of arsenic which is left in the ash, and the proportion which is volatile, and by far the greater portion, sometimes as much as 9-10ths, remain in the ash, and only 1-10th goes away, but sometimes more is volatile, although the bulk remains in the ash.

7914. Does it remain in the ash in a form from which it would not volatilise if heated to redness for instance?—It will not volatilise. I do not know in what form it may be, whether arsenate or arsenite of iron, but it is not volatile and not reducible by the carbon into elementary arsenic which would go away. But of course in a malting furnace there is always a considerable amount of coal dust flying about, and that dust is always arsenical.

7915. You consider that it is in combination with iron in the ash?—I have no direct evidence; one can only form ideas about it. I have no evidence whatever.

7916. Do you think there is any other objection than the expense to the Continental method being introduced into England?—I have not sufficient knowledge of the practical requirements of the brewer, and I can only say from hearsay, which is not worth much, that the Continental system of malting has been tried here, and has not given very good results. I, personally, know nothing about it.

7917. You do not know in what respects the results were inferior?—The suggestion is that the flavour of the smoke, as produced by the coal fumes, is required in English beer.

Continental  
system of  
malting.

7918. Can you describe the Continental method of drying the malt?—The malt is dried on impervious floors, metal floors often.

7919. Flat floors?—Yes, as far as I know.

7920. Are those floors heated?—Yes, by flues underneath, or by a double floor where the products of combustion of the furnaces go through.

7921. Do you know to what temperature the solid floor is heated?—I do not.

7922. Is the floor iron or stone?—When I knew it it was iron, but I am not a practical maltster, and I can hardly presume to give definite evidence on the point.

7923. Would any special arrangement be made for a current of air to be driven through the malt?—I do not know.

Traces of  
arsenic in  
refined sugar

7924. You have found minute traces of arsenic in some kinds of sugar?—Yes. I have examined numerous samples of sugar, and I have found them mostly to be free from arsenic, but in a number of cases I found even in refined sugars exceedingly minute traces, but still quite plainly discernible. The same applies to molasses, the refuse from sugar refining, and there I found in a few cases minute traces of arsenic.

7925. When you say "minute traces of arsenic in sugar," about how much would that be?—I think up to about .005 grains per pound; 1-200th of a grain per pound.

and  
molasses,  
in sodium  
carbonate  
and sul-  
phites

7926. And in molasses a greater quantity or about the same?—About the same.

7927. You found arsenic in some other substances—salts of sodium and potassium?—Sodium carbonate almost invariably; potassium carbonate almost invariably; sulphites, traces and more than traces.

7928. Larger quantities sometimes in sulphites?—Sometimes, but at present, where a great deal of attention has been drawn to it, the quantities are exceedingly minute, but absence, I think, cannot be insured.

in borax.

7929. Borax?—Yes, I have found considerable traces.

7930. About how much?—I have never determined it.

7931. Oxide of iron?—Yes, I should say in sulphate of iron sometimes very definitely, and in oxide of iron, which is obtained from sulphate, and used for colouring of chocolate and bleater paste, and so on, very strong traces of arsenic, up to 1-10th or more grains per pound—in oxide of iron which resulted from the heating of the sulphate of iron.

7932. These articles are all used for food materials?—Yes.

7933. Do you think the arsenic which may thus be introduced into the food is liable to be in poisonous amounts?—I think not. What I wish mainly to point out is, at present it is not reasonable to expect absolute freedom. I would wish that beer and food material could be free, but I do not see the possibility. I take, as an analyst, the greatest pains to get arsenic-free materials, and it is almost an impossibility. Even when I get from the very best makers pure so-called arsenic-free acid, I, as a rule, have to subject it to a further process of purification, and even when pure one day it may be impure the next, because I have found, with a number of my colleagues, that hydrochloric acid especially takes up arsenic from the glass bottles in which it is stored.

Absorpti  
of arseni  
acids fro  
glass bot

7934. Is there arsenic in the composition of the glass?—Of much glass, of white glass, as a rule; also of blue Winchester quart bottles. I have found in several cases acid quite pure stored in Winchester quarts has got arsenical from an analytical point of view, not to an extent capable of producing ill effects.

7935. Do you refer to hydrochloric acid, sulphuric acid, or both?—To both, but mainly to hydrochloric acid. Hydrochloric acid seems to attack the glass more than sulphuric.

7936. Have you any suggestion as to sulphuric acid brought into commerce?—I think that no sulphuric acid should be sold unless it has been subjected to a de-arsenicating process, or unless it is labelled "arsenical." There is, I believe, no great difficulty and no great expense connected with the practical removal of arsenic from sulphuric acid and manufacturers not using it in their own works, I think ought to sell it after it has undergone a de-arsenicating process, because the makers of sulphuric acid are comparatively few, while the users of sulphuric acid are many.

7937. With regard to sulphuric acid made from Sicilian brimstone, should you say that required de-arsenication?—From what I have said before, it follows that I do not mean the complete removal, which, I believe is from an analytical point of view commercially impossible, but it should not contain more than a certain quantity, to be laid down. In that case I should think that Sicilian brimstone-made acid would require in most cases no purification, although it may contain traces of arsenic.

7938. If acid is not arsenic-free in the sense you have explained, do you think notice should be given by the vendor?—I think it should be labelled. I think the notice should be incumbent on those who sell arsenical acid, not on those who have subjected it to a process. At present, if you buy acid, and you obtained a bottle labelled sulphuric acid, it is almost certainly arsenical. If you want it pure you get a separate label "free from arsenic," or "freed from arsenic." I think it should be the contrary. Sulphuric acid should be pure unless the contrary is notified.

Arsenica  
sulphuric  
acid shou  
be label  
such.

7939. Sulphuric acid not free from arsenic should be labelled "not free from arsenic"?—Yes, within limits to be laid down.

7940. Are you of opinion that a maximum limit should be laid down in respect to freedom from arsenic of any brewed beverage?—Yes, I think from my experience in most cases now the amount of arsenic is somewhat less than 1-100th of a grain per gallon, and I think from the experience I have collected both from analytical examination of beer and from experience with brewers, that 1-100th of a grain per gallon need not be exceeded with reasonable care. When I calculate it back to malt, that would come to about 1-100th of a grain per pound in the malt, and I do not think that need be exceeded. In fact, it might be somewhat less at the present time.

Maximum  
limit of  
permissi  
arsenic  
should be  
laid down

7941-2. In the case of beer and beer ingredients, a Committee of the Society of Chemical Industry is now engaged. I believe?—Yes, we have appointed a Committee, mainly with the view to settle upon a process for the detection and approximate estimation. We are all convinced that absolute freedom cannot be obtained, and that therefore limits will have to be laid down,

and we are anxious to find a method which shall be easily applicable and reasonably accurate, which could be adopted by all persons concerned.

1901. 7943. Can you give any provisional information or opinion regarding tests for arsenic?—I can give no official information, because the Committee has not arrived at a conclusion. I could give my own working and my own opinion, but I do not know whether that is worth having any more than that of any other analyst who has concerned himself with the question. I have personally always employed the Marsh method direct to the beer, working on very small quantities of beer, hardly ever using more than 10 cc. There are hardly any beers where in 10 cc. I cannot find a feeble trace of arsenic under rigid test conditions. I think this test when carefully carried out is the most sensitive and, for quantitative purposes, dealing with traces, the most accurate which we could wish to have.

7944. Better than the Reinsch test?—Yes, much better. The Reinsch test first requires a large quantity of beer, and is not so sensitive. In the second place it is not applicable to certain ingredients. For instance, when we have to deal with the cane sugar or a product of the inversion of cane sugar containing levulose, that, under the influence of the large amount of acid used in the Reinsch test, carbonises, deposits a large quantity of humus matter, which prevents the copper from attacking the arsenic. In fact, an arsenical sugar gives no Reinsch reaction.

7945. Have you tried the Bloxham electrolytic method?—No.

7946. Have you any opinion to express regarding it?—No.

7947. (Sir William Church.) Have you examined any foreign beers?—Yes, a few.

7948. Were they entirely free from arsenic?—Yes, entirely. I sent for some bottled beer, and I obtained some quite free, which gave no reactions under the conditions where I got a reaction in English beer.

7949. You do not, of course, know how the malt was prepared that the beer was brewed from?—No, and my experience with foreign beer is quite small.

7950. You have in your mind some way in which you think the whole of the arsenic might be retained in the ashes of the coke?—Experiments are being made at present with a process based on the same principle as that which was in use a good many years ago, to retain sulphur in coal and coke, which depended on the liberal addition of lime to the coal, which fixed all the sulphur, and I believe retains much of the arsenic. Whether it will do so fully I cannot say yet.

7951. That is not likely to be a process which would give off fumes which might be found prejudicial from a commercial point of view to the malt?—I should think not. I should think it would retain the sulphur and possibly other acid products of oxidation. But I think a considerable amount of the arsenic in malt is due to the coal ashes which fly up, and that seems proved by the fact that if I take a malt and determine the arsenic in it, brushing it well and cleaning it, as a rule the arsenic much diminishes.

7952. That might arise from the deposit of volatilised arsenic upon it?—It might, but when one thinks of the immensely small quantity, especially as the malt at first is moist and arsenic will stick to it, I think it is unlikely.

7953. The quantities that you found in these other materials, caustic soda, sulphurous acid, and sulphites, and so forth, although you say you are not a doctor, they are really such small amounts that they are quite negligible?—Especially those things like sulphites; no large quantity can be taken. In the case of oxide of iron, which I may find in connection with the colouring of confectionery, the amount of arsenic seemed to me sometimes appalling. A small pen-knife point sample of the substance gave actually innumerable stains by the old Marsh process, not by the Berzelius Marsh modification. I could obtain stains of arsenic from a very tiny quantity of oxide of iron. Knowing that oxide of iron may go into bloater paste, I have obtained a good many samples of bloater paste, but I could not trace any arsenic in them. But I do not think arsenical oxide of iron should be used in food.

7954. That is, used as a colouring material?—Yes.

7955. Do you know if it is used as colouring material in confectionery?—Yes, chocolates.

7956-8. (Professor Thorpe.) Have you had occasion to examine the dust from malt?—Yes, a few.

7959. But only for the arsenic?—Never for anything else but arsenic.

7960. You have not pushed your examination so far as to satisfy yourself it actually was coal ashes?—No. I think such an endeavour would meet with many difficulties because the dust brushed from malt is largely organic matter from the malt itself.

7961. But the determination of the ratio of the silica to the oxide of iron and lime would enable you to know whether it was actually coal dust?—It might. Many of my friends have taken samples of ashes from all parts of the malt houses, and it is plain in places where there can be no malt dust or probably there is none, that the arsenic is always present, and is in the form of coal ashes.

7962. I think the general impression which the Commission has gained from the evidence which has been presented to it, is that the arsenic has been deposited on the malt rather in the form of volatilised arsenious oxide?—That was the early impression we all had, that arsenic volatilised very readily from the coal or coke, and of course it would condense when it came in contact with the moist or cold malt. But since we know, quite contrary to most people's expectation, that most of the arsenic is not volatile at all, I think it alters matters more or less.

7963. If it is in that condition, how would you get it into the mash tun in a soluble condition?—There is undoubtedly some in the soluble condition. I have made experiments on malts. I can wash some arsenic off with water alone, and by washing with water and filtering, I obtain an arsenical reaction. But one obtains a larger quantity if one washes the malt with hydrochloric acid. It is not all in the water-soluble condition.

7964. But the impression which one gains from your evidence would be that if the arsenic be in the coal dust in the form of a presumably basic arsenate of iron, or perhaps arseniate of lime, it would be in an insoluble condition?—Yes, much of it.

7965. The greater portion of it?—That which is in form of ash.

7966. Therefore, when the malt is mashed, by far the larger proportion of the arsenic would remain sulphide of insoluble?—Of course, we have to deal with such small quantities that it is very difficult to be able to say, because a substance is insoluble, that therefore it would not go into solution; we would call arsenic sulphide insoluble, but we know it is soluble to the extent of, say, one in a million.

7967. The direct determinations you have made of the amount of arsenic in the fuel and the comparative estimations you have made of the amount of arsenic in the ash serve to show it must be in such a condition that it must remain insoluble?—That which is in the ash I believe remains mainly insoluble, but not all the arsenic is insoluble. There is a portion which is actually volatile, and which I believe to be present in the malt in the form of arsenious acid.

7968. What I want to get from you is that the amounts which are present in the malt, especially in those malts which have been treated with dilute acid, as in many cases they have, preparatory to the examination being made, do not really give us any clear idea of the amounts which might go into the beer?—No. If the chemist obtains a sample of malt from a malster, he determines the total arsenic which he can obtain from it.

7969. You rather led me to believe that at least 9-10ths or some such amount remains insoluble?—No. I hope not; not in the malt. Nine-tenths or thereabouts of the total arsenic in the coal is in the ash. I do not suggest all the ash goes into the malt. On the contrary, no doubt in most cases a fraction, say 1-10th, burns off, and probably is in the malt in the form of arsenious acid.

7970. But the larger proportion is in the form of this basic arseniate of iron or insoluble compound which must be insoluble?—In the coal ash, but not in the malt.

7971. What makes it soluble in the malt?—That insoluble stuff is in the coal ash, and the coal ash would not reach the malt otherwise than as dust, the bulk of the ashes remaining behind in the furnace.

Mr.  
O. Hehner.  
21 May 1901

Volatilised  
arsenic in  
coal.

Solubility of  
the arsenic  
would remain  
sulphide of  
insoluble.

Mr. O. Hehner. 7972. But such portion as does go still remains insoluble?—I suppose it would.

21 May 1901. 7973. (Chairman.) Have you ever filtered beer before testing it for arsenic?—Never.

Sediment of beer, more arsenical than the liquid. 7974. Have you ever examined the sediment in the bottom of a beer cask or bottle?—Yes; I have examined the sediment, which is mostly yeast, and yeast as a rule is more arsenical than the liquor from which it is deposited. Whether that is a matter of precipitation or the yeast assimilates the arsenic and then concentrates it, I do not know.

7975. Have you found arsenic in the deposit from beer in bottles or cask?—Not in bottles, but in casks.

7976. Can you give any idea of what quantity there may be in the sediment of a cask?—No; I do not know.

7977. In a beer in which there is no arsenic discoverable or only a minute trace, may there be a sediment more contaminated with arsenic?—I am afraid I cannot answer the question generally; I have too little experience to say. But in a few cases I have had sediments from beer where in the sediment the arsenic was easily discoverable, and many other chemists have found that the yeast deposited from the wort is more arsenical than the wort itself. I may say, on the other hand, there is often a disappearance of arsenic. I have had samples of beer in which I have carefully determined the arsenic and re-examined them after some weeks, and the arsenic was completely gone. The same applies to exceedingly dilute standard solutions, and the arsenic can vanish entirely from these.

probably is volatilised. 7978. In that case it must be deposited?—I do not know. I think it is volatilised. It is well known that certain fungoid growths, penicilliums, can volatilise arsenic, giving off arsenical gases, and that might be an explanation why, in samples of beer when they are kept, the arsenic diminishes.

7979. That must be when they are kept open?—Yes, and when they go bad.

7980. If the arsenic volatilises from beer in a cask, do you think it comes out into the air?—I do not know. I have no experience. I suppose it would not change.

7981. Nothing could get out of a corked bottle?—No.

7982. (Professor Thorpe.) These alkaline carbonates you speak of, do you imagine the arsenic you find in them comes from the sulphuric acid which has been indirectly used?—I believe in many cases it does, but in other cases not. I have some evidence in the case of alkali which has not been made with sulphuric acid at all, and where traces of arsenic could be found.

7982<sup>a</sup>. From the ammonia soda process?—Electrolytic.

7983. Have you found it in ammonia soda?—I do not think so.

7984. (Mr. Cosmo Bonsor.) In the refined sugar and molasses where you found the arsenic, have you any idea of the process in which the arsenic got in?—I have no idea. They were a certain kind of German sugars, and most of them were free. I examined a certain sugar product for a large firm, and I found small traces of arsenic, and they, being very careful, submitted every kind of sugar which had gone into their works. They traced it to a particular brand which always contained it, to a particular brand of sugar from a particular refinery, which always contained traces.

7985. (Chairman.) Was that West Indian sugar?—No, German beet.

7986. Have you found arsenic in West Indian sugar?—I have never tested it.

7987. Was your test for arsenic made after the outbreak of this epidemic?—Yes.

7988. You had never tested sugar for arsenic before?—Never.

7989. (Professor Thorpe.) How do you imagine the arsenic gets into sugar?—It is imaginable it came in by the liming of the sugar. In a lime kiln it is likely, I take it, that lime may retain a good deal of the arsenic from the fuel, and it might then come into sugar.

7989. Is it possible it comes in from the char?—I think it is imaginable, but it is not general.

7991. (Dr. Whitledge.) Have you made any direct experiments on the removal of arsenic by moulds from beer?—I have not made any pure cultures, if you mean that. Of course, it is well known that certain moulds,

pernicillium brevicaulis, and so on, do evolve arsenious gas. But I had some strongly arsenical beers in the early stages of this poisoning outbreak, and they diminished in arsenic. I kept a number of samples of less arsenical ones aside, and let them get mouldy, and the arsenic in some of them had vanished entirely.

7992. Have you any figures to show the amount of arsenic removed in that way?—No, I have no figures with me, but the amount in the original beer was something less than 1-30th of a grain in those samples I put aside.

7993. In some instances the whole of that disappeared?—Yes.

7994. (Chairman.) How had it been kept?—They were kept in sample bottles, probably badly stoppered. The beers had gone sour, and were put aside on the shelf.

7995. Glass stoppers?—No, corks. The cork had been pulled out, and no doubt was perforated and damaged.

7996. (Dr. Whitledge.) Have you formed any opinion as to the state in which arsenic is present in beer?—No, I have made some experiments to see the state in which it might be present. I had some samples of beer which were highly arsenical, and I tried whether any of the arsenic was in a volatile condition, but none of it was volatile. I distilled and examined the distillate. I found no volatile arsenic.

7997. You have not formed any opinion whether it is an organic combination or not?—I have not formed any. I do not see any way of ascertaining it with the small traces with which we have to deal.

7998. Would you say as a chemist it is unlikely it would be an organic combination?—No, I think very likely it is an organic combination.

7999. Would that mean in chemical combination with an organic substance, or simply that the arsenic behaved differently because of the presence of organic matter?—I can imagine that in a liquid like beer, where there is a good deal of fungoid life going on, the arsenic might entirely go into organic combination.

8000. You gave us some suggestions as to the amount of arsenic which might be regarded as negligible in beer and in malt, 1-100th of a grain per gallon and 1-100th of a grain per pound of malt. Have you any similar standard in mind as regards sulphuric acid?—I have made a calculation which I have not in my mind, but when one calculates how much sulphuric acid might be used in the manufacture of glucose, for instance, say 3 or 4 per cent., it may be that sulphuric acid can be strongly arsenical before it could introduce so much arsenic as 1-100th of a grain into a pound of glucose.

8001. And you would make your calculation with this data?—Yes.

8002. Is the Committee of the Society of Chemical Industry a large Committee?—It is a Committee of 7, I think. It is mainly an analytical committee; it is not a committee to lay down limits of standards, which are expected from this Commission.

8003. It is a committee of research?—Yes; to get at the best method of determining arsenic and detecting it in different substances. May I add also at the same time that as far as the Reinsch process is concerned the Reinsch process will not discover arsenic in some organic combinations. Cacodylic acids or cacodylates give no Reinsch reaction, whereas the Marsh process shows them as readily as inorganic arsenic.

8004. Are all the members of the Committee working with the Marsh process?—I do not know. Each works at present on his own lines on samples which are made up by some of us unknown to the others, and even the persons who make them up get them changed by the others, so that we are all at present working on samples of unknown composition. We propose to collect all the data and compare them, and select that process which is giving the most accurate results. I know a good many work with the Marsh process.

8005. These researches will be published in the form of a Report, I suppose?—That is the intention.

8006. May we expect that at an early date?—It depends how long the Commission is sitting.

8007. There is no intention to report early?—No, we intend to report as soon as possible, but the Committee is a committee of busy men, and works very slowly.

8008. You are an analyst under the Sale of Food and Drugs Act for several districts?—Yes.

8009. Do you advise the local authorities in these

Mr. O. Hehner. 21 May, 1901. Disappearance of arsenic from arsenical beer.

Question of combination of arsenic with organic matter of beer.

Some organic compounds of arsenic would not react to Reinsch, but would to Marsh test.

districts as to the steps they ought to take under the Sale of Food and Drugs Act?—Sometimes.

8010. Not in all cases?—You mean in reference to arsenic in beer?

8011. Speaking generally, do you advise or do you merely deal with the samples they send you?—As a rule, I deal with samples they send me. I carefully refrain from giving any advice as to what they ought to do, because I do not want to pose as a prosecutor, but if they directly apply to me, I give them advice.

8012. And some do apply to you?—Sometimes.

8013. Have you received samples, for example, of the bloater paste of which you told us?—Yes. I advised them as we were searching for arsenic. Some time before this outbreak in beer we were examining many substances for arsenic. There were a number of cases in the police courts against vendors who sold arsenical sodium phosphate, and from that I went a little deeper into the matter and got a large number of drugs collected, and I examined these for arsenic, but I found nothing so serious as was present in that sample of sodium phosphate which was the subject of the police court proceedings.

8014. How much was there in the sodium phosphate?—I do not remember. It was a large quantity; if I remember right, 1 per cent.

8015. You found arsenic in samples of bloater paste submitted to you officially?—No. I found arsenic in samples of oxide of iron which had been sent to me by clients in the trade for colouring food materials, and then I stopped that as soon as I could. I advised them not to use any article of the kind, and wrote to some of my county authorities about the matter suggesting that it might be well to look into it.

8016. But the results were negative?—Yes.

8017. Were the results alike negative in the other samples examined with the same object?—Yes.

8018. You mentioned chocolate and other forms of confectionery?—I have not had any from my districts from the police. I have had some from the trade. The quantities of oxide of iron used are very small.

8019. Are samples of sweets and golden syrups submitted to you?—Yes.

8020. Do you examine them for artificial glucose?—Yes. We have examined golden syrups for some years past for glucose, and there have been very many prosecutions for the sale of golden syrup consisting more or less of glucose, but sweets have practically not been examined for glucose, because the term "sweets" seems to be a very indefinite one, and there are practically no sweets without glucose.

8021. If you find glucose in golden syrup, do you report it as an adulteration?—Yes, and I have reported it as an adulteration in jams. I have had some prosecutions lately against vendors of jams using glucose without acknowledgment.

8022. In any of these cases have you found arsenic?—Never. I found traces of arsenic in sweets, but nothing very serious—in cheap sweets.

8023. Have all your authorities sent samples of beer to you for examination for arsenic?—Yes; all.

8024. Was it the practice prior to the Manchester outbreak to examine samples of beer for arsenic?—No; it never entered anybody's mind.

8025. What is the largest amount of arsenic you found in the beer samples?—1·05 grains per gallon.

8026. How much beer was sent to you as a sample?—As much as I asked for. If I got too little, I would ask them to send more; but, as a rule, I got about a pint.

8027. Did you instruct the officers of the Local Authority as to the amount to be taken as a sample?—No. If I got too little I would say—you must buy more. I always do with as little as I can, because the inspector should purchase samples as much as possible in the ordinary way of family trade.

8028. Are samples of beer still being submitted to you?—Yes; I have some now.

8029. Do you still find small traces of arsenic?—Almost invariably.

8030. But nothing approaching the quantity you gave me just now?—When I have less than one-hundredth of a grain per gallon it is my practice to report to my

authorities that it contains, in my opinion, an insignificant trace.

8031. If it contains, let us say, one-thirtieth of a grain per gallon?—I would report that it contains an undue proportion of arsenic.

8032. Would you forward a certificate which could be made the basis of proceedings, in that case?—I would now. I did not at first. At first there were many samples with one-thirtieth of a grain, and when I was asked I suggested the vendor should be notified. In fact, the vendors were treated very gingerly at first, as many of them were quite as innocent as the analysts themselves. But at a later stage they were warned, and prosecutions were instituted in some cases.

8033. What is the smallest amount for which prosecutions have been instituted in your district?—I don't know.

8034. Anything less than one-thirtieth of a grain?—No. I believe there have been some prosecutions in Nottingham for about '05. In many cases I do not know when there is a prosecution; but I have given certificates which could be used for prosecutions. But one-thirtieth of a grain would be rather rough on the vendor, I think.

8035. Did all your authorities send samples?—They have, yes.

8036. Varying very much in number?—Yes.

8037. Varying to an extent that cannot be explained plain by the population or any consideration of that kind?—These matters have got very much better in the last few years. The Local Government Board have more sharply looked after counties and districts which do not work the Sale of Food and Drugs Act. It is a very different state of things from what it used to be. There are still a few districts which work reluctantly, but the bulk of them have vastly improved since the Committee of the House of Commons some years ago inquired into the matter.

8038. You mean generally, and not with particular reference to beer samples?—Generally.

8039. Can you say what action the Local Government Board took?—The Local Government Board sent a circular to all authorities, drawing their attention to articles which might contain glucose, and, consequently, arsenic, at an early stage of this outbreak.

8040. That followed the Manchester experience?—Yes.

8041. But I understood you to refer to something earlier following on a Committee of the House of Commons?—Yes. The Local Government Board for years have been in communication with authorities that do not work the Sale of Food and Drugs Act sufficiently rigorously, in the opinion of the Local Government Board. At that time there existed no power to compel them to work, but now under the new Act of 1899 there is a provision which enables the Local Government Board or the Board of Agriculture to interfere and to take samples at the expense of the Local Authorities.

8042. In default of the local authority has that been done?—I have not heard of a case.

8043. (Professor Thorpe.) Lord Kelvin desires me to ask you a little more about the organic combinations of arsenic. Have you in your mind anything more clearly as to the form of organic combination of arsenic?—I have not. I believe from the fact that arsenic vanishes from liquid like beer it can only vanish in an organic form. I have never smelt any arsenical odour even in a highly arsenicated beer.

8044. Do you mean you have not smelt anything like diethyl arsine?—No. I have carefully looked out for that and have never smelt anything, and yet the arsenic vanishes not only from the beer, but from a very dilute standard solution when it becomes mouldy. I have taken the mould out of a standard solution, and can trace no arsenic in the mould itself.

8045. But in the *penicillium brevicaulis* it was found that the arsenic was assimilated by the mould?—Yes, and ordinary yeast does it. But *penicillium brevicaulis* produces a volatile arsenic compound which yeast, so far, is not known to do.

8046. Would the common mould, the other *penicillium*, assimilate arsenic like the *brevicaulis*?—I do not know.

Mr.  
G. Becker.  
21 May 1901.

Arsenic in  
beer now  
brewed,

and action by  
authorities  
under F. and  
D. Acts.

Position of  
Local  
Government  
Board as to  
enforcement  
of F. and D.  
Acts by local  
authorities.

Question of  
combination  
of arsenic  
with organic  
matter of  
beer.

Mr. O. Hehner. 8047. In beer, bread, potatoes, or anything of that kind it is not *brevicaule*?—No; it is *penicillium glaucum*.

21 May 1901. 8048. In the particular instance you cited where the arsenic disappeared, was there a mould present?—Yes. I have never had any pure culture, and so I have not examined it carefully. On a number of occasions I have had to make standard mirrors for various friends, and, using always the same solution, I noticed that the mirrors were getting feebler and feebler, and on making a fresh solution again, the original mirrors were once more obtained. If I let that solution stand, the arsenic vanished completely from it.

8049. When the arsenic is in the beer, before the mould does its work, do you imagine that the arsenic is in any organic combination?—I should not be surprised if it partly were.

8050. In what form do you imagine it might be?—I do not know. I can hardly give a theory.

8051. But it is not anything analogous to *cacodyl* or diethyl arsine?—No.

8052. These you tell us would not be recognised by the Reinsch test?—It is not.

8053. These arsenicated beers do give a strong Reinsch reaction?—They do.

8054. Would not that indicate that the arsenic was either in the form of arsenious acid?—Yes. On the other

hand, I have made many comparative experiments between the Reinsch and the Marsh, and I always got a stronger indication with the Marsh than with the Reinsch. Whether that is the fault of the process which does not allow the whole of the arsenic to be deposited, or whether it is due to a portion of arsenic being in a condition that it cannot be deposited on the copper I do not know, but the Marsh process gives a larger yield than the Reinsch process.

8055. In the quantitative estimation of the arsenic do you find it is necessary to break up the organic matter?—No, quite unnecessary. I have made many experiments by adding to beers which were obtained as pure as they could be obtained—in fact, I bought some of these Continental beers about which I was asked, in order to get pure beers—I added arsenic to the beer and recovered it back again by the Marsh process which I use—I got an amount in the shape of a mirror, as if it had been an aqueous solution.

8056. And you think it is not necessary to treat the beer with the drastic method of chlorate of potash and hydrochloric acid?—Not only not necessary, but even dangerous. I know that glass is often contaminated with arsenic, and, therefore, the less drastic the measures are which we have to take, the better.

8057. You mean that the materials used, as well as the glass vessels in which the operation is carried on, may contribute to the amount of arsenic which is found?—They may.

Mr. O. Hehner. Destruction of organic matter of beer undesirable.

21 May 1901.

## EIGHTEENTH DAY.

WESTMINSTER PALACE HOTEL.

Thursday, 20th June, 1901.

PRESENT:

The Right Hon. Lord KELVIN (*Chairman*).

The Right Hon. Sir WILLIAM HART-DYKE.  
Sir WILLIAM CHURCH.  
Professor THORPE.

Mr. COSMO BONSOR.  
Dr. WHITELEGGE.

Dr. BUCHANAN, *Secretary*.

Mr. CLARE SEWELL READ, called; and Examined.

Mr. C. S. Read. 8058. (*Chairman*.) You were Member of Parliament for Norfolk from 1865 to 1885?—Yes, with the exception of a short period in the year 1880, when I lost my election by one vote, and I was out for a few months.

20 June 1901. 8059. And you took part in the work of the Local Government Board?—I was Parliamentary Secretary to the Local Government Board in 1874 and 1875.

8060. You were Chairman of the Adulteration Committee of the House of Commons in 1875?—Yes.

8061. And you served, I believe, on the Beer Materials Committee?—Yes, for 2½ years, and I attended every sitting of the Committee with the exception of the last two, when they were considering the Majority Report. I heard all the evidence.

8062. You have been engaged in farming for many years?—Sixty years.

8063. You were appointed last April to represent the Central Chamber of Agriculture before this Royal Commission?—Yes, in conjunction with Mr. Henry Stopes.

8064. Have you any scientific knowledge of or practical acquaintance with brewing or malting?—None whatever.

8065. You wish to direct attention to the Minority Report of your Committee on Beer Materials?—I do very respectfully urge you to consider my recommendations, which I think the members of the Commission have had before them.

8066. Are you still of opinion that there are some malt substitutes injurious to health?—I believe so.

8067. Do you believe that they are deleterious to health?—I believe some of them are deleterious to health.

8068. Some are deleterious and some are not?—Some are not.

8069. You believe that some glucoses are not deleterious?—I should think that some of the sugars are not deleterious.

8070. But glucose in particular you think so?—I think from the evidence that we had before the Committee the manufacture of glucose is questionable as to the materials used.

8071. With proper materials, do you consider it would be necessarily deleterious to health?—No, not with proper materials. I think it would be cheating the public, but certainly not injuring their health.

8072. Had the Minority Report of the Beer Materials Committee been acted upon, would that have made any difference in respect to the Manchester poisoning?—I think if that report had been acted upon it is quite possible the Manchester poisoning case might have been averted.

8073. In what respect do you think the contamination by arsenic would have been avoided if that report had been acted upon?—By a proper supervision of the materials of which beer is composed.

8074. With regard to the action of the Excise officials or the authorities at Somerset House, do you consider that that action has been a safeguard to the public

Mr. C. S. Read. 20 June 1901.

Some malt substitutes injurious to health.

health?—A very good safeguard to the revenue, but a very poor safeguard to the public health.

8075. Has it been any safeguard at all to the consumer's interest?—I cannot say it has been, because they were of opinion in the evidence that was given before the Committee that there was nothing deleterious used in the manufacture of beer. Experience has proved the contrary.

8076. Do you consider a court of reference, such as is referred to on page 10 of your report of the Beer Materials Committee, should be speedily established?—I do. It was a recommendation of the Parliamentary Committee on the Adulteration of Food Products, and I quite endorse that recommendation. I think that a court of reference composed of competent experts and sound business men should be established for fixing the standards of purity and deciding other points arising under the Sale of Food and Drugs Act.

8077. You consider that guarantees from growers of barley or other produce are not desirable?—I think it would be perfectly ridiculous on the part of a farmer to give a guarantee about his barley. If I was a maltster I should not give any further guarantee than to say I had used the best fuel, and if I were a hop-grower I should say I had used all good materials in the drying of my hops. I should not say anything else.

8078. What have you to say on the opinions of chemical experts and others, some of whom were appointed on the Committee by the Manchester Central Brewers' Association?—Some of those gentlemen also gave evidence before the Beer Materials Committee, and they convinced the majority of that Committee that no ingredients harmful to health were used in brewing. Now, from this further investigation they seem to believe that almost every ingredient used in brewing is more or less poisonous. It seems to me to be this: that they can prove anything when they like, and they can prove nothing when they desire to do so. The effect upon farmers and others is that, as these continual scientific scares are proved mostly to be wrong, when there is any real sound, scientific discovery they are very slow to believe it. I think that is a very sad thing for us, and for the country generally.

8079. Did the chemical experts suggest it is impossible by analysis to ascertain of what materials beer is composed?—Most of them did, at any rate; one or two on the other side said they could discover any large adulteration, and they could also, they thought, discover adulteration even in small quantity.

8080. Did they think that substitutes used by brewers were harmless?—They did, and the majority of the Committee did.

8081. Have you read the report recently issued by the expert committee of the Manchester Central Brewers' Association?—I have read all that which refers to barley and hops and farming.

8082. Did that expert committee make any statement with reference to beer materials?—I suppose it did, but I have not taken any particular notice of that. I went mainly on what they said about the soils, the manures, and barley. I have the authority of Dr. Voelcker, the chemist of the Royal Agricultural Society, to say there are sundry soils which naturally contain arsenic. With regard to manures, I have never heard any charge brought against superphosphate until quite recently. With the permission of the Commission I should like to read a short extract from a letter I have received from Mr. Tom Brown, the managing director of the West Norfolk Farmers' Manure Company, in which he says that more than forty years ago, when they first began to use sulphuric acid for dissolving bones and coprolites, "boxes of soil were sprinkled with arsenious acid in various quantities, and vegetable seeds sown, in some cases immediately after the dressing of arsenic, in other cases a week or a month or three months after the arsenic was applied. When the seeds were sown immediately after the arsenic was applied, the plants perished, but when the seeds were sown a month or two afterwards the plants grew apparently with no hindrance. The conclusion arrived at was that the arsenic had taken an insoluble form not available to the plant. The plants that grew were removed and treated, some in a green state, others dry, and burnt in a hooded crucible, and in no case was any arsenic detected. Dr. Plowright, of Lynn, and Mr. Hamlet, now the superintendent of the New South Wales chemical laboratory, shared the labour of these experiments with me. I did not think at the time that they were of any public value. They were undertaken

at the suggestion of the chairman of this company, and none of us thought them of sufficient scientific interest to publish them."

8083. (Sir William Hart-Dyke.) What date is that?—That is about forty years ago.

8084. About 1861?—Yes; then he goes on to say, "It would be easy in this neighbourhood to point to a very large acreage where as much as 10cwt. per acre of superphosphate has been applied, to my knowledge, four if not five times during the last ten years. If therefore the arsenic and superphosphate could be absorbed by the potato crop, it would require a very small amount of labour to isolate the arsenic in the tubers grown in such soils. The 'Lancet' commissioner can end the matter in a few hours whenever he pleases by testing vegetable substances grown with superphosphate." It is a very common practice indeed in the Fens where potatoes are grown to apply as much as half a ton of superphosphate per acre.

8085. And sometimes more?—Sometimes one ton.

8086. (Chairman.) One ton to the acre?—One ton to the acre. The potatoes are actually on the manure. I have seen them taken up with portions of the manure adhering to them, and I have never heard of anybody's internal laboratory saying there was arsenic in them. With regard to superphosphate as applied to roots, nine-tenths of the superphosphates used in our county is used for the production of roots. I suppose the arsenic ought first of all to go into the turnip, then through the sheep, then into the barley, and then through certain malting and brewing processes; but I should have thought that the sheep would have been the first animal to take any bad effects from the arsenic. I never heard of it.

8087. Do you know if potatoes or turnips have been ever tested for arsenic?—I do not.

8088. Have you known cattle or sheep affected?—Malt culms. Not from eating malt culms or sproutings. This spring I had some lambs go wrong, ten of them dying, from eating the flower of some thousand-headed kale. I was very desirous of checking the disorder, and I had the greatest difficulty in getting malt culms. However, I got half a ton, and I have not lost a lamb since. The difficulty I experienced in getting these malt culms shows how very generally they are used, and how much they are prized by stock-owners and farmers. I have a letter here from Dr. Stutzer, the Professor of Agricultural Chemistry in the University of Königsberg, and his conclusion is this, "From these figures it would appear that we have to deal with such very minute quantities that there cannot be any question whatever of poisoning the plants through arsenic, and of course there cannot be any question of poisoned malt and beer through the soil, even if it could be proved that plants are entirely insensible to the poisonous action of arsenic, which, however, as we mention above, is not the case." I believe he is a German chemist of very high authority.

8089. Do you think beer ought to come under the operation of the Food and Drugs Act of 1875?—I do. As I was chairman of the Adulteration Committee upon which the Food and Drugs Act was founded, I may say that we wished to bring beer into that Act, but we found we could not do so, as there was no legal definition of what was beer.

8090. (Sir William Hart-Dyke.) As to whether it was food or drink?—No; what it was composed of. The report which I drew up was generally considered to be satisfactory, inasmuch as the public were assured that they were cheated and not poisoned. But it appears, in the case of beer, that they have been both lately.

8091. (Chairman.) Would you propose any official definition of beer?—I would. I would suggest the passing of the Bill which is now before Parliament, and which defines what beer should be. It is said not to be a "Pure Beer Bill." That is quite true, but it is a declaration and a definition of what beer should be, and I think it would be very disrespectful on the part of the promoters of that measure if they had attempted to legislate upon the question of arsenic, or adulteration in beer, when those questions were specially committed to this Commission. I think they were perfectly justified in not mission. I think they were perfectly justified in not

8092. You prepared the report of the Committee on which the Sale of Food and Drugs Act was founded?—

Mr.  
C. S. Read.  
29 June 1901.

Advocates  
a definition  
of beer for  
purposes of  
F. and D.  
Acts.

Mr.  
C. S. Reed  
20 June 1901

I did, and I was also principally employed with the Local Government solicitors in drawing up that Act. We found it very difficult to define what adulteration should mean, but we said that the "nature, substance, and quality of the article" demanded by the customer should be given, and that I believe has been generally a successful definition of adulteration. I have also had very considerable experience in investigating sewage farming, for I was appointed as a Departmental Committee with Sir Robert Rawlinson, the Chief Inspector of the Local Government Board, to investigate all the systems of sewage in Great Britain and on the Continent. Anyone who knows anything about sewage knows perfectly well that the most filthy substances are used for the purpose of irrigation over the soil, and very frequently over the vegetables, and grass growing, but I never heard of any disaster or poisoning happening to stock eating that grass or from the milk produced.

8093. Do you consider the present Beer Bill or some such measure should be passed?—I respectfully entertain the hope that this Commission will report in favour of some such measure. I have had the opportunity of reading carefully through Mr. Stopes' evidence, and I entirely agree with all that I know in it, and I believe in a great many things he will say which I do not pretend to know.

8094. (Sir William Hart-Dyke.) You have had special experience not only as a farmer but as a barley grower?—I have.

8095. East Anglia is particularly favoured in that regard; the lightness of the soil is in favour of growing what is called a good sample of malting barley?—We consider we can grow the best barley in the world.

8096. You urge that had your Minority Report been acted upon this disaster at Manchester might have been averted. Would that have been through the action of this court of reference composed of competent experts and sound business men fixing standards of purity and deciding other points arising under the Sale of Food and Drugs Act? Do you mean the action of a body acting as a Government Department to deal with these matters, or do you mean a Court for the purpose of fixing standards of purity?—I fancy there should be in addition to the Excise authorities, much more strict supervision of the various articles that are being used in brewing.

8097. I had better read the clause. What you recommend is: "A court of reference composed of competent experts and sound business men, to be established for fixing standards of purity and deciding other points arising under the Food and Drugs Act." Was it in your mind when you drafted this that these competent experts should fix a standard of purity and that some Government Department or other body with statutory powers should enforce that standard?—I think so. But there ought also to be a more diligent supervision of the ingredients used in beer—I should have thought by the Medical Officer of Health or some other officer of the local authority as well.

8098. You think in the first place a standard of purity should be fixed, and then that any Government Department which had statutory powers, such as the Local Government Board or the Inland Revenue, should do their utmost to secure that standard of purity?—That is my idea, and this Committee of Standards of Purity would work entirely in conjunction with the Excise. There can be no doubt that the Excise are very useful, particularly for the purpose of protecting the revenue, and if their attention had been called to poisonous ingredients I have no doubt they would have discovered them. You must remember that previous to the year 1880 there were all sorts of ingredients discovered in beer, but suddenly they disappeared from the list of adulterations discovered by the Excise.

8099. Then, when you urge that the Inland Revenue failed as regards this particular instance, you are yet of opinion that if the machinery under which they work were improved and fresh obligations imposed upon them it would be a great security?—I think it would, in conjunction with the local authority.

8100. Would you also suggest an amendment of the Food and Drugs Act if necessary?—I think if the Beer Bill were passed that would do all that I require. It would define what beer is and bring it under the purview of that Act.

8101. You think the Bill now before Parliament would indirectly prove an amendment of the Food and Drugs Act?—It would bring beer under the Act.

8102. You think the barley grower should have a free

hand as regards any guarantee that might be demanded of him when his product goes into the market?—I think it would be absolutely ridiculous to ask a farmer who sold a clean sample of barley to guarantee it.

8103. You think whatever guarantee may be given should be at a later stage in the manufacture of beer?—If there is to be a guarantee it should begin, not with the raw article, but with the manufacture of the article.

8104. With regard to malt culms, as a sheep farmer you have from time to time used malt culms extensively?—Yes, for lambs and calves particularly, and for the purpose of adding a nice flavour to coarse feeding materials. They are very useful.

8105. If there were really any deleterious results would they not be more severely felt in young animals, like lambs and calves?—I should say so, certainly.

8106. A lamb three or four months old would feel more immediately the deleterious effects than an older animal?—I should say so. I have known lambs to eat too much of them, they were so extremely fond of them.

8107. I suppose you have read some of the evidence that has been given before this Commission, especially with regard to the finding of arsenic in malt dust and malt culms?—Yes.

8108. Have you had any practical experience as a maltster?—No.

8109. You are aware that evidence has been given in some cases of a great quantity of arsenic being found in malt dust, the dust which gradually collects in the process of malting in the kiln. This malt dust has never been used for feeding purposes?—Never, but we use it very extensively as a manure. I should think that all the arsenic comes from bad fuel. I know a good many maltsters in Norfolk, and I am sure they use nothing but anthracite coal.

8110. You think the best security would be greater care in the selection of fuel by the maltsters in the future?—I do not like to speak with any authority, but I should think that gas coke had better be prohibited altogether.

8111. From what you have heard?—Yes; from what I have heard, that is my opinion. I think gas coke is very injurious to the men making the malt.

8112. Are you in favour of restricting the use of invert sugar or glucose by brewers?—Not at all, only I think they should let us know they use it.

8113. You prefer the provision in the Bill now before Parliament, which would insure to the consumer a knowledge of what precisely he is drinking, to any attempt to restrict the use of these materials?—I do not say I should not like to do it, but I should certainly not advocate it.

8114. As an agriculturist of 60 years' standing, have you ever had the least suspicion that either through the indirect process of manuring or through the feeding of stock there is any reason to suppose that danger has accrued through the use of malt culms?—No. It is my deliberate opinion that, if there is any arsenic adhering to the malt, with thorough good screening and proper brushing the whole can be taken off.

8115. (Sir William Church.) You say that you are still of opinion that some substitutes are injurious to health, and certain glucoses give rise to deleterious effects: what is your opinion based upon?—Upon evidence that we had before the Committee.

8116. I am afraid I am not so conversant with that evidence as I ought to be. What was the evidence that weighed with you?—The evidence of Dr. Schidrowitz, in which he said, "There are strong grounds for stating that at the present time materials which are possibly of an injurious nature are still employed," and he instances sulphuric acid as largely employed in inverting sugar, and says the use of salicylic acid as a preservative is open to grave objections. Then there were some experiments performed upon cats, and the result of that was that certain glucoses had deleterious effects on the cats.

8117. Your opinion is only formed on what you have heard or read; you have never had yourself reason to think that ill effects followed?—I have drunk some exceedingly bad beer in my time, and I believe a good deal of that was made from substitutes. I never took any harm from drinking malt beer.

8118. By substitutes you mean made from starch or meal rather than malt?—Made from substitutes for malt.

purposes of  
F. and D.  
Acts.

Beer Bill  
1901.

8119. You are speaking of substitutes as distinct from sugar substitutes?—I had rather class it under all substitutes.

8120. It is rather a strong expression to say you are of opinion they are deleterious if you do not make a distinction between what may be called raw material and manufactured material?—I only give you my opinion. That opinion is based upon the evidence of scientific men, analysts, chemists, and others, given before that Committee.

8121. Did they say that if the substitutes were good of their own nature they were less wholesome?—They said they made it less nutritious certainly. They did not say they were poisonous, and I believe some of them did not think they were deleterious.

8122. You spoke of sulphuric acid being used: was not that rather because of an idea in the public mind that sulphuric acid was actually added to beer?—I should say not; not those who knew anything about it.

8123. The evidence which weighed with you was given with regard to sulphuric acid being used in the preparation of these sugars?—Yes.

8124. On what grounds did that gentleman state that sulphuric acid used in that way was likely to make the beer unwholesome?—He thought that some of it contained arsenic.

8125. He was aware it might contain arsenic. Did he say that if the arsenic was removed the materials made by sulphuric acid would be unwholesome?—I do not know that he was asked that, but I am sure he would have said so if he had been asked.

8126. You cannot tell what he might have said?—I gather from his evidence that he thought sulphuric acid might, and did contain arsenic.

8127. That everybody knows?—And that if that was employed in the inverted sugar it would be very dangerous.

8128. (Chairman.) Was that evidence about arsenic given before the recent scare?—Yes.

Mr.  
C. S. Read.  
29 June 1901.

8129. (Sir William Church.) With regard to the present Bill for amending the law relating to the manufacture and sale of beer, you regard that rather as a desirable Bill in the interests of the public, but you do not regard that as being a Bill for the safeguarding of every beer made with substitutes?—No, it is not a Pure Beer Bill.

8130. This report expresses your own views of what you think in the interests of the public beer should be, and you give them the opportunity of knowing which sort of beer they are drinking?—Yes.

8131. So that you do not regard this Bill at all as safeguarding the public from the possible contamination of beer made in other ways?—I do not. The Bill will carry out my desire which I have had for the last 25 years, that beer should come under any Act to prevent the adulteration of the food and drink of the people.

Beer Bill will not safe-guard public from deleterious matters in beer.

8132. (Mr. Cosmoonsor.) Were you one of the Committee that drafted this Beer Bill? Who is responsible for the Bill?—I am not.

8133. Do you happen to know who the authors of it are?—I suppose Sir Cuthbert Quilter, and most likely Mr. Chaplin, and those members on the back of the Bill.

8134. You know that the Bill permits a certain addition of sugar after the beer is brewed?—Yes.

8135. Do you think that that should be allowed?—No.

8136. Then you do not approve of the Beer Bill?—I do not approve of Sub-section 1 of Clause 9; with that exception it has my entire approval.

MR. HENRY STOPES, called; and Examined.

8137. (Chairman.) You are a maltsters' architect and engineer, a member of the Council of the Central and Associated Chamber of Agriculture, a member of the Society of Engineers, and the Chairman of Judges of the Brewers' Exhibition?—Yes. I may say I have acted as Chairman of the latter body from the commencement of the Exhibition.

8138. You are also the author of "Malt and Malting," "Barley and the Beer Duty," and other works?—Yes.

8139. You were appointed in April last with Mr. Clare Sewell Read to represent the Central Chamber of Agriculture before this Royal Commission?—I was unanimously appointed with Mr. Read; there was no difference of opinion.

8140. You have had extensive experience and practice, and previously you had made careful study and observation abroad?—Yes, I have been practising in London for 21 years, and I have travelled somewhat extensively. I went through every country of interest from a beer standpoint in Asia, Africa, and America, and therefore I suppose I have had some extensive experience abroad. My chief study was in points now before the Commission, with respect to agriculture, malting, and brewing.

8141. I believe you invented and designed certain malt kilns?—Yes. The two-floor kiln was devised by me as the outcome of what I observed of drying on the Continent with kilns of similar construction, but differing in the methods of applying the heat, and such kilns have proved very effectual and useful in this country for the last 20 years.

8142. Will you describe that kiln to the Committee?—Practically the principle is that in the construction of a kiln I first make it effective in passing through the grain a sufficient volume of air to remove the moisture, a thing which is essential. Throughout the process of the removal of the moisture air is applied at such temperatures as will best effect the subtle, and I believe at present unknown changes occurring in the grain, which actually amount to the cooking of the grain throughout the process. By the adoption of two floors instead of one, one floor in this country having hitherto been the universal practice, I enabled the air which passed over one layer of malt, and which derived but a very small amount of moisture from such a layer, to go through a second layer of very green or wet malt

under the best possible conditions to remove the moisture and give the necessary heat, and also to give a portion of the empyreumatic products of combustion.

Mr.  
H. Stopes.

8143. Has the air in that case passed through the fire?—Yes, it is simply the products of combustion which, with the excess of air not used in the process of burning, has passed through the first layer of semi-dried, and ultimately completely dried grain, and then acts on the utterly wet grain, which is placed upon the upper floor.

8144. But you do not protect the malt from exposure to the fumes of the fire?—No, because it is absolutely essential and necessary that the products of combustion should come into contact with the malt. You cannot possibly make malt without such products of combustion coming into direct contact.

Fumes essential to flavour of malt.

8145. German malt is made without the air passing through the fire, but you say it is impossible. The thing you say is impossible is done in Germany?—Because in Germany they have a totally different system of brewing. If you adopt the English system of brewing, that is, the ordinary infusion system of mashing with the high temperature fermentation, which are the two main essentials of the English process of brewing, it is imperative that you have the products of combustion in your malt. If you adopt the low system of fermentation and the decoction system of mashing you are then indifferent to such products of combustion.

8146. We have had evidence before this Commission that hot air which had not passed through the fire gave malt that was fit for brewing in the English system?—I believe only one witness has given such evidence, and although he is a witness I know personally, and for whom I have the highest personal respect, I am absolutely certain he was mistaken. It is impossible to dry malt under the conditions he stated. When we can deal with a positive fact we can disregard opinion.

8147. You mean that in your opinion it is not possible?—Apart from my opinion, we must adhere to the facts. When you load into a kiln a quantity of green malt, which has just finished growing, and is ready for drying, you have in it a large volume of water, which must be removed, and in order to remove it it is absolutely necessary to have a given volume of air passing through it capable of removing such moisture.

Mr.  
H. Stopes.  
20 June 1911

8148. But that air may be hot air which has not passed through the fire?—That is another question. The point which I understood you were asking me upon was with regard to the evidence of Mr. Earp, who gave evidence of one of his kilns having become blocked up and thus prevented the admission of air, and yet he had made good malt. If you have a plate covering the kiln floor which does not admit any air at all you necessarily have a position in which you cannot dry owing to the want of admission of air.

8149. Then I understand that plenty of hot air through the malt is what is necessary?—No. It has been tried many times. Kilns have been constructed in this country with the view of drying as they do in Germany, where they use only hot air, but up to now no such kiln has ever produced malt which can brew satisfactorily. Therefore I hope I am justified in assuming that it is necessary to have the products of combustion as well as the hot air.

8150. In your opinion?—And as a matter of fact. It is an opinion which is not merely a matter of hearsay or of my own conjecture. It has been proved conclusively. I could tell you if you wished the names of places where kilns have been erected on the German principle where malt has been made, where the maltster who has made it has been unable to sell it, and where the brewer who has also attempted the principle has been unable to brew it. Consequently, I believe I am justified in asserting as a fact and not as an opinion that it is necessary to have the products of combustion in direct contact with the malt in order to ensure malt capable of being used.

8151. Is it the carbonic acid, or the carbonic oxide, or hydrocarbons from the fire that you consider to be necessary in air for properly drying malt?—I regret I have not the necessary chemical knowledge to answer that question as I wish. Of course, it is only a matter of opinion with me, as I have not the necessary knowledge. My opinion is an empirical one based only upon experience. It appears the combination of all three, plus some other thing which we at present know nothing about, is necessary. There are certain changes induced in the internal structure of the barley grain itself or in the starch and the other materials that constitute the barley grain which have never been fully investigated, which I cannot claim to understand, and upon which I greatly regret I cannot give fuller information; but the fact remains that you have to put the barley when in that state under such conditions to get the desired result. Why it is, I cannot tell you.

8152. You have designed and supervised the erection of the largest pneumatic malthouse in Britain?—Yes, and I believe it still remains the largest house. At the time of its erection it was certainly the largest pneumatic malthouse in this country.

8153. That is for spirits and not beer?—It was for a distiller's use. I mention that solely to show that I have some experience of the difference in the use of malts by distillers and the use of malts by brewers. That house is an exceedingly successful one.

8154. I believe that on behalf of British agriculture you have evidence which you think desirable to lay before us?—I wish to direct attention to the fact that arsenic is said to be present in hops, barley, and malt. I believe its presence in malt in very minute traces in almost every case has been proved, but I fail to see that sufficient evidence has yet been produced of the presence of arsenic in barley or in hops.

8155. You say in your précis that some soils contain arsenic naturally; has that any effect?—I have been informed by chemists of very high standing in this country that it is a fact that certain soils which contain pyrites do contain arsenic, but of course that is simply a matter upon which I have received information, and of which I have no knowledge. But I have put myself into direct communication with a number of the largest manufacturers of artificial manures in the country, and they are entirely at one in the information they gave me, that in the superphosphates and other manures used by barley growers or hop growers, the proportion of arsenic—assuming that even arsenical sulphuric acid has been used—is exceedingly small, and that that again is reduced by the fact that assuming arsenic to be added to the soil, a very small portion, if any, is picked up by the plant. They are all of the opinion that the amount contained, especially in the seed berry of the barley plant, is utterly negligible.

8156. What have you to say as to the fuel used by maltsters, or for drying hops?—May I say before an-

swering that question that I entirely confirm what Mr. Read said. I heard his evidence. He gave the opinions of two or three important people, and I have ample information to confirm them very fully. With regard to fuel, the amount of arsenic in coal, even if we admit there is arsenic in coal, is exceedingly small. With many oven cokes there is positively none, or it is so exceedingly minute as to be absolutely negligible. I believe charcoal has never been accused of containing arsenic in any form. The only fuel which is under suspicion is gas coke. With reference to that, I may say that, as the outcome of my experience, whenever I have found a maltster employing gas coke I have advised him to discontinue it, for the sole reason that it is an undesirable material to have owing to the effect it has upon the men. The men cannot work in the presence of the fumes arising from gas coke with the same comfort and the same pleasure that they can when a purer material is used.

8157. Would you consider common charcoal to be suitable?—When a man goes to the expense of using charcoal, I certainly consider he ought to be allowed to continue its use without any suggestion of impropriety. There are many good hop growers in Kent who I believe go to undue cost in providing charcoal to dry hops, believing that it is proper fuel, and as a consequence I should think it would be very undesirable to stop such men using it. I know of my own knowledge that a number of men employed in this business make a respectable living in burning the charcoal, and that the good hop growers who use this charcoal do so with the knowledge that it is really more costly than the best anthracite coal. They use it therefore in order to produce the best possible result. They want to grow hops thoroughly well.

8158. What have you to say with regard to the use of sulphur by hop growers or maltsters?—It has been said by one or two witnesses that sulphur is used very largely by hop growers, and that some maltsters use it. I believe that the number of maltsters who employ sulphur in that form, burning it upon the fire with the drying material, is exceedingly limited, and I believe as a matter of fact that the hop growers who use sulphur in that way do so solely with the view to pleasing their best customers—the brewers. The brewers like to have hops presentable to the eye; they like to have them nice in appearance, and the sulphur gives a better green, a nicer, brighter, and more living colour to hops than the hops without the sulphur would have. Consequently it is entirely in deference to the wishes of the brewers that the exceedingly small amounts of sulphur so burned are used by hop growers. That such a combustion of sulphur could add an amount of arsenic in the slightest degree harmful is to my mind simply ridiculous.

8159. In your opinion does any arsenic remain when malt has been thoroughly brushed?—I should say that if an efficient brushing apparatus be employed, unless it can be proved that the arsenic penetrates the skin of the barley grain, it would absolutely remove the whole of the arsenic. Any effective system of brushing would do that. With reference to that matter, I may say that fifteen years ago I put into Messrs. Barclay's experimental brewery an exceedingly severe form of brushing arrangement known as a smutter or wheat scalper, and that machine is running to-day, and I am authorised to say running with great satisfaction, cleaning the malt absolutely efficiently and thoroughly. I am perfectly certain that with the use of that machine, no matter what quantity of arsenic may have been deposited on the skin of the malt prior to its insertion in the machine, it would effectually and efficiently remove it. That is a thing capable of proof.

8160. You say in your précis that there are two systems of making malt?—I hope I may be permitted to say what I know with regard to the barley. I am chairman of the barley judges of the Brewers' Exhibition.

8161. That is scarcely a subject for this Commission. This Commission has not to decide with regard to different barleys?—But the farmers feel very grievously that a great deal has been said here with regard to the presence of arsenic in barley, which is extremely detrimental to their interest.

8162. (Mr. Cosmo Bonser.) By whom?—A great deal of evidence has been given before this Commission.

8163. (Chairman.) Very little evidence about arsenic in barley has been given before this Commission.

Mr.  
H. Stopes.

ble.

There has been evidence of arsenic in malt, but the evidence about barley has rather pointed to its not containing arsenic?—If it be accepted that that is the view of the Commission that barley does not contain arsenic, I will gladly pass over the point; but I wish there should be no misunderstanding. There has been, as far as I can remember, reference made that second-rate British barleys could not be used, and that sugar and foreign barleys have to be used in its place, or if sugar be prohibited, then a much larger quantity of foreign barley would be used.

8164. (Sir William Hart-Dyke.) That is apart altogether from the question of arsenic in beer or arsenic reaching the malt through the fumes of the fuel?—I was merely wishing to combat the suggestion that arsenic could be traced back to the barley. If I may take it that is dismissed, I am only too glad.

8165. (Chairman.) In your view arsenic is not found in barley?—I wish to confirm that absolutely. I say it is ridiculous. With reference to arsenic being liable to be present in the different systems of malting, I say there is no difference. So far as the indication of arsenic is concerned, it is just as liable to be introduced by any system of pneumatic malting as by the old-fashioned English system.

8166. You say in your *précis* that the two systems of making malt, by the old-fashioned open floor system, and the several types of pneumatic houses are alike unable to add arsenic to malt?—It is not able to do so—there is no liability.

8167. Do you contest the evidence that has been given that malt is liable to become coated with arsenic through the use of fuel, the fumes of which contain arsenic?—Up to the present the system of drying has been the same for both systems of malting, and the point I wish to make is that there is no difference whatever system of malting be adopted. It is purely a question as to how the fuel is used, and, still more important, as to the character of the fuel employed.

8168. (Mr. Cosmoonsor.) The system of malting you are alluding to on the floor is the system of germinating the corn, and whether that is on an open floor or in what is called a pneumatic drum, it is the same thing?—Yes.

8169. The question of the kiln comes later?—Yes.

8170. (Chairman.) I should consider making the malt to include, first, the germination, and, lastly, the drying. But your remark is limited to the first process, that no arsenic gets into the malt in the germination process?—Yes. In my *précis* I say that up to the present the modes of drying are the same for both apparatus.

8171. You go on to say in your *précis* that "air heated only cannot make good malt, as the products of combustion must be in direct contact with the malt when wet. The different flavours of black, brown, and numerous varieties of malt, are alone attained by attention to this law?—That is so.

8172. But in the process of making black malt, is not the final process, giving the distinct flavour, one in which the malt is heated to a high temperature in a cylinder, outside the products of combustion altogether?—That is so, but there again properly made black malt should have been subject to the influence of fuel on an ordinary kiln prior to being placed in the cylinder, because genuine black malt ought to be first of all germinated and dried in the ordinary course prior to submission to the higher heat of the cylinder which will caramelize it.

8173. Whenever malt is used by a brewer, do you think it necessary or a good thing to give it a final brushing prior to screening?—I think it is desirable that maltsters should clean malt efficiently prior to delivering it to a brewery.

8174. A primary brushing?—Yes.

8175. And the brewers should give it secondary brushing?—Yes, wherever a brewer has power it is certainly to his advantage to give it a complete brushing prior to use.

8176. You tell us that the Chambers of Agriculture are quite clear that the liability, should the presence of arsenic be detected in beer, ought, under no circumstances, to be carried back to the grower of hops and barley?—That is so; it is exceedingly unfair to throw the onus and responsibility upon the grower either of barley or of hops, and I believe not only do the

Chambers of Agriculture agree in that view, but almost every farmer and hop grower throughout the country.

8177. But you would agree that the responsibility of arsenic in malt should fall upon our makers of malt?—If they are contributory to the arsenic being present, most certainly.

8178. You have told us that the arsenic does not get into the malt from the barley?—Quite so.

8179. Therefore it can only get in by the process of making the malt; and you think the responsibility of no arsenic in the malt should be on the maltster?—In that case I do not think the maltster should be asked for a guarantee, because if a brewer wishes to buy malt from a maltster, especially with his existing knowledge, he has the power to test such malt. He has no necessity to shield himself from the use of such malt by getting a guarantee from the maltster.

8180. But should not the maltster himself make sure that he gives his malt without arsenic?—In the ordinary course of trading he would do so. Unless he was in a position to know his malt was pure he would not offer it to a brewer. My point is that it is not necessary or desirable that a brewer should insist on getting a guarantee from the maltster.

8181. You mean he must obtain arsenic-free malt from the maltster?—Certainly, and he has the power to secure that.

8182. And that a maltster selling malt to a brewer would imply that it was arsenic-free?—Certainly.

8183. But you would not have him give any guarantee in writing?—No.

8184. You would let it be understood that the maltster gives it arsenic-free, but you would not ask him to give a written guarantee?—Precisely, because the brewer has the power to determine that the malt is arsenic-free prior to purchase.

8185. If the maltster gives him malt containing arsenic, the brewer can find out?—Absolutely.

8186. (Mr. Cosmoonsor.) Not prior to purchase?—Certainly.

8187. (Chairman.) Do not you think the maltster himself ought to be held responsible, and not leave it solely to the brewer to find out his fault?—I think that the brewer in the ordinary course of business has ample opportunity to ascertain for himself that the malt he is about to purchase is arsenic-free.

8188. Then you correct the answer you previously gave, and you now say the maltster gives his malt without any guarantee, and tells the brewer, "Remember, I do not guarantee this malt arsenic-free"?—I do not say that. What I think is that he should not be asked to guarantee.

8189. That is to say, the maltster must give it on the condition, "I do not know whether there is arsenic in it or not. I give it to you as I have made it"?—I do not go so far as that.

8190. You would not let it be put in writing, but you would have it understood that was arsenic-free?—The maltster ought to know it was arsenic-free, and he should take every care that it was so.

8191. If he knows it, should he not say so to the brewer?—Certainly, but at the same time I do not think the brewer should go back on the maltster and insist on having a guarantee before purchase, because if anything arises he has the maltster to fall back upon.

8192. However much arsenic there is in the malt, the brewer should understand that the maltster washes his hands of it?—Certainly; he should buy the malt without arsenic. If the maltster does not know his business, and supplies malt with arsenic in it, the brewer, especially after recent occurrences, should be quite sufficiently up in his business to protect himself. What I object to, and what the farmers object to, is that the guarantee should be asked in the form that a number of witnesses appearing before this Commission have demanded, that there should be power to the brewer to fall back on the maltster with his guarantee.

8193. Let us leave the farmer out of it?—Leave both out of it.

8194. But the man who can put arsenic into the malt in the making of it cannot be kept out of it, and it is the first time we have heard it proposed by any responsible person that any kind of food business should be

Mr.  
H. Stoper.  
20 June 1901.

Maltsters should not be asked to guarantee malt as regards arsenic

Brewer should take responsibility of arsenic in malt.

Mr.  
H. Stopes.  
20 June 1901

conducted on the principle that, "I sell you something which may or may not contain arsenic, which you are to find out—I do not know, and I do not care whether it contains arsenic." That is what I understand you to make the maltster's position?—Put that way, yes, but if I may be permitted—the point may be a very fine one—what I wish to do is this. I stand up in the interests of the maltsters, and I say that they should not tie their hands behind their backs and give guarantees which may some day fall very heavily upon them, because they do not have the final disposition of this malt. If in the course of manufacture, the brewer employs any material which may contain arsenic, and then tries to fall back on the maltster, that guarantee may prove a very awkward thing.

8195. My question did not relate to that, but solely to the malt supplied to the brewer, and your answer is that the maltster gives it to the brewer, and ought not to be asked by the brewer whether it is arsenic-free or not?—No, the brewer should ask, and the brewer should compel the maltster to know, but he should not ask for a guarantee that could exculpate him completely. That is the point.

8196. (Sir William Church.) You confuse two things. You are saying that the brewer should not be exculpated if arsenic is in his beer by having a guarantee from the maltster?—Yes.

8197. No one suggests that. He would have to show that the particular malt was in default, and that his other ingredients were free from arsenic. But why should the maltster be excused from selling a pure article any more than the person selling other beer ingredients?—If it be put that way, I think as practical men that the brewers have the power to protect themselves prior to purchase. It is so simple a matter to test malt for arsenic, and therefore the brewer can protect himself.

8198. (Mr. Cosmo Bonser.) You have been at Mark Lane?—Yes.

8199. And you have seen brewers buy malt there by the samples? How can they test it—by their mouth or eye, or how are they to know that the samples contain arsenic?—Many brewers have now discontinued going to Mark Lane to buy malts.

8200. That is not an answer. I am asking you a question. You know that on Monday brewers go to Mark Lane, and do buy malt. How can they tell when they get a small bag of malt that that malt contains arsenic?—It might interfere with the dealing between maltster and brewer, and hereafter I believe no brewer will go to Mark Lane and buy by samples without investigation unless he is protected by a guarantee.

8201. (Chairman.) He will find out if it is not correct, but he will naturally want a guarantee from the maltster that it is free from arsenic?—The maltster can guarantee that he has used the best fuel he can employ, and I believe that ought to be the extent of his guarantee.

8202. The maltster can guarantee that he has himself tested his own malt?—Certainly.

8203. And would you disapprove of him testing it himself, and guaranteeing that it is free to the brewer?—I should say every maltster should test for himself, but should hesitate to give the guarantee.

8204. Should he tell the brewer he has tested himself, and believes it to be free from arsenic?—In the ordinary course of business if he were offering a sample of malt he would tell the brewer he knew it was arsenic-free, and I believe the transaction could stop there.

8205. (Sir William Hart-Dyke.) With regard to this question of fuel, I believe you urge that the quantity of arsenic in any coal, charcoal, or other fuel, is small. You are not a practical chemist, are you?—No.

8206. You do not test for yourself?—No.

8207. Where do you get this information?—From a variety of sources.

8208. What kind of sources?—Actual analyses by competent men.

8209. You say in your précis that no correct figures have been given in evidence before this Commission with regard to these matters?—As to the proportion of arsenic liable to be present in beer through the use of malt.

8210. Have you any evidence to offer us which would combat what we heard? It is an important statement to make?—It is.

8211. Have you any evidence you could produce before this Commission?—I would direct attention to one paragraph on page 7 of my précis, in which I say, "The assumed quantity of beer made in 1900, calculated at the official standard, was 36,578,000 barrels. But the actual quantity of beer or 'bulk barrels' was 29,473,000 barrels."

8212. That has nothing on earth to do with the question as to whether arsenic is in coke or other fuel. This is a two-fold declaration; in the first place, that very little arsenic is ever found in any variety of fuel; and further that the evidence which has been given is not correct. You say, "It is the same with fuel. The quantity of arsenic in any coal, coke, charcoal, or other fuel is small. No correct figures have yet been given in evidence before the Commission of the quantities of fuel used, and all statements as to amount of malt dried and quantities of malt brewed require correction." That is rather a strong statement if you have absolutely no evidence whatever to bring forward in support of it. Are you aware, for instance, that the Professor of Chemistry in Liverpool, Mr. Campbell Brown, has given evidence of having tested many varieties of fuel, and that in anthracite he has discovered as much as half a grain of arsenic per lb.? That evidence has been given before us, and there is other evidence of the same kind equally strong?—It is exactly that which I wish to answer. I cannot tell you of my own knowledge, as I have not examined the coal, but I have had submitted to me a large number of analyses by competent chemists wherein they have found no such amounts as you mention. In addition to that, in order to confirm what I there say, I wish to draw attention to the fact that the amount of malt dried by fuel has not been yet correctly stated, because there are many instances where maltsters are drying up to 60 quarters per ton of fuel. Ergo, if there be a small quantity of arsenic in the coal to start with, and if that coal be used so efficiently that it dries three times the quantity of malt assumed, certainly there must be a smaller quantity of arsenic carried through to the final product, the beer. I go further, and I say the amount of arsenic capable of being communicated to the beer by such means has not been correctly stated, for the simple reason that you have no statement yet before you which shows correctly and properly the amount of material used by brewers.

8213. I would ask you whether you are not of opinion that as regards malting, if the evidence shows that the only danger arises from the fumes of fuel, great care in regard to the choice of fuel is necessary, whether coke, anthracite, or any other?—That is the statement of one class of fuel which has not been confirmed. It is entirely beyond anything known by any other analysts. We know as a fact that there is a very large quantity of anthracite coal, used through the whole of the eastern and southern counties, and that the malts dried by those fuels have been subjected to the severest tests, and have passed through them without showing the presence of arsenic. Therefore it is fair to assume that that must have been exceptional coal, and as a matter of fact I have no hesitation in saying it is a coal used by no competent maltster.

8214. (Sir William Church.) You are leaving out of consideration another point on which we have a good deal of evidence, and that is, that the malt you allude to has been well screened and brushed?—Not all—I know that of my own knowledge.

8215. But you do not know of your own knowledge, and you can never say that the London and southern brewers use their malt unbrushed and unscreened?—A large number of the southern brewers do use their malt unbrushed, but not unscreened.

8216. Do you mean that they properly screen it?—They screen it to the extent of removing the culms. Malt when it is dried ready for use undergoes one or two rough screenings by the maltster.

8217. I will not go into that. You spoke as if the absence of arsenic from the southern malt must necessarily be due to the absence of arsenic in the fuel used in drying it, but we have a great deal of evidence to show that careful screening, even without polishing or brushing, does a great deal in removing the arsenic which does get upon malt in the process of kilning?—Yes.

8218. I only wished to point out to you that your inferences are incorrect, because you leave out, in assuming it is all due to the purity of the coal, the effect of brushing and screening?—Not so. I believe

Mr.  
K. Stopes.  
20 June 1901

No arsenic  
in malt dried  
with  
anthracite.

Mr.  
H. Stopes.  
June 1901.

that the brewers of Manchester have been quite as careful to get malt screened in the ordinary sense as any brewer in London or the southern counties. No maltster would dream of selling malt, and using it unless it had been efficiently screened. But that they brush it is another matter.

8219. (Chairman.) Do you know that much of the malt dust is found to contain a great deal of arsenic?—Yes, so it has been stated.

8220. (Sir William Hart-Dyke.) As much as two grains of arsenic per lb. of malt dust has been proved. You referred to one analyst just now; are you aware that no less than four analysts before this Commission have given conclusive evidence of finding arsenic in fuel? It is chiefly gas coke, but also anthracite, and all kinds of fuel used in the malting. The evidence is very conclusive. It is not as you suggest by one, but by four analysts, very high in their profession?—I do not wish to dispute that, except I do say—and I hope I may be permitted to repeat it—that the quantity of arsenic communicable to the malt is less than has been stated to you, and the malt itself is in such a position that it does not carry through the amount stated.

8221. That is no answer to my question. I am examining you upon a statement of yours in evidence as to the quantity of arsenic found in fuel. However, I will not pursue the point any further. I suppose you are of opinion that there are two processes by which with proper care and attention, security for the public may be absolutely provided, a process of cleaning and screening, and very careful attention to the use of fuel?—Quite so.

8222. Would you support that?—Absolutely.

8223. Many witnesses have come to that conclusion, that proper care must be taken in every case?—Undoubtedly, and if a man exercises proper care and caution in buying his coal and cleansing his malt efficiently, I should imagine there is no possibility of arsenical contamination.

8224. Are you aware that one of the largest brewers in Ireland uses malt only?—The largest brewer of all uses nothing but malt, and the next largest uses an exceedingly small quantity of sugar, but I am sorry to say it is used almost exclusively in the pernicious system of priming.

8225. Have you ever attempted to make any estimate in a bad barley growing season in this country, a wet season, for instance, by which you can tell the amount of English and foreign barley respectively the large firms of brewers in this country would use?—I have never known a season in which there has not been a sufficient supply for the largest brewers who pay a good price for the best barleys grown in this country.

8226. Even in a wet season?—The worst season. I have known every season since 1866. I have had to come into direct contact and judge the barleys of the season in a way which I suppose is not quite common, apart from Mr. Read, who has been good enough to act as one of the judges of the malting barleys at the Brewers' Exhibition. I have acted as chairman of that body for nearly 20 years. It has been my special and direct business to inquire most carefully into the actual quantity of the barleys grown season after season, and officially I state emphatically that I have not known any season in the whole of my experience when there has not been grown in this country a good quantity of barley suitable for the best uses of the best brewers. I believe Mr. Read will agree with me.

8227. Then in a bad season you think there is no excuse for any brewer to go to foreign barley to get a good barley?—That is another question. If there is not sufficient, and if it is necessary to import barleys because we have not grown enough, that would be only an ordinary business course. What I complain of is the very large and undue recourse to substitutes for barley made by brewers. They fly to foreign corn not when necessary, but solely with the view to depreciate the price of English grain, which is a totally different matter.

8228. (Professor Thorpe.) Assuming that malt substitutes, glucose and invert, continue to be used, would you extend the same principle that you laid down in the case of the maltster to the maker of those things—would you allow him to sell his product without any guarantee of its purity?—No, because he is conducting a purely chemical process which requires high training as a chemist; he is employing in the necessary process of his manufacture exceedingly dangerous and doubtful

materials, and therefore he is on a totally different plane.

8229. How is he employing exceedingly dangerous and doubtful materials?—I have never heard of invert or glucose being prepared without the use of sulphuric acid, muriatic acid, or other acids. It is one of the simplest and best known things, as I need not say to an experienced chemist like yourself, that these things are more or less dangerous or doubtful.

8230. How are they dangerous or doubtful?—It has been known for a very long period now that it is extremely easy for arsenic to get into their manufacture.

8231. Now when it is proved to you that arsenic is equally easy to get into fuel, what in principle is the difference between one class of manufacture and the other?—There is no difference in principle. If I were a maker of glucose or invert I should say, "Buy my stuff as it stands and test it on its merits; I give no guarantee."

8232. That is exactly the answer I desired you in the first instance to make. You would put the manufacturer of invert and glucose in precisely the same position in respect to the brewer that you put the maltster?—Yes, if they like to take that line. On the other hand, if in order to curry favour and sell their material they are prepared to give a guarantee, let them take the onus of giving that guarantee.

8233. You make that statement to us deliberately in view of the fact that the greater portion of this trouble has arisen through the manufacturers of these materials accidentally putting arsenic into them?—I do not admit it to be an accident.

8234. In view of these circumstances you nevertheless say if you were a manufacturer of invert or glucose you would recognise no obligation on you to furnish such certificates?—And I should think Bostock's are exceedingly comfortable in their minds that they gave no guarantee.

8235. If you were now in the position of a manufacturer would you still say there is no obligation on you to furnish that certificate?—If I were a manufacturer I should want to get out of giving the guarantee.

8236. (Sir William Church.) I should like to ask a question or two with regard to the suitability of English barley. I think you just now said there was no year in which there was not a sufficiency of good English barley produced for brewing purposes if the proper price was given for it?—Yes.

8237. You have rather changed your opinion, have not you, of late years as regards the suitability of English barley for brewing purposes?—What would you call the "late years"?

8238. The last ten or twelve years?—I have been for nearly 20 years urging upon the British farmers the desirability of improving their methods of growth and adapting the material they produce to brewers' needs. Probably 12 or 15 years ago there was not so large a quantity of good barley grown as recently. If you are referring to writings of mine 15 years since you might perhaps legitimately say that I have changed my opinion lately.

8239. In what way have the farmers improved their growths of barley?—In every way. They have given much more attention to the preparation of the soil; have been much more attentive to the quality of the manure; the quantities and the modes of adding the manure to the soil. They have been much more careful in getting the seed sown at an earlier date. Many of them have been urged to sow even winter barley. They have been extremely careful, the majority of them commendably so, to get the best seed possible; instead of sowing tail-corn they have employed expensive barley of a very high class, and have paid more attention to the period of cutting.

8240. What is the result of all that?—That we get a very large quantity of superfine barley which cannot be surpassed and is not equalled by any barleys grown abroad.

8241. In what way is the barley different now from what it was then?—Then they did absolutely the opposite to what I now advise.

8242. What is the chemical condition of the grain which makes it better now than it was before?—I am not prepared to give a chemical opinion as I do not claim to be a chemist, but I am told by chemists that there is the right relation of the nitrogenous and albu

mineral matters which enables the grain now grown to produce a malt entirely satisfactory to the brewer.

8243. (Sir William Hart Dyke.) Will it keep its colour after 24 hours of rain when it is cut? I have been connected with barley growing since I was ten years old as my father was before me, and should know something about barley, and one of the difficulties is to preserve the colour?—If you deal with a man who insists on having a white barley it will not, but if you are dealing with a man who likes to have a mellow and golden barley it will.

8244. Is it a question of climate?—No, it is not.

8245. As a large barley grower, and as I said connected with barley-growing ever since I was a youth, and having carefully watched its growth and studied it, I therefore ask you that practical question. Are the conditions you are describing such as to produce a good sample of barley after 16 or 18 hours rain?—Certainly it will, in a much better form. In the sale of barleys now, by great improvements in manure and if a man insists on having barley which is white, necessarily you cannot get it after 24 hours rain, especially if the barley has been laid or lodged.

8246. (Mr. Cosmo Bonsor.) Or grown?—It will not grow in 24 hours. If, on the other hand, you have the barley standing on proper straw, able to resist the influences of 24 hours rain, which you do not get in Kent, but which good Norfolk men know, it will stand 24 hours rain, and I have known barley growers get high prices for barley that had had 24 hours rain upon it.

8247. (Chairman.) Before being cut?—Yes, just prior to the time of cutting, when the barley is absolutely ripe and fit for the scythe. If there comes a period of 24 hours rain, and especially if the rain be heavy so as to beat the barley into the ground, it discolours it, spoils its appearance, and damages it very seriously.

8248. But it does not injure its quality except in appearance?—It injures its quality in this way, that if it is allowed to lie in the ground and get discoloured and sprout, but otherwise it does not. You can make absolutely as good beer with barley slightly stained with 24 hours rain as from the best barley grown in Kent. Of course, it is preferable not to have it stained if possible. Now, as the outcome of improved cultivation it is possible for barley to resist undue periods of wet in a better way than it did before.

8249. (Sir William Church.) I may take it that you would no longer write, as I think I am correct in believing you did some 12 or 14 years ago, that some proportion of foreign barley in the production of light beers was a practical institution, and that probably the fact of interference with the use of nitrogenous substitutes would be to increase the proportion of foreign barley. You stated that to another Commission?—Yes.

8250. Now, you think the agriculturist has so improved his agriculture that, notwithstanding a cold or wet season, he would still be able to produce malt for a light beer?—I do not think I should go so far as that. I do say unhesitatingly that the amount of barley grown under normal conditions is much larger, but if the condition of the season be adverse I fail to see that there would be the power to produce such barley. If the season was so bad that no barley grew at all it would be ridiculous to contend that the farmer could produce it.

8251. I may take it at all events that you think our barleys now, by great improvements in manure and other ways, are so improved that ordinary English malt does not contain nitrogenous constituents in forms that render fermentation, attenuation, and the final condition of beer unsuitable and defective?—That is so.

8252. You think we have made really so great an improvement in agriculture in these twelve or fourteen years that we have now got to a certain extent a non-nitrogenous barley?—I do not think so. I believe I am in the position to prove it as a fact. I say unhesitatingly, it is so.

8253. If we have, do you not think that we have greatly lowered the value of our barleys as feeding stuffs?—I know nothing of the value of barley as feeding stuffs. We have not lowered its value to the brewer, but the brewer has lowered the value to the farmer.

8254. You do not wish to give me an opinion. Most grains, as far as general feeding purposes are concerned, are valuable for the amount of nitrogenous matter in them?—I have no experience of the feeding value of barleys. My whole attention has been confined to the

brewing value. The brewer has taught the farmer that he requires barley with less nitrogenous matter, and the farmer has adapted his processes to the brewers' need, and produces barley which is less nitrogenous and more acceptable to the brewer, and I hope every brewer in this country will confirm what I say.

8255. I should like to know what you mean by a phrase in your *précis*. You talk about the "vital properties of malt." I do not in the least understand what that means?—It means that you must use malt to make beer, and that you cannot make beer without malt. There is some vital principle in malt which is not distinguishable by the chemist, which makes it imperative that the brewers should use some malt. I may use the wrong word very probably, but what I mean to say is that if you wish to brew beer you must employ some malt. I would argue further, and say that you cannot brew true beer if you employ a substitute for malt.

8256. (Mr. Cosmo Bonsor.) Not necessarily barley malt?—Yes, I have never heard of a single gallon of beer which does not contain some barley malt.

8257. (Sir William Church.) That is a statement of yours?—It is a fact.

8258. Can you give me an idea of what this vital principle is?—No, and no one else can. It is a matter simply provable; produce beer without barley malt, brew me a gallon of beer without any malt or any combination of malt.

8259. There are thousands of gallons of beer produced without any barley at all. It is not the same kind of beer, but beer all the same?—I am speaking of English beer as we know it.

8260. (Professor Thorpe.) This vital principle is not an entity, is it? Is it some quality which is capable of having material value attached to it, or what is this vital principle?—The value attached to it is that that alone enables you to produce beer. I cannot tell you what entity it has. No chemist has ever defined it. But there is a subtle something in barley malt which renders it imperative upon every brewer in Great Britain, if he attempts to brew beer, to use a proportion of malt. I have never heard of a single brewer in this country, with all my rich experience of brewers, attempt to brew beer without malt. I argue from that, that if it be necessary to use some malt, the more you displace that essential the further you drift from the true science of brewing, and the fluid you produce is not beer, and ought not to be so named.

8261. Your statement simply amounts to this, that malt is necessary to the manufacture of beer?—Yes.

8262. And you associate that with some transcendental principle or quality which is not material in the grain?—That is so. Here you have a large body of men with great capital, who are spending a large amount of intelligence in trying to produce beer by every process under the sun, and up to the present they have never succeeded in making beer without malt. Therefore, I say there is a something in malt which is not in anything else, and as a consequence beer ought to be defined as containing that to the maximum extent, and that everything else is made from substitutes which does not contain this essential essence is not fit to be called "beer," and ought not to be permitted to be called "beer."

8263. (Mr. Cosmo Bonsor.) May they be called ales and stout?—No, I think ale and stout with beer should be kept actually to the malt. It might be called a line, beerine, or stoutine, after the style of margarine.

8264. (Chairman.) You say that malt is necessary, but would you admit proportions of glucose and other substances?—I consider that when the public asks for beer it ought to have the product of malt only, without the addition of glucose, sugar, or any other substitute in any form, and that if all these things be added, there ought to be an intimation given to the consumer that it is so, and there ought to be a declaration made that a substitute has been employed, and it is not the genuine product of barley malt. There should be no hesitation or paltering or beating about the bush. That is a plain simple point that ought to be taken into account.

8265. (Sir William Church.) In the *précis* of your evidence in connection with this vital principle of malt (which you have not made any clearer to me than before) you go on to say that beer substitutes do not possess that vital principle, and, therefore, "recourse has necessarily been made to large quantities of powerful

Mr.  
H. Stopes.  
20 June 1901

Use of malt but would you admit proportions of glucose and other substances?—I consider that when the public asks for beer it ought to have the product of malt only, without the addition of glucose, sugar, or any other substitute in any form, and that if all these things be added, there ought to be an intimation given to the consumer that it is so, and there ought to be a declaration made that a substitute has been employed, and it is not the genuine product of barley malt. There should be no hesitation or paltering or beating about the bush. That is a plain simple point that ought to be taken into account.

antiseptics as preservatives in beer." To what do you allude to there?—I am very glad to have the privilege of answering that question, because I take it that that is really the chief point, if there be any value in anything I have said to you, which may be suggestive to you on that subject. In consequence of the poverty of the materials used by brewers, they now employ preservatives of many types, chiefly limes or sulphurs. Bi-sulphite of lime is the one more generally used. Salicylic acid is very largely used, and a number of very powerful antiseptics and preservatives are necessarily used.

8266. Do you mean by very powerful, "very powerful as antiseptic" or in other ways?—As antiseptics.

8267. Therefore it makes very little difference whether you use a very powerful antiseptic in very small quantity or a less powerful one in larger quantities so far as preserving your beer goes?—If you use sound good malt from good sound barley you have no need for preservatives.

8268. We have got beyond the malt. You have mentioned bi-sulphite of lime and salicylic acid; was there any other preservative present to your mind?—I mention a number, and there are many more—salicylic acid, borax, phylax, K.M.S., sulphites, bi-sulphites—they have been all referred to in previous evidence, and they are all used. In my opinion they are all dangerous, and the fact that they have been used has probably led to a number of dangers to the public health. It is harmful to me to have to swallow these things in the beer, and I should say it is harmful to other people. I feel them, and as I am a man of somewhat strong physique, I maintain that weaker organisms would feel them more keenly.

8269. Can you tell when you have drunk a gallon of beer which contains borax, or drink another gallon which contains salicylic acid, or another gallon which contains bi-sulphite of lime, which you have had?—I should feel very much ashamed of myself if I could not get to that point long before I drank a gallon. If there is bi-sulphite of lime added to beer I can tell you before I drink it by the mere smell, especially if it is added in the dangerous quantities it now is. It is the practice that every barrel that goes out from almost every brewery very nearly a pint is added, and sometimes more, of powerful bi-sulphite of lime.

8270. I find you have entirely changed your opinion also on the matter of antiseptics from what you held at the time you held out views about English barley, because at that time you thought that in adding such preservative agents first were necessary to enable the brewer to use English barley and suit the increasing fastidiousness of the public palate was only the greater advance of scientific knowledge. You did not at that time think they were the least injurious to health?—But since I have learned they are. You are referring to a period of fifteen years ago, and in that time I have heard of a great deal of harm arising.

8271. What evidence have you of any harm having arisen from any of these preservatives in beer?—You have the evidence that a large number of people have died and suffered in Manchester and elsewhere in a way not fully accounted for by arsenic alone.

8272. In what way is that not accounted for by arsenic alone?—I gather that from the reports I have read. Not being a doctor, I am not in a position to tell you in the language I should wish to use.

8273. But you have gathered an entirely erroneous conclusion from what you have read. You have not read carefully enough, or else you would have seen that the only question was the possibility of its being due to alcohol and the possibility of its being due to arsenic?—I cannot put my hand on the name for the moment, but I read a very important article by a doctor in the "Lancet" last week which appeared to confirm my own view. In the evidence which I have attempted to read intelligently for myself and to master, it has seemed to me there has not been any clear tracing back the epidemic to arsenic only. In the "Lancet" of last week there is an article\* which combats the point as to whether

the illness is really derivable from the alcohol or from the arsenic, and therefore I am only quoting someone who has a very much better knowledge of the possibilities.

8274. You did not quote. You made a definite statement to me that these antiseptics you know did harm, and I am most anxious to have that evidence?—I should say that my own opinion on the matter is evidence. I hope it will be accepted as such. I do know of my own knowledge that if I drink beer containing these things I suffer. I have not taken arsenic, otherwise I should have been a living or dead instance of its effects.

8275. When you have had an impure beer disagree with you, have you had it analysed to see the amount of antiseptics in it?—No, because no analyst could tell me what are the effects or influences.

8276. You told me just now you could tell the different effects of these different preservatives on yourself?—I can by the influence on myself and the effects on my palate. I believe I am not wrong in assuming that there are a number of things not capable of being determined by analysts which can be told by the palate.

8277. These antiseptics can be easily recovered from the beer, and therefore when you have beer that disagreed with you, had you sent it to an analyst, and he had told you it contained such and such a percentage of bi-sulphite of lime or salicylic acid, you would have had evidence. But the mere statement is worthless?—May I direct your attention to one answer to one question put to Mr. Estcourt, the City Analyst of Manchester? He stated that he was absolutely unaware that brewers used any of these things even up to December last year.

8278. I want evidence of these substances you have mentioned being prejudicial?—Assuming that I had submitted a beer that I thought was prejudicial, which I knew of my own knowledge I dare not drink without getting heartburn and suffering from inconvenience, to Mr. Estcourt, do you think he would have found bi-sulphite of lime present in the beer?

8279. I have not the slightest doubt of it. If you had submitted it to any single chemist, asking him to look for poison, he would have found it. The beers sent to analysts were merely for adulterations, but you thought you were poisoned, and if you had mentioned any poison he would have told you without a shadow of doubt whether it was present?—A great number of men were inquiring very anxiously what was the cause of the deaths in Manchester, and yet the City analyst of Manchester was unaware that the brewers used any of these things. He was employed by brewers, and ought to have had the knowledge.

8280. (Professor Thorpe.) Where is the direct evidence that bi-sulphite of lime is capable of exercising a prejudicial action?—I presume it carries sulphur in some form or other. I have no knowledge, and I ought not to assume to answer your question. I am not at all sure there may be combinations between sulphur and arsenic which give rise to a much more deadly influence than when they are not present.

8281. I am talking about bi-sulphite of lime, not in conjunction with arsenic or anything else, and I ask you where is the evidence that bi-sulphite of lime is of an injurious nature?—There is no evidence, for the simple reason that few people know that brewers use such things.

8282. Bi-sulphite of lime is a thing known for a very long period of time; its therapeutic and physiological action has been studied. Where is the evidence that it is capable of injury?—Where is the evidence that arsenic would injure any beer until last November.

8283. (Chairman.) But you do not need an analyst because you know these different substances yourself?—I feel them.

8284. Which do you consider the worst, salicylic acid, bi-sulphite of lime, or borax?—They are all bad, but of the three probably salicylic acid is the worst, and it is very bad and harmful to have a combination of it in every article of food one takes. I think it is monstrous that we have these things in the form we now do. We get borax on almost every piece of meat and fish we have sent us by the butcher or fishmonger. Almost all the

\* Alcohol and arsenic in the *Etiology of Alcoholic neuritis*. E. Farquhar Buzzard, *Lancet*, June 8, 1901, pp. 1593-5.

Mr.  
H. Stopes.  
20 June 1901.

wines which come to this country are charged with salicylic acid, and we get all these things in our beer. I contend that taking these things into our system is undesirable, and I know the effects on myself are prejudicial. I cannot define it, but I know it.

8285. (Professor Thorpe.) I should just like to positively and directly challenge a statement made as to the widespread use of antiseptics in articles of food. It is not the truth that borax is used practically in all meats and that salicylic acid is to be found practically in almost

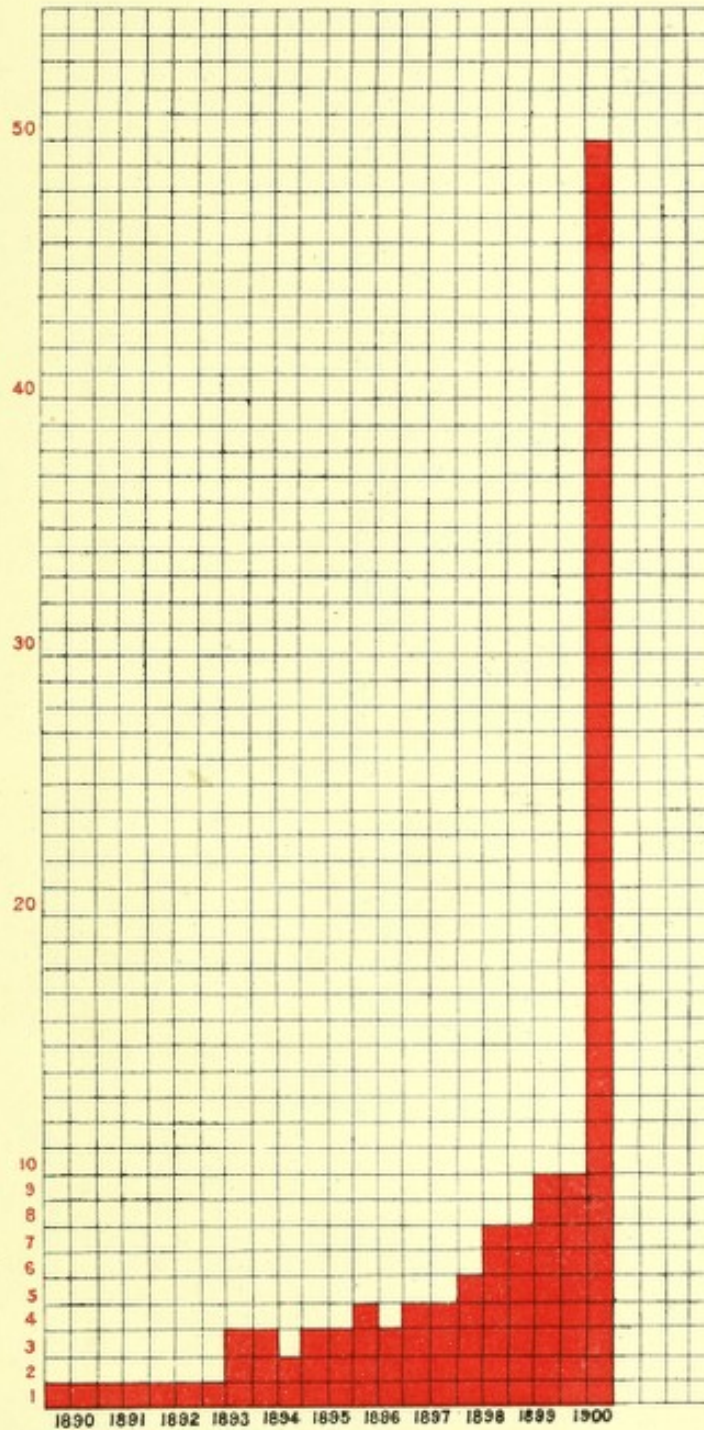

all wines and beers. That is not the fact. The exact proportion in which these things do occur has been recently inquired into by a Departmental Committee, and the precise nature of the facts is well established?—Do you say that bi-sulphite of lime is not used by nearly all brewers?

8286. I did not say that?—I contend that bi-sulphite of lime is used by all brewers. That is proveable. The other is only a matter of opinion.

Mr.  
H. Stopes.

No. 4.

HANCED in by Mr. Niven, Manchester.

MANCHESTER.—Deaths from PERIPHERAL NEURITIS and ARSENICAL POISONING from November 25th, 1900, to February 19th, 1901.

Date of Death.	Initials.	Sex.	Age.	Occupation.	Certified or Inquest.	Medical Officer's Classification Cause of Death.	Hospital (which).
1900. 26 Nov.	J. A.	M.	55 years	French polisher	Certified	Peripheral neuritis, phrenic paralysis.	—
30	W. H. H.	M.	43	Sick visitor for provident society.	Certified	Cirrhosis of liver, peripheral neuritis.	—
29	J. F.	M.	70	Fustian cutter (retired)	Certified	Senile decay, peripheral neuritis, hemiplegia.	—
25	M. E. P.	F.	44	Wife of warehouse porter.	Certified	Peripheral neuritis, 21 days; cerebral hæmorrhage, 5 hours.	—
25	G. R.	M.	58	Formerly a warehouseman.	Certified	Ch. peripheral neuritis, 1 year; dementia.	—
25	M. L.	F.	56	Wife of a joiner	Certified	Ch. peripheral neuritis, 1 year; dementia.	—
1 Dec.	W. B.	M.	56	Warehouse porter	Certified	Peripheral neuritis, 5 months; asthenia.	—
6	F. R.	F.	47	Wife of concreter	Inquest	She died from arsenic poisoning, no evidence to show how caused.	—
11	A. O.	F.	49	Wife of wood pattern maker.	Certified	Peripheral neuritis, cardiac failure.	—
10	E. H.	F.	50	Widow of bricksetter	Inquest	She died from bronchitis and alcohol, and arsenical poisoning.	Crumpsall Workhouse.
10	J. D.	F.	45	Widow of fitter	Inquest	She died from alcohol and arsenical poisoning.	Crumpsall Workhouse.
17	W. S.	M.	48	Billiard marker	Certified	Peripheral neuritis, exhaustion	Ancoats Hospital.
20	S. J. K.	F.	48	Property repairer	Certified	Peripheral neuritis, mitral regurgitation, hypostatic pneumonia, cardiac failure.	—
20	A. G.	F.	59	Wife of trunk maker	Inquest	She died from pneumonia, hastened by arsenical poisoning.	—
14	J. B.	M.	51	Hawker	Inquest	He died from peripheral neuritis from arsenic poisoning.	Crumpsall Workhouse.
16	A. S.	F.	32	Wife of labourer	Certified	Peripheral neuritis, phthisis, exhaustion.	Crumpsall Workhouse.
18	E. A. C.	F.	47	Wife of hardware salesman.	Certified	Peripheral neuritis	Prestwich Workhouse.
22	M. J. C.	F.	46	Wife of labourer	Inquest	She died from cardiac syncope, due to peripheral neuritis from arsenic poisoning.	—
22	M. T.	F.	49	Widow of engraver	Inquest	She died from tubercular disease, accelerated by arsenical and alcoholic poisoning.	—
23	J. A. S.	F.	44	Wife of painter	Inquest	She died from chronic arsenic poisoning.	—
25	M. G.	F.	50	Widow of porter	Inquest	She died from pneumonia resulting from peripheral neuritis.	—
25	J. C.	M.	34	Tinplate worker	Inquest	He died from cirrhosis of the liver, accelerated by arsenical poisoning.	Crumpsall Workhouse.
1901. 2 Jan.	E. I.	F.	62	Wife of saw maker	Inquest	She died from peripheral neuritis due to arsenic poisoning.	—
2 Jan.	C. N.	F.	54	Unknown	Inquest	Heart failure produced by alcoholic peripheral neuritis.	—
1900. 10 Dec.	M. N.	F.	38	Wife of labourer	Inquest	She died from paralysis of the diaphragm due to arsenical poisoning.	Crumpsall Workhouse
1901. 1 Jan.	M. L.	F.	59	Wife of clog iron maker	Inquest	She died from cardiac failure due to alcohol and accelerated by arsenical poisoning.	Crumpsall Workhouse.

## APPENDIX No. 5.

PAPERS handed in by MR. GORDON SALAMON.

Appendix  
No. 5.FIRST AND SECOND REPORTS OF THE EXPERT COMMITTEE APPOINTED BY THE  
MANCHESTER BREWERS' CENTRAL ASSOCIATION.

## First Report, December 1st, 1900

Gentlemen,—Our investigations and inquiries so far as they have gone point to the conclusion that the materials in current use in brewing in Manchester are free from arsenic, with the exception of certain sugars supplied by Messrs. Bostock and Company, Limited, of Liverpool. In appearance and price these sugars are indistinguishable from perfectly pure sugars.

We therefore recommend to the Association the immediate adoption for the present of the following provisional precautions:—

1. That all beer in the brewing of which any sugar bought from Messrs. Bostock and Company, Limited, has been used should be at once recalled, and if found to be contaminated should be destroyed.
2. That no beer should be sent out until it has been tested and shown to be free from arsenic.
3. That a certificate of freedom from arsenic should be given in respect of beer so tested, and that only such beer should be sold.

In view of the importance of the subject we should recommend that the Association should take the management of the testing by its officials, and that the certificates should be issued in the name of the Association.

If these precautions be adopted we are of opinion that they will be effectual in preventing further mischief.

We desire to gratefully recognise the cordial co-operation and assistance of the Medical Officers of Health for Manchester and Salford, which have greatly lightened our labours.

We are, Gentlemen,  
Yours faithfully,

(Signed) *Lauder Brunton,*  
*J. Fletcher Moulton,*  
*Thos. Stevenson,*  
*Alfred Gordon Salamon,*  
*Arthur P. Luff,*  
*Samuel Buckley.*

## Second Report December 15th, 1900.

Gentlemen,—The Commission has now examined the sugars and all the other materials used in brewing in Manchester (with the exception of the malt), and they consider that it is clearly established that the arsenic found in deleterious quantities in the beer has been solely due to the contamination by arsenic of the sugars supplied by Messrs. Bostock and Company, Limited, of Liverpool. The arsenic in these sugars was undoubtedly derived from the impure sulphuric acid used in their manufacture.

The measures recommended by the Commission a few days ago have, they learnt, been effectively carried out. The whole of the beer in the manufacture of which any Bostock sugar was used has been destroyed, and there is no further danger from this source.

All the other brewing sugars on the English market have been analysed, and have been found to be quite free from arsenic.

In view of the importance of the matter, the Commission have instituted inquiries as to the manufacture of brewing sugars in the United Kingdom, and in this they have been assisted by the whole of the manufacturers of such sugars—in a body—voluntarily offering them the opportunity of examining into the mode in which they conduct the manufacture. These manufacturers have stated collectively that it is, and always has been, their custom to use only acid free from arsenic, and they have requested the Commission to examine their invoices, works, etc., in order to verify these statements. Lack of time has prevented this being done by personal examination up to the present, but the fact that all the specimens of brewing sugars as well as of glucose used for other purposes on the market have been found to be free from arsenic, and the absence of any previous cases in which arsenic has been in such products, leave in the mind of the Commission no doubt that this statement, when examined into, will be found to be correct.

The Commission is quite unable to explain how Messrs. Bostock and Company, Limited, came to employ an acid

of the character actually used by them. The absolute necessity of using an acid free from arsenic in the manufacture of an article for human consumption must have been evident to everybody technically connected with the manufacture, and such acid is a common article of commerce. The price of the sugars in question was as high as any in the market, and, apart from this, the quantity of acid used in the manufacture of the sugars is so small that the difference in cost of the best and the worst would only make a difference of a fraction of a penny per hundredweight of sugar. So that it is not a case of an attempt to cheapen production by the use of lower priced materials. The Commission believe that it is this inexplicability which has rendered the matter so serious, and that the extent to which the mischief spread before it was detected was mainly due to the fact that the use of an acid containing arsenic in the manufacture of sugars was a contingency so improbable that it never occurred to those purchasing the sugars that it was possible that any danger could arise from that quarter.

The Commission has been unable to detect the presence of arsenic in brewing materials other than sugar supplied by Messrs. Bostock and Company, Limited, but they are aware that it has been asserted that traces of arsenic have been found in various samples of malt and hops. If such traces exist, they have probably been introduced in the operation of kilning, and the Commission propose to examine more fully into the matter. None of the specimens of hops have as yet yielded any traces. In any case, the amount so introduced would appear to be exceedingly minute, and not sufficient to have any deleterious effect.

The most important matter for the moment is to secure the adequate testing of beer in order that the public may be protected from all further mischief. Arsenic is a substance which can be detected in the most infinitesimal quantities by those who are practised in the tests, but these tests are so delicate that they are apt to mislead those who have not had experience in their application, and this is more particularly the case when the test is to be applied to a complex substance such as beer. Accordingly the Commission have thought it necessary to investigate and determine what is the most suitable method of testing beers for arsenic.

Test.—The Commission recommend that the Reinsch test should be used in preference to all others at present known, because their investigations have satisfied them that it is the best and most reliable test for arsenic in beer. The mode of performing it is as follows:—

Take 200 cc. of the beer in a porcelain evaporating dish. Raise the liquid to the boiling point, and then add 30 cc. of pure concentrated hydrochloric acid. Insert a piece of pure bright copper foil, about a quarter of an inch by half an inch in size, and keep the solution gently boiling for 45 minutes. If at the end of that time the copper remains bright and red, the beer is free from arsenic.

If a deposit is obtained on the copper the foil is to be washed successively with water, alcohol, and ether (care being taken that these are pure), dried at a temperature not exceeding 100° C., and subjected to slow sublimation in a thin reduction tube of small section, and not less than 2 inches long, the upper portion of which should be warmed before the sublimation begins. For the purpose of the sublimation a small spirit lamp flame should be used. If any sublimate is obtained, it must be examined under a magnifying power of about 200 diameters. Any sublimate which does not show well-defined octahedral or tetrahedral crystals is not to be considered arsenical.

N.B.—It must be borne in mind that the blackening of the copper or a deposit thereon from the preliminary operation does not demonstrate the presence of arsenic in beer. Abundant blackening and deposit may be obtained from the purest beer.

Reprint of article in "Chemical News," Jan. 18, 1901.

## ARSENIC IN BEER.

By MR. E. W. T. JONES.

I beg to lay before the readers of the "Chemical News" the method I have been using for the detection of arsenic in beer since the beginning of December last, when the scare inundated most public analysts like myself with beer samples. I do so, notwithstanding the report of the method published by the Commission of the Manchester Brewers' Association, because although in the main their method differs but little from mine, I personally prefer my procedure because it secures immediately on the addition of the acid the requisite conditions of Reinsch's test for the deposition of the arsenic on the copper. Before the addition of the hydrochloric acid there is no fear of arsenic being lost by the evaporation.

I also append the method I have employed with success for the estimation of the arsenic on the lines of Dr. Clark ("Journ. Chem. Soc.," 1893).

*Qualitative Test.*

250 c.c. of the beer are evaporated in a porcelain dish over a low Fletcher burner to about 100 c.c., then 25 c.c. of pure strong hydrochloric acid are added, and into the still boiling liquid is put a piece of fine copper gauze (I prefer this to foil), about 1 inch by  $\frac{1}{2}$  inch, and the boiling continued for a quarter of an hour; if no darkening occurs by this time certainly less than 1-40th grain per gallon of arsenic is present. If the gauze is suspiciously darkened, wash with hot distilled water, then with alcohol, and dry. Roll up into a small size, and introduce into a small glass tube about 3 inches long, and heat the gauze with a very small flame whilst holding the tube in a horizontal position; examine any sublimate under the microscope, using a 1-5th objective. The tubing I have found very convenient is of elliptical section (I had it made originally for absorption spectroscopical work); it lies conveniently on the stage of the microscope, held on to the usual glass slips by two thin india-rubber bands, and I prepare such pieces of tube by drawing out to furnish a shoulder for the piece of gauze, and also that I may concentrate the sublimate in the narrower part.

Unmistakable octahedral or tetrahedral crystals of arsenious oxide are obtained without the least difficulty by the above procedure when 1-20th grain per gallon is present.

For glucose, syrups, jams, etc., I use 50 grms., and make to 100 c.c. at once with hot distilled water, and proceed in the same way.

To prepare the copper gauze - heat a strip about an inch wide to redness in a Bunsen burner, and then remove the black oxide with nitric acid, well wash, and dry; from these beautifully bright strips I cut pieces off about  $\frac{1}{2}$  inch wide for the qualitative test, and about  $3\frac{1}{2}$  inches long for the rolls I use for the quantitative tests.

*Quantitative Test.*

250 c.c. (or more) of the beer are evaporated as above in a porcelain dish to about 100 c.c., and 25 c.c. of pure strong hydrochloric acid added, then a piece of the pure bright copper gauze 1 inch  $\times$   $3\frac{1}{2}$  inches, in the shape of a loose roll, is put in, and the liquid is kept just on the boil with occasional stirring for, say, an hour, addition of hot distilled water being made from time to time to prevent the bulk by evaporation getting too small; considerable concentration is advantageous before the bulk is brought back with distilled water. The roll of gauze is now removed and washed with hot distilled water, the first washings being returned to the dish, and then another roll is put in, and the boiling continued.

The blackened and thoroughly washed roll is now put into a small beaker,  $\frac{3}{4}$  inch diameter and  $1\frac{1}{2}$  inch high, containing 5 c.c. N. sodic hydrate diluted to just cover the roll, and then three or four drops of a 10 vol. solution of peroxide of hydrogen solution added; by moving the coil up and down this solution is mixed, and on standing in the cold the gauze is gradually denuded of its black coating, and on acquiring its original colour is removed and washed into another larger beaker, these washings being reserved.

## III.—BREWEES' SAMPLES.

RESULTS of Analyses of following samples received from 26th November to 16th January, from Brewers in Manchester and neighbourhood.

31 Brewers delivered 195 samples of Beer :

104 samples were genuine.

91 contained  $As_2O_3$  from  $\frac{1}{4}$  to  $\frac{1}{60}$  of a grain per gallon.

41 samples of Glucose and Invert Sugar were received :

21 were genuine.

20 contained  $As_2O_3$  from '005 to '03 per cent.

74 samples of Malt were received :

17 were genuine.

57 contained  $As_2O_3$  from  $\frac{1}{4}$  to  $\frac{1}{100}$  of a grain in 40 ounces.

[N.B.—40 ounces of Malt represent 1 gallon of Beer.]

## APPENDIX No. 10.

TABLES handed in by Mr. *Edward Sergeant*.

## COUNTY PALATINE OF LANCASTER.

TABLE I.

LIST of SAMPLES of BEER (including Ales, Stouts, &c.) purchased for analysis between 27th November 1900, and 28th February 1901, by the County Police acting on the instructions of the County Medical Officer of Health. For Summary see Table II.

(Note.—Samples purchased prior to 4th December were "preliminary" samples, and not followed by legal proceedings).

TABLE III.  
ADMINISTRATIVE COUNTY OF LANCASTER.

under Section 6 of the Food and Drugs Act, 1875.

Result of Analysis.	Date and Place of hearing.	Result of Prosecution.	Remarks.
1901 :			
Sample contains arsenic ( $\frac{1}{16}$ th grain per gallon).	18 January - Strangeways. Decision, 29 January.	Dismissed by Mr. Yates (Stipendiary) on the grounds that summons should have been under Section 3 and not Section 6.	Bostock's glucose used.
Sample contains arsenic ( $\frac{1}{16}$ th grain per gallon).	21 January - Bolton.	Withdrawn after conviction on sample No. 872.	Bostock's glucose used.
Contains much arsenic ( $\frac{1}{16}$ th grain per gallon).	21 January - Bolton.	Fined 5s. and costs. (Case stated on insufficiency of certificate, but appeal abandoned.)	Bostock's glucose used.
Contains much arsenic ( $\frac{1}{16}$ th grain per gallon).	21 January - Bolton.	Fined 5s. and costs. (Case stated on insufficiency of certificate, but appeal abandoned.)	Certificate of purity on barrel. Brewers have used Bostock's glucose, but not in this brew.
Contains serious quantity of arsenic ( $\frac{1}{16}$ th grain per gallon).	6 February - Kirkham.	Fined 5s. and costs. (Case stated on insufficiency of certificate.)	Bostock's glucose used.
Sample contains arsenic ( $\frac{1}{16}$ th grain per gallon).	7 February - Middleton.	Adjourned, pending decision of higher Court.	Glucose from Brooks, Shudehill, Manchester.
Sample contains arsenic ( $\frac{1}{16}$ th grain per gallon).	16 February - Nelson.	Fined 3s. and costs.	Bostock's glucose previously used, but returned stock on 30th November. Had certificate of freedom from arsenic.
Approximately $\frac{1}{2}$ grain arsenic per gallon	16 February - Nelson.	Fined 3s. and costs.	Bostock's glucose previously used, but returned stock on 30th November. Had certificate of freedom from arsenic.
Sample contains arsenic ( $\frac{1}{16}$ th grain per gallon).	28 January - Eccles.	Fined 5s. and costs. (Case stated on insufficiency of certificate. Appeal proceeding.)	Bostock's glucose used.
Contains small quantity of arsenic ( $\frac{1}{16}$ th grain per gallon).	31 January - Bury.	Dismissed on the ground that certificate of analyst was insufficient. Case granted. Appeal proceeding.	Brewed from malt and hops only.
Contains small quantity of arsenic ( $\frac{1}{16}$ th grain per gallon).	1 February - Ormskirk.	Fined 5s. and costs. (Case stated on the grounds that summons should have been issued under Section 3. Appeal abandoned.)	Brewers have used Bostock's glucose, but not in this brew.
Contains small quantity of arsenic ( $\frac{1}{16}$ th grain per gallon).	1 February - Ormskirk.	Adjourned pending decision of higher Court. (If against, defendant will plead guilty.)	Brewers have used Bostock's glucose, but not in this brew.
Contains serious quantity of arsenic ( $\frac{1}{16}$ th grain per gallon).	18 February - Radcliffe.	Fined 20s. and costs. (Case stated on insufficiency of certificate. Appeal proceeding.)	Bostock's glucose used.
Contains serious quantity of arsenic ( $\frac{1}{16}$ th grain per gallon).	14 March - Garstang.	Fined 20s. and costs.	Bostock's glucose used.
Contains serious quantity of arsenic ( $\frac{1}{16}$ th grain per gallon).	14 March - Garstang.	Fined 20s. and costs.	Bostock's glucose used.
Contains serious proportion of arsenic ( $\frac{1}{16}$ th grain per gallon).	25 February - Colne.	Fined 20s. and costs.	Bostock's glucose used.
Contains $\frac{1}{16}$ th grain arsenic per gallon	13 March - Rochdale.	Court sent sample to Somerset House. At re-hearing case dismissed on the ground of improper division of the sample.	Brewed from malt and hops. Somerset House find $\frac{1}{16}$ th grain.
Approximately $\frac{1}{16}$ th grain arsenic per gallon.	16 March - Preston.	Court sent sample to Somerset House. Subsequently case withdrawn, defendant to pay costs.	Brewed from malt and hops. Somerset House find $\frac{1}{16}$ th grain.
Approximately $\frac{1}{16}$ th grain arsenic per gallon.	9 February - Preston.	Fined 40s. and costs.	Brewers have used glucose (Bostock's), but not in this brew.
Approximately $\frac{1}{16}$ th grain arsenic per gallon.	14 March - Garstang.	Fined 20s. and costs.	Brewers have used glucose (Bostock's), but not in this brew.
Approximately $\frac{1}{16}$ th grain arsenic per gallon.	9 February - Preston.	Fined 40s. and costs.	Brewed from malt and hops only.
$\frac{1}{16}$ th grain arsenic per gallon	20 February - Heywood Borough.	Fined 40s. and costs.	Bostock's glucose used
$\frac{1}{16}$ th grain arsenic per gallon	26 February - Strangeways.	Adjourned pending decision of higher Court.	Brewed from malt and hops only.
$\frac{1}{16}$ th grain arsenic per gallon	26 February - Strangeways.	Adjourned pending decision of higher Court.	Brewed from malt and hops only
$\frac{1}{2}$ grain arsenic, calculated as arsenious oxide, per gallon.	—	Prosecution pending	—

\* Breweries used Bostock Sugars.

N.B.—In the column headed parts per 10,000,000, the actual results of analyses are given; when only one figure is given the quantity recorded may be considered as correct within less than  $\frac{1}{10}$  grain, when two figures are given the estimation is somewhat less accurate. The quantities in grains per gallon and per pound have been calculated from the amount estimated in parts per 10,000,000, only the mean being given when two extremes are given in the first column. The estimates in vulgar fractions are the least accurate, owing to the necessity of simplifying some unwieldy fractions.

TABLE II.—MALT.

No. of Sample.	Date.	Origin.	Special Marks.	Character and Remarks.	Arsenic estimated as Arsenious Acid.		Quantities of Material used for Analysis.		Maximum possible amount introduced in Beer brewed entirely from Malt (supposing 1 part of Malt to 4 parts of Beer).	Remarks.

TABLE IX.—ARSENIC IN THE BODY OF A BEER DRINKER.

Date.		Arsenic estimated as Arsenious Acid.		Quantity of Material used for Analysis.		Remarks.
		Parts per 10,000,000 weight.	Quantity of Arsenic contained in 3 lbs. of urine, i.e., per diem in grains.	Minimum Grammes.	Maximum Grammes.	
1900. Dec. 24	Urine from patient suffering from arsenical poisoning due to drinking Safford beer.	1.2	0.00252	16½	—	150

TABLE IX.A.

## FUEL.

	Material.	Parts per 10,000,000, about.	Grains per pound.	Quantity of Material used.
M 32	Soot deposited in flue of a chimney after burning good house coal (South Yorkshire Colliery) for one week . . . . . Flue cleaned once a week.	8,000	5.6	Grammes. 0.5
M 33	Soot deposited in flue of a closed stove, after burning Corporation Gas Works Coke for 15 days . . . . . Flue cleared once in a fortnight, the amount of soot obtained weighing about 113 grammes. This amount contains about half a gramme of arsenious acid.	40,000	28	0.025
M 34	Soot produced by a single gas jet (Manchester gas) burning for 3 hours and a half (combustion in confined space). Water produced during combustion added to the soot . . . . . No appreciable amount of gaseous compound of arsenic appears to be present in gas manufactured from coals from which the above coke was obtained (M 33), i.e., in purified gas as supplied to the consumer.	0 (?)	—	0.41

## DISSEMINATION OF ARSENICAL SOOT THROUGH THE AIR.

M 40	A. Leaves of evergreen shrubs (laurels, rhododendrons, ivy, holly), collected in a garden in Victoria Park (Manchester), leaves blackened by soot selected. There had been much rain for several days previous to the collection of the leaves . . . . . Thirty grammes of leaves represent an area of about 1,044 sq. c.m.	4	—	Grammes. 30
	B. Soot washed from the surface of 50 grammes of leaves (it was impossible to remove all the soot) . . . . . It was not possible to clean the leaves sufficiently completely to estimate what amount of arsenic (if any) had penetrated into the tissues of the leaves.	2	—	50
	C. Leaves of evergreen shrubs (laurels, ivy), collected in Streatham, near London, in a garden surrounded by large gardens and fields. There had been rain for several days. Old leaves were selected but no special care was taken to obtain only those covered with soot . . . . .	under 0.5	—	50
	D. Leaves of evergreen shrubs (laurels, ivy), collected in a small town garden in Montreux, Switzerland. The garden was surrounded by houses. There had been rain for several days. The oldest and most dusty leaves were selected, but none showed any evidence of the presence of soot. The town is very small. Of late coal fires have been used, but wood is still the chief combustible . . . . .	0 (?)	—	50

## COMBUSTION OF TOBACCO.

M 39	Products of combustion of half ounce of tobacco, obtained by bubbling slowly the smoke through water. No appreciable trace of arsenic was found . . . . . This experiment and the one on gas soot may be looked upon as control experiments for comparison with the others.	0	—	Grammes. —
------	--	---	---	---------------

Appendix  
No. 12.TABLE X.—GENERAL RESULTS OF AUTOPSIES OF FATAL CASES OF  
ARSENICAL POISONING.

To Professor Sheridan Delépine—In accordance with your request, I beg to submit the following information on the points specified by you as determined by autopsies on cases of "Arsenical Beer Poisoning."

No.	Sex.	Age.	Nutrition.	Associated Diseases.	
1	M.	53	Fair. No marked wasting of muscles.	Pulmonary tuberculosis	Tuberculosis of pleura and peritoneum.
2	F.	46	Emaciated. Marked wasting of muscles.	Pulmonary tuberculosis with cavitation.	Tuberculosis of pleura and peritoneum.
3	M.	31	Well nourished. No muscular wasting.	Pulmonary tuberculosis "consolidation."	General miliary tuberculosis.
4	F.	53	Fair. Muscles of extremities wasted.	Old tuberculosis at apices, recent pneumonia.	Tuberculosis of pleura, peritoneum, liver and kidneys.
5	F.	30	Fair. Muscles of extremities wasted.	Pulmonary tuberculosis with cavitation.	Tuberculosis of pleura and peritoneum.
6	M.	50	Fair. Muscles of legs wasted.	Extensive tuberculous broncho-pneumonia.	Tuberculosis of pericardium, pleura, peritoneum, liver, spleen and kidneys.
7	M.	44	Emaciated. Muscles of limbs much wasted.	Pulmonary tuberculosis not advanced nor extensive.	Tuberculosis of pleura and peritoneum.
8	M.	40	Well nourished. No muscular wasting.	Pneumonia (?) tuberculous	Tuberculosis of pleura and peritoneum.
9	F.	(?)	Emaciated. Muscles of extremities much wasted.	Hypostatic pneumonia	—
10	F.	42	Emaciated. Muscles of extremities wasted.	Pulmonary tuberculosis with cavitation.	Tuberculosis of pleura and peritoneum.
11	F.	34	Fair. Muscles of legs wasted.	Hypostatic pneumonia.	—
12	F.	(?)	Emaciated. Muscles of limbs wasted.	Pulmonary tuberculosis, not advanced.	—
13	F.	54	Fat. Muscles of extremities little wasted.	Broncho-pneumonia, old foci of tuberculosis in lungs.	—

In addition, it may be stated that typical periaxial degeneration of the peripheral nerves, varying in degree, has been found in such of the above cases as have been examined, viz., cases 1 to 12 inclusive. The livers in many of the cases presented irregularly-distributed congestion, degeneration, and varying degrees of cirrhosis. Further the skin in many of the cases was pigmented in varying degrees.

F. CRAVEN MOORE, M.Sc., M.D.,  
Assistant Lecturer in Pathology and Morbid Anatomy,  
Pathological Department, Owens College.

TABLE XI.

INTERIM REPORT of Dr. FRANCIS J. H. COUTTS on the PRESENCE OF ARSENIC IN FOOD PRESERVATIVES, &amp;c.

Reference Number.	Material.	Arsenic as $As_2O_3$ in parts per 10,000,000.	Arsenic in grains per pound, approximately.	Weight used.
M 129	English shrimps, in paper package . . . . .	2	1-700th.	Grammes. 100
M 128	"German" shrimps, in paper package, in cardboard box along with M 129. Said to be German, imported to be sold as English . . . . .	About 13	1-100th.	100
M 127	"Pure English" shrimps, said not preserved (a specimen received later than M 129) . . . . .	2	1-700th.	100

## Materials possibly used in Preservation of Food Stuffs.

M 121	Nitre (such as was formerly used for preserving pathological specimens) . . . . .	15	1-90th.	Grammes. 15
M 114	Potassium nitrate (bought from drysalter) . . . . .	Trace	—	15
M 120	Borax (bought from grocer) . . . . .	50 to 60	1-28th to 1-23rd.	15
M 112	"Refined borax" (drysalter) . . . . .	7	1-180th.	15
M 119	Boracic acid (from druggist) . . . . .	—	—	15
M 113	Boracic acid (drysalter) . . . . .	Trace	—	15
M 118	Common salt (household) . . . . .	—	—	15
M 117	Freezing salt . . . . .	Trace	—	15
M 111	"Bay" salt (drysalter) . . . . .	Trace	—	15

## Other Chemicals.

M 116	Sodium sulphate . . . . .	2 to 3	1-700th to 1-500th.	Grammes. 15
M 115	Sodium carbonate (crystals) . . . . .	6	1-240th.	15
--	"Pure" hydrochloric acid ("redistilled") . . . . .	Trace	—	100cc.

By FRANCIS J. H. COUTTS, M.D., D.P.H., F.C.S.,  
Assistant in the Bacteriological Laboratory,  
Pathological Department, Owens College.

J. Clouet (Annales d'Hygiène Publique 1878, p. 145), in searching for the source of the arsenic sometimes present in wine, found that fuchsin is often incriminated wrongly, but that the caramel which is frequently used in conjunction with fuchsin often contains a large amount of the poison. Ritter had previously shown this to be the case. These two observers found that the arsenic is derived from impure sulphuric acid which is not infrequently used in the preparation of glucose from which caramel is made. Arsenic is always more or less abundant in sulphuric acid prepared from arsenical pyrites. In addition to arsenic, glucose frequently contains a large proportion of free sulphuric acid, this being the effect of imperfect neutralisation of the acid after conversion of starchy matters. The results of Clouet's and of Ritter's analyses may be tabulated as follows:—

TABLE XII.

ANALYSES OF ARSENICAL PYRITES, SULPHURIC ACID, and GLUCOSE, by Professor CLOUET and Professor RITTER.

Substance.	Source.	Observer.	Arsenious Acid, in grammes per kilogram.	Arsenious Acid.

## APPENDIX No. 14.

HAIDED IN BY SIR LAUDER BRUNTON.

Extrait du Bulletin de l'Académie de Médecine, 1888. No. 27. 3<sup>e</sup> Série, Tome XX., p. 617.

Sur les communications de MM. VIDAL, MARQUEZ et DUBRANDY, relatives à l'affaire des vins empoisonnés d'Hyères au nom d'une Commission composée de MM. E. VIDAL et

A. OLIVIER, rapporteur.

Vers la fin d'hiver dernier, une maladie bizarre, avec des troubles digestifs, des exanthèmes sans forme déterminée, des accidents nerveux capables de faire songer à une affection de la moelle épinière, se développait dans une partie de la population d'Hyères; elle frappait de préférence des ouvriers et des petits employés, semblant épargner les femmes, les enfants et les classes aisées. Comme les premiers cas étaient peu graves, on n'y prêtait guère attention; à mesure qu'ils devenaient plus nombreux, la population s'émuet, les médecins échangèrent différentes observations au sujet des malades qu'ils venaient de traiter, et, en fin de compte, en reconnut de tous les cas de la prétendue maladie, épidémique d'Hyères étaient des cas d'intoxication par l'arsenic.

Toute cette affaire a été l'objet d'une enquête juridique et de débats sur lesquels nous n'avons pas l'intention de revenir. En revanche, l'Académie a reçu des documents intéressants au point de vue de l'étude clinique de l'empoisonnement par l'acide arsénieux administré à doses faibles, répétées, dans un produit alimentaire, le vin.

Le 19 juillet, un premier mémoire renfermant à l'observation détaillée et très précise d'un des faits en question lui était adressé par M. le Dr E. Vidal (*De la similitude des symptômes de l'acrodynie et de l'intoxication lente par l'acide arsénieux*). Ce travail contient en outre une analyse bien faite et une discussion très serrée sur la nature même de la maladie. Le 21 juillet

l'Académie recevait un autre mémoire de M. le Dr Marquez (*Acrodynie et arsénisme*) relatif aux mêmes faits; enfin, le 14 août, une étude du Dr Dubrandy (*Contribution à l'étude de l'empoisonnement chronique par l'arsenic*), portant sur une soixantaine de faits, venait s'ajouter aux deux précédents. Tous ces documents ont été renvoyés à une Commission composée de MM. Emile Vidal et Auguste Olivier, rapporteur. C'est au point de vue de ces travaux très détaillés, consciencieux, irréprochables au point de vue clinique, que je vais essayer d'esquisser l'histoire des faits qui se sont passés à Hyères à la fin de l'hiver 1887 et au commencement du printemps de l'année 1888.

L'hiver en question fut froid rigoureux, accompagné de gripes, dont quelques-unes présentèrent des phénomènes gastro-intestinaux et furent suivies d'un abattement, d'un affaiblissement musculaire plus marqué et plus persistant qu'il ne l'est d'habitude à la suite de l'influenza. A cet égard, la même remarque avait été faite par tous les médecins. Lorsque, plus tard, on eut découvert le *corpus delicti*, tous furent unanimes à déclarer que l'ingestion du vin était probablement pour quelque chose dans les accidents qu'ils avaient auparavant en l'occasion de noter à diverses reprises. Dès le 8 février, le Dr Vidal donne ses soins à une employée du chemin de fer, présentant les symptômes ordinaires d'un embarras gastrique de moyenne intensité. Ces symptômes s'atténuent sous l'influence du traitement et font place à une diarrhée modérée, mais persistante. Le 4 mars, se montrent sur différents points du corps des taches rouges, prurigineuses, urticariiformes, et dont la régression ne suit point la marche que suit d'habitude celle des plaques d'urticaire. Pendant tous le mois de mars différents phénomènes se succèdent irrégulièrement, sans qu'on puisse connaître les connexions pathogéniques qu'ils présentent. Ce sont: un catarrhe des voies respiratoires avec sécrétion peu abondante, mais accompagnée de toux spasmodique et d'accès de dyspnée, une inappétence et une diarrhée persistantes; enfin, le 31 mars, apparaissent les phénomènes paralytiques qui ont existé dans la plupart des cas observés et en ont constitué le caractère le plus frappant. Les jambes sont

le siège de différents troubles sensitifs (douleurs, fourmillements, élancements); les mains sont prises à la tour, et, malgré cela, il y a aux membres supérieurs comme aux membres inférieurs de l'hyperesthésie cutanée, à tel point que le contact des draps ne peut être supporté et que le malade est obligé de sortir presque constamment les pieds du lit; les mouvements sont difficiles, les jambes semblent trop lourdes pour la marche. En présence d'un pareil complexe, M. Vidal arrive à songer à une maladie épidémique, de nature mal connue, observée à plusieurs reprises, mais particulièrement vers 1830 à Paris et dans les environs, à l'acrodynie. Cette idée le conduisit naturellement à penser à l'alimentation des malades, car, malgré l'incertitude qui règne sur la nature de l'acrodynie, malgré le résultat négatif des recherches entreprises aux époques d'épidémie, l'opinion générale qui a toujours persisté relativement à sa nature, c'est que c'était une maladie d'alimentation plus ou moins comparable à l'ergotisme au lathyrisme et à la pellagre.

Des accidents analogues à ceux qu'a décrits M. Vidal étaient notés par tous les médecins d'Hyères; ainsi, du 13 février au 3 avril, M. Dubrandy est appelé par des malades qui tous se plaignent de faiblesse musculaire, de fourmillements, d'une douleur des membres inférieurs, parfois assez vive pour les empêcher de dormir pendant la nuit. Il est probable que, dès le milieu de mars, l'opinion s'était répandue dans le corps médical et même dans la population, que la maladie régnante présentait quelque chose d'anormal, et que, selon toute probabilité, il y avait un élément nocif, inconnu, dans les substances qu'on absorbait d'habitude. L'aspect clinique rappelait si bien une maladie due aux ingesta qu'à une date non précisée, mais certainement antérieure à la découverte de la véritable cause, le Dr Decurgis, soignant plusieurs ouvriers de M. X....., le propriétaire poursuivi plus tard, leur demanda formellement s'ils étaient bien fixés sur la nature du vin qu'ils buvaient. Après leurs protestations unanimes, il abandonna ses soupçons et chercha dans un autre sens.

Ce fut le Dr Charles Roux qui découvrit le premier la véritable cause. Le 4 avril, ce médecin déclarait à la commission d'hygiène d'Hyères que les accidents rapportés soit à l'acrodynie, soit à des gripes anormales, se développaient exclusivement chez des individus buvant un vin de provenance déterminée. Pour faire une pareille déclaration, il avait fallu que la conviction de l'auteur fût étayée sur des faits si probants, qu'à leur égard toute discussion fût superflue. Il ne s'agissait plus, en effet, d'une opinion scientifique, susceptible d'être soutenue ou combattue sans provoquer une vive émotion dans le public. L'opinion de M. Roux contenait une accusation capable de servir de base à une action juridique et d'avoir des conséquences commerciales faciles à prévoir. En fait, il y avait en dans le développement antérieur de la soi-disant épidémie une série de circonstances capables de donner à réfléchir. "Jusqu'au 20 mars, dit le Dr Dubrandy, j'avais toujours supposé que les accidents pourraient bien être d'origine alcoolique et produits par l'usage d'alcools absorbés en nature ou sous forme de vins vinés pris en excès."

La commission d'hygiène se réunit de nouveau le 16 avril. M. Roux renouvelle son accusation en nommant le propriétaire du chai. "Il expose, dit la relation publiée à l'époque, les principaux caractères de l'étrange maladie qui sévit à Hyères en ce moment, et s'élève contre l'opinion de ceux qui prétendent qu'elle n'est autre chose que la grippe." Il y a en, en effet, ajoute-t-il, quelques cas de grippe dans notre ville, mais aucun d'entre eux n'a été observé sur des personnes ayant bu

Appendix  
No. 14.

des vins de M. X..... Quant aux personnes qu'il traite pour la maladie dont il vient de faire la description, toutes ont usé de ces vins, et c'est à eux seuls qu'elle doit être attribuée. Il termine en demandant à ses collègues s'ils ont observé des symptômes semblables à ceux qu'il a constatés.

Cette manière de voir fut appuyée par le Dr Vidal. Il déclara partager absolument les idées émises par son honorable collègue, le Dr Roux. "Depuis quelques temps, dit-il en effet, les nombreux symptômes de l'acrodynie signalés par les auteurs ont été observés dans la population..... En présence des déclarations de M. Charles Roux, et considérant que l'acrodynie est toujours le résultat d'un état particulier de l'organisme, produit par des aliments de mauvaise qualité, il demande qu'il soit nommé dans le sein du Comité d'hygiène une commission de trois membres chargée de faire une enquête sur les faits développés par M. le Dr Roux." (*Hyères Journal*, 29 avril 1888.)

Cette mesure fut adoptée à l'unanimité. En même temps des échantillons du vin suspect avaient été envoyés pour l'analyse chimique à M. le Dr Sambuc, à Toulon. Le 17 avril, M. Roux recevait de lui une première communication mentionnant qu'il avait trouvé dans certains échantillons jusqu'à 8 centigrammes d'acide arsénieux par litre. Désormais la phase médico-légale va commencer.

La première phase, la seule qui nous intéresse et dont nous avons relaté brièvement les péripéties, va du mois de février au 4 avril; les cas, peu nombreux d'abord, augmentent au point d'éveiller l'attention de l'autorité.

Diverses opinions plausibles sont formulées jusqu'à l'époque à laquelle l'intervention du Dr Roux est décisive. C'est précisément pendant cette phase d'étonnement et d'incertitude qu'ont été observés les phénomènes cliniques les plus frappants de l'intoxication.

Comme de pareils faits sont rares, nous allons les passer en revue.

Ceux qui attirèrent surtout l'attention furent :

- 1° Des troubles digestifs ;
- 2° Des éruptions cutanées ;
- 3° Des phénomènes nerveux assez prononcés pour faire songer à une affection médullaire.

Les troubles digestifs, malgré leur fréquence, furent moins importants qu'on ne serait, *a priori*, tenté, de le croire. Le malade de M. Vidal était venu réclamer ses soins pour un embarras gastrique ; sous l'influence d'un traitement les nausées et les douleurs épigastriques disparurent, mais à ce moment survint une diarrhée qui dura encore quinze jours plus tard. M. Marques note la rareté des vomissements et fait remarquer qu'il y a de la diarrhée dans presque tous les cas. Avant et après la découverte de la cause du mal, M. Dubrandy soigne soixante-trois personnes intoxiquées qui ont présenté des éruptions cutanées ou des phénomènes nerveux. Chez huit, il n'y a eu ni vomissements ni diarrhée, mais seulement de l'inappétence et des nausées. Le même observateur a noté encore le ptyalisme avec sensation pénible de constriction rétro-sternale et épigastrique. M. Vidal parle de la présence de plaques rouges sur la muqueuse du voile du palais et celle du pharynx.

Il est difficile de donner des notions précises relativement à l'époque de l'apparition et à la forme la plus fréquente des manifestations cutanées. Tantôt, c'était un symptôme initial (du moins c'était à cause de lui que les malades s'adressaient au médecin) qui existait en même temps que les troubles digestifs ; d'autres fois, les exanthèmes ne se montraient qu'après l'apparition des paresthésies des membres ; enfin, dans certains cas, lorsque la plupart des autres phénomènes étaient rétrogradés, les éruptions tardives furent les plus opiniâtres.

S'il on voulait donner un nom adapté exactement à la forme de toutes ces éruptions, il faudrait épuiser la nomenclature dermatologique actuelle. Les taches se superposent et se remplacent sans qu'il soit possible de fixer de règle à propos de leur évolution. Le malade de M. Vidal a d'abord des plaques d'urticaire qui sont le siège d'un prurit pénible.

Le lendemain, l'aspect change ; on voit poindre entre elle des taches d'une nouvelle forme, qui, au bout de quelques heures, rappellent à s'y méprendre celles de l'éruption rubéolique ; elles subissent une desquamation assez rapide, et se résolvent en une sorte de poussière épidermique très fine. Tout n'est pas fini. Un autre exanthème à macules saillantes, de couleur café brûlé, se montre en différents points du corps, après avoir débuté aux jambes. La desquamation totale de la plante des pieds et de la paume des mains devient imminente ;

un sillon d'aspect cuivré indique la limite précise jusqu'à laquelle elle se fera. Dans un cas de M. Dubrandy, l'ongle d'un orteil tomba et ne tarda pas à se reproduire. Au milieu de ces éruptions confuses, deux méritent une mention particulière. Un malade de M. Marquez, un homme de soixante-sept ans, dont nous aurons l'occasion de dire un mot, eut une ulcération du gland qui ressemblait à s'y méprendre à un chancre. M. Dubrandy mentionne des plaques du couleur cuivré et à contour circiné, ressemblant au psoriasis syphilitique. Plusieurs de ces éruptions durèrent longtemps, certaines n'étaient même pas guéries à l'époque où les travaux ont été adressés à l'Académie. MM. Marquez et Dubrandy ont noté dans un cas, sur le rebord gingival, la présence d'un liseré semblable à celui de l'intoxication saturnine.

Les accidents nerveux ont été les plus importants ; c'est, comme nous l'avons vu, en tenant compte de leur modalité que M. Vidal est arrivé à songer à l'acrodynie.

En général, ils débutaient par une diminution de la puissance des muscles servant à la station et à la marche (muscles pelvi-trochantériens et des membres inférieurs) ; les malades étaient fatigués, ils avaient un peu de difficulté dans les mouvements, puis la sensation s'accroissait, leurs jambes devenaient pesantes ; ils ne marchaient plus que le tronc incliné en avant, en titubant comme s'ils avaient eu de la peine à détacher leurs pieds du sol et à reprendre l'équilibre à chaque pas qu'ils faisaient. Ils s'avançaient les jambes à moitié fléchies ; la pointe des pieds traînait et butait. D'autres malades s'affaissaient inertes sur eux-mêmes, lorsqu'ils essayaient de se mettre debout, et pourtant tous les mouvements des jambes étaient possibles dans le décubitus dorsal. La contractilité électrique des muscles était intacte. Il y avait des contractions, des tressaillements, surtout dans les mollets.

Il existait des troubles de la sensibilité en même temps que des troubles de la motilité ; les premiers persistaient souvent après les seconds et avaient une ténacité désespérante. La sensibilité à la pression était amoindrie ; certains malades ne sentaient plus le sol et pourtant accusaient des fourmillements, des douleurs intermittentes, fulgurantes, surtout la nuit ; il le caractérisaient par des comparaisons pittoresques telles que celle-ci : "des chiens me rongent la peau des mollets et de la plante des pieds" ; parfois les paresthésies étaient plus étendues, presque généralisées ; il y avait de la céphalalgie, des points pleurodyniques ; un enfant de neuf ans se plaignait qu'il avait des papillons dans les dos. Les diminutions et les modifications de la sensibilité s'accompagnaient d'une hyposthésie cutanée très pénible. Nous avons vu que le contact des draps ne pouvait être supporté par l'un d'eux.

Les altérations de la sensibilité spéciale furent moins constantes. Pourtant le toucher fut souvent émoussé ; un malade ne pouvant sentir sa piume *écrite*, a-t-on dit, avec le bras ; par suite d'une circonstance analogue, un enfant dut cesser momentanément de fréquenter l'école. L'audition fut peu altérée. M. Dubrandy a signalé des désordres oculaires de différente nature qu'il met sur le compte de l'empoisonnement ; ainsi, chez trois conturières, la diminution de l'acuité visuelle fut telle qu'elles cessèrent de pouvoir travailler ; à l'ophthalmoscope il constata une hyperémie rétinienne assez marquée ; l'amblyopie finit cependant par disparaître. Le même auteur croit également qu'une double cataracte à développement rapide avait eu une origine identique ; ce qui rend cette opinion vraisemblable, c'est qu'un trouble du cristallin observé dans les mêmes conditions n'allait pas jusqu'à l'opacité et cessa en même temps que les autres symptômes (Dubrandy).

Chez plusieurs individus, on a noté une impuissance sexuelle qui a duré plusieurs mois.

Pour avoir le tableau complet, il faudrait ajouter aux phénomènes que nous venons d'énumérer et qui demeurèrent la scène, d'autres manifestations moins fréquentes peut-être, mais parfois aussi importantes que les premières et capables de créer une physionomie propre à un cas donné. C'est d'abord un catarrhe bronchique contemporain des exanthèmes, assez intense pour avoir produit quelquefois une dyspnée inquiétante ; c'était, selon toute probabilité, une détermination morbide comparable à celle qui avait lieu sur la peau. Ce catarrhe s'accompagna de coryza, d'injection conjonctivale et, dans un cas, d'exophtalmie ; il a souvent plus éprouvé le malade que les troubles digestifs ; son existence permet de supposer, comme l'a cru M. Marquez, que bon nombre des gripes développées vers la fin de l'hiver n'étaient en réalité que des déterminations anormales. Viennent ensuite les œdèmes partiels

(bouffissure des paupières et de la face, enflure autour des genoux et des malléoles), l'amaigrissement, la glycosurie transitoire notée par M. Vidal.

Il résulte de ce que nous venons de voir que les ingestions répétées de doses dissimulables, mais relativement élevées, d'arsenic n'ont été suivies que d'accidents peu importants correspondant à la période d'absorption; les plus sérieux se sont montrés pendant la diffusion dans l'organisme et surtout l'élimination. Jamais probablement ils n'ont occasionné la mort. Onze personnes ayant bu du vin venant de la cave dangereuse avaient succombé pendant la période des empoisonnements. Par ordre de l'autorité, les cadavres furent exhumés et soumis à l'autopsie médico-légale. Trois fois seulement on trouva de l'arsenic et deux fois une dose capable d'occasionner la mort: les cadavres appartenaient à un phthisique arrivé au dernier degré de la maladie, et à un diabétique qui depuis assez longtemps avait une quantité considérable de sucre dans les urines. Ni les experts, ni les médecins traitants n'attribuèrent la terminaison funeste à l'acide arsénieux.

Fait curieux, cette substance paraît avoir exercé une ou deux fois, malgré les bizarreries du mode d'administration, un effet thérapeutique: un homme de cinquante-cinq ans, soigné par M. Marquez pour un asthme à accès fréquents, n'en eut plus depuis l'apparition des parésies d'intoxication; un vieillard de soixante-sept ans, dont nous avons déjà parlé, a été débarrassé d'accidents gouteux lui rendant depuis plusieurs années la marche impossible. Si satisfaisants que soient ces résultats, nous ne songeons pas à recommander aux partisans la méthode de traitement qui les a donnés.

Reste une question. M. Vidal a parlé d'acrodynie et cela avec beaucoup de sens clinique. Peut-on accepter son idée et se servir de l'épidémie d'Hyères, pour en expliquer d'autres restées comme autant de problèmes non résolus dans l'histoire de la pathologie? Ce serait une éventualité désirable. Les épidémies en question ne se perdent pas dans les brumes du moyen âge; on n'est pas obligé pour les connaître de faire un long travail d'archéologie et d'exégèse sur des chroniques naïves et mensongères; elles ont été étudiées par nos maîtres, par les médecins, les plus instruits du temps; elles sont presque contemporaines, et, malgré cela, nous sommes obligés de faire l'aveu désobligeant que nous ne savons ni quelle était leur nature, ni ce qui les produisait. Peut-on, après les épisodes du Midi, déclarer ces épidémies étaient une forme d'arsénisme due, selon toute probabilité, à l'addition d'acide arsénieux à des matières alimentaires?

Je ne le crois pas. Sauf dans l'épidémie observée pendant la campagne de Crimée, le processus clinique

fut notablement différent. A Hyères, les phénomènes gastro-intestinaux n'ont existé que pour mémoire; s'il n'y avait eu qu'eux, les malades les auraient supportés sans se plaindre et probablement les médecins n'auraient jamais songé à faire d'enquête.

Dans les acrodynies de Paris, de Meaux, de la Ferté-Gaucher, de Coulommiers, il y a eu des diarrhées rebelles, opiniâtres, absorbant encore l'attention à l'époque des parésies: des diarrhées cholériques et dysentériques. La seule différence dans la manière dont ce symptôme se comporta ne permet guère d'assimiler les acrodynies d'il y a soixante ans à l'arsénisme. Puis, il y a, dans celles-là, des bizarreries de diffusion. La maladie d'Hyères est restée cantonnée dans la zone où l'on débitait la denrée toxique; l'acrodynie sautait d'un quartier à l'autre, d'un département à l'autre, et aucune relation commerciale ne pouvait expliquer ces particularités. De plus, il y eut enquêtes sur enquêtes. On connaissait l'empoisonnement par l'arsenic à peu près aussi bien qu'on le connaît aujourd'hui. Tout fut scruté, examiné; les soldats qui ne buvaient pas de vin étaient malades, et les civils qui en buvaient dans le voisinage ne l'étaient pas; le pain des quartiers de Lourcine ou du Faubourg-du-Temple ne valait ni plus ni moins que celui des quartiers voisins. Jamais, nulle part un fait typique comme celui qui mit le Dr. Roux sur la voie (arsénisme chez le mari qui boit du vin, immunité du reste de la famille qui n'en boit pas) n'a été constaté. Malgré des similitudes indiscutables, nous ne trouvons pas dans l'évolution et la nature de la maladie d'Hyères une explication qu'on puisse adapter intégralement aux épidémies d'acrodynie, et nous en restons aux conjectures de nos devanciers. C'étaient probablement des maladies d'alimentation, mais on ne sait à quel produit rattacher les accidents qui les caractérisèrent.

Quoi qu'il en soit, les études que nous avons eu l'occasion de parcourir et que nous venons d'analyser sont intéressantes par l'importance des observations et la justesse des aperçus qu'elles renferment. Votre rapporteur a donc l'honneur de vous proposer d'adresser aux auteurs, MM. les Drs Vidal, Marquez et Dubrandy, les remerciements de l'Académie.

Bien, que M. Roux n'ait envoyé aucune communication à l'Académie, votre rapporteur croirait être injuste en ne rappelant pas aussi la grande part que cet observateur a eue dans la découverte de la véritable cause de l'épidémie qui a frappé la population d'Hyères.

Les conclusions du présent rapport, mises aux voix, sont approuvées par l'Académie.

Il résulte de ce que nous venons de voir que les ingestions répétées de doses dissimulables, mais relativement élevées, d'arsenic n'ont été suivies que d'accidents peu importants correspondant à la période d'absorption; les plus sérieux se sont montrés pendant la diffusion dans l'organisme et surtout l'élimination. Jamais probablement ils n'ont occasionné la mort. Onze personnes ayant bu du vin venant de la cave dangereuse avaient succombé pendant la période des empoisonnements. Par ordre de l'autorité, les cadavres furent exhumés et soumis à l'autopsie médico-légale. Trois fois seulement on trouva de l'arsenic et deux fois une dose capable d'occasionner la mort: les cadavres appartenaient à un phthisique arrivé au dernier degré de la maladie, et à un diabétique qui depuis assez longtemps avait une quantité considérable de sucre dans les urines. Ni les experts, ni les médecins traitants n'attribuèrent la terminaison funeste à l'acide arsénieux.

Fait curieux, cette substance paraît avoir exercé une ou deux fois, malgré les bizarreries du mode d'administration, un effet thérapeutique: un homme de cinquante-cinq ans, soigné par M. Marquez pour un asthme à accès fréquents, n'en eut plus depuis l'apparition des parésies d'intoxication; un vieillard de soixante-sept ans, dont nous avons déjà parlé, a été débarrassé d'accidents gouteux lui rendant depuis plusieurs années la marche impossible. Si satisfaisants que soient ces résultats, nous ne songeons pas à recommander aux partisans la méthode de traitement qui les a donnés.

Reste une question. M. Vidal a parlé d'acrodynie et cela avec beaucoup de sens clinique. Peut-on accepter son idée et se servir de l'épidémie d'Hyères, pour en expliquer d'autres restées comme autant de problèmes non résolus dans l'histoire de la pathologie? Ce serait une éventualité désirable.

Les épidémies en question ne se perdent pas dans les brumes du moyen âge; on n'est pas obligé pour les connaître de faire un long travail d'archéologie et d'exégèse sur des chroniques naïves et mensongères; elles ont été étudiées par nos maîtres, par les médecins, les plus instruits du temps; elles sont presque contemporaines, et, malgré cela, nous sommes obligés de faire l'aveu désobligeant que nous ne savons ni quelle était leur nature, ni ce qui les produisait.

NOTE on Administrative questions arising out of the recent Epidemic, by Dr. CAMPBELL BROWN (Q. 6938).

If recent events are followed by legislation, it seems undesirable to legislate for beer alone, which will be well looked after now that it is known to be liable to contain arsenic, and to leave out of account all the other things, known or unknown, which are liable, or will in the future be liable, to be in some way contaminated with other things. Any new legislation should aim at securing immunity from contamination for all kinds of food and drink.

*As regards Arsenic in Beer.*—Considering the fact that the use of arsenical glucose was the result of combined ignorance and carelessness, that it was immediately stopped when discovered, and that it is not likely to ever occur again, and considering also that arsenic is exceedingly likely to get into beer from malt, and that, in fact, minute traces are very seldom absent, it would be vain to prohibit the use of glucose and invert for the purpose of preventing arsenication of beer. The question of permitting or prohibiting the use of sugars must be settled on entirely different grounds.

I suppose the Inland Revenue officers can deal at present with both glucose and malt; the local inspectors under Sale of Food and Drugs Act can do so, but they can only take samples as they are delivered to the brewer, and with his consent. They cannot go to the malster or his coke merchant, nor to the sulphuric acid maker; nor could they take samples of coke or of sulphuric acid even as they are delivered to the malster or glucose maker. They ought to have this power.

*Necessity for Standards of Arsenic.*—Before going further on the subject of legislation I ought to mention another point as regards arsenic.

Arsenic is everywhere in more or less minute traces. The air of towns, yeast, malt, beer, bread, everything containing or made with soda, and so on, contain minute traces. These traces are usually negligible, and are neglected. They are called nothing quite properly, and articles containing them are called pure.

That is right, but the traces exist, and the question must arise, At what point does the negligible quantity and the important quantity meet?

It is useless to say no arsenic should be present. It must and will be present, and can be detected if sufficiently large quantity of sample is examined. It would be impracticable to prohibit any trace of arsenic alike in malt and in sulphuric acid and in other things.

The question of standards cannot be got rid of. Unless the Legislature provides some simple and efficient means of fixing the standard of arsenic and other things there will be a great deal of useless litigation and great want of uniformity. One analyst will give a common-sense opinion, that such-and-such a quantity is of no consequence, or is not more than is usual or inevitable. Another will say of a quantity so small as to be quite indeterminable with any approach to precision, although it can be detected with certainty, that it is "deadly poison," although he has probably a larger quantity in his own body at the time, he being in perfect health. The courts will give varying decisions, and no one will know what to do. No state of things could be worse for trade and the public.

Similarly with sulphuric acid. No maker will guarantee that his acid is absolutely free from any trace of arsenic. It is most difficult to get even a small quantity of sulphuric acid absolutely free. But any manufacturer will guarantee that his acid is purified down to any absolutely safe limit which can be reasonably fixed.

After giving much thought to the consideration of possible legislation, I venture to express the opinion that legislative machinery is needed in the following directions:—

#### A.—Duties of Manufacturers.

1. To make it compulsory for manufacturers to test every bulk or batch sent out of any article which is to be used in the preparation, manipulation, conveyance, or storage of any food, for any impurity which would "impair the wholesomeness of such food." (See Fertilisers and Feeding Stuffs Act.)

Manufacturers to be presumed to know the use to which the thing he sells is put, unless he shows that he could not reasonably be expected to find out.

2. To enact that if the article is sold for use in the preparation, treatment, conveyance, or storage of any food, then shall be implied a warranty that such article is free from all ingredients which would impair or injuriously affect the wholesomeness of such food.

3. Manufacturers buying any such article for the preparation or treatment, etc., of food, should be required—

- (a) To inform the vendor of the purpose for which he wants the article.
- (b) To check the purity of each bulk or batch delivered.

#### B.—Powers under Sale of Food and Drugs Acts.

4. The Sale of Food and Drugs Acts should be extended so as to give power (a) to Inland Revenue or other Local Government Board officers, and (b) to inspectors for local authorities, to take samples of and to trace back to the manufacturer or to its original source (even out of the inspector's own district) any article used in the preparation or manipulation, etc., of any food or drug (using the definition of food in the Act of 1899), taking samples at each or any stage, and to have the samples analysed to ascertain whether (1) and (3) have been efficiently complied with, and to prosecute if occasion arises.

#### C.—Regulations by Government Department.

5. To authorise the Local Government Board when desirable or necessary, or when called upon to do so, to make regulations after inspection and inquiries, fixing a standard quantity of any specified ingredient in any specified article of food or article used in the preparation of food, above which the article shall be presumed to be impure, and below which the said article shall be presumed to be genuine.

For example, a regulation might prohibit the use of more than 4 per cent. of lead in the metal for siphon lemonade, etc.

To specify a standard quantity under this fifth provision would be far more satisfactory and workable than the provision so often recently suggested that the legislature should prescribe a standard mode of testing. The idea underlying the latter suggestion is that a test should be so designed and carried out as to fail to detect a small quantity (of arsenic, for example) which might be considered passable, and which would at the same time easily detect penal quantities. Any such test would be most variable in practice, and lead to confusion. No two men would get the same result from the same sample. In respect of arsenic, the suggestion means that either Marsh's test—a most inexact and unreliable test in practice—or Reinsch's test—a good qualitative test—should be so conducted as to have an approximate quantitative value; and that this approximate value should have a legal compulsory recognition. To legalise a variable quantity would be foolish and disastrous. Either of these tests gives results which not only vary with the mode of working (which by hypothesis would be fixed by enactments), but vary also with the operator, with the circumstances and condition of the article, and the other things with which it is mixed.

The only rational standard for legislation to fix is an absolute standard of so much actual arsenic which can be determined by weighing or other exact means. This real quantity being fixed, then if any individuals or firms choose to take the short approximate way of ascertaining the quantity which they may find sufficiently reliable in the hands of their own chemists, they would be at liberty to trust to that mode of testing at their own risk; but the ultimate appeal would always be to the balance or some equally precise determination, and not to any method which is at best only a method of more or less happy guessings.

In fixing standards regard should be paid to what is practicable in working the Acts, and practicable for the manufacturer, and practicable for the inspector and analyst.

MINUTES OF EVIDENCE

AND ME

1949-1950-1951-1952-1953-1954-1955-1956-1957-1958-1959-1960-1961-1962-1963-1964-1965-1966-1967-1968-1969-1970-1971-1972-1973-1974-1975-1976-1977-1978-1979-1980-1981-1982-1983-1984-1985-1986-1987-1988-1989-1990-1991-1992-1993-1994-1995-1996-1997-1998-1999-2000-2001-2002-2003-2004-2005-2006-2007-2008-2009-2010-2011-2012-2013-2014-2015-2016-2017-2018-2019-2020-2021-2022-2023-2024-2025-2026-2027-2028-2029-2030-2031-2032-2033-2034-2035-2036-2037-2038-2039-2040-2041-2042-2043-2044-2045-2046-2047-2048-2049-2050-2051-2052-2053-2054-2055-2056-2057-2058-2059-2060-2061-2062-2063-2064-2065-2066-2067-2068-2069-2070-2071-2072-2073-2074-2075-2076-2077-2078-2079-2080-2081-2082-2083-2084-2085-2086-2087-2088-2089-2090-2091-2092-2093-2094-2095-2096-2097-2098-2099-2100-2101-2102-2103-2104-2105-2106-2107-2108-2109-2110-2111-2112-2113-2114-2115-2116-2117-2118-2119-2120-2121-2122-2123-2124-2125-2126-2127-2128-2129-2130-2131-2132-2133-2134-2135-2136-2137-2138-2139-2140-2141-2142-2143-2144-2145-2146-2147-2148-2149-2150-2151-2152-2153-2154-2155-2156-2157-2158-2159-2160-2161-2162-2163-2164-2165-2166-2167-2168-2169-2170-2171-2172-2173-2174-2175-2176-2177-2178-2179-2180-2181-2182-2183-2184-2185-2186-2187-2188-2189-2190-2191-2192-2193-2194-2195-2196-2197-2198-2199-2200-2201-2202-2203-2204-2205-2206-2207-2208-2209-2210-2211-2212-2213-2214-2215-2216-2217-2218-2219-2220-2221-2222-2223-2224-2225-2226-2227-2228-2229-2230-2231-2232-2233-2234-2235-2236-2237-2238-2239-2240-2241-2242-2243-2244-2245-2246-2247-2248-2249-2250-2251-2252-2253-2254-2255-2256-2257-2258-2259-2260-2261-2262-2263-2264-2265-2266-2267-2268-2269-2270-2271-2272-2273-2274-2275-2276-2277-2278-2279-2280-2281-2282-2283-2284-2285-2286-2287-2288-2289-2290-2291-2292-2293-2294-2295-2296-2297-2298-2299-2300-2301-2302-2303-2304-2305-2306-2307-2308-2309-2310-2311-2312-2313-2314-2315-2316-2317-2318-2319-2320-2321-2322-2323-2324-2325-2326-2327-2328-2329-2330-2331-2332-2333-2334-2335-2336-2337-2338-2339-2340-2341-2342-2343-2344-2345-2346-2347-2348-2349-2350-2351-2352-2353-2354-2355-2356-2357-2358-2359-2360-2361-2362-2363-2364-2365-2366-2367-2368-2369-2370-2371-2372-2373-2374-2375-2376-2377-2378-2379-2380-2381-2382-2383-2384-2385-2386-2387-2388-2389-2390-2391-2392-2393-2394-2395-2396-2397-2398-2399-2400-2401-2402-2403-2404-2405-2406-2407-2408-2409-2410-2411-2412-2413-2414-2415-2416-2417-2418-2419-2420-2421-2422-2423-2424-2425-2426-2427-2428-2429-2430-2431-2432-2433-2434-2435-2436-2437-2438-2439-2440-2441-2442-2443-2444-2445-2446-2447-2448-2449-2450-2451-2452-2453-2454-2455-2456-2457-2458-2459-2460-2461-2462-2463-2464-2465-2466-2467-2468-2469-2470-2471-2472-2473-2474-2475-2476-2477-2478-2479-2480-2481-2482-2483-2484-2485-2486-2487-2488-2489-2490-2491-2492-2493-2494-2495-2496-2497-2498-2499-2500-2501-2502-2503-2504-2505-2506-2507-2508-2509-2510-2511-2512-2513-2514-2515-2516-2517-2518-2519-2520-2521-2522-2523-2524-2525-2526-2527-2528-2529-2530-2531-2532-2533-2534-2535-2536-2537-2538-2539-2540-2541-2542-2543-2544-2545-2546-2547-2548-2549-2550-2551-2552-2553-2554-2555-2556-2557-2558-2559-2560-2561-2562-2563-2564-2565-2566-2567-2568-2569-2570-2571-2572-2573-2574-2575-2576-2577-2578-2579-2580-2581-2582-2583-2584-2585-2586-2587-2588-2589-2590-2591-2592-2593-2594-2595-2596-2597-2598-2599-2600-2601-2602-2603-2604-2605-2606-2607-2608-2609-2610-2611-2612-2613-2614-2615-2616-2617-2618-2619-2620-2621-2622-2623-2624-2625-2626-2627-2628-2629-2630-2631-2632-2633-2634-2635-2636-2637-2638-2639-2640-2641-2642-2643-2644-2645-2646-2647-2648-2649-2650-2651-2652-2653-2654-2655-2656-2657-2658-2659-2660-2661-2662-2663-2664-2665-2666-2667-2668-2669-2670-2671-2672-2673-2674-2675-2676-2677-2678-2679-2680-2681-2682-2683-2684-2685-2686-2687-2688-2689-2690-2691-2692-2693-2694-2695-2696-2697-2698-2699-2700-2701-2702-2703-2704-2705-2706-2707-2708-2709-2710-2711-2712-2713-2714-2715-2716-2717-2718-2719-2720-2721-2722-2723-2724-2725-2726-2727-2728-2729-2730-2731-2732-2733-2734-2735-2736-2737-2738-2739-2740-2741-2742-2743-2744-2745-2746-2747-2748-2749-2750-2751-2752-2753-2754-2755-2756-2757-2758-2759-2760-2761-2762-2763-2764-2765-2766-2767

AND MEMORANDA.

## INDEX TO

## MINUTES OF EVIDENCE &amp; IN THIS VOLUME

## AND MEMORANDA

## INDEX TO MINUTES OF EVIDENCE IN THIS VOLUME.

(The figures refer to numbered questions).

**ACETIC ACID :**

Liability of, to contain arsenic (Kirkby), 3704; prepared by the use of arsenical sulphuric acid (Davis), 6453; arsenic found in (Davis), 6453.

**ADDISON'S DISEASE :**

Diagnosed, in cases of arsenical poisoning with pigmentation (Reynolds), 411; (Kelynack), 3484; (Sergeant), 4226; (Raw), 6292.

**AGES :**

Of persons attacked by epidemic. *See* EPIDEMIC.

**ALCOHOL :**

Toxic effect of alcohol when taken along with arsenic (Luff), 2859-2861, 2938-9; (Kelynack), 354-6; (Brunton), 5944; (Raw), 6304-6312. Alcohol accentuates toxic action of mercury on nervous system (Brunton), 5944. Different kinds of alcoholic drinks have different toxic effects (Bury), 4388-4392; (Brunton), 5975-8, 5997-6002.

**ALCOHOLIC NEURITIS :**

First use of term in Nomenclature of Disease (Tattersall), 67-69; (Kelynack), 3588-3591; (Bury), 4383-5.

Clinical characters (Reynolds), 335; alcoholic neuritis in its relation to arsenic (Tattersall), 48-55; (Reynolds), 341-344; (Niven), 463-472; (Reid), 1989-1990; (Stevenson), 2289-2290, 2419-2427; clinical differences between alcoholic and arsenical neuritis not always apparent (Bury), 4373.

Influence of sex (Tattersall), 74-79; severity greater in women (Bury), 4422-6.

Exceptionally common in Manchester (Reynolds), 335 was so before the epidemic (Reynolds), 398-413; (Bury), 4345-4365; (Kelynack), 3577-3580; also in Liverpool (Raw), 6341-3, 6360-2; may have been partly due to arsenic (Bury), 4359-4365; (Brunton), 5947, 5972-4; (Raw), 6363; associated with beer and not with spirits (Tattersall), 72-3 (Reynolds), 344; (Raw), 6356.

At Manchester Royal Infirmary in previous years (Kelynack), 3573; (Bury), 4407-4413; at Mill Road Infirmary, Liverpool (Raw), 6289; in various parts of the country (Kelynack), 3592-3613; hospital figures (Kelynack), 3576; rare in Scotland (Raw), 6292, 6367-6372.

Deaths from, in Manchester before 1900 (Niven), 473 and Appendix No. 3; in Salford (Tattersall), Appendix No. 1.

*See also* NEURITIS.

**ALCOHOLISM, CHRONIC :**

In relation to poisoning by arsenic in beer (Tattersall), 214; (Niven), 490-2, 695-7, and Appendix 3; (Sergeant), 4226; statistics of alcoholism in Liverpool, 1899-1900 (Hope), 928; for England and Wales (Tatham), 2530.

*See also* CIRRHOSIS.

**ALCOHOLS, HIGHER :**

Higher alcohols and aldehydes in relation to peripheral neuritis (Tattersall), 7, (Delépine), 4850-8, (Brunton), 5997-6002; presence of in beer (Salamon), 1351-5; may explain different toxic effects of different forms of alcohol (Brunton), 5997-6002.

**ALL-MALT BEER :**

Risk from arsenic in all-malt beer much less than in beer made from glucose (Tattersall, 62-66; (Niven), 656-660.

Arsenic in (Tattersall), 83-87; (Niven), 661-667; (Salamon), 1343-7; (Estcourt), 3981-7; (Sergeant), 4145; (Bell), 4566-7; (Brown), 6710.

Proportion of malt in (O'Sullivan), 5786; (Hooper), 7883-6. Brewers not using adjuncts numerous, but their output small (Lovibond), 6953-6956. All-malt beer brewed as in Germany in little demand in this country (Lovibond), 7067.

**ANALYSTS :****PUBLIC ANALYST :**

Work and duties of (Niven), 704-720, 780-795.

Duties in respect of poisons in food (Estcourt), 3960. Usual nature and purpose of his analysis (Jones), 1806-1813. Analyses private samples also (Hope), 1048-1052. Was in some cases employed by brewers (Hope), 1048; (Groves), 1566; (Cowell), 5117.

Has no knowledge of origin of samples (Hope), 970-1.

Appointment of (Reid), 1914-8. Terms of his report (Reid), 1898-1905; (Estcourt), 4111-2. In the case of minute quantities of arsenic in beer (Hehner), 8030-4; (Bell), 4591-4600. Meaning of term "genuine" (Brown), 6921-6.

No central authority instructs as to examination of particular foods (Jones), 1858; (Bell), 4606; (Brown), 6932-6936. Should be left to his judgment (Jones), 1865-1870.

*See also* FOOD AND DRUGS ACTS.

ANALYSTS, DISAGREEMENT IN RESULTS WHEN ESTIMATING ARSENIC IN BEER:—(Deakin), 3854-6; (Sergeant), 4262-4; (Bell), 4549; (Blundell), 4967-4972; (Marshall), 5324-8; (Brown), 6831, 6856; (Hooper), 7855-7856a. Limits of error in estimating arsenic (Estcourt), 3966-3971.

**ANILINE DYES :**

Liability to contain arsenic (Kirkby), 3704.

**ANTHRACITE : (See FUELS.)****ARSENIC ACID AND ARSENATES :**

Toxicity of (Stevenson), 2314-2321.

**ARSENIC :**

Medicinal dose of (Tattersall), 19; (Niven), 882-8; (Reid), 2076-8. Poisoning by. *See* CHRONIC ARSENICAL POISONING.

**BARLEY :**

No arsenic in (Stopes), 8165. Arsenic in kiln-dried (Niven), 618; (Earp), 7096. Removed in steeping (Earp), 7095-7, 7099. No arsenic in barley grown on arsenical soil (Kirkby), 3701-3.

English barleys in relation to use of adjuncts (Lovibond), 6948-9, 7021-5; (Brunton), 6005-7. Sufficient English barley suitable for brewing even in bad years (Stopes), 8225-7, 8236-8255.

Foreign barleys largely malted for brewers (Baird), 7732, and for distillers, 7736; especially raw grain distillers (Baird), 7741.

Screening of (Taylor), 5463. Kiln drying of (Baird), 7759-7761.

**BEER:****MANUFACTURE OF:**

Use of malt adjuncts in beer (Primrose), 6555; necessary for light beer (Lovibond), 7020; objections to use of (Read), 8066-8071; (Stopes), 8255-8264.

German beer, manufactured without adjuncts (Lovibond), 7068-7070.

*See also* BREWING SUGARS, MAIZE.

Additions to beer after brewing (Primrose), 6555. *See also* PRIMING, PRESERVATIVES.

Modern beer consumed very soon after its manufacture (Hope), 1069-1070; (Sergeant), 4261.

**CONSUMPTION OF:**

Ordinarily very large in Liverpool (Hope), 930-4, 951-5.

By persons attacked during epidemic. In Salford (Tattersall), 8, 186-8; in Staffordshire (Reid), 2084-8; in Liverpool (Raw), 6314, 6294-6302; by 85 Manchester cases (Niven), 556-7; by 40 Crumpsall Infirmary cases (Luff), 2853-6; by patients showing pigmentation (Niven), 600; by cases which were fatal (Stevenson), 2233, 2247; only small quantities consumed in some cases (Reynolds), 385; (Niven), 602; (Bury), 4439-4440; (Raw), 6319-6324; effect of small quantity of highly arsenical beer (Sergeant), 4128; heavy drinkers affected (Stevenson), 2466-2471.

Diminished in consequence of the epidemic (Spencer) 5441-6; already diminished in Salford before cause discovered to be arsenic (Tattersall), 56-9, 142-9; near Warrington also (Kelynaek), 3519-3524; did not diminish in Liverpool (Hope), 1069-1103.

**BEER, ARSENIC IN:**

Will diminish on keeping (Brown), 6906-7; (Hehner), 7977; possibly volatilised (Hehner), 7978; may be more arsenic in lower than in upper part of a barrel (Sergeant), 4264. (Brown), 6906-7; presumably no difference (Lovibond), 7042-6; sediment of beer more arsenical than liquid (Hehner), 7973-6.

Presence of arsenic in various beers. *See* QUANTITIES. Other references, where quantity of arsenic not stated (Salamon), 1343-7; (Hope), 957-967; in non-Bostock beer (Salamon), 1521-3; (Jones), 1752; (O'Sullivan), 5743. *See also* ALL-MALT BEER.

Presence of arsenic in beer before the epidemic of 1900: (Niven), 654-5; (Hope), 904-911; (Mann), 3766-9; (Miller), 3408-3413; (Brown), 6764-6; in beer seven years old (Bell), 4532; present from time immemorial (O'Sullivan), 5743.

Possible combination of arsenic with organic matter of beer. *See* ORGANIC MATTER.

**BEER FREE FROM ARSENIC:**

No arsenic found in Munich and Vienna beers (Delépine), 4865, 5210-2, or in some English beers (Delépine), 4866, 5213-4. None found in foreign beer (Hehner), 7947-9. English beer can be rendered absolutely free (O'Sullivan), 5796-7; is rarely quite free (Hehner), 7910. No arsenic detected by Reinsch test in half litre of Newcastle beer (Lovibond), 6974-6981.

**BEER BILL, 1901:**

(Read), 8093, 8099-8101. Provides that use of brewing sugar in beer must be declared (Read), 8112-3. Would not safeguard public against deleterious matter in beer (Read), 8131.

**BEER MATERIALS, DEPARTMENTAL COMMITTEE ON, 1899:**

Evidence received by (Read), 8115-8128, in relation to risk of arsenic (Read), 8124.

**BERI-BERI:**

Possible relation to arsenical poisoning (Kelynaek), 3614-5.

**BONES:**

Arsenic in (Stevenson), 2284, 2308; (Mann), 3783. Much red marrow in beer poisoning cases (Mann), 3783.

**BORAX AND BORIC ACID:**

Arsenic in (Stevenson), 2357-2377; (Delépine), 5316-7; (Hehner), 7929, 7930.

Use as food preservatives (Stevenson), 2362-3. Not used in beer (Briant), 7236.

**BOSTOCK AND CO.:**

Explanation by, to Mr. Tattersall (Tattersall), 115-141. Increase in firm's business after 1896 (Tattersall), 150. Now in liquidation (Williamson), 7301. Works are in Garston, outside Liverpool (Hope), 1049. Statement presented to Commission on behalf of (Williamson), 7302-6.

*See also* BREWING SUGARS, BOSTOCK'S.

**BRAIN:**

Arsenic in, in cases during epidemic (Stevenson), 2221; (Mann), 3737. Quantity in grey and white matter compared (Mann), 3737.

**BREWERIES WHICH SUPPLIED ARSENICAL BEER:**

In Salford (Tattersall), 180-2; in Manchester (Niven), 561-3; in Liverpool (Hope), 1071; in Staffordshire (Jones), 1851-7; (Reid), 1882, 1993; in Lancashire (Sergeant), 4128, 4147.

List of breweries claiming rebate on arsenical beer destroyed (Hooper), 7857, Table I.

**BREWERS:****ACTION BY, IN RESPECT OF ARSENIC IN BEER:**

Destruction of arsenical beer at breweries; its recall from public-houses, or destruction on publicans' premises; and other steps taken by brewers on discovery of arsenic:—

In Lancashire (Sergeant), 4147-4162, 4203-4; in Salford (Tattersall), 8, 185; in Manchester (Niven), 732-6; (Salamon), 1293-9; in Liverpool (Hope), 974-1007, 1048; in Staffordshire (Reid), 1924.

At Cornbrook Brewery (contaminated beer destroyed on publicans' premises) (Blundell), 4965; at Groves and Whitnall's Brewery (Groves), 1551-1553a, 1676-1693, (contaminated beer taken back to brewery), 1693, 1736-1741; at Manchester Brewery Company's Brewery (Deakin), 3845-7; at Threlfall's Brewery (Tomson), 3037-3057; at Wilson's Brewery (Cowell), 5116-5132.

Destruction of arsenical beer delayed in some instances. Such beer kept on publicans' premises (Hope), 985-998; (Blundell), 5091-4; (Reid), 1928; sold by publicans after arsenic had been recognised; (Reid), 1933-8; (Estcourt), 4070-4080.

*See also* PROSECUTIONS.

Delay in destruction at breweries, for revenue reasons, (Hope), 1035; (Blundell), 5085-5094; (Reid), 1925-1932; (Cowell), 5142-3. Destruction of non-Bostock beer on account of arsenic. Not necessary at Cornbrook brewery (Blundell), 5017; was destroyed at Threlfall's (Tomson), 3096; rebate of duty claimed on such beer (Hooper), 7857, Table I, note 7.

Special action by Mr. Groves and others in Manchester district (Salamon), 1234-1243; (Groves), 1550-1553a. Appointment of Expert Committee by Manchester Brewers' Association (Salamon), 1244-9; (Groves), 1551.

*See* EXPERT COMMITTEE.

## BREWERS—continued.

Action by Country Brewers' Society. Circulars and recommendations to members (Lovibond), 6958-6962.

Precautions regarding arsenic taken by brewers since the epidemic; all new beer tested by Expert Committee's test, (Groves), 1551, 1732-4; (Blundell), 4988-4995; (Tomson), 3059-3069; (Cowell), 5153; precautions will be continued (Groves), 1580; special cleansing of brewing plant (Deakin), 3946.

Precautions at Bass' brewery (O'Sullivan), 5743-5754; at the Newcastle Brewery Company's (Lovibond), 6963, 6974-6981.

Brewing ingredients now examined for arsenic (Tomson), 3059-3069; not necessarily every consignment (Deakin), 3865.

See also GUARANTEES.

## BREWERS' BOOKS:

May show ingredients of each brew (Tomson), 3140; (Deakin), 3891-2. May not (Cowell), 5104.

Brewery would know what brews on sale at a given time and place (Blundell), 5043; might not (Cowell), 5108-5113.

## BREWERY HANDS:

## ARSENICAL POISONING AMONG:

(Niven), 551-5; (Reid), 2085-7; at Groves and Whitnall's (Groves), 1597-1602; at Cornbrook Brewery, no illness recognised (Blundell), 5061-2.

## BREWING SUGARS:

See also GLUCOSE, INVERT SUGAR, CARAMEL, DEXTRIN-MALTOSE.

## BOSTOCK'S BREWING SUGARS:

Arsenic in (Tattersall), 14; (Hope), 1073-5; (Salamon), 1261-7; (Groves), 1694-1700; (Jones), 1768-1775; (Delépine), 4877-4892, 5239; (Brown), 6709; (Hooper), 7869.

Use of Bostock sugars in beer concerned with the epidemic (Tattersall), 41; (Niven), 560; (Hope), 1131; (Reid), 1947-1967; (Kirkby), 3647. Proportions of Bostock sugars used varied at different breweries (Salamon), 1285-7, 1291-2. Brewers' custom in Manchester to use brewing sugars of different origins in the same brew (Salamon), 1338-1342; in Staffordshire also (Reid), 2034-5; Bostock sugars at Groves and Whitnall's Brewery (Groves), 1554; at Threlfall's Brewery (Tomson), 3011-6; at Manchester Brewery Company's (Deakin), 3835-3844; at Cornbrook Brewery (Blundell), 4934-4950; at Wilson's Brewery (Cowell), 5145-7; at Astley's Brewery, Nelson (Hooper), 7858-7862; at various other breweries (Hooper), 7863. Breweries using small quantities of Bostock sugar (Reid), 2010.

Use of Bostock invert in brewing (Blundell), 4937-4964; use of ditto for priming (Groves), 1603-1612; (Cowell), 5145-7; quantity of arsenic which such priming would add (Groves), 1713. Brewing value of Bostock invert satisfactory (Tomson), 3082.

Appearance of Bostock sugars (Salamon), 1357-1362 (Tomson), 3176-3183; (Blundell), 5075-7. Price of Bostock sugars (Salamon), 1339; (Blundell), 4956.

Disposal of Bostock sugars, no action by sanitary authorities to destroy (Estcourt), 4048; (Williamson), 7323-4. Quantity of arsenical brewing sugars remaining at Bostock's works in May, 1901 (Williamson), 7306-9. Precautions taken and promised with regard to their disposal (Williamson), 7312-7332.

See also SELENIUM.

## BREWING SUGAR—continued.

## BREWING SUGARS OTHER THAN BOSTOCK'S:

Examination of a series of these sugars for arsenic (Salamon), 1300-6; arsenic found in one sample only (Salamon), 1302; no arsenic found in (Jones), 1768; (Miller), 3337-3342; (Kirkby), 3689-3690; (Francis), 7353-4. Practically free from arsenic (Scudder), 4304. Glucose lately tested, and only an infinitesimal quantity found (Garton), 6151-7. Arsenic occasionally detected in (Estcourt), 3988-4006; (Sergeant), 4138; (Brown), 6709; (Hooper), 7870 (Table V.), 7888; (Stein), 5178-5182.

Precautions against arsenic in manufacture of: Brewing sugar makers obtain arsenic-free acid (Salamon), 1306, 1390, 1407. Duty of sugar makers to test purity of acid (Garton), 6232; (Salamon), 1419. Acid at his works was formerly tested for arsenic (Garton), 6199; is now tested with greater stringency (Garton), 6119-6201, 6247-9. Nature of records of tests made at his works (Garton), 6237-6246; every carboy of acid now tested (Francis), 7355; records of analyses kept at his works since the epidemic (Francis), 7386-9. Quantity of sulphuric acid used in preparation of brewing sugars (Salamon), 1466; (Delépine), 5239; (Garton), 6050-6064; (Francis), 7355-7362; (Wahl), 7431-9.

## BREWING SUGARS GENERALLY.

Not tested for arsenic before epidemic (Salamon), 1406; (Groves), 1612; (Tomson), 3073-3080; (Blundell), 4957-9. Constantly tested for brewing value (Groves), 1613-4; (Tomson), 3076; (Blundell), 4958.

Use of, in brewing: Highest ratio of sugar to malt in certain implicated beers (Hooper), 7863; average ratio (Hooper), 7863; maximum amount of sugar which might be used in beer (Hooper), 7878-7880. Quantity of invert used at his brewery (Garton), 6277-9; amount of glucose in different beers (Groves), 1728-1731; (Deakin), 3841-4; in Bass' beer (O'Sullivan), 5746.

Advantage of, in brewing (Garton), 6250-6281; (Brunton), 6005-7. Saving in storage effected by their use (Garton), 6259-6262; use is essential to modern brewing (Lovibond), 6944. Light beer prepared with adjuncts preferred by the public (Lovibond), 7020. Beer must be manufactured to suit local tastes (O'Sullivan), 5817. Some malt substitutes, including some glucose, may be injurious to health (Read), 8066-8071, 8115-8121. Pure glucose not injurious (Brunton), 5980-6. Much glucose in beer may be harmful, (Sergeant), 4261-2. Use of brewing sugars should be declared (Read), 8112-3; (Stopes), 8264.

Use of, prohibited in Bavaria (Wahl), 7446; but used in certain German breweries (Wahl), 7453-7462.

## CACODYL:

(Salamon), 1374-6, 1518-1520; (Miller), 3366-7; (Delépine), 5232-4; (Hooper), 7806-7; (Hehner), 8044.

## CALCIUM SULPHATE:

Arsenic in (Briant), 7212-9.

## CARAMEL:

Use of, in Groves and Whitnall's beer (Groves), 1701-1712; in Threlfall's Brewery (Tomson), 3191-5. Proportion used in beer (Briant), 7268-7278. Use of in other food (Bury), 7287-8.

Manufacture of (Groves), 1705-1710; (Miller), 3327-8; (Briant), 7268-7286.

Arsenic in (Miller), 3239, 3393; (Briant), 7283; (Estcourt), 4017-4026; (Kirkby), 3705. Non-Bostock caramel seriously contaminated by arsenic (Miller), 3329-3336.

## CARPETS:

Arsenic in (O'Sullivan), 5766-8.

## CASKS:

Did not take up arsenic from arsenical beer (Salamon), 1289, 1533; (Brown), 6766. Perhaps did (Kirkby), 3630. Experiments on the point (Delépine), 5292-9. Unequal distribution of arsenic in a cask of beer. See BEER.

## CHARCOAL FILTERS:

At Bostock's, contained much arsenic (Tattersall), 20; (Delépine), Appendix 12, Table VIII.

## CHRONIC ARSENICAL POISONING:

General clinical characters (Reynolds), 341-2; (Luff), 2922-8; (Brunton), 5942. Little knowledge of, before epidemic (Mann), 3761. May accelerate death from other causes (Mann), 3777-3781. Symptoms may not appear until arsenic has been discontinued (Brunton), 5943.

Toxic effect of arsenic (Brunton), 5942. Increased by alcohol (Reynolds), 434-6; (Hope), 1104-5; (Mann), 3810-3; (Bury), 4421. In beer, influenced by its great dilution (Luff), 2846-7; (Brunton), 5944. Experiments on rodents on this point and with regard to amount of food taken (Delépine), 5311. Effect of small quantities of arsenic in beer (Reid), 2078-2083; (Kelynack), 3560; (Bury), 4432-7.

## CIRRHOSIS OF THE LIVER:

Diagnosis of, in cases of poisoning of arsenic in beer (Tattersall), 214-227; (Niven), 490-500 and Appendix 3. May be caused by arsenic (Delépine), 5308. Commoner in Scotland than in Liverpool (Raw), 6377-9.

## CITRIC ACID:

May contain arsenic (Davis), 6423.

## COAL GAS:

Tried for malting, but slight traces of arsenic found in malt (Earp), 7116-7124.

## COKE, GAS AND OVEN: (See FUELS.)

## CONFECTIONERY: (See FOODS.)

## COUNTRY BREWERS' SOCIETY:

Action by, on discovery of arsenic in beer (Lovibond), 6958-6962.

## CUMULATIVE EFFECT OF ARSENIC:

(Reynolds), 370; (Stevenson), 2428; (Mann), 3790; (Raw), 6322-4. Greater in chronic than in acute arsenical poisoning (Mann), 3745.

## DEATHS during Epidemic. See EPIDEMIC.

## DEXTRINE:

Manufacture of (Wahl), 7422-5.

## DEXTRIN-MALTOSE:

Nature of (Garton), 6032-4.

## DUST:

In Manchester house (Delépine), 5248 Appendix 12, Table IXA.

## ELECTRIC HEAT:

Not been tried for malting (Earp), 7122.

## ELIMINATION OF ARSENIC FROM THE BODY:

Ways in which arsenic is eliminated (Reynolds), 439; (Stevenson), 2428-2465; (Luff), 2935-7; (Kelynack), 3571; (Mann), 3731-3745; (Brunton), 5942. Instances of slow elimination (Mann), 3791-2. Believed to be excreted in milk (Kelynack), 3549, 3553-9. See also HAIR, SWEAT, URINE.

## EPIDEMIC DUE TO ARSENIC IN BEER, 1900:

## GENERAL ACCOUNT OF:

In Salford.—Traced to beer (Tattersall), 7-295; to glucose contaminated by arsenical acid, 7; commencement of epidemic, 8; extent of epidemic, 7, 209-212; termination of epidemic, 30; at first regarded as one of alcoholic neuritis, 48-55; all implicated brewers used Bostock sugars, 168-170; no relation to influenza or antecedent debilitating conditions (Tattersall), 199-204. Arsenic not detected in earliest samples sent to public analyst (Bell), 4496-4535.

In Manchester.—Due to arsenic in beer (Niven), 528; (Stevenson), 2485; (Kelynack), 3485. Statistics for Manchester (Niven), 463-703. More cases occurred than were reported (Kelynack), 3487-3492. Statistics of cases in Manchester Workhouse Infirmary (Reynolds), 368, 379-380. In Manchester Royal Infirmary (Reynolds), 379; (Kelynack), 3541-5. No relation of epidemic to influenza or antecedent debilitating conditions (Reynolds), 448-450. Epidemic at first attributed to alcohol (Brunton), 5971.

Arsenical poisoning in Manchester before 1900 (Reynolds), 408-413. Alcoholic neuritis in Manchester before 1900 (Niven), 473-489; (Brunton), 5972.

In Liverpool.—Due to arsenic in beer (Hope), 903. Conclusions with regard to Liverpool (Hope), 1131. Commencement of epidemic, 900; extent of epidemic, 890-899, 928-930; termination of epidemic (Hope), 900-2. Less extensive than in Manchester (Raw), 6288. Statistics of Mill Road Infirmary (Raw), 6289-6291. Decrease in "alcoholism" since epidemic (Raw), 6348-6351.

In Staffordshire.—General account and statistics (Reid), 1969-1992. Local distribution of cases (Reid), 2002-2016, and map Appendix No. 7. Cases reported since December, 1900 (Reid), 2008.

In Lancashire.—General account (Sergeant), 4128; distribution of (Sergeant), Appendix No. 11, map. Epidemic in Heywood (Kelynack), 3484; (Sergeant), 4128, 4217-4222; near Warrington (Kelynack), 3519-3524. Inquests in (Sergeant), 4212-4; statistics incomplete as regards several districts (Sergeant), 4235-8.

## CLASS OF PERSONS ATTACKED:

(Reynolds), 452-5; (Niven), 522-8, 678-687. Persons who denied drinking beer (Niven), 548, 550. Did not attack spirit drinkers (Kelynack), 3484.

## AGE OF PERSONS ATTACKED:

(Kelynack), 3484. In Salford (Tattersall), 8. In Manchester (Niven), 518-9. At Mill Road Infirmary, Liverpool (Raw), 6364. Children not affected (Niven), 528.

## SEX OF PERSONS ATTACKED:

(Kelynack), 3484. In Manchester (Niven), 506-517. In Salford (Tattersall), 8. In Manchester Workhouse cases (Reynolds), 426-430. At Royal Infirmary, Liverpool (Raw), 6364. Women more seriously affected than men (Reynolds), 381-6; (Kelynack), 3531; (Mann), 3793-6; (Bury), 4422-6. Difference possibly related to quantity of food taken (Delépine), 5312. Greater fatality among women (Hope), 1090-4; (Luff), 2973-7. Medicinal administration of arsenic to men and women compared (Brunton), 5959-5960.

## FATALITY:

In Salford (Tattersall), 8. In Lancashire (Sergeant), 4128. Fatal cases of arsenical poisoning not certified as such (Tattersall), 48-55; (Niven), 491; (Sergeant), 4128; (Raw), 6301, 6365-6.

# EPIDEMICS, FORMER, OF ARSENICAL POISONING:

- In Paris, in 1828 (Reynolds), 350, 361, 456-8.
- In Hyères, in 1888 (Reynolds), 351-7; (Stevenson), 2270-1. Symptoms (Brunton), 5946. Due to arsenic in wine (Brunton), 5946. Report on (Brunton), Appendix No. 14.
- In Havre in 1889 (Reynolds), 358-360.
- In Würzburg, due to arsenic in bread (Brunton), 5945.

## EPSOM SALTS:

- Used for hardening brewing water (Briant), 7226-8. Arsenic in (Briant), 7226.

## EXPERT COMMITTEE:

- Appointed by Manchester Brewers' Association (Salamon), 1244-9; (Groves), 1551. Members of (Salamon), 1246. Work by and reports (Salamon), 1250-1260, and Appendix No. 5; (Luff), 2901-5; (Stevenson), 2220; (Brunton), 5942. Tests advised (Salamon), 1318-1329. Further work in progress (Salamon), 1335; (Luff), 2987.

See also TESTS.

## FÆCES:

- Arsenic in (Mann), 3734.

## FININGS:

- Use of, in beer (Briant), 7246-7267. May be cut by tartaric acid (Briant), 7246-7254, or by sour beer (Briant), 7258-7264. Outside London sediment after fining remains in cask (Briant), 7255.
- No arsenic found in (Jones), 1792; (Deakin), 3904-6.

# FOODS AND DRINKS (OTHER THAN BEER) IN RELATION TO ARSENIC:

- Considered generally (Stevenson), 2322-6, 2415-8. No arsenic found in foods made with glucose (Tattersall), 31-4. Arsenic in certain food preservatives (Delépine), Appendix No. 12, Table XI.

BAKING POWDERS: Liability to contain arsenic (Kirkby), 3704-6.

CLARET: Use of glucose in (Wahl), 7442-5.

COLOURED CONFECTIONERY: No arsenic recently found in (Stevenson), 2478. No arsenic found in (Jones), 1788-1791.

DRIED APPLES: (Stevenson), 2341-2351.

GOLDEN SYRUP: No arsenic found in (Jones), 1777-1780.

Use of sulphuric acid in (Stein), 5158. Quantity of acid needed (Stein), 5159-5168.

GLYCERINE: Might introduce arsenic into wine (Brunton), 5975.

HAMS: Smoked hams (Stevenson), 2356.

HONEY: Glucose in (Stein), 5175-7.

MINERAL WATERS: (Niven), 535-543. Sulphuric acid for mineral waters obtained free from arsenic (Kirkby), 3698-9; (Norris), 4800-9.

Arsenic in medicinal mineral waters (Delépine), Appendix 12, Table XIII.

MOLASSES: Traces of arsenic in (Hehner), 7926.

REFINED SUGAR: Traces of arsenic in (Hehner), 7924-6, 7984-7990.

SHRIMPS: Arsenic in potted shrimps, due to borax (Delépine), 5317.

SWEETS, JAMS ETC.: No arsenic found in (Stevenson), 2475-7; (Sergeant), 4129; (Niven), 529-534; (Hope), 912-5; (Jones), 1780; (Bell), 4488-4490.

# FOODS AND DRINKS (OTHER THAN BEER)—continued.

TOFFY: Arsenic in toffy made from Bostock glucose (Kelynack), 3549.

TREACLE AND TABLE SYRUP: No arsenic found in (Hope), 916.

Use of sulphuric acid in table syrup (Stein), 5158, 5197-5202. Quantity of acid needed (Stein), 5159-5168. Glucose in (Stein), 5171.

VEGETABLES GROWN ON ARSENICAL SOIL: May contain arsenic (Stevenson), 2309-2313.

## FOOD AND DRUGS ACTS, SALE OF:

Mainly a check on harmless adulteration (Tattersall), 312. Small numbers of samples taken in certain districts (Bell), 4502-4524, 4601-5. None during year in Congleton (Bell), 4523. Control by Local Government Board over administration (Tattersall), 248; (Hehner), 8041-2; (Jones), 1858; (Bell), 4606; (Brown), 6932-6.

Action under Acts must be taken against retailer (Tattersall), 257; (Hope), 977, 1020-2, 1040. Wholesale dealer or manufacturer might be reached if a warranty (Tattersall), 261-4, 324-8; (Hope), 1137, 1183-5, 1212-4. Effect of warranty on manufacturer (Hope), 1173-1192. Publican might be refused a warranty by brewer (Hope), 1163.

Advantage if manufacturer giving warranty could be reached at first hearing of case (Tattersall), 263, 326-7; (Hope), 1214.

No power under Acts to take samples from brewery (Hope), 1011-9; (Primrose), 6669. Should be such power (Niven), 676-7; (Hope), 1018. Power might be given (Primrose), 6667-6670, 6674-6681. Samples might be taken in transit with consent of purchaser (Estcourt), 4089. Quantity of beer sample required (Hope), 1116-1128; (Brown), 6877. Should not be too large (Estcourt), 4040.

No power under Acts to seize or destroy contaminated beer (Reid), 2125-2134. Acts of no service to stop its sale, 2125.

Penalties under, are inadequate for arsenical beer (Hope), 1129. Section III. of Act, as to poisonous substances, difficult to apply (Niven), 586-592; (Hope), 1193-1202. Penalties where retailer refuses to supply samples inadequate (Estcourt), 4040.

Various directions in which Acts might be amended (Tattersall), 28, 329-333; (Niven), 676-7; (Brown) Appendix No. 15.

Action taken under, in respect of arsenic in beer and food: In Manchester (Niven), 568-592, 641-2; in Salford (Tattersall), 8; in Staffordshire (Jones), 1744-1872; (Reid), 1884-1924, 2049-2074, 2188-2204; in Lancashire (Sergeant), 4128, 4198-4211; in Liverpool (Hope), 1048-1068; collection of samples (Jones), 1818; (Reid), 2201; police utilised (Sergeant), 4209; samples taken by local authorities independently of county council (Reid), 1906-9; by inspectors independently of Medical Officers of Health (Bell), 4619-4621.

Samples obtained from brewers sent to public analyst (Hope), 975; (Reid), 1923; in Salford and Manchester such samples tested independently (Niven), 704-710.

Beer should be defined for purposes of Acts (Read), 8089-8091; (Estcourt), 5917; by Court of Reference (Read), 8076-8098; administrative need for standard test for arsenic in beer (Reid), 2075; (Estcourt), 4035, 4096-4110; (Delépine), 5318; (Lovibond), 7047; (Hehner), 7940; (O'Sullivan), 5866-5872, 5909, 5917; (Brown), 6874, 6919.

Samples of beer seldom taken under Acts before epidemic, and never analysed for arsenic (Tattersall), 244; (Hope), 925-6; (Stevenson), 2522; (Bell), 4585-9.

See also PROSECUTIONS, PUBLIC ANALYSTS, OFFICIAL CONTROL.

## FUELS:

## MALTING AND OTHER, IN RELATION TO ARSENIC:

Malting fuels compared (Miller), 3250-3251, 3343-9; (Taylor), 5569-5577; (O'Sullivan), 5759. Cost of malting fuels (Taylor), 5522-8; (O'Sullivan), 5838-5844.

Unequal distribution of arsenic in coal (O'Sullivan), 5795, 5798. Form in which arsenic is present in coal (O'Sullivan), 5828-5835. Treatment of, in order to fix arsenic (Hehner), 7912. Arsenic in coal remaining in the ash (Hehner), 7913-5, 7950, 7962-7972. Selection of coal for analysis (Taylor), 5634-5643.

## GAS COKE:

Use of, in malting (Jones), 1763-7. Largely used by maltsters in North and Midlands (Taylor), 5710-4; (Earp), 7111-2. Given up at Threlfall's (Tomson), 3100-6, 3161-2; at Manchester Brewery Co. (Deakin), 3881; discontinuance at Burton (O'Sullivan), 5743; should be avoided as a malting fuel (Salamon), 1480-1; (Miller), 3247-9; never used at Newcastle Brewery Co.'s maltings (Lovibond), 6965-6; unfit for malting (Lovibond), 7032-3; use for malting would be difficult to prohibit (O'Sullivan), 5791.

Arsenic in (Jones), 1823-1833; (Delépine), 5247; (Earp), 7100. Arsenic in malt mainly attributable to (O'Sullivan), 5754. No arsenic found in some coke-dried malts (Tomson), 3128-3137.

Some gas coke gives objectionable flavour to beer (O'Sullivan), 5755. If suited for flavouring may be unsatisfactory *quod* arsenic (O'Sullivan), 5762. Seldom used for hop drying (Berry), 7602-3.

## ANTHRACITE:

Use of, for malting commenced at Manchester Brewery Co. (Deakin), 3881. Use recommended (Blundell), 5022-3. Not used in North of England (Lovibond), 6964. Gives cleaner flavour than coke (Earp), 7086. Preferred as malting fuel (Taylor), 5634. Selected for malting value (O'Sullivan), 5877. Hand-picked at collieries (Baird), 7666, and riddled at maltsters (Baird), 7666-8. Costs more than coke (Tomson), 3124-7.

Use by maltsters affords security from arsenic (Salamon), 1485; (Earp), 7172-4. Malt dried with, may contain traces of arsenic (Miller), 3251. Arsenic in (Delépine), 5247; (Brown), 6710, 6867; (Earp), 7099. Amount negligible (Taylor), 5531-5545.

Used for hop drying (Berry), 7600-1.

## OVEN COKE:

Used at Newcastle maltings (Lovibond), 6964. Not used in Ware district (Taylor), 5569-5575. Arsenic in (Brown), 6710; (Earp), 7100. Contains less arsenic than gas coke (Miller), 3291-9; (Brown), 6871.

## YORKSHIRE COAL:

Arsenic in (Delépine), 5247.

## CHARCOAL:

Former use of in malting (O'Sullivan), 5932; (Earp), 7107-9.

Used in hop drying, mixed with coal (Berry), 7604.

## PEAT:

Useless for brewers' malt (Lovibond), 7074; (Baird), 7698-7702.

See also MALT, COAL GAS, ELECTRIC HEAT.

## GAUTIER, M.

Statement that arsenic is normally present in certain tissues of body disputed (Stevenson), 2306-8; (Mann), 3787-9.

## GLASS.

Glass bottles may contaminate mineral acids with arsenic (Hehner) 7933-5.

## GLUCOSE:

ARSENIC IN VARIOUS SAMPLES OF GLUCOSE; USE OF GLUCOSE IN BEER: PROPORTIONS OF GLUCOSE USED AT IMPLICATED BREWERIES:—See BREWING SUGARS.

LIABILITY OF GLUCOSE TO CONTAIN ARSENIC: Known before the epidemic (Tattersall), 60-1; (Salamon), 1395-1403; (Delépine), 4900\*; observations of Clouet and Ritter thereon (Delépine), 4901-4926. Arsenic not uniformly distributed in contaminated glucose (Salamon), 1529-1530.

MANUFACTURE OF GLUCOSE: (Tattersall), 20; at Garton Hills, from maize, sago, and tapioca flours (Garton), 6036-9; at Manbrés, similarly (Francis), 7359-7367.

Rice and raw maize might be used (Garton), 6040-4; use of raw maize abandoned (Francis), 7363. Potato starch used abroad, too expensive for use here (Garton), 6107; (Wahl), 7408-7421; invariably used in Germany (Wahl), 7548; such starch free from gluten (Wahl), 7554-6.

Quantity of sulphuric acid employed (Salamon), 1466; (Delépine), 5239; (Garton), 6050-6064; (Francis), 7355; (Wahl), 7431-9. Nature of sulphuric acid used (Garton), 6111-6201; (Francis), 7336-7352; (Wahl), 7431, 7471-7483.

Manufacturers' precautions against arsenic in glucose (Salamon), 1306, 1407; (Garton), 6183-6201, 6237; (Francis), 7355, 7386.

Liquid and solid glucose compared (Wahl), 7526-7536. Amount of water in glucose (Wahl), 7512-9. Glucose adulterated with saccharine (Wahl), 7522-4.

IMPORTED GLUCOSE: Origin, and use of, in brewing (Salamon), 1306-8, 1384-1394. American glucose: used in brewing (Groves), 1555-9; arsenic in (Estcourt), 3988-4006. German solid glucose: used in brewing (Wahl), 7504, is consigned to agents, not to brewers direct (Wahl), 7508-7511; arsenic in (Estcourt), 3988; (Sergeant), 4138. Arsenic in liquid glucose (Hooper), 7888.

Glucose in confectionery, etc., etc., is generally imported (Stevenson), 2475; little liquid glucose is imported from Germany (Wahl), 7489.

Imported glucose should be tested at port of entry, and guaranteed (Salamon), 1384-9. No means of controlling its manufacture (Primrose), 6704-5. No special government inspection of glucose manufacture in Germany (Wahl), 7538.

USES OF GLUCOSE, other than in brewing. An addition to golden syrup (Hope), 941-950; (Jones), 1783 (Hehner), 8021-4; in jams, syrups and confectionery (Niven), 532; (Hope), 914; (Jones), 1777-1787; (Stevenson), 2475; (Wahl), 7490; (Hooper), 8018-8022; in honey (Niven), 532; (Stein), 5175; in mineral waters (Niven), 536; in claret (Wahl), 7442-5. Use for textile purposes and for leather (Williamson), 7311; (Francis), 7400; (Wahl), 7429.

## GOVERNMENT LABORATORY:

Various work done at, in consequence of epidemic (Hooper), 7777-7891; tested arsenical beer on which rebate claimed (Hooper), 7777; (Primrose), 6651-8. Method of testing beer adopted (Hooper), 7777-7856; meaning of "freedom from arsenic" at (Hooper), 7871-7.

Constantly examines metals supplied to Post Office for arsenic (Hooper), 7777. Examines beer for Army and Navy use (Hooper), 7893; recently these have been tested for arsenic (Hooper), 7892-8.

Reference samples in prosecution cases (Hooper), 7856A.

See also INLAND REVENUE, TESTS.

## GUARANTEES: AS REGARDS ARSENIC:

In connection with brewing, etc., may not have much value in practice (Lovibond), 7062-6; (Estcourt), 4126. Should be given (Reid), 2115-2124. Requirements of (Salamon), 1436-1457.

Obtained by brewer in respect of beer ingredients (Groves), 1637-1673; (Deakin), 3862; (Tomson), 3086-3099; (Cowell), 5099-5103; terms of (Groves), 1647-1650; how they might be systematically obtained (Groves), 1650-1673; and checked by revenue officers (Groves), 1662-7. Should be obtained by brewer (Primrose), 6613-8; inaccurate guarantee should involve penalty (Primrose), 6673.

*By brewing sugar maker to brewer:* (Salamon), 1435-1457; may have unequal value, 1442-3; should be specific and relate to a prescribed test, 1447-1450; manufacturer should be responsible (Salamon), 1452-7. Form of guarantee (Tomson), 3184-3190; (Deakin), 3867-3874; (Garton), 6187-6192; (Francis), 7383.

*By maltster to brewer:* Are required and given (Groves), 1568-1596; (Tomson), 3119-3123; (Blundell), 4996-5000; (Deakin), 3862; (Baird), 7770; (O'Sullivan), 5883-5890; do not specify absolute freedom from arsenic (O'Sullivan), 5891-2. Form of guarantee varied to suit customers; (Earp), 7185; (Estcourt), 4126. Maltsters at first unwilling to guarantee (Groves), 1615-9. Maltsters should not be asked to guarantee (Stopes), 8179-8204.

*In respect of fuel used by maltster:* Not demanded (Tomson), 3119; Lovibond, 7059-7060; (Baird), 7753.

*In respect of hops:* Not asked for (Tomson), 3,200-4; (Deakin), 3875; or now obtained (Blundell), 5078.

*In respect of chemical substances used by brewers:* Are given (Briant), 7299.

*By brewer to customer or retailer:* Hardly required (Salamon), 1502-3; nature of certificates given (Groves), 1624-1635; (Blundell), 5081-3; objections to (Deakin), 3931-3945; not given (Cowell), 5148-5150; (Tomson), 3144-9.

*By sulphuric acid maker to food manufacturer:* (Morris), 4767-4771; (Francis), 7347-7352; (Wahl), 7471; specific guarantee as to arsenic only since the epidemic (Morris), 4772-4; no written contract with acid manufacturer (Garton), 6128-6137; would not object to obligatory guarantee (Garton), 6183-6.

## HAIR:

Arsenic in (Mann), 3735, 3741-8; found in hair of alcoholic patients without symptoms of arsenical poisoning (Mann), 3737.

## HARDENING MATERIALS:

Use of, in brewing, and relation to arsenic in beer (Briant), 7200-7231.

## HEART:

Cardiac symptoms, in cases of arsenical poisoning (Tattersall), 214; (Reynolds), 378; (Brunton), 5942. Deaths from heart failure (Reynolds), 378; (Mann), 3753.

"Alcoholic heart" in relation to arsenic (Kelyack), 3585-7, 3615-3621; (Mann), 3752-9.

Appearance of, in chronic arsenical poisoning (Stevenson), 2300-2; (Brunton), 5942; (Mann), 3755-3760.

## HIDES:

Use of arsenic as depilatory (Stevenson), 2327-2333. Arsenical poisoning in tanneries (Stevenson), 2335-2340. 4576.

## HOPS

Occurrence of arsenic in (Niven), 619-622; (Salamon), 1493-5; (Miller), 3301; (Berry), 7605-7610, 7649; (O'Sullivan), 5743; (Tomson), 3200-4; Arsenic is derived from fuel (Berry), 7612.

Use of sulphur in hop kilns (Berry), 7595-8; (Stopes), 8158. Reasons for using sulphur (Berry), 7633-9. Sulphur guaranteed free from arsenic, 7650-7661.

Anthracite used for drying, gas coke seldom, charcoal used occasionally (Berry), 7600-4.

Hop insecticides, soft soap, quassia, &c. (Berry), 7563-7570. Not Paris Green, 7571. Use of tobacco extract, 7618-7621. No knowledge of insecticides used abroad (Berry), 7622-4.

Use of sulphur in hop growing, and nature of sulphur used (Berry), 7572-7594.

Sulphur in hops may act on arsenic present in a wort (Salamon), 1535-1543.

Quantity of hops used in beer (O'Sullivan), 5903-5.

*See also FUELS, GUARANTEES.*

## HYDROCHLORIC ACID:

Arsenic in (Davis), 6381, 6466, 6493. Cylinder acid should be used for food purposes (Davis), 6496.

## INLAND REVENUE, BOARD OF:

POWERS OF, AND ADMINISTRATION BY, IN RELATION TO ARSENIC IN BEER:

Duties and powers of excise officers at breweries (Spencer), 5331, 5359; (Primrose), 6546, 6526-6708. Excise supervision for revenue purposes (Spencer), 5331, 5359, 5407; (Blundell), 5059-5060. Excise officers take account of wort (Spencer), 5391-2. Have power to take samples of brewing materials, 5356-7. Such samples collected for revenue reasons (Spencer), 5408-5424.

Brewers' returns to Inland Revenue contain detail necessary for revenue purposes (Spencer), 5433-8. Do not show origin of ingredients of each brew (Tomson), 3141-3, 3207-8; (Deakin), 3895; (Blundell), 5042. Should do so (Sergeant), 4138. Excise officers could ascertain (Deakin), 3899-3900.

Act of 1888 provides against noxious ingredients in beer (Primrose), 6583; (O'Sullivan), 5935. Saccharine prohibited, for revenue reasons (Spencer), 5425-5432; (Primrose), 6542. No ingredients prohibited on ground of risk to health (Primrose), 6542-5, 6585. No action under 1888 Act in view of epidemic (Spencer), 5352-8; (Primrose), 6584, 6597-9.

Excise officers visit publicans' cellars for revenue purposes (Spencer), 5401-5. Addition of injurious substances to finished beer would be objected to (Primrose), 6555-6, 6573-6581. Certain preservatives sanctioned, 6568-9, including salicylic acid (Primrose), 6570-2.

Control by, inadequate as a safeguard to public health (Read), 8074-5. Excise superintendence might be utilised as protection to public health (Groves), 1662-7; (Reid), 2118, 2149, 2171-2184; (Sergeant), 4138; but only to a limited degree (Primrose), 6601-7, 6674-6681, and as regards beer ingredients, 6608. Primary responsibility for finished beer should rest with Local Government Board and authorities under Sale of Food and Drugs Acts (Primrose), 6540, 6609-6612, 6691-6708.

*See also REBATE OF DUTY.*

## INSECTICIDES:

Arsenical insecticides (Stevenson), 2341-3. Not used for hops (Berry), 7571.

**INVERT SUGAR:**

USE OF INVERT SUGAR IN BEER; PROPORTIONS USED IN IMPLICATED BEER; PRECAUTIONS TAKEN BY MANUFACTURERS: See BREWING SUGARS. See also PRIMING.

Definition of (Garton), 6024-7. Object of inverting sugar for brewing (Garton), 6066-7.

Quantity of sulphuric acid used in its manufacture (Tattersall), 20; (Salamon), 1466; (Garton), 6050-8; (Francis), 7394.

May be prepared without use of acid (Lovibond), 6983, by means of yeast (Lovibond), 6991-5. No invert made at his factory (Wahl), 7507.

arsenic in Bostock's invert (Salamon), 1267; (Jones), 1769-1775, 1803; (Delépine), 4896-4900; (Hooper), 7869. Quantity of arsenic added when priming with Bostock invert (Groves), 1713. Traces of arsenic in other inverts (Delépine), 4900, Appendix 12, Table IV.

**KAINIT:**

Nature, and use in beer (Briant), 7202-3; arsenic in (Briant), 7224-5, 7229-7231.

**KERATIN:**

Affinity of, for arsenic (Reynolds), 414; (Mann), 3737

**KERATOSIS:**

In chronic arsenical poisoning (Reynolds), 341; (Brunton), 5942. Common symptom in epidemic (Luff), 2886-2890; (Kelyack), 3514; (Bury), 4417. Especially at end of epidemic (Raw), 6344-7.

**LEAD:**

None found in implicated beer (Tattersall), 89.

**LEAVES OF MANCHESTER PLANTS:**

Arsenic on (Delépine), 5247, Appendix 12, Table IXA.

**LIVER:**

Appearance of, in chronic arsenical poisoning (Stevenson), 2294-5; (Brunton), 5942, 5953-6; (Delépine), 5308. In alcoholic cases in Manchester (Kelyack), 3582-4.

Arsenic found in, in fatal cases during epidemic (Stevenson), 2220-2257; (Mann), 3783. Not detected in certain cases (Stevenson), 2249-2254.

**LOCAL GOVERNMENT BOARD:**

irregular by, to local authorities in consequence of epidemic (Tattersall), 251; (Reid), 2189-2193. Inquiries by Inspector of (Stevenson), 2220; (Lovibond), 6961-2.

Relation of, to administration of Sale of Food and Drugs Acts, etc. See ANALYSTS, FOOD AND DRUGS ACTS, MEDICAL OFFICER OF HEALTH, OFFICIAL CONTROL.

**LOCOMOTOR ATAXY:**

Deaths from Arsenical Poisoning attributed to (Sergeant), 4226, 4230-4.

**"LONG PULL":**

In Liverpool (Raw), 6294-6397.

**MAIZE:**

Use of, in brewing (Blundell), 5001-5015. Preferable to glucose as an adjunct (Lovibond), 6985-8. No acid used in making maize grits (Lovibond), 6983-4, 6996-7002. No arsenic found in them (Lovibond), 7004; (O'Sullivan), 5899.

**MALT:****ARSENIC IN MALT:**

(Tattersall), 26; (Niven), 596-9, 613-6; (Hope), 1078-1085; (Salamon), 1474-1492; (Jones), 1761-7; (Luff), 2988-2992; (Miller), 3241-3251, 3274, 3381; (Sergeant), 4128; (Scudder), 4316; (Bell), 4524-4532, 4570; (Stevenson), 2511-2; (Estcourt), 3982-7; (Brown), 6709-6710, 6768; (Hooper), 7880a-2. Liability to contain arsenic unknown before epidemic (Salamon), 1496-1500. No arsenic in malt dried with anthracite (Stopes), 8213-8. Malt need not contain arsenic (Salamon), 1347, 1479; (Baird), 7704-6. Can be rendered practically free (O'Sullivan), 5788-5790. Ways in which arsenic in malt is being reduced (Earp), 7171.

Products of combustion must pass through malt to get flavour (Salamon), 1482; (Taylor), 5682; (Lovibond), 7071; (Baird), 7689-7697, 7766-7771; (Stopes), 8142-8151, 8171. Anthracite gives cleaner flavour than coke (Earp), 7086. Some brewers prefer flavour of coke-dried malt (Taylor), 5576. Satisfactory flavour without exposure to fumes possible (O'Sullivan), 5853-5; (Earp), 7125-7154. Malt should be dried with out fumes (Estcourt), 4123. This would mean great expense (Salamon), 1484. Fumes do not pass through German malt (Lovibond), 7071; (Baird), 7687-8; (Hehner), 7918-7923.

Arsenical malt which cannot be sold (O'Sullivan), 5780-5, 5792.

Sampling malt (Groves), 1572; (Taylor), 5737-9. Quantity necessary for testing (O'Sullivan), 5863-5. Malt examined for arsenic before purchasing (O'Sullivan), 5881. Now tested by maltsters (Taylor), 5552-5563. Need for "standard" test for arsenic in malt (Taylor), 5603-4, 5717-30; (O'Sullivan), 5866-5872; (Earp), 7183-4.

**PREPARATION OF:**

System of malting described (Taylor), 5451-5528; (Baird), 7664-7771. Changes in consequence of discovery of arsenic (Earp), 7089-7168. Temperature of malting (Taylor), 5473; (Lovibond), 7077-8. Duration of kilning (Taylor), 5517. Pneumatic malting in England no advantage as regards arsenic (Taylor), 5663-5680. Being adopted at Burton (O'Sullivan), 5878. Not so satisfactory as kiln (Baird), 7676.

**BLACK MALT:**

Roasted in cylinders without exposure to fumes (Taylor), 5654, 5661-2; (Baird), 7758; (Lovibond), 7079.

**BROWN MALT:**

Dried with wood (Taylor), 5654-5; (O'Sullivan), 5857-9.

**BRUSHING AND SCREENING OF MALT:**

Brushing reduces amount of arsenic (O'Sullivan), 5743, 5793-4; (Brown), 6710, 6770; (Earp), 7105-6. Should remove all arsenic (Stopes), 8159, 8173-5. Desirable apart from arsenic (O'Sullivan), 5846-7. Brushing by Newcastle Brewery Co. (Lovibond), 7057-9. Required by Manchester Brewery Co. before epidemic (Deakin), 3887-3890. Malt bought brushed and screened (Blundell), 5031-2. Brushing being adopted at Burton (O'Sullivan), 5779; at Threlfall's Brewery (Tomson), 3169. Screening already done (Tomson), 3166.

Description of process (Taylor), 5462-5515 (Lovibond), 6970-3.

Brushing should be done by brewer not by maltster (Taylor), 5578-5582; (O'Sullivan), 5849; (Earp), 7190; (Stopes), 8175.

Distillers malt not brushed or screened (Baird), 7722-5.

**MALT—continued.****MALT CULMS OR COMINGS:**

More arsenic in culms than in malt (Lovibond), 7041. None found in (Lovibond), 6964.

Used to feed stock (Lovibond), 7040; (Read), 8088; (Taylor), 5587-5590. Exported as cattle food (Baird), 7726-8. Not injurious to stock (Read), 8114.

**MALT DUST:**

Formation of (Niven), 670-5; (Taylor), 5548, 5594.

Arsenic in (Niven), 815-822; (Salamon), 1477; (O'Sullivan), 5775; (Lovibond), 6964, 7038-7041. Not used to feed stock (Lovibond), 7040; (Read), 8109. Not tested (Taylor), 5566.

*See also* FUELS, GUARANTEES.

**MEDICAL OFFICER OF HEALTH:**

Powers of, with regard to arsenical beer (Niven), 796-811; (Tattersall), 296-310. Under Public Health Acts to obtain destruction of beer (Tattersall), 259-260; (Hope), 975-6, 1023-1032; (Reid), 1890-3, 1921; (Estcourt), 4046-7, 4051-4069. Could not be used at a brewery (Niven), 741-8. Might possibly (Tattersall), 308-310.

Should be informed of cases of sickness in hospitals (Niven), 830-842. Should be informed of outbreaks of non-notifiable illness (Tattersall), 28, 279-287.

Of Garston, took no action regarding Bostock's sugars (Williamson), 7323-4.

*See also* EPIDEMIC, FOOD AND DRUGS ACTS, OFFICIAL CONTROL.

**MINERAL WATERS. *See* FOODS.****NEURITIS:**

Not hitherto separately recorded by Registrar-General as cause of death (Tatham), 2540. Classification of deaths from, 2525-2550; of deaths in 1900, 2530; deaths from, increased in 1899 (Tatham), 2527-9.

*See also* ALCOHOLIC NEURITIS.

**NICHOLSON AND CO.:**

Statement presented to Commission, page 97; explanations by (Tattersall), 35-40, 80, 111-141.

Sulphuric acid output of the firm (Tattersall), 127; use of acids in Bostock's sugars (Tattersall), 7; (Hope), 1131-4.

Arsenic in Nicholson acid (Tattersall), 12; (Dixon), 3430-3444, 3451-3460; (Salamon), 1264; (Tunnicliffe), 2635-8; (Delépine), 4876; (Brown), 6709, 6711-6736.

**OFFICIAL CONTROL IN RESPECT OF POISONOUS SUBSTANCES IN BEER AND FOOD.**

*See* FOOD AND DRUGS ACTS, GUARANTEES, MEDICAL OFFICER OF HEALTH.

Provision needed for continuous scientific investigation of food stuffs (Tattersall), 28. Stricter supervision over their manufacture necessary (Hope), 1135, 1155. Government inspection and supplementary inquiries by sanitary authorities of large towns advocated (Hope), 1136. Local authority might be given powers as regards beer (Reid), 2210.

Official inspection of chemical works as to poisons advocated (Tattersall), 269-270; of sugar factories (Stein), 5186-7.

Purchaser of chemicals should be obliged to state if required for food (Hope), 1221. All poisonous substances should be labelled (Tattersall), 28; (Niven), 865-881; (Hope), 1211-8, 1225. Arsenical sulphuric acid should be labelled (Hehner), 7938-9.

**OFFICIAL CONTROL, &c.—continued.**

Official "standard" tests needed for arsenic in beer (Reid), 2075; (Estcourt), 4035, 4096-4110; (Delépine), 5318; Lovibond, 7047; (Hehner), 7940; (O'Sullivan), 5866-5872, 5909, 5917; (Brown), 6874, 6919; and in beer ingredients (Taylor), 5603-4, 5717-5730; (O'Sullivan), 5866-5872; (Earp), 7183-4; (Garton), 6204-9. Authority by which they might be fixed (O'Sullivan), 5918-5931; for ingredients might be Board of Inland Revenue (Garton), 6210-1; Board of Reference (Brunton), 5987-5996, 6008-6014; (Read), 8076, 8080-8098.

General recommendations as to administration in respect of arsenic in food (Brown), 6938, Appendix No. 15.

**ORGANIC MATTER OF BEER:**

Considerations as to possible combination of arsenic with organic matter: (Niven), 623-5; (Salamon), 1365-1377, 1508-1520; (Stevenson), 2304-5; (Luff), 2862-4; (Miller), 3364; (Mann), 3823; (Delépine), 5228-5234, 5300; (Brunton), 5944, 5965-7; (Brown), 6761, 6787-6790; (Hooper), 7796; (Hehner), 7996-9, 8043-8054.

Some organic compounds of arsenic would not react to Reinsch, but would to Marsh test (Hehner), 8003.

Destruction of organic matter when testing for arsenic, *see* TESTS.

**OXIDE OF IRON:**

Arsenic in (Hehner), 8015; used in bloater paste and chocolate, 8018.

**PERMISSIBLE ARSENIC IN BEER OR FOOD:**

Opinions as to (Tattersall), 271-7; (Reid), 2078-2083, 2090; (Delépine), 5306-9; (Stevenson), 2413-8; (Mann), 3797, 3818-3820; (Sergeant), 4164.

**PHOSPHATES:**

Phosphate of soda, liable to contain arsenic (Niven), 542; (Stevenson), 2381; (Tunnicliffe), 2813-2839; (Kirkby), 3691; (Hehner), 8014; (Briant), 7289-7292.

Phosphate as manure contains arsenic (Blundell), 5063; which may be taken up by roots (Blundell), 5064-5072; not so (Read), 8082-7; risk negligible (Stopes), 8155.

**"PHOSPHOCITRIC" ACID.**

Liability to contain arsenic (Niven), 535.

**PHOSPHORIC ACID:**

Arsenic in (Stein), 5188-5196; (Davis), 6381. Much arsenic in sample used for sugar refining (Davis), 6453-6465.

**PIGMENTATION:**

As a symptom of poisoning by arsenic and observed during epidemic (Reynolds), 342, 411-3; (Hope), 1096-8; (Stevenson), 2248, 2264, 2273-2280; (Luff), 2848, 2875, 2885; (Kelynaek), 3499; (Mann), 3728, 3816; (Bury), 4415; (Brunton), 5942; (Raw), 6292; cases without pigmentation frequent (Mann), 3750-1; two kinds of arsenical pigmentation (Raw), 6325.

*See also* ADDISON'S DISEASE.

**POST-MORTEM EXAMINATIONS:**

In Manchester cases, where viscera tested for arsenic (Stevenson), 2219-2260; (Mann), 3782-3; (Delépine), 5314.

## POULTRY:

Use of arsenic in fattening (Stevenson), 2353-6.

## PRESERVATIVES IN BEER:

Sanction of Inland Revenue to use of (Primrose), 6568-6570; use of salicylic acid (Briant), 7232, 7237-7244.

Object and use of (Primrose), 6569; (Briant), 7232-7245; use objected to (Stopes), 8265-8286. Now tested for arsenic (O'Sullivan), 5893-4.

See also SULPHITES.

## PRIMING:

Amount added at different breweries (O'Sullivan), 5800-5810; at Groves and Whitnall's (Groves), 1560-5, 1603-1612; at Threlfall's (Tomson), 3017-3032; at Manchester Brewery Company's (Deakin), 3843-4.

Regulation of, by excise (Spencer), 5336-5351; (Primrose), 6555-6; limit allowed (Spencer), 5332; (Primrose), 6619; may be exceeded if priming sugar is termed "wort" (Tomson), 3017-3024; (Spencer), 5393-5399; duty charged on (Primrose), 6561-6.

Object of (O'Sullivan), 5811-6; not unwholesome (Brunton), 5986.

All arsenic added in priming remains in finished beer (Tattersall), 171-9; (Salamon), 1288; (Delépine), 5286-7; amount of arsenic added in priming (Groves), 1713-9.

## PROSECUTIONS:

Under Sale of Food and Drugs Acts, in respect of arsenical beer (Blundell), 4973-4987; (Tomson), 3044; in Manchester (Niven), 576-592; in Lancashire (Sergeant), 4128, App. X., Table I; in Shropshire (Reid), 1939-1941; at Nantwich (Bell), 4457; in Nottingham (Hehner), 8034; in Wales (Bell), 4556-8; at Wolverhampton (Deakin), 3851, 3918-3925; at Rochdale (Bell), 4549-4555, 4559-4565, 4572-6; (Marshall), 5324-8; (Hooper), 7856; reference samples tested in Government Laboratory (Hooper), 7856A; no prosecutions in Liverpool (Hope), 1195-7.

Quantity of arsenic which should entail prosecution (Estcourt), 4113; quantity in Lancashire cases (Sergeant), 4171; greater than that entailing destruction only (Sergeant), 4175, 4203-4.

See also FOOD AND DRUGS ACTS.

## PUBLICANS:

Reluctant to destroy arsenical beer (Salamon), 1294-9; instance of delay (Hope), 985-998.

## QUANTITIES OF ARSENIC DETERMINED:

## IN BEER PREPARED WITH BOSTOCK SUGAR:

(Tattersall), 19, 41-5; (Stevenson), 2470-4; (Delépine), Appendix 12 Table I.; (Scudder), 4298-4301; (Hehner), 8025. In Manchester (Niven), 7246; (Luff), 2942-2962. In Liverpool (Hope), 1053-1071; (Raw), 6313; (Brown), 6709. In Salford (Delépine), 4859-4864. In Lancashire, etc. (Brown), 6707, 6937; (Sergeant), 4128, Appendix 11, Table III. In Cheshire, etc. (Bell), 4451-4590. In various boroughs (Estcourt), 3961, 3977-9, Appendix 9. In Bostock beer sold in 1901 (Bell), 4457. In breweries claiming rebate classified in counties (Hooper), 7857, 7867-8. Classified according to months of brewing (Hooper), 7857.

## IN OTHER BEERS:

(Hooper), 7857, Table I., note 7, 7864-6; (Jones), 1752, 1834-6; (Deakin), 3909; (Cowell), 5153; (Kirkby), 3630, 3647-9; (Sergeant), 4128, 4143-5, Appendix 11, Table III.; (Delépine), Appendix 12, Table I.

## QUANTITIES OF ARSENIC DETERMINED—cont

## IN OTHER BEERS—continued.

Arsenic to be found in any beer by severe test (Miller), 3235; (Scudder), 5302. None in Munich and Vienna beers (Delépine), 4865, 5210; or in a few English beers (Delépine), 4866, 5210-2. None in half a litre of Newcastle beer (Lovibond), 6974 6981.

See also ALL-MALT BEER.

## IN MALT:

(Sergeant), 2511-2; (Estcourt), 3982-7; (Bell), 4570-1; (Brown), 6709, 6710, 6768; (Hooper), 7880a-7882.

## IN BOSTOCK BREWING SUGARS:

See BREWING SUGARS.

## IN OTHER BREWING SUGARS:

(Estcourt), 3988-4006; (Brown), 6709; (Hooper), 7870, Table V., 7888.

## IN YEAST:

(Estcourt), 4026; (Delépine), 5270, Appendix 12, Table V.; (Brown), 6709.

## IN HOPS:

(Delépine), 5290-1.

## REBATE OF DUTY:

In respect of arsenical beer destroyed: Claimed at certain breweries (Groves), 1677-1693; (Cowell), 5133-5143; not claimed at others (Tomson), 3151-3; (Deakin), 3947; not granted if beer left the premises (Blundell), 5053-8; (Cowell), 5136; (Spencer), 5368, 5439; beer tested where claimed (Primrose), 6651; (Hooper), 7777.

Powers of Inland Revenue to grant (Primrose), 6625-6650; (Spencer), 5360-5390. Not granted on unsound beer returned to brewer and destroyed (Primrose), 6642, 6699-6701. Granted on exported beer (Spencer), 5371-5385.

## SACCHARINE:

Prohibition of, in beer (Spencer), 5425-5432; (Primrose), 6542.

## SELENIUM:

Detection of, in Nicholson's acid (Tunncliffe), 2554-2572; (Brown), 6709, 6737-6747. None found (Delépine), 5301. Detection in Bostock sugar (Tunncliffe), 2684-2701, 2724-7. None found (Salamon), 1458-9; (Brown), 6748-6750; (Hooper), 7887. Detection in beer (Tunncliffe), 2704-2728. None found (Salamon), 1460; (Luff), 2908-2921. Not looked for (Miller), 3357-3362; (Jones), 1872.

A factor in the epidemic subsidiary to arsenic (Tunncliffe), 2600-1, 2765-2773. No reason to suspect this (Mann), 3821-2. Poisonous action of (Tunncliffe), 2737-2764. No knowledge of (Delépine), 5304-5.

In Japanese brimstone (Tunncliffe), 2554. In sulphuric acid, 2575; (Davis), 6499-6505; (Dixon), 3445-3450. May be in brimstone acid, but not in pyrites acid (Garton), 6175-6182. Would be removed by de-arsenication process (Brown), 6903-5. Acid containing selenium need not have unusual colour (Brown), 6897-8.

In Norwegian pyrites (Dixon), 3466; (Davis), 6498, 6502-5. In flue dust of acid works (Dixon), 3445-3450.

Method of testing for (Tunncliffe), 2678-2683, 2691-2701. Selenium mirrors deposited at low temperature (Scudder), 4328.

## SEX:

Of persons attacked by epidemic. See EPIDEMIC.

**SODIUM CARBONATE:**

Arsenic in (Hehner), 7927, 7982-3.

**SOOT:**

Arsenic in (Delépine), 5253-5262.

**SULPHATES:**

Arsenic in sodium and magnesium (Kirkby), 3704-5.  
In sulphates used in brewing (Briant), 7212-7228.

**SULPHITES:**

Largely used as beer preservative (Primrose), 6568.  
Quantities employed (Briant), 7232-5.

Manufacture of sulphurous acid (Briant), 7233.  
Arsenic in sulphites (Briant), 7233-5; (Hehner), 7927-8; (Miller), 3303-6. None found in (Jones), 1792.

Presence of, in beer, preventing detection of arsenic (Estcourt), 3971-6.

**SULPHUR:**

Arsenic in brimstone. *See* SULPHURIC ACID.

Addition of, to fire of malt kiln (Taylor), 5613-5633;  
of hop kiln (Berry), 7595-8.

**SULPHURIC ACID:**

Price of different kinds of (Salamon), 1461-4; (Morris), 4818, 4833-6.

Use, diluted, as a beverage (Morris), 4810.

Arsenical acid should be labelled (Hehner), 7937-9.  
Acid saturated with arsenic may be sold without declaration (Davis), 6418-6421.

History of manufacture of (Davis), 6381-6495. Construction of flues (Stevenson), 2401-8; in German works (Morris), 4691-8.

Action of Glover tower (Davis), 6383-6405. Arsenic in Tower acid and in Chamber acid, 6381, 6388-6393. Arsenic concentrated in Glover tower, 6516-6520. Tower acid not in practice de-arsenicated; form in which arsenic present 6381. Arsenious acid deposited on cooling but arsenic acid not, 6426-9.

**FROM NATURAL BRIMSTONE:**

(Morris), 4639-4676; (Davis), 6381-4. Qualities of, 6484; free from arsenic (Davis), 6381, 6438-6440. Is not de-arsenicated (Morris), 4830. Liable to contain arsenic (Salamon), 1413-8, 1423-5; (Dixon), 3475.

Arsenic in Japanese sulphur (Dixon), 3476. In Sicilian brimstone (Morris), 4653-4664, 4751-4766; (Davis), 6381.

Preferred for sugar manufacture (Francis), 7343. Should be used for food purposes (Tattersall), 20-21, 152-9; (Reid), 2109, 2156-2170; (Morris), 4819.

**FROM SPENT OXIDE:**

Free from arsenic (Dixon), 3477; (Seudder), 4307-9, 4314-5. Arsenic in (Morris), 4812-7; 4639-4676, 4703-4723; (Davis), 6381. Origin of arsenic (Davis), 6443-6452.

**FROM RECOVERED SULPHUR:**

(Dixon), 3475; (Davis), 6483.

**FROM PYRITES:**

Most pyrites acid used up at pace of manufacture (Davis), 6480-2. Constitutes bulk of German acid (Morris), 4684-4700; (Davis), 6487-6492.

De-arsenication process (Dixon), 3418; (Davis), 6428-6436. Removes arsenic as well as arsenious acid (Davis), 6470-1. Can produce acid free from arsenic (Francis), 7375-6; (Stevenson), 2391. Requires constant care (Dixon), 3472; (Davis), 6381. Difficulty in uniformly de-arsenating (Morris), 4665-4682, 4744-7. Cost of de-arsenication (Morris), 4668-4674, 4678-4680; (Garton), 6171-2; (Davis), 6407-9.

**SULPHURIC ACID—continued.****FROM PYRITES—continued.**

With precautions may be used by sugar manufacturers (Salamon), 1426-1433; (Garton), 6111-6139; (Francis), 7338-7352; (Davis), 6524-5.

Mines supplying pyrites (Dixon), 3416. Arsenic in different ores (Dixon), 3461-5; (Seudder), 4312; (Davis), 6381. Pyrites ores lately more arsenical (Davis), 6394-6400.

**SYNTHETIC PROCESS:**

(Stevenson), 2398.

"SULPHUR ACID," "BRIMSTONE ACID," "STONE ACID," "B.O.V.," "R.O.V.":

Trade meanings of (Tattersall), 23-5; (Morris), 4701-2, 4712, 4733-5, 4775-4784; (Davis), 6381, 6472-3. Pyrites acid represented as "Brimstone acid" (Francis), 7338-7341, 7370-4.

*See also* GLUCOSE, SELENIUM.

**SUSCEPTIBILITY TO ARSENIC:**

Individual susceptibility (Tattersall), 19-20; (Reynolds), 371-4; (Niven), 608; (Stevenson), 2410-11, 2452-2465; (Luff), 2965-2972, 2983-4; (Kelynack), 3528; (Mann), 3798; (Sergeant), 4128; (Delépine), 5307; (Brunton), 5943; (Raw), 6348. Cannot be fully met (Stevenson), 2412-8. In men and women compared (Brunton), 5959-5960. In children, 5961-2.

**SWEAT:**

Arsenic in (Mann), 3735.

**SYMPTOMS:**

During epidemic, general account, (Reynolds), 363-396; (Luff), 2848-2858, 2865-2937; (Kelynack), 3484. Clinical differences between earlier and later cases (Tattersall), 8, 228-9; (Kelynack), 3484; (Raw), 6292. Different types (Reynolds), 370. Stages of poisoning in beer drinkers (Kelynack), 3548.

Instance of rapid development of (Kelynack), 3567; (Niven), 849-851. Earliest symptoms (Niven), 688. Duration of illness (Reid), 2103.

CATARRHAL: (Kelynack), 3504-5.

ERYTHROMELALGIA: (Reynolds), 341; (Luff), 2848; (Brunton), 5942.

*See also* KERATOSIS.

FEBRILE ATTACKS resembling enteric fever (Mann), 3781.

GASTRO-INTESTINAL: (Reynolds), 420-4; (Stevenson), 2285-8; (Kelynack), 3527; (Mann), 3729.

HEART: *See* HEART.

HERPES: (Reynolds), 341; (Kelynack), 3506-7; (Brunton), 5942.

HUSKINESS: (Luff), 2871-4.

LIVER: *See* LIVER.

MENTAL: (Reynolds), 459; (Bury), 4400.

MUSCULAR TENDERNESS AND ATROPHY: (Luff), 2857; (Bury), 4394-4405. More marked than in alcoholic neuritis (Mann), 3799-3802.

NEURITIS: (Niven), 470. *See* ALCOHOLIC NEURITIS.

OEDEMA: (Kelynack), 3615-3621; (Brunton), 5942.

SKIN: (Niven), 692-4; (Luff), 2891; (Kelynack), 3512-3; (Bury), 4366. *See* PIGMENTATION.

RELAPSE: Return of symptoms though no fresh arsenic taken (Raw), 6327-6333.

SYRUP, GOLDEN AND TABLE: (*See* FOODS.)

## TARTARIC ACID:

Liable to contain arsenic (Kirkby), 3704; (Davis), 6423. Quantity of arsenic in (Briant), 7246-8.

## TESTS FOR ARSENIC:

Different tests compared (Stevenson), 2475; (Luff), 2993-3006; (Delépine), 4928-4932; (O'Sullivan), 5819-5825; (Mann), 3803-9; (Seudder), 4320; (Bell), 4577-4584. Being investigated by Societies of Chemical Industry and Public Analysts (Salamon) 1471-3; (Hehner), 7941-3, 8002-7. Uncertainty of results obtained by different methods (Kirkby), 3639. Arsenic in beer often understated (Brown), 6761-3. (See also ANALYSTS.)

Organic matter of beer should be destroyed (Brown), 6832. Not necessary (Hooper), 7796; (Hehner), 8043-8056.

"Standard" tests for arsenic advocated. (See OFFICIAL CONTROL.)

## GUTZIT TEST:

(Stevenson), 2475; (Kirkby), 3630. Advantages claimed for (Kirkby), 3650-3685.

## MARSH TEST:

Advantages of, for beer (Hehner), 7944. Use of, at Government Laboratory and delicacy (Hooper), 7871-7. Objections to (Hooper), 7822a-3.

"Minimetric" application of (Seudder), 4268-4330. Use of hydrogen from outside source, 4271. Method would remove all arsenic even if in cacodyl (Seudder), 4289-4296.

## REINSCH TEST:

Quantitative modification of (Jones), 1793-1803; Appendix 6 (Reid), 2066-2072. Quantitative use of, by comparing sublimates (Delépine), 4928-4932, 5208-9, 5217-5225; (Tattersall), 288-295.

Application of (Luff), 3002-6; (Brown), 6757-8, 6881-6895; (Miller), 3283-3290, 3350-4; Sensitiveness in beer and water compared (Miller), 3229-3233, 3319-3324; (Delépine), 5227; (Estcourt), 3963; (Brown), 6879.

## REINSCH TEST ADVISED BY BREWERS' EXPERT COMMITTEE:

(Salamon), 1318-1329, 1534-8 (Stevenson), 2475; (Seudder), 4321. Provisional only (Salamon), 1318, 1525; (Stevenson), 2492; (Luff), 2978, 2986. Delicacy of (Salamon), 1329; (Stevenson), 2493; (Luff), 2981; (Miller), 3223-8,

## TESTS FOR ARSENIC—continued.

3261, 3307-3315; (Brown), 6878. Used at breweries (Groves), 1732; (Blundell), 4988; (Tomson), 3059. Beer passing it condemned by Public Analysts (Miller), 3401.

## ESTIMATION OF SULPHIDE OF ARSENIC:

In beer after destruction of organic matter (Brown), 6759, 6790-6830. Method adopted by Government Laboratory in 1901 (Hooper), 7777-7796; Without destruction of organic matter in beer, 7778-7796. Delicacy of method (Hooper), 7814-7839. Pure beer with added arsenic differs to test from beer brewed with arsenic (Brown), 6804-6830. No alteration made by fermentation if arsenious or arsenic acid added (Hooper), 7796. Would not recover cacodyl, 7806-8. Method tested with malt worts and malt (Hooper), 7791-5.

Solubility of sulphide of arsenic (Hehner), 7966.

## TIED HOUSES:

System of, facilitated withdrawal of arsenical beer from publicans (Lovibond), 7016. Would be refused warranty by brewer (Hope), 1163.

## TOLERANCE OF ARSENIC:

Given medicinally (Stevenson), 2452; (Delépine), 5307. During epidemic (Tunnicliffe), 2793-2799; (Luff), 2894-5; (Kelyack), 3529; (Delépine), 5307; (Raw), 6348.

See also SUSCEPTIBILITY.

## URINE:

Arsenic in (Kelyack), 3571; (Mann), 3731-3; (Raw), 6336-6340.

## YEAST:

Affinity of, for arsenic (Tattersall), 26; (Niven), 627-638; (Salamon), 1363-4; (Stevenson), 2513-5; (Miller), 3369-3379; (Sergeant), 4130-8; (Delépine), 5270-5285; (Hooper), 7846-7852. Arsenic causing degeneration of (Niven), 698, 738-750. In implicated brews had normal appearance (Tomson), 3196-9. Might contaminate ginger-beer (Sergeant), 4135-8. Did contaminate certain beers (Hooper), 7857.

Interchange of, between breweries (Blundell), 5046. Arsenic in Chinese yeast (Delépine), 5279.

YEAST FOODS: Nature of, and use in brewing (Briant), 7289-7291; now required to be free from arsenic (Briant), 7292.

## MEMORANDA.

I.—TABLE OF EQUIVALENTS OF PARTS PER MILLION AND GRAINS PER GALLON AND GRAINS PER POUND, RESPECTIVELY.

Parts per Million.	Equivalent to Grains per Gallon.	Equivalent to Grains per lb.
.048	.0033 = $\frac{1}{300}$	.0003 = $\frac{1}{3000}$

1000'0	70'0	7'0

## II.—MISCELLANEOUS.

1 gallon = 8 pints = 4.54 litres = 4,540 c.c.

1 gallon water weighs 10 lbs. = 70,000 grs. = 4,540 grammes.

1 pint = .567 litre = 567 c.c.

1 litre = .22 gallon = 1.76 (say  $1\frac{3}{4}$ ) pints.

1 litre water weighs 1,000 grammes = 2.2 lbs. = 35.2 ozs.

100 c.c. = .022 gallon = .176 pint (say  $\frac{1}{8}$  pint).

A barrel of beer = 36 gallons = 163.44 litres.

A quarter of malt = 8 bushels =  $8 \times 42$  lbs. = 336 lbs.

*Percentage of Glucose* (or other brewing sugar) means the weight of glucose per cent. of the total materials (malt plus glucose, &c.) used.

*Equivalent of Glucose* (or other brewing sugar) to *Malt*.—For Excise purposes 28 lbs. of cane sugar, or 32 lbs. solid glucose or saccharum, are deemed equivalent to 1 bushel (42 lbs.) of malt.

*Priming*.—Excise allows priming up to  $1\frac{1}{2}$  per cent. by volume (or half-gallon per barrel) of a syrup of specific gravity not exceeding 1.150.

To ascertain weight of sugar corresponding to a given quantity of priming solution, divide the excess degrees of specific gravity above 1.000 by 38.6; result is lbs. of sugar per gallon of priming solution.

Thus the maximum weight of sugar allowed as priming per barrel (half-gallon) would be  $\frac{1}{2} \times \frac{1.150}{38.6} = 1.94$  lbs.

This maximum, 1.94 lbs. per barrel, is equivalent to the addition of .054 lb. priming sugar per gallon of beer.

1. The first part of the paper is devoted to a general discussion of the problem of the origin of life. It is shown that the problem is one of the most important and interesting in the history of science. The author discusses the various theories of the origin of life, and shows that the most probable one is the theory of spontaneous generation. This theory states that life originated from non-living matter, and that it has since developed into the various forms of life that we see today. The author also discusses the evidence in favor of this theory, and shows that it is supported by a large number of facts. The second part of the paper is devoted to a discussion of the evolution of life. It is shown that life has evolved from simple to complex forms, and that the process of evolution is still going on. The author discusses the various theories of evolution, and shows that the most probable one is the theory of natural selection. This theory states that the fittest individuals survive, and that they pass on their traits to their offspring. The author also discusses the evidence in favor of this theory, and shows that it is supported by a large number of facts. The third part of the paper is devoted to a discussion of the future of life. It is shown that life is still evolving, and that it may develop into even more complex forms in the future. The author discusses the various theories of the future of life, and shows that the most probable one is the theory of the emergence of a new form of life. This theory states that a new form of life will emerge from the current forms of life, and that it will be even more complex than the forms we see today. The author also discusses the evidence in favor of this theory, and shows that it is supported by a large number of facts.

# ARSENICAL POISONING

## (VOLUME II.)

NINETEENTH DAY.

AT WESTMINSTER PALACE HOTEL.

Friday, 7th March 1902.

PRESENT:

The Right Hon. Lord KELVIN (*Chairman*).

Sir WILLIAM CHURCH.

Dr. WHITELEGGE.

Dr. BUCHANAN (*Secretary*).

Dr. ERNEST S. REYNOLDS, recalled; and Examined.

Dr. E. S. Reynolds.

7 Mar. 1902.

E. S. Reynolds.

1902.

tion of cal oms in 1900.

olic

gnen-

8287. (*Chairman*.) We had the great benefit of evidence from you in the early part of this Inquiry, and we should like now to hear what further information continued researches of your own enable you to give?—Since I was here last I have been looking out, of course, extremely carefully, for what has been happening in the case of patients with neuritis, not only at the Poor-Law Infirmary at Crumpsall, but also among out-patients at the Manchester Royal Infirmary, and I may say that I have had a great opportunity of seeing a large number of patients. As regards the arsenical symptoms, I am able to state that they have practically now all disappeared in Manchester—there are no longer any of keratosis, there are none of true arsenical neuritis, and there is no arsenical pigmentation to be seen.

8288. That is patients at the Manchester Royal Infirmary out-patient department and also at the Manchester Workhouse Infirmary? What you say applies to patients in both those institutions?—Yes, to the whole of the Manchester district. And I would also say that so-called "alcoholic" dilatation of the heart has also almost entirely disappeared from the Manchester district. Herpes has likewise very much diminished, and even the pigmentation which one used to so commonly associate with patients with vermin on them has much diminished. It still occurs in very dirty patients, but it has also much diminished.

8289. When it occurs in very dirty patients you do not think the pigmentation is arsenical?—This pigmentation used to be supposed to be always due, in the pauper class, to the presence of vermin, and we used to see a very great deal of it. We see some of it still, but nothing like to the same extent, which looks as though some of it, at any rate, formerly was related to arsenic. It has not all disappeared, but it has very much diminished even with those patients.

8290. Can pigmentation due to vermin be mistaken for arsenical pigmentation?—It is almost exactly the same to look at.

8291. By external appearance?—Yes.

8292. Have you any means of distinguishing by close washing or any examination of the skin?—I do not  
4576. 1500.—Wt. 28817.—12/03. Wy. & S.

know of any at all. I do not think it could be distinguished; it is practically the same kind of pigmentation. Then in June and September of last year we did see a few cases with arsenical symptoms, but on inquiry we always found that these were patients who had been affected during the epidemic itself. In July I saw two women who said they had not been affected during the epidemic, but the hair of both of these women, examined by Professor Dixon Mann, was shown to contain considerable quantities of arsenic, and the beer that one of them had been drinking even in September contained one-hundredth of a grain of arsenic per gallon. Of course, that is comparatively speaking nothing—a very small amount.

8293. It appeared there was arsenic in the hair?—Yes, that was present in both of these women.

8294. We hope to have some information from you on that subject later. But first can you tell me if arsenic appears in the pigmentation? Is the substance arsenic found in the pigmented skin?—I believe not, my Lord. It is not arsenical.

8295. That, of course, could not be examined generally except after the post-mortem?—Not easily, but I think it has been examined, and that is not arsenical. That is really one of the ordinary skin pigments such as you get in the negro.

8296. In scurf rubbed from the skin of pigmented patients is arsenic found?—It is found in the scales of skin that are given off when the skin scales, as it does in many of these cases of keratosis, for instance. Arsenic has been found in the scales.

8297. Especially from the scales coming from the parts where there is pigmentation?—Not necessarily; no. It has been found more on the scales from the feet and the hands. On the palms of the hands and the soles of the feet there is no pigmentation, and yet the scales from these contain a considerable quantity of arsenic in arsenical cases.

8298. And the nails both of the fingers and feet?—Those, again, have been found to contain arsenic.

8299. Have you any measured quantities of arsenic which have been determined in the hair?—No, my Lord,

No arsenic in pigmented skin;

but found in scales in keratosis, &c.,

and in nails, and hair,

A

*Dr. E. S. Reynolds.*  
7 Mar. 1902.  
I have not. examinations of hair have been done, and the results simply returned to me as "considerable quantities" or "traces," but I have not any definite amount at all. These examinations of hair have been nearly all done by Professor Dixon Mann.

8300. Have you yourself any knowledge of arsenic in the hair of people taking no arsenic?—It is a difficult thing to say that they are taking no arsenic. I have some analyses of hair which Mr. Scudder, the chemist in Manchester, gave me yesterday, and it contains minute traces of arsenic—something like, I think, 1-100th of a grain in two grains of hair.

8301. The 100th of a grain of arsenic?—Yes, in two grains of hair.

8302. That is 1-200th of the weight of the hair?—I have his figures here somewhere.

8303. That would be enormous?—No; it is .003 per cent.

8304. That is 1-300th per cent., or 1-30,000th of the weight?—Yes.

8305. That was in the hair of a healthy person not known to have been taking arsenic in any way?—Yes.

8306. Is the inquiry so far advanced that we can say that arsenic may usually be found in the hair or in the beard of ordinary healthy people?—In some cases, certainly, but not in all. In some cases it is certainly found in apparently healthy people.

*Gautier's statement as to arsenic in thyroid.*  
8307. You know, no doubt, the investigation of the French chemist, Gautier, in which arsenic in considerable proportion is found in the thyroid gland of healthy human beings, men and women?—I know all those researches.

8308. May we consider it proved that arsenic is an essential ingredient in the thyroid gland?—No, my Lord, I should not like to bind myself by Gautier's researches.

8309. Does Gautier's investigation go so far as to say that it is found in every case, or that he found it in certain cases, and did not find it in others?—I think he wished to make out that it was practically a normal constituent; but knowing what we do now of the prevalence of arsenic in all sorts of things, I think it is quite possible it got there from outside sources into the body in the cases he examined.

8310. (*Sir William Church.*) I should like just to clear up one point with regard to the presence of arsenic in the thyroid gland. What would be your opinion on that? Would it be probable or improbable that arsenic might remain locked up in the thyroid gland for a long time if it once got there?—I should think that it is extremely probable it would do, because it is a gland, of course, which has no duct, and I should think it is very likely it might get locked up in the tissues there.

8311. Do you know anything about the constitution of the thyroid gland—whether there is any affinity of any of the tissues, or their excretions, for arsenic? Can you express an opinion about that?—I should not like to express an opinion about it, but I know Professor Dixon Mann has been examining the thyroid gland, and he has not found arsenic, and, of course, he is a most thoroughly reliable observer.

8312. (*Chairman.*) He has not found arsenic?—No, my Lord. I think the experiments of Gautier ought to be taken certainly with some reserve until they are confirmed.

8313. (*Sir William Church.*) Supposing a person had either medicinally or in some way taken arsenic a considerable time before the thyroid gland was examined, you think it is not improbable that traces of arsenic might be found in it?—I think it is extremely likely, and especially as it strikes one the thyroid gland is probably the only place where iodine is found as far as I know in the body, which is not very far distant, of course, from arsenic.

8314. And it is yet an open question whether arsenic is or is not an essential ingredient of the hair?—I do not think it is an essential ingredient, because of the number of blank results that have been obtained. Some of those results I can give you in a few moments in speaking of beri-beri.

8315. Have you any patients left at Crumpsall still suffering from paralysis?—Yes, two, and these are gradually recovering. Those are the only two. We have had altogether at Crumpsall from November 30, 1900, to July 20, 1901, thirty deaths; seventeen were women and thirteen men. Of those ten men and four

women were also found to be suffering from rapid consumption. Of course, these cases do not include those which may have died before the cause of the outbreak was known. That is only from November until July. It is extraordinary the number of these cases that have died of consumption—a very large proportion—ten out of the thirteen men and four out of the seventeen women.

8316. (*Dr. Whitledge.*) Was consumption of recent origin in those cases?—That one cannot say; one finds often old consumption in these pauper cases; but it certainly looks as if it had been awakened up. Another interesting point, medically at any rate, is that the ascites in these cases, which is generally supposed to be due to liver disease, we found to be due to tubercular peritonitis in a very large number of cases.

8317. Tubercular peritonitis is included in what you call consumption?—Yes.

8318. (*Sir William Church.*) Just merely to make what you said to Lord Kelvin quite clear, the pigmentation that you observed both during the period that arsenical poisoning was going on and also since, has been generally situated on those parts of the body which are most subject to pigmentation?—No, I do not quite think so. It has not been the pigmentation situated in the same places as Addison's disease. That is to say, during the whole epidemic the face was fairly free. The pigmentation was more on the body, beginning, if anything, below the neck.

8319. With the exception perhaps of around the eyes, the face is not the place in which you get usually pigmentation from other causes than Addison's disease?—I see what you mean. That is so, exactly. But, of course, in a person exposed much to the weather you get more pigmentation on the face normally.

8320. Normally, yes; but in most arsenical cases the pigmentation has been in the axillae, the groins, and in these parts of the body in which pigmentation generally occurs, from whatever cause it may be?—Certainly.

8321. Since 1901, your experiences of neuritis, and of other changes which have been referred to arsenic in Manchester, have approximated to the experiences of other large towns?—I should imagine so, yes.

8322. You still have met with cases of peripheral neuritis attributable to alcohol?—That brings me to the next point. During this period of course I have seen in hospital work, and also in private, a considerable number of very heavy drinkers, and during this time, in the last nine months, I have only seen two cases, and those were both in private, where there were symptoms of neuritis—two isolated cases. One was a cab driver, who drank at least a bottle of whisky a day; and another was a lady that I saw only about a fortnight ago, who was also drinking, as far as we could make out, at least a bottle a day. In both these cases there were signs of neuritis. In the cabdriver there were pains in the limbs. There was some loss of power, but there was no wasting, and there were no other signs at all of any arsenical poisoning, and I do not think that he took beer. I went very carefully into the case, and I think his statement that he always took whisky was quite true. The lady was bed-ridden, and certainly took no beer. She took whisky only. In her case the symptoms were coming on rather fast. There was some wasting; there was distinct loss of power, although she could walk, and there were marked pains in the limbs. Again, there was not a single sign of any other arsenical symptom. So that these two cases—and there have been only two in all the enormous number of alcoholics I have seen during the last twelve months—these are the only two cases I have been able to pick out in which beer drinking could be excluded absolutely, and, at the same time, in which there were signs of peripheral neuritis. So that, personally, my own opinion is that alcohol will cause peripheral neuritis, but that, considering the large amount of spirit taken by various people in this country, it is certainly one of the rarest diseases if unassociated with arsenic. In pure beer drinkers there is now no peripheral neuritis in Manchester. It has all gone; it has entirely disappeared. You never see a case in the hospital, and this is not only my experience, but it is the experience of Dr. Dreschfeld, Dr. Bury, and others. And I should like to add that Dr. Graham Steel has also told me that he has not lately been able to find any cases of "alcoholic dilatation of the heart," which he had previously written upon to a large extent, and which for many years—not merely during 1900—was common in Manchester.

*Dr. E. S. Reynolds.*  
7 Mar. 1902.

Tuberculosis among epidemic cases.

Sites of pigmentation.

Rarity of "alcoholic neuritis" apart from arsenic.

None in beer drinkers.

Disappearance of "alcoholic heart" in Manchester.

Sufferers from epidemic still under treatment, 1902.

Dr. E. S.  
Reynolds.  
Mar. 1902.

8323. (Dr. Whitelegge.) These "alcoholic hearts," which have now disappeared, were found in considerable numbers?—Yes.

8324. Did they occur in heavy drinkers only?—Yes, I think so, speaking from my own experience, of course; heavy beer drinkers.

8325. Did they occur apart from neuritis or pigmentation?—Some of them did, but most of them, if carefully examined, had neuritis.

8326. Have you any records of this condition of heart occurring apart from alcohol—from arsenic derived from other sources than beer?—I have not; but in the cases reported—in Brouardel's cases at Havre—the same condition occurred. I think it was in this Havre outbreak, where the poisoning was homicidal, in which arsenic had been directly administered, that Brouardel describes œdema occurring, and heart failure, and so on, and the dropsy coming on also.

8327. You mentioned that besides this heart condition, neuritis, herpes, and pigmentation have very much diminished, and even the pigmentation attributed to vermin?—Yes.

pigmenta-  
n.

8328. What significance do you attach to that? Do you regard it as meaning that the arsenic caused a tendency to that form of pigmentation, or that what was truly arsenical poisoning was mistaken for the other?—I think that a great deal of what we called the pigmentation due to vermin was arsenical.

8329. But do you think that, given chronic arsenical condition, the tendency to pigmentation from vermin would be increased?—I certainly think so, because you get a double irritation of the skin layers.

herpes.

8330. In the case of herpes, do you think the general distribution of arsenic among the beer drinking public increases the tendency to herpes?—I think it frequently caused a great deal of the herpes.

8331. But some herpes still remains?—Certainly. I should not like to say all herpes is arsenical.

8332. I only want to be clear whether you meant that arsenic as a predisposing cause to herpes has now been removed?—Certainly it has been removed. The number of cases is now quite few. You occasionally meet one in the ordinary way in hospital practice, whereas before one saw quite an epidemic of them.

8333. The pigmentation has diminished greatly. Will you kindly tell us in what light you are now inclined to regard the pigmentation in terms of arsenic, and of alcohol?—Would you expect to find pigmentation from arsenic alone?—Certainly. I do not think alcohol will cause pigmentation.

8334. I meant in combination with arsenic. You would expect to find pigmentation from arsenic alone?—Yes, I have seen that. It is well known that arsenic, given as a drug, may cause most marked pigmentation.

8335. Of the same kind that you have described?—Exactly the same type. I do not think alcohol had anything at all to do with the pigmentation.

8336. You do not think alcohol adds to the tendency?—Not the slightest.

8337. (Chairman.) Alcohol drinkers who have no arsenic whatever would not show pigmentation in any case?—No, I do not think so.

8338. (Dr. Whitelegge.) Would you say the same thing of neuritis—that the alcohol does not add to the tendency?—There I am rather inclined to think that the alcohol may, because, as I have said with regard to these two cases, I cannot now get away from the idea that alcohol will cause neuritis, but I certainly think it is extremely rare if it does, and, of course, it has never been of the marked type of the arsenical neuritis. I have never seen such marked types except from arsenic.

ity of  
ritis  
sed by  
alcohol.

alcoholic  
ritis in  
Manchester  
in other  
towns  
compared.

8339. (Sir William Church.) Then you would think that your numbers, so far as they go—you must remember it is only a few months—would now show that alcoholic neuritis is less common in Manchester and its district than it was hitherto supposed to be in other large towns; I mean, that was one of the points that struck me so much, the large number of cases of peripheral neuritis that you used to have in Manchester as compared with what we were acquainted with in London?—Yes. Now I can give you some numbers which will show that. When I was at the infirmary as Resident Medical Officer, from 1887 to 1891, there were 20 cases of alcoholic paralysis, so-called, a year, in 118 beds or 120 beds. Now I have 800 beds of my own

at Crumpsall, and I have a very large out-patients' department. I do not know how many cases are received there, but it is a very large department, and amongst all those hospital patients I have not seen a case of neuritis in the last nine months, except such as one could trace to the previous epidemic of arsenic—people who had had arsenical neuritis, and who either came back and said their pains were a little worse again, or something of the sort. I have seen only two cases in private.

8340. (Chairman.) In respect of alcoholic neuritis, Dr. Kelynack told us in the Manchester Royal Infirmary from 1892 to 1899 they had from twelve to twenty-one in-patients each year. That, I think, agrees with what you have been telling us?—Those are a different series of years, and you see the same proportion holds.

8341. Would you say there is none now?—We have not seen a case, I think, for the last nine months in the Manchester Royal Infirmary.

8342. That illness of which there were twelve to twenty-one in-patients each year between 1892 and 1899—there is no more of that now?—No cases at all. We have not seen one in the Manchester Infirmary for about the last nine months.

8343. Would it be right to infer that those cases which prevailed so much from 1892 to 1899 were really due to arsenic?—Inductively one would say yes. You have certainly removed, as I shall be able to show, a factor—namely, beer containing noteworthy amounts of arsenic, and the results which previously were attributed to beer as beer or as alcohol, have gone. By induction one would be inclined to say that previously arsenic had been the factor which occasioned these results.

8344. And there is no other difference in the régime between 1892 and 1899 and the present régime than that which has resulted from the inquiry into arsenic, and the means taken to prevent arsenic from getting into beer?—I do not think so, my Lord. I am sure the people are still drinking; they have not stopped drinking, that is quite clear. The Revenue Returns, I think, would show that.

8345. (Sir William Church.) I might ask you one or two questions. We have the returns from some other large hospitals besides Manchester. For instance, at St. Bartholomew's we find that out of a total of medical in-patients per annum—6,400—there were in five years forty-two cases of peripheral neuritis. Take the medical cases alone—there was an annual average of 2,441. That would be over 11,000 medical patients, among whom we get forty-two cases of peripheral neuritis?—That is an average of about eight a year in over 2,000 patients. In Manchester we got twenty a year in an average of 1,300 patients.

8346. Quite so, but I wanted to compare the condition of Manchester now with the condition of some of the other large towns in former years, so as to see what it is like now. We imagine Manchester is free from arsenical poisoning, and I wanted to see whether the numbers we now get approximate to the cases which were in other large centres of the population, and if that was the case we might conclude that they had been arsenic-free in former years?—I see the point, and I should imagine yes, or that perhaps Manchester may now be below other towns. Of course, I have not seen absolutely every case that has occurred in these two hospitals during the last nine months, and it is quite possible there may have been two or three from pure alcohol, just as I have seen two cases in private undoubtedly from pure alcohol—undoubtedly from spirit drinking.

8347. Considerable weight was laid by those who thought that all the neuritis in Manchester might be due to arsenic upon the fact that so-called alcoholic neuritis was very rare in Scotland?—Yes.

8348. But I find that in Scotland, in the Glasgow Royal Infirmary, out of a total number of 2,420 medical cases in five years, that would be the average number of medical cases a year?—That is the average.

8349. That the total number in five years was fifty-three, which you see is higher in Glasgow than it is in St. Bartholomew's in London?—Yes, but I should like to point out a fallacy there. It is generally supposed that in Edinburgh and in Glasgow the working man drinks spirits, and even Scotch physicians have told me so. But it is not the case at all. If you ask the employers of labour about it, who know the habits

Dr. E. S.  
Reynolds.  
7 Mar. 1902.

Dr. E. S.  
Reynolds  
7 Mar. 1902.

of these men intimately, you will find they undoubtedly drink beer, and they especially drink beer in Glasgow. They do not always drink spirits, by any means.

8350. That is not my point. My point is that your figures are now approximating, and I want to see how nearly they approximate, to what has been the figures of this disease in the other big centres. We know that your population were poisoned by arsenic; we do not know at present whether the populations in the other big centres were in any way affected by arsenic or not?—I see; but of course it has been shown—

8351. I think the evidence given to us from Manchester would hardly have led us to imagine there were as many as fifty-three cases of peripheral neuritis in the Glasgow Royal Infirmary in nine years, when we were told it was so excessively rare?—Yes, and so was I told that too. Sir William Gairdner was very strong on that point.

8352. In the Western Glasgow Infirmary, out of an average of 1,440 medical cases a year, we find that in five years there were nineteen cases of peripheral neuritis, and at Dundee, curiously, the figures are about the same—we are informed that there were nearly the same number of medical patients, 1,423 per year, and that the total in five years was eighteen?—That only amounts to three a year, with a larger number of patients than they have at the Manchester Royal Infirmary, whereas with us it was twenty.

8353. Now you think you may have had two in the months between November and July?—It is quite a possibility that there may have been two or three.

8354. That is rather approximating to those numbers that we got in our other returns?—That is so. I should say, taking it broadly, that Manchester now is in the condition of Glasgow and Dundee as regards neuritis.

8355. The highest figures, of course, are those which we got from the London Hospital in the East-End of London, and there, with an average of 4,600 medical in-patients a year, they get as many as 129 cases of peripheral neuritis in five years?—That is about twenty-five a year, with more than three times the number of beds than the infirmary. Of course, there they are largely gin drinkers in the East-End of London, are they not?

8356. I think that some of them drink many things. We have actual returns of only one year—out of sixteen cases during part of 1901 four drank beer only, three spirits, and eight both. You would be prepared to say now that the number of new peripheral neuritis cases in Manchester has dropped down to the level, or even below the level, of the cases in the other large centres of population?—I should say certainly below the level. It is extraordinary how free it is. You do not see them; they have gone.

8357. (Dr. Whitelegge.) Then you would not attribute the whole of that drop in Manchester to the use of a particular glucose—because, if I remember rightly, that did not begin until about 1899, and the pre-eminence of Manchester in the matter of neuritis existed before then?—No. Apart from the big epidemic in 1900 I think it was not necessarily the glucose, but very largely the malt also.

8358. You think there has been an improvement in the malt as well?—An enormous improvement. The South Yorkshire cokes they will not have now for malting.

8359. Cases of neuritis attributed to alcohol, without mentioning arsenic, are still going on in small numbers, and especially in London, as Sir William Church said. Would you suspect some of those to have relation to arsenic still?—I should see that every case was most carefully gone into before I would be prepared to exclude arsenic, even in London.

8360. Is there any practical suggestion you could make by way of a crucial test in determining whether a case of neuritis put down to alcohol had any arsenical origin?—There is one thing which sounds almost an impertinence, I was going to say. The investigation of the patient must be extremely searching. I say that because I have seen extremely good men examining these cases and entirely miss some of the symptoms—absolutely miss them; look at them and not notice them, and then confess they were there when they were pointed out to them. It seems rather an impertinence to say so, but I have seen so many extremely well-known men miss the symptoms of keratosis and pigmentation that the examination of the patient must be extremely searching. Another point is that the hair should in all cases be examined. If it contains a mere trace I should not think much of it; if it contains a con-

siderable trace, or a considerable quantity, then I certainly think the history of the patient should be gone into, that all the foods and drinks, or some of them, at any rate, should be examined before you can exclude arsenic, especially the drink.

8361. (Chairman.) Would not the examination of the hair be a very elaborate chemical process?—I believe now that it is fairly simple. I do not quite know what it is. I am not a chemist, I am sorry to say; but Dr. Dixon Mann has got now a fairly simple method, and Mr. Scudder also, and it does not take so long as it did, and it is much more reliable than it was; but it requires great care.

8362. If there is no arsenic found in the hair, you would take that as evidence, *pro tanto*, against the fact that the disease was due to arsenic?—Not necessarily. I think it would be in favour of it not being from arsenic; but, again, I have asked Professor Dixon Mann whether he would take it, if there was no arsenic in the hair, that the case was absolutely not arsenical, and he said, "No, you cannot go that far." The other day he had a case at the Salford Hospital, in which he felt pretty clear that there was some arsenical symptoms, and there was no arsenic in the hair. So that he says you cannot take it as an absolute rule.

8363. (Dr. Whitelegge.) What importance do you attach to the discovery of arsenic in the urine? It has been suggested that there are cases in which arsenic is found in the urine of persons who are not supposed to be taking arsenic?—I should want very strong proof of that.

8364. Is it not within your experience or knowledge that arsenic is found in the urine of people who are not taking arsenic in one form or another?—No. To show how difficult these cases are from an analytical point of view, Professor Dixon Mann tells me that if he has used for these investigations a flask in which there has been arsenic in the flask in his experiments, he has then cleaned that flask and examined it in a good light, and there has not been a single speck or stain inside the flask; it has been apparently absolutely clean. He has taken that flask again, and in not a few cases without putting anything further into it obtained his arsenical mirror. He says you cannot depend on a flask which has once contained arsenic in making the next experiment. The result is that he never uses a flask a second time in which arsenic has been present. He says you cannot rely upon it being absolutely arsenic-free, if arsenic has been once in it. That shows how many results, such as these examinations for urine you are mentioning, may be fallacies. He keeps one set of flasks which are absolutely arsenic-free, and if there has been any arsenic in the flask he never uses it again.

8365. You have not only examined the hair for arsenic, but you have examined the urine?—Yes.

8366. And if you found arsenic in one or the other you would consider there was ground for assuming arsenical causation?—Most certainly, if it was in the urine.

8367. Just one other question. You told us of one 100th of a grain of arsenic being found in the beer consumed by certain patients?—Yes.

8368. When was that?—That was in September.

8369. Beer containing that proportion of arsenic was consumed recently and associated with recent cases?—I have here some tubes Mr. Scudder did for me yesterday for the Commission and asked me to bring down, in which he has collected a considerable number of Manchester beers, and two-thirds of them are arsenic-free. He can get no reaction whatever.

8370. At what date was that?—This week—since Monday.

8371. Recent samples?—Yes. The one-third of them contain traces, and the worst contain not more than 100th of a grain per gallon of beer. That is this week. Those tubes I have here. (Tubes exhibited.)

8372. (Sir William Church.) Those are presumably beers which have been recently brewed?—I should imagine so.

8373. (Chairman.) Going back to the question of the presence of arsenic in beer for years past, what would be considered safe in respect to the quantity contained in beer? Given a susceptible person taking a moderate quantity of beer, say two or three pints a day, containing say one-fiftieth of a grain per gallon, might harm result, and on what grounds would you say that harm may result or harm could not result?—I should say, taking it at

hair

10 grain  
arsenic per  
gallon of  
beer would  
probably do  
harm.

E. S. four pints, if I may, that is half a gallon, if it contained one-fiftieth of a grain per gallon I do not think any harm could result. That would only mean taking one-hundredth of a grain of arsenic per day—one minim of liquor arsenicalis, a very small medicinal dose. But, given a susceptible person, I should not like to see this dose much exceeded, especially as there is no need for it to be there.

8374. But you do not think harm could result from two or three pints of such beer per day?—I do not think so.

8375. Do you know anything about the alleged tolerance of the Styrian peasants to arsenic?—Only what I have read, that certain of them can do so.

8376. It is said that after a little time they can take large quantities of arsenic without being poisoned?—Not in my own ordinary experience in hospitals; if you go on increasing it you are certain to get poisoning—in England, at any rate; I do not know about Styria.

8377. Can you give instances of what we are all told so often about Styrian peasants. Do you think it is true or not true?—I should not like to say. They have only to produce one of the Styrian peasants to negative anything I might say about it. It is quite possible some of them may be able to take large quantities of arsenic. I am informed by a late manager of the tin mining works in Singapore that the coolies who smelt the tin work all day long in an atmosphere containing considerable quantities of arsenic do not suffer, and they are men, moreover, who have not been affected with beri-beri. They are the men who have been gradually selected in the course of years from the coolies who have been able to stand the mining. They are big men and specially fed, because it is supposed to be a dangerous occupation more or less, and these men do not get any symptoms, although they are working in an atmosphere containing large quantities of arsenic. It looks there again as if certain men could stand it. That is the only evidence I can bring, apart from the Styrian statements, to show there may be something in it.

8378. Those men must inhale considerable quantities of arsenic?—Yes. My information I had direct from the manager of these works.

8379. Are they sometimes attacked with beri-beri?—He says very rarely, the smelters. But again he says that these are picked men who have been able to stand the mining.

8380. What class is it that is affected by beri-beri?—The ordinary mining coolie is very much affected, but of course they are imported fresh every year, thousands of them.

8381. Is it now considered probable that the beri-beri is arsenical poisoning?—If I may go into that point, with a little more detail I would say that some time during the epidemic, speaking with Major Ross, and knowing that beri-beri was so like the so-called alcoholic neuritis, I thought it was possible and worth investigation whether the beri-beri—which, of course, is a terrible disease in the tropics—was possibly associated with arsenic. Major Ross, about September last year, brought over from West Africa an American lady, a missionary's wife, suffering from beri-beri, and asked me to see her with him in Liverpool. I went to see her. She was certainly not an alcoholic; she was a total abstainer, and yet she had all the symptoms of neuritis well marked, and also slight pigmentation, very marked pains in the legs, and the ordinary typical appearance of an arsenical case. She had had some rash also. She was a fair-haired woman, and therefore we thought it was possible there would not be any pigmentation. Her hair was examined by Professor Dixon Mann, and was found to contain, as he says, not mere traces, but considerable quantities of arsenic. Where she got it from we could not tell. She had lived almost entirely on tinned Californian fruits. Those fruits, I may say, have been again examined by Mr. Scudder, who asked me to bring the tubes here, and they have been found practically free. He has examined pears, apricots, and a whole lot of Californian fruits, and they are practically free. The most he found was 100th of a grain in a gallon of syrup, and, of course, nobody would take that. I think the Californian fruits, so far as his examination goes, can be set aside. Those tubes I have here also. It was at first thought that this idea of it being arsenical was very far-fetched, but quite recently evidence has been forthcoming to show that it is not quite so far-fetched. In the Indian Medical Gazette for September, 1901, Major Anderson reports two outbreaks of beri-beri on board ship, in which mouldy rice, heat moisture, insanitary

conditions, scurvy, and alcoholism could be excluded, but the epidemics were by him clearly traceable to supplies of food obtained from Bombay in each case of the epidemic. Of course, he did not know at that time anything about arsenic. Then in the Perak Medical Report for 1900, Dr. Fox, the Acting State Surgeon, mentions that attention is being paid to the fact that arsenic may be the cause of the neuritis in beri-beri, and he quotes Dr. Conolly, the district surgeon at Batughia, who, in his annual report, says that up to the present a chemical analysis, of a not profound character, it is true, has failed to find arsenic in the urine of beri-beri patients. He goes on: "and in support of the arsenic theory I would point out that 95 per cent. of beri-beri cases treated are Chinese; and quite 90 per cent. are miners by occupation. When we know that arsenic in combination with other metals is common in the soil, where these Chinese have to stand for hours while searching for tin, we may regard the possibility of arsenic as a cause for beri-beri as being something more than problematic." Since then Professor Dixon Mann, if I may give this evidence, has, I know, examined the hair of 24 cases of beri-beri patients who have been sent to him from various parts of the world. Eighteen of those were blank; there was nothing in them. Six of them contained arsenic; I do not know in what amounts. Then Dr. Hughes, of Her Majesty's ship "Hamadryad," the hospital ship at Cardiff, recently sent me the hair of beri-beri patients who had come from Rangoon. This hair I again asked Dr. Dixon Mann to examine, and he very kindly did so. Two of them yielded no arsenic; one of them yielded an appreciable amount of arsenic, and one of them, the fourth, yielded more than a trace of arsenic. So that although I do not think that the arsenical origin of beri-beri is proved, still I think it is a subject that is well worth investigating, in the tropics more thoroughly, because it is such a fearful disease there. It is so very prevalent, and so extremely fatal. Then there is another point in the tropics also. The Hon. W. C. Brown, M.D., has informed me by private letter that in Acheen, an island somewhere opposite Singapore, they spread arsenic on the rice fields to kill the rats off the crops they put arsenic on the field. He has lived there, and he says it is well known. So that, at any rate, I think it is well worth investigating by tropical observers.

Dr. E. S. Reynolds.  
7 Mar. 1902.

Arsenic in hair of beri-beri cases.

Use of arsenic on rats.

8382. (Chairman.) Beri-beri has been sometimes, I believe, traced to the use of rice that was supposed to have suffered from fermentation or other injurious process?—Yes.

8383. Would that be rice dosed with arsenic in the way you now describe?—I should think it is quite possible it is in the grain, if they put it on the fields. I should think it is very likely in the grain. It has been clearly shown in some epidemics to be due to rice. In the Japanese Navy, I think, by altering the diet they got rid of beri-beri altogether. It used to be extremely prevalent in the Japanese Navy, and by re-arranging the diet they got rid of the beri-beri entirely. So that in that case it was food in some way or another.

8384. Do you know what the alteration was?—They lessened the rice, and I think they gave more nitrogenous food, as far as I remember.

8385. Is that custom of putting arsenic on the rice fields largely prevalent, or only in some exceptional cases?—That is the only evidence I have, and I could not say.

8386. The suggestion, which seems worth further inquiry, is that if giving up rice in the Japanese Navy was one of the means adopted successfully to do away with beri-beri, the rice might have been poisoned?—That is merely a suggestion for the basis of future work. I think it is being investigated by a good many tropical observers now.

8387. Going back to the case reported by Major Ronald Ross regarding the American missionary lady who was a total abstainer, we are told that arsenic was found in the hair—"it contained not a mere trace, but a considerable quantity of arsenic." Might it have been that it got in by an arsenical hair wash?—No. We inquired about that, of course, very carefully. She had not had any hair wash, and she had not as far as she knew—and she was an extremely intelligent woman—she had never taken any arsenic as a drug. Of course, she could not be absolutely certain. She knew what she had taken up to a certain extent. She said she has been taking quinine and some other drug, but that she had not taken any arsenic.

Dr. E. S.  
Reynolds.

7 Mar. 1902.

8388. Had she been taking rice—living much on rice on the West Coast of Africa?—She said she had lived principally on tinned fruits, and tinned foods generally.

8389. Can you say anything of the quantity of the hair of that lady which was examined?—I am afraid I cannot give the exact weight, but I cut it off myself. It was about eighteen inches long and about the thickness of a pencil. I took a long piece so that it could be examined from end to end.

8390. Details of the chemical examination would be very useful to the Commission?—Dr. Dixon Mann's letter was "From 3 grammes of the hair—that is five grains, of course—I got as much arsenious oxide as I did from the same weight in the general run of cases at the time of the outbreak of epidemic arsenical poisoning." From 5 grains of the hair he got as much arsenic as he did from the same weight of hair in the cases during the arsenical outbreak—the beer cases.

8391. Five grains of hair, that is 3 of a gram. ?—Yes. He says, "You may accept it that the arsenic I found proved that a considerable quantity had been taken into the system of the patient either by administration as medicine or in some other way." Of course, he did not know how it had been obtained any more than we did.

8392. You have told us that the lady had not taken any arsenic medicinally?—She had not, as far as she knew.

8393. From the large quantity it seems that somehow accidentally she must have taken arsenic?—Yes, certainly. And, of course, one may mention that beri-beri did occur in the same district. She came from somewhere up-country—I forget just now where—on the West Coast, and it was known there. Major Ross saw her there and brought her over himself, and he told me that nobody there doubted for a single second that she had beri-beri. It was diagnosed as being a typical case of beri-beri, and he was asked to bring her home because she was supposed to be dying.

8394. Did the lady recover?—Yes; she got all right as in the arsenical cases.

8395. Was she damaged in her health?—No. She was doing extremely well the last time I saw her, beginning to move her limbs and going on all right.

8396. But she was so ill when she left West Africa that she was considered to be like a dying person?—Yes. She was not supposed to be going to get home alive or live more than a few days, but it was the only chance to remove her outside of the district. That is the usual treatment for beri-beri, to remove the patient out of the district.

8397. There was no doubt it was something in the food or air of the district?—It certainly looked like it in that case.

8398. (Sir William Church.) You mentioned the coolies who worked at the tin smelting. Have you made any inquiries yourself as to the workers in arsenic in this country?—No, none at all.

8399. We shall perhaps have other evidence on that. You have not made any inquiries about beri-beri in Java, have you?—No, I have not had any opportunity at all. This, of course, is a question which ought to be investigated on the spot.

8400. I mean it is stated, and I think proof has been brought forward, that Europeans in Java suffer largely. There are a large number of cases of beri-beri among the Dutch troops?—I believe that is so.

8401. But you have no information?—No, I have no information at all.

8402. (Chairman.) Would you go back to the question of the presence of arsenic in beer for years? Will you kindly give your own statement from your *précis*?—From my clinical observations during the last seven or nine months I am driven to the conclusion that the disappearance during this time of so many symptoms which were formerly described as due to alcohol can only be explained by the elimination of arsenic from alcoholic beverages, and as a corollary that arsenic has been present in alcoholic beverages to an extent dangerous (at any rate to a few drinkers, especially susceptible) for many years, and possibly from a source entirely independent of contaminated glucose.

8403. Can you also tell us about cases which we understand have recently occurred at Halifax?—The Halifax cases I visited on January 21st at the request of Dr. Hodgson. They were in St. Luke's Hospital, Halifax. I saw there five cases, four men and one woman. I do not know whether you wish for the names. One man,

named Lee, had very marked pigmentation, a hoarse voice, marked loss of power, and pains, but he had no keratosis. This man was the colour of chocolate.

8404. All over?—Yes, all over.

8405. Over the face and body?—Not so much the face; that was darkish, but not so marked as on the body.

8406. How long might it have taken for that colour to be developed over the whole body?—I should put it possibly at two or three months.

8407. Had he that colour when he came in the hospital?—I believe so, yes. A man named Whalan had marked loss of power, marked pains, some keratosis, and no pigmentation. In a man named Marsden I did not notice many symptoms. I believe, as a matter of fact, some arsenic had been found in his urine; but clinically, apart from the chemical question, there were not many symptoms. A man named Shearing had very marked keratosis and loss of power, and marked pain, and a hoarse voice. A woman named Lowrie had pigmentation and pains, and keratosis, and loss of power. So that four of these cases, three men and one woman, were clinically most undoubted cases of arsenical poisoning of a fairly marked type. Some of them were of a very marked type; there was no doubt about them whatever. You could tell when you went into the ward. In two cases I went straight up to the patients; they were strange wards to me, but from the look of the patients I went straight up to them. There was no doubt of them at all; they were marked arsenical poisoning cases. Where the arsenic had come from I do not know. But clinically there was no doubt they were arsenical poisoning cases.

8408. Was there peripheral neuritis in each of those cases?—In each case except Marsden, in which I say the symptoms were very few so far as I made out. In each of the others there was some neuritis, loss of power, and pains.

8409. In an original fatal case mentioned, Dr. Hodgson chemically proved the presence of arsenic in the body?—That I do not know anything about. I did not see the case to which you refer, the one the first inquest was held upon. The man—McNulty, I believe his name was—was dead when I was there, and I do not know anything about him.

8410. Had the urine been examined?—That I cannot say; I do not know.

8411. Is it usual to examine the urine of patients admitted to hospital and suspected of being arsenical?—Yes, one would examine certainly in a recent case suspected to be suffering from poisoning by arsenic.

8412. (Dr. Whitelegge.) Then four, at least, of these cases were well-marked arsenical poisoning?—I do not think there is the slightest doubt about it.

8413. They were diagnosed by Dr. Hodgson before you saw them?—Yes.

8414. Dr. Hodgson had seen cases at Crumpsall?—Yes. He had seen them at the Manchester Infirmary—my out-patient department.

8415. But he had seen them with you at Manchester?—Yes. He was one of the students there.

8416. Were they recognised by the other medical men at Halifax?—That I cannot say. I do not know at all.

8417. I have a report here of the inquest, and the question arose how far the death in the case of Lee—it was the second inquest, was it not?—Yes. That was the man I saw.

8418. The question being put: What, in your opinion, was the cause of death? the reply from Dr. Woodyardt was, "I should say that he died from acute croupous pneumonia. There is no doubt he had arsenic in the system, but I cannot express an opinion whether it contributed to his death or not. Before the post-mortem I was of opinion that he died from arsenical poisoning; after the post-mortem my opinion was very much modified." You saw Lee some days before his death?—I saw him on the 21st January; I do not know when he died.

8419. The inquest was on February 7th?—He would die within ten days, at any rate.

8420. At that time did you regard his as a grave case of arsenical poisoning?—Yes, I thought Lee was going to die as soon as I saw him.

8421. From arsenical poisoning?—Well, from his general condition, which was arsenical poisoning. The

Dr. E. S.  
Reynolds.

7 Mar. 1902.

"Alcohollic neuritis before 1899 attributable to arsenic."

Halifax outbreak, 1902.

Symptoms.

fact that he died from pneumonia certainly does not exclude arsenic in a peripheral neuritis case; that is what they often die of.

1902.

8422. You say arsenical poisoning is arsenical poisoning even if it occurs in a diseased person?—Certainly; these neuritis cases not infrequently, and paralysis cases generally, not infrequently die of pneumonia. Pneumonia is a mere termination of the illness, but because they die of a termination you cannot say the primal cause is not the cause. That is the cause which puts them on their backs, and puts them in a weak condition.

8423. You gave us particulars of cases in which at the time of death phthisis had been given as the cause?—Yes.

tuberculosis of the lung.

8424. You regard those in the same light?—Certainly. I cannot help thinking that, contrary to what is being done just now in giving arsenic to phthisical cases, arsenic puts a person in such a condition that they get very rapid phthisis. One cannot get away from the idea; the phthisis in these cases is so extremely rapid and so prevalent—10 out of 13 men. The proportion is too great to neglect.

8425. (Sir William Church.) Just to clear up one point. I rather gather from what you said before that these cases were rather what we should term cases of general tuberculosis than phthisis. You said that the ascites was due to tubercular infection of the peritoneum?—That is so.

8426. Later leading to more rapid disintegration of the lungs?—That is so. It is quite possible that some of them may have been old tubercular subjects. That I do not know; but as soon as they have apparently got this arsenical poisoning the consumption runs riot in the most extraordinary way.

8427. Did any of them die with tubercular meningitis?—No, I do not think so. I do not remember a case of that.

8428. But especially with general disseminated tubercle through the abdominal organs?—Yes.

8429. Were there any masses of tubercle in the organs as well as on the peritoneum?—No. It was more on the surface of the peritoneum. The greatest mass of the tubercle was in the lung.

8430. Do you think that in all cases it was in the condition of breaking down in the lung?—Yes; it was mostly a rapid breaking down.

8431. Not quiescent?—Not quiescent.

ask.

8432. (Dr. Whitelegge.) Can you suggest why an outbreak should have occurred in Halifax and not elsewhere? Are you aware of any other local outbreak since the epidemic in Manchester and elsewhere?—No, none.

8433. Can you suggest any reason why it occurred in Halifax?—I should think their beer ought to be examined. I do not know whether it has been, and I should think the malt ought to be examined too; that is all I can suggest.

8434. You do not think an outbreak of that sort could occur and escape observation?—It might do by careless observers; but I do not see how you could possibly miss those cases at Halifax, especially when several came under the notice of a single observer in a short time; they were so marked.

8435. Dr. Hodgson identified all, did he not?—He identified every one.

8436. And as far as you know other medical men in Halifax were equally on the alert?—It is quite possible. I know a good many of them, but I do not think any had seen the Manchester cases except Dr. Hodgson.

8437. Very many medical men, not only in Manchester, but in neighbouring counties, have been to see the cases at Crumpsall—to see your cases?—Yes; a good many have seen them.

8438. So that knowledge of the symptoms is now pretty widely diffused?—I think so now. I think if a distinct outbreak such as the Halifax outbreak occurs in any other town it will be certainly found out.

8439. Would you say as much of an outbreak of that kind occurring before the Manchester epidemic to which you drew attention?—No.

8440. Assuming for a moment that it had happened five years ago?—I feel pretty certain it would not have been found, and my reason for saying that certainly is this: That able physicians in Manchester, until I hap-

pened to find out what the cause of it was, let all these cases go for six months. I did myself. We put it down to beer and so on.

8441. So that this, which in your own opinion was an epidemic of arsenical poisoning through beer, would have escaped notice altogether?—I have no knowledge that it was through beer in Halifax.

8442. But it would have escaped notice before this outbreak of arsenical poisoning had called attention to the matter?—I do not think there is any doubt about that. I think it would have certainly escaped notice.

8443. Just two questions here on details. You said in reply to Lord Kelvin that you thought small quantities, such as 1-100th grain daily, could not in practice cause mischief?—No more than 1-100th grain—I do not think it would.

1½ grain of arsenic daily, considered harmless.

8444. In what light do you regard the cases to which reference is made on the top of the second page of your proof. You mention that with "two exceptions they were women who said they had only recently (about May) become affected; in each of these cases Professor Dixon Mann found a fair quantity of arsenic in the hair, and Mr. Scudder, in my presence, examined some beer and stout (which one of the women had consumed), and minute traces (about 1-100th grain  $As_2O_3$  per gallon) were found." Do you think of that quantity of arsenic as having done no harm, and as not being related to the disease?—In that particular woman at that time?

8445. Yes?—I do not think so. I think it was an old case.

8446. They had consumed beer containing a greater proportion of arsenic than that?—Yes, and previous to that. I do not think it was that one-hundredth that did it. I only mentioned it to show that it was arsenic in that beer she was drinking. I obtained it. Mr. Scudder examined it.

8447. And even in a susceptible person you would say one hundredth of a grain consumed daily is practically harmless?—I should think so. I have given large quantities of arsenic in all sorts of doses, and I have never seen one minim of liquor arsenicalis produce any symptom.

8448. I want to be clear as to what inference you draw from the absence of arsenic in the hair of a suspected case of arsenical poisoning. Do you mean that the real absence of arsenic is not a disproof of arsenical causation of mischief, or do you mean that the analysis requires great skill, and, therefore, a reported absence does not prove much unless you can depend on the skill of the analyst?—No. Taking the skill of the analyst as the highest and supposing arsenic was found absent, it certainly would be a point against the case being arsenical poisoning. But I do not think it would be an absolute proof, from what Professor Dixon Mann has told me.

Significance of arsenic in hair.

8449. So that although arsenic has an affinity for these tissues, it is not to be assumed it always finds its way into the hair?—According to what Dr. Dixon Mann tells me, and he has made most careful investigations over a very large number of cases.

8450. (The Chairman.) In a well-known text-book "Principles and Practice of Medicine," by Ostler, 1901, we have a remarkable statement:—"J. J. Putnam, an American Chemist or Physiologist, has shown that it is not uncommon to find traces of arsenic in the urine of many persons—thirty per cent.—in apparent health." If in thirty per cent. of people in perfect health apparently arsenic is found in the urine, how are we to explain where that came from, and what must we reckon from arsenical testing of the urine in cases of poisoning?—I should want that confirmed.

and in urine.

8451. You do not feel quite confident in the statement I have read?—I should want several observers to find exactly the same before I believed it. It may be true.

8452. (Dr. Whitelegge.) Would not you go further than that and say if the arsenic has been excreted it must have been acquired in some way?—Yes.

8453. So that all that that would amount to would be that there was arsenic which was being excreted, and had not given rise to symptoms which were noted?—Yes. It must be coming from somewhere. Supposing it is always present in the urine from those patients, it has got to come from somewhere; if there is an output there must be an input somewhere; it cannot be coming from nothing.

Dr. E. S.  
Reynolds.

7 Mar. 1902.

8454. (Sir William Church.) You have already drawn our attention to the apparent fallacy that unless the examiner of the urine is aware of the difficulty of cleansing the flask or of the possible contamination from the glass of the flask a fallacy is introduced?—Exactly. What might happen quite easily would be; he has say two sets of apparatus, if you like, and in one he gets arsenic from a person who has been taking arsenic. He goes on with a flask, and cleans it, and goes on examining the next person's urine, and again gets arsenic, and so he gets this 30 per cent. easily enough if he is not aware of that point. He may be; but extreme care ought to be taken in these cases. I think that statement requires very strong confirmation before one can act upon it at all. There are some of these tubes here, which, perhaps, the Commission may like to see. They have been given to me by Mr. Scudder for the purpose. That is a tube showing the arsenic from one grain of reduced iron in the market; it contains one per cent.

8455. (Chairman.) One grain of reduced iron?—What we use in medicine, *ferrum redactum*.

Arsenic in  
reduced iron,  
1 per cent.

8456. That drug must have contained a great deal of arsenic?—A very great deal—one per cent. It has been found that reduced iron used in medicine contains about one per cent. of arsenic.

8457. Is that general, or is it only a particular

specimen of iron which contains so much?—Every specimen that Mr. Scudder buys on the market. He has got it straight from the manufacturers, and each specimen, even those which are guaranteed to be made according to the formula of the "British Pharmacopoeia," one stated to be made according to the "British Pharmacopoeia," contains about one per cent. That is one of these tubes.

8458. That is a somewhat alarming statement?—One only gives one grain or two grains of the iron.

8459. How much per cent. did you say?—One per cent.

8460. One per cent. of arsenic, if that medicine is prescribed, and used by patients a good many grains at a time?—One does not use very much of it. One does not use more than two or three to five grains at the outside.

8461. But it would introduce a considerable quantity of arsenic taken three times a day; the arsenic would soon run up?—Yes. And that is quite a possibility. I think it is just as well it should be known; it is so. Personally I only give very small doses of this iron.

8462. You would think it important for medical practitioners to take note there is one per cent. of arsenic in reduced iron?—Yes, I think so.

Mr.  
A. Angell.

8463. (Chairman.) You are Public Analyst for the County of Hants, and for the City of Winchester, and the Borough of Guildford?—Yes.

8464. And you made some investigations in association with Mr. Arthur French Angell?—Yes; he is my son, and assistant.

8465. What were the objects of the experiments?—It was to satisfy us upon an interesting point; to determine whether or not plants took up and assimilated arsenic from arsenicated manures.

Experiments  
as to absorp-  
tion of  
arsenic by  
certain  
plants.  
Using  
arsenicated  
manure;

8466. Your soil was manured with arsenicated phosphates. Is that the only suspected way in which arsenic can get into the manure?—It is the only way that indicates itself to my mind distinctly, because all the superphosphates contain arsenic; but these experiments were done with a specially arsenicated manure—arsenicated with a half per cent., which was seventeen times greater than any quantity I have ever found to be present in ordinary phosphates of commerce, so that the trial is a drastic one—an extremely drastic one.

8467. By arsenic you mean arsenious oxide, and the weight you speak of are weights not of the arsenium but calculated as arsenious oxide?—Quite so.

8468. In the phosphates is the arsenic supposed to be present in that combination, arsenious oxide? Is that known?—I should anticipate that the acid present would probably render it more soluble than the oxide would be in its free condition.

8469. You use an ordinary superphosphate of lime, and mix it with a half per cent. of the oxide?—Yes, which is now called arsenic.

its applica-  
tion.

8470. How was the application of the manure made?—Half the manure was applied at time of sowing and half when the young plants were well above ground; care being taken on each application to avoid actual contact between the manure and seed or plant.

8471. How was the solubility of the arsenic in the manure tested?—That was an important point, which was determined by experiment. It was to show that the arsenic in the superphosphate was readily soluble in cold water, and therefore would be soluble in the moisture of the soil.

Method of  
testing the  
plants.

8472. What was the method of the estimation of arsenic you followed?—We have given that the name of Hehner's modification of Marsh's process, which I think must be the same as the tubes which the last witness produced. We have come to the conclusion it is the best process for the estimation or determination of minute traces of arsenic, and it yields very close approximations of the actual quantity present in dilutions of one part of arsenic in ten millions.

8473. You made reference mirrors?—We made a series of mirrors from known quantities of arsenic for comparison with the mirrors we obtained, and by that means one can make a very fair approximate estimation of the actual quantity the mirror represents.

Mr. ARTHUR ANGELL, called; and Examined.

8474. Did you take precautions as to the purity of the acid?—There was difficulty found in obtaining arsenic-free acid. One would anticipate, and we had anticipated, that the boiling of hydrochloric acid would free it from arsenic, but some samples were found which did not free themselves even after very prolonged boiling.

8475. Did the same difficulties occur with zinc? Metallic zinc is very apt to contain arsenic, is it not?—That is so. We succeeded in getting a good quantity of zinc arsenic-free, even from the shadow of a trace.

8476. What apparatus did you use?—I sent up a sketch of the apparatus, which the Secretary informs me he sent back to me. I have a rough pencil sketch here, from which the drawing was made, although I am not sure it is large enough to be of any value. (Drawing put in.) That is simply a rough pencil sketch made in the laboratory at the time.

8477. (Chairman.) It is quite clear. Can you describe it with reference to this sketch?—A description, I take it, my Lord, would not be necessarily the size of every part, but simply general?

8478. Simply general?—The apparatus consisted of a flask furnished with a separating funnel, the size of the flask being 300 cc., and the funnel 100 cc. The usual cleansing and drying tube was used, a plug of cotton wool coming first, then lead paper, then calcium chloride, then lead paper again, and then cotton wool again. After that one of the small tubes with which Hehner first associated his name by bringing them before the notice of the Society of Chemical Industry. That is why I have used his name in conjunction with Marsh's.

8479. Is Hehner's tube an addition to or rather a modification of Marsh's method?—The method has not been altered in any way except that it has been brought down to a much more manageable form by Hehner. The first few of our experiments were made with the larger form of tube, and bigger apparatus altogether. When I saw the tubes at this meeting I spoke about, I at once saw the manageability of the thing was very much greater. I think the tubes shown here just now were made in the same manner that Hehner makes his tubes.

8480. What was the *modus operandi*?—I took 20 grammes of zinc, 50 cc. of hydrochloric, or an equivalent of sulphuric acid, and placed 100 cc. of water into the funnel and allowed sufficient to flow into the generating flask to cover the zinc and fill the stem of the funnel; added sufficient acid to set up the action, and after a short interval ignited at the capillary point. Even if not air free, the explosion will not go further back than the cotton wool plug in the drying tube. I heated the hard glass tube five minutes blank, and then added gradually the fluid to be tested. The experiment should last 15 minutes, and more if foaming takes place, as the foam retains the arseniuretted hydrogen. In some

Dr. E. S.  
Reynolds.

7 Mar. 1902.

Mr.  
A. Angell.

Mr.  
Angell.  
Mar. 1902.

instances the foaming in the generating flask became unmanageable; this can be avoided by first gently heating the plant or seeds in dilute acid for some hours in an open beaker and subsequently filtering.

8481. Have you compared the mirror formed when you use sulphuric acid and when you use hydrochloric acid?—I find no difference.

8482. I think Dr. McGowan has found in experiments for us, and perhaps Mr. Hehner has also found, that a mirror when sulphuric acid is used is not comparable with that from hydrochloric acid?—Do you know the meaning of the word comparable in that instance?

(Dr. McGowan.) We have so far always used the sulphuric acid mirror until quite recently, but the hydrochloric acid mirror seems to be of a different type, and I should say rather more marked than the sulphuric acid mirror. I have not had much experience yet of the hydrochloric acid, but it strikes me it is rather more marked, so far as my experience goes.

(Witness.) I have not noticed that.

(Chairman.) You can get a good mirror with one or the other?

(Dr. McGowan.) You can get a good comparable mirror with one or the other. I think the hydrochloric acid is rather the more delicate.

(Witness.) I think I would agree to that last remark that it is rather more delicate if anything.

(Sir William Church.) I gather that you mean hydrochloric acid mirrors ought to be compared with hydrochloric acid mirrors, and sulphuric acid mirrors compared with sulphuric acid mirrors, but that being done there is not much difference between the two.

(Dr. McGowan.) It is a matter of personal taste really.

(Witness.) I agree with that.

8483. (Chairman.) In your determination of arsenic in superphosphates, was the aqueous acid solution of the superphosphate introduced directly into the apparatus?—Yes.

8484. Was there no interference with the test from any small quantities of organic matter in solution?—No, not in the case of superphosphates, no interference.

8485. Were precautions taken to prevent any arsenic getting accidentally on to the leaves of the growing plants? Was there any wind?—The danger was the introduction of arsenic either carried by wind or the splashing of rain, or otherwise, on the surfaces of plant or leaves. That was a source of danger, and we kept it before us the whole time.

8486. Did you use any precautions to prevent it, or wash off the arsenic?—We washed all the plants and all the parts of plants carefully in every instance.

8487. In your use of the Hehner-Marsh method what kind and size of drying tube for the escaping hydrogen was used?—The drying tube was 14 inches in length and five-eighths in diameter. The mirror tube was five-sixteenths outside diameter, and about nine or ten inches long.

8488. What length of chloride of calcium did you have in the drying tube?—Rather more than half the entire length; that would be seven inches.

8489. In fragments, small lumps?—Yes, calcined and in fragments.

8490. Does your use of the Hehner-Marsh method involve any treatment of the leaves, seeds, etc., before Marshing?—Usually it was better to cut up the pieces of plant or crush the seeds, and gently heat them in an open beaker with a little acid with them. That was my usual plan. It did away with a good deal of the danger of foaming in the flask.

8491. Did you use the whole liquid and solid together, or filter?—In some instances it was necessary to filter, but if it was a thing you could pulp down sufficiently to get through, I preferred not filtering.

8492. Why did you prefer not to filter?—Because some of the arsenic would be probably left in that portion which was upon the filter.

8493. If there was no previous treatment of the leaves and so on, were estimations made with the same samples after the destruction of the organic matter? If you did not treat previously, did you take any means to destroy the organic matter before Marshing?—In most instances, it was not necessary. The result of maceration was sufficiently free from organic matter to permit the process to be carried out.

8494. If the organic matter was destroyed, how was it done?—I do not think it is necessary with these vegetable infusions to destroy the organic matter.

8495. Did you never destroy the organic matter?—Not entirely.

8496. What quantities of the samples did you employ?—Taking the first instance, which was on the 21st April, we took rhubarb stems, that is the leaf stems of the rhubarbs used for feeding purposes. We took 50 grammes and boiled in dilute hydrochloric acid, and from that we obtained a slight trace of arsenic.

8497. Did you take about 50 grammes in all these experiments in each case?—In each case, right through.

8498. Did you get any appreciable evolution of sulphuretted hydrogen along with the arseniuretted hydrogen?—In one or two instances only, not as a rule, but where it occurred it was picked up by the lead paper.

8499. Assuming no previous treatment of the sample in a sufficient number of cases, when the sample yielded no arsenic, did you make a control experiment with another similar sample and a given small amount of arsenic?—No. That is to say did I ever introduce arsenic to prove that if it had been there I should have found it?

8500. Yes?—No. I have done this in a certain way. It has happened that a negative result has been obtained from a quantity of a non-arsenicated plant or substance, and then afterwards my son, to corroborate what I have done before, with a portion of rhubarb stem in which we had found arsenic, has gone on with the experiment in which I found none by adding some of the arsenicated rhubarb, and then has got his mirror. That therefore is something of the same sort.

8501. Did you ever recover the whole of the arsenic that was added in any one of your experiments in which a known quantity of arsenic was put in?—That could be only in the case where I tested my manure. I could not expect in any way to get back again the arsenic I had put into the soils quantitatively.

8502. Did the organic matter in the flask retain any portion of the arsenic so far as you know?—Not so far as I know. I found it was extremely slow in coming off; extremely tardy. So that it was a question sometimes of hours before the last trace of arsenic came off if there was a thick foam forming on the surface of the boiling flask. I take it the bubbles contained arseniuretted hydrogen; and therefore as long as any of that foam was there there was danger of arsenic in the flask, so I continued until I had boiled it out.

8503. There is a prevalent idea, I believe, that organic matter may seize hold of the arsenic and prevent it going away in the Marsh test?—Retaining the whole of the arsenic present?

8504. No, keeping a part of it?—I think that is possible, but I have not had experience of that.

8505. Did you ever allow the blank to run over the same length of time as was taken up for that actual estimation?—Yes. I have allowed it to run to the point of absolute total exhaustion; that is to say, until the whole of the hydrogen has come away, simply for a blank experiment.

8506. Did you ever obtain any false mirror—one that was carbonaceous?—No. I know nothing of that. I have seen a slight discolouration which has led one to suspect a mirror was about to be formed, but I have never had a case where it was not sufficiently decisive if you actually got arsenic to be able to detect the fact.

8507. Were the solutions and extractions reduced to the arsenious state before Marshing?—No steps were taken before the liberation of the hydrogen to reduce it. The question, I think, means this: were any steps taken to reduce a possible arsenic compound to the arsenious state before its introduction into the flask?

8508. Yes?—The answer is no.

8509. Has it been ascertained that the whole of a given quantity of arsenic acid would be reduced and deposited in fifteen minutes?—Although fifteen minutes is the time that we give as being in most instances sufficient, we have never confined ourselves to a rigid line about time. As long as there was the slightest evidence of further deposit we would go on; and in some instances it was a very long time indeed.

8510. It would be very interesting to understand what degree of confidence may be placed in results in which the answer is negative, "No arsenic mirror discovered"?—I see the importance of the point.

Mr.  
A. Angell.  
7 Mar. 1902.

Organic matter was not entirely destroyed before Marshing.

Control and blank experiments, and their efficiency.

Mr. A. Angell.  
7 Mar. 1902.

8511. We want to prove that there was no arsenic there?—I am firmly convinced from my own experience that if arsenic is present it must be due to carelessness of the operator if he does not find it.

8512. Dr. McGowan informs me that with smaller quantities of re-agents it sometimes takes from three-quarters of an hour upwards for the arsenical mirror to appear in estimations which have been made?—Were those organic mixtures of plant matters?

(Dr. McGowan.) Mixtures in which the organic matter was destroyed.

(Witness.) What class of organic matter was it? Animal matters? If so that hardly comes in as regards our cases.

(Dr. McGowan.) Principally animal matters, but I think one or two vegetable matters as well, though I could not say from memory.

(Witness.) We carried our experiments in every instance a long way past the fifteen minutes. If any indication came, it always came within the fifteen minutes; a slight indication, any possible change or deposit, was sufficient to make us go on with our experiments until we were perfectly sure we had exhausted them.

8513. (Chairman.) In other experiments, in the case of arsenious acid, it has been found the deposit completed in most cases in twenty minutes?—I agree with that.

8514. It might in future experiments add greatly to the value if we had distinct evidence that the whole of the arsenic was taken out by a continuation of the process?—In the presence of organic matter?

8515. Yes?—I will undertake to do that.

8516. And whether the original form of the arsenic was arsenic acid or arsenious oxide?—We will undertake to experimentalise with the two forms of oxide, the arsenious and arsenic conditions, under the conditions you are indicating; that is to say, we will make a blank with our vegetable solutions or decoctions, or whatever you call them, and then we will add in one set of instances arsenious oxide.

8517. Add it to the vegetables, not the vegetable decoction—to the vegetables before decocting?—I do not see how that is to be done.

8518. Add it to the liquid before macerating?—Yes, I see. I could not add it to the vegetable matter. If I have the opportunity of sending up my notes I will undertake to carry those experiments out.

8519. (Chairman.) What about testing the ground?—I thought it was a point of interest to know that we had sufficiently arsenicated the soil to show that a plant had been submitted throughout its life history to the conditions under which, if it was capable, it would take up arsenic, and therefore we took samples of the earth after the experiments had been finished with the plant, and found that it still contained arsenic.

8520. As if the plant had taken some arsenic, but had not taken all the arsenic?—That was not the only object. The object we had in view was to show that the plant during the whole of its career had been under the influence, at all events, of an arsenicated environment.

8521. That the arsenic had not been washed out of the soil?—Yes, just so. That is what we wanted to show.

8522. What were the plants and seeds tested?—The plants and seeds experimented upon were wheat, barley, rye, oats, peas, buckwheat, maize, beans, cucumber, tomato, rhubarb, mangolds, carrots, lettuce, and cabbage.

8523. At what date were the seeds planted?—The rhubarb was in my own garden, and I do not know how long it had been planted, but it was arsenicated immediately as it was appearing above the ground; that was before the 21st April, about the time it springs from the ground.

8524. Which was arsenicated, the soil or the rhubarb?—The soil was arsenicated. It was arsenicated around the plant. The plant threw up three or four growths, and this was arsenicated in a little ditch round the plant and covered in with earth. That I did myself. The following is the list of the experiments:—

#### LIST OF EXPERIMENTS: 1901.

April 21:

No. 1—Rhubarb stem, taken 50grms.; boiled in dilute hydrochloric acid. Slight trace of arsenic.

No. 2—Rhubarb leaf blade. A slight trace of arsenic.

May 3:

No. 3—50 grms. peeled rhubarb petiole. A faint trace of arsenic.

No. 4—The peelings of leaf stalk. Very faint trace of arsenic, less than 1, 2, and 3.

May 11:

No. 5—Cabbage, 50 grms. of the heart. No arsenic.

No. 6—50 grms. of stump. No arsenic.

May 22:

No. 7—Barley. Whole plants pulled up by root. Faint trace of arsenic.

No. 8—Oats. Ditto. No arsenic.

No. 9—Buckwheat. Ditto. No arsenic.

June 19:

No. 10—Growing green stalks and bursting ears of barley, 50 grms. Not a trace of arsenic.

June 24:

No. 11—Maize, tops of plants only. No arsenic.

June 26:

No. 12—Buckwheat. Flowers and stems cut 6 inches from ground. No roots. Very faint trace of arsenic.

No. 13—Second sample ditto ditto. Rather more arsenic than in No. 12.

June 29:

No. 14—Ryegrass in green ear. Upper parts of stems and ears only. Faint trace of arsenic.

July 1:

No. 15—Broad beans. Pods and seed, young and green, nearly fit for table. Well-marked mirror of arsenic, estimated as one part in thirteen millions of the solution.

July 2:

No. 16—Broad beans. Foliage and stalks, no pods nor seeds. Arsenic same as in No. 15.

July 4:

No. 17—Green barley ears. No arsenic.

July 27:

No. 18—Barley ears nearly ripe. A fine specimen. No arsenic.

No. 19—Buckwheat seeding heads. No arsenic.

July 31:

No. 20—Green peas; no pods. No arsenic.

August 5:

No. 21—Ripe barley. A fine sample. No arsenic.

No. 22—Ripe oats. No arsenic.

August 8:

No. 23—Lettuce. No arsenic.

August 10:

No. 24—Ripe barley. Second sample. No arsenic.

August 13:

No. 25—Carrots. No arsenic.

August 19:

No. 26—Male flower of maize. No arsenic.

August 22:

No. 27—Green maize, corn cob with sheath. No arsenic.

August 30:

No. 28—Tomatoes; fruit. No arsenic.

September 3:

No. 29—Broad beans. Ripe seed. No arsenic.

September 5:

No. 30—Ripe wheat seed. No arsenic.

No. 31—Mangel. No trace of arsenic.

No. 32—Cucumber. No arsenic.

8525. (Chairman.) Is No. 31 the mangel wurzel?—Yes.

Possible retention of arsenic by organic matter; should be investigated.

Soil contained arsenic after growth of experimental plants.

Nature of plantsexperimented with.

Results.

Mr. A. Angell.  
7 Mar. 1902.

Mr. Angell. 8526. (Sir William Church.) These dates that are given, are they the dates of the experiments or the date when the arsenicated manure was put on?—These were the dates of the experiments—laboratory dates.

8527. When did you apply the arsenicated manure to the growing rhubarb? I understood you to say you applied the arsenicated manure on the 21st April?—I was wrong in that. That is when I made the estimation; it must have been previous to that—I should think at least a fortnight.

8528. Therefore these dates given are the dates of the laboratory experiments?—Yes.

8529. And I understand from what you have said before that in the case of all the seeds some was applied at the time of sowing and some subsequently?—Yes.

8530. Does that apply to the cabbage too?—Yes, but not to the rhubarb.

8531. It applies to all in fact, excepting the rhubarb?—Yes.

8532. (Chairman.) Some arsenic was put into the manure before the sowing of the seed, is that so?—The whole of the manure was arsenicated at one and the same time.

8533. Was the manure applied before the sowing of the seed in some cases?—No; at the time of sowing. The first manure was put adjacent to the seed at the time of sowing, not actually touching. I do not know that there was any reason why, but putting a large quantity of strongly arsenicated manure there might have been some action preventing the sprouting of the seed, so we avoided that, and put it in close proximity to the seed, and then covered the seed in the ordinary way. The seed was sown by a practical man in my presence, better than I could have done it myself. Subsequently, before the young corn had got more than a very green show of grass, another portion of manure was put around it at a further distance from the plant than before.

8534. In a circle round the plant?—Being in rows in these instances they were in straight lines.

8535. You did not mix some of the manure thoroughly with the soil at the beginning?—It would be so, because it was sown in a long trench, and then raked over with a rake so as to mix the soil with it.

8536. In the first experiment you say "slight trace"; was that too small to be estimated?—Yes; it was too small to be estimated.

8537. In No. 12 you say "very faint trace of arsenic"?—That very faint trace of arsenic would be like one of the faintest tubes you had before you this morning. I should not attempt to make a quantitative statement, on a mirror, at all events, not less than that. Those mirrors fade very quickly unless the tube is sealed off when containing hydrogen, and even then I find they fade somewhat.

8538. This mirror is one of the cases when you would term a very faint trace?—Yes. I should not venture to estimate that mirror. And yet there might be an estimation given, but if so that tube has faded since it was made, or I should think so.

8539. (Sir William Church.) This was not sufficient to be estimated. This is from one of the Californian fruits?—That would be my report on it.

8540. (Chairman.) In respect to August 5th, Nos. 21 and 22, about how much barley may have been tested?—50 grams of the barley and 50 grams of the oats.

8541. In No. 29 was that a later crop of broad beans than those examined on July 1st?—No, the same plants, but on the 1st July the plant is spoken of there as "young and green; nearly fit for the table." On the 3rd September pods and seeds were taken and cut up together, when I obtained one part in thirteen million. And the ripe bean was taken on the 3rd September with the view of strengthening, or otherwise, then arrived at conclusion in our minds that none of the ripened grains of any kind had assimilated arsenic, and we found that was so with the broad beans. If we had taken the broad beans separately on July 1st the probability is that we should have found no arsenic. I cannot prove it this season.

8542. But the same seeds showed no arsenic after ripening?—Quite so.

8543. What became of the arsenic they had in them?—There is no evidence they had any at all. I took

pods and seeds together. With my experience now I have a strong opinion that there was none in the seeds themselves at that time.

8544. And that it was in the pods?—Yes. If you will notice, on the 1st July it is broad beans, pods and seeds; but on the 3rd September it is ripe seed.

8545. The inference you draw is that probably it was in the pods?—That is my own opinion now.

8546. And probably what you examined on the 1st July did not contain the arsenic in the seed?—Not in the seed.

8547-51. One part in thirteen million: does that mean thirteen million parts of solution made, or thirteen million parts of substance taken—seeds and pods, for instance?—Substance taken.

8552. (Sir William Church.) With regard to July 31, No. 20 green peas, was that only the pea or the pea and pod?—Only the pea; not the pod in this instance.

8553. Then I think "no pods" should be put in so as to make that, comparable with the peas?—I think that should be done. But you see one's experience was not comparable at that time.

8554. (Sir William Church.) Quite so; but I only wanted to know whether you took the pods and peas as well?—No.

8555. (Chairman.) What are your conclusions on the whole of your experiments?—The result of our experiments, which have been carried as far as one season will permit, goes to show that the roots of plants are capable of taking up arsenic from soils manured with arsenicated phosphates. From the roots the arsenic can rise in the fibro-vascular bundles by a process of suction and capillarity, and may be present in measurable quantities in the early stages of succulent growths. Arsenic was found in rhubarb petioles and leaf blades, and in the young leaves or grass of rye and buckwheat, and in the stems and leaves and green pods of broad beans. There you see I have stated green pods as a matter of opinion really because the green pods were never taken alone, and it remains for that to be done. I think it must be looked upon as an opinion, that it was in the pods and not in the broad beans. That being so, in no instance was the faintest trace of arsenic present in the fruit or seed of any plant.

8556. Can you suggest any explanation of that?—It thus appears that in those parts of the plant which are remote from the influences of mere mechanical forces, and where vital or physiological energies predominate, a selective power is brought to bear, and arsenic, even if present, is rejected.

8557. So that you think the arsenic may be excreted?—Refused at that point where starch grains are being formed and other truly physiological processes of an intricate character. We are of opinion that even if the arsenic reaches that point a refusal takes place, and excretion in some form or other.

8558. And in no instance was the faintest trace of arsenic present in the fruit or seed of any plant?—In no single instance.

8559. It seems that in cabbage and in maize there was no arsenic found at all; even in the petioles?—The young leaves of cabbage and maize were free from arsenic.

8560. But the young leaves of other vegetables were not free?—Not in all instances. The young leaves of rye and buckwheat, and the stems and leaves and green pods of broad beans yielded arsenic.

8561. (Sir William Church.) What becomes of arsenic when you add it to the soil?—Do you mean what changes take place chemically?

8562. No. For instance, your arsenicated manure which is supplied to the soil; would you be able to recover the arsenic after a good many months?—That was one of our experiments.

8563. No. You said you found the soil still contained arsenic, but I am wanting to know what becomes of the arsenic? Could you recover the whole of the arsenic?—One would not anticipate that possibility. There must be some loss from rains which carry the arsenic right down into the soil. We wanted to see that we put sufficient arsenic to take care of that.

8564. You have not turned your attention to the fact whether arsenic after a time enters into any soluble

Mr. A. Angell.  
7 Mar. 1902

arsenic in pods;

in roots and young leaves;

none in fruit or seed of any plant examined.

Mr.  
A. Angell.  
7 Mar. 1902.

condition in the soil?—It was soluble in the soil at the end of the experiments; it was dissolved out with cold water.

8565. You have settled the point so far that there was still, in the soil you were experimenting with, soluble arsenic, but you did not go further to see what quantity of your arsenicated manure had disappeared during the course of your experiments?—It is hardly possible unless we commence with that object in view, and knew the quantity of soil we had added the manure to.

Form in which arsenic taken up by plant.

8566. In what form would you think arsenic is taken up by plants?—I should be inclined to believe that the arsenic is dissolved as a sulphate or in the excess acid of the superphosphate; but I have no evidence of that and I do not know. What I wanted to prove was whether arsenic could find its way through the building up powers of the plant. I should not expect to find the oxide existing as such in a superphosphate at the temperature at which superphosphates are made in the presence of an excess of sulphuric acid.

8567. You would not find arsenious oxide free?—No.

8567\*. But you have not formed any opinion as to what especially it is that is soluble and passes into the plant?—No, I have not.

8568. (Chairman.) It might pass into the plant, into the root and sap, and yet not be assimilated by the plant?—That is my point, that it does enter with all other soluble matters through the spongioles of the roots, and finds its way through the bundles of fibres in those succulent forms of plants in which the arsenic was found. But immediately the powers of assimilation come into work—which is not the case I take it in the mere tubular portions of the stalk of a plant—the physiological functions take the ascendancy; as soon as it becomes a question of forming the germ of the new plant in the seed. Then there is the power brought in which I am satisfied in my own mind is a sufficient safeguard against the entrance of arsenic into barley or any other seed of a similar nature.

Such arsenic not necessarily assimilated.

8569. Everything that comes up in a sap must remain in the plant; the sap does not come down again. Whatever is in the sap remains in the plant?—Quite so.

8570. Is there any security that it will not get into the grain if it is in the plant?—It has not done so in any of our cases.

8571. In the case of rye or oats or wheat, do you think that there is arsenic in the leaves and blades, but not in the grain?—Not in the grain. We have found it not always, but in many cases in the leaves, especially in the younger growth of the plant. We have found it in the leaves and stalks; not in any instance in the ripe fruit or seed.

8572. Have you found it in sufficient quantities in the blades, for instance, to make hay or straw poisonous for cattle?—It is a point that has not struck me at all. When I have been talking about grass it has not been meadow grass. It has been rye certainly.

8573. The question of the safety of arsenicated manures would not be altogether settled even though it were proved that no arsenic gets into seeds?—Not for grazing, because I found on the 29th June, rye grass in green ear. Upper parts of stems and ears only; faint trace of arsenic. Therefore your question leads one to be cautious not to say that this proves that the use of arsenicated manures can in no form injure the cattle that feed upon the products.

8574. Suppose arsenicated manures were applied to meadow land to be used for grazing. Might arsenic get into the beasts and make their flesh poisonous to mankind?—I should hardly expect to find that, but upon principle, at all events, it is an objectionable practice to allow any cattle to graze upon a plant in which you know arsenic is present.

8575. With all your experience as public analyst and your chemical and physiological knowledge, do you think that for the safety of the public it is necessary that chemical manures should be carefully examined?—No, I do not. I do not think that the result of our experiments lead us to that. We took 22 phosphates, and examined, and found arsenic in all of them, and they varied very little, and the usual quantity was .03 per cent. of the weight of the manure.

Amount of arsenic in commercial super-phosphates much less than in experimental manures.

8576. These were the ordinary manures of commerce?—These were the ordinary manures of commerce. The 22 samples came from three factories and were all labelled with the percentage of soluble phosphates. So that they were not all one batch.

8577. Did you find nearly the same proportion in the different factories?—Very nearly.

8578. Did you find any individual samples in which there was considerably more?—Not a great variation; not sufficient for us to have taken a particular note of any particular sample.

8579. .03 is a large percentage?—Yes, it is.

8580. .03 is 3 parts in 10,000?—Yes.

8581. That seems a large amount. Is that in parts by weight of the phosphate?—In parts by weight of the entire phosphate.

8582. For your experiments you added arsenic to the extent of 17 times as much as that?—Yes.

8583. And that did not introduce large quantities of arsenic into the plants in any case?—And that did not introduce large quantities in any case.

8584. (Sir William Church.) Granting that the arsenic in whatever form it may be passed into the plants through the spongioles by a sort of capillary attraction, how do you explain that it is present in some plants and not in others? Cabbages seem to be quite free?—If you remember, the growth of the cabbage is an extremely small root as compared with the size of the plant, and the stem of the cabbage is of a very hard woody nature. The cabbage, although succulent in the leaf, is very woody in the under parts, and that is one reason why I did not get it in the cabbage, I believe.

Differences results as regards different plants.

8585. Maize has a small root, but it is a very succulent free open growing plant. There is no arsenic in the tops of maize and no arsenic in the green maize cob with sheath?—We should not anticipate that a plant which might take up arsenic would necessarily do so in all instances. There must be a chapter of accidents surrounding the question of whether or not that particular spongiole does come at all in connection with the arsenicated manure even. It may happen that it would not be. I should anticipate that it would be.

8586. I am only going with regard to your theory that when physiological action in a plant is more advanced, then there comes in the power of rejection and selection. Carrots do not seem to have had any trace of arsenic in them?—No. I quite expected to find it, but it was not there. I want to point out that the carrot is not a fruit.

8587. It is a root?—Yes. The carrot seed if I had grown it as seed would not have had any arsenic in the seed, even if arsenic was present in the root.

8588. But the root has no arsenic in it?—No.

8589. And mangold you tell us had none?—No.

8590. There, again, that is a very succulent plant, containing a large quantity of aqueous matter?—Yes. It seems to be somewhat opposed to the results obtained, but the results obtained in other instances you see have been always straight stem plants, which would have capillary tubes much more easily accessible possibly than the same tubular structure of the root. But, of course, that is theory.

8591. Where were these experiments carried out?—They were carried out by myself and my son in my own laboratory at Southampton.

8592. I mean the growth of the plants?—They were all carried out within three or four miles of my own place.

8593. All on the same plot of ground?—No, not at all. That is a very important point, of course. Those that were taken by myself were in my own kitchen garden. Those that were taken by Messrs. Toogood and Son and treated were carried out between four and five miles away from the ground I operated upon myself, and then a third, a Mr. Sawyer, had his ground about half-way between the two. There were three different positions. Sawyer's ground was on the top of a considerable hill, and a more stony soil than the rest. Toogood's experimental grounds are down in a loamy valley and my own is some stiff clay soil.

Places of experiment

8594. I take it that probably the rhubarb, the peas, and the beans, would be carried out in your garden, and the corn would be carried out in one of the other places?—The rhubarb, peas, beans, and cucumber, were our home growth. The cabbage, barley, buck-wheat, maize, were grown by Sawyer, and the rest, the roots, were grown by Toogood.

8595. You did not get corn from two different localities?—No. All the corn came from Sawyer's ground.

8596. You heard the evidence, I think, of Dr. Reynolds, when he told us that he had been told by those

Mr.  
Angell.  
Mar. 1902.

who had been analysing hair and other substances for arsenic, that there was very great difficulty in cleansing the flasks. Have you found that?—That is not in accordance with my experience. Of course, the usual drastic and careful cleanliness must be attended to. It would not do to continue a thing in a flask. Nearly the whole of these experiments were done in one flask, and we have a great many more negative results than positive ones, and the positive ones are interspersed amongst the negative ones from the same flask. I was struck at the time when I heard the evidence that it was not in accordance with our experience.

8597. Have you any suggestion to make with regard to the difference?—I should not like to make the suggestion that dawns on my mind. There is more risk of positive results than there is of negative results through the whole of these experiments. It wants very great care to get negative results. If the arsenic is present, any ordinary fairly skilled analyst can find it.

8598. But is it not possible that you may get negative results from want of sufficient care in carrying out your experiments?—I think that is covered by my remark that an ordinary careful operator would be sure to find it if it is there. I cannot see why not.

8599. (Dr. Whitelegge.) Can you say how much superphosphate is usually put upon the land? I am told about 4 cwt. per acre?—Yes. That is a liberal but still an ordinary quantity to use.

8600. That works out at about 2,000 grains of arsenic to an acre, taking your estimate of .03?—Yes.

8601. Or half a grain of arsenic per square yard?—Yes.

8602. Can you say what the length of your hydrogen flame was?—It is kept under control. The length of the flame should not exceed the size of a barleycorn to work well. I do not like a fierce current; that is a dangerous thing.

8603. You did not measure, nor was it possible to measure in the experiment, the amount of manure. You did not put so many grammes of manure near so many plants?—No.

8604. Did you measure the distance away at which they were put?—It would be something like two inches.

8605. Was there uniformity of condition as to watering or washing by rains?—Notes were taken as to the rainfall. I have not them here, but I can send them to you in a general sense whether it was wet weather or dry.

8606. It was not possible to make any estimate of the amount of arsenic that was or might have been absorbed by the roots of a given plant?—No.

8607. Therefore, it would be useless to attempt to measure the amount of arsenic which reached the plant?—Quite so.

8608. Still you found it in some of the tissues, and more especially the succulent tissues?—Yes.

8609. In a form demonstrable by the methods you used?—Yes.

8610. In pursuing that analysis you oxidise the organic matter?—Yes, to a certain extent. In some instances.

8611. You failed to find any at all in the seeds, either green or ripe?—Yes. The question of the bean is *sub judice*.

8612. Exactly. Your view is that there is none in the seed?—Yes.

8613. That is just the point is it not, at which phosphorus is ordinarily assimilated?—Yes.

8614. So that in your view the behaviour of arsenic is precisely the reverse of phosphorus?—That is to say the behaviour of the plant towards it?—Yes.

8615. The phosphorus in the seed enters into a new form of combination does not it?—Certainly.

8616. Which possibly might give a different result in analysis?—Yes.

8617. Might not the same sort of thing happen in the case of arsenic? Do you think it is perfectly clear that if you had oxidised the whole of the organic matter in the seed you might not have found some arsenic there?—It is a point of a considerable amount of interest; but I have not tried it.

8618. If you are pursuing these investigations it might be worth considering?—I think so; that is to say would you insist upon an entire destruction

8619. I am thinking of the evidence we have had, that conceivably, under certain circumstances, arsenic may enter into organic combination with some thing or another and hide itself in so doing?—You would be satisfied if the entire mass of the seed was broken up and decomposed if we obtained by this process a mirror of arsenic. Supposing I oxidise my organic solution from the seed entirely or nearly entirely, would you be satisfied then if I got a negative result?

8620. What you have said already is a strong suggestion of absence, but that would strengthen it, to my mind?—I shall certainly make a point of finding that out. I am very much interested in the point myself.

8621. (Sir William Church.) You have paid great attention to these questions. Would it not be possible to grow plants in arsenic-free soil in pots and water with known quantities of arsenic manure, and see if they did take up larger quantities into their tissues in proportion to the amount of arsenicated manure they were supplied with?—That would be possible.

8622. That seems to me almost a more satisfactory experiment?—The great bulk of the arsenicated fluid would have to be put on in solution.

8623. (Dr. Whitelegge.) Would it not be a more convincing way to take a sufficiently diluted solution of arsenic, and simply water the plant?—Yes, simply take a solution of arsenic and water your manure for the purposes of the plant growth.

8624. (Sir William Church.) I only throw that out as a suggestion. It is like the demonstrations given to you of the value of other salts, potash and soda salts?—Now would be the time to commence those experiments. It would be very interesting to work them out. I do not know whether we should get quantitative results that one could very well rely upon, because the bulk of the arsenicated fluid at all events would pass through the pot, would it not?

8625. No doubt?—Would you have to catch that and put it through again?

8626. I should put the pot in a saucer. You may get it so concentrated at last that the plant would die?—That was a point I was thinking of. Your observation is one I will take note of.

8627. If you found in your dying or dead plant that there was a very large percentage of arsenic present in its tissues, it would not invalidate the experiment?—No, not at all.

## TWENTIETH DAY.

Friday, 21st March 1902.

AT 8, DELAHAY STREET, WESTMINSTER

PRESENT :

The Right Hon. Lord KELVIN (*Chairman*).The Right Hon. Sir WILLIAM HART-DYKE.  
Sir WILLIAM CHURCH.Professor THORPE.  
Dr. WHITELEGGE.Dr. BUCHANAN (*Secretary*).Mr.  
H. H. Smith.  
21 Mar. 1902.

Mr. H. HAMMOND SMITH, called; and Examined.

Mr.  
H. H. Smith.  
21 Mar. 1902.8628. (*Chairman*.) You present this report, which has been sent to us?—Yes.

REPORT by Mr. H. Hammond Smith on Alleged Cases of Poisoning, attributed to Arsenical Beer, at Halifax.

Outbreak of arsenical poisoning at Halifax, 1902.

In view of statements in the "St. James's Gazette" of January 7th, 1902, and also in the "Daily Mail" of January 13th, to the effect that a man, McNulty, had died in the Halifax Infirmary from arsenical poisoning supposed to be due to beer drinking, and that other cases were in the Infirmary suffering from similar symptoms, I received directions from the Commission to make local inquiries.

Cases in Halifax Infirmary.

On January 15th, 1902, I went to the Poor Law Infirmary, Halifax, where the alleged cases of poisoning were under treatment. Here information was given me by Dr. W. Shaw and Dr. Woodyatt (visiting Medical Officers of the Infirmary), by Dr. Hodgson (resident Medical Officer), and by Dr. West Symes, who was representing the interests of the Halifax brewers. I found that altogether there were then in the Infirmary four suspected cases of arsenic beer poisoning, in addition to McNulty, who had died.

I may here state that subsequently two other cases were admitted, one of whom (T. Lee) has since died, and that, in addition to these seven Infirmary cases, a few others have been heard of in Halifax which have been treated at their homes. To these I will allude below.

Inquest on McNulty.

At the date of my first visit, an inquest which had been ordered by the Halifax Coroner on McNulty was adjourned pending inquiries instituted by the Coroner, and I attended the adjourned inquest on January 23rd.

Dr. Hodgson had stated at the previous sitting that, as a result of clinical observations which I note below on the next page, he had formed the opinion that death was due to arsenical poisoning attributable to drinking beer, and that the man also suffered from a fatty heart, bronchitis, and hypostatic pneumonia.

Arsenic in viscera.

At the adjourned inquest Dr. Woodyatt, the visiting Medical Officer, said that in his opinion the cause of death was bronchitis and heart failure, and that arsenical beer poisoning, if any, had no concern in the fatal result. He claimed in particular that the pigmentation was not arsenical. Mr. Allen, Public Analyst of the Borough of Sheffield, etc., and a member of the Joint Committee of the Society of Chemical Industry and Society of Public Analysts which has investigated tests for arsenic, was called, and gave evidence as to analysis of post-mortem specimens from McNulty, which had been sent him by the Coroner. He had found arsenic in minute amounts in the liver, viz., 1-700th of a grain in from three to four ounces of liver substance. He had also found about 1-400th of a grain of arsenic in the contents of a jar containing portions of other viscera, mainly pieces of small intestines and left kidney.

Mr. Allen also gave evidence as to certain beer samples taken by the Coroner's officer from public houses frequented by McNulty.\*

In these he had found the following amounts of Arsenic in arsenious oxide:—

- (a) In beer from the "Britannia" Inn, 1-18th of a grain per gallon.
- (b) In beer from the "Black Horse" Inn, 1-24th of a grain per gallon.
- (c) In beer from the "Brewers' Cellar," 1-16th of a grain per gallon.

The brewers who supplied the above public houses were respectively:—

- (a) Messrs. Webster and Sons, Halifax.
- (b) Messrs. Ramsden, Halifax.
- (c) The Yorkshire Brewery Company, Leeds.

Mr. Allen exhibited Marsh mirrors obtained from the beers submitted to him, and also his standard mirrors. In the end, the jury returned a verdict of "Death from natural causes, accelerated by bronchitis."

In view of the above indications I continued my inquiry on several dates in January and February, with the view to discover the origin of the beers associated with the cases and the opportunities of their contamination by arsenic. In the first instance I called on the medical officer of health of Halifax, Dr. Neech, who told me that these cases had not been reported to him by Dr. Woodyatt or by Dr. Hodgson, and that the first intimation of them he had was through the coroner. At the date of my first visit the matter had not come before him in such a way as to indicate the need for special inquiry, but subsequently he has not only given much ready assistance to me as representing the Royal Commission, which I would gladly acknowledge, but also he has himself made a series of investigations on parallel lines, the results of which I understand he is about to submit to the Sanitary Committee of the Town Council in a Report, a copy of which he has also undertaken to transmit to the Commission.

Action of Halifax M.O.H.

In February Dr. Neech sent a letter of inquiry to medical practitioners in Halifax, asking to be informed of cases of alcoholic neuritis or of suspected poisoning by arsenic in beer. Up to the present Dr. Neech informs me that four such cases in the private practice of medical men in Halifax have been heard of. Whether these four cases, together with the seven in the infirmary, represent all the recent illness possibly attributable to arsenical beer in Halifax I am unable to say. In view of the recent inquests and of the association of the disease in the public mind with persons of the ne'er-do-well, heavy drinking class, it is possible that medical men may hesitate to involve their patients in the risk of being associated in inquiry of this kind.

\* The Coroner's officer took samples from these public houses in bottles. From them the Coroner filled smaller bottles for Mr. Allen's examination. The remaining portions he has since given to me, and I have forwarded them to Professor Thorpe.

Mr. H. Smith. At the date of my visits only one of the four above cases were brought to my notice, a man F, and this is the only case, other than those in the infirmary, which I have dealt with in this report.

## INFIRMARY CASES.

The Poor Law Infirmary is quite a new building, being opened to patients only at the end of last year. Three of the cases had been brought there from the old Halifax Workhouse Infirmary, in which they had previously been under treatment.

Case No. 1.—William McNulty, aged 84, man of the tramp class, admitted on the night of January 4th, 1902. Symptoms on admission, according to Dr. Hodgson: Suffering from bronchitis. Dropped feet; absence of knee jerks; pain on pressure in the calves; pains in the feet. Face and feet puffy; running at eyes and nose; voice husky. Heart dilated; irregular pulse. Extremely weak; no appetite. Tongue silvery. Temperature not above normal. General pigmentation of the skin of trunk and extremities, well marked in places, and in appearance characteristic of arsenical pigmentation. This man rapidly grew worse, and died on January 8th. At a post-mortem examination made by Dr. Hodgson, in the presence of Dr. Woodyatt, the heart was found dilated and showed fatty degeneration; the lungs showed evidence of bronchitis and "hypostatic pneumonia." Liver normal in size, but fatty and friable; kidneys, slightly cirrhotic; capsule adherent; spleen soft; abdominal glands and suprarenals normal. The result of analysis of viscera has already been given.\*

This man had been a heavy beer drinker; he spent seven months out of the twelve in Halifax, where, I am informed by Mr. Crawshaw, the chief meat and food inspector, he chiefly frequented the Britannia Inn, supplied by Messrs. Webster and Son. He had been staying at Halifax and frequenting this public-house for some months before his admission.

Case No. 2.—George Shearing, shoemaker, age 61, admitted November 14th, 1901, into the old Workhouse Infirmary (where he was treated on the supposition that he suffered from Bright's disease), and shortly afterwards transferred to the new Infirmary. Symptoms on admission there:—Marked pigmentation of skin of the trunk and neck with clear patches; keratosis of the feet and scaly condition of the lower part of the legs. Loss of power in all four extremities; unable to walk; knee jerks absent; hands clenched; legs flexed. Puffy face; very husky voice; eyes running; seemed muddled when spoken to; and generally very weak. On January 30th, when I saw this case, the above signs and symptoms were apparent and the keratosis was particularly well marked.

This man was a heavy beer-drinker, getting all his beer at a public-house called the "Cross Keys" in Halifax.

Case No. 3.—L. Whalan, 65, wire cleaner, admitted to infirmary January 10th, 1902; stated on admission that he had a "feeling of electricity all over him" for eleven weeks; and that his feet had been swollen and painful so that he could not stand. Skin slightly mottled, but no obvious pigmentation; some peeling of skin on feet and hands. Loss of power in extremities; no tendon reflexes; slight dropped foot; complaining of numbness and tingling of hands and feet; anaemic; heart sounds weak. Although there was no doubt peripheral neuritis in this case, I did not think when I first saw him that there were any clinical appearances affording strong grounds to suspect arsenic as a cause. Since my first visit, however, Dr. Hodgson has on more than one occasion found arsenic in this man's urine by Reinsch's test. On my second visit on January 30th, the peeling and scalliness of the palms and soles had become more marked, amounting to keratosis. The man did not appear to have improved. This man had been a fairly heavy beer-drinker, and up to eight weeks before his admission (when he is said to have given up beer-drinking because it made him sick), he had been drinking as much as five pints or even more a day. His beer was obtained almost solely from the "York Inn" supplied by Messrs. Whitaker.†

\* I may note that taking the quantity of arsenic found in 4 oz. of liver at 1-700th of a grain, and the weight of the liver as 53oz., there would be about 1-60th of a grain in the whole liver. This result is not dissimilar to those obtained by Dr. Stevenson and Dr. Dixon Mann in fatal cases in Manchester in 1900.

† Note by Witness (April 18th).—See, as to this, Evidence by Mr. G. S. Thompson (Q. 8849), and by Dr. Neech (Q. 9093).

Case No. 4.—Nancy Wilkinson, single, silk spinner, aged 35. Admitted 8th October, 1901, into the Workhouse Infirmary. She came from Brighouse, a district which is outside Halifax, but comprised in the Halifax Union, and stated on admission that she had been suffering from "rheumatism." Symptoms were: Much pigmentation of skin of the trunk (according to Dr. Hodgson, a "typical arsenical" condition), inability to walk, no tendon reflexes, pain on pressure of the calves, dropped feet, complaining of having had "pins and needles" in extremities, keratosis of soles of feet.

This woman is now improving and on January 30th was in a convalescent ward.

This woman had the appearance of an habitual beer drinker, and obtained her beer from the "Black Bull," at Brighouse, supplied by Messrs. Ramsden.

Case No. 5.—Mrs. Lowrie, widow, aged 50, admitted October 29th, 1901, to old Workhouse Infirmary, and shortly afterwards transferred to new Infirmary. Symptoms on admission to the latter: Marked general pigmentation of skin all over the trunk with clear patches, particularly around the waist. Complaining of pricking sensations and pains in the feet, knee jerks present, no obvious paralysis, no keratosis, but skin generally somewhat scaly though smooth to touch, some bronchitis. At the date of my visit the above symptoms were present; the woman was stated to be improving. I am informed that in March she developed definite keratosis. She was a thin, wasted-looking woman, and stated she was practically a teetotaler, but told me that she took a gill of porter at times, and sometimes a glass of beer. I subsequently heard through Dr. Neech that this woman's landlord has often seen her taking beer at home, obtained from the "Victoria and Albert" public-house.

Case No. 7.—T. Lee, carter, aged 54. Admitted January 15th, 1902. Symptoms on admission: Very well marked pigmentation of the skin all over his body, typically arsenical, and with an almost metallic lustre between the shoulder-blades, silvery tongue, husky voice, dulness of upper lobe of left lung, rales to be heard all over chest, systolic murmur heard all over heart area. Reflexes slow, gait ataxic, sick in the morning; suffering also from stricture, which required surgical relief, and incontinence of urine; eventually he showed signs of heart failure, with abdominal breathing, due to paralysis of diaphragm (?), ineffectual cough; on February 4th the intercostal spaces were sucked in. The temperature was very irregular.

On January 15th it was 97.2.

23rd " 98.4.

Night of 24th " 99.6.

Morning of 25th " 98.6.

Night of 25th " 100.

gradually rose to 102 night of 28th, then having a morning rise to 101.4, and night fall to 99 till February 1st; on the night of February 2nd it rose to 103, and then gradually fell till he died on February 5th.

Dr. Hodgson had found arsenic twice in this man's urine on January 21st and 22nd. He died on February 5th, 1902. At an inquest held on February 7th, a verdict was returned of "Death from pneumonia accelerated by arsenical poisoning." A post-mortem examination was made.

From notes by Dr. Woodyatt and Dr. Hodgson, I gather that the principal appearances were:—Lungs; Consolidation of the whole of upper lobe of right lung, which presented appearance of grey hepatization. (There seems to be some uncertainty whether this consolidation was recent, Dr. Woodyatt regarding it in this light, while Dr. Hodgson pointed out that in his view this mischief was of longer standing, and organisation was taking place, an opinion which receives some confirmation from a report on microscopical examination of a specimen sent to Professor Delépine). In lower lobe signs of "hypostatic pneumonia." Fatty degeneration of heart muscle (Delépine), atheroma of aorta and aortic valve. Liver large and fatty. Kidneys slightly cirrhotic, with pelvis dilated. Suprarenals normal.

The viscera were not examined chemically in this case.

Case No. 8.—H. Marsden 50, admitted from Norland, a district just outside the borough, January 17th, 1902. On admission face blotchy and puffy, eyes and nose running, feet swollen, red, and painful, particularly when warm. Pigmentation around nipples where pigmented skin was peeling. Tendon and superficial reflexes exaggerated, calf muscles very tender, slight bronchitis. Some incontinence of faeces and urine. Dr. Hodgson

Mr. H. H. Smith.

Wilkinson.

Lowrie.

Lee.

Inquest on Lee.

Marsden.

Mr. H. H. Smith, 1 Mar. 1902. found arsenic on three occasions (January 19th, 22nd, and 24th) in this man's urine. On February 14th this man was discharged from the hospital by Dr. Woodyatt, and so is no longer under Dr. Hodgson's observation. At the date of his discharge distinct keratosis had developed.

#### CASE IN PRIVATE PRACTICE.

Private cases.

Case 6.—This case was shown me by a medical man, Mr. F., aged 45, no occupation; first seen by Dr. Leech, December 27th, 1901. Always been a big drinker, but lately has been drinking heavily of beer from the "Cross Keys" public-house. His custom was to have three or four pints in the morning, sleep the greater part of the afternoon, and to have a further three or four pints in the evening. His symptoms when I saw him were: Well-marked pigmentation of skin, especially on the face, of a well-defined "pinhead" character; hand grip weakened, loss of power in extensor muscles, tottering gait, tenderness on pressure in the calves, slight keratosis, liver enlarged and slightly nodular, some recent oedema of the legs, failing memory.

#### REVIEW OF ABOVE CASES.

Outbreak one of arsenical poisoning.

Taking all the symptoms of the above cases into consideration it is clear that clinically, and especially in respect of affections of nerves, they present almost identical features with those of the sufferers from the 1900 epidemic as described to the Commission by Dr. Reynolds, Dr. Nathan Raw, and others. Pigmentation, upon which stress has been laid as demonstrating the arsenical origin of a case not otherwise to be distinguished from one of "alcoholic" neuritis, was observed in several instances, and the character of this pigmentation was the kind particularly associated with arsenic. Marked keratosis, again, which was a common symptom in the Manchester cases, and which may be considered specially indicative of arsenic, was observed in six cases, Nos. 1, 2, 3, 4, 6, and 8. Arsenic was detected by Dr. Hodgson in the urine of three cases, and specimens of urine from the same three cases were sent to me by Dr. Hodgson and transmitted to Professor Thorpe, who has confirmed the presence of arsenic in two instances, although the amount was minute. In the only case in which chemical examination has been made post mortem, arsenic has been found in the liver and in other viscera.

I may note that Dr. Hodgson, who has recognised the probable nature of these cases, had made a careful study of the cases which occurred in Crumpsall Infirmary during the epidemic in Manchester in 1900. Last month Dr. Reynolds, at Dr. Hodgson's request, examined these Halifax cases, and as he has already informed the Commission, he was satisfied on clinical grounds that they were attributable to arsenic. The cases in the infirmary, as has been said, were seen and treated by Dr. Hodgson in his capacity of resident medical officer; but they were also, in the hospital sense, under the care of the visiting medical officer, Dr. Woodyatt. Dr. Woodyatt did not agree at first with Dr. Hodgson that poisoning by arsenic in beer was the cause of illness in these cases, and at the first inquest (McNulty) this difference of opinion was made very patent. At the second inquest Dr. Woodyatt informed the coroner that, although he had suspected arsenical poisoning in Thomas Lee during life, the post-mortem appearances had made him alter his mind, and that he was satisfied that the cause of death was croupous pneumonia. Dr. Hodgson, on the other hand, said that the condition of the lung in his view could be sufficiently accounted for by weak action of the

heart, which again might be attributable to arsenical poisoning.

None of these patients had been taking arsenic medicinally, so far as could be ascertained, before onset of illness. None of them were exposed to arsenic by reason of their work. As has been said, all beyond question were beer drinkers, and some consumed heavy quantities of beer habitually.

Mr. H. H. Smith, 21 Mar. 1902.

#### SOURCES FROM WHICH THE ABOVE PATIENTS OBTAINED THEIR BEER.

From enquiry which I made of the patients, and from information supplied to me by the chief sanitary inspector of Halifax, and by Dr. Hodgson, it appears that the places from which the above cases habitually obtained beer shortly before onset of illness were as follows:—

- Case 1.—"The Britannia" (Messrs. Webster).
- "The Brewer's Cellar" (The Yorkshire Brewery Company).
- The "Black Horse" (Messrs. Ramsden).
- Case 2.—"Cross Keys" (Publican-Brewer).
- Case 3.—"York Inn" (Messrs. Whitaker).\*
- Case 4.—"Black Bull," Brighouse (Messrs. Ramsden).
- Case 5.—"Victoria and Albert" (Messrs. Alderson).
- Case 6.—The "Cross Keys" (Publican-Brewer).
- Case 7.—"Three Pigeons" (Messrs. Webster).†
- "The Druids" (Messrs. Whitaker).
- "William the Fourth" (Messrs. Ramsden).
- Case 8.—"Moor Cock" (not a tied house, but supplied chiefly by Messrs. Whitaker).
- "New Rock" (Messrs. Whitaker).‡
- Another public-house (Messrs. Ramsden).

Thus two patients, 1 and 7, had each consumed beer derived in part from Messrs. Webster; three cases, Nos. 3, 7, and 8, beer from Messrs. Whitaker, one of these, No. 3, being supplied almost wholly from this brewery; No. 5 obtained beer almost wholly from Messrs. Alderson; case No. 4 obtained beer solely, and cases 1, 7, and 8 partly, from Messrs. Ramsden; while two cases (No. 2 and 6) obtained beer almost wholly from the publican-brewery, the "Cross Keys."

#### LOCAL ENQUIRIES AND ACTION WITH REGARD TO ABOVE CASES.

Dr. Neech informed me that in 1900 he had suspicion of arsenic having been present in beer from one brewery in Halifax, but this beer was recalled by the brewers before a sample could be obtained. The brewery in question, Messrs. Brear and Brown, is understood to be the only brewery in Halifax which in 1900 was obtaining brewing sugars from Messrs. Bostock. Since that date until recently Dr. Neech has never had occasion to suspect arsenic in Halifax beer.

At the date of my first visit Dr. Neech had not taken any steps to trace the actual beer associated with the cases, but he had caused certain samples of beer on sale at public-houses in Halifax to be collected as follows:—

Notes by Witness, April 18th, 1902.

\* See note on p. 15.

† In draft of this report the words Whitaker and Webster were accidentally transposed. See Mr. G. S. Thompson's evidence, Q. 8851-2.

‡ I have since been informed that Messrs. Whitaker do not own the "New Rock." See Mr. G. S. Thompson's evidence, Q. 8854; and Dr. Neech, Q. 9095.

From 13th January to 16th January.

Date of Collection of Sample.	Name of Inn.	Name of Brewer.	Number of Sample.
13 January 1902	"York Inn"	R. Whitaker and Sons	162
13 "	"Victoria and Albert"	Alderson's	163
13 "	Grocer, Mr. Fox	Whitaker's	164
13 "	"The Peacock"	Brear and Brown	165
14 "	"Cross Keys"	Swift's	166
15 "	"Cross Keys"	Swift's	166a
16 "	"Cross Keys"	Swift's	167

The above samples were submitted to Mr. Ackroyd, Halifax Borough Analyst, who reported them free from arsenic in each instance.

Mr.  
I. Smith.

Additional samples were obtained by Dr. Neech's direction on January 17th, 20th, and 21st, viz. :—

Mr.  
H. H. Smith.

Jan. 1902.

21 Mar. 1902.

Date of Collection of Sample.	Name of Inn.	Name of Brewer.	Number of Sample.
17 January 1902	"Cross Keys"	Swift's	169
17 "	"Cross Keys"	Swift's	170
17 "	"Victoria and Albert"	Alderson's	1
17 "	"York Inn"	Whitaker and Son's	2
17 "	"Foundry"	Ramsden's	3
20 "	"Cross Keys"	Swift's	174
20 "	"Gibbet Tavern"	Webster's	175
20 "	"Victoria"	Alderson's	176
20 "	"Mechanics"	Halifax Brewery Company	177
21 "	"Mitre"	Stocks	6
21 "	"Wheat Sheaf"	Brear and Brown	7
21 "	"Northgate Hotel"	Webster's	8

The above samples were submitted to Mr. Richardson, of Bradford, who reported as follows :—

No. 169, 1-35th grain; No. 170, 1-16th grain (both "Cross Keys" beer); 1, 1-250th grain; 2, 1-250th grain; 3, 1-170th grain arsenious oxide per gallon. Nos. 174 to 177 only very minute traces. Nos. 6 to 8 only very minute traces.

Dr. Neech informed me that samples 169 and 170 were of the same brews as the "Cross Keys," which a day or two before had furnished respectively samples 165—166a, and 167, sent to Mr. Ackroyd and returned by him as free from arsenic.

In the last week in January, after the inquest on McNulty, Dr. Neech again had samples of beer then on sale at public-houses in Halifax collected. He kept these samples for a time as he had hesitation in sending them to the borough analyst in view of the latter having failed to find arsenic in the "Cross Keys" samples submitted to him on January 14th to 16th.

Eventually, with the concurrence of the sanitary committee, these samples were sent to Mr. Allen, at Sheffield. I have now heard from Dr. Neech that Mr. Allen's results are as follows :—

Mr. Allen's.

Date of Collection of Sample.	Number of Sample.	Public-house.	Brewer.	Result.
24 January 1902	183	"Duke of Leeds"	Bentley and Shore	1½ grain per gallon, about.
24 "	184	"Prescott Arms"	Yorkshire Brewery Company.	" " " " "
24 "	185	"London Tavern"	S. Webster and Son	7½ " " " "
24 "	186	"Mechanic's Arms"	Halifax Brewery Company	1½ " " " "
24 "	187	"Kimberley Arms"	Boardmans	Free from arsenic.
24 "	188	"Mitre Hotel"	Stocks	No arsenic detected.
24 "	189	"Westgate Hotel"	Aspinall, Halifax	1½ grain per gallon, about.
24 "	190	"Peacock Inn"	Brear and Brown	No arsenic detected.
24 "	191	"Sportsman Inn"	Ramsden and Son	Sample lost in transit.
24 "	192	"Waggoner's Arms"	J. Smith, Tadcaster	No arsenic detected.
24 "	193	"New Inn"	Alderson and Company	Free from arsenic.
24 "	194	"Hop Pole Inn"	R. Whitaker and Sons, Halifax.	½ grain per gallon, about.
25 January	195	"Ring-o'-Bells"	C. B. Whitaker, Luddenfoot.	No arsenic detected.
25 "	196	"Queen's Road Hotel"	Filden and Company, Halifax.	No arsenic detected.

As one of the cases, No. 4, obtained all her beer at one of Messrs. Ramsden's public houses at Brighouse, outside Halifax, I asked Dr. Martin, the medical officer of health at Brighouse, to make some inquiries. He at once procured samples of beer then on sale from the public house in question, and sent them to Mr. Allen for analysis. They were returned, however, as arsenic-free by Mr. Allen. Dr. Martin has also instituted some inquiries amongst medical men in his district as to suspected cases of arsenical beer poisoning, but so far, I understand, with negative results.

I called on Mr. Ackroyd, the borough analyst of Halifax, on January 15th, and again on the 18th. He informed me that he has during the past year been constantly engaged in testing beers and brewing ingredients for brewers in and around Halifax. Some of the brewers have their beers tested by him every quarter. I gather that as a matter of fact he has hardly ever by the test which he employs found arsenic in any sample of beer or of brewing ingredients submitted to him during the latter half of 1901 or during the present year. The test which he used in all cases is the Reinsch test in the form first advised by the Brewers' Expert Committee in their Report of the 31st December, 1900. With regard to the "Cross Keys" sample, in which he had found no arsenic, Mr. Ackroyd showed me a sublimate which he believed to be the one which he had obtained from the Reinsch copper in one of these beer samples, and told me that in his opinion, although a sublimate had been obtained in this instance, it was not arsenic. He was not, however, able to identify the tube in question with any degree of certainty, as it had not been labelled. At the date of my second visit, Mr. Ackroyd was engaged in

analysing a large number of samples of beer and brewing ingredients sent to him by the brewers in consequence of the present allegation. The certificates of analyses thus made by Mr. Ackroyd for brewers were produced at the inquest on McNulty, by Mr. Waugh, who stated that the beers examined were absolutely free from arsenic. I learn that since my visit, Mr. Ackroyd has modified his methods of testing, and that he has now adopted the form of Marsh Berzelius test recommended by the Committee of the Societies of Chemical Industry and Public Analysts.

On January 18 I called on Mr. Sergeant, the chief officer of excise at Halifax. He informed me that he had seen the newspaper reports of the inquest on McNulty, but he had not considered it necessary to take any steps in the matter, having received no specific instructions to do so from the Board of Inland Revenue. At that date he had sent no special samples of beer or brewing ingredients to the Government Laboratory to be tested for arsenic; but since then, I understand, a large number of samples of recently brewed beer from Halifax breweries (particularly breweries implicated in respect of the above cases), and also of their brewing materials, have been collected by the local excise authorities and transmitted to the Government Laboratory.

The suggestion made by Dr. Hodgson at the first inquest that the cases in the infirmary were attributable to arsenical beer poisoning, and the statement by Mr. Allen that amounts such as 1-16th and 1-18th of a grain of arsenic per gallon had been found in beer purchased in Halifax, were at first received by the brewers with incredulity, and, naturally enough, with some hostility.

Excise officers sent samples from breweries after out-break.

Attitude of Halifax Brewers.

Mr. H. Smith. I am informed that it was intimated on behalf of the brewers that no efforts would be spared in instituting legal proceedings against Dr. Hodgson and Mr. Allen if their statements to the coroner could be confuted. The same incredulity no doubt led certain of the brewers to view with disfavour the action of the coroner, by which attention had been pointedly drawn to these cases; and the coroner at the second inquest on the man Lee on February 7th publicly took objection to a visit which had been paid to him by one of the Halifax brewers before his inquiry. At both inquests the Halifax brewers were represented by a barrister, Mr. Waugh, who in each instance made the most of the view taken by Dr. Woodyatt, that the cause of death was not arsenical poisoning, and at the first inquest laid great stress on the fact that the Borough Analyst had found no arsenic in any sample of beer from the breweries implicated. He also produced certificates of analyses relating to other samples of beer from the breweries in question which stated that they were free from arsenic. The brewers engaged on their behalf the services of Dr. West Symes, of Halifax, who frequently visited the infirmary cases and advised the brewers on medical questions involved. Mr. Buckley (managing director of Messrs. Webster), who is chairman of the local Brewers' Association, informed me that after the suggestion of arsenical poisoning had come to his notice he called a meeting of the principal brewers and advised them to have all their beers analysed. As has been said, in the middle of January such analyses were being made by the Borough Analyst, with the negative results referred to above. Later, in February, I learned that a large number of samples of beer, as well as malt and other brewing materials, were being sent for analysis by Halifax brewers not only to the Halifax Public Analyst, but also to Mr. Richardson, of Bradford; Dr. Luff, in London, and others.

#### INQUIRY AS TO ORIGIN OF PARTICULAR BEER ASSOCIATED WITH THE ABOVE CASES.

Source of beer consumed by out-rioters.

On January 23, and on later dates, I visited all the breweries from which particular beers had come under suspicion either by having been found to contain arsenic in noteworthy amounts by Mr. Allen or by other analysts, or by having been drunk wholly or in part by the patients above referred to. My object in each instance was to trace the particular beer, if possible, back to its brew, and then ascertain details of the ingredients used in such brew.

I have to acknowledge my indebtedness to brewers and maltsters for the information which they kindly placed at my disposal.

The breweries in question were:—

(Table 1.) Messrs. Webster (Halifax), who supplied beer consumed (along with that of other breweries) by cases 1 and 7, and whose beer at the "Britannia" Inn was found by Mr. Allen to contain 1-18th of a grain of arsenic per gallon.

(Table 2.) Messrs. Ramsden (Halifax), who supplied beer consumed (along with that of other breweries) by cases 1, 7, and 8, and whose brewery had been almost the sole source of beer taken by case No. 4; and whose beer, also, at the "Black Horse" was found by Mr. Allen to contain 1-24th of a grain of arsenic per gallon.

(Table 3.) Bentley's Yorkshire Brewery Company (Leeds), who supplied beer consumed (along with that of other breweries) by case 1, and whose beer at the "Brewers' Cellar" was found by Mr. Allen to contain 1-16th of a grain of arsenic per gallon.

(Table 4.) Messrs. Whitaker (Halifax), who supplied beer consumed (along with that of other breweries) by cases 7 and 8, and whose beer at the "York" Inn had been almost the sole source of beer taken by case No. 3.

(Table 5.) Cross Keys Brewer (Halifax), whose beer at the "Cross Keys" had been almost the sole source of beer taken by cases 2 and 6.

(Table 6.) Messrs. Alderson's (Halifax), whose beer at the "Victoria and Albert" had been almost the sole source of beer taken by case 5.

In the case of Messrs. Webster and Messrs. Ramsden I was informed by the brewer that his records enabled him to refer with certainty beer, in which Mr. Allen found respectively 1-18th and 1-24th of a grain of arsenic per gallon, to brews of specific dates, made with ingredients the origin of which is recorded in each instance. At Messrs. Webster's, the date of the brew

in question was December 13th, 1901; at Messrs. Ramsden's, it was either December 12th, or December 18th, 1901.

In the case of the Yorkshire Brewery Company, I was informed that though the exact brew from which was derived the sample in which Mr. Allen found 1-16th of a grain per gallon could not be identified, it was one of four brews of December, 1901, all of which were prepared with ingredients of the same origin and in the same proportions. As regards the publican-brewery in Halifax, the "Cross Keys," the brewer had no doubt that the beers in which Mr. Richardson found respectively 1-16th and 1-35th of a grain per gallon were prepared solely from malt, hops, and flaked maize on December 5th and December 27th, 1901, respectively; but he did not keep any book by which this statement could be verified.

As regards Messrs. Whitaker I had no chemical results respecting the beer to go upon, but only the evidence that three patients admitted to the Halifax infirmary in January, 1902, had obtained beer from this brewery; one (case No. 3), almost exclusively; the other two along with beer from other breweries. At this brewery, therefore, I selected arbitrarily for enquiry beer brewed about the middle of December, 1901. Similarly at Messrs. Alderson's, where likewise I had no chemical results respecting the beer to go upon, I took for enquiry the brews of August and September, 1901, which appeared most likely to have furnished the beer consumed at the "Victoria and Albert," by case No. 5, prior to her admission to the Halifax old workhouse infirmary, in October, 1901.

When the particular brews thus selected and enquired into at the several breweries are compared, the results are briefly as follows:—

GLUCOSE.—Glucose entered in all the brews enquired into except the "Cross Keys." None of the remaining five breweries, I was informed, had ever been customers of Messrs. Bostock. The glucose which had been used was obtained as follows:—

At Messrs. Webster, from the Liverpool Saccharum Company.

At Messrs. Ramsden, from the Glasgow Sugar Company.

At the Yorkshire Brewery Company, from the Mambé Company.

Messrs. Whitaker, American Glucose, obtained through agents (Ince, Pickering and Company).

Messrs. Alderson, American "Climax" Glucose, through agents, Messrs. Thompson, of London.

Each of these brewing sugar firms supplies glucose to large numbers of brewers elsewhere than in Halifax; and (except at Messrs. Alderson) I saw the invoices, which in each instance guaranteed the products to the brewer as "free" from arsenic. I could obtain no information of arsenic having been found in any specimens of glucose from any of the above firms. On this point no doubt ample information could be furnished by the Government Laboratory.

INVERT SUGAR.—Invert sugar entered into the brews enquired into at three of the breweries only, and was obtained as follows:—

At Messrs. Webster, from Valentine and Tod.

At Messrs. Ramsden, from Fowler and Company.

At Messrs. Whitaker, from Valentine and Tod.\*

Invert sugar was added as priming to the brew at one brewery only, namely, Messrs. Whitaker's. No priming of any kind was said to have been used in any other of the brews enquired into.

The above remarks with regard to glucose apply equally to these invert sugars.

It will be noted that the proportions of glucose or invert sugar used at the five breweries in question was, generally speaking, not excessive.

At Messrs. Webster's brewery for instance, the quantity of invert sugar which entered into a gallon of finished beer was .079lb., and the quantity of glucose .059lb. Assuming that both invert sugar and glucose had contained arsenic and in equal proportions, and that all this arsenic had entered into the beer, then, for the beer to contain as much as 1-16th grain of arsenic per gallon it would be necessary for the glucose and the invert to have been contaminated to the extent of .45 grain, or nearly  $\frac{1}{2}$  grain of arsenic to the pound. The

\* Note by Witness, April 18th.—Apparently the source of invert sugar at this brewery was the Liverpool Saccharin Company, not as here stated. See Mr. Thompson's evidence, Q. 8859-8860.

Mr. H. H. Smith.  
21 Mar. 1902.

Origin of glucose used;

of invert sugar;

Mr. H. H. Smith. Commission has not received evidence that any glucose or invert sugar, other than Bostock's, in 1900 or since, has contained arsenic in anything approaching this proportion.

of flaked maize:

**FLAKED MAIZE.**—Flaked maize was used in the particular brews enquired into at Messrs. Webster, Ramsden, Whitaker, Alderson, and "Cross Keys," not at the Yorkshire Brewery Company. I have met with no evidence that arsenic has at any time been found in samples of flaked maize, either at Halifax or elsewhere, and I understand that no mineral acid is used in its preparation.

of preservatives:

**PRESERVATIVES, ETC.**—In view of the evidence which the Commission has received as to the very slight degree in which it is possible for beer to be contaminated by arsenic through the use of hardening substances, yeast foods, finings, or preservatives, it is not perhaps necessary here to detail such particulars as I have collected with regard to the use and origin of these materials in the particular brews enquired into, but if the Commission consider it desirable for the sake of completeness, I will do so.

of hops:

**Hops.**—I have not as yet made complete enquiry as to the origin of hops used.

and of malt.

**MALT.**—I could obtain no evidence at the several breweries that in the particular brews enquired into malt of a common origin had been used, or, indeed, that any two of the breweries in question obtained malt from one and the same maltster. Accordingly it is necessary to deal with the malt in each of the brews enquired into separately.

**Messrs. Webster.**—Visited January 24th and February 13th, 1902. Up to the end of January, 1902, last season's malt, i.e., 1900-1901, was being used exclusively at this brewery, and would have been used in the brew under enquiry, which was made on December 13th, 1901. I was informed that the Yorkshire malt used in this particular brew was made as far back as February 5th to 13th, 1901.

Before February 20th, 1901, no fuel other than Halifax and Barnsley gas coke had been used at Messrs. Webster's maltings. Some foreign malt had also entered into the brew enquired into, and this, the brewer informed me, had been made just after he had, in consequence of the "beer scare," given up gas coke and taken to anthracite. When this foreign malt was made (between March 31st and June 5th) he was using anthracite on the kiln, either solely or with some admixture of gas coke. I saw the invoice relating to the first purchase of anthracite, which was dated February 14th, 1901. Before the fuel was thus changed from gas coke to anthracite the kiln was swept out.

Messrs. Webster's maltings are close to the brewery, and all their malt is screened and once brushed in a Barron's machine at the maltings, which was put up in December, 1900. I was also informed that the February 5th to 13th malt, stated to have been used in the brew under inquiry, had "damped" in the malt bin, and had been redried and again brushed before being used.

**Messrs. Ramsden.**—Visited February 13th, 1902. The malt used in the beer here enquired into (brewed on December 12th and December 18th) according to the books which were shown to me, was new malt of this season's malting. It was made up of malt coming from Messrs. Ramsden's Elland, Brighouse, and Caulder maltings. I visited the Brighouse and Elland maltings of this firm. At each malting I was informed that the fuel used this season has been oven coke and anthracite. The brewer put the proportions as two-thirds of oven coke to one-third of anthracite, but the maltster spoke of anthracite and a "little" oven coke. At both maltings, however, I was informed that last season, 1900-1, a variety of fuels had been employed, viz., gas coke, oven coke, or anthracite, but almost entirely gas coke from local sources. At Elland all the malt is screened and brushed in a Barron's machine before leaving the malting. At Brighouse the malt is hand-screened only and not brushed. All malt is brushed besides at the brewery in a Nalder's machine, which has been in use for eleven years.\*

I ascertained from the Elland maltster's books that

\* The possibility that an old brushing machine might contaminate malt if for many previous years it had been used to brush arsenical malt may perhaps be worth inquiry.

the last of the 1900-1 season's malt was sent to the brewery on the 26th November, 1901; the first of the new malt was sent on November 4th. I ascertained also from the brewer's books at the brewery that all last season's malt was finished by December 5th, and this tends to support the brewer's statement that both the brews under enquiry (one or other of which, according to Mr. Allen, gave beer containing 1-24th of a grain of arsenic per gallon) had been prepared with new malt. It may, however, be noted that although beer from Messrs. Ramsden's brewery was being consumed by three of the infirmaries cases, Nos. 1, 7, and 8, up to January, 1902, these men in each instance were getting beer from other suspected sources as well, and thus there is not any strong evidence that harm resulted from Messrs. Ramsden's December beer. But there is more definite evidence suggesting that other and earlier beer from this brewery produced illness in the circumstances of case No. 4 (Nancy Wilkinson). This woman, whose illness had become established by October 8th, 1901, when she was admitted into the infirmary, had obtained all her beer from the "Black Horse" at Brighouse, supplied by Messrs. Ramsden. As Messrs. Ramsden did not begin to use this season's malt till after November 4th, the beer that she drank would have been brewed from last season's malt, made almost wholly over gas coke. At Messrs. Ramsden's I was shown several reports that malt (and other brewing ingredients and beers) had been analysed and found free from arsenic. These reports were principally by the borough analyst of Halifax, Mr. Ackroyd; one by Mr. Lawrence Briant, which related to Brighouse malt of the 10th January, 1901, stated that it contained a small but negligible trace of arsenic. This particular sample Messrs. Ramsden inform me had been made over gas coke.

**The Yorkshire Brewery Company.**—The particular beer here enquired about (that in which Mr. Allen found 1-16th of a grain per gallon) was at first stated by Mr. Badley, the company's brewer, to be one of two brews between December 9th and December 16th, 1901, either brew No. 209 or No. 211; but in a letter dated February 16th he mentions four brews as "implicated," viz., Nos. 201, 211, 216, and 219, and does not mention 209. According to this letter all the brews contained 15 quarters of old Yorkshire malt (i.e., of malting season 1900-1) to 5 quarters of new malt.

I may note that at the time of my visit casks of beer from the above brews were still in use; Mr. Dawson, the Company's chemist, had procured samples of these brews and had sent them to Mr. Fairley, their consulting chemist, and Public Analyst of Leeds—I have not heard what results. I may mention, however, that Dr. Cameron, Medical Officer of Health for Leeds, has lately obtained samples of beer from public houses belonging to this brewery in Leeds, and Mr. Fairley has in two, which do not appear to have been taken with the formalities prescribed by the Sale of Food and Drugs Acts, reported 1/40th of a grain of arsenic per gallon. Since Mr. Allen's statement at the inquest, and before my visit to the Yorkshire Brewery Company, Mr. Fairley had, however, examined 27 brewings of this brewery and found them all free from arsenic, except one, a strong beer, brewed on January 16th 1902, in which he found under 1/100th of a grain per gallon.

At the Yorkshire Brewery Company they make their own malt. This season they have used a mixture of anthracite and oven coke, principally the latter, on account of the construction of their fire-pans. Last season, up to February, 1901, they were using gas coke alone, and I was assured that the 15 quarters of old Yorkshire malt in the above brews would have been made comparatively early, and almost certainly over gas coke from Rothwell. The invoice corresponding to the first delivery of anthracite at their malting was dated February 18th, 1901.

**Messrs. Whitaker's.**—Visited January 24th and January 29th, 1902. The beer from this brewery was not one of those which came under suspicion as a result of chemical analysis, but two of the infirmaries patients, cases 7 and 8, had got their beer partly from this brewery, and one case, No. 3, almost wholly. Accordingly, I enquired as to beer from this brewery which was on sale about the end of December, 1901. I was informed that last season's 1900-1 malt was in use up to December 21st, 1901. From the brewer's books I ascertained that beer brewed on the 18th December, 1901, contained 15 quarters of last season's malt to 3 quarters of new malt. Case No. 3 was admitted to the infirmary on the 10th January, 1901, so that presumably the beer which he had been drinking would have been made principally with this old malt. At this brewery they make their

Mr. H. H. Smith.  
21 Mar. 1902

Mr.  
H. H. Smith.  
21 Mar. 1902.

own malt over anthracite and Halifax gas-coke. They use a three-floor kiln with a fan, and claim that as they dry their malt on the upper floor and finish on the lower floor, the malt being dry when it comes in contact with the furnace fumes on the lower floors is not so likely to become arsenical as it would if it were wet. They have made no difference, I was informed, in their fuel this season as compared with last. On inquiry I ascertained that the percentage of anthracite used this season and last was no more than 15. All malt is brushed as soon as it has been made in a Boby's machine, and is now again brushed and polished before being used in brewing.

The above four breweries make their own malt entirely, with the exception of porter malts, which they buy either from Messrs. Plunkett, of Dublin, or Messrs. Warmley, of London. At the two remaining breweries the malt is bought.

"Cross Keys."—Visited January 17th, 1902. This is a public-house with a small brewery attached, kept by Mr. Swift. The brews which I enquired into here were those in which Mr. Richardson found respectively 1-16th of a grain and 1-35th of a grain of arsenic per gallon. Mr. Swift bought his malt crushed, and ready for the mash tun, from Messrs. Firth and Blackburn, of Cleckheaton, and Messrs. Broadbent, of Bingley. Now he obtains his malt from a third maltster. The brew in which 1-16th of a grain per gallon was found was prepared solely from Messrs. Firth and Blackburn's malt delivered at the brewery on December 5th, 1901. Mr. Swift uses no glucose or invert, but only malt and a small quantity of flaked maize. Messrs. Firth and Blackburn, whose maltings I visited on February 14th, were formerly maltsters on a large scale, but have now sold their biggest malting and only retain a small one. This season they commenced to malt in December, and before that month they had sent out to "Cross Keys" and elsewhere only their old malt of last season. Up to this season they have always used gas-coke from Lowmoor for malting. Since last December they have been using oven-coke. Their malt is screened, but not brushed; it is not brushed by Mr. Swift. In April, 1901, Messrs. Firth and Blackburn had a consignment of malt returned to them by some Lancashire brewer as being too arsenical to be used.\* On April 15th, 1901, they sent a sample of malt to Mr. Fairley, who reported 1-30 grain arsenic per lb. Mr. Firth informed me that they have not sent any sample of malt to be tested since. Mr. Swift had never caused any malt which he purchased to be analysed. The brew in which Mr. Richardson found 1-35th of a grain was prepared, according to Mr. Swift, with a mixture of malt from Messrs. Firth and Blackburn, and from Messrs. Broadbent, of Bingley. At Messrs. Broadbent's maltings, I was informed that any malt supplied to the "Cross Keys," and used there in December, would have been made this season. Last season the firm had failed and all malt on the premises was sold by the solicitors for the benefit of the creditors. The maltings had been started afresh in December, 1901; the first fuel used in September was gas-coke, but subsequently oven-coke has been substituted. Messrs. Broadbent's malt is screened but is not brushed.

Messrs. Alderson.—Visited January 29th, 1902. Beer from this brewery was not of those which came under suspicion as a result of chemical analysis, but one of the cases, No. 5, obtained her beer wholly from the "Victoria and Albert," a public-house supplied by this firm. As the onset of illness in this case appears to have been in October, the beer in question would probably have been brewed in August or September of last year, or before. Such beer, I was informed, would have been brewed with old malt of the season 1900-1. Messrs. Alderson in 1901 used to buy malt from Messrs. Worsick, of Northowram, who also have a malting at Elland. Early portion of their 1900-1 season's malt was, I was informed, made from "gas-coke and a little anthracite": the later portion over anthracite. Messrs. Worsick's Northowram malt was being used at Messrs. Alderson's about last August. Their Northowram malt is generally despatched to their Elland maltings, and there screened and brushed before sale, but I

\* This was what Dr. Neech and I understood Mr. Firth to tell us on February 14th. At a later visit, however, Mr. Firth informed me that no malt was returned to him by the Lancashire brewer, but that the latter, who furnished no particulars regarding the amount of arsenic found, cancelled the contract—a proceeding to which Mr. Firth appears to have made no objection.

learned at Elland that last summer the malt sent to Messrs. Alderson was frequently despatched direct from the Northowram malting, in which case it would be unbrushed. Messrs. Alderson also got last season up to the end of May, 1901, some malt from Mr. Ben Stead, of Brighouse, and informed me that they had it tested, and found it arsenical, and consequently gave up using it. The malt at Mr. Ben Stead's was made over gas-coke. There is no brushing machinery. Whether or no Mr. Ben Stead's malt was being used by Messrs. Alderson in the summer or autumn of last year in brewing the particular beer enquired into, I am unable to say. Mr. Alderson informed me that the greater part of the malt which they were using in September was obtained from Messrs. Worsick.

In considering the probability that the beers enquired into became contaminated with arsenic by the use of arsenical malt, the following points are worthy of note:—

The proportion of malt used in the several brews was approximately as follows:—

Brew enquired into at—	
Messrs. Webster's	1-35 lbs. per gal. of finished beer.
Messrs. Ramsden's	1-4 " " "
The Yorkshire Brewery Co.	1-5 " " "
Messrs. Whitaker's	1-1 " " "
The Cross Keys	2-0 " " "
Messrs. Alderson's	1-4 " " "

If it be taken for purposes of calculation that the beers associated with the Halifax cases were contaminated with arsenic to the extent of 1-16th grain per gallon, and that 1-4lbs. of malt went to the gallon of finished beer, then, if all the arsenic in the malt got into the beer, the malt must have contained about 1-22nd grain of arsenic per lb.

It will be remembered that Mr. Hooper of the Government Laboratory, informed the Commission in May last that he had met with 22 samples of malt in which the amount of arsenic lay between 1-50th and 1-20th grain per lb. and that proportions of arsenic in malt, such as 1-20th grain per lb. have been referred to by other witnesses.

It is known, however, that some of the arsenic introduced into the mash-tun is removed by yeast in the process of brewing, or otherwise does not reach the finished beer.

Again, it will have been noted that some of the malts in question were brushed before use, and the Commission has had evidence that brushing, especially if several times repeated, may diminish the quantity of arsenic in malt very materially. Here I would note, however, that I met with no instances in which attempt had been made to ascertain chemically the extent to which arsenic in a given malt was reduced by one or more brushings in the machine, with a view to discovering and adopting the method of brushing most efficacious in removing arsenic.

Reverting now to the above calculation, and making the (purely arbitrary) assumption that, by reason of brushing and of brewing, only half the arsenic present in the malt reached the finished beer, the malt would originally have contained, not 1-22nd grain but 1-11th grain of arsenic per lb.

Dr. Campbell Brown (Q. 5709) informed the Commission in May last that he had found certain malts which contained respectively 1-9th, 1-7th, 1-6th, and 1-4 grain of arsenic per lb. Mr. Estcourt (Q. 3982) mentioned an instance of malt containing up to 1-4th grain per lb. Mr. Wm. Thomson, I understand, has prepared evidence for the Commission to the effect that in a few malts which he examined between July and December, 1901, he has found arsenic in amounts from 1-30th up to 1-10th grain per lb.—and it would seem from his précis that all these malts came from Yorkshire, a county which has been specially mentioned by witnesses to the Commission in connection with arsenical malt.

These considerations, I think, suffice to show that the suggestion that the beers enquired into became contaminated to the extent indicated through use of arsenical malt cannot be dismissed as *prima facie* improbable.

For proof to be afforded, it would of course be necessary to know the amount of arsenic present in the implicated malt in each instance. This, unfortunately, arsenic

Mr.  
H. H. Smith.  
21 Mar. 1902.

Proportions of malt used in implicate brews.

Evidence that beer obtained its arsenic through malt.

Malt seldom tested for arsenic.

Mr. Smith. is at this stage impossible. It is true that since June, 1901, at all the breweries except the Cross Keys publican-brewery, a few samples of malt were occasionally analysed and were stated by the analyst not to be arsenical, or else to contain a negligible quantity of arsenic. But I have no evidence that the particular malts used in the implicated brews were among these samples in any case; and I note that at certain breweries the chemist to whom the malt samples were submitted, Mr. Ackroyd, Borough Analyst of Halifax, was using the form of Reinsch test first recommended by the Brewers' Expert Committee, not the more stringent method which they have subsequently put forward.

The malts which entered into the brews inquired into of course could not be recovered at the date of my visit. Moreover (with the doubtful exception of Messrs. Ramsden, page 19), they all had been malts of the 1900-1 season, whereas, usually, the malts in use at the dates of my visit were malts of the present season. At Messrs. Webster's, Whitaker's, and the Yorkshire Brewery Company's breweries, I was supplied by the brewer with samples of malt stated to be of last season, and these I have placed at the disposal of Professor Thorpe. Looking, however, to the large output of these breweries, and the quantities of malt used, and to the improbability that at any one of them arsenic would have been present in last season's malt in uniform proportions, it would seem that results of these analyses cannot be expected of themselves to settle the question of the derivation from malt of arsenic in the particular beers enquired into.

It appears, moreover, that there is substantial reason for drawing a sharp distinction between the malts used in the brews under enquiry and malts now in use.

In each instance there is evidence affording a more or less strong presumption that the fuel used to prepare the implicated malts was local gas coke, whereas in later malts (and particularly all those of this season, save at Messrs. Whitaker's) no gas coke had been used.

For example, in the case of the "Cross Keys" publican-brewery, where it was more easy to trace the malt, there appears to be no doubt that the brew in which Mr. Richardson found 1-16th grain of arsenic per gallon was made from malt delivered at the "Cross Keys" on December 5th, and that this malt (unbrushed before using) was made by Messrs. Firth and Blackburn last season, and over Lowmoor gas coke. I have already noted that I ascertained from Mr. Firth that in April, 1901, his malt was considered by a Lancashire brewer too arsenical for use.

At all the breweries visited I found that most of last season's malt was being used up at the end of last year, and this fact, together with the difference in the fuel used, tends to explain the comparative freedom from notable amounts of arsenic of samples of recently brewed beer in Halifax, which appears to be indicated by the analyses of Messrs. Richardson and Allen, given on p. 17.

The advice given by the Commission in their first report that fuel used in the kiln should be carefully selected on account of freedom from arsenic has thus, as regards this season, and in a sense, been adopted at nearly all the maltings which supplied the malts to the breweries in question. Except at Messrs. Whitaker's anthracite or oven coke, or both these fuels, have been substituted for gas coke, the liability of which (and particularly some Yorkshire gas coke) to contaminate malt has come to be generally recognised. In each instance, however, it appeared to me that the maltster was content with the fact that he had changed his fuel, and with the vendor's statement that the new supply was "free from arsenic." Hardly any steps seemed to have been taken at any malting to ascertain what amount of arsenic the new fuel contained, or to what extent its use could be relied upon to ensure safety as regards arsenic in the malt. I may note that at one maltster's I observed several lumps of pyrites of large size in the heaps of anthracite ready for the kiln.

I visited one malting, at Brighouse, where gas coke alone was being used as fuel in the kiln on January 30th. The maltster informed me that the whole of the malt thus made was used at his brewery in Bradford.

\* An exception may, perhaps, be made in the case of Messrs. Webster, who gave me a small sample tin, which they informed me contained black and white malt made on 1st February 1901, which (along with other malt) had entered into the brew specially enquired into. This sample was sent to Professor Thorpe.

8628\*. You visited Halifax on behalf of the Commission on January 15th, and subsequently, and inquired there about the cases mentioned in this report?—Yes. 21 Mar. 1902.

8629. These cases came to light in the Halifax workhouse infirmary, and public attention was called to them by inquests on two which were fatal—McNulty and Lee?—Yes.

8630. We understand that the Medical Officer of Health of Halifax suspects other cases to be due to arsenical poisoning, besides the eight which you deal with?—Yes. I know that he has three other cases which are not dealt with in my report at all, each of which is supposed to be arsenical.

8631. Do you know any particulars of those three cases?—No, I have no particulars of them. Dr. Neech draws attention to them in his report. We have now a formal report from Dr. Neech.

8632. That has just come in, and will be before us?—Yes.

8633. Have there been any more cases in the infirmary besides those dealt with in your report?—There have been three suspected cases that I have not seen. In one of them the man died very suddenly from heart failure after being admitted, and Dr. Hodgson suspected that might be a case of arsenical poisoning. Then, he tells me, there are two other cases in which the symptoms are not very marked.

8634. We understand from your study of the cases you deal with, and from the observations of Dr. Hodgson and others, which you give in the report, that you are of opinion that they are attributable to arsenical poisoning?—Yes.

8635. Does any medical man who has seen these cases doubt that they are arsenical?—No, I do not think anybody doubts it. There was a difference of opinion at first. Dr. Woodyatt at first said that he did not think they were, but afterwards he said he did; but nobody, so far as I know, is of opinion that they are not arsenical; in fact, there is a letter that I should like to read to the Commission which Dr. Woodyatt wrote to the "Halifax Evening Courier" on March 10th, 1902. On the 8th March there had been a short report in the "Halifax Evening Courier" of Dr. Reynolds' examination before the Commission the other day, in which it was mentioned that Dr. Reynolds visited these cases at Halifax at the request of Dr. Hodgson. On the 10th March Dr. Woodyatt writes to the same paper to this effect:—

"To the Editor of the 'Halifax Courier.'"

"Sir,—As principal Medical Officer to the Halifax Union Poor Law Hospital, I think it is my duty to correct a false impression which seems to have gained credence with regard to the arsenical cases at the hospital. It will, perhaps, come as a surprise to many when I tell you that I was the first to detect these cases at our new hospital. Why Dr. Reynolds, in his evidence before the Commission, says he is not aware whether these cases had been detected by any other medical men than Mr. Hodgson, is best known to himself. I may tell you, sir, that I wrote to Dr. Reynolds months ago and told him of these cases. I am sure he got my letter, because I have a reply to it in my possession.

Now, sir, I do not wish to take any credit to myself for detecting these cases, for, as Dr. Reynolds says, they were well marked and ought not to be missed by anyone, but there is one gentleman who, I think, ought to come in for a little kudos, and that is Dr. Dolan. He was the first to detect arsenical cases in Halifax at the old workhouse infirmary more than twelve months ago.

"Believe me, sir, yours truly,

"J. F. WOODYATT.

"21, King Cross Road, Halifax,

"March 10th, 1902."

I think I should be right in saying that neither Dr. Woodyatt nor other medical men who have studied these cases have said that they were not arsenical.

8636. You could not ascertain that any of these cases have been taking arsenic medicinally or had been exposed to arsenic by reason of their work?—No, none of them. I made inquiry, and I got Dr. Hodgson to inquire as well.

8637. You ascertained, however, that in some cases beer from public-houses which they had frequented had been analysed in January, and amounts of arsenic from

Cases elsewhere than in Halifax Infirmary.

Additional suspected cases in infirmary.

Dr. Woodyatt's opinion on cause of outbreak.

1-16th to 1-30th grain arsenic per gallon in certain beers.

Mr. H. H. Smith. one-sixteenth to one-thirtieth of a grain per gallon had been determined?—Yes, that is so. You will find that on page 18 of my report.

21 Mar. 1902. 8638. You took steps to ascertain the source from which these cases severally obtained their beer?—Yes. I took a great deal of trouble over that. I asked the patients myself, and I got Dr. Hodgson to ask them, and I also got the Medical Officer of Health's inspectors to go into the question as well as to where the beer came from.

8639. And you made special inquiries at six breweries respecting the particular beer which was on sale at places which these persons frequented before these cases were admitted to the infirmary?—Quite so, I did. I went into all the particulars I could get at those breweries.

8640. You traced them as far as possible back to the brews, and ascertained the ingredients used?—Yes, in every case where I could do it. In some cases I could get the exact brew, and in other cases I could not; but I got the ingredients used in the brews about the dates in question.

Implicated  
brew in  
which no  
glucose or  
invert was  
used.

8641. With regard to glucose, you found that one brewery—the publican brewery—of Crosskeys, used nothing but malt, flaked maize, and hops—no glucose or invert?—Yes, no glucose or invert was used there, nothing but malt, flaked maize, and hops.

8642. All the five other breweries used glucose, but from different manufacturers?—Yes.

8643. And with regard to invert sugar, three brewers only used it in the beers inquired into, and it came from two different manufacturers?—Yes.

8644. You could get no evidence that these glucoses or inverts were contaminated by arsenic, and you show that if arsenic to the extent of one-sixteenth of a grain per gallon was in the beer, and came from glucose or invert, or both, the contamination must have been much more than anything we have heard of apart from Bostock's. As a matter of fact, you could find no reason to suppose that the glucose or invert was arsenical in any case?—That is so.

8645. With regard to the malts, we understand that four of these brewers made their own malt and two bought it?—Yes—two were not malting brewers at all. The other four made their own malt, except black malt.

8646. You give an account of the inquiries you made to ascertain when and where the malts used in the special brews inquired into were made?—Yes. I show that also in the tables.

Evidence  
implicating  
gas coke.

8647. Speaking generally, you find that in some of the brews the malt was certainly made over local gas coke, and that there is strong reason to believe that this was the case with all the others?—That is so. With regard to the Crosskeys brewery, for instance, I traced the malt back, and Dr. Neech traced it with me, and we arrived at the same opinion, that it was made from malt that was undoubtedly made over gas coke at a place called Cleckheaton. It was some of the old season's malt, season 1900-1, and it was supplied to this brewery on the 5th December last year. At the same time I found out that this particular maltster had not begun to make any malt at all in the present, 1901-2, season until December, 1901. So that the malt he supplied to the brewery in question on the 5th December must have been some of his old malt left over from last season when he was using gas coke as a fuel. In this particular case, from Mr. Firth at Cleckheaton, I had a great deal of difficulty in getting evidence. He did not like me going there at all.

8648. Is he a brewer?—No, a maltster. Going back to the 5th December malt, he told me that he had a large contract with a Lancashire brewer, and that in April, 1901, this Lancashire brewer sent to him to say that the beer brewed with his malt was very arsenical. The first time I went to Mr. Firth with Dr. Neech, we both came away with the impression that this actual malt had been returned to the maltster, but on a subsequent visit he told me that the actual malt was not returned to him, but that a sample of the same malt that this Lancashire brewer had objected to as being arsenical was sent to the Crosskeys in December. Evidently it was the same malt.

8649. (Professor Thorpe.) December of what year?—December last—1901; and that was used to make beer in which Mr. Richardson found 1-16th of a grain of arsenic per gallon.

8550. (Chairman.) Were not those who sent to a brewer malt which seemed opened to suspicion very much in fault?—Mr. Firth went somewhat further than that. He told me that on April 15th, 1901, he had sent a sample of the malt to Mr. Fairley, the analyst at Leeds, and he reported 1-30th of a grain of arsenic per lb. in the malt. After that he never had another sample of malt analysed at all.

8551. Whom do you mean by "he"?—Mr. Firth; he is the maltster. He sent these malts out in a crushed state to the Crosskeys. The Crosskeys man is a small publican brewer who never had heard of such a thing as arsenic in malt. He had never had his malt analysed, and he had never had his beer analysed, but Mr. Firth had had the malt analysed, with the result I have said.

8552. And yet he sent it out?—Yes, he sent it out.

8553. (Professor Thorpe.) Is that absolutely clear? Is it absolutely proven that the malt so sent out was identical with that which had been certified as being arsenical?—I will answer that in Mr. Firth's own words. On March 11th I went to see him again. The first time I went to him he had given me to understand that the Lancashire Brewery did return the malt to him, but on the second occasion he said they had not actually returned the malt, but a sample of the same malt was sent to Mr. Swift at the Crosskeys on December 5th. I put it to him, "Is the malt that was sent to Mr. Swift at the Crosskeys on December 5th the same malt, or of the same bulk of malt as the malt that was supplied to the Lancashire Brewery?" and he answered, "A sample of the same malt was sent to Mr. Swift at the Crosskeys."

1-30th  
arsenic  
lb. in  
Firth's  
previous

8554. Did you ascertain from Mr. Swift whether he was in the habit of getting his malt from this firm?—He had been in the habit of getting his malt from two firms, from Messrs. Firth and Blackburn, and from Messrs. Broadbent, at Bingley. Messrs. Broadbent, at Bingley, failed about twelve months ago, and all the old malt on their premises was sold by the solicitor for the trustees at Keighley, and they did not commence malting again until 1901, in the month of September, so that they had no old malt on their premises. They only had one little lot of malt done over gas coke at the very commencement of September, and all the rest of their malt in 1901 was done over anthracite. But none of their malt was used by Mr. Swift till later—I think it was on December 25th that Mr. Swift used a mixture of Broadbent's malt with this old malt of Mr. Firth's, and that beer was not found by Mr. Richardson so arsenical as the earlier beer made only with Mr. Firth's malt.

8555. (Professor Thorpe.) I am asking this question because, in searching among our Revenue samples which have been sent up to us from time to time by Excise officers, I have discovered a sample of wort from Swift's at the Crosskeys brewed as far back as May, 1901, which I have analysed, and which gives us some idea of the character of the beer that he was turning out at that time. It would appear that the amount of arsenic it contained was not more than that of December 22nd contained; it was substantially the same amount. So far as we can trace the wort of the Crosskeys, as well as of other Halifax brewers, I shall place the results before the Commission in due time.

8556. (Sir William Church.) In the evidence which you have put together for us, you say that on April 15th they sent a sample of malt to Mr. Fairley, who reported one-thirtieth of a grain per lb. Then Mr. Firth just after that says that he sent a sample to Mr. Swift, but did he send the bulk? Mr. Swift may have rejected the sample?—I do not know. The same malt was sent to Mr. Swift for brewing with.

8557. A consignment?—Yes, that is what I mean.

8558. But that really is not the bulk?—He sent a bag or two. A little brewer like Swift would not buy much at a time.

8559. He did not send a sample: he sent the malt for brewing?—Yes, quite so.

8560. (Professor Thorpe.) He is a publican brewer?—Yes.

8561. (Chairman.) You are of opinion that if the malts in the brews inquired into at the several breweries were arsenical to the extent which we know to have occurred in the case of some malts made over gas coke, there will be no difficulty in accounting for the presence of amounts of 1-16th to 1-30th of a grain per gallon of beer made from them?—Yes.

Arsenic  
malt  
of ex  
arsenic  
implicat  
beer.

8662. Have you the results of analysis of any of the malts which went into the beers you inquired into?—I do not think I have. I could not get them. At Mr. Firth's both Dr. Neech and I tried to get a sample of the old malt. Dr. Neech showed me a letter from the medical officer of health at Cleckheaton, saying that Mr. Firth had a large bulk of old malt left on his premises. But if this was the case, he must have got rid of it all very quickly, at any rate, we could not get a bit. I had some trouble in getting information from Mr. Firth, but he eventually took me all over the malt kiln. I hunted everywhere for old malt. I went further. He had had at one time two old malting kilns, and one of these he had sold, last autumn I think it was, which was bought by a man named Swyres. I went up to Mr. Swyres' malt kiln, and asked him if he could find me a bit of the old malt. He said, "No, every bit of it has been cleared off," and he could not get me any of the old malt. The same thing happened at Mr. Firth's own malt kiln, I could not get a bit. I particularly wanted it, because I thought it would have been very interesting, to send it to Professor Thorpe.

8663. Was there an exceptionally low stock of malt in Mr. Firth's place when you visited it?—A very small stock. It is a very small kiln that he now works, and there was only just the stock that he was going to sell off this year. He had only begun to malt in December.

8664. He had got rid of all the old malt?—I think he got rid of every bit of it.

8665. Going back to the maltsters you saw as a whole, you found that gas coke malt was in most instances made last season, and that the maltsters are now generally using anthracite or oven coke?—They told me it was the custom last season always to use gas coke. In one or two instances I found there were maltsters who had used a little anthracite last season, but they had used principally gas coke. At Whitaker's, and again at Worsick's, they had used anthracite last year in small quantities; now Mr. Worsick is using anthracite. Where I heard of anthracite being adopted last season, I found out to the month when that anthracite came in. In one case a man proved to me that he did buy some in December, 1901, but, in most cases, it came into use about the middle of the month of February.

8666. Last February?—February, 1901. It occurred to me that that really might explain how we were getting arsenical beer, as it seemed, just at one time last year, and towards the end of the year, notwithstanding the change in fuel. Looking at these maltings I found that except in one instance the maltster when he is making up his store of malt fills a bin from the back wall to the front. For example, his bin is like a very long room, a big place, and when he has made his malt he throws it against the wall, and he gradually fills up to the front of his bin. In some instances the bins are so constructed that when they are getting malt out they can get out the back malt first, but that I saw in rare instances only at malt stores in new breweries. In the old maltsters' bins, such as these that we have been talking about, Mr. Firth's, or at Ramsden's brewery, or Whitaker's brewery, they told me that they would get out last the malt made earlier in the season. Take the months of January, February, March, and April. Supposing you are filling a bin with malt, and have begun to use solely anthracite at the end of February, your February and January malt having been malted over gas coke. At a place like Alderson's brewery, let us say, they go to the maltster regularly throughout the year for supplies; the maltster naturally goes to his bin as required, opens it, and sends the malt which comes first, so that in the months of June and July the brewer may be brewing with malt made over anthracite, but when it comes to August and September he would be brewing with malt that is made over gas coke. If there is anything in that theory at all, and if anthracite is safer to use than gas coke, it would suggest that the beer made during the summer of last year from the outside of the malt heap might be comparatively free from arsenic, being made over anthracite, while the beer brewed in the autumn might be arsenical, having been made with malt made over gas coke. However, there are some few of the bins out of which they could get this malt first.

8667. What you describe involves filling up the bin in the first place, and then emptying it before more is put in?—Yes, and it is then swept out and filled again. I think I ought to say that I asked several of the maltsters if there was anything in that theory at all. They

said it had never occurred to them, but they thought it very likely that use of gas coke malt in this way explained those special beers.

8668. Do you think that all the malt made before this time last year is now got rid of, or is there still some of it remaining?—Yes, there is a little remaining in one brewery.

8669. Have they tested it?—That I cannot say. I have very few analyses of malts given me by any of these breweries. They are having them done, but I cannot give them to you.

8670. Have the brewers commenced testing the malts themselves now?—Some of them are sending them to be tested.

8671. Can you say what steps were taken by breweries in Halifax before these cases occurred to test their beers and malt for arsenic?—Yes. Some of these brewers had their beers examined very carefully at one time during the Manchester scare; that is, at the beginning of 1901, and then it seemed to them that everything was over, and they did not examine again until lately.

8672. When you say lately, do you mean since the Halifax outbreak?—Perhaps I had better give instances. At Messrs. Webster's the malts were occasionally tested before the present malting season. Since the 14th August they have sent, I was informed, one specimen once a month to Mr. Ackroyd, the Halifax borough analyst, to be tested for arsenic. That is not a specimen of each malting, but one specimen of malt once a month. The beers here used also to be occasionally tested by Mr. Ackroyd, but since the Halifax outbreak the beers have been tested also by Dr. Luff, Mr. Hehner, and Mr. Richardson, and malt has once been tested by Mr. Richardson. Take another brewery, Messrs. Ramsden. I find there that the malt was tested on the 2nd January, 1901, and it was never tested again until the Halifax outbreak.

8673. Was it found free from arsenic in January, 1901?—Yes, it was passed free.

8674. (Dr. Whitelegge.) By whom?—By Mr. Lawrence Briant.

8675. (Dr. Buchanan.) I think there was a trace?

8675. (Sir William Church.) It is stated here in the report, on page 19, at the bottom of the first paragraph, "a small but negligible trace of arsenic." That is one examined by Mr. Lawrence Briant?—Mr. Lawrence Briant tested everything for this brewery.

8676. (Sir William Hart-Dyke.) That would be over gas coke?—Yes. I was referring to a certificate of the 2nd January, 1901. These people had three maltings, Elland, Brighouse and Caulder. The Elland malt was passed free from arsenic; the Brighouse malt had "slight, but distinct traces of arsenic," reported as negligible. The beer was analysed on the same date, the 2nd January, 1901, and was passed free from arsenic. Another analysis by Mr. Lawrence Briant on the same date was shown me, and one in which a trace of arsenic was found by Mr. Marshall, of Huddersfield. From that date they never had anything examined until after this recent scare, and then they had their beer examined again on the 3rd February, 1902, and subsequently.

8677. (Chairman.) You have stated that the malt in January, 1901, contained a small but negligible trace of arsenic. What is meant by a negligible trace?—That I cannot say; I cannot tell you what this analyst calls negligible.

8678. (Sir William Hart-Dyke.) The word, I suppose, is employed to show that there was arsenic there, but not in sufficient quantity to be injurious to health?—Yes, that is the way I should read it.

8679. It was there, but the quantity was so small as not to be injurious?—Yes, the analyst did not consider it injurious: that would be the analyst's opinion. I do not think that you can read the word negligible in any other way. To come to the next brewery, the Yorkshire brewery, since March, 1901, they have employed a chemist of their own. They had an enormous number of beers and malts examined in March, 1901, and they are all passed free, or nearly free, by Mr. Fairley, the public analyst of Leeds. Since March, 1901, they have had their own chemist, as I said, and he is said to test everything, brewing ingredients and everything else. He informed me that he tests every brew, but I have not got any record from him of any examination of malt and ingredients, although he told me that all the beers sent out were tested by him. I have been given copies of a large number of analyses from that brewery.

Mr.  
H. H. Smith.  
21 Mar. 1902.

Mr. H. H. Smith. 8580. (Sir William Church.) You say that Mr. Dawson since March, 1901, has tested all the beers of the Yorkshire Brewery Company, and also malts and other materials?—Yes.

8581. But then you go on to say that Dr. Cameron, the Medical Officer of Health for Leeds, has lately obtained samples of beer from public houses belonging to this brewery in Leeds, and in these Mr. Fairley has officially reported 1-40th of a grain of arsenic per gallon. Would that be in the same beers that Mr. Dawson reported as free?—Presumably, yes. If Mr. Dawson has analysed every brew, except a few on the 10th August, when he happened to be taking his holiday—he had ten days' holiday—I do not see that there is any other assumption to be made.

8582. It seems to me an important paragraph, because you then go on to say that since Mr. Allen's statement at the inquest, Mr. Fairley had examined 27 brewings of this brewery, and found them all free from arsenic, except one, a strong beer, as much as to say that the analysts by their own action had been much stricter since the inquest than they had been before?—They sent 27 beers from this brewery to Mr. Fairley, and in one of them, a strong beer, he returned arsenic less than 1-100th of a grain. I saw Dr. Cameron, of Leeds, and asked him what they were doing in Leeds about this question. I said: "How is it that arsenic is only found in Halifax, and not in Leeds?" He sent out and obtained a number of samples, five altogether, from this brewery, but in four of those samples the analyst returned 1-40th of a grain per gallon. The four samples were taken from different houses.

8583. (Professor Thorpe.) All Leeds beer?—Yes; some from the same brewery—Yorkshire Brewery Company.

8584. Does "lately" mean before or since Mr. Allen's statement?—Decidedly this is since Mr. Allen's statement, because these beers were collected after my visit to Leeds.

8585. I do not quite understand that. You go on to say that since Mr. Allen's statement at the inquest Mr. Fairley had examined 27 brews, and found them, with one exception, free from arsenic. Was it subsequent to the examination of the 27 that some were found, or one was found with as much as 1-40th?—Yes; I can answer that question decidedly. The same day that I called on Dr. Cameron I called on the Yorkshire Brewery Company, and Dr. Cameron had not collected his beers at the date of my visit to him, while this statement of Mr. Fairley, having seen 27 brewings, was given to me that day at the Yorkshire Brewery, so that these beers taken for Dr. Cameron must have been collected subsequently to those 27.

8586. (Dr. Whitelegge.) The 27 were forwarded by the brewery?—Yes.

8587. After the inquest?—Yes.

8588. And after your visit?—No; before my first visit, because they told me of them at the date of my first visit.

8589. At the beginning of the paragraph, you say, "Mr. Dawson, the company's chemist, had procured samples of these brews, and had sent them to Mr. Fairley, their consulting chemist." That was an exceptional course?—Yes.

8590. The usual routine was for him to examine them himself?—Yes; his position there is to examine all the beers or whatever they want examined, for the brewery. He has his small laboratory, and does nothing else; but if they want to check anything they send it to Mr. Fairley.

8591. (Sir William Church.) Those 27 brewings, presumably, were taken at different times, between March and the end of the year?—No; I take it otherwise. These 27 brewings were taken after the inquest, and before my visit.

8592. The inquest was at the end of January?—It was on the 17th or 18th January, I think.

8593. So that there really was no check whatever upon the analyses of the beer which was turned out between the appointment of Mr. Dawson, in March, 1901, and the end of the year. They did not send any beers to Mr. Fairley during that time?—I could not positively say no; they might have done.

8594. They might have done, but we have no evidence of any check upon Mr. Dawson's analyses?—No; I have no evidence that they did. Although I have been supplied with quite a large number of analyses from that

brewery, there is nothing from Mr. Fairley that comes in between those dates—between the 10th March, 1901, and the date of the inquest.

(Professor Thorpe.) I thought Sir William Church's question was what was done prior to the appointment of Mr. Dawson as a regular chemist?

8595. (Sir William Church.) My point is rather this, that Mr. Dawson's appointment may or may not have been a protection to the public, according to the accuracy of his analyses; and we have no evidence either in support of the correctness of his analyses or invalidating his analyses between March 1901 and the inquest. That was my point?—Just so. The next brewery I take is the Crosskeys. They never had anything analysed at all. Then at Alderson's Brewery they showed me several analyses of malts used last year. They had found arsenic in one of their malts, which was sold by a Mr. Ben Stead, of Brighouse. After that arsenic was found, by Mr. Ackroyd, they did not use any more malt from that malting; they left that malting. But since, they have had no malt analysed for six months. They had some beers analysed by Mr. Ackroyd, but I obtained no record of them. But in January, 1902, since this Halifax outbreak, they have had beers passed as free from arsenic both by Mr. Miller and Mr. Ackroyd. I have seen another analysis from Dr. Luff, quite a recent one, which does not quite agree as to freedom from arsenic. Then, as regards the testing which has been done by maltsters who are not brewers, at Messrs. Broadbents I was told casually that their malt was tested a year ago, and said to be free, but they could not show me anything. At Messrs. Firth and Blackburn's, as I have said, the malt was tested on the 16th April, and 1-30th of a grain was found. It has never been tested since. Then I think I ought to put in, in common justice to the maltsters—having said all this about those who have done so little testing—what has been done by Mr. Worsick. He is a maltster who first used anthracite. He sent me a list of analyses by Mr. Miller, in which I see that from the 14th February, 1901, he has had at least two samples of malt tested every month, and they are all passed arsenic-free. This man has been taking a great deal of trouble.

8596. (Sir William Hart-Dyke.) He uses anthracite exclusively now?—Yes.

8597. And also during the period mentioned?—Yes.

8598. (Chairman.) Do you know whether any of the maltsters have had their fuel analysed?—One. Mr. Ben Stead, of Brighouse, told me that he had had his fuel analysed. He sent a sample to Mr. Rimington, who told him it was arsenic-free.

8599. (Sir William Hart-Dyke.) Is that gas-coke?—No; anthracite. I asked him to show me the analysis, but he could not do so. He said that he had sent it away to a friend.

8700. (Dr. Whitelegge.) Is that the same man who is mentioned in your report?—Yes; the same man as is mentioned in Alderson's Brewery. Aldersons were having malt from him last May; it was examined by Mr. Ackroyd, and reported to contain arsenic, and they discontinued their contract with Mr. Ben Stead in consequence. It was in consequence of that being found that Mr. Ben Stead changed his fuel from gas-coke to anthracite.

8701. (Chairman.) With regard to the action of the Halifax authorities, do we understand that the Halifax Town Medical Officer of Health is about to publish a report?—Council and He has sent me an advanced copy of his report. I asked, when I was at Halifax last time, if it was going to be printed. The Chairman of the Sanitary Committee, whom I saw there—Mr. Coe—informed me that he did not mean to bring the matter before that committee; that he would not have the report printed for publication to his committee or to the public, but that he would have some copies printed only for this Commission. He did not mean to bring the matter before his committee at all.

8702. How many samples of beer were sent officially to the Halifax Borough Analyst during 1901?—I looked through the medical officer of health's returns for 1901 and I could not find in those returns that any beer at all had been sent officially to the borough analyst in 1901; but the borough analyst does return one sample of beer as having been examined in the early part of 1901, and he passed it arsenic free.

8703. (Dr. Whitelegge.) That might have been submitted by the consumer?—I think it is very likely that it was supplied by a private consumer.

Mr. H. H. Smith.  
21 Mar. 1902.

Little or no testing by maltsters for sale in some cases.

No sample of beer submitted to Public Analyst during 1901.

- Mr. Smith. 8704. Under the Act?—Yes.
- Mr. Smith. 8705. (Chairman.) He has tested many samples in 1901 for brewers, but seldom found arsenic?—Yes.
- Mr. Smith. 8706. In what way did you find that brewers or maltsters were keeping records of any analyses that had been made for them?—They were kept in different ways. At Whitaker's I found them all regularly filed; every analysis was put on a large file. Whitakers had an enormous number of analyses, but they were more for the brewing quality than anything else. They had the beer analysed regularly for its qualities, not for arsenic. They had their malts analysed regularly for moisture and for brewing qualities, but not for arsenic; they only had them occasionally examined for arsenic. All these analyses were kept on a file. In most of the other places the analyses were kept in a drawer wrapped up, with an elastic band round them; they were not kept systematically in books. You would think, in dealing with such an important question, they would have kept a systematic record in books.
8707. It would be very important that they should keep the analyses and bind them together?—I should have thought so.
8708. (Sir William Hart-Dyke.) These analyses are no protection as regards arsenic?—Some. For instance, they might send occasional samples to be examined for arsenic, while the ordinary analysis required would simply be analysed for the strength and qualities of beer or its ingredients.
8709. (Professor Thorpe.) With reference to the first remark, of course the Commission must bear in mind the system under which the analyst makes a report. The brewing chemist fills up a printed form, and the details are entered into that, and it would be somewhat difficult for the brewers to paste these things in a book. They might keep them on a file, but that is the extent of the ordinary arrangement in which it would be possible to do it?—Perhaps you would like to see the way in which the analyses are sent. Here are some. (Handed in.)
8710. (Sir William Hart-Dyke.) It seems that there has been a division of opinion amongst the medical men as to the cause of death in these cases. I think you rather impressed upon us the fact that Dr. Woodlyatt at first was of opinion that these deaths were not caused by arsenical poisoning?—He said there was a difference of opinion, but that was mainly on the first and fatal case, McNulty.
8711. I see you say in your statement on page 18 that the gentleman who represented the Halifax brewers at the inquest made much of the fact that Dr. Woodlyatt stated that the cause of death was not arsenical poisoning?—He said that at the inquest.
8712. Can you tell us how it was that he came round to the other opinion?—The remark in the paragraph you are reading refers to McNulty, the first inquest. At the first inquest Dr. Hodgson said that the case was arsenical poisoning, and at the second inquest Dr. Woodlyatt came up and said the cause of death in this case was not arsenical poisoning, it was due to hypostatic pneumonia. But when Lee came into the hospital, he told me that the case of Lee was undoubtedly one of arsenical poisoning, and that if he died he should report it to the coroner. He then showed me some other cases, the case of Marsden, Lowrie, Wilkinson, and Shearing. He agreed that those four cases—and he has written a letter to-day to say so—are arsenical poisoning. Some of these cases were seen by Dr. Reynolds, who has told the Commission his reasons for thinking them to be arsenical poisoning.
8713. The subsequent cases led him to change his opinion as regards the diagnosis of the previous case?—I do not know that it did that.
8714. He gave a very decided opinion that a certain case was not arsenical poisoning?—I do not know that he changed his opinion of the cause of death in the first case.
8715. But he had no doubt as regards subsequent cases?—I did not understand that he had any doubt.
8716. With regard to your statement that there was suspicion that there were certain cases which had not been tested; was there any evidence of that?—I do not quite follow you.
8717. In an earlier statement with regard to those cases you said there were suspicions that there had been other cases of arsenical poisoning in the Halifax Infirmary besides those in your report?—Quite so.
8718. Is there any evidence to warrant this suspicion that there were other cases?—I have none besides what is stated in a letter which I have received from Dr. Hodgson.
8719. There was a case mentioned of a death from heart failure, but death from heart failure is not an uncommon thing, surely?—In this case all that I know from Dr. Hodgson is that the man when he came in was in a very critical condition. There was keratosis of the skin on the soles of the feet. Dr. Hodgson did not have time to examine the reflexes. There was a scar on the body which was very light in colour with the skin all round.
8720. Was that the case of heart failure?—Yes. He had not time really to examine it, because the man died so rapidly. I do not suppose for a moment that unless he had had the other cases in the hospital he would have had the slightest suspicion of this one, but having the other cases he also suspected this one. He knew that the man was a very heavy beer drinker.
8721. I suppose you saw a great many brewers and maltsters during your visit?—Yes.
8722. How many maltsters did you see, roughly speaking?—Including the brewers—four of the brewers are maltsters.
8723. I am including them?—I saw, I think, twelve maltsters.
8724. My point is this, what is the general result of your conversation with them, and the general evidence which you collected with regard to the use of gas coke? Are you of a decided opinion that the fact of these malts becoming impregnated was due to gas coke? Is that the judgment you have formed?—Yes, and these maltsters have evidently formed the same opinion themselves.
8725. I was coming to that in the next question. In regard to these maltsters, did they seem also to have come to a pretty unanimous conclusion as regards the use of gas coke?—I take it that most of them have come to abandon gas coke as a commercial advantage, or necessity. I found that some brewers ask for malt that is made over anthracite.
8726. (Chairman.) Had these brewers been in the habit of asking for it before this scare?—Not before the Manchester scare. In the same way I found that maltsters for sale find it difficult to sell a gas coke malt. Therefore they have taken to anthracite. Mr. Worsick took to it from actual analysis. He was selling malt up in the Manchester district, and he heard of arsenic in malt. He went back and had his malt tested, found it was arsenical, and changed to anthracite as early as December, 1900.
8727. (Sir William Hart-Dyke.) Therefore it can be no hardship whatever, as regards the business of a maltster, if to-morrow the use of gas coke were forbidden?—I understand that some of these maltsters would have to alter the structure of their kilns in order to burn anthracite, but they can burn oven coke in their kilns at present.
8728. But as a matter of business it would be no hardship if the brewers are demanding such malt?—No, as a matter of business the brewers are asking for it. I learned that last July, when I was making some inquiries of maltsters. They told me then that the brewers were asking for it.
8729. (Professor Thorpe.) Asking for malt made over anthracite?—Yes.
8730. Exclusively?—Some say anthracite or oven coke, and some say anthracite.
8731. What did you learn—that there was any special preference in favour of anthracite, or that they would take readily malt which had been certified to be made over oven coke?—I heard then that they were asking for anthracite or oven coke.
8732. As an alternative?—Yes, that they did not mind which in some cases; but in the summer I heard that they were asking for anthracite, I heard that in several places.
8733. (Dr. Whitelocke.) Were these the Halifax brewers?—No, these were maltsters. I went round and saw a few.
8734. In Halifax?—No, I saw them in different parts of the country.
8735. (Professor Thorpe.) With regard to the alternative preference, was that based in your knowledge on the results of analyses? How did they arrive at the

Additional cases in Halifax infirmary.

Maltsters abandoning gas coke.

Brewers demanding malt prepared with anthracite.

Mr.  
H. H. Smith.  
21 Mar. 1902.

conclusion that it did not matter whether it was anthracite or oven coke?—I think it was because they had heard of arsenic in the malt, and that the arsenic was attributed mainly to gas coke, and so they got frightened. But I have really no evidence as to their reasons.

8736. The point of my question is this, the brewers did not find it absolutely necessary to demand only and solely anthracite-made malt?—No, I do not think they did, but last summer I only saw a few maltsters, not the brewers they supplied. There is occasionally a lot of this sort of stuff comes out of the anthracite. Here is a piece of pyrites, picked up in one of the furnaces at a malting near Halifax.

Lumps of  
pyrites  
amongst  
anthracite.

8737. (Chairman.) Probably there is arsenic in this?—That happened to be a piece that was thrown away because it was a heavy piece. The maltster noticed the weight of it on his shovel, and threw it out. I then went up to the fire pans, and I pulled some of the fire pans about, and I found a piece of it burning in the pan; that is, the fire that is underneath the kiln floor.

8738. (Dr. Whitelegge.) What date was that?—The last time I was up there, February 15th.

8739. (Chairman.) This lump is vastly greater in specific gravity than anthracite?—Yes; it was so heavy that they noticed it by its weight.

8740. Did not they use sifted anthracite; did they get the anthracite coming in in lumps?—Yes, all round the Halifax district they get it sent up in large lumps. In the summer, I forget whether it was Mr. Taylor or Mr. Earp told me that it was very much better to buy the anthracite hand-picked in small pieces. They have it about as big as a tangerine orange. But all over the Halifax district the anthracite comes in large lumps, and some of these lumps that I picked up were so big and heavy that I do not think I could have taken them up in one hand.

Maltsters  
who continue  
to use gas  
coke.

8741. Do not they break it into small pieces themselves?—No. They do break it up, but not very small. Some of the maltsters use nothing but anthracite, but in other places they have used a great deal of oven coke with it. They were using several different fuels at Halifax when I was there. At Messrs. Whitaker's, on the day of my visit, they were using gas coke and anthracite. I said, "How much do you actually burn?" and it came out that they burned 85 per cent. of gas coke and 15 per cent. of anthracite. They were actually using gas coke when I was there.

8742. What date was that?—That was the 15th February, 1902. They said they were going to change to oven coke.

8743. (Professor Thorpe.) Did you go to Messrs. Brear and Brown?—Yes, I did.

8744. Did they tell you that at any time they were using Bostock's glucose?—Yes, they gave me the reason for it.

Halifax  
brewery  
implicated  
during 1900  
epidemic  
destroyed  
their beer.

8745. Why?—They ordinarily went to Garton Hill's. Garton Hill's ran short of their supply of glucose, and asked Brear and Brown as a favour to them to take Messrs. Bostock's glucose, because they were short. They could not go on.

8746. (Chairman.) When was that?—This would be during the beer scare of 1900. They found the arsenic in the beer they sent out, and had it destroyed.

8747. (Professor Thorpe.) Have you any evidence that they actually had their beer destroyed?—I had it from three sources: first of all I was told they destroyed their beer by Dr. Neech, the Medical Officer of Health; I was told by Mr. Brown that it was destroyed, and in the presence of the Excise officer at Halifax.

8748. Did you ask Mr. Sergeant, the Excise officer at Halifax?—I asked Mr. Sergeant, and my impression on that point is that he told me it was destroyed—a note to that effect is in my notebook.

8749. He saw it?—Yes.

8750. Did you ascertain from Messrs. Brear and Brown what they did to cleanse their vats and apparatus from the arsenical contamination which they had received?—No, I did not.

8751. In the course of your inquiries have you had occasion to see oven coke made?—No, I very much want to. I have never seen it made.

8752. You do not know what process of sifting the coal goes through?—No, I do not.

(Chairman.) Why should oven coke be freer from arsenic than gas coke?

(Professor Thorpe.) Because it is specially picked in the first instance from a coal supply, which is as free from sulphur as it is possible to get it. Oven coke is very largely used in iron smelting. It is a necessity that it should be as free as possible from sulphur, and that incidentally helps to make it free from arsenic. It is usually hand-picked before it is put into the oven, so that the possibility of a mass of pyrites getting in, such as you saw in the case of this anthracite, is very largely eliminated.

(Chairman.) Do you consider that oven coke on the whole is safer than anthracite?

(Professor Thorpe.) I am not prepared to say that. I am prepared to say it is a reasonably safe fuel. If due care was exercised in the selection of anthracite to the exclusion of pyrites, anthracite might be probably an excellent fuel; but there is always the danger, as you see, of masses of pyrites getting into the anthracite.

(Chairman.) It must be hand-picked anthracite to be safe in the malting oven?

(Professor Thorpe.) No doubt.

(Witness.) With regard to anthracite, I may mention that when Dr. Neech and I were going round one of these maltings, we went into a malting where they used nothing but anthracite, and Dr. Neech collected some of the dust from the wall of the kiln; that is, dust that was lying over the malt, that was being malted. That dust was given to Mr. Richardson, of Bradford, and he estimated the arsenic in that dust to be as much as one and two-fifths grains per pound.

Arsenic in  
kiln dust  
where  
anthracite  
used.

8753. (Chairman.) That does not appear in your printed report?—No, it was not related to the beers I inquired about. This dust actually being over the malt can fall on the malt, and no doubt does so when the men go in and stir the malt about, as they must disturb that dust which is all round the walls.

Such dust  
may fall on  
to malt.

8754. Was that a maltster's kiln?—Yes, this was in the kiln of Mr. Ben Stead, who had used gas coke in the old days, but who is now using anthracite. He has used anthracite ever since last September (1901). He said that before he took to anthracite he had all the floor of his kiln taken out, washed, and relaid, so as to get as much arsenic out as he could, and his kiln was whitewashed down—they whitewash them every summer. After using anthracite all through the winter this result was obtained from the dust.

8755. The dust resulting from the use of anthracite for malting?—Yes.

8756. (Sir William Hart-Dyke.) This was from anthracite?—Yes; this came from anthracite. I did not find any bits of pyrites in that kiln.

8757. (Chairman.) That suggests the need for very careful hand-picking in the use of anthracite?—Yes.

8758. Had hand-picking been practised in that particular case?—Not by the maltster. I cannot say how much it had been done at the colliery, but it had not been done by the maltster. Hand-picking at maltings merely means throwing out a lump of stuff which a man notices as unusually heavy or brassy, so far as my limited experience goes.

May be little  
hand-picking  
of anthracite  
at maltings.

8759. What size of lumps were there in this particular malting?—He was using about the size they were all using—as big as this box.

8760. Could hand-picking clear out the dangerous pieces in that case?—I do not know. I really would not like to answer that question. I cannot tell you how small the pyrites might be, but I suppose it would help.

8761. (Professor Thorpe.) In the hand-picking, they not only look at the thing, but they take it in the hand. It is so heavy relatively to coal that it at once attracts attention, and if there is any considerable quantity of pyrites in a lump it excites suspicion because of the weight?—No doubt that is so.

8762. (Dr. Whitelegge.) You told us that there was a general demand now for anthracite?—Yes; I heard a good deal of that in the summer.

8763. It did not extend particularly, or perhaps at all, to the Halifax region which you have been visiting lately?—No; there I found a great deal of oven coke used.

8764. I think your evidence goes rather further than that—that the maltsters, including some brewers who con- who are their own maltsters, are using gas-coke even now?—Yes; I found that in Whitaker's brewery they are using 85 per cent. of gas-coke now, and 15 per cent. of anthracite. Then, again, I might say something

Maltsters  
that—that the maltsters, including some brewers who con- who are their own maltsters, are using gas-coke even now?—Yes; I found that in Whitaker's brewery they are using 85 per cent. of gas-coke now, and 15 per cent. of anthracite. Then, again, I might say something

Mr.  
H. H. Smith.  
21 Mar. 1902.

Less arsenic  
in oven coke  
than in gas  
coke, due to  
hand-picking  
of coal.

Mr. H. Smith. with regard to a malting which I visited at Brighthouse, which had no connection with the beers I inquired into. I would like to explain that the men whom I saw at these maltings were the labouring men. These men told me that they always used anthracite at this place. I said, "What are you doing now?" I was on the malting floor, and I could smell the stuff. They said, "We are out of anthracite, so we are using coke." They were doing the malting with gas-coke.

8765. (Chairman.) Was it oven coke that the workman meant when he said coke?—No; gas-coke. I went down and saw it. At Messrs. Websters' they changed as far back as February, 1901, from gas-coke to anthracite. I saw a lot of analyses of their malts the other day when I was up there, and curiously enough, some of the latest-made malts showed more arsenic than usual. I asked them what they had been doing, because I had a paper from Dr. Neech, giving me the sales of gas-coke from the Halifax Corporation Gas Works, which showed that Messrs. Websters had had a sale of coke made to them last December, that is December, 1901. I said to them, "You have been using gas-coke again." The brewer laughed, and said, "Yes, we were out of anthracite last December, and we did use some gas-coke." So that, after having taken the trouble to clean his kiln and use anthracite, he had run the risk of fouling his kilns again with gas-coke.

8766. Was any examination made of the dust in that kiln?—I did not get any of the dust there.

8767. (Dr. Whitelegge.) So that in this particular region there has been carelessness even up to the present date on the part of some of the maltsters in regard to the use of fuel?—Yes, I suppose it would be carelessness.

8768. They continue to use gas-coke?—Quite so.

8769. When they use anthracite, is it usual to require any sort of assurance as to freedom from arsenic?—They showed me a great number of guarantees that the anthracite was free from arsenic.

8770. Does that take the form of affirming that the fuel is free from arsenic, or that it is hand-picked?—They use the actual phrase, "This fuel is free from arsenic."

8771. In the particular case where you found the lumps of pyrites, was there any such assurance given by the vendors?—Yes, I saw it.

8772. The lump of pyrites which you have was from coal guaranteed free from arsenic?—Yes.

8773. Was that in writing?—It is printed on the head of the invoice. I have also seen a large number of letters from colliery owners and colliery agents, saying that the coal they sold had been analysed, and was found free from arsenic.

8774. That is a general statement?—Yes.

8775. I understand you that on the invoice of the consignment it says that the consignment is free from arsenic?—Yes, "this coal," I do not like to use the word this consignment, "this coal is free from arsenic."

(Professor Thorpe.) You understand it does not mean "this consignment"?—

8776. (Dr. Whitelegge.) I want to know what they actually said on the certificate going with the coal?—It is generally in the form of a general guarantee.

8777. It amounts to a guarantee, if an assurance of freedom from arsenic is attached to a particular consignment. I did not raise the point whether that particular consignment has been analysed. Does the assurance come on each invoice?—In some of these places they will send a general guarantee, and in some they guarantee each invoice.

8778. (Professor Thorpe.) One is a special guarantee and the other is a general guarantee.

8779. (Dr. Whitelegge.) Then it does not always appear on the invoice?—No.

8780. In such cases it is given at the time the contract is made?—Yes.

8781. You mentioned in your report that where glucose was used, "Except at Messrs. Alderson's, I saw the invoices, which in each instance guaranteed the products to the brewer as free from arsenic." Were those printed?—Yes. It is printed or stamped across the bottom of the invoice.

8782. Did you gather that that was in consequence of a request from the purchaser, or that it was done as

a matter of routine?—It appeared to be done as a matter of routine.

8783. Harking back to the anthracite, did you gather that the certificate, whether general or particular, was given at the request of the purchaser, or as a routine?—Routine, I think, entirely.

8784. Take the condition of matters in the Halifax breweries let us say on December 31st last: There had been some cases of arsenical poisoning at Halifax at the time of the earlier epidemic, had there not?—Yes; I believe there were a few—I forget how many—about the end of 1900.

8785. The attention of the Halifax brewers had been directed to arsenic then, and public attention had been drawn to it as well?—Yes.

8786. What new precautions were they using at that time? I gather from what you told us that they had at one time made some analyses, but that generally the precaution of analysing for arsenic had been given up?—Yes.

8787. It was kept on in a few instances only?—Yes.

8788. One firm, you tell us, had appointed a chemist?—Yes.

8789. Other firms, I presume, had not?—Yes, that was the only firm.

8790. And apparently some samples escaped that chemist's vigilance, which were found elsewhere to contain a material proportion of arsenic?—Yes.

8791. So that the analyses of either finished beer or wort, or of glucose or invert, were not receiving that attention which we were led to expect by what was done by the brewers in Manchester?—I should say in most of the cases it was not. Some of the brewers, as I told you, have done nothing at all between the beginning of 1901 and January, 1902.

8792. Although some of them were using anthracite, others, you told us, were still using gas coke, and a number were using oven coke. The assurance of freedom from arsenic that they received in the case of the anthracite was not given at their own request, but as a matter of routine?—Yes, I am afraid it is a matter of routine.

8793. And the same applies to the glucose?—Yes.

8794. That is also routine?—Yes. I may mention that I happened to come across a member of a firm which I have mentioned here, Messrs. Thompson, of London—in fact, it was Mr. Thompson himself. I asked him what the value of the guarantee across this invoice of glucose was worth. I said, "You are a merchant, how is this done?" It works out in this way, that they guarantee all American glucose. When the American glucose comes over to England it is guaranteed free. The merchant does not have it analysed, but he guarantees it on that guarantee to the broker; the broker does not have it analysed, but he guarantees it on the merchant's guarantee to the consumer. So that they guarantee a thing of which they have no personal knowledge whatever.

Guarantees with glucose, given by middlemen.

8795. The malt is usually brushed?—Yes.

8796. But frequently it is not brushed?—I do not think the smaller brewers or maltsters brush it at all.

8797. Is any guarantee asked for by the purchasers of malt, that it has been brushed?—No, I never heard of it.

8798. I am speaking now of your recent investigations?—I never heard of it.

8799. There are no precautions taken in that direction either?—No.

8800. Did you find among the brewers and maltsters whom you saw any recognition of their own default in these matters?—I think they were very much upset; some of them, of course, were exceedingly upset because this disturbed their trade. They said they thought they had been doing everything, and that they were safe.

8801. Did they admit default on their own part?—No.

8802. It did not occur to them that they had fallen short of what had been expected of them?—No.

8803. Do the brewers still deny that these cases were arsenical poisoning?—I do not think they do now. Some of them say it is all rubbish; that is perhaps the general impression about it.

Attitude of Halifax brewers; extent of their precautions against arsenic.

Mr. H. H. Smith. 8804. You did not hear from them any expression of regret for anything they had left undone in the matter of reasonable precautions in the past?—No, I did not.

8805. With regard to the epidemic, let us take the contrast between the conditions last year before the recent Halifax epidemic and the conditions now. Gas coke is still continued in use by some of the maltsters?—At the Brighthouse malting I spoke of, yes. At my last visit to Whitaker's brewery they were still using gas coke, although they intended to change.

8806. (Chairman.) Do they have their malt analysed before they send it out for sale?—No.

8807. They do not have it tested for arsenic?—No. Whitaker's were using gas coke, and they only very occasionally had a sample tested. They did not sell their malt, they used it in their own brewery. At the Brighthouse malting, where I saw them using gas coke, they were going to use it in their own brewery at Leeds. I think I may give a second-hand piece of evidence here. Dr. Kay told me that at Selby there was a man using gas coke and selling his malt regularly, and he said he was not going to change from gas coke for anybody; he liked gas coke best, and he was going to continue to use it.

8808. (Dr. Whitelegge.) There has been no analysis in that case?—I understand not.

8809. To go back to precautions taken since this Halifax outbreak, is all the malt brushed now?—No; the malt that comes out from the small maltsters receives no brushing. It is hand screened.

8810. (Chairman.) It goes into the beer without being brushed?—Yes.

8811. (Dr. Whitelegge.) Have any additional brewers in that region begun to employ chemists of their own?—No, I was asked a question by several of them whether it would not be a wise thing to do so, and I always answered them in the affirmative. I am under the impression that one firm, Messrs. Websters, are going to put up a laboratory and employ their own chemist.

8812. There has been a considerable increase in the amount of analyses of beer?—Yes, very great.

8813. Can that be said of malt?—I have not obtained nearly so many analyses of malt as of beer.

8814. So that you would say now that the brewers are frequently examining their beer for arsenic?—Yes.

8815. But you cannot tell us that they are also carefully examining the malt?—No, I cannot. I have a table here which shows the different things that have been examined so far as I could ascertain. I find at Websters' brewery the beers have been analysed a great deal, but they have comparatively few analyses of malt. At Ramsden's they did not seem to find much arsenic, but they found some.

8816. They found arsenic in what?—In the malt. The Yorkshire Brewery Company sent me an enormous number of analyses, but I have obtained very few analyses of malt even from them.

8817. So that the examination of malt is not general now even after a second epidemic?—No.

8818. And even in the district where that epidemic occurred?—I do not think it is. They may have got a good many analyses that I do not know of.

(Dr. Whitelegge.) But you are not able to tell us that they are doing that?

(Professor Thorpe.) I think you are leading him wrong. It is within my knowledge that the examinations of malt have been very largely done by the brewers; I am speaking of the Halifax district.

(Dr. Whitelegge.) Since the epidemic?

(Professor Thorpe.) Yes. I think what Mr. Hammond Smith meant to say was that it was not within his knowledge. As the question was put and the answer was given it would imply that it was not being done.

8819. (Dr. Whitelegge.) Since the epidemic, but not until then, they began to examine their malt systematically. There is one other point about the old malt of 1900-1901 make, which was made largely with gas coke, even by those firms which bought anthracite afterwards. No precaution appears to have been taken from what you have told us to clear out the old stock, whether it was verified as containing arsenic, or not?—I can answer that very definitely. It went into use; that I know.

8820. (Professor Thorpe.) For the manufacture of beer?—Yes.

8821. (Dr. Whitelegge.) And if there is any of the old stock remaining still that may be going into use?—It is going into use.

8822. You told us that one brewery, I forget which, used fifteen quarters of old malt in every present brew?—Yes.

8823. That is a malt which may be arsenical?—Yes. In that brewery they have an enormous bin which holds about 4,000 quarters of malt. Of course, they fill up the bin with small maltings of about 40 quarters at a time, perhaps less, and the maltings of the greater part of the 1900-1 season were done with gas coke. I found that the old malt they were using was almost certainly made over gas coke. I put that question very definitely to the brewer.

8824. Was that malt tested for arsenic?—I could get no evidence of that.

8825. It is within your knowledge that they are using it for present brews; but you cannot tell us whether it has been tested for arsenic or not?—No, I cannot tell whether it has been tested.

8826. You have told us of a number of things that the brewers and maltsters have left undone in the past, and some things they are leaving undone now. I want to go on to the public authorities. You ascertained that up to the end of 1901 in the County Borough of Halifax there were no samples of beer taken?—None were taken.

8827. With whom does the administration of the Sale of Food and Drugs Act rest in Halifax—with the Health Committee?—I think it is.

8828. Dr. Neech, the Medical Officer of Health, is the executive officer?—Yes.

8829. Did he give any reasons for not taking samples of the beer?—No, he gave me no reason at all. I do not think the Public Health officers in general have been examining beers much. I looked through the returns at Huddersfield, and for the last twelve months there has not been a beer examined.

8830. So that the sanitary authorities were not doing much?—They were not examining beers.

8831. With regard to the public analyst, you mentioned a number of analyses returned from Mr. Ackroyd. Can you say whether in any given sample of beer he failed to find arsenic which was found by other analysts?—Yes; in the beer from the "Crosskeys"; I think that is the best sample to take.

8832. In the same lot of beer?—It was not what you would call an identical sample. One bottle was sent to him and one bottle sent to Mr. Richardson, but the bottles were not drawn at exactly the same time; they were drawn on consecutive dates, but, according to Dr. Neech's report, they were the same beers.

8833. Did you ascertain what methods Mr. Ackroyd is using?—I did.

8834. Earlier on, at the time of the epidemic, or up to the time of the epidemic, he was using the Brewers' Expert Committee's first test?—Yes.

8835. Since then he has used another?—Yes; he has used one recommended by the Society of Chemical Industry and Public Analysts' Committee.

8836. Have you records of positive results obtained by him with the later methods?—No; I understand that Mr. Ackroyd has found arsenic subsequently, but he has not sent in any reports of arsenic in official samples to my knowledge. I have no records.

8837. The Excise officers have not been taking any particular steps; they had no instructions at the time of the epidemic?—Not at the time I went up; not until after my first visit there.

8838. You refer in your report to some action on the part of the brewers, which I should like to know a little more about. One was their action in disputing the nature of the mischief. Is it within your knowledge personally, or is it only second-hand information, that you say there was some attempted intimidation of the medical men?—Only second-hand information, and what is said in a letter which I will show the Commission. Nothing has come of it, and I am not prepared to say that it is more than gossip.

8839. There is a reference here also to representations made to the Coroner?—Yes.

Mr. H. H. Smith.

21 Mar. 1902.

No sample of beer taken under F. D. Acts in Halifax during 1901.

or at Huddersfield.

Halifax Public Analyst test first recommended by Brewers' Expert Committee.

No action to arsenic local excise officers by outbreak.

Mr.  
F. Smith.  
Mar. 1902.  
representa-  
made  
Coroner  
half of  
er.

8840. How did that come to your knowledge?—There is no difficulty about that whatever; that is not a question of letters. I was sitting in the room and heard the Coroner make the statement. At the end of the inquest the jury were just getting up, and the Coroner called them back, and said, "Gentlemen, I wish you to sit down again; there is something I want to tell you." They sat down. On his left were the brewers and the brewers' representatives. He said to the jury, "I wish it to be known that before this inquest a gentleman called upon me and told me how to conduct my business, and it was one of the brewing interest."

8841. The name did not come out?—Not from the Coroner.

8842. (Chairman.) That was said in the Court?—Yes.

8843. (Professor Thorpe.) It appears in the newspapers?—Yes.

8844. (Chairman.) I see from one of your manuscript tables that  $\frac{1}{2}$  of a grain per gallon seems to have been found in the dregs of a cask of beer at the "Crosskeys Brewery?—That beer was collected by Dr. Neech; Dr. Neech mentions the subject in his report here. I should like to read it. He says several of the brewers complained about the different results obtained by different individuals, and he then tries to explain it himself. He says, "There may be some slight difference in the methods adopted for the detection and calculation of arsenic," and so on, and lastly he says, "There may easily be a

difference in the number of yeast cells present." He goes on to say that in his opinion the beer drawn from the bottom of the cask was not so free from arsenic as the beer from the top. He got some beer from the bottom of a cask that was brewed on December 16th, 1901, from the same malt that produced the beer that Mr. Richardson said contained one-sixteenth of a grain of arsenic. At the bottom of the cask, well shaken up, Mr. Richardson obtained one-eighth of a grain of arsenic per gallon.

8845. (Professor Thorpe.) The turbid beer at the bottom?—Yes.

8846. (Chairman.) That is beer that might have been drawn for consumption?—No, it was beer that was left after they had finished drawing.

8847. (Professor Thorpe.) It was the lees or dregs of the beer that no customer would drink?—No doubt.

(Professor Thorpe.) Mr. Hammond Smith gave us a considerable number of samples which he collected. We have also had a considerable number taken by the Excise officers, and I have now prepared a short report on them, which I would read to you, if I may.

(Chairman.) Certainly; it should be put on the minutes and printed.

(Professor Thorpe.) Yes, I desire it to be printed, if you please; I will hand it in afterwards.

The following is the report handed in by Professor Thorpe:—

REPORT on the results of the Examination made in the Government Laboratory of Beers, Brewing Materials, &c., received from Halifax and District during January and February 1902.

#### Handed in by PROFESSOR THORPE.

In consequence of the recent occurrence of alleged arsenical poisoning in Halifax, samples of beer and brewing materials to be tested for the presence of arsenic have been received at this laboratory from the Inland Revenue officers at Halifax, as well as from the offices in Bradford and Dewsbury Excise Districts.

The samples were taken from:—

#### I.—BREWERS.

Messrs. Alderson, Halifax.  
Messrs. Brear and Brown, Halifax.  
Messrs. Ramsden, Halifax.  
Messrs. Swift, Halifax.  
Messrs. Webster, Halifax.  
Messrs. Whitaker, Halifax.  
Messrs. Stocks, Shibden Head, near Halifax.

#### II.—PUBLICANS.

Mr. J. Bailey, "Black Bull Inn," supplied by Messrs. Ramsden.  
Mr. J. Carson, "Crown Inn," supplied by Messrs. Stocks.  
Mr. S. Fossard, "Duke of York Inn," supplied by Messrs. Whitaker.  
Mr. J. Hanson, "Britannia Inn," supplied by Messrs. Webster.  
Mr. E. B. Wilkinson, "Brown Cow Inn," supplied by Messrs. Webster.

Note.—The "Black Bull Inn" is at Brighouse, near Halifax, in Dewsbury Excise District and Messrs. Stocks' Brewery is in Bradford Excise District.

The supervisor of Inland Revenue at Halifax states that he has sent samples from the whole of the Halifax brewers.

One sample of wort and three samples of glucose received from Halifax District in May, 1901, found among the samples which have been preserved since attention was first called to the occurrence of arsenic in beer, have also been analysed for arsenic. These samples represent older material than can now be obtained by sampling at the breweries.

It must be pointed out that, except as regards Messrs. Alderson, Brear and Brown, and Stocks, the brewing materials sent by the Revenue officers were not part of those actually used in the brewings sampled.

The total number of samples, including the older samples referred to above, received from the Revenue officers is 51. They comprise:—

Beer	13
Wort	2
Malt	10
Hops	7
Glucose	10
Invert sugar	4
Flaked maize	2
Caramel	2
Caramelised malt extract	1
	51

#### Beer and Wort.

Of the fifteen samples of beer and wort, one contained an amount of arsenic estimated at 1-25th of a grain of arsenious oxide per gallon; two were free from arsenic, and the remainder contained amounts varying from 1-30th to 1-100th grain of arsenious oxide per gallon.

#### Malt.

Ten samples were examined, of which none was free from arsenic. The largest amount of arsenious oxide found in the samples of malt received from Revenue officers was 1-60th grain per lb.

#### Hops.

Seven samples were examined. One was free from arsenic. The maximum amount of arsenious oxide found in any sample was about 1-100th grain per lb.

#### Flaked Maize.

Two samples were examined, and both found to be free from arsenic.

#### Glucose.

Ten samples were examined, of which seven were found to be free from arsenic. The largest amount found was about 1-250th grain of arsenious oxide per lb.

Halifax outbreak, 1902.  
Beers, &c., examined at the Government Laboratory.

21 Mar. 1902. Invert sugar.

Four samples were examined, of which one was found to be free from arsenic, the rest contained amounts from about 1-200th to 1-1000th grain of arsenious oxide per lb.

Caramel.

Two samples were examined, of which one was free from arsenic; the other contained about 1-1000th grain of arsenious oxide per lb.

Caramelised Malt Extract.

One sample was examined, and found to be free from arsenic.

The annexed Table of the Revenue samples received for examination for arsenic shows, where the information is available, date of brewing, quantities of materials used, gallons of wort produced, and its gravity. The Supervisor is unable to furnish this information in the case of the retail samples, with the exception of that from the "Crown Inn."

21 Mar. 1902.

SAMPLES OF BEER AND WORT sent by REVENUE OFFICERS for EXAMINATION for ARSENIC.

Note.—None of the above beers was primed.

## REVENUE SAMPLES.

The details of the examination of the foregoing samples are as follows:—

## Samples from Messrs. Alderson.

One beer, brewed 27th December, 1901: Original gravity, 1,040°; arsenious oxide, 1-100th grain per gallon.

The malt contained 1-160th grain of arsenious oxide per lb. The other materials examined were free from arsenic. The amount of arsenic found in the malt accounts for the presence in the beer of 1-140th grain of arsenious oxide per gallon.

One bottled beer, date of brewing unknown: Original gravity, 1,051°; free from arsenic.

## Samples from Brear and Brown.

One beer, brewed 16th December, 1901: Original gravity, 1,053°; arsenious oxide, 1-70th grain per gallon.

The malt used in this brewery contained 1-500th grain of arsenious oxide per lb., and the hops 1-100th grain per lb. The invert sugar was free from arsenic.

No sample of the glucose actually used in this beer could be obtained, but a sample from a consignment subsequently sent by the same maker, and believed to be of identical character with that employed on 16th December, was found to contain 1-700th grain of arsenious oxide per lb.

The quantities of arsenic found in the materials account for about 1-250th grain of arsenious oxide per gallon, on the assumption that all the arsenic present in the materials found its way into the finished beer.

## Samples from Messrs. Ramsden.

One beer, brewed 17th January, 1902: Original gravity, 1,044°; arsenious oxide, 1-60th grain per gallon.

The materials sent by the Revenue officers were not the same as those actually used in making this beer.

Malt (English) contained 1-160th grain of arsenious oxide per lb.

Malt (foreign) contained 1-250th grain of arsenious oxide per lb.

Glucose contained 1-500th grain per lb.

Invert sugar contained 1-250th per lb.

The amount of arsenic found in the materials examined, which were stated to be from similar supplies to those used in the above beer, accounts for 1-125th grain of arsenious oxide per gallon of beer.

One beer from the "Black Bull Inn" at Brighthouse, a public-house supplied by Messrs. Ramsden: Original gravity, 1,043°; arsenious oxide, 1-40th grain per gallon.

The Excise officer reports that Messrs. Ramsden had in stock, at the time of sampling, no beer identical with that supplied to this particular public-house.

The sample from the brewery was such as would be supplied to the "Black Bull Inn" in the ordinary course of business, and was the oldest common beer in stock.

## Samples from G. Swift, of the "Cross Keys."

One beer, brewed 2nd December, 1901: Original gravity, 1,044°; arsenious oxide, 1-25th grain per gallon.

The materials sent by the Excise officer, in connection with the beer brewed at the "Cross Keys," were not those actually used in the sample of beer above referred to.

The malt contained 1-500th grain of arsenious oxide per lb. The hops (both English and foreign were employed) contained about 1-200th grain of arsenious oxide per lb.

The above materials would yield about 1-250th grain of arsenious oxide per gallon on the assumption that all the arsenic present found its way into the beer.

r. 1902. One wort received at the laboratory in May, 1901, was examined and found to contain 1-30th grain per gallon.

#### Samples from Webster and Sons.

One beer, brewed 24th December, 1901: Original gravity, 1,045°; arsenious oxide, 1-50th grain per gallon. The materials sent for examination were not those actually used in brewing this beer.

The English malt contained 1-60th grain of arsenious oxide per lb.; the foreign malt 1-200th grain; the hops 1-100th grain; and the saccharum 1-200th grain. The glucose and flaked maize were free from arsenic.

These quantities of arsenic would have accounted for 1-60th grain per gallon, had these materials been used in the beer sampled.

One sample of beer from the "Britannia Inn," a public-house supplied by Messrs. Webster: Original gravity, 1,037°; arsenious oxide, 1-50th grain per gallon.

One sample of beer from the "Brown Cow Inn," also supplied by this firm: Original gravity, 1,035°; arsenious oxide 1-30th grain per gallon.

The dates of brewing of these two samples from retailers cannot be given by the supervisor.

One sample of beer, brewed 10th February, 1902: Original gravity, 1,039°; arsenious oxide, 1-100th grain per gallon.

A duplicate determination gave 1-80th grain per gallon.

#### Samples from Whitaker and Sons.

One beer, brewed 9th January, 1902: Original gravity, 1,039°; arsenious oxide, 1-60th grain per gallon.

The materials sent were not those actually used in the beer sampled. The malt contained 9-1000th grain of arsenious oxide per lb.; hops, 1-200th grain per lb.; glucose and invert sugar each 1-250th grain per lb.; the flake maize and caramel were free from arsenic, and the caramelised malt extract was also found to be free from arsenic. The quantities found in these materials would have accounted for 1-100th grain of arsenious oxide per gallon had they been used in this beer.

One beer, from the "Duke of York Inn," which is supplied by this firm: Original gravity, 1,037°; arsenious oxide, 1-40 to 1-50th grain per gallon.

The supervisor was unable to supply particulars of the date of brewing of this beer.

#### Samples from Stocks and Co.

One wort, brewed on 19th February, 1902: Original gravity, 1,068°; arsenious oxide, 1-100th grain per gallon.

The materials sent were those actually used in brewing this beer. The malt was of two kinds, viz., English and foreign, each of which contained 1-300th grain of arsenious oxide per lb. The hops showed 1-500th grain per lb., and the glucose was free from arsenic. These quantities account for about 1-100th grain of arsenious oxide per gallon.

One sample of beer from the "Crown Inn," which is supplied by this firm: Original gravity, 1,072°, free from arsenic.

This sample was brewed on 30th October, 1901.

#### Samples of Glucose received from Halifax Excise District in 1901.

Three samples which arrived here in May, 1901, and which had been preserved, were examined and found to be free from arsenic. All were from the brewery of Messrs. Whitaker.

#### DR. HAMMOND SMITH'S SAMPLES.

21 Mar. 1902.

In addition to the foregoing samples from the Revenue officers, we received certain samples from Dr. Hammond Smith, of which the details, as supplied by Dr. Smith, are as follows:—

Samples from Swift, of the "Cross Keys Inn" and Brewery.

One sample of common beer: Original gravity, 1,045°; arsenious oxide, 1-30th grain per gallon.

One sample of best beer: Original gravity, 1,057°; arsenious oxide, 1-50th grain per gallon.

One sample of ground malt (marked No. 1), prepared by Firth and Blackman. This contains 1-200th grain of arsenious oxide per lb.

One sample of ground malt (marked No. 2), prepared by Broadbent. This contains 1-140th grain of arsenious oxide per lb.

If the malt marked No. 2 had been used in brewing these beers, the amount of arsenic found in it would have accounted for 1-83rd grain and 1-66th grain of arsenious oxide in the common and best beer respectively.

One sample of beer from the "Brewer's Cellar," a public-house supplied with beer from Bentley's Yorkshire Brewery. This sample was marked "No. 1, c. 23." Its original gravity was 1,042°; arsenious oxide, 1-25th to 1-30th grain per gallon.

This sample was a portion of that taken by direction of the Coroner, and analysed by Mr. Allen, who found in it 1-16th grain per gallon.

One sample of beer from the "Britannia Inn," a public-house supplied by Messrs. Webster: Original gravity, 1,039°; arsenious oxide, 1-25th to 1-30th grain per gallon.

This sample was taken by direction of the Coroner: Mr. Allen found in it 1-18th grain per gallon.

This sample is marked "No. 2."

One sample of beer, brewed 13th December, 1901, and sent by Messrs. Webster to Dr. Smith. Its original gravity was 1,037-85°; arsenious oxide per gallon, 1-25 to 1-30th grain.

It was marked "No. 5," and was stated by the brewer to Dr. Smith to be part of the same brewing as the sample from the "Britannia" immediately preceding, (marked No. 2).

One sample of beer from the "Black Horse Inn," a public-house supplied by Messrs. Ramsden.

The sample was marked "No. 3," and was taken by direction of the Coroner. Its original gravity was 1,044°; arsenious oxide, 1-30th grain per gallon.

Mr. Allen, who analysed a portion of this sample, reported 1-24th grain per gallon.

Two samples of whole malt from Messrs. Webster's brewery.

(a) Foreign black and white malt, sample marked "No. 2."

It contained 1-60th grain of arsenious oxide per lb.

(b) Old Yorkshire malt from Bin 5; contained 1-250th grain per lb.

Samples of urine from patients in the Halifax Infirmary, sent by Dr. Smith:—

Three samples of urine from Halifax patients have been examined. Two of them yielded indications of traces of arsenic of about 1-80th and 1-90th grain per gallon respectively. The third was free from arsenic.

Halifax outbreak, 1902.

Examination of samples at Government Laboratory.

Arsonic in urine of Halifax patients.

## TWENTY-FIRST DAY.

AT WESTMINSTER PALACE HOTEL.

Friday, 11th April 1902.

## PRESENT:

The Right Hon. Lord KELVIN (*Chairman*).  
The Right Hon. Sir WILLIAM HART-DYKE.  
Sir WILLIAM CHURCH.

Professor THORPE.  
Dr. WHITELEGGE.

Dr. BUCHANAN (*Secretary*).

Mr. G. S.  
Thompson.

11 April 1902.

Mr. G. S. THOMPSON, called; and Examined.

Mr. G. S.  
Thompson.

11 April 1902.

Halifax  
outbreak.

Evidence in  
respect of  
Whitaker's  
brewery.  
Observations  
on Mr. H.  
Smith's  
report.

8848. (*Chairman*.) You are here at the instance of your chairman, Mr. Whitaker, who has not been able to attend personally, to give information in reply to the Commission's request?—That is so.

8849. A copy of the draft of Mr. Hammond Smith's report was sent for Mr. Whitaker's information, and you draw attention to some points in which you tell us that the information was incorrect. With regard to Case 6, the man Whalan, in Dr. Hammond Smith's report, we understand you admit that he obtained beer from the York Inn, owned by Whitaker's Brewery, but dispute that he was a regular customer at the York Inn?—Yes.

8850. On what grounds is that disputed?—The landlord says that he did not know the man intimately. He had only called at the house a few times. He knew the man by sight very well, but not intimately.

8851. You point out a clerical error on page 5 regarding the beer obtained by Case 7, where "Whitaker" and "Webster" should be transposed?—Yes, that is so.

8852. Will that make it correct?—Yes.

8853. It is not disputed that part of the beer obtained by Case 7 was obtained at the Druids, and came from Whitaker's Brewery?—We only know that the man said so. We have no knowledge of the man at all.

8854. As regards Case No. 8, Marsden, you say that the "New Rock" reported as one of the public houses which he frequented is not supplied by Whitaker's brewery?—No, it is not.

8855. On page 6, where Mr. Hammond Smith quotes a return of analyses made by Dr. Neech, you say that the "Fox" is not one of Whitaker's houses?—No; we have no knowledge of it at all. I do not know where the house is, or who it belongs to; it is not one of ours.

8856. It seems that information has been given by Dr. Neech that the "Fox" in quotation marks is a misprint; that it was really Mr. Fox a man, a grocer, who sells Mr. Whitaker's beer?—That may be so.

8857. On the same page you say that Mr. Buckley is not chairman of the Brewers' Association?—I merely call attention to that. I thought perhaps it was a clerical error; that is all.

Formation of  
a brewers'  
association  
in Halifax.

8858. It seems that the Brewers' Association was only just recently formed; it was formed, in fact, in consequence of the arsenic scare in Halifax. Mr. Buckley took the leading part in its formation?—That is so.

8859. You say that the invert sugar used in the brew inquired into by Mr. Hammond Smith came from the Liverpool Saccharine Company, not Valentine and Tod as he understood?—Yes; I may possibly have given Mr. Hammond Smith a wrong name; it may have been my mistake.

8860. But it really was from the Liverpool Saccharine Company?—Yes.

8861. However this may be, you are customers of Valentine and Tod, and use their invert sugar?—Not their invert sugar.

8862. You do not use their invert sugar?—No.

8863. But you are customers for other articles supplied by Valentine and Tod?—Yes.

8864. In this *precis* you say that in your kiln the malt does not come in direct contact with the furnace fumes, which have first to go through a dust chamber. Is this some special contrivance at your kiln, and specially adopted as a safeguard against arsenic?—Yes. If you would like to see a sketch of it, I have one with me. I thought perhaps it might assist you in your investigation.

8865. We would like to see it?—This is it. (*Sketch produced.*)

8866. Has the security which it gives against arsenic been tested in any way?—Yes. We have had an analyst from June, 1901 (*explains sketch*). The fumes of the furnace come up *here*; the heat is drawn through *these* holes into the chamber.

8867. *These* holes represent transverse bars?—No; it is arched over.

8868. How do the fumes go?—The fumes go up and then come in *here*.

8869. The fumes come in through the malt *here*?—Yes. In the first place when the barley is taken off the floor it is put on the top floor, and it is dried.

8870. It is heated by air drawn up from the furnace?—Yes, heated by hot air from below.

8871. What does the fan do?—The fans draw the hot air, and takes all the moisture from the barley.

8872. This fan is really for sucking air out?—Yes. When the barley leaves this floor it goes on to the second floor lower down. When it comes to the second floor it is practically dry. All the moisture has been taken from it. It is on there 24 hours, and then put on to the first floor, and there it is 24 hours, and it is dried off.

8873. On this floor it is heated to a high temperature?—Yes.

8874. What are *these* squares?—They are ventilators for each floor to regulate the temperature, which open out into *these* flues which go to the top of the building.

8875. Then what is the security which this kiln gives against arsenic?—It does not come in direct contact with the furnace fumes until it is dried, and is practically malt.

8876. But do not the furnace fumes go all through up to the top floor where it is green?—No, because each floor has malt on it at the time that the green malt is on the top floor.

8877. But the fumes go through that malt?—Yes, but it is practically hot air when it reaches the top floor. The air is drawn out by means of this fan.

8878. All the arsenic has been taken out of it on the way?—Yes. We maintain that it is impossible for it to get contaminated on the top floor. If there is any contamination at all, of course it would get on in the bottom floor.

8879. The fumes go, containing all the ingredients unchanged, including what arsenic there may be, through all the floors?—Yes; the hot air will go through all the floors undoubtedly.

8880. Am I correct in calling it green malt?—Yes; it is barley when fully grown; when it is first put on to the kiln to dry we call it green malt.

8881. In that moist condition at the top floor the fumes from the furnace do go through it?—Yes; undoubtedly the hot air reaches it after passing through the hot-air chamber and the two floors of malt.

8882. Has there been any investigation to test whether or not the malt is free from danger of arsenic by this arrangement?—Yes; we have tested it periodically, and we have only had a very slight trace of it after coming off the bottom floor, and that was before it was screened and brushed. When it is taken off the bottom floor it is screened and brushed before it goes into the bin. It is then screened and brushed again before going into the wash tun.

8883. You have no means of testing differentially this process from your previous process in respect to freedom from arsenic?—We have had this all along. It is not a new idea at all.

8884. It is not a new method then?—No; the kiln was erected about 1896.

8885. (Sir William Hart-Dyke.) I should like a little explanation of this. If there be contamination it takes place on the first floor you say?—No, on the top floor. We maintain that if there is any contamination takes place it would take place while the malt is green, in its moist state.

8886. That is on the top floor?—Yes; but before our malt leaves the top floor it is dry; before it reaches the furnace fumes it is practically malt. The ordinary kiln has only one floor.

8887. That is why I am questioning you, because I am aware what the ordinary kiln is. It is only in this certain stage that the contamination, you believe, can take place before it becomes malt on the top floor?—Yes.

8888. And this brushing takes place, when?—After it leaves the bottom floor.

8889. That is the concluding process?—That is the concluding process. Therefore, if there is any contamination it would come off in the brushing, because it would be practically dust.

8890. Has this brushing process always taken place in your business?—Yes.

8891. (Chairman.) Which is the dust chamber referred to?—It is called there "hot air chamber."

8892. The lowest part?—Yes. It is a dust chamber, too.

8893. Does dust settle in that chamber?—Yes.

8894. And it is occasionally swept out?—Yes; we have it cleaned out.

8895. Cleaned out how often?—We have had it cleaned out twice this season—once before we commenced, and again about the latter end of January.

8896. Have you ever analysed the dust swept out from it?—Yes.

8897. Do you find arsenic in the dust swept out from the dust chamber?—Yes.

8898. Large quantities?—No, not large quantities.

8899. Does your special malting kiln owe whatever safety it has to the dust deposited in the dust chamber?—Yes, and by means of the fumes of the fires not coming into direct contact with the floor. They must go through the dust chamber before they reach the floor.

8900. Are there other points on which you question the statements in Mr. Hammond Smith's report?—I do not know of any. I think you have gone through them all.

8901. Do you wish to give evidence as to the precautions you have taken against arsenic since the Manchester scare and before this Halifax outbreak?—Well, of course, we maintain we have always taken precautions, and since the Manchester scare we have employed an analyst to analyse all the materials and the beer before leaving the brewery. Since the Halifax scare we certainly have taken stronger precautions by using better fuel.

8902. Better fuel for malting?—Yes.

8903. (Sir William Hart-Dyke.) By better fuel what do you refer to specially?—Better coke.

8904. Do you refer to a better class of fuel or a more carefully analysed and selected fuel?—A better class which has been submitted to analysis.

8905. But it is the same type of fuel?—Yes.

8906. That being what?—Oven coke.

8907. Not gas coke?—No, oven coke and anthracite.

8908. Were you using anthracite and gas coke before the Halifax calamity took place?—Yes.

8909. (Chairman.) Before the Manchester scare you did not habitually have analysis of beer made?—No.

8910. After the Manchester scare and before the Halifax outbreak you had analyses made?—Yes.

8911. How often?—Practically every week.

8912. By whom?—By Mr. Thatcher, of Burton-on-Trent, an analytical chemist.

8913. Had you an analyst in your own employment?—No, we have not.

8914. What reports did you receive from the analyst from whom you requested investigation?—Very good ones always.

8915. Was any arsenic detected in any case?—There have been one or two cases where there have been faint traces.

8916. Was that in the beer or the malt or sugars?—A faint trace in the malt and a faint trace in the beer; none in the sugar or other materials. It is only about two occasions, and so slight that it has been impossible to approximate the quantity.

8917. Since the Halifax outbreak you have had your beer analysed by more than one analyst?—Yes.

8918. Has arsenic in such a quantity as 1-50th or 1-30th of a grain per gallon been found in any sample or sample?—The analysts vary so considerably. There are scarcely two analysts who agree upon that point, and if I have your permission I should not like to really answer that question publicly.

8919. (Sir William Hart-Dyke.) Not as to what you discovered by analysis?—No.

8920. When you say the analysts varied, you refer to the test being applied to precisely the same sample by different analysts giving different results?—Yes.

8921. You mean that clearly and distinctly?—Yes. On one occasion we had it analysed by three analysts and they all differed.

8922. With a practically identical sample?—Yes.

8923. Was that a sample of malt, or brewing material, or finished article?—A sample of finished beer.

8924. And you wish the Commission to understand that in the case of one sample of finished beer three different analysts brought three distinct results?—That is so.

8925. You would rather not give the results, you say. You do not wish for trade reasons to give the actual figures?—No.

8926. You could not place a concrete case before the Commission?—No. I should not care to this morning. We came here with the idea that this was really a private sitting, and for trade interests, which is a very serious matter to us, we should not like to divulge anything of that sort. We are quite prepared to give the Commission all the assistance we can.

8927. But you acknowledge this is an important point. Although this is a public inquiry, this is an all important point; that is to say, that there should be one standard of analysis applied to all these cases?—It is a very important point. Certainly we brewers—I believe I am voicing their sentiment—are very dissatisfied with the present system.

8928. Would you go so far as to say from your experience with regard to analyses in general that you put no faith whatever in analyses which produce results so contrary?—It does certainly shake our faith, but I should not like to go as far as that.

8929. It shakes your faith considerably, at all events, when you have results so divergent?—That is so. They all say approximate to such an amount. There is nothing definite.

Mr. G. S. Thompson.

11 April 1902.

Oven coke now substituted for gas coke.

Extent of analyses of beer and malt.

Mr. G. S.  
Thompson.

11 April 1902.

8930. (Chairman.) You could perhaps give privately for the use of the Commission a statement of the reports that you have had with respect to quantities?—We shall be very glad to give the Commission all the assistance and information we possibly can.

8931. (Sir William Church.) You would not object to putting in the analysts' reports without their appearing in the Press? You have said that you have had the same identical beer analysed by three analysts, and that the amount which they say is present is very different?—That is so.

8932. It is very important that we should have that, I think, although we would withhold it from appearing in the Press. Would you mind giving it for the use of the Commission?—Certainly I will give it.

8933. (Chairman.) Your malting fuel, up to lately, was 85 per cent. of Halifax gas coke?—To about the latter part of January.

8934. January, 1902?—Yes, the latter part of January.

8935. Had this gas coke ever been analysed for arsenic?—I believe it has on one occasion.

8936. Have you the report of the analysis?—I really could not answer you that just at present. I am not certain on that point.

8937. But you could perhaps give information to the Commission on that point?—Yes, I have no doubt I shall be able to find it.

8938. Has the anthracite been analysed?—Yes, and also guaranteed by the proprietor.

8939. And the result of the analysis was what?—That it has been free.

8940. There was no trace of arsenic?—No.

8941. Those who supply it to you guarantee its freedom from arsenic?—Yes.

8942. Your malt is brushed before use?—It is brushed twice. It is brushed immediately on leaving the kiln, screened and brushed, and then it is brushed and screened before going through the rolls for mashing purposes. I may say that we have all the latest machinery, Bobby's machine, practically new.

8943. For brushing?—Yes, we have taken the precaution to have new brushes put in, so that if there is anything on the outside of the malts it will be taken off by the brushes.

8944. How long is it since you have performed all that brushing?—We have done that regularly.

8945. Before the Manchester scare?—Yes.

8946. And you have not made any change since in your process of brushing?—Only that we have renewed the brushes.

8947. But the same amount of brushing you gave formerly as you give now?—That is so.

8948. Have you ever examined the dust that is brushed off for arsenic?—No; we have not.

8949. Have you any experimental test as to the effect in respect to arsenic of the brushing you have given to the malt?—Where there has been a trace on the bottom floor after the brushing—when it has been ready for the mash tun—there has been no trace present, so that we take it it has been taken off by the brushing.

8950. (Sir William Church.) Let me understand you. Have you taken a sample malt, perfect malt, from the bottom floor, and have you found arsenic before brushing?—We found a trace of arsenic in that.

8951. After brushing have you found traces?—No.

8952. Not a trace?—No.

8953. But you have before?—Yes; we have before brushing.

8954. With regard to your plan you have adopted of malting, has the deposit in the hot-air chamber ever been examined?—Yes.

8955. What was it found to contain?—The arsenic in that has never been estimated; it is not a large quantity—call it a trace.

8956. Is it always arsenical?—Certainly; it is in the dust in the hot-air chamber.

8957. But has any of what is deposited on the walls of the hot-air chamber been examined?—That is what I am referring to. Most of it is deposited on the floor, of course.

8958. Has any of the deposit in the ventilating flue from the top chamber ever been examined?—I really could not say that. I do not know whether we have taken it from that part.

8959. You seem to think that what arsenic might be in the hot air would all be deposited on the green malt at the top?—No; it would not affect the green malt at the top at all. By reason of the hot air being filtered through the two floors, it would not affect the malt on the top floor.

8960. You told us just now you thought it was only the damp malt which was in danger?—Yes; but we maintain by having three floors that danger is obviated—that we are free from that. I should like to impress upon the Commission that point.

8961. But you never have examined any of the deposit from the sides of the ventilating flue to see if there is arsenic there?—Not on the top floor.

8962. It is going on the assumption that all arsenic would be deposited as the temperature cooled before it reached that top floor?—That is so; in the hot-air chamber.

8963. But then it clearly is not deposited all in the hot-air chambers, because we find it in the finished malt of the bottom floor?—There is a certain amount of dust in turning the malts on any of the floors.

8964. But the dust, if it was all deposited in the hot-air chamber, would not contain arsenic?—The dust in the chamber would be practically from the flues and from the malt on the bottom floor. Each floor is entirely separate.

8965. That is what I do not understand. I thought the hot air passed through the two lower floors and then passed through the third floor?—Yes.

8966. Therefore you have the hot air passing through the drier malt to the wettest malt at the top?—That is so.

8967. And it is the same air?—Yes.

8968. And you have evidence that arsenic is on the floor next to the hot-air chamber, because you say that before brushing you get traces of arsenic, and after brushing you do not?—That is only on one or two occasions. It has not been regular.

8969. But it is on some occasions?—Yes.

8970. Have you ever tried the middle floor?—No, we have not. It is only on the finished malt off the bottom floor. We tried it before being screened and brushed.

8971. Could you tell me the temperatures of the different floors?—We do not take the temperature on the top floor or middle floor, but the temperature of the bottom floor is about 210° to 220°.

8972. So that really no comparative experiments have been made with regard to whether the dust in the upper floors contains traces of arsenic or not?—May I ask Mr. Thatcher a question? Have we had a sample from the top floor?

(Mr. Thatcher.) We found some in the dust round the iron girders, but hardly any in the malt.

(Sir William Church.) How do you account for anything being on the iron girders?

(Mr. Thatcher.) It is simply carried up by the fan. We have a fan at the top of the kiln which practically creates a draught so strong that when you open the door you can hardly stand. It carries everything upwards.

(Sir William Church.) From the hot-air chamber?

(Mr. Thatcher.) Yes.

(Sir William Church.) That is carried up flues and not through the malt?

(Mr. Thatcher.) No, it goes up the side. The great thing about this kiln is that if you can get the green malt without any arsenic, should any contamination result from the dried malt it can be easily brushed off, but on the green malt it cannot be so easily removed by brushing. That is the great object of this kiln, and the analytical results show it.

(Sir William Church.) I do not understand it as proved.

8973. (Chairman.) In some cases arsenic has been found—in rare cases, I think you say?—Yes, on the bottom floor.

8974. You do not know in which floor that arsenic got into the malt?—It would be on the bottom floor we maintain, in being dried off.

Mr. G. S.  
Thompson.

Testing  
malts for  
arsenic.

G. S.  
Thompson.  
April 1902.

8975. Would it not be a good thing to test malt from each floor?—We might take that suggestion.

8976. In any case in which arsenic is found in the malt on the lowest floor, you might analyse from the same malting the produce of the three floors above, and you would find in which floor the arsenic got in?—The same malt, of course, would not be on the other floor.

8977. You need to go backwards?—Yes. We should have to take the green malt first on the top floor, and then when it is let on to the second floor take a sample, and a sample when it gets on to the bottom floor. But we will adopt your suggestion and see the results.

8978. That, I think, will tell you in which floor the arsenic gets into the malt?—Yes, if there is anything at all.

8979. (Sir William Hart-Dyke.) You have been testing from the bottom floor because that is the article you are about to use?—Yes.

8980. That is what led you to do that?—Yes, it is the finished malt.

8981. Practically you have said to yourself, "This is the article we are going to use for brewing purposes, and before we so use it we will test whether it contains arsenic." That was your line of conduct in the management?—Yes.

8982. And you have not, therefore, tested the other floors, because in the case of the other floors it has not arrived at that stage at which it will be used for brewing purposes?—No.

8983. You have only tested it before brushing, and the brushing is the final process?—Yes.

8984. After testing it to see whether it contains arsenic, you have been in the habit of brushing it?—Yes, twice.

8985. (Chairman.) But it would help to avoid the introduction of arsenic in the future to learn at what stage of the process it comes in?—Yes; we will take the suggestion.

8986. (Professor Thorpe.) You tell us the arrangement which you described to the Chairman has been in use with practically little alteration except as regards the fuel used since 1896?—In the malting.

8987. The arrangement described here has been in use in your place since 1896?—Yes, I think that is the date when it was erected.

8988. That is previous to any trouble having arisen with regard to arsenic?—It was not known at that time.

8989. I think there is a slight inconsistency in your evidence comparing what you just now said with what you said at the outset. I think you led the Chairman to believe that if there were any arsenical contamination it would be in the top floor, viz., on the green malt?—Yes. My meaning when I said that was that I was referring to the ordinary kiln floors where they have only one floor.

8990. You are describing this arrangement?—I am sorry if I gave the Chairman a misunderstanding there. I was referring to the old arrangement—one floor. They simply have a distributing pan over the fire. The fumes come in direct contact with the green malt.

8991. As your evidence will be on the Notes, it certainly will appear that in your opinion the greatest contamination came on the green malt on the top floor?—I do not want to give that impression, sir.

8992. That is what I want to get quite clearly from you, that that is not what you mean?—We maintain that is our safety.

8993. You think now, whatever arsenical contamination there will be, will be on the floor where you finish off?—Yes.

8994. That is the lowest floor?—Yes.

8995. There the maximum amount of arsenic, if any, will be found?—Exactly.

8996. Of course, that fan which is arranged at the top is running at a pretty high velocity?—Exactly.

8997. There is a considerable volume of air being drawn through the whole system; is that so?—Yes.

8998. Have you any idea how much air is travelling through there?—I have no idea.

8999. We have heard from Mr. Thatcher that there is a very considerable volume of air passing through?—Yes, a great volume.

4576.

9000. You are of opinion that the greater quantity of the arsenic which may be volatilised from the fuel will be condensed as dust in the hot-air chamber?—Yes.

9001. But will it settle, considering that the air is travelling at this high velocity through that hot-air chamber?—It does not disturb anything in the hot-air chamber at all.

9002. But supposing even that arsenic is volatilised and then condenses as solid particles of arsenious oxide, they will be mechanically swept along in the air current?—It would be impossible owing to the construction of the kiln.

9003. But the air current is moving, and this matter must be swept along with it?—There is corn on both the floors; there is not a free passage from one floor to the other. At the time the green malt is on the top floor there are malts in different stages on the other floors.

9004. Do not let us get at cross purposes. If there is an air current travelling at this velocity the condensed matter, the solid particles, that is, will be mechanically swept along?—In my opinion they would be carried up the flues, and not come in contact with the corn at all.

9005. That may or may not be the case, but to the extent that the air passes through the corn the particles will be carried on, and they will be obviously filtered out by having to pass through the interstices of the grains. That will act as a great filtering agent. The dust-laden air will be more or less filtered by being passed through that grain?—Certainly; it will act as a filter.

9006. Very well; but you say in addition to the air percolating or transpiring through the mass of the grain, a considerable volume of air is going up through the flues?—Yes.

9007. And that which does not escape filtration by means of the malt on the several floors will be carried along in the flues—is not that so?—Yes, I should say so, and would go out through the fan.

9008. What are the diameters of these flues?—I could not say exactly.

9009. Is there any dust found in those flues?—Yes; there will be a certain amount of dust.

9010. The walls are more or less rough, of course. They are brick?—Yes.

9011. There will be a certain deposit along the rough side?—Yes.

(Mr. Thatcher.) The walls are glazed tiles.

9012. (Professor Thorpe.) Glazed tiles; is there any deposit on those glazed tiles?—No.

9013. In so far as the dust is there it will be carried into the upper chamber; is not that so?—That will be taken out by the fan.

9014. May I point out that your drawing shows that the flue ends in the upper chamber above the third floors?—Yes.

9015. These you tell me are iron girders?—Yes.

9016. On which you have already told us occasionally the dust settles?—Yes.

9017. From time to time unless those girders are looked to that dust will fall down?—Those girders are cleaned.

9018. Are they systematically cleaned?—Yes.

9019. Have they been always cleaned?—Yes, always.

9020. Since 1896?—Yes.

9021. Is it a constant practice of maltsters to clean their girders?—Yes, they should clean everything.

9022. They should, but do they?—Well, I should say so. Cleanliness is a very great thing in the malt-ings.

9023. You had a chemist you told us since 1901?—Yes.

9024. Has he been exclusively occupied in testing the materials you used?—No.

9025. What are his other duties?—He is an expert brewer and analyst. Mr. Thatcher is here.

(Mr. Thatcher.) I am that gentleman, sir.

(Professor Thorpe.) Let us know precisely what you have been doing. Are you a brewer or chemical analyst?

(Mr. Thatcher.) I am head brewer to Marston, Thomas and Sons, Limited, Burton-on-Trent. That is my pro-

Mr. G. S.  
Thompson.

11 April 1902.

Necessity of  
cleansing  
girders, &c.

Extent of  
analyses  
since 1901.

*Mr. G. S. Thompson.* fession, and I do a large amount of analytical work, consulting work, among brewers in England and Ireland.

11 April 1902. 9026. You are not in direct employment of Messrs. Whitaker?

(*Mr. Thatcher.*) No; they send me samples.

9027. You are merely their consulting chemist?

(*Mr. Thatcher.*) Yes; that is all.

9028. (*Professor Thorpe.*) You do not dispute, Mr. Thompson, that arsenic is to a greater or less extent in your beer?

(*Witness.*) Yes, we do.

9029. That it has never been in?—There have been traces, but it has not been general.

9030. The discrepancies to which you have alluded as between different analysts are they very serious, or are they we will say of such an order as that one man says 1-50th, another man says 1-70th, and another 1-100th of a grain?—No; they are wider than that; I would much rather not give any amounts.

9031. (*Sir William Church.*) You will give us the amounts privately?—Yes.

9032. *Dr. Whitelegge.* You told us that Mr. Thatcher had examined samples almost every week?—Yes, weekly.

9033. For arsenic?—For arsenic.

9034. And has that been so since June, 1901?—Practically so.

9035. You directed his attention to arsenic?—Yes.

9036. You have given us some results of analyses, and you told us that there were traces of arsenic found in the dust from the finished malt on the first floor?—Yes, and the dust chamber.

9037. Was that found by Mr. Thatcher?—Yes.

9038. Can you tell us anything further as to the amount found?—No, Mr. Thatcher has never tried to estimate the amount.

9039. So that it was merely a qualitative analysis?—Yes. We called it either a slight trace or heavy trace as the case might be.

9040. At what time was that examination made; before you gave up the use of gas coke or since?—Before and since.

9041. And even since a trace of arsenic has been found?—Perhaps Mr. Thatcher can give the date.

(*Mr. Thatcher.*) That would be the 31st January this year.

9042. At the time when dust was found on the girders in the top chamber was gas coke being used?—Yes.

9043. So that you are not able to tell us what is found in the dust on the girders of the top chamber with the use of oven coke?—No.

Analysis of fuels.

9044. Is the oven coke examined by Mr. Thatcher?—Yes; he has had a sample of it.

9045. One sample only?—Yes.

9046. Does that one sample represent the whole of the oven coke you have used, or have you obtained a number of consignments?—We have obtained a number; we are continually using it.

9047. But the one examination was negative, confirming the certificate?—Yes.

9048. And you rely upon that?—Yes.

Selection of anthracite.

9049. Has the anthracite been examined by Mr. Thatcher?—Yes.

9050. With a negative result?—I think he said there was a slight trace in it.

9051. Is it picked over?—Yes.

9052. By whom?—It is not picked in the brewery.

9053. But it comes to you guaranteed as being picked?—Yes.

9054. Is it subjected to any examination so that if there were any pyrites in it it would be found?—Of course, we have called our maltster's attention to it. I think he would remove them if he saw them. I have never come across any myself.

Gas coke abandoned.

9055. You have changed your practice with regard to gas coke. Do you regard it as wrong to use gas coke in malting?—I cannot say that we did in ours.

9056. You do not regard it as wrong?—No, not in ours.

9057. Because of the construction of your kiln?—Exactly.

9058. But still you have made the change?—We have made the change to remove any prejudice which might exist by our using gas coke. As other brewers are using oven coke and anthracite we have followed the same system.

9059. Would you hold yourselves at liberty as brewers to revert to the use of gas coke?—I do not think we could now. We have no intention of going back again. We want to place ourselves in line with other brewers.

9060. You have read, no doubt, the Report of the Manchester Brewers' Expert Committee?—I cannot say I have.

9061. Do you know that one of their recommendations, dated May 11, 1901, is to this effect: "We recommend, therefore, that the maltster be required to give a guarantee to the brewer that he does not employ gas coke in the preparation of his malt"?—My attention has been called to that.

9062. But still you did not alter your practice until six months later?—I did not know of it at the time. It is only recently I have had my attention called to that.

9063. You are not aware, perhaps, that a similar recommendation was made in the preliminary report of this Commission?—I submitted our malts to analysts. They have been certified as being free. We did not think it desirable to change.

9064. But you did not comply with this recommendation. I understand you were not aware of it until many months afterwards?—Exactly.

9065. As I understand you the novelty in the construction of your kiln was not originally aimed against arsenic?—No. I do not think it was known at the time.

Recommendation of Brewers' Expert Committee not adopted at Messrs. Whitaker's.

9066. But you think it happens to exclude arsenic now that that danger is known?—Exactly.

9067. The novelty is in two directions: first that you have three floors instead of one; and secondly, what you call the dust chamber?—Yes.

9068. Is the dust chamber to be regarded as peculiar to your kiln. Is there not something corresponding to that dust chamber in almost every malt kiln?—The ordinary kiln has simply a plate, a disperser underneath the floor.

Construction of kiln.

9069. What do you claim for your kiln more than an increased degree of that dispersing plate?—By the hot-air chamber.

9070. Is not the hot-air chamber common to all?—It is arched over the fires.

9071. Does it amount to this, that instead of the ordinary baffle plate you have a special baffle plate?—No, it is not a plate; it is bricked over.

9072. Of whatever material, does it not amount to this, that in your kiln the ordinary baffle plate is enlarged and has a different shape?—It entirely covers the whole of the fires.

9073. A large baffle plate can easily cover the whole of the fire, but does it amount to more than a baffle plate?—I think it does.

9074. Will you explain in what way?—By being covered, by being bricked and arched over, the floor is covered entirely, and I do not think it is by a plate altogether.

9075. Do you suggest that by reason of it being larger and of its shape and position it intercepts more of any arsenic dust and fumes than an ordinary baffle plate would?—I should say so.

9076. But you admit that arsenic does pass by it and gain access at all events to the lower parts?—In very small quantities.

9077. Truly, but some arsenic is passed?—Certainly.

9078. Has the arsenic which is found on the girders at the top also passed that baffle plate?—I should say so.

9079. I gather from the sketch here that it must do?—Certainly.

Mr. G. S. Thompson. 9080. So that all you claim for this is that its construction is such as to intercept more of the arsenic dust and fumes?—Yes.

April 1902. 9081. But not by any means to intercept all?—No.

shing 9082. I understand another peculiarity in your works is that the malt is brushed twice?—Yes.

9083. That has been always your practice?—Yes.

9084. Is that an invariable practice of yours?—Yes. It has been since the kilns were erected.

9085. Would you say it was wrong to omit brushing in the case of any malt?—I should, at the present time.

9086. By reason of the danger of arsenic?—Yes.

9087. (Professor Thorpe.) Why do you mean at the present time?—Since the arsenic scare.

9088. But you do not contemplate reverting to the old state of things. When you say "at the present time," you mean in the light of present information that it would be wrong to omit it?—Certainly.

9089. But with the idea of continuing to practice it?—Certainly. We have had it always, and should not now alter our system.

Mr. G. S. Thompson.

11 April 1902.

JAMES THOMAS NEECH, M.D., D.P.H., Medical Officer of Health, called; and Examined.

9090. (Chairman.) You are Medical Officer of Health to the Borough of Halifax?—I am.

9091. We have had your report on the outbreak of arsenical poisoning in the borough?—Yes.

9092. And you have seen Mr. Hammond Smith's draft report?—I have.

9093. As regards the points raised by the last witness, can you say whether the man Whalan was a regular customer at the York Inn, supplied by Messrs. Whitaker?—That is my information.

9094. From trustworthy information or conjecture?—I think trustworthy. It was obtained by my food inspector, and obtained not only from the man himself, but also from his son and his daughter.

9095. Can you say from enquiries whether the man Marsden frequented one or more of Messrs. Whitaker's houses?—The man Marsden frequented a house which was not a tied house, which was supplied at the time by Messrs. Whitaker. The same house, the "Moor Cock," had been also supplied partially by another brewery.

9096. In your report you deal with the eight cases Mr. Hammond Smith dealt with, and appear to have come to the same conclusion?—Yes.

9097. But there are other cases which we have not heard of so far. What were they, and from whence did these additional cases obtain their beer?—Case No. 8 in my report is a case which was received into the Poor Law Hospital, the same hospital as the cases were admitted to, which Mr. Smith saw. The case was received on March 1st complaining of symptoms which there is not the slightest doubt were due to arsenical poisoning. He had been in the habit of drinking Messrs. Whitaker's beer, Messrs. Alderson's beer, Messrs. Stocks' beer, and also had beer from Mr. Swift, of the "Cross Keys." The next case was a private patient, which I omit, as you have already received a report about it from Mr. Hammond Smith. Then there is private patient B. C., which was not a particularly well-marked case, but a slight case. Still, on examination, when I saw this case, which was reported to me privately and confidentially by a medical man, I quite thought it was a case of arsenic poisoning. This patient had her beer from a house or shop belonging to Messrs. Whitaker. Private patient C. D. in my report, also a female, was, I think, an undoubted case. There was more pigmentation in this case than in the previous case. She had been drinking beer supplied by Messrs. Alderson and Messrs. Whitaker. Private patient D. E. was an undoubted well-marked case, and he had been having his beer from the same places, Messrs. Alderson and Messrs. Whitaker. There has been also admitted within the last few days another case of a female, Elizabeth Marshall, who is, I consider, a well-marked case. She practically has all the symptoms of arsenical poisoning. She tells me that up to twelve months ago she never tasted drink of any kind, and about twelve months ago she went to live as servant at a house called the "Duke of Leeds," evidently her intemperance began when she went to the public-house. She lived at that house for six months, and had also beer from a house called the "Malt Shovel." She had been drinking whisky as well in considerable amount recently. The "Malt Shovel" belongs to Messrs. Webster. The "Duke of Leeds" belongs to Messrs. Bentley and Shaw, Lockwood Brewery, Huddersfield. Those are all the cases, thirteen cases in all.

9098. (Sir William Hart-Dyke.) I think you say in your report, after quoting certain results on page 13: "The above results certainly prove beyond any doubt that there was arsenic present in the beer sold in Halifax,

and in several cases the amount found was dangerous in quantity." What should you define as a "dangerous quantity" of arsenic either in malt or in the finished material?—I think when we come to 1-50th of a grain it is certainly dangerous. I think no more than 1-100th of a grain ought to be allowed.

9099. You describe anything between 1-50 and 1-100th of a grain as negligible?—I should not like to do so.

9100. Do you think that where a man was an excessive beer drinker, constantly imbibing beer, anything between 1-50th and 1-100th of a grain in such beer would affect his health materially, or cause the symptoms such as you describe in one or two patients?—In some people. In persons who were susceptible to the poison of arsenic it might do.

9101. You are aware that the last witness referred to the difference in the results of analyses for the detection of arsenic?—Yes.

9102. You refer to that yourself in your report?—Yes, but only with regard to beer.

9103. You consider it is more difficult to ascertain with accuracy the quantity of arsenic there might be in beer than if you were examining malt?—Of course, I am not an analytical chemist.

9104. Quite so; but you refer to this in your report?—I have one or two ideas upon it which I have put in this report. Those ideas have occurred to me as the result of certain analyses which have been supplied to me. For instance, yeast takes up a considerable quantity of arsenic.

9105. With much greater facility than other ingredients?—Yes. The beer drawn from the bottom of the cask, if taken from the cask, and I think when beer is rapidly drawn off from the bottom of the cask a larger amount of yeast cells are likely to get in the second and third sample than the first sample taken out, especially when you get near the bottom and when the cask is tilted.

9106. You think that if a customer goes to a public-house very thirsty and happens to have a glass of beer from the bottom of the cask he would run a graver risk from arsenical poisoning than the more fortunate customer who arrived at the beginning of a new cask?—I do not say he would get sufficient in the single drink to do any injury. I only make that suggestion in regard to the variation in the analysis. With regard to malt, I take it, that vapours of arsenic are liable to pass through certain parts of the kiln floors, and in that way samples will vary taken from various parts of the kiln floor.

9107. You put two points in your report where you say that the great difficulty of analysis arises probably from the difference in the methods used. That is rather a wide term, is it not? If there is a difference in the methods used for analysis there will be very divergent results, will there not?—I have had some experience of that. Our borough analyst has been using Reinsch's test up to a little time ago, and I find that other analysts have been using other tests.

9108. And then when it comes to the final result of the analysis, after all, it is a question of estimate where these very minute quantities have to be ascertained?—That is so.

9109. They are practically ascertained at the end by estimate?—Yes, by judgment.

9110. Therefore a certain amount of conjecture must come into the analysis?—There is, of course, an error of judgment to allow for.

Mr. J. T. Neech, M.D., D.P.H.

Arsenic in sediment of casks and in yeast.

Divergent analytical results.

Mr. J. T.  
Neech, M.D.,  
D.P.H.

11 April 1902.

9111. But whatever difficulties there might be as regards analysis, I suppose you wish the Commission to understand, speaking as a medical man, that you have no doubt whatever in regard to these symptoms?—Not the slightest doubt.

9112. In the case of one or two of these patients you have no doubt whatever, speaking as a medical man, that these symptoms proceeded direct from arsenical poisoning, whether to a smaller or a greater extent?—I have no doubt about it.

9113. You refer later in your report to other analyses which were taken with regard to beers which were brewed after these occurrences. Your report deals on page 15 with the analytical results of certain samples of malt taken?—Yes. I am referring to the malts there. These are analyses of malts.

Difference  
between  
1900-1 and  
1901-2 malts.

9114. But with regard to this malt, were these samples malted after the deaths had taken place which led you to the enquiry?—I could not give the exact dates when these were malted, but all these malts are this season's malts.

9115. But they have borne, I presume, a severe test of analysis?—They were tested by Mr. Richardson, of Bradford.

9116. But they show an infinitesimal quantity?—Very small quantities.

9117. A negligible quantity?—A negligible quantity.

9118. That is to say, they either show on analysis that there was no arsenic whatever in these samples or the quantities in each case were of a negligible character?—That is so.

9119. Would that rather lead you to this conclusion, that in the case of these patients mentioned in your report if the poisoning took place it was rather through carelessness in the cleaning of malt?—No, I think the conclusion they point to rather is that—and from information we got through our investigations—they arose from beers which were brewed from older malt—the previous season's malt.

9120. But my point is this, that there were two classes of specimens, if I may so term it?—These are all new malts.

Implicated  
beer from  
1900-1 malt

9121. Yes, but the beer from which the patients suffered was brewed from the older malts?—Yes. And unfortunately we were unable to secure samples of these malts. I was unable to secure a single sample.

9122. In that case you could only analyse the beer?—Yes, only the beer.

9123. Surely you must have in your mind how this arsenic appeared in the beer? The question I am putting to you is, Are you of opinion that this beer was contaminated by arsenic through the medium of malt?—That is my opinion.

dried over  
gas coke.

9124. Do you not also consider that there was not sufficient care, for instance, in the fuel used for this malt: that there was some carelessness with regard to the use of fuel, picking it, examining it before use, or the class of fuel used: some carelessness which contaminated this malt?—Yes; I think gas coke was chiefly used during the previous season's malting.

9125. Do you think the use of gas coke was really the cause of it?—I think so.

9126. As these other samples were taken subsequently, do you not think it was the greater care taken which produced those samples?—That is the only opinion that one can come to.

9127. Very well, then. Is not the result in your mind at this moment, after all these investigations, that care in the use of fuel or as regards the class of fuel used should be taken in the future?—Yes; greater care should be taken in regard to the fuel in the future, certainly.

Arsenical  
poisoning in  
Halifax in  
1900.

9128. (Chairman.) Have you known of any arsenical poisoning in Halifax attributed to beer before this outbreak?—I saw during the Manchester scare one or two cases, I cannot remember which, in the workhouse during that scare; and I also heard there were one or two cases in private, but the doctors at that time refused to give me the names, so that I was unable to see them, and of course could not investigate the cases myself.

9129. Between the Manchester scare, and this recent outbreak in Halifax, had you any reason to expect that prejudicial quantities of arsenic might be present in the Halifax beer?—No reason whatever.

9130. Have you any results to give on the experiments mentioned on page 20 of your report?—Mr. Buckley, the managing director of Messrs. Webster and Company, kindly had erected for me a small experimental kiln at his maltings, and I have made a few experiments on that kiln with the able assistance of Mr. Heard, their head brewer, who was a great help to me in the matter, but unfortunately I have been so busy during the last few months that I have not carried out the number of experiments I hoped to do. I have, however, carried out four experiments. In the first experiments ordinary gas coke was used, and the malt was placed upon the kiln in a very wet condition. The analysis of the first malting is as follows: Firstly, unbrushed malt was found by Mr. Richardson to contain 1-355th grain of arsenic per lb.; the brushed malt of the same malting 1-285th of a grain per lb.

9131. (Chairman.) That is rather more than the unbrushed?—Yes. We shall see directly how it comes about. In No. 2 experiment the malt was hand dried, and put on to this small kiln practically dry. On analysis it was found unbrushed to contain 1-200th of a grain of arsenic per lb. The brushed malt was found to contain 1-230th grain of arsenic per lb. Both these samples were malted with ordinary gas coke—Halifax gas coke. The next two samples were also malted with Halifax gas coke, but I arsenicated the coke with a small quantity of arsenate of sodium, and I arsenicated the coke as evenly as I possibly could from judgment. The first experiment, again very wet malt, was applied to the kiln, and on analysis that gave 1-9th of a grain of arsenic per lb. The same malt brushed on analysis gave 1-8th of a grain per lb. In Experiment 4, with the same coke and arsenicated, as far as one can judge exactly the same, the malt was put on dry, exactly as in the second experiment, and on analysis it gave 1-18th of a grain of arsenic per lb. unbrushed, and brushed it gave 1-24th of a grain per lb.

9132. (Sir William Hart-Dyke.) It was an ordinary kiln, I suppose?—No, an experimental kiln.

9133. (Professor Thorpe.) How did its construction differ?—We put in two floors really, but it was only the upper floor we used, so that the space between the lower floor and the upper floor might act as a sort of distributing chamber.

9134. (Sir William Hart-Dyke.) But the fumes were direct?—Yes; the fumes went direct through the malt straight from the fuel.

9135. There was no check?—No check except this chamber between. Both floors were made of perforated tiles, so that the fumes went direct through. In the brushed malt of No. 2 experiment, and the brushed malt of No. 4 experiment, I removed the husk of a small quantity of each, and submitted them to Mr. Richardson for analysis. The grain after the removal of the husk gave these results: From the brushed malt of No. 2 experiment, 1-300th of a grain of arsenic per lb.; from the brushed malt of No. 4 experiment, 1-210th grain of arsenic per lb. That showed that arsenic does even penetrate the centre of the malt, but it is chiefly deposited in the husk.

9136. (Chairman.) All that is in the husk is removed by brushing, or can be removed by brushing?—No. It is a very tedious process removing the husks.

9137. So that brushing does not remove all the arsenic from the husk?—No, I think not.

9138. And, of course, it does not remove arsenic from the core?—No, not from the interior. I was rather astonished at these experiments. I expected to find that the wet malt would take up more arsenic than the dry malt. These experiments are too few to dogmatise, but I expected the wet malt to take up more arsenic than dry malt. In the first two experiments made with ordinary coke the dry malt took up rather more arsenic than the wet malt, but, of course, ordinary coke may vary; there might be more arsenic in one lot of coke used than in the other, although it was from the same bulk. But in the second pair of experiments I think the coke was practically the same, as far as I could judge. The dry malt, hand-dried and practically dry before being put on the kiln, took up only half the amount of arsenic that the wet malt did. The wet malt when brushed seemed to show more arsenic than unbrushed. The dry malt shows rather less arsenic after it is brushed than before being brushed. Mr. Richardson made analyses of the culms from the third and fourth lots of malt. The culms

Mr. J. T.  
Neech, M.D.,  
D.P.H.

11 April 1902.

Experiments  
in miniature  
kiln.

J. T. from the malt in the third experiment gave 7.20th of a grain per lb., which is rather over 1.3rd of a grain per lb. The culms in the malt of the fourth experiment gave 1.26th of a grain per lb.

April 1902.

9139. (Chairman.) How do you account for the greater difference?—In the one case the malt was very wet when it was put on the kiln, and in the second case the malt was dry when it was put on the kiln. The culms of the dry malt took up less arsenic than the culms of the wet malt. Mr. Richardson says: "No. 7 culms gave an unexpected result (No. 7 is the culms of the dry malt) as they contained a trifle less arsenic than the brushed malt, and yet I have no doubt as to the result. It is possible that in some cases the culms may not take up any more arsenic than the grains themselves." Then he says, "I think I can account for the slight difference in the result of the analyses of the malts. At the bottom of the packet containing the malt I have found a quantity of the culms which seem to have broken off, and settled to the bottom; and it will interest you to know that in No. 5 malt (the malt of the third experiment) the culms contain '28 grain of arsenic per lb., and this, as you will allow, is a very large quantity; and it would seem to be very difficult to mix these culms with the malt grains so as to make an average sample in a small way." I take it from what Mr. Richardson says, the reason why the brushed malt in the third experiment contains more arsenic than the unbrushed was because the culms contain an excessive amount of arsenic.

9140. (Professor Thorpe.) Before you pass to another point may I ask whether steps were taken to ascertain that the barley itself was free from arsenic?—No. I did not take any steps to see that. As far as I understand, it was the same barley in each case that was used. These experiments were all done in the course of a few days. These would be two maltings of the firm. The malt was taken from the ordinary germinating floors of the malt kiln, and No. 1 and No. 2 experiments would be exactly from the same malting, and No. 3 and 4 from the same malting.

(Mr. Buckley.) Our barley was examined before it was malted.

9141. (Sir William Church.) Your experiments would lead us to think that brushing is not so great a safeguard as the last witness, for instance, wished us to conclude?

(Witness.) Of course these experiments are only a few in number, and I should not like to dogmatise upon them, but these experiments seem to indicate that.

9142. With regard to the first experiment with the wet malt in which the culms took up so much, they would make a very much closer filter bed when they were wet and swollen than dry malt?—They would, and also I should think any arsenic that was present would more readily penetrate the soft culm than the hard dry one.

9143. Could you tell us what the temperature of the escaping fumes would be from the green malt in these experiments?—I should think nearly 200°.

(Mr. Buckley.) About 200°.

9144. (Sir William Church.) After having passed through the malt?

(Witness.) No. The thermometer in the malt showed from 150° to 200°, I believe.

9145. You are not a professed chemist?—No, I am not.

lty's

9146. Might I just ask you a question or two upon your report? Did you see McNulty during life?—I did not.

9147. Were you present at the inquest?—I was.

ood-

ee.

9148. You said, "Dr. Woodyatt was examined, and gave it as his opinion that the deceased had not suffered from arsenical poisoning, and did not die from the effects thereof." Are you quite certain of that?—That was the impression I gathered from his evidence.

9149. What I gathered was that it seems to me Dr. Woodyatt might have said the man did not die from arsenical poisoning, but that would not be any reason why the man was not suffering from it. A man need not necessarily die from the poisoning; he might die from something else?—That was what I really gathered from his evidence.

9150. What I want to be clear of is that he gave his opinion that the deceased had not suffered from arsenical poisoning?—Perhaps it ought to have been, "did not suffer at the time."

9151. Or, put it in another way, your impression was that Dr. Woodyatt's evidence went to show that he did not think the man had at any time suffered from arsenical poisoning?—At that time. At the time while he was under his care that was the impression. That was the impression I gained, and the impression I intended to convey here.

9152. What were his grounds for coming to that conclusion?—I understand his grounds were the conditions he found on the post-mortem examination, which are given in the appendix to my Report. He thought the pigmentation was not due to arsenic in this case. I remember he stated that.

9153. Did he explain the condition of the heart?—Yes.

9154. What did he consider it was due to? You will see in the appendix you say the heart was dilated and very flabby?—He admitted that.

9155. His opinion was that the bronchitis which apparently was what killed the man was not connected with his general state of health which might have been produced by arsenic?—I do not think he considered his general state of health was due to arsenic. That was my impression. He did not say it was not, but only gave it as his opinion.

9156. Did you see Thomas Lee?—I did. I have some photographs. (Photographs shown.) The dark man is Thomas Lee, and the other is put by the side of him to show the difference between the two.

Lee's case, Dr. Woodyatt's evidence.

9157. (Chairman.) Was he dark all over like a negro?—Yes.

9158. Is that exaggerated in the photograph?—I do not think so. When I first saw him he was practically as dark as that.

9159. And the darkening is pigmentation all over?—Yes.

9160. (Sir William Church.) In the case of Thomas Lee, did you attend the coroner's inquest?—I did.

9161. Dr. Woodyatt in that case was of opinion that death was not caused by arsenic?—He was; but he admitted that the man was suffering from arsenical poisoning on his admission to the hospital.

9162. That is the point I wanted to draw out. You do not know whether he admitted that in the case of McNulty?—I do not know.

9163. But he did not question it in the case of Lee? He only questioned what was the immediate cause of death. He did not question that Lee suffered from arsenical poisoning?—No; he admitted that.

9164. But he was of opinion that recent pneumonia was the actual cause of death?—That was his opinion.

9165. There is no reason why pneumonia should not occur, is there, in arsenical poisoning?—I think it is very liable to occur.

9166. Is it within your own knowledge that with cases of arsenical poisoning the actual cause of death has been pneumonia?—Not from observation, but only from reading.

9167. You did not see any?—I have only seen actual post-mortems in these cases at Halifax. I have read the accounts of the Manchester cases.

9168. Could you tell us whether you know what Dr. Woodyatt's opinion was of the other cases, Louisa Lowry?—Louisa Lowry is not Dr. Woodyatt's case. It belongs to the other visiting medical officer, Dr. Shaw. This case was shown to our Medical Society as a case of arsenical poisoning, so that I take it he must have a definite opinion with reference thereto. (Photograph shown.)

Other infirmaries cases.

9169. Nancy Wilkinson was not Dr. Woodyatt's patient?—No, but I think it was an undoubted case.

9170. And Shearing was not Dr. Woodyatt's patient?—Yes; Shearing was his patient. The same thing happened with regard to Shearing. He showed it at our Society as a case, so that I take it he has made up his mind it is a case.

9171. Did you see Marsden yourself?—I did.

9172. Were you of opinion that he was suffering from arsenical poisoning?—I was.

Mr. J. T.  
Necch, M.D.,  
D.P.H.

11 April 1902.

Whalan's  
case one of  
arsenical  
poisoning.

9173. He is now, I think, discharged from the hospital?—Yes; I do not know where he is now.

9174. Did you see Whalan?—I did.

9175. Was it your opinion that he was suffering from arsenical poisoning?—It was. That is the man. (Photograph shown.)

9176. Whalan is now dead?—Yes.

9177. There was no coroner's inquest upon him, was there?—No.

9178. You had no doubt Whalan was suffering from arsenical poisoning?—No doubt at all.

9179. Do you know what Dr. Woodyatt put on his certificate?—Pernicious anaemia. Of course the man suffered from anaemia, but I have ascertained that Dr. Hodgson carefully examined the blood on several occasions and, while the blood gave indications of anaemia, it did not of pernicious anaemia. There was not the irregularity in shape of the blood corpuscles, and the blood corpuscles formed very good rouleaux. I think that is an indication rather against pernicious anaemia.

9180. The symptoms of arsenical poisoning and those of pernicious anaemia are very similar in many ways?—Yes. But as far as my investigations go, and I have only investigated the blood conditions of these cases with Dr. Hodgson. I have seen his specimens, and as far as my experience of these cases go the blood corpuscles formed rouleaux very freely, which does not happen in pernicious anaemia.

9181. Was there any determination made in the amount of haemoglobin?—Yes, Dr. Hodgson has done that, but I did not bring the figures.

9182. Were you of opinion that the coroner ought to have had an inquest on Whalan?—A difficulty arises when a medical man has given a certificate; I should not like to say he ought.

9183. Perhaps I ought not to have asked that question. Had you communicated with the coroner about Whalan?—Yes, I saw him. I believe I had a chat with the coroner on the same day he died.

9184. But you had no official communication?—No, nothing official. It was simply an unofficial chat I had with him.

9185. The coroner did not refer to you officially?—No. The only time the coroner referred to me was in the case of McNulty, the first case. He officially telephoned to me, and gave me the information with regard to McNulty and the other cases which were in hospital.

9186. I think we ought to have it on the Notes; who is the coroner now?—Mr. Hill. He is mentioned in the first page of my report.

9187. Is he a medical man or not?—A lawyer.

9188. I think John Whitehall was not Dr. Woodyatt's patient?—Yes, he was. All males are his patients in the hospitals at present, and all females Dr. Shaw's patients.

9189. Did you see him yourself?—Yes.

9190. Had you any doubts as to his case?—No.

9191. (Chairman.) Did John Whitehall die?—No, he is not dead; I believe he is discharged.

9192. (Dr. Whitelegge.) In your experiments did you make any determinations of the arsenic in the dust?—No, I did not.

9193. During 1901 were any samples of beer taken in Halifax officially for analysis under the Sale of Food and Drugs Act?—I believe there was one sample taken, but that would be in the very beginning of 1901, after the official samples which we took during the Manchester scare.

9194. What date would those samples be taken?—I am sorry I cannot give you the date. Unfortunately I did not remember to bring the certificates which I got from the analyst in those cases.

9195. During 1901, apart from any samples which were taken at the time of the Manchester outbreak, there were none officially taken?—None at all that I am aware of.

9196. Is it not the practice to take samples of beer among other things?—I had never taken samples of beer prior to the Manchester scare.

9197. I am speaking now of the period since the Manchester scare?—I did not take any samples during the course of 1901. I had no reason to suspect. I thought

with everybody else that with Bostock sugar the arsenic scare had gone. I had heard that malt was somewhat liable to be arsenical, but I had no idea whatever that Yorkshire malt was more specially liable than any other malt.

9198. In the light of what has happened, would you propose to take samples of beer in future years as a matter of routine?—Yes.

9199. Every year?—Every year.

9200. And quite apart from any outbreak, locally or otherwise?—Yes, certainly.

9201. After the Manchester outbreak did you receive any instructions from the Local Government Board specially bearing on the question of arsenic?—I think we did receive a circular, but I do not remember.

9202. Will you tell us briefly what steps you took as Medical Officer of Health regarding the outbreak?—The recent outbreak or the first outbreak? Action by M.O.H.

9203. The recent outbreak?—As soon as I became aware of the existence of these cases in Halifax I at once had samples of beer taken, and submitted them to analysis. beer samples taken.

9204. How many?—In the first lot there were six, and they were submitted to our public analyst, whose certificates are here. He reported them to be absolutely free. The six were taken on January 13. Then I heard privately that a certain brewery was suspected, and I had samples taken of those beers. Reports by public analyst.

9205. Are these certificates in the ordinary terms which Mr. Ackroyd uses?—Those are the ordinary certificates he sends in. In case of prosecution he makes out a special certificate.

9206. You understand the certificate to mean absolute freedom from arsenic?—Yes, in those cases.

9207. Beyond taking these samples, what did you do?—On January 17 there were three other samples taken. On January 18 two others from this suspected house; on the 21st three more; on the 17th two more from the same house; on January 20 a further one from the suspected house, and four others. On January 24 twelve samples were taken. On the 25th two from the same suspected house again.

9208. We will take it generally you took a number of samples, guided by such clues as you have, and submitted those officially?—I submitted the first lot to Mr. Ackroyd, and he found in one sample a sublimate of some kind which he could not say was arsenic or not, and I was specially suspicious that there was arsenic in this beer. I consulted with my Chairman and the Town Clerk, and we submitted samples to Mr. Richardson, of Bradford. Mr. Richardson's reports

9209. So that you took samples and submitted them for examination both officially and unofficially?—Yes. This was just after McNulty's case. I took twelve official samples, which I did not know what to do with for a time.

9210. What did you do with them?—Eventually I sent them to Mr. Allen for analysis. I was rather awkwardly placed with regard to our public analyst. He had said there was no arsenic present in the beer, and then Mr. Richardson sent me reports showing there was arsenic, especially in two samples I sent; and that was the position of matters.

9211. Did you send the same samples to Mr. Ackroyd?—Two or three.

9212. And not always with concurring results?—Mr. Ackroyd got hold of a more recent method of estimating arsenic. I sent him later one sample, which I also sent to Mr. Richardson, and Mr. Richardson reported 1.40th grain and Mr. Ackroyd 1.60th of a grain, so that there was not a great divergence. I sent also one or two to Mr. Allen, and also to Mr. Ackroyd. There was perhaps about the same divergence, or perhaps a little wider divergence in those cases. Mr. Ackroyd's later report.

9213. Taking it generally from one analysis or another, you had confirmation of the presence of arsenic?—Yes.

9214. Did you report it to the Health Committee?—This report has not yet been submitted to the Health Committee. It has been submitted to the Chairman of the Health Committee. M.O.H.'s report to Town Council.

9215. And will no doubt come before the Town Council in due course?—Yes.

No beer  
officially  
taken be-  
tween 1900  
epidemic  
and out-  
break.

Mr. J. T.  
Neech, M.D.,  
D.P.H.

11 April 1902.

M.O.H. no  
knowledge as  
to new kilns.

J. T. 9216. Have you sent a copy of it to the Local Govern-  
ment Board?—I have not.

J. T. 9217. Then you undertook a number of inquiries,  
which you mentioned in your report, inside and outside  
the borough?—Yes.

H.'s 9218. Did you meet with any difficulty in making  
ries those inquiries?—I must say that on the whole I had no  
de difficulty, and certainly everyone seemed, except in one  
agh. case, to give me all the information and assistance they  
could. In one case I did get a little obstruction.

9219. Is that the one mentioned on page 10; it is out-  
side your district, is it not?—Yes. His malt kiln was  
also unfortunately just outside the boundary of the  
district of the medical officer with whom I went.

n facili- 9220. In the case of those premises you visited inside  
ty the borough, you had no difficulty in gaining admis-  
sion?—No difficulty whatever.

ers. 9221. Do you consider you have any right of entry  
there?—Do you mean into the breweries and the  
maltsters' premises?

9222. Yes?—I am rather doubtful about that.

9223. At all events that question did not arise, as  
you met with all facilities?—I did. I did not know  
whether they could be entered as a workshop or not.

owers to 9224. You mentioned the samples of malt which were  
malt taken. Were those taken officially under the Sale of  
Food and Drugs Act?—I am afraid we cannot take malt  
officially.

Drugs 9225. (Professor Thorpe.) Why not?—The malt is not  
on sale.

9226. But if anything enters into composition of a  
food, it is by statute defined to be a food, or a drink?—  
That may be so. But I have been looking out to  
see if I could find power to do that.

9227. Under the amending Act of 1899, would not  
you have power. There is a much wider definition  
given there of what a food is?—I consulted our Town  
Clerk, and I am not sure that I have power, and do not  
know whether I have power to enter into a malt house  
and take samples.

9228. (Dr. Whitelegge.) Your conclusion was reached  
after consulting the Town Clerk?—Yes.

9229. What do you consider your power would be to  
take samples in the case of beer in a brewery?—I do  
not know that we have power.

9230. As a matter of fact, did you take samples of  
malt at the maltster's and beers at the brewery?—Yes.  
Malt at the maltster's and beer at one or two breweries.

9231. Did you take any samples of brewing ingredi-  
ents at the brewery?—All these brewing ingredients  
were taken at the brewery, with the exception of a few  
taken at malt houses.

9232. Did you inform the coroner in cases where you  
found reason to suppose that the cause of death was  
suspicious? In those cases in which it appeared that  
there was a question of arsenical poisoning, and which  
ended fatally, did you communicate with the coroner?  
—These cases were not under my care.

9233. They came to your knowledge officially?—Yes.  
They came to my knowledge, but two cases had been  
already reported to the coroner. The first case that  
died, and the second case were reported to the coroner.

9234. So that there was no occasion for you to com-  
municate with him?—No. But in the third case I did  
not know whether it was going to be reported or not,  
and I got information of the death of Whalan, and I un-  
officially had a chat with the coroner.

9235. Were you in communication with the public  
analyst?—We have been in constant communication  
with one another.

9236. Were you in communication with the officers of  
the Board of Inland Revenue?—No.

9237. You had no conference with them?—No.

H.'s re- 9238. I was going to ask as to the action taken by  
to Town the Town Council on the receipt of your report, but I  
ail. gather that the report has not reached them?—When I  
had the reports of Mr. Richardson giving the results of  
his analysis I had a consultation with the Town Clerk,  
and the Chairman; and Mr. Hammond Smith was  
present at the time.

9239. The action you have taken was with their  
authority as well as your own?—Yes.

4576.

9240. But without coming in any formal way before  
the Committee or the Town Council?—Yes.

9241. You refer in your report to some points in the  
faulty construction of malt kilns (page 18). Did you  
meet with any which were constructed in a manner  
which satisfied you in all respects?—Yes. There are  
some kilns which, as far as I know, seem to be quite up  
to date.

9242. Are plans for new constructions of this kind  
submitted to the Town Council?—I think so.

9243. Do they come before you in any way?—No.

9244. Do any plans come before you?—The only  
plans that have come before me since I have been in  
Halifax chiefly are dairies and cow sheds.

9245. What amount of beer was taken for samples  
in Halifax?—I think usually a quart.

9246. (Professor Thorpe.) With respect to the point Power to  
I raised, viz., as to your power to take samples of malt, take samples  
you are aware that in the 1875 Act the definition of malt  
food was "Every article used for food or drink by man  
other than drugs or water"?—That is the original  
definition.

9247. Are you not aware that in the present Act, the  
amended Act of 1899, the definition has been extended  
by the addition of these words, "And any article which  
ordinarily enters into or is used in the composition  
or the preparation of human food"?—Yes.

9248. Malt is used in the preparation of human food  
in that sense?—It is.

9249. And it is on sale by a maltster?—Yes. But  
there are certain steps to go through with regard to  
collection. I do not see how we could buy it in small  
quantities to submit it to analysis under the Act.

9250. You may apply for such an amount as you like,  
and tender what the man thinks is the equivalent value  
of it. You may take the malt and tender what he  
considers is its value?—I have not attempted anything  
of that kind. I have considered the matter, and I  
thought we had not power.

9251. Have you been advised by the Town Clerk you  
have no power?—I believe that was his opinion. I  
cannot just remember the exact grounds.

9252. With respect to the statement you made to Sir  
William Hart-Dyke as to your view whether these dis-  
crepancies in the statements of analyses may be  
accounted for, when you said that there might be an  
error of judgment because the amounts of arsenic were  
not weighed, but had to be estimated, what did you  
mean by that?—I take it that it is a question of judg-  
ment, and one man's judgment might differ slightly  
from another man's judgment.

9253. Is it your opinion that when the analyst has a  
small quantity in a tube he looks at it and says, "That  
is 1-100th of a grain or equivalent to 1-100th of a  
grain"?—As I told you I am not an analyst, and I have  
only seen these tubes. I have never made one.

9254. Are you not aware that the practice is that  
the analyst takes a standard tube and applies that  
standard?—Yes.

9255. And the standard mirror is the result of a  
definite amount?—Quite so.

9256. That is the way the estimation is made, a  
direct comparison?—Yes, I am aware of that now.

9257. Then your surmise that the discrepancies Effect of  
between analysts may be due to a greater or less sediment on  
quantity of sedimentary matter in the beer analysed analytical  
is drawn from the analytical information which has results.  
been furnished you?—Yes.

9258. If the beer, for example, is not perfectly  
bright, it may happen that one analyst has taken it in  
the same turbid condition, and the other has drawn  
off his sample when the beer has been allowed to settle?  
—Yes.

9259. And that the suspended yeast cells, which, of  
course, we all know secrete or are liable to secrete quan-  
tities of arsenic, might be really the cause of the  
difference?—That was simply an opinion I expressed for  
what it was worth.

9260. I quite agree with you that is so. It is not  
merely an opinion, but a fact. The amount can be con-  
siderably different due to that circumstance?—How  
yeast cells get into it, I take it, is because beer is drawn  
from the bottom of the cask, and when the beer comes  
to get near the bottom the cask is tilted upwards.

F

Mr. J. T.  
Neech, M.D.,  
D.P.H.

11 April 1902.

9261. Has it come to your knowledge that the amount of arsenic in beer is liable to alter with the age of the sample?—No, I have not heard of that.

9262. You have not heard, for example, of any moulds getting into the beer and the amount of arsenic present in solution gradually getting less and less?—I am aware that there are certain moulds that will take up arsenic besides yeast.

9263. You are not aware that as a further cause of discrepancy something may depend on the age of the sample analysed?—I have not taken any samples with the view of ascertaining anything of that kind.

Mr.  
F. Buckley.

Halifax  
outbreak.

Evidence in  
respect of  
Webster's  
brewery.

9266. (Chairman.) You are managing director of Messrs. Webster and Sons' brewery at Halifax?—I am.

9267. Can you tell us what precautions regarding arsenic have been taken in your brewery during 1901, after the Manchester scare, and again since arsenic was reported in the beers at Halifax?—In November and December last year, 1901, we had all our materials analysed, and we had all our beers which were going out to our customers analysed by the borough analyst of Halifax. I sent down to Dr. Buchanan the results of the analyses of all our materials and the analyst's reports on what we have been using for the last twelve months, and we, as brewers, consider them favourable and satisfactory.

9268. On the 14th August, 1901, four samples of malt were sent to the borough analyst, is that so?—I cannot say positively, but we have sent very many samples to the borough analyst regularly.

Extent of  
analyses  
made for  
brewery in  
1901

(Secretary.) Looking through the analyses which Mr. Buckley was kind enough to send in reference to the year 1901, that is the period since the Manchester scare, but before arsenic was reported in the beers at Halifax, I notice that the total number of analyses he had sent us with regard to malt were four samples on August 14th, which were sent to the borough analyst, and one sample on the 20th November, 1901, sent to the borough analyst. I do not think there were included any samples of beer at all. Very likely there were additional samples, but so far as your question, sir, is concerned, we have only evidence from the analyses which Mr. Buckley has sent us, that malts were analysed on two dates during 1901.

9269. (Chairman.) Have you the results of those analyses?—Yes, I think we have somewhere. There is one August 14th, 1901, from the borough analyst of Halifax.

9270. (Sir William Hart-Dyke.) An analysis of malt?—Yes.

9271. (Chairman.) How many samples?—Three samples of malt.

9272. What was the result of the analyses?—All free from arsenic.

9273. On the 20th November, 1901, what was that?—We had just built a new kiln and wished to make ourselves secure. We were afraid of a little moisture in the malt, and so sent this particular sample to ascertain what moisture was in the malt, and also any trace of arsenic. The borough analyst gives us 1.7 of moisture and no trace of arsenic on November 20th, 1901.

9274. All we have evidence of is the analyses of four samples during the year 1901?—Yes.

and since  
outbreak

9275. Did you have any beer examined by analysis?—The beers we have had analysed were principally this year, 1902. All the beers we have sent out we have had carefully analysed.

Implicated  
beer made  
from gas coke  
malt.

9276. Do you agree that, as was suggested by Mr. Hammond Smith, your brewery would have been sending out beer in December, 1901, made with malt dried in February, 1901, before you discarded gas coke?—I do.

9277. Would malt thus used have been specially tested for arsenic?—I cannot say. It was specially tested in February, 1901, but I may add we have now new machinery of the very best kind, new brushing machines, and we should not expect to find any trace of arsenic in the malt that would be detrimental to the beer.

9264. We have had it in evidence here by analysts that it is known the amount of arsenic tends to get less and less if the beer shows any symptoms of becoming mouldy. You are not aware of that?—I am not aware of that fact, but I can quite understand that would take place, because I know there are moulds that take up arsenic readily. I have details here of a case of arsenical poisoning with well-marked paralysis due simply to the administration of medicinal doses of arsenic. It occurred in Halifax.

9265. (Sir William Church.) We know that condition very well?—I have a photograph of the case here (photograph shown). It was due to ten minim doses daily, extending over three weeks.

Mr. J. T.  
Neech, M.D.,  
D.P.H.

11 April 1902.

Medicinal  
dose of  
arsenic  
causing  
paralysis.

Mr. F. BUCKLEY, called; and Examined.

9278. Does the new machinery include any new arrangement of kilns?—It is a perfectly new kiln, now working its second season, a very large kiln, 120 quarters.

9279. Are there special improvements in that kiln?—The latest improvements in machinery we could get without regard to cost or anything.

9280. Improvements to guard against arsenic?—Yes, and for brushing the malt to make it perfectly clean.

9281. Could you describe the precautions against arsenic shortly?—As far as the precautions against arsenic go, we have taken great precautions in drying our English barley before steeping it up to Christmas, but after that we consider it has ample time to sweat in the stack, and does not require drying. We take every precaution when we take the malt off the kiln floor to have it very carefully brushed with these machines and stacked away in the wood bins, and before it goes to the brewery, which is 100 yards away—we never keep a sack of malt at the brewery, sending it up for immediate use in small quantities—before it goes up it is carefully brushed again, so that no trace of arsenic can remain on the barley when it leaves the malt kilns.

9282. Have you tested the effect of the brushing in removing arsenic?—I cannot say that we have. We have tested malts, of which I have submitted to you the analysts' reports of this year from Mr. Richardson, of Bradford, Mr. Hehner, of London, Mr. Thompson, of Manchester, and others. We have been most careful this year to have all our malts analysed before we use them, and all the beers before we send them out.

Precautions  
taken against  
arsenic.

No experi-  
ments on  
effect of  
brushing  
malt.

9283. You mean in this year 1902?—Yes.

9284. Have you many analyses made in 1902?—Yes, I think you have seen them, but I will put them in again. (Analysts' reports put in.)

9285. What you hand in is a statement of the analyses which have been made since the beginning of 1902?—Yes.

9286. Have you any objection to the whole or any part of this being published in our report?—I would much prefer it not being published. I do not think it would be to our interest, and it would not be to the interest of the public generally to publish those reports, particularly the analysts' reports.

9287. (Sir William Hart-Dyke.) The analysis is very favourable, is it not, so far as your position is concerned—it rather goes to prove the precautions you have taken?—It is quite true, but there are reporters of newspapers and editors who take a liberty with the trade and do it serious injury. We as brewers in Halifax have a large Brewers' Association representing, I should think, a million of capital, and we know that the Lancashire brewers have suffered very much from the newspaper reports when they were using every effort to produce a good saleable article, the same as we are doing to-day. And that is the reason I, personally, on behalf of our firm, would very strongly object to the analyses being published; but, of course, we are in your hands. We are very wishful to give you all the assistance we possibly can.

Formation of  
Brewers'  
Association  
in Halifax.

9288. You are pleading this not recklessly, but after the experience of the Lancashire brewers?—Yes, and from what I have gone through personally myself these last four or five months. I have taken a great interest in this matter, and have met a medical gentleman and gone into the matter carefully, and I think it will be unwise to publish these reports.

Mr. 9289. (Chairman.) You have helped to found the  
Buckley. Brewers' Association, I believe?—I have.

April 1902. 9290. You and others in the business have consulted together as to the best means of attaining to perfect security in respect to arsenic?—That is so.

9291. It is interesting for the Commissioners to have these reports of analyses. I do not think it is necessary they should be published?—I have no objection at all to the Commissioners having any particulars.

9292. (Sir William Hart-Dyke.) So far as I am concerned, I may say that you volunteered to give us all the information you can, and we ought to consider you?—I speak for the brewers, and I am sure we are quite willing to give you all the information we can from our books, from our breweries, and from the maltings. We are quite as anxious as you are in the public interest. I am sure that every brewer will be pleased to open his books for perusal at any time.

9293. (Chairman.) Could you give us any general remarks regarding the present position of the Halifax brewers as regards the arsenic question?—In the first place many of them were using gas coke or oven coke before the Manchester scare, but since then many of them have gone over to anthracite, and some of them have changed back again to coke. They found that they could produce a better malt in some cases than with anthracite, but we have never used anything but anthracite for more than five months. I think the result has proved that anthracite is far the better material to use than oven coke.

9294. In what respect better?—We found the results better in our malts when we have examined them afterwards.

9295. Do you mean in the flavour of the malt?—In the less percentage of arsenic in the malt by using anthracite than with oven coke.

9296. You find it does produce a less percentage of arsenic than the coke you have been using?—Yes. We should be very glad, I am sure, if you have any suggestions to make to us as to what kind of coke to use, or anthracite. We should be very pleased if you could recommend any fuel from any particular district. It would not be a question of cost in getting that material.

9297. (Professor Thorpe.) The statement you have just now made is so important, namely, that in your experience a better result is given by the use of anthracite than by oven coke, that we should be glad to have the analytical evidence upon which that is based, if you can furnish us with it. It is very pertinent to the whole inquiry?—Mr. Hammond Smith will bear me out, I think, that when Dr. Smith came to Halifax about this scare in the town we immediately gave up oven coke and commenced using anthracite, and the proof is in the analyst's report now that we find less in using anthracite than by using oven coke.

9298. Have you ever used gas coke?—Yes.

9299. You are clear as to the distinction between gas and oven coke?—Quite.

9300. (Chairman.) Gas coke produced more arsenic in the malt than oven coke?—I would not say that in all cases. Some brewers say not. They vary very much in respect to that. If you will allow me to make a statement, we are very anxious to get at a sound basis of analysis. The Excise officers took a sample, on which I received a letter from the Inland Revenue at Somerset House on the 21st March, that the sample had been sent by the Excise and they found 1-80th of a grain per gallon. I immediately wrote in reply to say that I would send the duplicate sample to Mr. Richardson of Bradford, and would acquaint him of the fact that a sample had been sent to Somerset House to be analysed, and to most carefully give his attention to the matter, and let me have a detailed report of the analysis of the sample. Before that I had the malt that this beer was brewed from analysed, and the one sample, the Yorkshire malt, was 1-700th of a grain per lb., and the foreign 1-1000th part of a grain per lb. I then got from Mr. Richardson of Bradford an analysis of a duplicate of the sample which was sent to Somerset House, whose analysis was 1-80th, but Mr. Richardson's was 1-500th.

9301. (Sir William Hart-Dyke.) An identical sample?—Yes. He said "In my opinion he is quite mistaken whoever has analysed that." I told him who it had

gone to. We feel very much upset when we get two reports like that in one week from one sample of beer, divided into two, one sealed and left with us and the other sent to Somerset House. We very much desire that a second or third person should be appointed to analyse this beer, if a prosecution should be ever taken or a standard of any kind fixed upon. We are quite satisfied ourselves that this beer which is now being consumed is a good sound wholesome beer, and not detrimental to the customer, in spite of the fact that Somerset House said it had 1-80th.

9302. (Sir William Church.) Might I ask what you mean by an identical sample?—The sample was taken by the Excise officer and divided into two. He seals it up, takes one away with him, and leaves the other with our brewer.

9303. (Professor Thorpe.) That was a sample of beer brewed on the 10th February, 1902?—It was.

9304. (Sir William Hart-Dyke.) You are deeply anxious, and the trade generally is deeply anxious, maltsters and brewers alike, for future security? With regard to malt dust, are you not of opinion that cleanliness in regard to this matter in all malt kilns is a very necessary element?—I am.

9305. Are you aware that in this malt dust considerable quantities of arsenic have been found?—Yes, I am quite aware of that.

9306. In that dust itself?—Yes.

9307. And you think, in addition to the extreme care in regard to the selection of fuel, that cleanliness is one of the first objects as regards the malting business?—Yes, most essential.

9308. The more especially as regards the malt dust?—Yes.

9309. Is this malt dust ever used for stock feeding purposes?—Do you mean the dust that comes from the machines?

9310. Yes?—Yes, it is.

9311. Is it used for feeding sheep and calves?—Yes, but only the culms, you know.

9312. There is a distinction between that and the dust which collects in the kiln. What is done with the dust that collects in the kiln, not the culms?—We do not sell that at all.

9313. (Chairman.) What is done with it; is it burned or buried?—It is carried away and put on to the tip as rubbish.

9314. (Sir William Hart-Dyke.) You say that you would be glad to submit to any restriction imposed as regards the use of any particular kind of fuel?—Yes.

9315. You suggested that you would be glad to get any hint with regard to the use of any particular fuel. Taking the trade generally, whether the malting or brewing trade, you would not consider it any serious monetary loss to you, or any charge upon your trade, if restrictions were placed upon you in regard to this or that kind of fuel?—No, I do not think we should object.

9316. Provided you could get security, and were in a more secure position as regards this danger?—Exactly. I may add that the maltsters and brewers in the district who are using coke and coke and anthracite mixed, are now liming using lime, and taking all precautions possible to prevent any contamination taking place in the malt.

9317. They are using lime, are they?—Yes, many of them.

9318. (Professor Thorpe.) With reference to the statement you have made as to the discrepancy between the result of different analyses, and your desire, in which I deeply sympathise, that there should be some definite method laid down, I find that the beer which was brewed on the 10th February, 1902, was reported by the Inland Revenue to contain 1-80th of a grain per gallon, whereas you say the same sample you sent to Mr. Richardson was reported to you to contain 1-500th of a grain?—That is quite true.\*

9319. I find you sent to Mr. Otto Hehner a sample of your beer on the 3rd February, 1902?—Yes.†

9320. And that Mr. Hehner reported that that beer contained 1-80th of a grain per gallon?—Yes.

\* This was No. 25 Gyle, brewed from all new malt.

† This beer was brewed from all old malt.

Mr. F. Buckley. 9321. Would that beer be in any way different from the beer brewed on the 10th February?—It was not the same beer.

11 April 1902. 9322. Probably not, but would it be brewed from the same malt?—Yes, it probably would.\*

9323. Then there is a substantial agreement between Mr. Hehner and what was reported from the Inland Revenue laboratory as to the amount of arsenic present?—Yes. It depends whether it was common beer or best beer.

9324. There might be a slight difference in the specific gravity no doubt, but that slight difference in the gravity would not make any very perceptible amount of difference in the result?—Would you mind my looking at Hehner's certificates? It does not say what class of beer it was.

9325. Have you any means of knowing what the original gravity of that beer would be?—I could ascertain. I could not tell you from memory now.

9326. You have no knowledge at all? Would it be a heavy or light beer?—I could not say from memory.

9327. You cannot give me any idea of any of these?—Not from memory, but I could if I were at the brewery.

9328. I also find at the same date you also sent to Mr. Hehner another sample which was marked No. 10X, and which was reported by him to contain 1-60th of a grain of arsenious oxide per gallon. Would that beer be brewed from the same materials as the one I have just mentioned?—I am sure I could not tell you without I was at the brewery. I could refer and let you know, and should be very pleased to do so.

9329. Inasmuch as it was sent at the same time, have you reason to believe the materials are very different? It would be probably from the same malt?—I do not think it would be very much different.

9330. It would be from the same malt, but probably in different proportion?—We make our own malts, and the proportions would vary somewhat.

9331. There are two independent results, you see. The beer you have mentioned of the 10th February, which was found to contain by the Inland Revenue chemists 1-80th, has also been subsequently re-analysed, and the duplicate is given as 1-100th. There is a discrepancy between 1-80th and 1-100th. Those are discrepancies I think you will admit of an order which may occur; 1-70th, 1-80th, to 1-100th are all magnitudes of very much the same order?—Yes.

9332. A sample of beer brewed by you on the 24th December, 1901, would be brewed from malt which probably was made by the use of gas coke?—Some portion of it; not all of it.

9333. Can you tell me relatively what proportion would be made from gas coke? I have details from your returns of the actual amount of malt employed; probably some of it would be made from English barley and some from foreign barley?—Yes, some from Yorkshire barley and some from foreign.

9334. But it would be all heated by the same fuel?—Yes; it was in our own kilns.

9335. You say some of it would be made by the use of gas coke?—Some portion of it.

9336. A large portion of it?—Not a large portion.

9337. What would be the other fuel used?—Anthracite.

9338. That beer was a gravity of 1045. Would that in your judgment be a stronger beer or not than this one sent to Mr. Hehner?—I am sorry I cannot answer that question. I have no particulars with me.

9339. That was reported to contain 1-50th grain per gallon. Do you think that is out of the question?—I do.

9340. Although it was made partially from malt made with gas coke?—Probably another analyst analysing the same beer would put it 1-200th or 1-150th.

9341. But you have no other reason to suppose that the result is inaccurate? Why do you say that it is out of the question that it contains the amount of 1-50th of a grain?—We have had so many varied reports. We never get two alike.

9342. The "Brown Cow" is an inn which you supply?—Yes.

\* I find this was not brewed with the same malt.

9343. Is it a tied house?—Yes, the "Brown Cow," Burnley Road, Halifax.

9344. A sample of beer taken by one of our officers from that house contained 1-30th of a grain per gallon. He was unable to ascertain when that beer was brewed or what materials were employed. In the same way do you think that is a quantity which could not be by any possibility be in?—I think it is a grave mistake on someone's part. I do not think they obtained that percentage. I trust all these figures are not going out to the public, gentlemen?

9345. (Sir William Church.) You introduced them yourself, not the Commission. You introduced them by saying you had an analysis in which there was 1-80th of a grain and the other 1-500th, and out of that it is necessary to go into the analyses?—I did introduce the figures, but I certainly introduced them in the interest of the brewers, that we might have a better system of analysis than we have, when we have such conflicting evidence as I have brought before you to-day.

9346. That is the very point we are trying to bring about ourselves, and it is very valuable we should know all about it. Here there is not conflicting evidence. You do not seem to have had these beers analysed which you are now being asked about. There is only one analysis?—Some of those reports are last year's, 1901, not this year's.

9347. But in 1901 you knew there was danger of beer being contaminated by arsenic?—We have taken every precaution since that date. There was no report of any arsenic in our district. It was in Lancashire.

9348. Probably most of your beers which went out before Christmas time were brewed with malt made with gas coke in the preceding year?—Yes, and anthracite. They were mixed.

9349. You used nothing but gas coke at all up to 20th February, 1901?—No, we had been only malting then one season; we used nothing but coke the first season. Since then we have used anthracite.

9350. So that a great portion of the beer sent out in 1901 would have been made by gas coke malt?—Yes.

9351. I rather gathered from what you have said to Lord Kelvin that you think brushing the malt is a very great safeguard?—I do.

9352. But you have never determined the difference between unbrushed malt and brushed malt so far as the percentage of arsenic present is concerned?—No, I do not think we have.

9353. Therefore it is a perfect assumption of yours that your brushing cleans the malt?—No, it is not an assumption. I have heard of other brewers doing it, and they have found a great benefit in brushing it.

9354. But it would be brushed long before there was any knowledge of arsenic being liable to be in it?—Not so much as it is now.

9355. That I grant you. But you do not know of your own knowledge that your malt was more highly contaminated before it was brushed than afterwards?—We have found by paying special attention to the brushing that on analysis the malt has been much freer from any objectionable arsenical matter.

9356. It has been a good sample, but you do not seem to have had the unbrushed malt analysed?—No, I cannot say we have.

9357. (Chairman.) Would it not be a good thing to have the malt examined at different stages, one stage being the end of the kilning process, before brushing, and then a sample of the same malt after brushing, which would show how much arsenic is taken out by the brushing?—

9358. (Sir William Church.) You say that you have lately put up a large kiln for 120 quarters with improvements. To what end are those improvements directed, with regard to the admission of hot air, or what?—We have all the latest improvements in the machinery for dressing and cleaning both the barley and the malt.

9359. Not any new plan of passing the hot air through?—No.

9360. (Chairman.) Have you any experience of kilns in which the fumes from the furnace do not pass through the malt?—No.

9361. In all your kilns the fumes of the furnace do pass through the malt?—Yes.

Mr. F. Buckley.

11 April 1902.

Use of gas coke malt before out-break.

Effect of brushing.

Construct of his new kilns.

Mr. Buckley. 9362. (Dr. Whitelegge.) In your new kiln is there more than one floor?—Only one floor in the kiln itself.

9363. You have a dust chamber?—Yes.

9364. Did you hear Mr. Thompson's evidence this morning?—I did not.

9365. There is a dust chamber below?—Yes.

9366. Is anything interposed between the fumes and the under surface of the drying floor?—There is a large disperser at the top.

9367. Against which the fumes must strike before they go upwards?—Yes.

9368. I understand that up to a certain date you used gas coke?—Yes.

9369. After that time I understand that you substituted oven coke; is that right?—Yes.

9370. And afterwards you gave up both gas coke and oven coke, and had anthracite only?—That is so.

9371. Can you say at what date you ceased to use coke of any kind?—I could not remember. It would be about December or January last.

9372. So that for about ten months you have used oven coke?—Yes.

9373. As the result of your own experience, and of what you have learned, do you consider that gas coke is a proper fuel to be used in malting?—I should not like to say.

9374. You have given it up in your own works?—Yes. We have found the anthracite coal better.

9375. But better by reason of the exclusion of arsenic, I gather from your evidence?—Yes.

9376. If it is better by reason of exclusion of arsenic, does not it follow that gas coke is not the right fuel to use?—In some cases it might do.

9377. Do you think you would like to revert to the use of gas coke in your own works?—No.

9378. But you are not prepared to say it would be wrong in other works?—I should not.

9379. Are you acquainted with the report of the Manchester Brewers' Expert Committee?—I read it through at the time, and I have gone into it occasionally.

9380. When it was issued in May, 1901?—Yes.

9381. Do you remember one of the recommendations is that the maltster be required to give a guarantee to the brewer that he does not employ gas coke in the preparation of his malt?—Yes.

9382. You noticed that at the time?—Yes.

9383. But you did not take any action upon it at that time?—No; we were only just commencing at that time.

9384. It is within your knowledge that other brewers in the Halifax district took action upon it?—It is not within my knowledge. I do not know what they did.

9385. Another recommendation is "That the malt culms be regularly tested for the presence of arsenic." Was that done?—No, I do not think it was.

9386. You brushed all your malt?—Yes.

9387. Would you say it is wrong to omit brushing as a matter of precaution?—Yes.

9388. In any case?—I should certainly recommend brushing it.

9389. Who is your chemist?—We have not a fixed chemist. Our borough analyst is the man we employ.

9390. You mention Mr. Hehner and Mr. Richardson. You have sent samples to different chemists at different times?—Yes.

9391. For examination for arsenic?—Yes, positively.

9392. Since when is that?—The last four months.

9393. Since the occurrence in Halifax?—Yes.

9394. But not before then?—No, not regularly. Perhaps twice a year.

9395. Do you propose to continue that practice?—Yes.

9396. Irrespective of any further mischief?—Certainly.

9397. Do you buy malt as well as make it?—No, very seldom indeed.

9398. If you were to buy malt, would you require a guarantee?—Certainly.

9399. Of what kind?—That it was free from arsenic.

9400. Would you require any guarantee as to the malt being prepared with a particular kind of fuel?—We should now, yes.

9401. And that would be right in future time?—Yes.

9402. Do you test the fuel that is used?—We have had it tested; tested about a month ago.

9403. You have had it tested on your own behalf?—Yes, by the borough analyst.

9404. Do you require a guarantee with that of freedom from arsenic?—Yes, we get them to certify that.

9405. Do you require a certificate that it has been picked over, or is it picked over at your works?—It is carefully gone through by our maltster.

9406. You told us of the discrepancy of analytical results in the case of beer; can you say anything about a similar discrepancy as regards malt? Have you submitted samples of malt to different analysts?—Yes; we have submitted a few, and I have the reports.

9407. A sample of the same bulk was sent to two different analysts?—Yes.

9408. And with discrepant results?—Yes.

9409. Would you expect in the heap of malt containing arsenic to find the arsenic equally diffused?—In some cases, yes. Do you mean in a bin of malt?

9410. Yes; take a bin of malt. I understand you have given a good deal of attention to this, and I am asking for information. Given a bin of malt or a heap of malt, would you expect arsenic to be equally diffused?—Yes.

9411. How does the danger arise of the arsenic getting into the malt?—I should think it arises from the fumes.

9412. And dust?—And dust.

9413. Dust entering direct into it from the current of hot air and also dust falling into it that has been allowed to accumulate on a surface above, is not that so?—Yes.

9414. Would not dust falling into it tend to be very unequally diffused?—Yes, I should say it would.

9415. So that you would not always expect to find uniformity, would you?—It is very uncertain.

9416. But you have not made any observations in that direction?—No, I have not.

9417. (Chairman.) Is there any mixing of the malt in moving it; mixing it up with a shovel or anything else?—No, we keep the different qualities separate.

9418. (Dr. Whitelegge.) If dust falls in, it remains there, does it?—It is brushed before it leaves the malt kiln, and brushed again before it goes up to the brewery. We always rebrush it before it leaves the maltings.

9419. You told us that the sample that was sent to Mr. Richardson was identical with the one taken by the Excise officers. In what way did you hear the result of the analysis at Somerset House?—I had a letter from them, which I have laid before you.

Mr. F. Buckley.  
11 April 1902.

Guarantee should be obtained with purchased malt.

Contamination of malt by kiln dust.

(Sir William Hart-Dyke in the chair.)

Mr. Worsick. 9420. (Chairman.) How many years have you been in the malting trade?—This is my twentieth year.

9421. You have been actively employed in the trade for twenty years?—That is so.

9422. Before these circumstances at Halifax you heard and read a good deal concerning the Manchester scare?—Yes.

Mr. A. WORSICK, Maltster, of Elland, called; and Examined.

9423. Upon reading the accounts in the newspapers of the proceedings of this Commission did you take greater precautions with regard to the fuel you used in your business to protect the malt from the danger of arsenic?—Yes.

9424. Can you tell us what special precautions you have taken? I am putting on one side for the moment

Mr. A. Worsick.

Mr. A. Worsick. 11 April 1902. Precarious since 1900 epidemic.

what happened at Halifax?—The first intimation I had of it was in December, 1900. I, like most maltsters, was flattering myself we were all right; that it was the sugar which was wrong. According to the reports, beers on being analysed without any glucose and sugar were still found to be more or less contaminated. I then heard that malt had been tested, and was found to contain arsenic. I sent my samples off immediately, about the middle of December, 1900.

9425. Where did you send them?—To Dr. Miller, of Manchester. He reported that they were not as clear as they ought to be. He said they were not right. I was very much surprised at this, and went to have a chat with him, and asked him what he considered would be the best fuel to use. At that time he could not tell me. He said he thought anthracite coal would be the best, and I immediately changed on to anthracite at that time. I dried a few kilns of malt with it, and I sent them to be tested. He reported they were pure. I also put in new machines; I had a machine at that time with beaters in it, a centrifugal "Baron," and I heard that brushes were much more effective; and I had the brushes attached to the beaters which rubbed the malt alongside of the screen. It certainly took out all the culms, and I had also aspirators attached to the machines which sucked out pretty well all the dust, took it away into a stove room, or dust room. Then I put a similar machine in. I still found on the second machine that I have more or less, and I have a sample here of the different culms.

Anthracite substituted for gas coke.

Malt brushed, &c.

9426. Malt samples?—No, samples of the culms and the dust.

9427. This Manchester analyst, Dr. Miller, communicated to you that there was arsenic in these samples which you sent up?—Yes.

9428. And suggested to you that probably the presence of this arsenic arose from the fuel which you were using, and suggested that you should change the fuel you had been using and use anthracite?—That is so.

9429. Did he tell you that there was danger from using gas coke?—I do not think he did. I do not remember. He was still in doubt about it himself. It was a very early stage at that time. There was a great deal of uncertainty expressed as to which was the best. Many people thought coke was the best fuel. He could not really help me, but he said he thought anthracite would be the best, and it proved to be so in my case.

9430. Can you say yourself from personal experience that you think gas coke is undesirable for malting? As a general opinion; I do not wish to tie you down too closely?—I think it is.

9431. Do you think that opinion is largely held by maltsters in Yorkshire at this moment, that gas coke is not a good fuel for malting purposes, that it is more likely to contain arsenic than anthracite?—That is so.

9432. That is the general opinion in the Trade?—That is so.

9433. Can you show us any reports of analyses you have had made?—Yes.

9434. Can you quote one or two to the Commission, or do you wish to hand them in as evidence?—No, I do not.

9435. You would rather not?—Yes. I was asked to state what precautions I have been taking, and the analyst's papers I have here date back from December, 1900, up to the present time.

9436. Since December, 1900, you have been having constant analyses of your maltings?—Yes, the last is March 20th, 1902, but I have one at home that came this week, which I have not brought here. It is still the same report. He says, "March 20th: I have tested for arsenic the samples of malt brought from you today. The results are as under: Northowram is pure, and Elland is pure."

9437. Taking those analyses before you as a whole, what is the result of them as regards the presence of arsenic in any sample that you sent up?—I find them to come out fairly consistently pure since I have taken precautions of being careful in the selection of my fuel. I have been careful in selecting the anthracite because I found that to vary.

9438. You found even with the use of anthracite some care should be taken in regard to the coal used?—That is so.

Care needed in selecting anthracite.

9439. Do you think it should be picked over by hand or examined closely?—I instructed my foremen when they were taking in fresh loads of coal to look out for any of the pyrites, and now and then one has found a metal substance, and they have instructions to pick that out. It is very rarely we do come across it.

9440. But when found it should be picked out at once?—Yes.

9441. Do you wish the Commission to understand that since you have been more particular as to the use of your fuel and used anthracite carefully examined before use, that the analyses have shown a great improvement as regards the presence of arsenic?—That is so.

9442. That is what you wish the Commission to understand?—Yes, and many of my customers of Lancashire both test the malt itself and submit it to other brewers' chemists for their testing. Most of my customers had Dr. Miller as their analyst; some have had Dr. Campbell Brown of Liverpool. The samples have come out all right.

9443. With regard to the brewers, your customers, have you had requests from them to give any guarantee as regards the malt you supply, or as to special treatment with regard to fuel?—Yes, I have sometimes. I had a customer in Salford at the time of the Manchester scare. They had no difficulty with their beers at that time, but at the same time they were very anxious about it, and they said that all malt would have to be guaranteed free from arsenic. The malt I sent I put on "guaranteed pure" across my invoices. Their results were I believe perfectly satisfactory.

9444. Have you made any effort to get a guarantee from the persons you buy fuel from?—I have asked them for it.

9445. Have you endeavoured to get anything like a guarantee as to freedom from pyrites?—They have sent me analysis of their coal, which is quite free from arsenic, as they state, but at the same time most of them are very chary about giving you a guarantee about freedom from arsenic. They know you are quite liable to have more or less in all coal.

9446. In each case, where possible, do you get a guarantee as to freedom?—No, I do not. Of course, knocking about myself, doing most of my own travelling, I come across many maltsters, and we have a chat with one another, and we have found out in that way a few collieries whose coal has proved itself to be very good. I have never asked them for a guarantee of purity at all. I have received their reports, and I think I have one or two here. There is a tender here, "I beg to thank you for your esteemed favour of the 25th, and I have much pleasure in handing you our price for best malting coal free from arsenic, as you will see from report of our analyst, copy of which we send you herewith." There is the analysis of the coal.

9447. You wish us to understand that if maltsters travelled about like yourself, and were careful as to the selection of the colliery, it would be more valuable than the paper guarantee?—Yes. It is very easy to say, "They are guaranteed free from arsenic"; but I do not see really what good that is to us. The thing that we must go by is the purity of our malt after being dried. I have found that the best way. I do not think much about their guarantees. They do not bind themselves in any way. The analysts tell me they can get hold of a piece of coal that is perfectly free, but it does not say the whole truck is free. In a huge piece of coal—and anthracite coal is in very large blocks, indeed—in breaking them down it is quite possible at times to come across a little of the pyrites. You might analyse several pieces of coal out of the same truck and find them pure, and still find one piece with the pyrites which would give arsenic. At the same time there are no doubt seams which are really very free from sulphur, and where sulphur is, I believe arsenic is.

9448. Were you using in your malting process in August last gas coke, or last year at all?—No.

9449. You were not using any gas coke in 1901?—No, not at all.

9450. Only anthracite?—That is so.

9451. But during the previous season did you use any gas coke?—I used a very little gas coke, because the season does not commence until the end of September or the beginning of October, and I changed in December absolutely to coal. For two months I had a blend in the 1900-1901 season.

Mr. A. Worsick. 11 April 1902.

Precaution have reduced arsenic in malt.

Guarantee of malting fuel unsatisfactory.

Some gas coke used in 1900-1 season.

9452. You might have been applying in August last malt which had been dried possibly by gas coke?—I should think it was very unlikely at that time. That is something like eight or nine months afterwards.

9453. It has been suggested by Mr. Hammond Smith that some malts supplied by you to Alderson's Brewery from your town malting in August last might have been made over gas coke?—I should think not.

9454. You think it is not possible?—No. The principal coke I was using there before I changed over to anthracite was made at a pit just above the kiln, and the coke I had been using was principally from that colliery, which has a reputation of being very free from sulphur.

9455. (Sir William Church.) That would be oven coke?—That is so.

9456. (Chairman.) Not gas coke at all?—That would be oven coke. But you asked me if I had used any gas coke, and I said "Yes." I had about two or three loads of gas coke, but the principal fuel was this oven coke.

9457. You believe in the brushing process as a valuable process?—It takes all the loose material from the corn, and polishes it up. Sometimes in corns you will find a bit of husk loose, what we call beeswing. It brushes all that off; takes that away, and leaves you a clean malt.

9458. The idea being if there is any mischief occurring the fumes will attach to these portions, and that is where arsenious oxide is likely to be, and that by the brushing process you do away with the danger?—That is so.

9459. I suppose you have never taken the trouble to test any malt for arsenic before the brushing process to see the distinction between the two?—I have not; not to give you an approximate amount. But I have done this. I have had samples taken out of a heap and sent off for the test; just taken out of the heap, and then I have had samples put through the brushers out of the same heap, and sent that; and the analyst told me that the brushed malt came out very well indeed—"a shade purer, at any rate, than the other," that is how Dr. Miller put it.

9460. That is to say pure as regards the presence of arsenic?—That is so.

9461. (Dr. Whitelegge.) Did he say a shade purer?—Yes.\*

9462. (Chairman.) There was a difference at all events in favour of the brushing, and his expression was "a shade purer"?—Yes.

9463. (Dr. Hammond Smith.) Perhaps you can clear up this suggestion of mine. Some malt was supplied by you to Alderson's Brewery in August last. I think that was your statement. I have it here written down, that you were frequently supplying Alderson's, and some of that went straight from the Northowram malting to Alderson's?—That is so.

9464. Some of the malt went from the Northowram malting in August last?—Yes.

9465. To Alderson's?—Yes.

9466. That at the date in August the malt sent might probably have been some of the older malt made by you before you changed to anthracite, malt stored up at your maltings?—I do not think so.

9467. That is what I understood from you?—I should not think so. I could not tell you from memory.

9468. But you could hardly tell in any other way than from memory, because your malt at Northowram is stacked in great heaps against the wall in the malt room?—Yes. But it is a kiln where I am working regularly taking the malt away.

9469. At what date did you change the fuel at Northowram?—About 20th December, 1900.

9470. That is exactly the date I have in my hands. I rather gathered from your foreman that in August, 1901, there would have been some stock of malt made before that date?—I could not tell you.

\* I find on reference that Dr. Miller stated the brushed malt was a distinct improvement on the unbrushed, and not as stated to the Commission.

9471. (Sir William Church.) You have told us that the anthracite you received is in large blocks, and that you have to break it up before putting it on the furnaces?—That is so.

9472. Could you, as a practical man, tell me whether it would increase the labour that your stokers should pick out any lumps which look as if they contained pyrites. They can easily learn to recognise them, cannot they?—Quite easily. It is a metallic substance. It is easily detected as different from the coal.

9473. I suppose you have given those instructions to them?—That is so.

9474. Do you find often lumps of pyrites?—Very rarely indeed, but just at isolated times.

9475. When maltsters are preparing their anthracite for putting upon the furnaces, it would be, comparatively speaking, an easy thing to eliminate most of the pyrites accidentally present?—That is so.

9476. (Dr. Whitelegge.) Do you use any lime?—I have used a little.

9477. With the view of checking the dissemination of arsenic?—Yes.

9478. You attribute the freedom of the malt from arsenic to the precautions you take in the matter of fuel. You do not attribute anything, do you, to any peculiar construction of your kilns?—No, I do not. I have tiled floors, and I clean out the chamber regularly where what we call the rock comes—that is, the dust which drops through the perforations in the tiles. They drop on to the arches below. The drying kiln is formed with arches coming down to the fires, and the loose cumin more or less drops down through these holes, and we have that to clear away. It is a dust of no use for feeding or anything of that sort. We call it rubbish.\*

9479. Have you more than one floor?—No.

9480. Do you clear out the kilns?—Yes.

9481. Do you remove the dust from the walls?—Yes.

9482. Are there any girders, or beams, or rafters overhead in the drying chamber?—Yes.

9483. Are they cleared of dust at short intervals?—Yes; all brushed down and the place is whitewashed each year.

9484. When you send out malt to customers do you send them any assurance as a matter of routine that it is free from arsenic?—No; they take my word for it now pretty well.

9485. But you give them your word for it?—I know this, that if they found arsenic in it they would not have it.

9486. But does the invoice contain any statement as to freedom from arsenic?—I think I have two customers to whom I simply put "guaranteed pure" on the invoice.

9487. Otherwise you rely on a general understanding without any expression on the invoice or otherwise?—That is so. I know my customers personally. It has been one of the topics of conversation for about fifteen months talking the business over, that chiefly—and the business being my own—I have been making an effort to get my malt as pure as ever I can. I have spared no expense in the price of coal. I have given up to 35s. 3d. a ton delivered to my place, and I have given as low as 25s. I have found them, sticking to about two collieries, to come out very satisfactory.

9488. Under no circumstances do you send out malt unbrushed, do you?—No, not now. We do not send anything but now except what is brushed.

9489. Is that by way of additional precaution against arsenic?—Yes.

9490. Or for other reasons?—No. It is merely to try and get the malt as clean as possible and get all foreign matter off the husk, and get the culm away.

(Chairman.) The Commission has appreciated very much the early precautions you took to ensure immunity from danger.

\* I do not, of course, wish to convey the idea that my malts "are free from arsenic," but to say they are reported "pure" by Dr. Miller, who has rather a strict standard of commercial purity.

Mr.  
A. Worsick.  
11 April 1902.

Exclusion of  
pyrites by  
maltster.

Construction  
of his kilns

and their  
cleansing.

Guarantees  
not usually  
given with  
malt.

No malt now  
sent out  
unbrushed.

# TWENTY-SECOND DAY

Thursday, 17th April 1902.

AT WESTMINSTER PALACE HOTEL.

PRESENT :

The Right Hon. Sir WILLIAM HART-DYKE (*Chairman*).

Sir WILLIAM CHURCH.  
Professor THORPE.

Dr. WHITELEGGE.

Dr. BUCHANAN (*Secretary*).

Mr. J. F.  
Woodyatt.

Mr. JOHN FREDERICK WOODYATT (of Halifax), called ; and Examined.

Mr. J. F.  
Woodyatt.

17 April 1902.

Halifax  
outbreak.

Cases in  
Halifax  
infirmary  
in 1900.

9491. (*Chairman*.) You have been for some time visiting surgeon to the Halifax Poor Law Infirmary?—I am the principal medical officer at the Halifax Union Poor Law Hospital. It is a new institution, which was opened in October last, and that is when I received my appointment.

9492. How long have you been in the profession?—I was qualified in 1888.

9493. Previous to these events in Halifax, concerning which you have come to give evidence, have you taken personally any interest in the cases which occurred in Manchester with regard to arsenical poisoning?—I have. About eighteen months ago we had several cases of chronic arsenic poisoning at the old Workhouse Infirmary, which was then under the charge of Dr. Dolan. These cases were on that occasion diagnosed, and he asked me to see them. I was then a kind of deputy medical officer to him, and when he was away I took charge of the hospital. I saw the cases then, and was very interested in them.

9494. Did you form any judgment as the result of your investigation?—The cases were seen by many medical men, amongst whom were the Medical Officer of Health, and I do not think anyone had any doubts that they were arsenical cases. I myself was certainly convinced that they were chronic arsenical poisoning cases. I have the names of those cases which were given to me a little while before I came up by Dr. Dolan. He says here : "Cases of arsenical poisoning from the workhouse, some of which were seen by Dr. Neech, Medical Officer of Health, Dr. West Symes, Mr. Woodyatt, and others." Then he goes on to give the names, and at the end he says : "These cases were reported to the Halifax Board of Guardians at the time."

9495. Have you a copy of that report?—I have only the names in Dr. Dolan's handwriting. I do not think at the old hospital any very careful records were kept of cases. I am afraid this is all we have.

9496. How many cases were there?—There were eight. He puts eight cases down here.

9497. Had you personally examined each one of those eight cases?—I saw them. I cannot say that I carefully examined each case. I did examine them, of course, and I was very interested because there was one man who had very marked diaphragmatic paralysis.

9498. And it was partly from your own observation and partly from what you heard of others that you formed an opinion?—On that occasion, quite so.

9499. It was partly hearsay evidence and partly general observation?—My attention was drawn to it first by Dr. Dolan, and then I formed my own opinion afterwards.

9500. With regard to the cases which have now been reported to the Commission, that would be later, would it not?—Yes.

9501. With regard to the nine cases reported from the new Halifax Infirmary, how many of those nine cases were actually under your care and supervision?—All but three. I saw them all, of course, but all but three were actually under my care. The staff at our hospital

is a responsible medical officer (myself), an assistant medical officer, who is my colleague, and a resident medical officer, who is the house surgeon practically.

9502. How often would the resident medical officer visit the infirmary?—He lives in the hospital. In his rules he is supposed to visit night and morning.

9503. You wish the Commission to understand that in six, at all events, out of these nine cases you had intimate knowledge of each symptom, and an intimate knowledge of the cases?—I had an intimate knowledge of all the cases, because I was very interested, and I visited the cases of my colleague, Mr. Shaw.

9504. In one or two of these cases there was a very marked difference of opinion, was there not, between yourself and other medical men in the district in regard to the diagnosis?—With regard to some of them, yes.

9505. In regard to how many?—If you will kindly allow me I will go through the cases. I have the hospital bed tickets with me, and I can explain that difference. The day the hospital was opened, October 8th, the first case was admitted in the ordinary way in the receiving room, and I received her when she came to the ward. With regard to cases No. 1 and No. 2, I may say in passing they were both diagnosed by myself in the first instance, and that no one suspected arsenical poisoning but myself. I not only suspected it, but I put it down in writing on the bed ticket at the time. I was sure they were arsenical cases.

9506. Can you mention the names of those two patients?—Wilkinson, who was admitted on October 8th, was diagnosed then by myself as peripheral neuritis, arsenic. The patient was unable to walk ; had no tendon reflexes, and much pigmentation of skin. Those were my notes taken at the time of admission and examination. The other was Shearing. The history I have down was "Ill many years every winter with pain in the back or joints ; worked up to six weeks ago ; condition on admission : patient very anæmic, oedema of face, had trace of albumen in the urine." That was not diagnosed by anyone when he came into hospital ; it was thought to be a case of chronic Bright's disease, but after he had been in a few weeks I was not satisfied with the diagnosis, and carefully examined the patient and diagnosed him as a well-marked case of arsenical poisoning. That is case No. 2. Case No. 3 came in from her own home with marked pigmentation and branny desquamation.

9507. (*Sir William Church*.) Is that Louisa Lowrie?—Yes. This I took to be characteristic of arsenic ; not only the pigmentation but the branny desquamation. There were no other marked symptoms in Lowrie. She gave a history certainly not of being a beer drinker, but I believe her friends said she was.

9508. (*Chairman*.) What was your conclusion in regard to this case?—I considered it was chronic arsenical poisoning. I think she did not look "beery," if you understand the expression. I do not think she was an alcoholic. I think it is just possible she might have got it from some other source, but I cannot say. The other two, Wilkinson and Shearing, were undoubtedly beer drinkers. Lowrie certainly said she was

Arsenical  
poisoning  
diagnosed  
certainly

Cases during  
outbreak,  
1902.

J. F. not, but her neighbours—who may or may not be reliable  
 dyatt. —said she was. She certainly had not that appearance.  
 The next case, case No. 4, was brought in at night in an  
 17 April 1902. extremely filthy condition. He was a man of 81 years  
 of age, and he died under four days—he died on the  
 8th.

9509. What was his name?—McNulty.

9510. (Sir William Church.) His age was given to me  
 as 84—I have it 81. The patient was in that filthy  
 dirty state, and evidently moribund, that the symptoms  
 one has I am afraid are rather more general than other-  
 wise. I saw him after admission, and saw him on other  
 occasions before he died, and I certainly came to the  
 conclusion that he was not dying of arsenical poisoning.  
 I did not consider the pigmentation that he was sup-  
 posed to have, according to the house surgeon, was  
 arsenical. His skin was very dirty and had scabby,  
 scaly sort of sores that one gets in a man in a filthy  
 condition. I am told he had slept about the country,  
 in and out of houses for many years. From that I do  
 not consider that any slight change in the colour, which  
 might be a matter of dispute between two medical men,  
 justified one in calling him an arsenical case. I may  
 say he was drunk when he came in. He had been going  
 about and doing his ordinary hawking. He was a  
 hawker, and the history to my mind was not that which  
 one got in the other cases, and certainly his condition  
 was not the condition I have seen in the people before.

9511. (Chairman.) Is there any other case you can  
 place before the Commission where there was a distinc-  
 tion or difference of opinion of that kind between you?  
 —The next case is Lawrence Whalan, who was an old  
 feeble man, very anemic, and developed keratosis soon  
 after admission to the hospital. I considered the case  
 to be one of pernicious anemia. He died on March 24th,  
 a little over two months after being admitted to hospital.  
 He never improved, but gradually, as one sees in per-  
 nicious anemia, went out, and no treatment seemed to  
 have any effect upon him at all. He was given the  
 various drugs we give for pernicious anemia except  
 arsenic, because there was arsenical poisoning. He was  
 an arsenical case, and therefore I did not give him  
 arsenic. Unfortunately I was not able to get a post-  
 mortem in this case. I tried very hard, but the people  
 were Irish, and the Irish are rather averse to post-  
 mortem examinations, so that I was not able to get it.

9512. Who signed the death certificate?—I did.

9513. And when you signed the certificate you had  
 no reason to suspect this was a case of arsenical poison-  
 ing?—That is so.

9514. (Sir William Church.) Six were under your  
 personal care?—Yes. But I saw them all, and ex-  
 amined them carefully. To my mind there is no differ-  
 ence between one set and the other. I have given you  
 the cases in the order of admission to the hospital.

9515. (Chairman.) Before these occurrences at Man-  
 chester which led to the appointment of this Commis-  
 sion, had you, as a medical man, any suspicion what-  
 ever with regard to even the possibility of poisoning by  
 arsenic in beer?—I had not, but I have formed a con-  
 clusion since the Commission sat, and since the two  
 outbreaks of these cases in Halifax.

9516. At first it was the Manchester outbreak that  
 brought to your mind the possibility?—That is so.

9517. I suppose you never considered such a question  
 before, and it was never brought under your notice as a  
 medical man?—No. I often gave arsenic to patients.  
 I have been in various hospitals for over six years as  
 resident.

9518. It is not an uncommon practice, is it?—The  
 only symptoms I could say I have seen are vomiting,  
 and the watering of the eyes, and then one generally  
 stopped or decreased the dose, and the patient got all  
 right.

9519. During the cases of arsenical poisoning in  
 Manchester and the surrounding district did you see  
 any of those cases?—No, not in Manchester. At the  
 time the cases were in Halifax, and I saw them there,  
 I received from Dr. Reynolds, who was formerly resident  
 with me at the Manchester Royal Infirmary, his  
 brochure, which was very descriptive, and contained  
 numerous copies of photographs, which I, of course,  
 studied.

9520. Will you kindly tell the Commission when and  
 where you first saw a patient suspected to be suffering

from arsenical poisoning due to beer?—At the end of  
 September, 1900, at the old Workhouse Infirmary,  
 Halifax. It was the winter of 1900, late in the year of  
 1900.

9521. But some while before these occurrences which  
 you have mentioned to us in the Infirmary?—Yes.

9522. (Sir William Church.) Would you kindly tell  
 the Commission what are your exact duties as visiting  
 officer to the Halifax Infirmary?—I am the responsible  
 Medical Officer appointed by the Guardians, and ap-  
 proved by the Local Government Board. I am re-  
 sponsible really for everything in the institution. My  
 definite duties are not drawn up. It has been a new  
 appointment, and the guardians somewhat hesitated  
 to define one's duties very definitely, and have not yet  
 done so. But I may say that I have been to the hos-  
 pital a great deal, and I very seldom have missed a day.  
 Some days I have been there twice. Of course, I am a  
 medical practitioner in the town now, and this is just  
 an appointment which I hold. I think I may tell you  
 that I have been a hospital resident for a number of  
 years, and I take a great interest in hospital work and  
 administration, and I think that is what has got me this  
 responsible appointment.

9523. You are responsible for all the patients in the  
 Infirmary?—When put in that way, yes. I have two  
 assistants. Their title, which is in the Local Govern-  
 ment Board Order, is Assistant Medical Officer, and  
 the third one is the Resident Assistant Medical Officer.  
 They are, therefore, practically under me, and I am re-  
 sponsible for all that takes place in the institution.

9524. Would you kindly tell us what is your routine  
 when you pay a visit?—I go in the morning, and I in-  
 variably see all new cases that are admitted. I ex-  
 amine them, and prescribe for them, and very often  
 diagnose them, or, if they have been already diagnosed,  
 I either confirm or alter that diagnosis.

9525. You examine all the new patients yourself per-  
 sonally?—Well, there are certain cases that have been  
 allotted to the Assistant Medical Officer. I have done  
 that myself to relieve myself of responsibility. Our  
 institution is one of three hundred people almost, and  
 that is a large number. We have not many daily ad-  
 missions. There are principally old chronic cases that  
 you get in other workhouse hospitals.

9526. What we rather wanted to know was whether  
 you, as a matter of routine, examine all patients your-  
 self, or only examine those your Assistant Medical  
 Officer or Resident Officer draws your attention to?—I  
 may say practically I have examined all male patients  
 who have been admitted to the new hospital since it was  
 opened in October last, and those female patients that  
 my attention has been drawn to by the Assistant or  
 Resident Assistant Medical Officers.

9527. Do you prescribe for them as well as diagnose  
 the case?—Very often.

9528. When you diagnose the case, do you write the  
 diagnosis upon the board, or is that left to a later  
 date?—I generally like it done at the time, and if it is  
 not done already I very often put it down in my own  
 handwriting, which you will see if you care to see my  
 bed tickets here.

9529. Do you consider you have any other duties  
 besides those in the infirmary?—No public appoint-  
 ment.

9530. Visiting the patients in the wards completes  
 your duty as far as the Poor Law hospital is concerned?  
 —I attend the Infirmary Committee meetings once a  
 week; not that it is necessary, but I go just to report,  
 and to see what is going on in the house. Except for  
 that I have no clerical duties beyond the medical work.

9531. What do you include in the medical work?—  
 Examining, diagnosing, and treating cases and dis-  
 charging patients.

9532. Do you generally attend in the post-mortem  
 room or not?—Very often.

9533. Is that part of your duty, or do you go there  
 yourself?—I go down, and sometimes make the post-  
 mortem myself, and sometimes the house surgeon does;  
 or we do it together. I have attended most post-  
 mortems that have taken place since the hospital  
 opened.

9534. You consider that that is part of your duty  
 almost?—Quite so.

Mr. J. F.  
 Woodgatt.

17 April 1902.

Dr. Wood-  
 gatt's  
 examination  
 of cases at  
 Infirmary.

Mr. J. P.  
Woodgatt.

17 April 1902.

Does not  
usually  
certify  
deaths, but  
did in  
Whalan's  
case.

Wilkinson.

Shearing.

Lewrie.

McNulty.

9535. With regard to the certificates, of those who die in the hospital, do you usually sign the death certificate or not?—I do not.

9536. I think you did sign the death certificate of Whalan?—I did; and if you will allow me I will give you my reason for doing so. At two former inquests which were held there was a difference of opinion between me and the house surgeon.

9537. I do not think I need go into that, but as a matter of fact you did sign the death certificate; there were reasons that made you sign it, but that was an unusual course?—It was an unusual course, yes.

9538. I should like you to kindly give the Commission some information about some of these cases. The first case in which you recognised arsenical poisoning was Mary Wilkinson?—Yes.

9539. She got well?—Well, she is in hospital now; she is convalescent.

9540. But at all events she is getting well?—Yes.

9541. And George Shearing?—He is now in the hospital. I examined him on Monday last time, and I consider that he is making practically no progress. His paralysis has passed off to a very great extent; he can just totter with help.

9542. But with regard to those two cases, you have no doubt yourself that they are arsenical?—Absolutely none.

9543. Louisa Lowrie?—I have no doubt in my own mind.

9544. She is still in the hospital?—She is still in the hospital.

9545. I think that McNulty was the fourth?—That is so.

9546. I rather gather from what I hear that you considered him during life to be an arsenical case?—No, I did not. I considered he was an old bronchitic; that he had an acute attack on top of his chronic condition, and that he died from that cause.

9547. The pigmentation on McNulty you considered was due to dirt?—I did.

9548. Was there not something peculiar about the pigmentation if it was due to dirt?—I do not think so. I carefully examined him both during life, and in the post-mortem room, and I could not see it.

9549. Did you notice anything about the soles of his feet?—I did. I did not think his feet were more scaly than one usually finds in tramps. In people of that class, if you examine their feet you will always find the skin thickened and scaly to a certain extent.

9550. You think he had no foot drop?—I do not think he had. I may tell you I did not take his reflexes, because the house surgeon told me that he had tried them, and they were absent. Seeing his condition I did not feel justified in setting him up, and carefully testing for the tendon reflex. I took it for granted he had none.

9551. He had a good deal of puffiness in the face, and running from the nose and eyes?—I do not think so. That is just a matter of opinion, where I think medical men may disagree. In an old man in that condition one man might think there was some running, while another man might think there was not.

9552. But arsenic was found in his urine?—No, not.

9553. Arsenic was found at the post-mortem investigation of the liver?—That is so.

9554. On what ground do you exclude the possibility of arsenic having played a part in producing the man's condition?—I do not exclude it. I gave my opinion before any chemical examination. I gave my opinion from the clinical examination, and from the post-mortem examination.

9555. What I want to put to you is the fact that the man having bronchitis does not exclude his suffering from chronic arsenical poisoning, does it?—No. But he had dilated tubes in the post-mortem room; the tubes were very evidently dilated. They stood up out of the lung tissue, and were unnaturally dilated. That proved to me that the man had been suffering from bronchitis for many years. I do not think tubes get into that condition quickly. It must take a considerable time. That was what convinced me.

9556. But supposing he had been a sufferer from chronic bronchitis for many years, he might also get

arsenical poisoning?—I cannot say he had not been drinking beer that contained arsenic; I do not wish to say that for a moment, but the symptoms I have seen in other cases were not evident in this man. That is my argument. I am not surprised that arsenic was found in his tissues seeing he was a heavy beer drinker.

9557. You thought his general appearance differed very considerably from those cases which did not die?—That is so.

9558. Still, considering that a considerable amount of arsenic was found in his viscera, that is rather an assumption?—Well, I remember Mr. Allen at the inquest said that there was not more than 1-400th of a grain in the whole of the tissue he examined.

9559. But the whole tissues he examined were only four ounces?—I think they were a little more than that. I have not got the exact amount of tissues he had; he did not say how little it might have been. It might have been a very small trace as far as I could gather. He said "not more than 1-400th of a grain." He did not say it was 1-400th of a grain.

9560. The statement made in this report, which you have seen, "I may note that, taking the quantity of arsenic found in four ounces of liver at 1-700th of a grain, and the weight of the liver as 53 ounces, there would be about one-sixteenth of a grain in the whole liver. This result is not dissimilar to those obtained by Dr. Stevenson and Dr. Dixon Mann in fatal cases in Manchester in 1900"?—I have only the information the analyst gave at the coroner's inquest, and that is what he told the coroner. I remember distinctly his words, because it rather impressed me that a chemist should say "not more than." He also said at the end of his evidence, something which I did not attach much importance to, that the amount was quite insignificant and did not mean anything. I will not admit it was of no importance, because I think it was. He did say "not more than," I am quite convinced.

9561. You had no doubt that Thomas Lee during life was suffering from arsenical poisoning, had you?—None whatever. He was certainly the most marked pigmentation case I have seen. I have had his photograph taken, which perhaps you have already seen, as I gave Dr. Hammond Smith a copy.

9562. His death was due, in your opinion, to what?—To acute croupous pneumonia.

9563. I suppose you would consider in Thomas Lee's case that his chronic arsenical poisoning was a contributory fact to his death?—I will tell you what evidence I gave before the coroner, and perhaps that would be the best way to explain it. I described Lee as a well marked case of arsenical poisoning, and I produced this photograph to the coroner, and he showed it to the jury. I described his condition, and then I described the post-mortem, and what I found in the post-mortem room. If you wish it I will read the post-mortem report, although it is rather lengthy.

9564. I do not think we need to have that?—With regard to my opinion as to the cause of death, I was asked very definitely by the coroner, and I said I was of opinion that Lee had died of acute croupous pneumonia, but what part, if any, had been caused by the arsenic the patient had undoubtedly taken I was not prepared to say. Those were the exact words I gave to the coroner.

9565. Could not you say that of almost all these cases?—I think if Lee had died without his acute croupous pneumonia, which, I take it, is the condition caused by the pneumo-coccus, if he had died with congestion of the lungs with that amount of pigmentation, I would not have hesitated in saying that arsenic had caused his death; but Lee was a man who had various other diseases, which were only found out on the post-mortem table. He had a stricture of the urethra, and a hypertrophied bladder. He had granular kidneys, a hypertrophied heart, and aortic disease, and acute croupous pneumonia.

9566. But does not that only show that a patient suffering from arsenical poisoning may die of other causes, whether acute pneumonia or septic poisoning, or whatever it may be?—Of course the man died, and he was an arsenical case, but what part the arsenic played I really cannot say. Lee improved considerably. When he came in he was very shaky, and had bronchitis; he had a very husky voice. His bronchitis cleared up, and he was taking the ordinary hospi-

Mr. J. P.  
Woodgatt.

17 April 1902.

J. F. tal diet, the diet on which we put convalescents and ordinary surgical cases. It was not a special diet we give to invalids. He was going to the lavatory, and his condition altogether was not bad. He improved; and his bronchitis went away. I had him brought to the theatre and the photograph was taken. The man did not look ill. He had very marked pigmentation. Then at a certain date (I have the chart here), about the 23rd of January, the temperature commenced to go up.

9567. The first week he was in hospital his temperature was normal or subnormal, and during the second week it gradually rose, and during the third week it became irregular, and at the end of the third week he died?—Yes, that is practically so. I take it that this rise of temperature was due to the pneumonia he had.

9568. Do you know at what time it was Dr. Reynolds saw him?—On the 21st January.

9569. I think he died on the 5th February?—Yes.

9570. Do you know what Dr. Reynolds' opinion of him was when he saw him?—I have Dr. Reynolds' letter here which he wrote after he had got home. Dr. Reynolds visited the hospital when, unfortunately, neither the house surgeon nor I were present, but he wrote the letter directly he got home, and this is what he says: "The male patients, Lee and Shearing, are well marked cases of arsenical poisoning of comparatively recent origin—that is to say, four months—and the woman Lowrie is also well marked, but possibly of an older date. I am not at all certain of Marsden, but he may be one." That is the report Dr. Reynolds sent after he returned home.

9571. He told us that when he saw Lee he considered him a very grave case, and thought that he was going to die, and that would be before he became so very ill of pneumonia, would it not be?—Yes, before his temperature began to rise.

9572. Now, with regard to the fifth case on which there has been a good deal of difference of opinion—Whalan. You think that Dr. Reynolds did not see Whalan?—Of course, I only have the evidence of the nurse. I asked the nurse whether Dr. Reynolds had seen him, and she said he had not seen him, and he does not mention it in his letter he wrote directly afterwards. Therefore, I came to the conclusion that he had not seen him. If Dr. Reynolds said he did I am quite prepared to accept his word for it.

9573. We were led to believe Dr. Reynolds did see him, but you think there might be some confusion between Whalan and Marsden—That is my own opinion, I think he was thinking of Marsden when he gave his evidence.

9574. Did you see Whalan when he came in in the ordinary routine and examine him on the first day?—If I did not examine the first day I must have done so on the second. I make my visits fairly early in the morning, and go through all the wards as a rule.

9575. You have no note of what opinion you formed on the first time?—I formed a very definite opinion. I saw him and got him up and walked him about, and examined him carefully, and I formed the opinion that he had no pigmentation, that his reflexes were present, that he had no drop ankle, and there was no oedema; there were no symptoms except the anaemia that presented themselves on examination.

9576. Do you remember what he complained about chiefly?—Of weakness. I remember asking Whalan what was the matter, and he said he was terribly weak. If you put leading questions to some of these people I find you can get almost what you want, especially if they are worried a good deal. Our cases were examined by many doctors; all sorts of people used to come and see them, and put leading questions to them, until very often they sometimes say things they do not quite feel. I think sometimes the history is rather unsatisfactory.

9577. He made no complaints to you of a curious feeling of electricity about him?—No; I see that is put down on the bed ticket by the house-surgeon that he had a feeling of electricity all over him. But I do not remember him using the term to me.

9578. No tingling in his hands and feet?—When I put leading questions like that I can get any reply. I have done it since. I have asked people who have a certain amount of heart failure, who are bedridden perhaps, or are suffering from various conditions, whether their

feet tingled, and a lot of people will tell you yes. I have tried to test what people of this class would say to leading questions.

9579. In your opinion it was an error of observation of the house-surgeon to say that his feet had been swollen and painful?—I will not say that. He had not got that when he came in. The house-surgeon does not say that. That is from asking him whether his feet were swollen, and he would say yes.

9580. There is another note which says there is well marked keratosis of the hands and feet?—That was not so on admission. He developed the well marked keratosis. Of course I admit he had very marked keratosis of the feet and a little of the hands. The feet were constantly shedding their thickened epithelium into the bed clothes.

9581. There was little or no pigmentation I think in this case?—I consider there was none. I see the house-surgeon puts his skin "slightly mottled." That is a matter of opinion where I think medical witnesses will very often differ.

9582. In pernicious anaemia, is there any change in the colour of the skin?—I am not aware that there is any pigmentation. They get exceedingly anæmic, as you are aware, and the anaemia does not pass off with treatment, as Whalan's did not.

9583. Are not you aware of any colouration which is not uncommon in pernicious anaemia?—I am not aware of it.

9584. You are not acquainted with what is called the "lemon tint," which so many of the cases of pernicious anaemia have?—He had that excessive pallor, and probably he had that, but I cannot say that I have ever heard the expression before.

9585. Were the conjunctivæ of that colour, too?—They were exceedingly anæmic. I did examine the blood.

9586. There was nothing about his colour that at all attracted your attention?—Nothing, except the extreme pallor, and of course in a patient who is extremely pale you see a yellow case of the skin, as in old people, who are exceedingly pale. To see him you would think perhaps he had some malignant disease.

9587. What is the period of life when people are most apt to get pernicious anaemia?—I think he is rather old for it; I should say the common age is somewhat younger than Whalan's age.

9588. This man is 65?—That is the age given; I think it rather old for pernicious anaemia, but I do not consider his age excludes pernicious anaemia.

9589. No investigation I think was made of the blood of this man?—I examined his blood, and I may tell you I am not a practical pathologist. I have examined patients' blood very often, and I know there is a good deal written about it just now, and a lot of different cells described. The impression I got from the blood was that it was exceedingly pale when drawn. The red cells were exceedingly deficient, and they did not form rouleaux as the ordinary blood does.

9590. Did you examine the blood more than once?—Only on one occasion.

9591. How did you examine it?—Just in the ordinary way under the microscope.

9592. You did not use any reagents or staining?—None.

9593. Would you kindly tell the Commission under what circumstances Dr. Mantle was met? I do not quite understand how Dr. Mantle was brought in to this case?—There was a difference of opinion with regard to McNulty and one, which did not amount to much, in the man Lee. I did not think it was very dignified for two doctors to get up at an inquest, and one pronounce one opinion and another another, and I thought to avoid any repetition of the same thing I would get an independent medical opinion. I considered Dr. Mantle would give an independent opinion. He is the only medical man in Halifax who is a physician solely, and is the only member of the Royal College of Physicians, and I took it that his opinion would be of some value, and that is why I suggested Dr. Mantle should see him. I may say that Dr. Mantle's opinion was that the man had pernicious anaemia. I may tell you that the house surgeon thought he was dying of arsenical poisoning, and, seeing there was a difference of opinion, I would not take the responsibility. I thought I would get another opinion, and that was the

certificate.

opinion of Dr. Mantle, that he had pernicious anæmia. I went to the coroner and gave the coroner the full opinion, that one doctor said he was dying of arsenical poisoning—

9594. I want to clear up Dr. Mantle first before we get to the coroner. Dr. Mantle came merely at your request?—At my request. I suggested Dr. Mantle; it was a professional visit, and he was paid.

9595. By you?—No, by the solicitor who was representing the brewers.

9596. Was it, therefore, not at their request as much as yours?—No, it was my own. I telephoned and told the solicitor that I thought it was in the interests of my own reputation.

9597. Had you communicated with the solicitor of the Brewers' Association before you called Dr. Mantle in?—I suggested a third party should see him; that was the first communication I had with them.

9598. You agree with the statement that this man Whalan had arsenic in his urine?—Yes. If you have evidence to prove he had arsenic I am quite willing to admit that, and I think the keratosis might or might not have been due to arsenic. I may say I have seen marked keratosis in old people who have a very dry skin, when they are thrown on to their back. I have often seen it. I have cases in hospital, one I am thinking of particularly now, a man who has very marked keratosis of his feet, who came in for disconnected semi-lunar cartilage a short time ago.

9599. You told us you greatly regretted you could not get a post-mortem examination of this man?—Yes.

9600. But, surely if you had stated to the coroner there were considerable doubts about this case, and you thought in the public interest there should have been a post-mortem, the coroner would not have objected to a post-mortem and an inquest?—I wanted a post-mortem for my own personal satisfaction, to prove, if possible, that there was no other organic disease that had not been diagnosed. That was my object in asking the friends for a post-mortem examination.

9601. Just now you rather told me you called Dr. Mantle in, in order that you might have no difficulty in signing the certificate as that of pernicious anæmia?—I called in Dr. Mantle so that there should be no difference of opinion at an inquest. I do not think it is dignified to the medical profession for doctors to differ, and their opinions to be published in the Press. That was the only reason why I called Dr. Mantle in. It was more for my own reputation than anything else.

9602. Still the Brewers' Association paid Dr. Mantle his fee?—That is so. At least I understand they did; I told them I thought they ought to.

9603. And they were aware that you were calling Dr. Mantle in?—Yes.

9604. There would have been no difficulty in obtaining an inquest on Whalan, would there?—No, none whatever. If I had told the coroner I had wanted an inquest he would have said, "Certainly, have one by all means." I left it with him. I simply gave him the evidence, and he formed his own opinion.

9605. Therefore, so far, the result of these cases you have had in the infirmary at Halifax is that those who died did not die with arsenical poisoning, and those who lived you admit have had arsenical poisoning?—My argument is more that I will not say they have not had arsenical poisoning. My argument is that I did not consider they have died of it. That is my opinion.

9606. I want to press you a little upon that. How do you generally fill up a certificate of death?—The ordinary certificate says, I attended him in his last illness, and that I saw him last on a certain date, and that in my opinion he died of the following disease, and I put down the disease.

9607. In many death certificates at all events the immediate cause of death and the preceding condition of the person is mentioned?—Yes. I must say myself if the patient dies of anæmia I put it down. Take another disease, sometimes there are several predisposing causes. One does not put down everything on a certificate. I think that is the experience of most medical men; they save the registrar a little trouble perhaps and make it easier for him to get out his reports. They put down the immediate cause of death unless there is something very definite causing it. If I had a man with stricture, for instance, and surgical kidneys, I could put down surgical kidneys consequential to stricture of the urethra, but where there is a doubt that

his pernicious anæmia was caused by arsenic one would in any case leave out the arsenic. If one had known that the arsenic had caused his pernicious anæmia one would have put it in.

9608. Do you know on what grounds Dr. Mantle came to the conclusion that the man was suffering from pernicious anæmia, did he examine the blood?—No.

9609. Did he recognise any peculiarity that patients with pernicious anæmia often show when he saw him? He made a very careful examination. He stripped Whalan; got him up—

9610. That would not help you, stripping him. Did he remark on the unusual thing of a man of 65 having it?—No, he did not, not to me. I simply got him there to form his opinion. He made his own examination; took his own history and notes, and formed his own opinion.

9611. You must have conversed with Dr. Mantle about it, and I wish to know what were the symptoms or physical signs that led him to form a definite opinion?—I told Dr. Mantle everything—that arsenic had been found in this man's urine, and I told him that I knew about him, and he examined him very carefully to find any cause. We all know that excessively anæmic people sometimes become so from organic disease, malignant disease, or something else.

9612. It is a very different thing to try to exclude the presence of a disease to the definite statement that it is present?—Pernicious anæmia is, I take it, a strange sort of thing. It is a thing that does not give rise to very many symptoms. There is not very much to show for it except the extreme pallor. The man on two occasions had epistaxis, which is, of course, a symptom in pernicious anæmia.

9613. So Dr. Mantle came to this conclusion without making any examination either microscopically of the blood or by the hæmoglobin test. Of course, there was no opportunity, as there was no coroner's inquest, of examining the viscera for those changes we find in pernicious anæmia?—That is so.

9614. He had no opportunity of seeing the man more than once, I think?—I think he only saw him once.

9615. After all, it comes to this, that the two cases that died, and which you did not think, for reasons you have given us, were suffering from arsenical poisoning, had evidence in their body of arsenic; in McNulty's case arsenic is found in the viscera, and in Whalan's case it is found in the urine?—That is so. When you come to say that I did not think they were arsenical, I may say that when I am told there is arsenic in the urine and a man has keratosis, I should say the arsenic is the cause of the keratosis.

9616. But it is not contributory to his death?—Is not contributory to his death. That is my opinion.

9617. What led you to sign these certificates yourself and not leave it to the house surgeon to do so?—As I told you, we had differed very materially—at any rate in McNulty's case. There was very slight difference in Lee's case; we both admitted he was arsenical. As I said before, I think it is rather undignified that medical men's evidence should be put in the papers in this fashion, that one says one thing, and another another, and to save a repetition of that I called in a third opinion.

9618. You think if the house surgeon had signed the certificate of Whalan that he was suffering from arsenical poisoning there would have been an inquest?—I think there would.

9619. And you were very anxious to know the condition of the man. You told us you were very anxious for a post-mortem?—If there had been an inquest I should have been bound to give my opinions, and Dr. Hodgson on oath would have been bound to give his. I knew his opinions and he knew mine. As I have said before, I wished to avoid the difference of opinion coming before the public, as it would do if there had been an inquest. That was my only object in saving an inquest, absolutely. I selected Dr. Mantle simply for the reason I have told you, that he was a physician, that he has recently been made a member of the Royal College of Physicians, and I considered his opinion was perhaps the best one to take.

9620. But surely you came to your diagnosis of pernicious anæmia on rather slight grounds? There was none of that characteristic tint which is found in the cases; you made but one examination of the blood,

Mr. J. F.  
Woodgott.

17 April 19

Woollyatt.

April 1902.

and that not using reagents; and you did not take into consideration that it is not common to get it in advanced life, and yet there was arsenic present in the man's urine and keratosis?—Well, of course, I formed my own opinion from various information which I had.

9621. And you took steps that there should be no inquest?—I did. I have given you my reasons for avoiding an inquest, and that was absolutely the only reason I had for not forcing an inquest, if you put it that way. The coroner had every information; he could have had an inquest if he liked.

9622. I suppose the brewers would not have liked another inquest?—I suppose really they would not. If I had asked them I have no doubt they would not have liked an inquest.

9623. You were in pretty constant communication with the brewers' solicitor?—No, I was not. I may say there was a certain medical man in the town, Dr. West Symes, who was watching the interest of the brewers, and he asked me as a professional man to keep him informed as to how many cases, and so forth, we had in the hospital, and he asked my permission to see the cases at the hospital, which I freely gave.

Mantle's  
son of  
Lan's

9624. (Dr. Whitelegge.) I understand Dr. Mantle formed the diagnosis of pernicious anemia?—He did.

9625. Did he go further and pronounce any opinion as to the presence of any degree of arsenical poisoning?—When I told him that there was arsenic in the urine he admitted, as I did, of course, that when there is arsenic in the urine, if you have a man who is a beer drinker, and you have evidence that beer contains arsenic, therefore one comes to the conclusion that he had been drinking arsenical beer. Dr. Mantle admitted that, as I did.

9626. Did Dr. Mantle agree with you in recognising that though arsenic was present, still it was not a case of arsenical poisoning?—That is so.

9627. And he agreed with you that the arsenic was not the cause of the man's death?—That is so. I had a definite opinion, because I was very anxious that the difference of opinion should not come into the Press, because I did not think it was dignified to the profession.

9628. How long before Whalan died did Dr. Mantle see him?—Whalan came in on January 10th, and died on March 22nd. When I saw that the end was not very far distant I got his opinion then.

9629. With the view to a possible inquest?—Yes.

9630. Is an examination made in all the cases in the infirmary of the urine and hair for arsenic?—No.

9631. I mean of all the arsenical cases?—I cannot say. I am not a chemist, and I would not trust analyses made by myself.

9632. Steps are not taken as a matter of routine to confirm the diagnosis?—No: the Guardians have never paid for analyses. They will not do that.

9633. Has it been suggested to them?—No. I mentioned to our chairman, after the two first cases were admitted, and before McNulty came in, that we had some arsenical cases. I would like you to understand that I have been quite open about these things. I have reported them to medical men, and I was the first one to diagnose it. I mentioned it to our Chairman of the Board of Guardians. I think in the report Dr. Neech, the Medical Officer of Health, said the cases were not reported to him. That is so. Of course, I knew that Dr. Neech had seen arsenical cases more than twelve months previously, and I did not think it was necessary to draw his attention to them, or I would otherwise have done so. If they had been our first cases in Halifax I should probably have drawn the attention of the Medical Officer of Health to them.

9634. You referred to a list of cases in Dr. Dolan's experience?—Yes.

9635. On what occasion did those occur?—It was the time of the Manchester epidemic.

9636. Those were reported to the Guardians?—Dr. Dolan says so. I have his rough notes here if you would like to see them, and he says that.

9637. They were reported by Dr. Dolan?—That is so.

9638. Have you made any report to the Guardians on the recent cases?—I cannot say I have in a written report. I have brought it before them at their infirmary meetings. Very early on, before McNulty came in at

all, when we had the first three, Wilkinson, Lowrie, and Shearing, I mentioned them to the chairman of the Board of Guardians, before there was any inquest or anything. You can see from that that I have been quite willing that the officials and the medical practitioners in the town should know. I read a paper before the Halifax Medical Society on chronic arsenical poisoning on the first Tuesday in February; I showed cases then, and I showed photographs, and there was considerable discussion on those cases and chronic arsenical poisoning generally.

9639. You told us that in Lowrie's case, which you regard as one of chronic arsenical poisoning, it was possible that the arsenic came from some other source?—She told me very distinctly that she did not take any beer—practically no beer. She did not look "beery," or look a woman who drank, even when she came in. She looked anything but a woman of that type. Her friends, landlord, or neighbours, said she was drinking a good deal, but I think one ought to discount sometimes those reports. That is what made me think it possible that she might not get her arsenic from beer.

9640. But you do not suggest any alternative source for arsenic?—I do not. She was one of the patients I showed to the Society, and I do not think there was any member there, except Dr. Neech, the house surgeon, and myself, who thought it was arsenical. They doubted very much whether it was arsenical. But she was not quite so typical as when diagnosed by me. Then she had the branny desquamation, which had passed away, and she simply had a little pigmentation left.

9641. With that exception, do you regard all the recent cases in which arsenical poisoning has been established as due to beer?—I should say so. When I am told that beer contains arsenic, and of the former epidemics, and the Manchester epidemic, and other epidemics in Halifax, I am of opinion that these people who show symptoms of arsenical poisoning get it from beer. I have no personal experience of the analysis of beer. I am taking the evidence of analysts for that.

9642. (Chairman.) With regard to the symptoms of arsenical poisoning, what symptoms should you say would most clearly bring to your mind first of all in a patient that he or she was suffering from arsenical poisoning?—It depends upon the quantity. If we have a lot of arsenic, I think the first symptoms we should get would be sickness and diarrhoea, puffy eyes, watering eyes, and a certain amount of dropped foot, and early rashes of an erythematous nature, and the various rashes one gets. If there was very little, I think those symptoms are very masked, in fact hardly present at all, but you get the more remote symptoms shown, such as pigmentation, paralysis, and keratosis.

9643. Take pigmentation of the skin, for instance; does that occur in cases of patients without the presence of arsenic?—Yes.

9644. Do you know cases?—Oh, yes.

9645. Are cases of extensive pigmentation of the skin common among patients not suffering from arsenic?—No. I do not think any pigmentation like that shown in this photograph is due to anything but arsenic.

9646. You have never seen a case like that except caused by arsenical poisoning?—No. I have never seen such a case as that even in arsenical cases, none quite as dark as Lee.

9647. On this question of granting certificates of death, is it customary for medical men to state what the contributory cause of death is, or is it usual to place the disease that is the direct cause of death without saying death was hastened or contributed to by other causes?—It depends whether those other causes are of importance. Take, for instance, scarlet fever. If you have a case of scarlet fever nephritis, one would naturally put scarlet fever and nephritis following. One would put both causes, because one is convinced the scarlet fever is the original cause.

9648. In that case it would be a sequence of the original disease?—Yes. I should put it as I have done on former cases. Unless there is some special indication I do not often put more than one diagnosis down on the death certificate.

9649. (Sir William Church.) You make use of the usual official certificates of death?—Of course.

9650. Are there not two columns that may be filled up?—I believe there are three.

Mr. J. F.  
Woollyatt.

17 April 1902.

not  
ted to  
H.

Mr. J. F.  
Woodgatt.

9651. And you only fill up one habitually?—I very often put a primary and secondary cause.

17 April 1902.

Whalan.

9652. (Chairman.) With regard to the patient, concerning whom you called in Dr. Mantle to assist in the diagnosis, what would be your opinion supposing he had not suffered from this pernicious anaemia? Would the fact of his having drunk this beer, and the quantity of arsenic that was subsequently found in his body have caused his death apart altogether from the disease?—No. That is really what I wish you to understand, that I do not think if he had taken that amount of arsenic without pernicious anaemia, he would have died. I think he would have got better, as most cases do. Dr. Reynolds reports about 500 cases, and I think he gives 15 deaths. That is not a very high percentage. If we have had three deaths, which I do not admit, our percentage would be abnormally high. Even with the doubtful cases we can only muster 9, and that would be 3 deaths out of 9, which is a very high percentage compared to what Dr. Reynolds has found in Manchester. His cases, I take it, were very acute. The early symptoms were very well marked. People were diagnosed going about the street. There has been nothing of that kind with us. I have dotted a few notes down here, which, perhaps, might give you a better idea of my views on the subject. What has struck me mostly about the cases is, first, the fewness of their number. Our hospital draws from a population of 200,000 people. Taking the well marked cases with the doubtful ones we can only number 9 in the hospital. Secondly, absence of acute poisoning symptoms such as vomiting, diarrhoea, running eyes, rapping step, etc., found in the Manchester cases. Thirdly, the chronic nature of these cases, which suggests to me the long-continued use of little contaminated beer. This will also account for the fewness of the cases. Fourth, the fact that those attacked are people badly fed and clothed, often sleeping out, and also people whose organs have commenced to degenerate from various diseases. Fifth, I have carefully examined heavy beer drinkers, men who told me that they drank from 10 to 30 pints a day, and have

Opinions  
regarding  
outbreak.

found in these people no signs of arsenical poisoning, except in one case, a man who had loss of reflexes. I stripped the men and examined them carefully. I thought it would be rather interesting if I could see heavy beer drinkers and see more pigmentation or some of the early symptoms, which I failed to find. Sixth, most of the beers that have been examined have given traces of arsenic. Therefore, taking a heavy beer drinker, and examining his urine, you will find arsenic, whether the arsenic gives the physiological fact or not. Seventh, one case I am convinced, viz., Shearing, had arsenical poisoning about five years ago, and again two years ago, the last attack being his present one. With regard to Shearing, the patient who is now in hospital, I very carefully went into his case, and I am of opinion now that Shearing years ago had arsenical poisoning. I think he is a very susceptible man. His symptoms, as far as I can gather from him, are identical now to what they were years ago, and they pass off after a certain stay in hospital.

9653. (Dr. Whitelegge.) Will you add the date?—About five years ago was his first attack. Then again two years ago, and lastly the present one. I have no definite day for the first attack. Eighth, I am of opinion that most of the cases have come to the Medical Officer of Health, not because of the notice he sent round to the practitioners, but because most of the medical men in the Halifax district have seen these cases. I myself brought the cases before the Halifax Medical Society on the first Tuesday in February of this year, when I read a paper on arsenical poisoning. The meeting was well attended. One case, Lowrie, no one present would admit was arsenical, except Dr. Neech, the house surgeon, and myself. Then again with regard to the history. I think the history is rather unreliable. I think if you put leading questions to these people sometimes you can get always what you want. With regard to the amount of beer they take, persons very often underestimate. If you ask a man how much beer he drinks he will say very little, and his friends will say an enormous quantity. I think it is very difficult to get the absolute facts of the case.

Mr. J. F.  
Woodgatt.

17 April 1902.

Mr.  
W. Thomson.

Mr. WILLIAM THOMSON, called; and Examined.

Mr.  
W. Thomson.

9654. (Chairman.) You have had many years practice as an analytical chemist?—Yes, I have.

9655. Are you at the present moment public analyst for Stockport?—Yes.

9656. You are what is termed a consulting chemist, and work at the Royal Institution Laboratory, Manchester?—Yes.

9657. Will you kindly tell the Commission the extent to which your work has gone as an analyst, that is to say, with regard to any particular industries. Have you examined for the textile trade, or chiefly beer, or what?—My practice is a very miscellaneous one, to a large extent connected with the textile industries, also with mining and chemical products, and so on.

9658. Have you been going through the ordinary work of an analytical chemist for brewers?—Yes, to a very considerable extent.

9659. And therefore your work has really spread over the whole of the area that an analytical chemist might have to work in: it covers the whole of the work of an analytical chemist?—Yes. I have done a great deal of toxicological work also.

9660. With regard to your analyses for brewers, have you done the general work of a brewers' analyst, that is

to say, testing as regards the component parts of their brew?—I have from time to time done so, but not as a general rule.

9661. But you are aware that many of the larger brewers do employ an analyst of their own?—Yes. It would be only in exceptional cases in which my services would be wanted.

9662. Did you have much work to do with regard to the unfortunate catastrophe at Manchester?—A great deal.

9663. Since that time you have been employed in analysing beer for arsenic?—Yes, constantly.

9664. In Lancashire?—Yes.

9665. And also as regards Yorkshire and other districts?—Yes.

9666. Have you had samples sent you from those districts?—Yes.

9667. At the time of the Manchester scare did you examine glucose?—Yes.

9668. Since that time have you been in the habit of analysing glucose?—Yes.

9669. You have sent the Commission some tables, have you not, of the results of some of your recent analyses?—Yes.

Recent  
analyses for  
arsenic of  
beer, malt,  
and brewing  
ingredients.

Mr.  
Thomson.

\* This was a highly roasted grain different from ordinary malt.

15 January 1902.

Mr. W. Thomson. 9670. A table with some 217 samples taken from Lancashire, Yorkshire, Cheshire, and Cumberland?—Yes.

principally from Yorkshire.

9671. The great majority of these samples appear to have been taken from Yorkshire, 155 out of 217 samples?—Yes. That is in recent times, from July to December of last year.

9672. Have these samples been taken from a very large area, or do they consist mainly of a very large number of samples from one brewer or one maltster?—A considerable number of those are from one brewery in Yorkshire, and they were getting their supplies I understand from different places.

9673. You mean the supply of ingredients?—Malt, hops, and so on.

9674. The ingredients for their brewing came from different places?—Yes.

9675. Can you say from how many brewers or breweries in Yorkshire these 155 samples came?—You may take it there might be two or three in all.

9676. Only two or three?—That is all.

9677. But although they only came from two or three breweries, you wish us to understand that the ingredients cover a large field, because the ingredients came from various sources?—That I presume; I cannot tell you from my knowledge.

9678. This test was applied to the finished article, the beer, in each case?—Yes.

9679. Do you believe in most cases the Yorkshire beer was brewed from Yorkshire malt?—I cannot say.

9680. But it would be most probably the case, would it not, considering there are large maltsters in Yorkshire?—Yes.

9681. You would naturally suppose in most cases this malt was Yorkshire malt?—I suppose it would be prepared in Yorkshire to save carriage. They would sell cheaper in Yorkshire on account of the carriage.

Quantity of arsenic in beers.

9682. I see by your tables that 78 out of these 217 beers show that between 1-60th and 1-20th of a grain of arsenic per gallon has been discovered under your analysis altogether?—Yes. From between 1-50th to 1-80th. One column is 1-50th to 1-60th; the other 1-60th to 1-80th. There are 118 out of 217.

9683. Begin with the 58 and take it backwards?—Yes, 78 out of 217.

All arsenic should ultimately be excluded from beer.

9684. In your experience as an analyst have you formed any judgment as to what would be a quantity dangerous to health to find in beer, or what you would term a negligible quantity?—I do not think it is possible to form, perhaps, any clear notion about that at all, but it seems to me that there is only one method of dealing with it, and that is ultimately to preclude the existence of arsenic in malt.

9685. You think that is the direction in which security should lie?—Yes. That can be done, and will be done if you ask for it.

Samples free from arsenic.

9686. Perhaps you would like to tell the Commission at once what advice you would give to brewers in cases where arsenic has been found in their beer?—All the beers I have examined since 1901 until the present time have contained arsenic, except two. That is by the appliances which I employ for the detection of arsenic, which I have here, and can show you.

9687. Your arrangement for the detection of arsenic?—Yes. The two samples came from Bass. I do not say that all their beers are free from arsenic, but these are the only two samples in eighteen months that I found to be free from arsenic according to my test.

Form of Marsh test employed;

9688. What is this test which you apply?—This test consists in using a much smaller piece of apparatus for generating the hydrogen than usual. The larger the apparatus the less delicate it is. The apparatus I have is shown here. The bulb holds about 50 cc., and it is attached in this way to this tube containing chloride of calcium, and then to this long tube, in which the arsenic is deposited. (Apparatus shown.) The beer or malt is first treated in a flask of about 200 cc. I take 50 cc. of the beer or 5 grammes of a solid, as it is assumed the 50 cc. of the beer would contain about 10 per cent. of solids, which would be about 5 grammes of solids in the beer, as compared with 5 grammes of solids which I should take of malt or other solid substance. This is treated with pure nitric and sulphuric acids until the

destruction of organic matter.

organic matter has been converted into carbonic acid and water and nothing remains but the mineral constituents. The amount of sulphuric acid left in this flask is just sufficient to go into this apparatus, which is arranged with a thistle tube going, not to the bottom, but simply through the stopper, of the flask. This tube is provided with a glass rod going to the bottom, rounded and ground watertight at the end of the thistle tube. Into this tube is poured the material to be tested. By simply raising the glass rod you can allow the whole or part to run in without the risk of air passing in. By using that apparatus I can detect what is equivalent to 1-1,000th of a grain of arsenic trioxide per lb. of solid material, or about the same amount per gallon. The tubes in which the deposits are made are shown here. They are drawn out in the manner you see, and there is placed in the front of each tube a small roll of dry paper containing acetate of lead. The point near to where the arsenic is to be deposited is heated by a small Bunsen flame, and the arsenic is deposited along the tube. The tubes can be drawn out as nearly as possible to the same diameter, and give therefore a very fair comparison with standard mirrors.

9689. (Chairman.) You are aware, are you not, that there have been great divergencies as regards results in many cases from the same sample of beer or malt?—I am aware of that, and therefore I have made a large number of experiments with a view of getting at a reliable method of working this, so that we can get proper and reliable results. I may pass you these tubes, which will show you the results of different quantities of arsenic which I have added to a sample of wort, which I found to be free from arsenic, and having added these to different portions of this wort I submitted them to the process which I have just described. (Tubes put in.) If I might do so, I would put in here a description of this process. (Diagram shown in Appendix 18a, p. 200 below.)

The following is the document referred to:—

Process for estimation of arsenic in beer and stout, malt, caramel, etc.

Beer.—Take of the sample 50 cc., and evaporate on a sandbath or iron plate to a syrup in a 200 cc. Jena glass flask. Add 25 cc. strong nitric acid and 5 cc. strong sulphuric acid, and place on a hot sandbath, having taken away the flame, and allow the first violent action to subside. Then apply a Bunsen flame to the sandbath, and evaporate till the liquid begins to darken, then add strong nitric acid in quantities of 3 cc. at a time (the total quantity of nitric acid required varies from 30 to 50 cc., depending on the quantities of organic matter present), until on further heating it continues colourless and fumes strongly of sulphuric acid, cool, dilute with 10 cc. of water, and boil down to break up the nitro-sulphuric acid formed; by this treatment all traces of nitric acid are removed. When cold, dilute with 10 cc. of water, and deliver into the Marsh-Berzelius apparatus, the capacity of which should not exceed 50 cc., and the gas evolved should be dried over calcium chloride.

Testing re-agents.—A blank on the re-agents and apparatus used should be made by boiling down 100 cc. HNO<sub>3</sub> and 5 cc. H<sub>2</sub>SO<sub>4</sub>, till all nitric is expelled, diluting and boiling down, again diluting and testing in the Marsh-Berzelius as above described.

Process for malt, sugar, caramel, hops, yeast, etc.—Take 5 grammes malt or other solid organic substance, add 25 cc. HNO<sub>3</sub>, and heat till the first violent action is over, then add 5 cc. sulphuric acid, and proceed as for beer (a total of from 50 to 75 cc. of nitric acid will be required).

The Marsh-Berzelius apparatus (50 cc. flask) contains about 20-25 grammes zinc. The CaCl<sub>2</sub> in the drying tube should be renewed as soon as the first few pieces become wet.

Action is started by adding 5 cc. of dilute sulphuric acid (10 parts concentrated sulphuric, 20 of water, and 1 part of a 10 per cent. solution of pure copper sulphate) by volume. Allow the evolution of gas to go on (the exit tube for the hydrogen being heated in the usual manner by means of a small Bunsen flame) until the hydrogen nearly ceases to be evolved, then fill up the tube and thistle or funnel of the Marsh-Berzelius apparatus with the solution, previously treated as above, and then raise the stopper rod and allow the whole to run in if only a very minute quantity of arsenic is supposed to be present; or run in an aliquot part if a larger quantity is supposed to exist. In about fifteen minutes the flask is washed with

Mr. W. Thomson. 17 April 1902.

5 cc. more of the above acid which is added to the hydrogen flask in small quantities at a time to keep up the evolution of gas for a total of from 30 to 35 minutes after the first introduction of the previously treated beer, by which time with this sized apparatus all the arsenic will have passed off.

The hydrogen flame should be about two mm. long, and maintained as constant as possible; too slow a flow almost invariably gives double mirrors, too fast flow gives irregular ones difficult to compare with the standards.

Zinc.—20 grammes of zinc should be tested by the 30 minutes; the action being started with 5 cc. of the above-mentioned acid containing copper sulphate, there should be absolutely no trace of arsenic mirror on the drawn-out portion of the glass tube.

Another experiment should then be made, adding a minute quantity of arsenic, say equal to the 1-500th of a grain per gallon (when working on 50 cc.), equal to 0.029 parts per 1,000,000, or an actual weight of 0.00143 milligramme, and compared with a standard tube to make sure that the zinc contains nothing which will hold back minute quantities of arsenic.

The glass tube for the mirrors should be about  $4\frac{1}{2}$  mm. internal diameter and about  $6\frac{1}{2}$  mm. external. It should be drawn out in the middle and at the end, the length of the drawn-out portions respectively being 30 mm. and 70 mm., and the portion of tube between the drawn-out portion being 60 mm. The diameter at the beginning of the drawn-out portion for receiving the mirror is about 2 mm. internal diameter.

A piece of fine iron wire gauze 20 mm. wide is wrapped round the tube at the point A, and heated by the Bunsen flame. This is a more satisfactory plan than applying the flame directly to the tube, and conduces to the formation of more even mirrors.

B. is filled with a roll of dry lead acetate filter paper to absorb any traces of sulphuretted hydrogen which may be formed.

Bunsen flame.—This should be about 4 inches long and protected till near the point by a conical iron or copper chimney of about  $2\frac{1}{2}$  in. high by  $2\frac{1}{2}$  in. at the lower, and  $1\frac{1}{2}$  in. diameter at the higher part of the cone.

Heating the tube.—This should be heated from the shoulder or drawn-out portion for about  $\frac{1}{2}$  in. at the point (A).

9690. You have also examined during the same period a good many samples of malt for arsenic?—Yes, I have.

9691. In eight out of the forty-nine cases, you discovered between 1-60th and 1-10th of a grain per lb. I think the three highest are taken from Yorkshire malts. Can you tell the Commission what your experience is with regard to the use of fuel in Lancashire or Yorkshire by maltsters?—I think in Lancashire there is now only anthracite employed.

9692. Has this anthracite been employed exclusively since the Manchester catastrophe?—Yes, I believe so.

9693. I do not want to tie you down to every possible case, but as a general result of that catastrophe you believe anthracite is being used by maltsters?—I believe so.

9694. That is what you hear?—That is what I hear, and I understand that the coke market has been seriously affected. The gas coke previously employed for that purpose is no longer used, and it has produced a considerable influence on the market.

9695. You have had a large experience as an analytical chemist in Yorkshire and Lancashire, and you would probably know about the use of this anthracite. When a sample of malt is sent to you it would be sent with the precise information as to what fuel was used?—Yes. I have been told in many cases that coke has been entirely given up, and that only anthracite is used.

9696. When you refer to coke, do you mean gas coke or oven coke?—Gas coke and oven coke, both. Anthracite always contains arsenic, but the coke contains, as a rule, a great deal more.

9697. To avoid possible poisoning in future from arsenic would you recommend great care in the selection of fuel?—I should suggest that the operation be entirely modified so that the fumes from the fuel be not allowed to pass through the malt. This I should think can be done if it is insisted upon; the passing from an old process to a new one is always a difficult step, but if

it is done I believe you can do away with any trace of arsenic in beers or in malts being found, even with my apparatus. I have had some malt dried over very hot steam-pipes, and the malt gave absolutely no trace of 17 April 1902. arsenic by this apparatus.

9698. Was the malting as thoroughly and as well carried out, as far as you can judge, by that process as by the ordinary one?—The maltster, who made the experiment on a considerable quantity, was not quite sure, but he thought it was not quite as good. But still the same conditions which exist at present can be brought about by the use of other means. For instance, it is possible to heat a number of bricks to redness by ordinary fuel, and then to radiate the heat on to the malt and to allow the hot air to go up to dry without bringing the products of combustion into contact with the malt.

9699. Have you often found much difference in two samples from the same bulk of malt?—There is sometimes considerable differences from the same samples. It is obvious that grains of malt lying for the longest time in contact with the floor would contain more arsenic than those at the top of the heap.

9700. The impregnation would not go as far up?—Not so thoroughly. You would get a greater quantity on that which lay longest nearer the floor, and which, therefore, received the gases first. The arsenious oxide I believe condenses on the surface of the grain.

9701. Are you of opinion that by the use of anthracite, or, in fact, any coal or coke carefully picked and selected, security might be obtained?—It depends on what security means. I do not think you will ever get malt without containing appreciable quantities of arsenic by the present methods of drying the malt.

9702. You think that unless some method is adopted of obtaining the heat minus the fumes there will be always some danger of impregnation?—Certainly.

9703. Do not the statistics you have kindly formulated in these columns rather show that, although there is an almost inappreciable quantity of arsenic in very many cases, care has been used in the selection of fuel?—Certainly.

9704. Would not the public be sufficiently safeguarded if you could be assured that in the case of all malting operations the same care was observed as produced these results?—If you will allow me I will show you a card upon which I have fixed the results of tests made during January, February, and March of this year, which show diminishing quantities of arsenic in the malt.

9705. I am anxious you should understand what I mean?—I think I understand.

9706. You give here analyses of 217 cases. Certainly there are some cases which would point to the fact that negligible some carelessness exists as regards the selection of fuel arsenic in or the use of gas coke, but there is a considerable number of other cases where the quantity of arsenic is inappreciable?—It depends on whether you would say 1-100th of a grain of arsenic per lb. is inappreciable.

9707. What is termed negligible?—Whether it is a negligible quantity. Of course if  $2\frac{1}{2}$  lbs. went to the gallon of beer, assuming the whole of the arsenic went in, it would be  $2\frac{1}{2}$ -100th of a grain, which would be about 1-40th. It might be interesting if you would see the results of some tests. These will show you the amount of arsenic from 5 grammes of malt, and the actual amount of arsenic shown in the mirrors, and will give you an idea of the change that has come over the quantities of arsenic found even in recent weeks. (Tubes put in.)

9708. In the case of a brewer sending you some beer to analyse, if you found 1-30th or 1-35th of a grain of arsenious oxide in the beer, should you give any advice to the brewer as to what precautions he should take?—No, I should not.

9709. You have not done that?—No.

9710. You merely record the fact?—Yes.

9711. Can you give any information to the Commission with regard to these cases where the larger quantity of arsenic was discovered in the beer: any information as to the particular class of fuel used in those cases?—I am afraid I cannot.

9712. You cannot identify the larger quantity of arsenic in the malt or subsequently in the beer with the use of any particular fuel?—No. But I should assume that in the large quantities, coke must have been used entirely or partially in the drying of the malt.

Mr. W. Thomson.

Unequal distribution of arsenic in malt.

Mr. W. Thomson. 9713. Have you examined any beer from the breweries of Halifax?—I think not; not that I know of.

9714. (Mr. Hammond Smith.) Did not you get one from Messrs. Webster?—I might have done so.

9715. But I do not think you were told where it came from?—I might have had it.

9716. (Chairman.) But you could not call to mind at the moment?—No.

9717. Can you give the Commission any information with regard to the process of brushing malt?—I have no doubt that brushing will improve the quality as regards the quantity of arsenic present.

9718. But you are of opinion that to procure absolute immunity there should be some change in the system of malting?—There must be.

9719. (Professor Thorpe.) These samples, of which you give us an account in the digest, came to you professionally?—Yes.

9720. You received them from clients?—That is so.

9721. In the case of the Yorkshire samples, of which you have tested 155 samples, you told us, I think, they came from two brewers?—Two or three. The great bulk from one.

9722. Do you mind telling us in what particular Rading in Yorkshire that was?—Perhaps it would not be wise to mention anything which might identify any special brewer.

9723. The samples of malt you examined from Yorkshire came from the same brewery?—Chiefly.

9724. That is to say, the beer which you examined was prepared from the malt which you examined?—Yes.

9725. In the case of the food and drugs samples, those you got exclusively from Stockport, of which you are the analyst?—Yes.

9726. What happened in the case of the sample which was reported by you to contain 1-30th to 1-40th of a grain per gallon; was any action taken?—I think not.

9727. Why?—I do not know.

9728. Was any action taken in Stockport at all by the local authority?—I believe not, except warning a great many of them about the quantities of arsenic which were present.

9729. In your certificate would you have drawn attention to the fact that in your opinion such amounts as you give here, say from 1-50th to 1-60th, or from 1-30th to 1-40th, were quantities which ought not to be present in beer?—I drew attention to that, but I did not give any advice as to whether it was or was not objectionable.

9730. But you would let the local authority believe that that was an amount which was in your opinion inadmissible?—Yes, that was my own impression about it; and I gave them to understand by drawing their attention to it that that was so, and I believe what they did do was to point these things out to the various brewers, and to warn them, so that the same amount should not be found in future in their beers.

9731. Were these beers that you examined brewed in the neighbourhood of Stockport or in Stockport itself?—In Stockport and the neighbourhood chiefly, but I believe they were also brewed in other places.

9732. I should like to ask you or two questions about the method of analysis that you have brought before us, because it is obvious you have had a very considerable amount of experience in testing for arsenic by that method. I gather that you prefer a modification of the Marsh method?—Yes.

9733. Why do you prefer that to any other?—Because I have tried all the other methods, and I have been working on it constantly for the last eighteen months by all sorts of devices in all the other methods, modifications in all sorts of ways, and this is the only one that gives tolerably reliable results.

9734. What do you mean by "reliable"?—I mean that if you weigh out a minute quantity of arsenic and give it to me, I believe I can determine within fairly narrow limits what that amount was with almost dead certainty.

Size of flask. 9735. Do you imagine as you work the process that you get away all the arsenic which is introduced?—Yes, within the limits of the flask. I have found that if you take a flask four times that size you would pass a beer as free from arsenic which you would not pass as free if

you took the flask that size. It makes a difference even between 50 cc. and 75 cc. capacity. In other words, if you take a 50 cc. flask you will get in half an hour the whole of the mirror; if you take a 75 cc. flask it will take you ten minutes more before you get the whole of the mirror. But if you take it larger than that you may easily miss and pass as free, beer which contains perhaps 1-200th or 1-250th part of a grain of arsenic.

9736. It is your experience that in from half an hour to 40 minutes, depending on the size of the flask, all the arsenic which has been introduced into the flask may be deposited as a mirror in the tube?—Yes, I think practically all. I have some experiments in which I have dissolved the arsenic from the tube and put it back again, and I have got nearly the same deposit as possible in the one as in the other.

9737. In the same length of time?—Yes. In this apparatus I reduce the whole thing to a very small bulk; in other words, I take in all cases 50 cc. of the beer and evaporate it down in the 200 cc. flask like this to a syrup, then treat that with 25 cc. of nitric acid, and after the first rush of nitrous fumes have gone off I add a little sulphuric acid (5 cc.), and then about 3 cc. at a time until the whole of the organic matter has been destroyed and nothing but the 5 cc. of sulphuric acid, which I had originally, remains, together with the arsenic which is present. It is obvious that on diluting this sulphuric acid, and again evaporating down to get rid of the nitrous fumes, and then diluting that to about 10 cc., and washing it into the apparatus, you get the whole of the arsenic present there without anything to interfere with it. Consequently you get it in a very small volume. I may say that I had, only yesterday, a case in which a most excellent experimenter tested two samples of beer and found 1-33rd grain of arsenic per gallon in each. They were brought to me by another chemist who could not find that quantity, but he found a very small quantity indeed. With this apparatus I found that they contained in one case 1-250th, and in the other case 1-300th of a grain per gallon. He used the Reinsch test, a modification of which he works in an exceedingly expert manner. He is a most able experimenter, but yet we differ in these two methods as between 1-33rd and 1-300th.

9738. I suppose in your experience the Reinsch test is by no means so delicate as the Marsh test?—That is my experience, that it is not satisfactory at all for estimations of arsenic.

9739. What do you mean by not "satisfactory"? Is it not so delicate or is it more difficult to work?—It is not nearly so delicate according to my experience of it. It is not so reliable to compare a delicate white film on the one hand as a black film on the other; the black gives you a much better means of comparison than the white, and you lose arsenic by evaporation in the process, and you do not get the whole of the remainder on the copper.

9740. Does that remark also apply to a Gutzeit test where what you have to compare is yellow?—I have made a large number of experiments with the Gutzeit test, and I thought I had obtained a satisfactory result by hanging cotton sewing threads down a long tube and passing the gas up and observing what length of the thread would be coloured yellow by the arsenic in the material which was given off. At first it appeared to give satisfactory results, but afterwards I found it was utterly unreliable. I tried the test with papers, and that, so far as actual figure work is concerned, was utterly unsatisfactory. The test gives an exceedingly pale yellow, which alters very much according to the character of the light by which it is examined. I threw this method over after working with it for a long time. I have tried the tests with nitrate of silver, which gives you a black colour. That I found entirely unsatisfactory, although it is apparently an exceedingly delicate test. After treating the one and the other, and comparing the results, I have been driven to the position that the one which I show here is the only reliable form from which I have been able to get satisfactory results.

9741. In testing by your method, have you found it necessary to be careful of the character of the glass of which your apparatus is made?—Yes; it is better to use Jena glass, but the amount of arsenic dissolved from the glass is very minute indeed. I have some tubes here which would show you the effect of hydrochloric acid standing in contact with the glass. The hydrochloric acid has a great deal more effect upon the glass than sulphuric acid, but it dissolves only an exceedingly

Arsenic in his public analysts' samples of beer.

Report to local authority.

Method of testing.

11902. —  
ation  
o-  
acid.

minute quantity, not more than 1-1000th of a grain to the gallon. I prepare hydrochloric acid by a special method which I have devised after a great number of experiments. It consists in diluting fuming hydrochloric acid of about 1.175 sp. gr. with half its bulk of water, down to 1.10 sp. gr., and then treating it with about half gramme of chromic acid to the pint, and distilling. By that means you get over hydrochloric acid contaminated with free chlorine, which, of course, would interfere with the test. It was a difficult matter to get rid of the free chlorine. I made a large number of tests with a view of getting rid of it, such as adding urea and other things to the distillate, but finally I came to this, that on passing air through this distillate containing chlorine I could remove every trace of chlorine in about two hours, and then I got hydrochloric acid which was arsenic free and pure. On leaving that for seventeen days in a bottle I find it had dissolved some arsenic even from the Jena glass, but the amount was exceedingly minute, and would not amount to more than 1-1000th of a grain per gallon. It might be almost left out of account. I think I can show you the tubes here on which that experiment was made. These are the tubes showing the amounts of arsenic.

9742. (Chairman.) Those are the tubes you have been referring to?—Yes. You can see that there is a certain amount in the last six tubes. In certain lights you will see that a little has been dissolved after seventeen days, and still more in thirty-five days.

9743. (Professor Thorpe.) That was an ordinary white glass bottle of English glass?—No. That was a Jena glass flask in one case, and in the other case it was standing in a green glass bottle. There is certainly a little dissolved, but the amount is exceedingly minute.

9744. Have you used in all these examples the same character of glass throughout?—Yes, the same character of glass throughout.

9745. I notice that in the January samples the glass is highly devitrified, whereas in the February and March samples there is no trace of devitrification?—That may be due to using an open flame or a flame covered with a little wire gauze.

9746. In the latter cases you have wrapped wire gauze round the tube?—Yes, and sometimes we have allowed the naked flame. Recently, we have used the wire gauze because it gives rather better mirrors, but there is not much difference.

9747. I notice you prefer to use oil of vitriol rather than hydrochloric acid?—Yes, because I could not buy hydrochloric acid free from arsenic. I have had all sorts of samples sent from all sorts of places recommended by chemists to be absolutely free from arsenic, and I found they were all contaminated, and therefore I preferred to make the sulphuric acid myself, which was more readily prepared pure and free from arsenic than hydrochloric acid. I could not buy even sulphuric acid which was free from arsenic, and therefore I had to devise a method of preparing an acid which was free from arsenic, and that is done in an exceedingly simple manner by distilling with chromic acid. Adding about one gramme of chromic acid to the pint of sulphuric acid and distilling you get the whole of the arsenic left behind in the retort. One of these two tubes shows the acid containing a large quantity of arsenic, and the other tube shows the result after distilling with chromic acid.

9748. (Professor Thorpe.) Is there not a possible objection in the use of sulphuric acid owing to the formation of nascent sulphuretted hydrogen?—You get a trace of sulphuretted hydrogen off almost constantly in all the tests, but by putting a little dry lead acetate paper in the neck of the tube you remove that sufficiently so as not materially to affect the mirrors.

9749. But is there not evidence to show that this nascent sulphuretted hydrogen would cause the retention of arsenic in the flask?—It does not seem to show that. It has been stated that hydrochloric acid gives you better mirrors than sulphuric acid. I have made a number of experiments upon that, and I find no difference if you get pure hydrochloric acid, but the difficulty is to get pure hydrochloric acid.

9750. Of course, I know what is stated; but anyhow you have paid particular attention to the point I have raised?—Yes. I always use pure zinc, which is very difficult to get. I first test zinc samples to see that they are free from arsenic, and afterwards I test them by adding an amount equivalent to the 500th of a grain per gallon of beer, on the basis of using 50 cc. of the sample, to see that I get the proper size of mirror. The electrolytic zinc, for instance, contains a considerable quantity of metallic iron, and the metallic iron holds back the arsenic, and in fact, the iron salts hold back the arsenic when they are in considerable quantities. That is to say a gramme of proto-sulphate of iron added to the Marsh, for example, will keep back a very considerable mirror of arsenic. I have a series here which I think I can show you which will exemplify the effect of iron in retaining arsenic. (Mirrors put in.)

9751. Do you not prefer to use electrolytic zinc?—No, you cannot use it.

9752. On account of the iron which it contains?—Yes.

9753. How do you know that is not electrolytic zinc? I have written to all the dealers in zinc, and have got a large number of samples, tested each in the manner I have suggested, and when I came across a lot which gave the conditions I required, I purchased it all.

9754. How do you know that is not electrolytic zinc?—I do not know where it comes from, but the electrolytic zinc with which I have been supplied was from Brunner, Mond and Company. It might have been electrolytic zinc from which I obtained the required supply, I do not know. It is possible by distilling electrolytic zinc you may get it free from iron and arsenic. At all events, I have had very great difficulty in getting zinc free from arsenic. I have had a large number of samples submitted to me as free from arsenic, and I have tested them and found them to contain arsenic. So that when I find, say, 20 lbs. of a certain kind of zinc which is free from arsenic, and gives the proper size of mirror when working with 50 cc. of a solution containing the 500th of a grain per gallon, I purchase it all—14lbs., 20lbs., or whatever it is I can get.

9755. (Dr. Whitelegge.) With what object do you destroy the organic matter in your test?—Simply to get the conditions the same in each case.

9756. Have you made any comparison to show whether the amount of arsenic recovered is increased if the organic matter be destroyed?—The mirrors are not so satisfactory when the organic matter is not destroyed. You do not get the same clearness of mirror when the organic matter is present; beers frequently contain sulphites which interfere with the test, but which are removed by my process, and in many cases the mirrors are not obtained at all when the test is made directly on the beer. Those are my reasons for not having the organic matter present at all.

9757. It is not from any idea that the organic matter will keep back the arsenic?—No, it does not always keep it back completely.

9758. The printed tables relate to samples examined by you in the second part of 1901?—Yes. I have a further table showing the results up to April, 1902, which, if you wish it, I might put in. The following is the table:—

Mr.  
W. Thomson,  
17 April 1902.

Zinc used.

Object of  
destroying  
organic  
matter.

Improvement  
in beer and  
malt in 1902.

Mr.  
W. Thomson.  
17 April 1902.

NUMBER of SAMPLES of BEER, MALT, &c. Examined for ARSENIC from 1st JANUARY to 8th APRIL 1902, and PARTICULARS of the AMOUNTS of ARSENIC TRIOXIDE FOUND.

Mr.  
W. Thomson.  
17 April 1902.

9759. In the second part of 1901 there were still samples of malt containing very considerable proportions of arsenic?—Yes.

9760. And two containing upwards of 1-20th; one containing upwards of 1-30th; and two containing upwards of 1-40th of a grain per lb. ?—That is so.

9761. Can you say when those malts were made?—I cannot.

9762. You have compared those figures with the results you have obtained since that time?—The amounts have been gradually going down. I believe at one time there were train loads of malt, about the beginning of last year, which could not be used, sent into the Manchester district. What became of these train loads of malt I do not know; but they had to supply a better class of malt to the Lancashire brewers than to any of the other districts of England, I understand.

9763. The latter table shows that out of 31 samples examined this year none contained more than 1-50th?—That would be right.

9764. Whereas out of 49 examined in the second half of 1901, six contained a larger amount than that?—Yes, that would be so.

9765. In the return you were good enough to send to the Commission you say that as the result of analyses under the Sale of Food and Drugs Act you give a formal certificate in all cases, but up to the present time you have only regarded as adulterated those samples of beer containing more than 1-100th of a grain?—That is my personal view of the matter. Of course, it would not be anything more than a personal view.

9766. But that represents your practice at that time?—Yes.

9767. And your present practice?—Yes. I should prefer that there should be none present, but as all beer contains arsenic you must fix some limit for the present at all events.

9768. And in the case of beer containing more than 1-100th of a grain per gallon you would give a certificate in an official form which would enable the local authority to take proceedings?—Yes, I draw attention to it, and let the medical officer take proceedings if he thinks it advisable.

9769. A formal certificate complying in all respects with that which would be required if proceedings were to be taken?—Yes.

9770. You say also you are not in favour of a standard test for arsenic; do you still hold that opinion?—I needed. think at the time I expressed that opinion there was nothing very clear or definite to go by. I do not know that it will be advisable to fix any standard test now, but I think it is desirable to have an official test, if possible, because there are so many tests and so many methods of doing these things, that it would be desirable to have an official test.

9771. You told us that, in your opinion, it would not be possible to exclude arsenic altogether unless the malt-ing were so conducted that the fumes could not gain direct access?—Yes, I am satisfied on that point.

9772. Are you able to point to any place where that is done on a commercial scale?—So as to prevent the fumes?

Personal view that over 1-100 grain per gallon is adulteration.

Mr. Thomson. 9773. Yes?—No. But I know of one place where an appliance is being arranged for that purpose.

9774. Is that the case of which you gave us particulars?—One where bricks are heated to redness, and the radiated air from the bricks allowed to go into the malt.

9775. That plan is, I understand, being tried experimentally by a maltster in this country?—Yes.

9776. With a view to adopting it on a large scale if it proves successful?—That is so.

9777. Is that the same case as that which you have already mentioned in which a brewer was making experiments?—The brewer does also his own malting to some extent, and it is the brewer who is making that experiment.

9778. I only want to be clear that it is the same case?—That is so.

9779. Does it fall to your lot to advise the brewer who is a maltster, or maltsters, as to the conduct of the process?—No, not at all.

9780. Can you give us any idea of the amount of dust that is removed from the malt by brushing?—I cannot tell you that. It cannot be a very large amount, I should say.

9781. You mentioned that in one case you found 1-30th of a grain of arsenic in a sample of beer?—Yes.

9782. And that in your case you did not make any representation to the brewer?—I did not make any representations to the brewer.

9783. That I follow; so that you can tell us nothing of what happens in the case of those contaminated beers?—I do not know what happens. I cannot tell you whether they are sent out or what they do with them.

9784. You have examined, no doubt, not only these substances which are included in the list, but also samples of fuel?—Yes.

9785. Can you say how much arsenic is found commonly in anthracite?—I have given it in some of my papers, but I cannot remember exactly the amount. It comes to something like 1-100th or 1-50th of a grain per lb. It is a very small amount.

9786. Even less than that?—Probably less than that. (The figures are:—Coke from 3rd to 1-100th, anthracite from 1-100th to 1-500th.)

9787. Have you arrived at any conclusion as to what the proper method of sampling fuel would be—anthracite in particular?—The only method of sampling would be to take a considerable quantity, break it into small pieces, and mix it together thoroughly, and pick a lot of that, break it into smaller pieces, gradually breaking down until you get nearly to a powder. Then take a sample of that for the analysis.

9788. But all this after first removing any obvious lumps of pyrites?—If it is the custom to remove pyrites they should do that first. But if it is not the custom to remove the pyrites then the pyrites should be mixed together with it in proportion as nearly as possible.

9789. But you would regard it as necessary to remove pyrites as far as possible?—I should say so, certainly. If you had pieces of pyrites you would not burn them.

9790. In your return you mentioned finding arsenic in a sample of chicory?—Yes.

9791. Have you formed an opinion as to the source of the arsenic?—Not at all. I only assume that the chicory must have been roasted over the fumes of the fuel.

9792. Do you give us the amount of arsenic found in that case?—I think I have done so. I have not got it at hand.\*

9793. Dr. Buchanan tells me it is not given in the return?—I know that it was determined.

9794. You also found arsenic in liquorice sweets, did not you?—Yes.

9795. There also we have not the amount. Would it be possible for you to supply it to us?—I think I have the amount. I can let you have it.

9796. (Chairman.) You might forward it to us?—I will do so.\*

\* The following are the amounts of arsenic I have found in these articles:—

	Approximate amount of arsenic expressed as arsenic trioxide.
Liquorice junubes . . . . .	1-35th of a grain per lb.
Stick Spanish juice . . . . .	1-70th " "
Chicory . . . . .	1-150th " "

9797. (Dr. Whitelegge.) Can you tell us anything of arsenic in connection with textile goods?—Yes. I have had a large experience in that. There is a considerable quantity of textile fabrics containing arsenic in minute quantities. That is regarded most seriously by the Norwegian and Swedish Government, where they take notice of very minute quantities.

9798. Is this entirely in the colour?—Chiefly in the colour.

9799. And the regulations of Norway and Sweden prohibit the import?—Yes. They used to prohibit the import of any cloth containing even the most minute trace of arsenic; now they allow a little, but it is very small indeed.

9800. Does any similar rule prevail in other countries?—I think so to some extent, but they are not so strict as they are in Norway and Sweden.

9801. (Chairman.) You have had very many years' experience as an analytical chemist?—Yes, about 30 years.

9802. And, of course, since this Manchester catastrophe you have given additional time and labour evidently to this process of analysis?—I have.

9803. I suppose you admit, do you not, that your evidence here to-day goes to prove conclusively that extreme care is necessary as regards analysis for the detection of arsenic?—If the process is carried out in a certain way only the ordinary care is required.

9804. But you quoted before us a case which happened within the last few days where there was a difference between 1-33rd and 1-300th from the same sample?—Yes.

9805. If you were to change places with myself, and were pursuing an investigation of this kind, you would find that rather a disturbing element where you are investigating a matter of very serious moment to the public health?—Yes.

9806. If you had to come to a conclusion and write a report, you would find it a very disturbing element?—Certainly. But the Reinsch's test is one which depends upon the personal equation to a very large extent. In the test I use it does not depend on the personal equation. Anyone can get results from this method I have pointed out to you, but they cannot get the same result by other methods. I am satisfied that the Reinsch's test is not satisfactory for determining minute quantities of arsenic.

9807. You condemn that as a test?—Yes, as a quantitative test.

9808. But you are of opinion that uniformity of treatment and method in the case of analysis are necessary?—I think so now.

9809. From recent experience and from cases you quoted to-day you have rather modified your judgment as to necessity for uniformity of treatment?—It seemed to me there were so many methods of treating the matter at one time that it was not advisable to arrive at a decision as to the process until it had been investigated thoroughly. From my own investigations I think there should be now a definite process adopted.

9810. Is the test which you have been detailing to us to-day so thorough a test that it is of universal application?—Yes, almost, but there are certain modifications which I have suggested to you. One of them, notably the size of the flask and the others the methods of purifying the reagents. There has been suggested a method of purifying hydrochloric acid by adding bromine to it. I have been unable to get hydrochloric acid free from arsenic by that method, but I have got hydrochloric acid absolutely free from arsenic by the method I have described, by means of chromic acid. These are the conditions which must be first attended to. The question of the purity and suitability of the zinc, and of the purity of the sulphuric or hydrochloric acids, is most important. Nitric acid is almost certain to be free from arsenic, but it should always be previously tested.

9811. As it stands to-day, in the light of your experience, is this test which you now apply in general use amongst analytical chemists?—Yes, some modifications of it. They usually employ larger flasks than I do, and they will not get such delicate or accurate results.

9812. (Sir William Church.) You said that you would approve of an official test, but not a standard test?—I think that if there is an official test you might use any test you like, but you must make one official test, and show what the result is by that one test. You then concentrate attention upon that official test and cut it to pieces if possible. If you can get a better official test

Mr. W. Thomson. 17 April 1902. in textile goods.

regulations in Norway and Sweden against arsenic.

(Objections to quantitative Reinsch method.)

Nature of official test recommended.

Mr. W. Thomson. 17 April 1902. you may adopt it. But I think the Marsh-Berzelius test, under stipulated conditions, might be used as the official test; and if you can by any other means get a better test than that, it would be permissible to make use of that other test, providing you can show it is better than the official test.

9813. You mean by "official test" what I should have meant by the standard test; that is, you think it would be possible to have an official test that everything should have to pass?—Yes, I think so.

9814. It is a difference in terms?—Yes. A standard test may be taken as the test, from which there would be no moving; that must be the test which would absolutely fix it. My notion is, that if you can find arsenic in malt, beer, or other food by any means whatever, we should, if possible, try to get rid of it, and that its presence should condemn the material. But if you have a standard test you may find there is some method which

is better than that standard test, or simpler, which might ultimately be adopted, and I think therefore the test should be regarded simply as an official test, and not as a final one. But if you have one test put forward it allows criticism in that test to be made by a large number of chemists so as to get a better test if possible. In this test I estimate so many grains per gallon, or so many parts of a grain per gallon, based on the assumption that you take 50 cc. for a test, and you get a certain figure from the arsenic mirror produced of so much per gallon based upon the 50 cc. being taken, which is equivalent to a sherry glass full.

9815. I think I understand that an official test would be the test in which the quantities of the materials to be analysed and the various steps in the analysis could be laid down, and you objected to the term "standard test" because you thought you could not go beyond it?—That is so.

Mr. THOMAS FAIRLEY, called; and Examined.

Mr. T. Fairley. 9816. (Chairman.) You have been for many years an analytical chemist?—About 30 years.

9817. How long have you been public analyst of Leeds?—From 1873.

9818. Have your analyses been with reference to many articles of food materials and manufactured materials?—A great many different kinds of things, food and waters, coal-gas, and coals, and articles referring to the local manufactures of the West Riding of Yorkshire.

9819. With regard to analysing samples of beer, I suppose you have had long practice of that?—As regards arsenic in beer only since the scare began in Manchester. The question was not raised before that time. I had no idea that arsenic might be present.

Limits of Expert Committee's test. 9820. Have you acted as a special analyser of beer for any firm?—From the beginning of 1901, two of the large breweries in the Leeds district employed me to test, either by myself or through my assistants, all the brews for a time. That was done by means of the test recommended by the Brewers' Association at Manchester, which, of course, is not a delicate test, as Mr.

Thomson has said. According to my experience, as a rule it has detected 1-20th of a grain per gallon, and with special care 1-50th of a grain per gallon.

9821. For detection?—Yes. Beyond that without concentration I think it fails.

9822. You mean that in a case where there was 1-150th of a grain only present that the process you used would fail to detect anything?—The process I used up to about February, 1901, for passing these beers for these at outside breweries would not detect at the outside more than 1-50th grain 1-40th of a grain or 1-50th of a grain.

9823. That is to say, the presence of arsenic less than that would go undetected?—Yes, undetected without concentration, which was not done.

9824. I suppose since the Manchester scare you have had plenty to do with regard to analysing samples of beer?—I have summed up the number of beers that I have done during the time, and they are close on 300, really 298. I have brought with me a table showing the results which I obtained. (The following was handed in):—

#### ARSENIC IN MALTS.—TESTED DURING 1901-2.

Malts free from arsenic	43
Malts containing arsenic	10
Total	53

The 10 arsenical malts contained the following amounts in grains per pound.

	Arsenic trioxide.
One sample	0.052 or about 1-20th.
One sample	0.035 " 1-30th.
One sample	0.020 " 1-50th.
Two samples	0.016 " 1-60th.
One sample	0.010 " 1-100th.
One sample	0.008 " 1-120th.
Two samples	0.004 " 1-240th.
One sample	trace

#### ARSENIC IN COKES, &c.—TESTED DURING 1901-2.

Cokes free from arsenic	2
Coke containing 0.17 grain of arsenic trioxide per pound	1
Coke containing 0.013 grain of arsenic trioxide per pound	1
Total	4

The cokes containing arsenic were gas cokes from coals obtained locally. The cokes free from arsenic were from coke manufacturers from washed or picked coal.

#### ARSENIC IN TILES AND DUSTS FROM MALT KILNS.

See paper "The Analyst" July 1901, page 177.

#### ARSENIC IN DUSTS ELSEWHERE.

Dust from shelves, Fairley's laboratory, 0.7 grain per pound.  
Dust from shelves, Mackey's laboratory, 0.77 grain per pound.  
Dust from shelves, Metallurgical laboratory, Leeds Institute, 1.4 grain per pound.  
Dust from bookcase over books, Fairley's office, 0.4 grain per pound.  
Dust from shop, Commercial Street, Leeds, 0.3 grain per pound.

Mr. T. Fairley. 9835. Do you know why he did so?—Only from what he would read in the newspapers. I do not know that he observed any illness.

17 April 1902.

9836. With regard to this sample of beer, I do not ask you to detail to the Commission what brewery precisely it emanated from, but could you follow it sufficiently to be able to tell the Commission whether the malt used in the brewing of it was made with the use of gas-coke or anthracite coal?—I can only tell you from what I was told outside. I was told that Bostock's sugar had been used in making this particular beer, but I do not know that for certain.

9837. But you have heard that?—Yes.

9838. Did you hear it given as a reason for finding this large quantity of arsenic?—No.

9839. But you heard it stated in the case of this sample that Bostock's sugar had been used?—Yes.

9840. Could you give us the date?—December, 1900. I can give you the exact date.

9841. (Sir William Church.) That was just after it had been discovered?—Yes.

9842. (Chairman.) With regard to the two following examples, in each case 1-30th and 1-40th, did you identify that at all with Bostock's sugar?—No, I am not certain about that at this moment. It might have been.

9843. But you could not identify them?—No.

9844. Have you been testing samples of beer up to quite lately?—Yes. I am constantly testing them. In all the samples we have tested this year, and for part of last year, we have abandoned the Reinsch test and are using the Marsh apparatus. The apparatus I use is four to six times the size of Mr. Thomson's, but I agree with him the small apparatus with a small quantity of zinc and a small quantity of acid would be a better arrangement than mine.

9845. You think it would tend to give a more accurate result?—I think the smaller the quantity of chemicals you use for testing for a given substance, speaking generally, the more accurate your results would be, considering the extreme difficulty of getting substances chemically pure.

Quantity of arsenic in recent beers,

9846. Could you tell the Commission whether during the last few months you have tested any samples of beer which have produced a considerable quantity of arsenic per gallon, say anything like 1-40th or 1-50th?—During the last few months I think I have had one or two containing 1-70th. That was sent to me by a brewing firm for which I act as analyst. That was evidently unsafe for them to send out.

9847. You think 1-70th would be unsafe?—For a brewer to send out, yes.

9848. But you have not found many such samples?—Very few.

9849. And you think, on the whole, that the fact that greater care is now taken on the part of the brewers and maltsters in testing all the ingredients has produced good result?—Yes, so far.

9850. Does your experience in testing samples, which you are doing every day, go to confirm the improvement in this respect?—I am not prepared to say that about malts.

9851. You produce 296 samples of beer out of which 280 you mention to be free from arsenic?—A large number of these would have been tested by the Reinsch test only.

9852. You say if a more severe or searching test were applied, arsenic in very small quantities might have been discovered?—Yes. When it is worked out I think that the Reinsch test would not have enabled me to report that. The Marsh test as employed by me, with a four to six ounce flask, would not enable me to go to anything like the thousandth of a grain. About 1-250th would be about my quantity. I have not reported in this statement anything below that amount.

and in recent malts.

9853. Have you examined many malt samples during the last twelve months?—53 have been done during 1901-1902, and about half of them has been done during the last year.

9854. Will you tell the Commission generally what results?—About 25 per cent. of these were found to be arsenical by the test which I use; 10 out of 53, or more like 20 per cent.

9855. What about the average of arsenic tri-oxide found; could you give us the maximum and the minimum?—The maximum is .052, or 1-20th of a grain; the

minimum was one marked "a trace," which I did not attempt to define; the minimum that I have estimated here is the .004, or 1-250th of a grain. I have not put down decimals beyond the third place, so that the numbers do not exactly correspond.

9856. Were there many samples in which the maximum amount occurred that you mention there?—I think one.

9857. Then I suppose you are prepared to state that the result of your examination of these malt samples, taken as a whole, was satisfactory?—Taking the 53, it was satisfactory as regards the 43 that I passed; but I think it shows the need for further care on the part of the 10.

9858. Could you give us any information with regard to where the higher results were obtained, as to what fuel was used in such instances?—I do not know for certain, but I believe gas-coke was used. I am not always informed by the maltsters or brewers who send me these malts.

Analyst not always informed of fuel used.

9859. I suppose now they are quite awake to the fact that there is danger where there is carelessness as regards fuel?—That is so. I attempted to draw their attention to the point that it was not sufficient to change from gas coke to a pure coke or anthracite, but that they must clean out their kilns very carefully. I made an investigation myself, examining the tiles of the malt floors, and the dust on the underside of these tiles, and the dust on the side walls above the malt floors. The walls were sometimes brick walls of a rough surface, and the dust was accumulating there. I found very considerable quantities of arsenic in that dust, not only from an old-fashioned kiln where the fireplaces were put in the very thick walls round the lower chamber below the upper chamber, which was the malting process place proper, but also in the most recent kiln, the modern form of kiln. I found in the dust from the lower side of these floors as much as one per cent. of arsenic in this dust, an astounding and extraordinary amount, which I could not believe at first. But we repeated the test a good many times. I have the dust; if anyone would like to prove it I should be willing to supply it to them.

Arsenic in tiles of kilns

in kiln dust up to 1 per cent.

9860. You have still a sample of this dust?—Yes. I also found in some of these tiles, some of the older tiles, what are called Stowmarket tiles, containing not ordinary fire clay, but clay containing a good deal of lime; the tiles are somewhat porous. They could not be fired in the ordinary way of tiles, as they would have run. I found in the substance of these tiles, in the material itself, very considerable quantities of arsenic. When I found this out I recommended to the breweries that employ me to by all means clear out the kilns thoroughly, do away with all the old tiles, and have the roughly sound glazed tiles put in their place, otherwise they might change their fuel without changing the results, and still get arsenic in their malt. I made a calculation. Taking the average of the arsenic that I found in the ten arsenical malts, how much of this bad dust would be necessary in the quantity that chemists usually operate upon, ten grammes, about one-third ounce, to give the average arsenic which I have found, something like .015, and of the very worst dust 1-40th of a grain of that dust adhering to the malt would be sufficient to explain these results. There was the dust on the side walls, of which a larger quantity would be necessary, I think about one grain. In order to try, if possible, to throw some light on the extraordinary differences which different analysts have got when testing malts, I began testing, as I found that some of the London chemists said that the dust in their laboratories, if it got into their apparatus, would be liable to affect the results. I tested the dust on shelves in my own laboratory, and in another chemist's laboratory in Leeds, and in a metallurgical laboratory in Leeds, and I found in my own .7 grain per lb. of arsenic, and in my colleague's .77, and in the metallurgical laboratory 1.4 grain of arsenic per lb. of the ordinary dust. I also brushed down the dust from the tops of some of my books in the office, apart from the laboratory, and I found in that .4. Also in the shop in a main street in Leeds I spoke to a friend who got the dust from some of his shelves, and I found in that .3. So that where there is a large amount of black smoke, sooty smoke, prevailing, as we have in many of our manufacturing towns, and especially where fireplaces do not draw very well, and you have smoke coming into the rooms, you will find arsenic in the dust. That shows the extreme precautions necessary.

in dust off towns.

Mr. T. Fairley. 17 April 1902.

9861. You think that the necessity for cleanliness and great care as regards preventing any deposit of malt dust anywhere in a malting establishment is most essential?—  
 Yes, and the very careful cleaning of the malt by brushing.

9862. I suppose you are equally alive to the fact that a large amount of evidence has been given in regard to gas coke; that where gas coke has been extensively used arsenic has been found in the malt. Can you give the Commission any suggestion or recommendation with regard to the use of fuel or what fuel should be used?—I think that with carefully prepared coke, prepared from coal that has been picked or washed, as some of it is, washed so as to get rid of the dirt and most of the pyrites, you might get a coke which does not show arsenic up to a certain limit of test. But with gas coke I have found 17 grain of arsenic per lb. of coke, and I analysed two samples of coke, and found in another one a smaller quantity, about 1.10th of that. I analysed two cokes sent by coke manufacturers which were prepared mainly for use in the ironworks, and are also sold to the maltsters, but I was not able at that time, early last year, to find arsenic in these cokes.

9863. Can you tell the Commission your experience with regard to the brushing of malt?—The malts which I have passed as free from arsenic were all of them carefully brushed.

9864. Do you think that is a necessity?—Certainly.

9865. Have you ever found any discrepancy in the finished material, the beer, and in the amount of arsenic found in the malt used. Have you found a difficulty in tracing the precise amount?—I have not been able to follow that.

9866. Discovering arsenic in a malt and following it on into the beer?—No.

9867. Have you found a case, for instance, where a malt has been found nearly wholly free from arsenic, and an appreciable amount has been found afterwards in the finished article?—Not that I can speak with any degree of definiteness. I do not know as a rule when I test samples of beer what malts were used for that. I do not test the malts at the same time so as to connect the one with the other.

9868. You have not been able to follow the process through?—I think it is very desirable it should be followed through by somebody, but I have not done it—beginning with the coke and going on right through.

9869. When you are engaged in testing samples for brewers for their protection and the protection of the public generally, do you use precisely the same test that you use in your capacity as public analyst?—Certainly; whenever we find arsenic the tests are repeated at least three times. If the amount is at all great, then we get the Reinsch test, and get the arsenic crystals as confirmatory evidence. I had a maltster complaining to me the other day that I had reported more arsenic than somebody else reported. I said, "I can show it to you; here it is." I showed him the crystals in the tube.

9870. Was that the third and last test?—No. I was speaking of three times by the Marsh test. I was not meaning that as a quantitative test at all.

9871. Did you convince him?—I think so. He might think it was in my materials.

9872. Is it true that, according to the analyses given to the Commission of the Yorkshire Brewery Company, you have tested their beer up to February last by the Manchester expert's test?—I had a large number of samples from them, but I do not know where these beers were sent or anything about them. I tested them either in my office or at their works.

9873. That is all you knew?—That is all I knew.

9874. By that test would any arsenic be liable to escape recognition?—At what date is the test you refer to?

9875. February this year?—We should use the Marsh test.

9876. Have you anything to say with regard to plants taking up arsenic from arsenical soils or otherwise?—I began investigations last year, and wrote to a large number of farmers and agricultural clubs which I happened to know in the county of Yorkshire. In some cases I got responses, and the results are tabulated in one of these sheets. I was easily able to detect and estimate

the arsenic in the manures and in the soil, but so far not in the plants, unless in the roots of the plants, where there was a doubt whether the traces of the arsenic I found might not be due to the soil adhering. I am perfectly aware that my experiments were different from what a chemist at Newcastle has discovered, but his experiments were made on plants cultivated in pots, and I think his arsenic was dissolved in the alkaline solution. My opinion, from the results I have got, is that the basic constituents, such as oxide of iron, appear to neutralise the arsenic that might be present, so that it never enters into the circulation of the plants. We do know from the experiments made in Germany that a very minute quantity of arsenic kept in solution by excess of alkali applied to plants in pots kills them, just as it kills other living beings. It interferes with the physiological processes. (See note at end of evidence.)

9877. So far as you have gone then, the results are satisfactory?—They are negative in the sense that I have not proved the presence of arsenic. It would have been better if I had made a full analysis of the soils.

9878. So far as your researches have gone as regards the process, the effect on a growing plant, the evidence is satisfactory?—The evidence is that it has no influence.

9879. (Professor Thorpe.) What led you to employ the Manchester test in the first instance?—It is a convenient test, and I thought at the time it would be sufficiently accurate for this purpose. I admit I was mistaken. I did not know what I know now, that it might pass amounts which might be dangerous.

9880. Then you certainly would not recommend that the Manchester test, as we may call it, should be used as an official test?—I should recommend, if used at all, it should be only used as a confirmatory test.

9881. You heard Mr. Thomson's evidence, I think?—Yes.

9882. Do you agree with him that in the present state of matters it would be desirable that somebody should prescribe an official test?—I agree with him in a great measure; but at the same time I do think the whole subject requires further investigation. For instance, this question of zinc sold as pure, sometimes it keeps back arsenic when we put it in. The cause of that is not understood. You have only to consider this impurity (or extreme purity which ever it may be) balancing a minute amount of arsenic in the zinc, in order to get a condition of things which would be very misleading, and which may possibly explain some of the differences in results by different tests.

9883. When you say that zinc keeps back arsenic, what idea have you of the way in which that is done?—I think it may be probably due to some metallic oxide or sulphide present in the zinc depending on the process employed in the purification of zinc. That is only an idea in my own mind, which wants testing by actual trial.

9884. Are you quite sure of the fact that you can get the sample of zinc that has this property of keeping back arsenic?—I am not only sure of it, but I have met other chemists who are sure about it.

9885. Is it the zinc or possibly the acid which is the means of keeping back the arsenic?—It is more readily shown when sulphuric acid is used than is all I can say; but it is the zinc. One sample of zinc does this, and another sample of zinc does not.

9886. It may be the fact that it is more readily shown in the case of sulphuric acid than in the case of hydrochloric acid, which is the only other acid commonly used; is not that some evidence that it is not due to the zinc, but rather due to the acid?—Not necessarily. It points in that direction I admit; but it is not absolutely necessary that that should be so. However, the thing wants testing.

9887. I admit that point wants clearing up. But is it not conceivable that it is, as I put it to Mr. Thomson, the possibility of the formation of sulphuretted hydrogen. Whenever the liquid gets hot when sulphuric acid is used sulphuretted hydrogen is produced in a greater or less quantity. Sulphuretted hydrogen might conceivably keep back the arsenic by forming insoluble sulphide of arsenic?—If you have two similar experiments done with two different lots of zinc, working as nearly as you can tell at the same temperature, with the same size of apparatus, and the same conditions throughout, and the same acid, the zinc only

Mr.  
T. Fowler.  
17 April 1902.  
No arsenic detected in plants grown on arsenicated soil.

Zinc keeping back arsenic in Marsh test.

Mr.  
T. Fairley.

17 April 1902.

different, in one case you can put arsenic in and not get it out by the Marsh test, and in the other case you do get it out. I think it points to the zinc.

9888. That is an experiment you have actually done?—Yes.

9889. You told us that in the case of the beer which had so large a quantity as 1-6th of a grain you were informed that that was brewed from Bostock's glucose?—Yes, I was.

9890. That was a sample of beer brewed in the West Riding, was it?—Brewed in the West Riding, but the sample was sent me from Saltburn.

9891. Do you know what happened to that beer?—Proceedings were taken, but through some technical flaw in the proceedings—it was the first time this authority had taken such proceedings—no fines were inflicted.

9892. Was anything done with the bulk of the beer?—I do not know. I suppose some was thrown out.

9893. Was it recalled or destroyed?—I had samples sent me subsequently from the same neighbourhood, and I did not find arsenic.

9894. So that you think the beer was withdrawn from consumption?—Yes.

9895. You have no knowledge that it was actually destroyed?—No, I do not know, except that I analysed samples from the same district taken by the same authority.

Sulphur and arsenic in fuel compared.

9896. Have you analysed the coke for iron smelters or persons who use coke for foundry purposes?—Chiefly for sulphur. Only since this enquiry arose have I tested for arsenic. Sulphur is considered to be a substance which interferes most with its use in iron manufacture.

9897. I suppose in practice there will be a rough connection between the sulphur and the arsenic?—I think there is in most of these minerals. You will not be far wrong if you estimate arsenic as corresponding roughly to one per cent. of the sulphur.

9898. It comes practically from the mineral which yields the sulphur?—Yes.

9899. Therefore, I suppose that material that iron smelters say should not contain sulphur would presumably be a good form of fuel for the maltster?—Yes, would be better than the ordinary coke.

9900. It is of course a fact that the iron smelter and the person making foundry iron take great pains to use coke as free as possible from sulphur?—Yes, it destroys the quality of the best Yorkshire iron.

9901. Have they very much difficulty in practice in finding suitable cokes?—As a rule, the sulphur does not exist more than about one per cent. in the coke and sometimes less. That is so far as my experience goes.

9902. Of late you have made determinations of arsenic in the same coke in which you have been determining sulphur for the purpose of the iron smelter?—No.

9903. Of late I think you said you had been searching the same coke for arsenic?—No, I did not mean to say that, not identically the same coke.

9904. Can you give us any information from your actual knowledge that the coke which was a suitable coke for an iron smelter by reason of its freedom from sulphur, would be also suitable fuel for a maltster by reason of its freedom from arsenic?—I believe that the more pure it is, the freer it is from sulphur, the freer it will be from arsenic. That is my own belief.

The arsenical kiln dust obtained in Yorkshire.

9905. Those dusts that you analysed from the tiles and walls of a malt kiln were obtained from a Yorkshire malt kiln, were they?—They were from several. They were obtained from two in the Leeds district, and I wrote a circular to a large number of maltsters all over Yorkshire, and offered to make the tests without any expense—and I got a considerable number sent me in that way, and the results which are given in this paper are the results of these tests. Each test is reported there, so that the total number of tests made can be counted up.

9906. I presume this malt would have gone into local consumption?—Certainly.

9907. It went into beer brewed in the neighbourhood of Leeds?—Yes.

9908. The malt which was made in that kiln which contained this dust was used locally?—Yes.

9909. Would the malt be used to your knowledge in Halifax?—I do not know where the malt would be used, but I know that one of these firms who supplied me with these things—I may say that these samples were given to me in confidence; I was not to publish anything without the consent of the maltsters and brewers who sent me the samples.

9910. You would rather not say?—Not without their permission.

9911. Have you had the opportunity of examining any green malt? Malt before it has been kilned?—No.

9912. (Dr. Whitelegge.) Can you say in what form the arsenic was present in the dust that you collected from the walls of the kilns?—Arsenic tri-oxide.

9913. Without further combination, simply as such?—Mainly as such, I think.

9914. Have you any idea what percentage of malt becomes dust. You have spoken about the kiln dust?—This dust corresponds to fine dust from an ordinary fire. It is not derived from the malt itself, but it is adherent.

9915. But the dust removed from the malt in brushing?—That is the culms.

9916. Can you say what proportion it bears to the malt itself?—No, I cannot say from memory; it is a small proportion by weight.

9917. Would it be 1 per cent.?—I should think more than 1 per cent.; but I do not know.

9918. Do you advise the maltsters as to the construction of their kilns?—No, I am not a brewing expert.

9919. But you made certain suggestions about the use of glazed tiles?—Yes.

9920. Have you given any other advice of that kind?—To sweep down the walls, clean the place out thoroughly, or else it was no use changing the fuel. They might have these bricks and walls loaded with arsenical dust, which, if a stronger heat current from the fire came on, would shift that arsenic on to the malt.

Imports of clean kilns.

9921. At the present time are those precautions being observed generally?—I cannot say. I know at least two of the breweries took these precautions to heart, and, as far as I know, carried them out.

9922. You have examined anthracite and fuel generally, have you not?—Only a small number.

9923. (Chairman.) To make quite clear a point on which your work has touched on the Halifax inquiry, it has been mentioned in Mr. Hammond Smith's report. I have before me that "Dr. Cameron, of Leeds, has lately obtained samples of beer from public-houses belonging to this brewery (that is the Yorkshire Brewery Company), and Mr. Fairley has in two, which do not appear to have been taken with the formalities provided by the Sale of Food and Drugs Act, reported 1-40th of a grain of arsenic per gallon." Is that correct?—Yes, that is so.

Arsenic in Halifax.

# TWENTY-THIRD DAY.

Friday, 9th May 1902.

AT WESTMINSTER PALACE HOTEL.

PRESENT:

The Right Hon. Sir WILLIAM HART-DYKE (*Chairman*)

Sir WILLIAM CHURCH.  
Mr. COSMO Bonsor.

Professor THORPE.  
Dr. WHITELEGGE.

Dr. BUCHANAN, *Secretary*.

Mr.  
F. Moulton,  
K.C., M.P.

Mr. FLETCHER MOULTON, K.C., M.P. called; an Examined.

[9 May 1902]

9924. (*Chairman*.) I believe that from the very commencement of what you have termed in your précis the Manchester scare, the epidemic of arsenical poisoning, you took a very active part in a thorough investigation of the causes?—Yes. I was consulted, I believe, immediately after Mr. Gordon Salamon, and the whole case was put before me by Mr. Groves. The question of what were the proper steps to take was discussed, and when it was decided that a Committee of Experts should be formed, I had the question as to the most suitable members for that Committee put before me. Almost immediately after this discussion, which was between Mr. Gordon Salamon, Mr. Groves, and myself, the members were selected, and we proceeded down to Manchester to investigate the matter on the spot.

9925. I suppose you had a good deal to do, had you not, with the preparation of this report of the Committee of Experts which we received earlier in our proceedings?—Perhaps I may describe what occurred when we first took up the investigation on the spot. It was perfectly clear to us that the mischief was very widely spread, and that the Manchester brewers themselves for the most part were incredulous as to the possibility of there being any serious arsenical poisoning. It was a thing so utterly without precedent that at the time we arrived they believed that something had gone wrong with one particular brewer's product, and they had no appreciation of the extent to which it was common to the whole trade. The consequence was that our first effort was to make the whole of the brewers realise that the mischief was not confined to any one brewer, but that a large number of brewing houses must necessarily be implicated in it, because it came from sugar which was largely used in the neighbourhood. Our object at first was, by means of making the brewers realise the scale of the calamity, to get some measures adopted immediately which would put a stop to all future mischief. At our first two or three meetings in Manchester that which mainly occupied the attention of the members of the Committee (next to this task of putting before the brewers the actual extent of the evil) was to find some measure which would give adequate safety and which could be promptly applied. I wish to put that before the Commission, because in my opinion there never was any vacillation or change of view on the part of the members of the Committee of Experts with regard to the tests to be used or the measures to be adopted. But the problem of finding some immediate step, some test which would be practical and which would prevent future mischief, was a very different task from deciding what should be the precautions to be used in future, when the object was not to stop the possibility of a present danger, but to give absolute security for the future.

9926. You mean there was the emergency part of the question to be dealt with separate from all future security as regards sugar?—Quite so. In the early discussions as to the test to be recommended, and the precautionary measures to be taken, the members of the Committee always kept in mind that these were emergency precautions. I think I am bound also to say that as soon as the brewers had been assembled, and the case had been put to them with great ability by some

of the leading men, we had every possible assistance from them. I do not believe myself that from that time any beer was sent out which could possibly cause any mischief—except, perhaps, by accident. I think I remember one case coming before the Courts in which contaminated beer had been sold subsequent to the announcement of the precautionary measures, but it was obviously an isolated case, and due to the confusion between two casks. But substantially, from the time that the brewers became aware of the nature of the calamity, and of what steps ought to be taken by way of precaution, all further evil, I believe, ceased.

9927. The report to which I have alluded was received by us earlier in our proceedings, and has been published. You have kindly forwarded a summary of evidence which you wish to give to the Commission, but I suppose you are aware, are you not, that this summary does deal with a vast amount of information concerning which we have already had very ample evidence?—I understand that.

9928. You would consider it advisable, would you not, that this summary, which has been very carefully prepared, should be printed, and go in with the evidence?—That is entirely according to the opinion of the Commission. Perhaps you will allow me formally, as having been honoured by my colleagues with the position of President of the Committee, to present the final report which the Committee made. That final report came long after the preliminary report, and long after all trouble from the Bostock sugar had ceased. But we very soon came to the conclusion that, although the mischief was substantially due to the Bostock sugar, there was absolutely certainly one other source of arsenic in beer, namely, malt. All other sources seem to me to be capable of producing only infinitesimal quantities of arsenic in beer, but the malt is obviously a very serious question. The Committee resolved that they would not give a final report until there had been a most searching examination of all the materials used in beer, to discover the possibility of arsenical contamination. That part of the work I can speak of, as it was entirely done by my colleagues, and I must say that the amount of careful analysis which was done for the purpose of this report was something quite beyond anything that I should have expected.

9929. How far is this later report in circulation?—I think it is in circulation only by having been sent to the Manchester Brewers' Central Association. I believe it was printed by the Manchester papers when it was delivered. Perhaps I may formally hand in a copy of the final report. (*Handed in.*)

9930. You mentioned rather emphatically, do you not, in your statement, the question of the possibility of arsenical poisoning through the medium of malt? You say: "On the other hand, I think it is almost certain that arsenical contamination has frequently existed in beer from due precautions not having been taken in selecting coal and coke for malting which is free from arsenical pyrites." You state that with great certainty, do you not?—Yes.

9931. Have you anything to say on that point, because that is emphatic language: it might be useful if you

Later work  
and final  
report.

Arsenic in  
importance.

Mr.  
F. Moulton,  
K.C., M.P.  
—  
9 May 1902.

could enlarge upon it and give the Commission some information of the causes which have led you up to that conclusion?—The evidence of it is the series of analyses referred to in the final report. They point to a very large amount of arsenic in certain portions of malt, in what is called the malt culms, and also a considerable amount of arsenic probably adhering to the skin of the malt. I think that came as a surprise to every one of us, but it undoubtedly arises from the fact that there is arsenic in a great deal of English coal. I remember Sir Edward Frankland produced at the Royal Institution some crystals of arsenic which he had obtained from the air of London, and which he attributed to the burning of the Midland coal in very large quantities, so that the soot contained traces of arsenic. The English method of malting, I understand from Mr. Salamon, differs from that used in some countries in that the direct products of combustion have access to the grain, so that the arsenic which is carried off in them can be deposited on the malt. You will find in that report reference to some specimens of malt which gave quite a considerable amount of arsenic. What made me attach most importance to this was the impression which was made upon my mind, as a mere observer and not a person at all entitled to speak from a medical point of view, by the close resemblance which all the medical men found between the neuritis which characterised this epidemic and alcoholic neuritis which had never been attributed to arsenic; and at the same time the statements that I heard made by other medical men that this particular form of alcoholic neuritis occurred rarely amongst spirit drinkers, and in places where beer was not drunk. Although I should not wish to give any evidence at all on the subject, because the medical side of the Committee was so very strong and so infinitely more capable of forming an opinion than I could be, yet, as an ignorant observer, the proceedings left on my mind a suspicion that arsenic had played a considerable part in what was called the alcoholism produced by beer, and that probably the neuritis associated with it was due to the fact that this contamination in malting had been very common in past years, and that, small as the contamination was, it had in certain constitutions produced morbid effects. That was certainly the impression left upon my mind, and although I feel it is a matter about which individually I have no right to speak, I think it is a suspicion which should not be too completely banished from the mind by theoretical arguments of the smallness of the contamination. There was a circumstance which also made me cling to that suspicion, namely, the peculiar irregularity, so far as the results were concerned, in the connection between the quantity of beer drinking and the arsenical poisoning. There was no doubt in my mind that people who must have taken very large quantities of beer contaminated with arsenic, did not suffer. The peculiarity of this case is that we know accurately when and to what extent the arsenic passed into circulation. We know to a week when the arsenic-tainted sulphuric acid was sent to Messrs. Bostock. They used nothing but that. We know the quantities of sugar they produced; we know the localities where that sugar was used. We have, therefore, for something like nine months the certainty that fairly heavily charged beer was sold. We know the breweries where it was sold. I inquired of the employees of two or three breweries at the time, especially at one from which we obtained very complete information on every point, and I think, with one exception, the employees—although they notoriously drink a good deal of beer, and entirely the beer of their firm—had not suffered. The impression which it gave me was, that the more poorly-fed people suffered rather than the people who were the most alcoholic, and took most beer. There were very many cases of people who obviously took too much beer, but I cannot help thinking from the cases I saw—and I think the doctors will tell you the same—that there were a great number of instances in which there was no evidence of extreme alcoholism. I do not think that want of food had determined the effect entirely. The sort of impression left on my mind was, that constitutional peculiarities made a very great difference in susceptibility to poisoning by these small quantities. If you combine, therefore, the very irregular influence of constitutional peculiarity with the possibility that there has been for years a small contamination due to this difficulty in malting, it may account for this alcoholic neuritis, and I should not be surprised if, now that the attention of the brewing public has been called to it, and malt is no

longer allowed to be contaminated, it will make a very great difference in the presence of this alcoholic neuritis which has been so associated with beer. I hope the Commission will quite understand I am only giving them the views of an onlooker, and not of an expert.

9932. And as a listener—of course, you have heard a great deal of discussion among the medical men with whom you were associated?—A very great deal.

9933. You have heard these matters discussed again and again, and that helped you to form this general opinion, which you have given to the Commission, in addition to the other evidence?—Yes, that is so. Our relations were most intimate. I believe I was present at almost the whole of their discussions, and I took a very great interest in them.

9934. With regard to this report which you have formally presented, has any further work or any investigation been carried on by this expert committee since it was issued?—I do not think there has been any analytical work since this report, but if you examine the report and see the number of analyses which have been made for it, you will see that there was very little left to be done. Mr. Gordon Salamon, I understand, is to give some further evidence, and he will probably show the Commission the way in which the analyses were made and tabulated. They form a most extraordinarily interesting body of tests, which in my opinion quite adequately investigate this complicated question.

9935. Are you aware whether the recommendations of this report have been adopted by any brewers' association, or recommended by them to their several members?—Beyond the general recommendation which I should say was implied by the circulation of the report among the members of the Manchester Brewers' Association, I cannot of my own knowledge speak of any. I should fancy that beyond exercising generally more care, the brewers are largely waiting for the result of the present Commission. I think the brewers are exceedingly anxious to have guidance on the matter, but as I have very little to do with brewers except in this particular instance, I cannot of my own knowledge say whether they have adopted this test. I am quite satisfied that the brewing firms are on their guard against arsenic. Let me say that I think there is absolutely no danger lurking on the side of brewing sugars, because the mischief arose not from danger in connection with brewing sugars, but from security, if I may say so. The fact that sulphuric acid is contaminated by arsenic is so widely known that nobody connected with an industry of that kind would ever dream of using sulphuric acid which contained arsenic, and all the firms assured us that they took the greatest precautions. It was, however, so obviously wrong a thing that Messrs. Bostock had fallen into a state of security in imagining that when they bought, as I am quite satisfied they intended to buy, arsenic-free acid, there was no danger of arsenical acid being supplied. And, in my opinion, a scare like this makes it quite impossible that in a chemical industry of that kind such a blunder can be again made. I have much less certainty with regard to malting, because you cannot test your coal as you can test your sulphuric acid, and therefore malting will be rendered safe first by better methods—perhaps the American method—whereby the fumes do not go directly on the malt; or by better tests or better selection of fuel. But with regard to that I think the brewers are likely to have held their hand and waited until this Commission can authoritatively lay down the precautions which they ought to take.

9936. I see there is a recommendation that brewers should make it a rule to require a written guarantee of freedom from arsenic in the purchasing of brewing materials of every kind. With regard to that I should like to ask you what is the real significance of this guarantee which they advised brewers to obtain from the sugar-makers and maltsters. For instance, would such a guarantee in your opinion indemnify the brewer who suffered damage from arsenic in his beer, through the default of the maltster or sugar-maker?—I do not think it will indemnify him. The real good of that is that it dins the word "arsenic" into the persons who are selling the goods. It is too much security which is the source of the danger. And if in connection with the selling of brewing materials there is a guarantee pointing to arsenic, people are always on their guard, and are kept on their guard against it. Nothing is easier than to keep it out. The

Mr.  
F. Moulton,  
K.C., M.P.  
—  
9 May 1902.

Brewers of this report have been adopted by any brewers' association, or recommended by them to their several members?—Beyond the general recommendation which I should say was implied by the circulation of the report among the members of the Manchester Brewers' Association, I cannot of my own knowledge speak of any. I should fancy that beyond exercising generally more care, the brewers are largely waiting for the result of the present Commission. I think the brewers are exceedingly anxious to have guidance on the matter, but as I have very little to do with brewers except in this particular instance, I cannot of my own knowledge say whether they have adopted this test. I am quite satisfied that the brewing firms are on their guard against arsenic. Let me say that I think there is absolutely no danger lurking on the side of brewing sugars, because the mischief arose not from danger in connection with brewing sugars, but from security, if I may say so. The fact that sulphuric acid is contaminated by arsenic is so widely known that nobody connected with an industry of that kind would ever dream of using sulphuric acid which contained arsenic, and all the firms assured us that they took the greatest precautions. It was, however, so obviously wrong a thing that Messrs. Bostock had fallen into a state of security in imagining that when they bought, as I am quite satisfied they intended to buy, arsenic-free acid, there was no danger of arsenical acid being supplied. And, in my opinion, a scare like this makes it quite impossible that in a chemical industry of that kind such a blunder can be again made. I have much less certainty with regard to malting, because you cannot test your coal as you can test your sulphuric acid, and therefore malting will be rendered safe first by better methods—perhaps the American method—whereby the fumes do not go directly on the malt; or by better tests or better selection of fuel. But with regard to that I think the brewers are likely to have held their hand and waited until this Commission can authoritatively lay down the precautions which they ought to take.

No danger now from brewing sugars.

Malt less certain

Advantage and limitations of "guarantee"

Mr. Moulton, M.P.  
y 1902.

danger is forgetting it. The real value to the public of that guarantee would be, that it would be impossible for persons producing brewing materials ever to forget the danger of arsenic. With regard to the indemnity, I do not think it would be an indemnity as against the persons suffering. The persons suffering would be entitled to recover from the brewer, because he had sold them beer which was not good beer; the brewer would then be able to recover from the person who sold bad materials, but the brewer himself would be liable for any consequence of the bad beer he sold, even though he were quite unaware that it contained arsenic.

9937. Then you wish the Commission to understand that if there be any indemnity in the matter it is through an indirect method, and that the security arises through a method of constant advertisement, that there is danger not only with regard to the use of glucose, but especially with regard to the malt in the case of the fuel used?—Yes.

9938. It would be a continual hint to the maltster to secure that his fuel is not only well selected, but well picked over and examined before he uses it?—Yes. I think that that is quite adequate to put an end to the danger, because the danger arises from forgetfulness and carelessness, and not from any inherent difficulty in keeping it pure.

for  
I tests  
good  
which  
e easily  
it.

9939. Would you agree that these recommendations in regard to the guarantee might be materially strengthened if official tests were prescribed by the Board of Inland Revenue for brewing ingredients, as recommended in the interim report of this Commission?—I think they would be greatly strengthened, because they would be made intelligible. They would then have a definite interpretation, and if the Board of Inland Revenue could get a test which is practical and easy of application, and gives a substantial security, that would be the greatest service they could possibly render. I do not think an absolute test that was difficult of application would be nearly so useful as a practically sufficient test which could be certainly and easily applied, because I think the danger of rejection is such that the existence of a practical and easily applied, and therefore frequently applied, test would make maltsters adopt methods which would keep their malt perfectly free from arsenic. They would not run the risk of the great loss both to reputation and to pocket which would follow rejection. I think the frequency of the application and its readiness would be very much more serviceable than what you might call its scientific infallibility.

9940. (Chairman.) Again, you think that although your method is indirect, it would not afford the less security?—I think it would afford more security.

9941. You think that, after all, the result in regard to the security would be good?—I think it would be practically certain. With regard to this I think there is no evidence before us at all of the existence even in this case of any beer which produced evil effects otherwise than by repeated drinking. The toxic character of the beer never rose to such a point that once drinking would produce any result. So that you always have this to be relied upon, that it has to be a course of immunity from detection which could allow anything which would hurt the public; therefore a practical and frequently applied test would, in my opinion, give almost certain protection.

on of  
tests to  
er.

9942. Do you agree then that a standard test which should entail the condemnation of arsenical beer should be fixed for the purposes of the Food and Drugs Act?—Yes, but I suggest that tests should be prescribed higher up the scale than that with regard to the brewing material, because the investigation of the beer is a little late. You want to have something which brewers know is a sufficient protection to them; that if they will apply it they cannot be accused of negligence. Then if it is an easy and satisfactory test it will be applied, and what is more it will be applied by the producers themselves; and no method which yields a malt which will not pass that test will in the future be adopted. If there is a discussion as to what is an adequate test, if there is nothing authoritative, then the maltsters are not themselves scientific enough to take judicious action; but if they have something which they have to live up to, they will take care they have no methods which do not give them a malt which will stand that test.

9943. Can you suggest an authority which should have the duties of watching over the purity of the articles

of food and drink also—that they should know the conditions of food manufacture and prescribe standards for reference by duly appointed public analysts?—Of course it must be the Board of Inland Revenue. I think the most important thing is that this Commission, either by appealing to the Board of Inland Revenue, or to some other high authority, should state what they think is adequate and practical in the way of watchfulness on the part of the producers. Then the ordinary powers of public analysts under the existing statutes would enable them to test beer or brewing materials. I think brewing materials should certainly come for this purpose under the class of food. I do not remember the definition; I do not quite know whether they do so now.

9944. (Professor Thorpe.) They come under the Act of 1899: anything which enters into the composition of food is *ipse facto* food?—I am obliged to you for that. That is just what I was doubtful about. I had forgotten whether there was a definition clause to that effect. It is much more important that people should know what they have to live up to than that there should be a vague duty of their products being absolutely pure. I think the latter leads to very costly and very difficult litigation, whereas if purity means being up to a particular standard, tested in a particular way, much of that would be avoided, and the results to the public would be very admirable.

9945. (Chairman.) Are you aware that the Departmental Committee on Food Preservatives recommended the appointment of an official court of reference for this purpose? Have you anything to say upon that?—I am afraid I am not very fond—if I may use a phrase which you have heard during the last few days—of “Courts *ad hoc*.” I cannot help thinking that it is difficult to get good Courts—and as we have good Courts in our judicial system I should prefer to leave it to the existing Courts. But the definition of duty I think should be a practical one.

9946. Have you any other suggestions to make which strike you at this moment which would give greater security against arsenical poisoning. Have you any general observations to make?—No, I have not. I think the important thing is by making it almost a duty of brewers to get these certificates with regard to their brewing materials, to keep the danger before the minds of the whole trade, including all the producers. Advice ought to be given to enable them to know when they are safe; that is to say they should be told what are reliable and good practical tests, and then I think the danger will cease. I do not think it ought to be made at all a statutory duty to require a warranty. I do not think that is the way to do it. The proper way is to say that you think it would be an act of great carelessness for a brewer to buy without it. That is quite sufficient; if you are going to say that it is the statutory duty there may be a great number of questions as to what comes within the meaning of the word warranty, and it becomes a technical question; but if you put it that a man who has a sufficient conception of his responsibilities would not, in the opinion of the Commission, act otherwise, that would have a more wide-reaching effect than putting upon him a statutory duty. For instance, supposing a man did not do it; he would know that if any trouble came he had neglected to do it at his peril, and that would have a really wider effect, and at the same time it would be less onerous and less technical than if it was embodied in legislation and made a statutory duty. I think the greatest kindness that this Commission can do to the public, and especially to the trade, is to state what they think is the duty of a person aware of his responsibilities, and to state in detail how, in their opinion, he can adequately discharge that duty.

9947. (Sir William Church.) Did the Expert Committee obtain any evidence or statistics with regard to the frequency of so-called alcoholic neuritis in any of the large centres of population?—I do not think they obtained statistics, but I know they discussed it a good deal. We were brought into contact with many medical men, and I know for my own part—and I believe I may speak on the part of the medical portion of the Committee—that the question was raised very frequently as to whether alcoholic neuritis was equally common in large centres of population where beer was not drunk. For instance, I remember Glasgow being spoken of.

9948. I mean where beer is drunk, because the impression left upon my mind—and I think upon the

Mr.

9 May 1902.

More arsenic  
in northern  
malts.

minds of the other members of the Commission—was that there was a very large discrepancy between the comparative numbers of those suffering from so-called alcoholic neuritis in the Manchester and Liverpool districts, and in the metropolis, or in Scotland?—I think I remember learning that during the process of the Commission, but why I am rather disinclined to say positively that I did do so is because I remember that in the subsequent investigations we found that the southern malts were much freer from arsenic than the northern, and I should be a little bit afraid lest I had unconsciously allowed my belief as to the distribution of neuritis to be influenced by that fact. I think we found that out, but I will not be perfectly sure.

9949. I asked you that because to my mind now one of the important things before the Commission is to see whether there is evidence that malt made without due care as to the fuel used in drying it, has been in the past prejudicial, and therefore would be likely to be prejudicial in the future. That seems to me now to be the most important part of our duty almost, because it is clear that the outbreak of actual poisoning was due to what may be accidental causes?—Mr. Gordon Salaman probably knows as much as anyone about the distribution of the malt made in different parts of the country among the brewers. Unquestionably we came to the conclusion that the southern malts were more free from arsenic than the northern malts, and if it could be shown that the places where the northern malts were largely used were more liable to alcoholic neuritis, it would have the greatest influence in pointing towards the arsenic in malt being a cause of the prevalence of this disease.

Difficulty of  
controlling  
arsenic in  
fuel by  
analysis.

9950. (Dr. Whitelegge.) You said that coal could not be tested like sulphuric acid?—Yes.

9951. What sort of practical difficulty have you in your mind as regards coal?—In this way. Pyrites is so patchy. You may test a coal and forbid it, and you may test a coal and accept it; but you have to accept it as a class of coal. You cannot satisfactorily test a particular parcel of coal. In the case of sulphuric acid you may test a cargo with certainty, but you cannot test a cargo of coal, because the occurrence of the arsenical pyrites is not uniform throughout.

9952. So that you have no guarantee of a proper adequate sample?—No, that is what I meant.

9953. You said, if I remember rightly, that you wished to have standards not only for finished beer but for beer ingredients?—Yes, standards defined by tests.

Application  
of Food and  
Drugs Acts  
to beer  
ingredients.

9954. And that these should be available not only for any purpose that the Board of Inland Revenue might desire, but also for the purpose of the Sale of Food and Drugs Acts?—Yes, in this sense that I think the Commission should state that the articles should answer such and such a test, and then I think that if they get beyond that they would naturally come under the Sale of Food and Drugs Acts.

9955. The evidence we have had from the representatives of local authorities points to some doubt in their minds whether they can apply the Sale of Food and Drugs Acts to wholesale supplies, and particularly those which are sold for the purpose of manufacture. In the case of brewing materials, would you think it right that the standard for the purpose of the Sale of Food and Drugs Acts should be applicable to the manufacture of a brewing ingredient sold wholesale and not to the consumer?—I think it should; but may I say I think the existence of these tests would make the brewer himself the person in fear of whom the manufacturer lived. The responsibility it would throw on the brewer, the knowledge of the danger and the knowledge of the test which he ought to expect his materials to answer, would make him the person to whom the manufacturer would be liable. All you want is to impress the manufacturer with the need of care, because a manufacturer on a large scale never need allow these things to occur. It is not a question of allowing casual contamination of a particular parcel or anything of that kind. If he knows what is going to be the definition of his duty before his customers and before the world, he will naturally arrange his method of production, and live up to it.

9956. That would be quite true, no doubt, in the case of many brewers. Do you think the same principle

could be fairly extended to the manufacture of substances intended for food but not for beer?—Most emphatically. I think it should be a general principle.

Mr.  
F. Moulton,  
K.C., M.P.

9 May 1902

9957. (Professor Thorpe.) The only point I should like to ask about is in order to clear up some doubt in my mind as to precisely what you mean in suggesting that something like tests should be laid down by the Board of Inland Revenue or some other authority, and that those tests in the first instance should be thoroughly practical tests and easy of application. Have you in your mind that those tests should be applied by the maltster or by the brewer in the first instance?—I think they ought to be capable of it.

Nature of  
tests advo-  
cated.

9958. Is it your opinion that they ought to be such that a man without any technical or expert knowledge of chemical manipulation could apply them?—I do not know whether you have ever seen the way in which men at sea will reckon lunar distances—a very complicated and difficult thing for a mathematician to do, but which they get accustomed to do as a rule of thumb—and although they are guiltless of the faintest understanding of the process through which they go, they will calculate with very considerable accuracy where they are by this recondite method. In the same way I think that with care a test which is quite adequately rigorous might be devised, and the means of carrying it out might be defined so that people, with no more education than I trust we shall have soon among those concerned, will be able to apply it.

9959. I venture to say there are no chemical tests which cannot be reduced to that kind of rule of thumb procedure, and that the most delicate determinations you like to make are susceptible of that kind of definition and application?—I think that is a thing to be distinctly considered in defining a test.

9960. That clears up one part of my doubt, because it struck me that if you had in your mind something of the nature of a rough-and-ready test, and that a non-expert unaccustomed to chemical manipulation should use that test, he would certainly in his finished beer be judged by a much more stringent test when that beer passed through the hands of the public analyst?—I do not deny the value of what I may call an exploratory test of a rough kind which might be done quite readily, but I think the great point is to have a test which could be applied in the way I say—which would be pretty well a definition of duty. I do not believe in the theory that the duty of purity is to be limitless, that traces which improved chemistry can find are sufficient to make a thing impure. I think that in all these things what you want is something which gives practically adequate results, and its applicability is much more important than rigorous accuracy.

9961. The difficulty to my mind is this: you invite the Commission or some other authority to lay down a test which is susceptible of application by what I may call a practical man, the brewer or the maltster. We know, of course, he will not ultimately necessarily be judged as regards the finished product by a test of that exploratory or tentative character; he will be judged by something more stringent?—I think that the stringent test should also be formulated, and should be of a kind which could be applied by a practical man—I mean after proper training. I think it most important. You may give an exploratory test, only meant to be, as it were, additional, in order that a person might at any moment see that things were not going very much wrong; but I think that whatever test you take of purity should be a test that all live up to. I do not believe in testing a man when he comes into court by something you do not expect him to live up to in practice. I think it is much more important that you should have a reasonable severity in your test, and that the test should be one which could be applied.

9962. Both by the analyst and the practical man?—Yes.

9963. That settles my point, because I see a little difficulty in prescribing or giving official sanction to what is called an exploratory test, the man being afterwards liable to be judged by something which may be more stringent; he lives under a sense of false security?—Exactly. An exploratory test would be simply of the nature that it may give a warning, but the other must be a test of his duty.

A. G.  
Salamon.

Mr. ALFRED GORDON SALAMON, re-called; and Examined.

Mr. A. G.  
Salamon.

9 May 1902.

9964. (Chairman.) You have forwarded us a very ample document concerning matters upon which I believe you are prepared to be examined. I see on the first page of your *précis* you mention "that in consultation with some of the leading authorities in Manchester it was agreed that a danger of further poisoning would be stopped if the amount of arsenic (calculated as arsenious oxide) did not exceed 1-50th of a grain per gallon of beer." Is it your opinion that anything below 1-50th grain may be considered in every case as a negligible quantity?—I cannot speak as a medical man on that point. When we were at Manchester in consultation with the medical authorities they came to the conclusion that 1-20th of a grain per gallon was a dangerous quantity, and that anything less than 1-50th of a grain per gallon so far as poisoning was concerned—that is, poisoning in the sense of producing quick results—could be regarded as negligible. Those were our instructions in Manchester. We had to keep to a limit of less than 1-50th of a grain per gallon, and then we were regarded as safe. That was what we endeavoured to do in working out the tests.

to 1-50  
exclud.  
Expert  
littee's  
est.

9965. (Professor Thorpe.) That really was under an emergency?—Clearly. At that time we did not know of the existence of traces of arsenic in malt—no one knew it. We had to find out how it was at a later period that these beers would not pass the test we gave them, and that led us and others to the discovery of traces of arsenic in malt.

It can  
be  
ed by

9966. But looking at it from our present point of view, do you consider that 1-50th of a grain is where the line should be drawn?—No, I do not. I think it ought to be a stricter line than that. It is very difficult to define the limits. It would be better to exact precautions which would ensure safety all round. I can say, however, that a brewer can well work within 1-150th of a grain per gallon now that we know what precautions should be taken.

How

9967. There is no necessity for the beer to contain more than one-hundredth of a grain per gallon?—I think not. I should say that beer, as brewed to-day, does not contain anything like that quantity as an average; in fact, I am in a position to assert that it does not. There are a few cases where beer does contain more, but they are very rare.

test  
ble  
led  
t.

9968. (Chairman.) In paragraph 12 of your *précis*, referring to this great question of tests and their application, you say that for use by skilled chemists you favour, and always have favoured, the use of the Marsh-Berzelius test. Would you amplify that, and give us some reasons why you so favour this test?—The question of arsenic testing by the Reinsch or the Marsh-Berzelius test was elaborately considered by the Committee appointed by the French Academy of Science, of which I think the great chemist Regnault was the reporter, and it was further elaborately examined by that great expert in toxicology, Gautier, and both these investigations pointed to the conclusion that the Marsh-Berzelius test was undoubtedly the best if properly applied. But they also pointed to this, that in order properly to apply the Marsh-Berzelius test it was necessary that the precautions taken should be of an ultra-refined character; and unless those precautions are adopted to-day, I should prefer the Reinsch test to the Marsh-Berzelius test. But if those precautions are adopted, then I greatly prefer the Marsh-Berzelius test to the Reinsch test. Again, the report of the Joint Committee of the Society of Chemical Industry and the Society of Public Analysts has even further refined the precautions necessary to be taken. Therefore when we come to discuss what Mr. Fletcher Moulton has called an exploratory test, I cannot help thinking that the Marsh-Berzelius test is quite unsuited to be placed in the hands of an ordinary manipulator, such as one would find in a small brewery. And I would venture to point out to the Commission that it is very necessary to cater in these cases for the small brewer and for the brewer of comparatively small means, rather than for the large brewer, the important brewer, who keeps his chemist upon his brewery, or who engages a professional analyst; because in the future the larger brewer will, as he is doing to-day, take every possible precaution to prevent his raw materials being contaminated with arsenic. But the small brewer, who has to compete against the large brewer, and who has often seriously to compete in prices, will be tempted by

ed for  
a

cheap material, which is possibly impure. I know, for instance, that much of the malt which was made with gas coke was offered to the large brewers and refused, because it contained more arsenic than is now considered desirable; and I know that that malt has been taken up by the smaller brewers because it was offered at a cheaper price. It has now been worked off, and I do not suppose we shall have any more of it. But I do suggest that the Commission ought to approve of a test which would enable the small maltster or the small brewer to be sure that what he was sending out was free from arsenic. I do not consider that the Marsh-Berzelius test would enable him to do that in practice, but I do consider that a proper application of the Reinsch test would enable him to do it.

9969. When you say that, do you mean that because the first test is far more difficult of application? You describe here two tests, the Marsh-Berzelius, and what for unskilled use.

You call the rough-and-ready Reinsch test. You wish us to understand that one is more easy of application than the other?—I do, that is my point. I should like to show these tests to the Commission. I found by the Marsh-Berzelius test 1-140th of a grain of arsenious acid per lb. of malt. I applied the Reinsch test upon the same quantity of the same malt, and I immediately obtained the blackened copper. That proved to me that the Reinsch test, which is easy of application, would put the maltster upon the *qui vice*, and show him that even in the case of 1-140th grain to the lb. of malt, it would give him a test which he could readily apply to every sample of malt he sent out. I suggest, however, that that would not be the case with the other test.

9970. (Mr. Cosmo Benson.) What would 1-140th of a grain to the lb. of malt mean in a gallon of beer?—It would be less than 1-70th of a grain, because you have to count the amount taken out by the yeast, and that is a very important factor. There is considerable elimination during the process of brewing. This is, therefore, a very delicate test, and one very easy of application. I do not suggest it as an official test, but I suggest it as a test which may be used for the purpose of manufacture.

9971. (Chairman.) You mean that it would be the first hint that there was something wrong?—Quite so.

9972. Supposing this were done, and a dangerous state of things existed, it would not protect the brewer, if any liability were thrown upon him, from a further analysis by a Government official?—Dr. Thorpe will know that in sulphuric acid works the ordinary testing for arsenic in the process of manufacture would probably be conducted by a lad, and would not generally be made by the Marsh-Berzelius test, but upon a rougher test; but tests connected with the subsequent deliveries of the finished acid would be made upon the Marsh-Berzelius test. In the one case there would be a rough test for the purpose of the factory, and in the other there would be the refined test, which would give very great accuracy.

9973. (Professor Thorpe.) I am sorry to say I cannot agree with that statement. I know that the exact opposite is now the case. I know in sulphuric acid works that before the oil of vitriol is sent out the Marsh-Berzelius test is applied?—Yes, on the finished product. I was speaking of the process in the course of manufacture, in order to see whether the elimination was complete, and I happen to know that the Marsh-Berzelius test is not applied in those cases; at least, I know works where it has not been applied. I have seen the tin test and the Gutzeit test employed. In any case it illustrates my point, and that is why I gave it as an example. I should like to add also that it would have been absolutely impossible for us to have stopped the spread of the epidemic in Manchester in the time we did had we been wholly dependent upon the Marsh-Berzelius test, in which test, be it understood, I thoroughly believe. We could not have applied it with sufficient rapidity, and we could not have placed it in the hands of a sufficient number of men in time to have made all the tests which were necessary in order to deal with the matter quickly.

9974. (Chairman.) In your *précis* you say that you are of opinion that much benefit would result from periodic testings for arsenic in beer being made at the Government laboratory upon the samples taken from all beer advertised throughout the country?—I think it is most important that that should be taken in hand if it be practicable.

Reinsch test

vo-  
cated.

Mr. A. G. Salmon.  
9 May 1902.

9975. Do you mean to say that this process should go on to the exclusion of control by public analysts?—No, I do not. I rather had in my mind when making that suggestion that if the Government authorities were, through the Inland Revenue, to make periodic tests, they should inform the brewer that they were taking those samples for the purpose of arsenical testing, and that the brewer should, in every case, be informed as to the result. If the Government authorities found that there was an amount of arsenic in those samples which was pointing towards the agreed limits, they would, I take it, in their discretion inform the brewer, and very quickly again take samples. If they then found a dangerous amount, after having warned him, I take it they would communicate with the local authorities, who would take action. The result of that would be that the brewer, and particularly the small brewer, would know that he was constantly under the possibility of control, and he would be on the *qui vive* as to what materials he employed.

Gas coke should be prohibited or malting

9976. You deal here with the question of fuel and the use of gas coke; do you still hold to the opinion expressed in the Expert Committee's final report that the use of gas coke should be prohibited altogether in the process of malting?—I do, strongly. My experience is that there is no necessity to use gas coke at all, and even that there is no necessity to use coke at all in the making of good malt. The best maltsters do not use it. Gas coke is used solely for the purpose of economy. Now, that it has been established that it is a source of possible danger, I do not think its use ought to be permitted in the making of malt, and I am quite sure that no respectable brewer desires that it should be employed.

9977. Do you think it is being used to any great extent now for malting purposes, or has this late scare led to its exclusion?—I think the late scare must have largely led to its exclusion. My analyses show within the last six months that the amount of arsenic in malt, even by way of trace, has very materially diminished; and I am quite sure that that is very largely due, perhaps wholly, to the elimination of gas coke in the manufacture of malt.

9978. (Mr. Cosmo Bonser.) The price of coal has gone up, has it not, and the price of coke down?—Yes, I believe so.

even if limed. 9979. (Chairman.) With regard to the fixing of arsenic in gas coke by the use of lime, you think that is a process which had better not be adopted? You think it would be better altogether to prohibit the use of gas coke than allow it to be used?—Personally, I think that the process for fixing the arsenic by lime is good, and if the process is properly applied I think it is reliable. But the Commission has to deal with the possibilities of negligence, and if the lime is not properly applied in the fixing of arsenic, then it may be of no value whatever. The difference which the use of gas coke would make in the price of a quarter of malt is so small that I think it would be well to eradicate the possibility of contaminating the food with the poison; and for that reason I should be inclined to say that it would be far better to prohibit the use of gas coke than to allow it to be doctored with a material which might not be properly applied from time to time.

Flavour of fumes essential to malt.

9980. Have you anything to add with regard to your statement about the roasting of malt? You mentioned that out of 53 samples so dealt with, only one was found to contain arsenic, and that a very minute trace?—It points to the fact that the contamination of malt by arsenic comes from the products of combustion, because the malt is roasted without those products being passed over it; but I do not think it would be possible, or practicable, at any rate, to-day, to produce a malt suitable for the production of our present ales by the application of radiant heat to the malt. I do not think that you could eliminate the effect which the products of combustion have upon the malt in curing, any more than you could cure a ham by radiant heat and get the same flavour in it as you do by the way in which it is cured to-day. I think the flavour of malt, and subsequently of the beer, is very largely influenced by the passage of those fumes through the malt itself. Again, if you were to attempt to heat by radiant heat—it may come perhaps some day—the interference with the trade would be enormous. It would mean the reconstruction of practically every malting kiln in the country, and I do not think that is practicable.

Alteration of kilns means enormous interference with trade.

9981. With regard to anthracite, you state very truly that it may contain pyrites, but when you mention that it is to be selected, is there any special process through which you think it should be put beyond picking it over by hand?—Have you any suggestion to make with regard to that?—I should like to point out that those two samples, the tests of which I handed to the Commission, were prepared from anthracite. The samples were sent to me quite recently by a very intelligent maltster, a man who desires to produce the best article, and he told me that they were prepared from the best anthracite. I think it would be interesting to the Commission if I privately handed in the letter which I received from him, as it shows that arsenic may be introduced into malt in infinitesimal quantities even from anthracite. The whole question, of course, is the selection of the anthracite by means of hand-picking and washing, so as to eliminate the pyrites. (The Witness handed in the letter.)

Mr. A. G. Salmon.  
9 May 1902.

Arsenic in anthracite dried malt

9982. The tests showed 1-140th of a grain?—Yes. The sample was sent by the maltster for the purpose of his own information. He sent it to me in my professional capacity in order to examine for arsenic.

9983. It is a fact, is it not, that certain collieries, or certain seams of anthracite in certain collieries, contain less pyrites than others, and that some have a better name for purity?—I believe that is the case.

9984. Therefore it would be an extra security if the maltsters were to apply to collieries for their materials which were known to be more pure with regard to pyrites?—It is a question of selection. I do not know if it would be practicable for the maltster to attempt to analyse his fuel, because the very difficult question of sampling comes in. The maltster can make periodic analyses, and they will be worth something, but he could not be expected to analyse every delivery of fuel—it would not be practicable. He could not sample it, even if he could analyse it.

Difficulty systematic analysis of fuel.

9985. (Mr. Cosmo Bonser.) With regard to the letter which you have handed in, are you aware whether that maltster used to use coke?—I do not think he ever used it—I remember him telling me he never used it.

9986. I asked you because I know of instances where coke used to be used in a malting house. This year anthracite was used, but traces of arsenic were found in the malt. The presumption was that the arsenic had lodged in the kiln, and had been blown into the malt when the draught came?—That is quite reasonable, but I do not think it could have occurred in the case I have referred to, because I remember the maltster told me that he had never used coke.

9987. (Chairman.) You consider that cleanliness throughout the malt kiln and throughout every process is absolutely necessary?—Yes. I have found in my investigations that the malt culms have a particularly preferential power of taking up and absorbing arsenic. I think it is very necessary that the kilns should be cleaned out more often, because the culms that drop through would give a fresh absorbing couch of culms.

9988. Cases have been adduced before us in evidence in which a very considerable amount of arsenic has been found in some malt dust which had been a long while collecting. That points, does it not, to the necessity for extreme cleanliness, so as to avoid the collection of any old malt dust in large quantities?—Quite so. In the case of dust which I examined, where gas coke had been employed, the amount of arsenic was really very considerable. But I feel so strongly upon the necessity of not allowing gas coke to be employed, that I would suggest the desirability of making it penal to employ gas coke in the preparation of malt, regarding malt in the light of a food product.

Arsenic in kiln dust.

9989. You refer here to analyses in the Government Laboratory which would effectively, in your opinion, control the operations of the maltster—you referred there to the analysis of beer, I presume?—Yes, because if the Government analyses were found to be unfavourable to the brewer he would, of course, for his own protection, trace it back, and unless he could trace it to the employment of any other material that was injurious, he would throw it back upon the maltster, and examine the malts, so that it would effectually control him.

Government Laboratory control.

9990. Do not you think the recommendation of the Commission that the Government Laboratory check should be applied to the malt itself, would be a good safeguard?—It would be scarcely practicable for them to do it upon every delivery, but if they were to control

the beer, or even the yeast, it would be better, because it would be a more sensitive control in the brewery, and they would then be easily able to keep it in check. They have not so much control over the malt kilns as they have over the breweries. There they have access to all parts, and everything would be organised for their taking the samples, but I do not think, subject to correction, they would have the same facilities in connection with malt kilns.

9991. (Professor Thorpe.) Might I suggest that the practical way would be to examine the wort, because it is part of our duty to collect the wort; we do that?—I agree, subject to this, that as you know the wort does not constitute in all cases the final beer as it leaves the brewery, because ready-made beer is frequently added to it in connection with returns, and so forth. I do not think the wort would quite control the problem so as to actually and adequately safeguard it. I think the beer itself would thoroughly control it, but I am not quite sure that the wort would.

9992. But even the beer that is added must have been wort at some time?—Yes, but you do not know where it has been since.

9993. Of course we should have to obtain fresh powers to check the beer in that sense, but now it is part of our duty to check the worts, and worts constantly come to the Government laboratory as a matter of official routine?—I think it would go a very great way if you were to work upon the worts, but to make it quite satisfactory I do think additional powers should be given to you to take these samples of beers.

9994. (Chairman.) You have handed us in a summary of analyses since January, 1901. You show there a great improvement in the malt samples sent to you by brewers since October, 1901. Have you anything further to state to the Commission with regard to these analyses?—I believe you are responsible for each and all of them?—Yes, they have all been done in my laboratory, and they represent many hundreds of samples. I would like to point out that from January to April of 1901 I found 70 per cent. of the samples free from arsenic; 3 per cent. contained under 1-300th of a grain to the pound, 19 per cent. contained above 1-300th and under 1-150th of a grain per pound. Then there were 8 per cent. of what one might term, speaking of traces, notable quantities, that would be above 1-150th but under 1-20th. Then from the period of May to September in that year there were 43.4 per cent. free from arsenic, 2.6 per cent. contained more than 1-700th of a grain per pound, but less than 1-300th; 38.5 per cent. contained from 1-300th to 1-100th of a grain per pound, and 15.4 per cent. contained over 1-100th and not exceeding 1-28th of a grain per pound. It must be remembered that the malt, of which I have given these results was substantially the malt that was made during the season of the epidemic, and it had not then been pointed out that gas coke was injurious. These were in all cases malts from all parts of the country—from Yorkshire, Lancashire, and from all parts.

9995. Chiefly the north?—No, all parts of the country. Then we come to the period as from October, 1901, when the new malting commenced, to March, 1902. That would cover the new malt. There we find a vast improvement in the elimination of these traces of arsenic. There are 34 per cent. free from arsenic; 25 per cent. contained under 1-700th of a grain, 19 per cent. contained about 1-700th of a grain, 15 per cent. contained about 1-350th, 6 per cent. contained above 1-300th and under 1-100th of a grain per lb., and 3 per cent. only contained above 1-100th and under 1-27th of a grain, so that there was substantially 97 per cent. of the malt which I examined during that period which would not have imparted to the beer a sufficiency of arsenic to have been regarded, according to the present limits, as even an appreciable trace. I think that shows a very highly satisfactory state of things, and shows that the use of gas coke has substantially ceased.

9996. Are you prepared to state to the Commission your belief that in a great measure this change was due to the cessation of the use of gas coke in malting?—I do state that; I believe it to be so, and probably also by increased cleanliness in the kiln—that is to say, the dust in the kiln was more frequently removed. That, coupled with the discontinuance of the use of gas coke, is, to my mind, the explanation of that vastly improved state of affairs.

9997. This statement is not based altogether upon inference, but on knowledge?—From knowledge within my own experience. I know that maltsters have given up using gas coke.

9998. Therefore, you state that as definite information?—Yes, as regards my own experience.

9999. With regard to the point you mention here in your *précis* of the desirability of considering whether the use of arsenic-free sulphuric acid should not only be made compulsory for food purposes, but also should be extended to the preparation of artificial manures, have you anything to say upon that point? For instance, can you adduce before us any concrete instances in which you are aware of arsenic having been communicated to barley or other grain?—I have examined some samples. You will find in the report of the Committee that samples of barley do sometimes contain minute quantities of arsenic. Fourteen samples of typical malting barley, we say, grown in different parts of the country, were submitted to analysis, and five out of the fourteen contained minute quantities of arsenic, and one sample of unkilned barley—of course, you must deal with unkilned, otherwise it may have been contaminated on the kiln—contained 1-400th of a grain of arsenious acid per lb. I think it is clear that barley is liable to contain very minute quantities of arsenic from the fertilised soil of arsenicated manure. But it will be within the recollection of the Commission that Mr. Weld Blundell gave evidence respecting what he thought was contamination of root crops and roots, through arsenical manure. I believe that the gentleman is dead, otherwise he was to have appeared again before the Commission. He sent me some of the roots that he had collected to examine. I examined them, and I found most unmistakable traces of arsenic in those roots which the sheep had been feeding upon.

10000. What were the roots—swedes or mangolds?—Swedes.

10001. When you say unmistakable quantities of arsenic, what quantity do you mean?—I have not the tests with me, but, speaking from memory, it would be something like the same as we found in the barley—about 1-400th of a grain per lb. It was within the region of that quantity.

10002. When you refer to these roots, are you referring only to the letter of Mr. Blundell?—He sent me the samples.

10003. Did you yourself test those roots?—I did.

10004. He says at the end of the letter: "The season is too far advanced to allow of any examination of roots to make any experiment."—Yes. He was just in time to get some, and able to send them to me.

10005. But what percentage of arsenic was found in this barley you mention?—The barley was about 1-400th of a grain to the lb., and I should say that the amount in the roots was about the same.

10006. It was entirely a negligible quantity in each case?—Quite so.

10007. You say in your *précis* that if the Marsh test is adopted as the official test, as you consider it should be, the standard then should be officially issued, so as to avoid discrepancies with regard to the results. Will you explain a little more to the Commission what you mean on this point?—I was assuming that an official test would be devised and laid down. I have had the advantage of seeing some of the tubes that Mr. Thomson had prepared. Everyone knows the immense amount of care that he has taken with his arsenic work, and the extreme ability with which he has conducted it. I have tried to be careful with my work, too, and yet I was amazed to find that Mr. Thomson's tubes were of an entirely different calibre to mine, and that the manner in which he collected his arsenic on the mirror was quite different from mine. I had devised this form of standard to test my tubes with. (Handed in.) I find that he had his of a different diameter altogether. That brought me to this, that it seemed to me that the Commission ought to lay down a form of standard test which would prevent one analyst giving 1-33rd of a grain, and another analyst 1-300th of a grain, as I believe has been the case. I thought it would help to secure that if the Commission would devise a permanent standard print of colour as representing a certain percentage of arsenious acid, if the permanency of those colours could be secured. The mirrors in the tubes do not keep permanent in light, as Dr. Thorpe will know,

Mr. A. G. Salomon.

9 May 1902.

Arsenic-free sulphuric acid should be used not only for food purposes but for manures.

Arsenic in roots.

and barley.

Kind of official test recommended.

Mr. A. G.  
Solomon.

9 May 1902.

but if they could be printed in some permanent form, and then circulated by authority, they would serve as standard tests which, in the case of a prosecution, would ensure uniformity of result being obtained by different chemists. That was the point that occurred to me as being necessary. It was a matter that would want studying out, so as to get the proper fixation of the colouring. Then, also, they would be able to give the proper dimensions of tube, and other details of the apparatus, and that would be shown on the plan they would send out, which would be accompanied with a minute description of how the test had best be made.

(Professor Thorpe.) I do not think there would be any difficulty in that.

10008. (Chairman.) I do not know whether you have read the interim report in which the Commissioners said: "We have evidence that at the present moment analysts are by no means agreed as to the best official test to detect minute quantities of arsenic in beer. In view of these circumstances, we consider it essential to institute further inquiries before recommending the standard test that should be imposed." You understand that the Commission has considered this as an all-important point, and one on which we, of course, have to hear and seriously consider further evidence?—Yes. Those standards I have handed in are made with magnesium, because I could not get arsenic-free zinc at the time. They would not be quite the same as the zinc mirrors. I have noticed that the mirror is not quite the same. There are some small points of that kind which it seems to me require to be cleared up by the Commission, so that uniformity may be obtained.

Should be  
penal to use  
acid for food  
purposes  
which is not  
arsenic-free.

10009. There is a paragraph in your statement which says: "The extra cost of purifying the pyritic acid so as to make it arsenic-free within the limits of infinitesimal traces, would not, according to the inquiries of witness, exceed 3s. to 4s. per ton of 70 per cent. oil of vitriol." I would like you to go into that subject a little?—Personally I suggest that the sulphuric acid which is required for the preparation of foodstuffs and for pharmaceutical purposes ought to be commercially free from arsenic, and I suggest that it ought to be made penal to employ for those purposes sulphuric acid which is not commercially free from arsenic. The cost of purifying sulphuric acid from arsenic is not more than from 3s. to 4s. per ton of 70 per cent. oil of vitriol, and the public certainly would not, I consider, feel the extra cost of that acid, and they would be safeguarded to a very great extent; because although today guarantees are given of purity, still there might be an accident, and if it were prohibited under a penal offence to employ any but arsenic-free acid for the purpose of medicinal preparations and foodstuffs, it would not hurt the manufacturer, it would not hurt the public, but it would be a very great security. The extra cost involved is so small that I believe the manufacturer would readily be able to do this. And I would point out, as Dr. Thorpe will well know, that there is not a manufacturer of sulphuric acid who has not to hand the means of taking out the arsenic, either by the new catalytic process, or by the old method of arsenic purification. It is a method which he could easily carry out. It is a horror to think of the possibility of the recurrence of a delivery such as was made from Messrs. Nicholson's works to Messrs. Bostock, and I think it could be largely obviated by dealing with it in the manner I suggest.

10010. (Sir William Church.) Among these samples of malt that you found were free from arsenic altogether, could you tell the Commission whether the majority of them came from the south or the north? You say they came from all parts of England?—I should say they were very evenly divided; they came from all parts of the country. I am able to say that, because a number of brewers have now insisted that all their samples shall be examined by way of advance samples, and the maltsters have to send them to me for these breweries I represent before they are passed by the brewery, before they are delivered in bulk to the brewery, and then they control that afterwards by further tests from the bulk deliveries themselves. Therefore I happen to know that these do come from all parts of the country. It is not that the brewer merely sends it to me to see whether it is free from arsenic or not, in which case I should not know where it came from; but I do know because of the advance samples being sent to me. Therefore I can say that they fairly represent the malts throughout the country.

10011. You made use of an expression with regard to malt culms, that they seem to have an affinity for arsenic. I suppose that is only because of the open mesh-work through which the currents of air pass; they cannot pass through the solid body of malt?—I think there is a physical reason, and I am largely inclined to the belief that there is also a chemical reason. I think it is very much on the same lines as the greater absorption—the preferential absorption—of arsenic by yeast. I believe that certain albumoses have the power of forming definite compounds with arsenic, and I have some slight experimental data already in that direction. I would not like to put it forward as conclusive or exact, but if you ask me if it is solely physical, I do not think it is. I think there is a chemical reason as well as a physical reason for the greater absorption of arsenic by malt culms and also by yeast. I think the two are on all-fours.

10012. I presume that when the green malt is placed upon the kiln it is only for a very short time that anything like vital action can be going on in it; it would soon be killed by the heat?—Yes, but for some considerable time the amount of air is very large in proportion to the products of combustion. The endeavour of a maltster who does not hurry his work too much, and does it conscientiously, is to pass a very large volume of air at the early stages of drying. Therefore it would be prolonged somewhat longer than you think; I think so. But it would be at that stage that the bulk of contamination would take place. I do not ignore the suggestion you make as to the physical conditions favouring that absorption. I think they do; but this is certain, that I have found that if you want to test for arsenic in a malt-house, the proper place to go to is the malt culms or the dust. That is where you will get the first indication and the best indication.

10013. Have you seen the evidence which was given very lately by Mr. Arthur Angel with regard to the arsenic in growing plants taken up from the soil?—I have read it.

10014. You have noticed perhaps that in his evidence he states that he found no evidence of arsenic being taken up into the seeds of corn, either of wheat or oats or barley?—I have a recollection of reading that.

10015. Traces were found in various plants, in the leaves and growing stems?—He found them in roots too, did he not?

10016. No, I am going on to that. Among the roots he had only examined mangolds and carrots, and in neither of them was any arsenic found, although they were growing upon an artificially arsenicated soil. I just wanted to ask you another question with regard to that. Mr. Blundell sent you these turnips; were they turnips that the sheep which died was supposed to have been fed on?—I could not tell you as to that. I only mentioned this case because I thought it due to him to do so. He sent me these samples, and I tested them, and I did find the minute quantities of arsenic I have mentioned. But I do not think I am in a position to give any exact data as to the conditions. With regard to barleys, I should like to point out that the barleys reported in the Committee's report were divided between Dr. Stevenson, Dr. Luff, and myself. We found certain of them to be free, in the numbers I have said, and certain of them to contain these very distinct traces. They are only minute, but they are distinct. To that extent I cannot agree with the evidence of Mr. Angel.

10017. I do not suppose that your experiments were conducted in the same way; you do not know whether they were found in the husk or in the actual seed?—I could not tell you that.

10018. You have not told us anything about your views in regard to brushing the malt?—I think brushing is most beneficial. The more the desirability of the use of a Boby machine, or some similar machine, can be impressed upon the brewer and the maltster the better. Both the maltster and the brewer should brush the malt as much as possible; I think there is no question as to that. Of course, they want to take care in doing that to brush it prudently, and not to break the malt. A good deal of it is broken. It ought to be done carefully. As to the desirability of doing it, there can be no question whatever.

10019. Do you think it is right for the brewer to use any unbrushed malt?—Substantially I do not think he does. It is bound to be brushed in a measure. The question is, to what extent.

Mr. A. G.  
Solomon.

9 May 1902

Affinity of  
culms for  
arsenic.

Arsenic in  
roots.

Advantage  
of brushing  
malt.

10020. We have had it in evidence that while some maltsters never send out unbrushed malt, others do, and the brewer may or may not subsequently give it a brushing at the brewery?—That would not be within my experience. If that is so, I think it would be very desirable that it should be brushed by the maltster.

10021. The malt should be brushed by the maltster?—I think so.

10022. Would you suggest that it should be brushed by the brewer as well?—It would be advisable as an additional precaution, but I do not think it is absolutely necessary if it is well brushed at the malting. One must not put too much work upon the brewer: he has to conduct his operations within a given time. He has to start early in the morning, and finish his work at 5 or 6 o'clock. You must not make the operation too lengthy, or else it will not be a practicable process. If you interpolate some extra hours' work into his day's run, he cannot get through.

10023. Does not that apply equally to the maltster?—No, he has comparatively nothing to do for a large portion of the year. He has his stocks of material, and he can always brush them up again if he wants; but it does strongly apply to the brewer.

10024. In your opinion it matters but little at what time the brushing takes place: it is not necessary that the brushing of the malt should take place soon after the drying process; it may take place at any time before the maltster delivers his malt?—Yes, I think so. There is no evidence that I know of to make one think it is necessary to brush it immediately. I should think if it were brushed later it would be equally good, so far as I know.

10025. (Professor Thorpe.) What steps have been taken to make public in the brewing industry your final report?—We were instructed by the Manchester Brewers' Central Association, and when our report was finished it was communicated to them. I believe they have sent it to every member of their Association, and I think it also appeared in the "Brewers' Journal," but I do not think that any other steps have been taken. Then, of course, notices were sent round. I will take, for instance, one of the very large breweries in London that I act for. They took this report, and they carried out every recommendation except one, which they found impracticable, namely, the recommendation as to hops. They could not carry that out, but subject to that they carried out all of it. As to how far the report has been spread I really could not tell you. Of course we simply reported to those who instructed us, and they issued it to the members of their Association.

10026. In that second report you use a test which is rather more stringent than the provisional or tentative test used when you had to deal with an emergency?—Very much more so.

10027. We have it in evidence, however, that as regards certain samples of brewing materials which were employed in Halifax, the analysts had been directed to make use of the method which you suggested on the first occasion, and that they had been content to rely upon that method?—They should not have been. At the time we gave that first test we did so in ignorance of the existence of traces of arsenic as derived from malt, and when a year ago almost to-day, we issued this report we had then discovered the existence of these traces. We were sure that they were there, and we thought it was the duty of the brewer to exact a more stringent test.

10028. Although you say the analyst should not have prosecuted that test, I think he rather did it through inadvertence: he probably had not the knowledge of your other report before him?—You are quite right, I ought to have put it in that way, I think.

10029. Now let me come back to my original question—that it would be certainly desirable for you to take steps to make it more fully known that you no longer rely upon what I may call the emergency test as a sufficient and stringent safeguard?—I do not know what steps one could take, except by writing a letter to the "Brewers' Journal."

10030. The final report is a document addressed to your clients?—Quite so.

10031. And it is their property?—Yes, but they have no objection to its being freely used: I have no doubt about that.

10032. Could not steps be taken so that it could be freely used in the sense I indicate, so that brewers may not labour under any misapprehension?—I think it could probably be done by writing a letter to the "Brewers' Journal." I should be pleased to do that.

10033. I think it would be advisable that you should at once take steps to let the analysts know, and everybody concerned know, that you no longer rely upon what I call the first method as a sufficiently stringent safeguard?—Yes, I will do so.

10034. (Mr. Cosmo Benson.) I should think the different brewing societies could circulate it, after what Dr. Thorpe has said?—If you suggested it to them I think they would do so.

10035. (Chairman.) You see the importance of the point, do you not?—Yes.

10036. (Professor Thorpe.) I gather from what you have said that you yourself have a slight personal predilection in favour of the Reinsch test?—No, not as a for unskilled refined test, but as a test that could be used where the other is not practicable. I have no predilection. I think each one has its own particular application. I have said that as regards the official test, I should keep to the Marsh-Berzelius test, but I should not put that into the hands of a lad to make any tests in the brewery. These tests, if the Reinsch test can be applied, are so easy that just as in chemical works they give a man testing to do, so they can give him these Reinsch testings to make, and if he gets anything suspicious he can bring it to the notice of his superior. There is no difficulty in that, whereas if you ask the brewer to apply the Marsh-Berzelius test in such a form he could not do it.

10037. I want to know why he could not do it, assuming that an official form of apparatus was devised which was purchasable from recognised dealers in chemical apparatus, and that these tubes were prepared, the whole method of procedure carefully laid down, and printed forms issued. Where is the difficulty in its application by an intelligent youth?—He has first of all to be sure that he has pure materials, and that is part and parcel of the whole thing.

10038. But he tests that to begin with?—I know: that is what I am coming to. He has to do that before he can apply the test at all. But all that is a question of time, and there is a difficulty in getting these materials quite pure. You might tire the man before he has come to work it in a going concern, whereas with the other it appears to me to be so simple.

10039. He would have to do that in connection with the Reinsch test?—But they are much fewer. You have only hydrochloric acid there. You have four or five substances in the other. Acid, zinc, calcium chloride, and lead acetate paper have to be used, and it becomes a complicated process to my mind. I do not know whether these test tubes would always be supplied of the proper calibre: if not, he would have to make them himself.

10040. My suggestion is, that a sufficient supply of these little tubes should be furnished by the dealer with the apparatus?—It appears to me to be a case in which you could educate boys or lads to make the Marsh-Berzelius test—I do not doubt it for a moment: but the Reinsch test is one which will adequately guard against any danger, and it can be applied in a brewing room or anywhere else without any trouble whatever. That is why I fancy it, not only because it is more practical, but it is useful for rough purposes.

10041. But my difficulty is—and I am sure the Commission will appreciate it—that you have two competing tests which are not strictly comparable one with the other in operation?—I do not call them competing in this sense. We recommend in our report that if we get a coloured copper by the Reinsch that should earmark the material operated upon, and it should then be tested as a final test by the Marsh-Berzelius test.

10042. By whom?—That is a matter for arrangement. If the lad who makes the Reinsch test is able to make the Marsh-Berzelius, well and good; but at any rate, it is pointed out to him as he runs through these things very quickly that there is a sample which is suspicious, and has to be re-tested. It is a matter of arrangement, a question of organisation.

10043. Just think what would happen in a works. A man makes this test, and finds that his materials are suspicious. He has no method of knowing what the

Mr. A. G.  
Sullivan,  
9 May 1902.

Mr. A. G.  
Solomon.  
9 May 1902.

danger amounts to, but he has to stop. Whereas if he went on to use what I hope will eventually be prescribed, this Marsh-Berzelius test, prescribed with the details that you suggest, he would at once know where he was?—I have seen as many as 400 or 500 of these Reinsch tests going on in one laboratory at a time in Manchester. I do not think you would be likely to see as many Marsh-Berzelius tests as that going on in a room.

10044. Those were beers, were they not?—Yes; I am speaking of a lad employed at a brewery, where you run 20 or 30 of these Reinsch tests at a time. It is impossible to do it with a Marsh-Berzelius. Supposing a brewer wants to control his stock; he says, "I will employ a young chemist at £50 or £100 a year to test my material." He can do it like that with the Reinsch, and except in cases of danger he will pass everything fairly and quickly, whereas if he employs the Marsh-Berzelius test it is not practicable for every-day work. I quite admit it is the best test; I am not confuting that for a moment.

10045. I do not think he would have such an enormous quantity of malt to look over; he would have a certain number of samples to test; he would have a certain amount of invert or glucose coming in; he would not have a large range of materials, and he would not have a great multiplicity of tests to conduct?—There are a great many. As you know, the brewers do not use one class of malt, as a rule; then there are all the raw materials and the preservatives.

10046. A lad could easily do a dozen Marsh-Berzelius tests in a day?—It would be more than he could do, I think.

10047. I am speaking from experience, and our official hours are not so long as those that are worked outside?—Then we cannot get the assistants to work as rapidly as they do at the Government Laboratory. I do not think I could get men to make as many tests as that; whereas I am sure I could get 40 or 50 by the Reinsch.

Modification  
of kilns.

10048. You have told us that you have considerable professional dealings with maltsters?—Yes, that is, as an analytical chemist.

10049. Is it not the fact that one difficulty there would be in carrying out any re-arrangement as to structural alterations arises from the fact that in many cases—I believe in the majority of cases—the premises are not the property of the maltster; he is a mere tenant?—I could not speak as to that.

Anthracite  
preferred to  
oven coke.

10050. You told the Commission that you think anthracite is distinctly preferable to any form of coke?—I think so.

10051. Even to oven coke?—As regards certainty, yes.

10052. Why do you give preference as regards oven coke?—Because, as I understand it, the coal for making oven coke is particularly selected on account of its freedom from pyrites because they do not wish the coke to contain sulphur. That is merely a question of selection, whereas the anthracite is naturally freer from sulphur than the coal from which the coke is usually made; therefore there is a chance even of oven coke becoming contaminated.

10053. Unless the same process of selection were gone over in the case of anthracite, namely, hand picking, you would be liable to a recurrence of this state of things?—You would. But you must bear in mind that, as far as I know, they would never malt with coke alone. They use a mixture of coke and coal, and they use it at different stages of the kilning. Supposing you were to employ a washed oven coke, you could not malt with that only; I never knew of a maltster who did.

10054. Is it not a fact that the distribution of pyrites in coal is so fortuitous that it is no necessary security to say that a certain colliery is reasonably free? It might be free for a week, and then the next week you might come upon a seam where a considerable quantity of pyrites might be present?—That is so; but of course we must take the average of these statements, and it is perfectly practicable, as I find and as I understand the position, to get anthracite which is substantially free from pyrites, if care be taken in the selection.

10055. In looking it over?—Yes, it is advisable that it should be looked over; I quite agree with that.

Effect of iron  
in soil on  
arsenic in  
plants.

10056. With reference to the question that was put to you about experiments on the soils and the assimilation of arsenic by plants, would it not make a great deal of difference to the results if, for example, the soil

contained any sensible quantity of ferruginous material, say hydrated oxide of iron or carbonate of iron—would not that make a great deal of difference as to where the arsenic went?—I should think it would.

10057. In other words, you might add arsenic to a soil containing ferruginous material and practically it would be all locked up by the iron?—I think that is a very proper and just objection; I quite think that that might happen.

10058. You have no proof that arsenic could not under certain circumstances be assimilated by a plant growing in a soil, because in certain soils such plants have been found to be free from arsenic?—I think that is also a very just objection. It is a question which ought, in my opinion, to be taken in hand by such a body as the Royal Agricultural Society. These questions certainly arise in connection with the statement that has been made as to non-assimilability and non-absorption. I think there are many other kindred questions that would arise in connection with this problem.

10059. (Dr. Whitelegge.) With reference to the anthracite, you told us that the brewer could not analyse it. What precautions do you think it would be proper for a brewer to take in getting his anthracite: what steps ought he to take to insure that the anthracite he gets is free from arsenic? Should he require a certificate?—It might be well for him to get it.

Anthracite  
should be  
guaranteed  
as picked  
selected.

10060. A certificate of what?—I would rather ask for a certificate of general purity in terms of an assurance that it has been particularly well hand picked and selected than that he should ask for a guarantee as to its freedom from arsenic. It is so difficult to guarantee a cargo of coal. The question of sampling comes in. It is so extremely difficult to sample the bulk.

Guarantee  
freedom in  
arsenic of  
value.

10061. The proper course would be, not an assurance that it had been analysed, but that it had been washed and picked?—Yes, washed, picked, and carefully selected; I would ask for that assurance. I should not attach any value to his guaranteeing it as free from arsenic, because he would not be able to check it; it would be upon his guarantee.

10062. You would also take into account some selection in the seam of the colliery?—Yes.

10063. (Sir William Church.) Would it be possible to do that; is not anthracite delivered in large blocks which are broken up by the maltsters themselves?—I do not think the maltster could undertake to pick and select the anthracite. As I understand it from the maltsters, when picked and selected anthracite is delivered to them it is picked by those who supply it. It may be that the large blocks are picked, and perhaps that gives them quite sufficient indication, but I do not think you will get the maltster to break up the anthracite small and then pick it over, and so on. It would be out of the question, at least as far as my experience goes.

10064. (Dr. Whitelegge.) The difficulty is in obtaining a sufficient and adequate sample of the class of coal?—Yes, a true sample.

10065. Does not that difficulty apply to some extent to malt? What precautions do you ask for in sampling malt?—I do not think the same difficulty applies, because it is generally taken from the bins, where you have large storage accommodation, and it represents a bulk supply. They dip well into the bin.

Sampling  
malt.

10066. We have been told of accidents happening from accumulations of arsenical dust falling down from the ratters, and so on; you would not think that a material consideration in sampling malt in general?—No, I would not.

10067. You gave us the results of a number of analyses of malt pointing to a more satisfactory condition in recent months; were those samples sent to you for analysis by your clients?—Yes.

10068. Do they represent in any large number the smaller brewers?—Yes, both large and small.

10069. You told us that you anticipate difficulty rather in the case of the small brewers than in the large ones in the matter of precautions?—As to their liability to use impure materials I should.

10070. Would you suggest that the public should be protected in the case of the small brewers if your recommendations were carried out?—In the same way as the large—that the Government Laboratory should analyse and report upon samples so as to control and warn him if necessary.

A. G. 10071. But those would be infrequent samples, would they not?—Yes, but it would be quite enough for him to know that he was under control.

10072. They would be samples of finished beer or wort, and have no regard to materials?—If they found that the wort or finished beer contained an undue amount of arsenic they would at once be thrown back upon a searching investigation of the raw materials, and they would warn the public authorities, as I suggest, that they should devote their attention to this particular brewery, as there was danger of the public health not being safeguarded.

10073. Do you mean the local authorities?—Yes.

10074. You do not mean the Inland Revenue?—No, the local authorities; that the Laboratory should communicate with the local health authorities of the district where that brewery was, and notify the brewers in question what had been done.

10075. In order that the local authority may take action under the Sale of Food and Drugs Act?—Yes.

10076. Presupposing a standard made statutory in some way?—Yes, and that the brewer was found by the local authority, after having been warned by the Government Laboratory, to exceed that standard.

10077. Then you would pay no attention to the amount of arsenic that might be present in one or more of the brewing materials?—Eventually one would have to trace it down and find the reason. Perhaps he would stop the beer going out, which is what you want to do.

10078. But it might have been consumed?—It would be quite impracticable to test all the beer that is brewed. Therefore you must make it a question of periodic testings.

10079. Do you think that the reference to the local authorities would be a sufficiently speedy manner of dealing with it; you know probably better than I do that the procedure under the Sale of Food and Drugs Act is not quite the most rapid?—I am afraid I could only suggest that someone ought to take the matter in hand, and act as speedily as possible in such a case.

10080. I quite understand that you limit your suggestion to the beer and the wort. Would it not be a further protection if in the same way the materials could be safeguarded?—Undoubtedly, and I have suggested that in order to safeguard those materials you should make it penal to employ any arsenicated acid in the production of the materials used as raw materials.

10081. That would not be the brewery?—No; and that you also make it penal to use gas coke in the preparation of the malt. Then, having those two safeguards, I think the other would be a sufficient one. If you have too many safeguards you will not get them observed. You must make them as simple as you can in dealing with a great industry like this.

10082. Would you not advocate a standard test for raw materials, as regards malt?—As regards malt, I think the Commission might very well pass a certain standard beyond which it should be considered contaminated. But as regards the other materials, I think they ought not to be allowed to contain it at all. It can easily be kept out, and at a very small added expense, and I believe the brewers are perfectly willing to do it.

10083. As regards the prohibition of sulphuric acid containing arsenic, the Board of Inland Revenue could not administer that?—No, they could not do that.

10084. Would you suggest that the local authorities should do it?—I am not quite competent to make suggestions in that direction. I have only given the idea for what it may be worth. I have examined many food products, and I have been surprised at the number in which you do find traces of arsenic, and in medicinal products as well. I think that ought not to be permitted, seeing it could be avoided at a very small cost.

10085. You mentioned certain things that the brewer ought to do: how would you propose to bring home the responsibility in any way to the brewer? I am assuming that you accept the recommendations of the Committee of which you are a member. Have you thought of any way in which those recommendations can be brought home to the brewers in general? You do not think of them, I suppose, as statutory obligations, but you think they should require certificates?—No, it is only a moral obligation on the brewer, knowing there is a danger, to do his best, and I am sure he has done it. I am quite sure that since the brewer knew the danger of contamination by the malt he has adopted either these suggestions or similar ones, with the result that we know to-day.

10086. I do not think you mentioned in the evidence you have given this morning anything connected with the importation of substances intended for use in breweries?—It follows that if the Commission recommend legislation controlling the purity of sulphuric acid and prohibiting the use of gas coke, for instance, imported articles, such as foreign glucose, caramel, and so forth, should be equally pure, as would be produced by the use of materials such as are suggested in this country. Otherwise it would be very unfair to the home producer. I may say that it is no cheaper, as far as my information goes, for a foreign manufacturer of sulphuric acid to purify from arsenic than it would be for an English manufacturer, so that the English manufacturer would not be prejudiced.

10087. Would there be any difficulty in showing that it was intended for the manufacture of food?—I do not think so, because it carries its own definition. Glucose, we know, is intended for food. It would merely be as to what was the interpretation of the term.

10088. (Professor Thorpe.) Has the attempt been made Briquettes, to use anthracite dust in the form of briquettes in malting?—I have seen it done, but I am not sure whether it was anthracite dust or a mixture of anthracite and other dusts; but I know that the use of briquettes is extending somewhat in maltings. It is curious that you should ask me, because I was consulted about it not very long ago.

10089. Are the results favourable? Is there any difficulty in the use of briquettes in maltings?—I would not like to give an opinion yet, because I do not know sufficient about it; the matter has only recently been brought to my notice.

10090. You observe the point of my question, that if the coal were reduced to dust, a fine powder, there would be very much less chance of any considerable quantity of pyrites being mixed with it; it would undergo a preliminary sifting?—Quite so.

10091. And the earthy material which is part of the briquette would also tend to retain, or it might be so arranged to retain, even such quantities of arsenic which escaped the sifting process?—I would not like to give an opinion as to the results that have been obtained at present in that connection. I can only say that I know it has been tried, and as far as I can see and say, the results have been satisfactory.

Mr. A. G. Salomon.

9 May 1902.

## TWENTY-FOURTH DAY.

*Friday, 13th June, 1902.*

AT WESTMINSTER PALACE HOTEL.

PRESENT :

The Right Hon. Lord KELVIN (*Chairman*).

The Right Hon. Sir WILLIAM HAET-DYKE.  
Sir WILLIAM CHURCH.

Professor THORPE.  
Dr. WHITELEGGE.

Dr. BUCHANAN, *Secretary*.

Mr. OTTO HEHNER, re-called; and Examined.

Mr.  
O. Hehner.  
13 June 1902.

10092. (*Chairman*.) I believe you appear here by request of the Royal Commission as the delegate of the Council of the Society of Chemical Industry, and, together with Mr. Alfred Chapman, as one of the delegates of the Council of the Society of Public Analysts?—That is so.

10093. You gave evidence before the Commission about a year ago?—Yes, some time ago.

Report of  
Arsenic Com-  
mittee of  
Societies of  
Pub. Anal.  
and Chem.  
Ind.

10094. Since that time you have been working at the subject in order to be in a position to recommend the best process for the detection and approximate estimation of minute quantities of arsenic?—The Society of Chemical Industry jointly with the Society of Public Analysts appointed a committee for that object, and I was one of that committee, and the chairman of it. When I was here last this committee had been appointed, but no report had been made. Since then a unanimous report has been issued. The Council of the Society of Chemical Industry was asked whether they would ascertain the opinion of those of their members who had tried the process recommended by the committee, but the Council of the Society of Chemical Industry did not see its way to arrange a discussion of the report by the members, as that society has seven separate sections in England, and two in America and Canada. The Society of Public Analysts, however, held a meeting, to which I, as chairman of the London section of the Society of Chemical Industry, invited the members of that society. The Public Analysts' Society sent out circular letters, with certain questions, to their members. Answers have been received, which my colleague, Mr. Alfred Chapman, will put in evidence before the Commission. They also held a meeting to discuss the committee's report.

Meeting and  
discussion  
thereon.

Marsh-Berze-  
lius test re-  
commended.

10095. I understand that the Joint Arsenic Committee unanimously recommended the Marsh-Berzelius process?—They laid down, as minutely as can be done in an analytical process, the conditions under which the best results, in their opinion, are obtained, and they gave some additional information to their members of how, in their opinion, the materials necessary for the test could be best obtained in a state of freedom from arsenic. They found that when pure material (acids and zinc) had once been obtained, this method is the simplest, most rapid, and most certain method in detecting minute traces of arsenic and estimating the amount with very considerable accuracy.

Satisfactory  
zinc.

10096. One great difficulty is to obtain a zinc free from arsenic?—It is a very great difficulty to obtain pure acid and pure zinc, and to maintain them pure.

10097. Is it not an easier matter to obtain pure acid than to obtain pure zinc?—Yes. The zinc can be obtained by electrolytic processes, but such zinc is so pure that it is not well applicable to the test. It will not evolve hydrogen with the acids when it is in a state of great purity. At the same time, we have made experiments with the view to deprive commercial zinc of its arsenic, with some considerable measure of success.

10098. Would not one great difficulty be obviated by doing away with the zinc altogether?—Yes, if it would work, undoubtedly it is the theoretically ideal method.

10099. The electrolytic process simply involves putting the electrolytic generator into the cell in which the substance to be tested is placed. If you take the electrolytic generator to another cell you do away with one great difficulty?—Undoubtedly, but the plain electrolytic method, without a metal which goes into solution like zinc, simply taking platinum electrodes, does not seem to have been attended with any success in the hands of those who have tried it.

10100. If they try again, I think they should succeed. It should be, and in point of fact it is, essentially easier and simpler than the Marsh-Berzelius process?—It may be, but we, as analysts, have to deal not with an ideal process. If the conditions were once really well worked out, so that all the arsenic should be given off in a state of arseniuretted hydrogen, and none deposited or transformed into other substances, it obviously would be the best method.

10101. You have told us that pure zinc constitutes in itself a difficulty because the bubbles will not rise from it. If you laid a piece of platinum upon the zinc, that difficulty would cease, and you could use pure zinc?—No.

10102. You do not get the bubbles to rise from the zinc; but you do from a piece of platinum touching the zinc?—With the very greatest respect, I may say that experiments we have made show that if platinum, for instance, is put on the zinc, the evolution of arsenic is very very far from quantitative. You will presently have, from my friend, Mr. Chapman, some results which have been obtained in that direction. We have found that whenever a metal is added to pure zinc, arsenic free zinc, it retains some of the arsenic.

10103. It would be easy to arrange a pure electrolytic process with wires leading into the cell?—We should be delighted if we could get the information from you as to the exact conditions under which this can be done.

10104. I think the arrangement ought not to present any difficulty. Chemists have not generally followed—perhaps they have no time to follow so great a science besides their own—electrolytic methods; but I think if you try you will find the difficulties may be altogether imaginary?—Chemists are not good enough electricians as a rule to work a process of that kind.

10105. That is a fault easily mended, if it is a fault. There seems no doubt whatever that you have found the Marsh-Berzelius process to be the best?—From a chemical point of view. We have a great difficulty in getting pure materials; but the pure materials having been once obtained and zinc having been proved to be sensitive—we have frequently met with zinc which is far from sensitive, from electric reasons no doubt—the most minute traces of arsenic can be detected and approximately determined in quantity.

Mr.  
O. Hehner.  
13 June 1902.

Question of  
electrolytic  
method of  
applying test.

Zinc.

10106. It seems desirable that zinc should not be put into the cell at all which contains the substance to be examined; that is to say, that the electro-motive part of the apparatus should be in a separate cell?—If your Lordship could give us an idea of how to prevent the separation of arsenic in the elementary state, instead of its being evolved in the form of arseniuretted hydrogen, it would be valuable to us.

10107. There is a distinction, of course. The public analyst of Nottingham has sent to the Commission an account, which is in Dr. Thorpe's hands, of a process which he claims to be successful, in which he has taken advantage of the electro-motive force in the electric light wires; but that is not at all necessary. It should not be possible to fail in carrying out an electrolytic process tried in the simplest possible way?—If your Lordship could tell me how small a quantity of arsenic was discovered I should be obliged. We can all evolve arsine and detect it in that way; but we find that we can detect smaller quantities by the actual chemical method than by the strictly electrolytic method.

10108. The smallest quantity that can be detected by the electrolytic process, I would say, is as small as could be detected by any other process whatever. There is no doubt that, even with the zinc, you can by great precautions get good results by the Marsh-Berzelius test?—We can get excellent results.

10109. You had a meeting of the Society of Public Analysts?—Yes. We held a meeting in order to give the members an opportunity of either adding to our knowledge or criticising the process as laid down, and a great many suggestions were there made as to minutiae of working the process and the purification of materials, but with one eminent exception all the members were agreed that of chemical methods the Marsh-Berzelius was the proper method for this purpose. That exception I lay some stress upon, because it was Dr. Stevenson, who was of opinion that the Reinsch process was good enough for the purpose.

10110. While you were unanimous, with one exception, that the Marsh process is preferable to the Reinsch, one member maintained that the Reinsch had certain advantages?—Yes.

10111. Did he maintain it was the best in all cases, or only in some cases?—He said it was the best process for commercial purposes, but he said that at the same time its limit for beer was 1-50th of a grain per gallon, and that it could not go beyond that. We, however, generally think that 1-50th of a grain and a smaller quantity ought to be easily discoverable.

10112. By the Marsh-Berzelius test it is easily discoverable?—Quite easily.

10113. At this meeting of public analysts it was felt that the Reinsch test was not sufficiently sensitive for practical purposes, and that deposits formed on the copper in many arsenic-free beers might give rise to mistakes in the hands of more or less unskilled operators?—Yes; in many cases a deposit is obtained when there is no arsenic at all, and that has to be identified as arsenic, which is not an easy matter.

10114. On the other hand, you find that the Marsh-Berzelius method can be readily worked, given pure materials, by comparatively unskilled persons?—Yes; the difficulty is to get pure materials. When once obtained, a small amount of experience and skill will enable a man to work it. There is the additional advantage that the arsenic deposit in the tube, however minute, can be very readily identified as arsenic.

10115. Were any slight modifications suggested at the meeting?—Yes; small modifications were suggested.

10116. What did those modifications deal with?—In the first instance, with the purification of the acids required for the testing. We had recommended a method of depending on the volatilisation of arsenic from the acid, and then distilling the remainder, first getting rid of the arsenic from the acid, and then distil the remainder, and thus get it arsenic-free. A good many of our members were of opinion that it was simpler to oxidise the arsenic to the arsenic condition, and then distil, when, in their opinion, arsenic would not distil off, and pure acid would thus be obtained. Experiments show, however, it is quite impossible to boil a solution containing arsenic acid without getting some reduction at the same time.

10117. Were there other modifications, such as cooling the glass tubes?—Yes, with a little piece of blotting-paper and things of that kind; but it has really nothing to do with the method itself.

10118. Did any of these proposed modifications touch the essential principle?—There were small analytical modifications.

10119. And the process as laid down by the committee you consider practical and easily followed?—The process as laid down by the committee, given pure materials, is very easily followed, and gives sufficiently accurate results with a minimum of trouble. We have in the meantime found out that we can purify the acid somewhat more effectually and certainly by a slight modification of the process here laid down. I have also found, in the meantime, that zinc containing arsenic can be readily freed from the arsenic so that it becomes pure.

10120. It seems to you that it is preferable to choose a method that is capable of showing exceedingly minute traces of arsenic, traces much smaller than are likely to do harm to human beings; it is much better to adopt such a method than to adopt a blunt method?—

Yes. Of course it may be of no practical importance to discover the most minute things, because it is not well to create unnecessary alarm. It has been often suggested that a comparatively blunt method like the Reinsch method should be taken, and whatever articles of food do not show arsenic with the Reinsch should be considered to be good enough. Against that I wish to urge this: Supposing the Royal Commission made some limit of some kind, as I suppose will be done, and that later it was found that this limit was unduly severe, then the limit of quantity allowed could be easily altered; or it might be found that more minute traces of arsenic do harm. If we have a blunt method, in ten years' time we shall have no experience whatever of small traces. All our experiments will be wiped out. It is better, I think, to know exactly what there is. I want to get exact results, from which in future times we may be able to draw some really good conclusions.

10121. The intelligent operator ought to have the responsibility of passing or rejecting samples, knowing exactly how much arsenic is present?—I think so. It should not be the method that rejects it; it should be the operator.

10122. You do not think it would be good policy to throw the onus on a comparatively indiscriminate method?—I think it would be better to have a good and delicate method.

10123. Have you seen any reason to change your view that in beer 1-100th of a grain of arsenic as arsenious oxide might be the limit?—Of course, I am not a physiologist, and I can only judge from my chemical experience. I find that very many beers contain now less than 1-100th of a grain per gallon, and that a brewer can with reasonable care manage to get beer with less than 1-100th of a grain per gallon. It might be difficult to work to a much smaller quantity. The malt as now made contains none or so little arsenic that the beer can be readily made with 1-100th of a grain per gallon, or less.

10124. You think that absolute freedom cannot with certainty be obtained?—I think not; it could be often obtained, but not quite certainly.

10125. You would recommend the Marsh-Berzelius process alone; you would not advise alternative processes, the Reinsch process for some cases?—Not for beer and malt, because the quantities we have to deal with there are less than those which the Reinsch process can discover. But in other materials, not to be used in quantities like beer, the Reinsch process might possibly do, because obviously all substances cannot be judged by the same limit.

10126. Confining our attention for the moment to beer and malt, you would dismiss the Reinsch test?—Yes. I would dismiss the Reinsch process absolutely.

10127. But for other materials, other cases of testing, might the Reinsch process have advantages?—I do not know whether it would have advantages. I do not see any advantage in the Reinsch process. Once having pure materials for operation, I can identify a deposit which one believes to be arsenic more certainly by the Marsh process than the Reinsch.

10128. So that while the Reinsch process might in some cases give good results, you would still prefer the

Mr. Marsh process?—I would. There are a good many chemical details which may be worth discussing, and many of these will be referred to by my friend, Mr. Chapman.

O. Hehner.  
13 June 1902.

Pure acid.

10129. Would you now wish to add or alter the method of your committee in any points of detail?—Not the method. I divide this report really into two portions; the one deals with the analytical method, and there I have nothing to add or alter in any way; the second part deals with the preparation of reagents required, and of course that was not really the essence of the method, but was only to make the work easy to our members. Formerly, and, in fact, even now, some members preferred to go about to every chemical dealer, and find acid which is pure or find zinc which is pure, and then lay in a stock, and in that case the preparation of materials does not come into consideration. But we went out of our way to some extent to inform the members of the two societies how, in our opinion, they might obtain pure acid. I have since added a little paper, published in the journal of the Society of Chemical Industry, on the preparation of pure zinc. We have found that sometimes hydrochloric acid cannot be purified by the process laid down here, which depends upon dilution of the hydrochloric acid, the addition of bromine, and the addition of sulphurous acid; that is to say, the addition of hydrobromic acid. Generally, an acid thus treated gives a pure arsenic-free product, but sometimes it refuses to do so, for reasons that we do not understand. But we have found that if the acid is not diluted, it fuming acid is taken and treated with hydrobromic acid, and the first deposits rejected, we have no difficulty in obtaining a perfectly arsenic-free distillate from crude yellow highly arsenical acid. As to the zinc, I would like to add that if arsenical zinc—and some commercial zinc is highly arsenical—is fused, and pieces of sodium are added, and the sodium allowed to oxidise, it takes out the arsenic with it, as magnesia helps to remove the arsenic from iron. It takes out the arsenic in a form I do not know—the quantities are too small to test. If such zinc is poured into any crucible and treated once more to remove the last traces and then granulated, it is found to be perfectly free from arsenic. But great care has to be taken to remove the sodium as completely as possible by oxidation, or otherwise the zinc becomes insensitive, that is to say, it does not show arsenic in minute traces when the arsenic is added to it. Mr. Chapman will tell you that we found the addition of almost any metal lying far away in the electric scale from zinc prevents us getting a delicate result. That is all I have to add to the details given in this report.

Satisfactory zinc.

Delicacy of Arsenic Committee's test.

10130. The committee's method is delicate, to 1-100th of a grain per gallon. Can you say how much less than 1-100th of a grain?—In operating on 20cc. of beer, without destruction of organic matter, one can discover .003 of a grain per gallon, which is 1-300th of a grain per gallon. But if one destroys the organic substances and operates in that case upon a larger quantity, which is quite easy, one can discover a much smaller quantity, according to the quantity operated upon. Without the destruction of organic matter it is not so easy to work upon more than 20 or 30 cc.'s, and then the limit of sensitiveness is about 1-300th of a grain per gallon.

10131. The mere evaporation of two or three volumes of beer down to one volume or less would not destroy the organic matter?—No. The organic matter must be destroyed by agents like nitric or sulphuric acids. All the oxidised matter must be removed and the mineral solution tested.

Destruction of organic matter

10132. What would the effect of destroying the organic matter be?—That one can concentrate a large quantity into a very small bulk, and thus get results of any delicacy one chooses. Beer itself, either in its unconcentrated or concentrated condition froths so much with the evolution of hydrogen in the apparatus that it is difficult in a small apparatus to keep the frothing within bounds. If one takes a larger apparatus it naturally becomes a less sensitive operation. It is a mechanical difficulty.

10133. Does beer always froth in the Marsh-Berzelius test?—Not always. Some of the heavy and very black beers are apt to froth, and the beer has to be introduced quite slowly, so that the froth does not fill the flask. The bulk of beers do not froth.

10134. That really is an objection against concentrating the beer by evaporation?—Yes.

10135. For practical purposes it would be too long a process, but for scientific purposes, and for discovering the minutest trace, beer might be evaporated down to 1-10th of its volume?—Yes, but it would be better to destroy the organic matter, as we have recommended as an alternative in the report, by adding nitric and sulphuric acids and charring all the organic matter, or oxidising the organic matter entirely.

10136. None of the arsenic would be really lost?—None; we have made careful experiments.

10137. Are we to understand that your committee recommends in certain cases the destruction of the organic matter?—Yes. Where we can avoid destruction, for the purpose of simplicity we work without destruction. When any mechanical difficulty presents itself, like frothing, or in connection with yeasts which froth greatly, and destruction is necessary, we have given an alternative process of destruction, and that alternative process allows of the use of as large a quantity of the material as the operator chooses to take.

10138. You may go, in that case, to a greater sensitivity than 1-300th of a grain per gallon?—To a far greater degree of sensitiveness.

10139. Does the mirror report all the arsenic?—I am afraid I cannot answer the question. I know of no method sensitive enough to discover any residual arsenic, but as the mirrors obtained from different minute amounts of arsenic appear proportional in density, there is no reason to think there is any residual arsenic in the flask under proper conditions. In some cases there is, because with so-called insensitive zinc there must be a residuum.

10140. What volume of liquid is used in the Marsh apparatus?—20cc. is, as a rule, sufficient, and 10 is sometimes sufficient. With highly arsenicated beers I have obtained strong mirrors with 1cc. of beer.

10141. In the same apparatus can you use a larger or smaller quantity?—Yes.

10142. Do you get the same mirror from the same quantity of arsenic whether you use 10cc. or 20cc. or 50cc. of liquid?—Within those limits, yes. If I add to the apparatus in which only the zinc and acid is present, a standard solution of arsenic, introducing, we will say, 1-1000th or 1-2000th of a milligramme, I get a mirror which is identical in depth, whether I dilute the standard solution with 10cc. of beer or 20 or 40cc. I do not think, if I used a much larger quantity of dilution, this would be the case, or, at least, a longer time would be required to obtain the same mirror, as obviously there would be less chance of the molecule of arsenic coming into contact with the zinc.

10143. The mirror would be formed more rapidly in one case than in the other?—Yes.

10144. But the ultimate appearance is the same for the same quantity of arsenic?—Yes.

10145. In the case of malt, is all the arsenic removed by digestion at 50 degrees centigrade with hydrochloric acid, as recommended?—I can only answer that in this way. If malt is charred by nitric and sulphuric acid, or if it is extracted with warm acid, the results have been the same.

10146. Supposing it was required to condemn any beer containing arsenic, say, 1-100th of a grain per gallon, would you say that it would be safe for administrative purposes to fix 1-100th of a grain, or should the administrative limit be lower, say, 1-200th of a grain in order that there may be no question about the 1-100th of a grain?—I think that would be rather too great a difference. I do not think if a limit of 1-100th were fixed, anybody should be prosecuted on a quantity so little larger as would lie within the limits of experimental error.

10147. (Sir William Hart-Dyke.) With regard to the possibility of fixing an amount of arsenic which is so infinitesimal as to be harmless to the drinker of beer, you are aware, are you not, that evidence here has been given in favour of rejecting the finished article in any case when there is any arsenic, however small a quantity detected?—Then you had better shut up all the breweries in the kingdom, because no brewer could possibly guarantee every batch of beer brewed by him, whatever care he takes, to be arsenic-free.

Allowance  
for error in  
estimating  
quantity.

Objections to  
guarantee  
based on  
"blunt"  
tests.

10148. That being so, the question of a guarantee is a very difficult one to consider?—Yes.

10149. The guarantee could not be given?—No. Many dealers, maltsters, and so on, have guaranteed their malt to be arsenic-free because blunt tests by their chemists had been applied, which showed it to be free from arsenic; but more delicate tests will often show the presence of arsenic, or by taking a larger quantity for the test it could be discovered. A man would inevitably, under these conditions, get into trouble for giving a guarantee for something he really cannot guarantee.

10150. You think by the constant care in the use of ingredients in brewing, the brewer could give a guarantee as to safety to the public, where he could not give a guarantee as to absolute freedom from arsenic?—Undoubtedly. I do not think a brewer should be always obliged to say to the public that his beer contains arsenic. It would be obviously to his prejudice in the eyes of the ignorant; but that which is below a quantity to be fixed by the Commission should be called quite pure.

10151. In your scheme of analysis you reject altogether what you consider is a blunt method?—Yes.

10152. The blunt method being a method which stops at the discovery of a certain quantity?—Yes.

10153. And is practically useless beyond that?—It would be misleading, and it is misleading the brewer and the maltster.

10154. You rather hold out, do you not, the possibility of allowing considerable discretion to the analyst in the selection of samples? You say that the intelligent operator ought to have the responsibility of passing or rejecting samples, knowing exactly how much arsenic is present. Would you develop that a little, and just say what is running in your mind?—It seems to me that, telling the blunt test, is like an ostrich putting its head into the sand; it does not want to see a certain thing, and, therefore, does not see it. I think the analyst ought to know how much there is. If a limit is fixed, say, 1-100th of a grain, and the analyst finds, say, something less, he naturally would pass it. The responsibility ought to be put upon him to say whether a beer complies with the requirements of the Commission. Supposing he finds a trifle more than 1-100th of a grain, within limits of experimental error, I think he ought to have the responsibility of passing that beer. He must know himself how near he can work the method. In any case, we ought to know how much arsenic there is.

10155. Assuming this Commission did not take the responsibility of laying down what was the precise quantity of arsenic that might prove injurious to health, would you suggest that some department of the State should do it—the Local Government Board, for instance?—Certainly. I think it is most urgently required that a limit should be laid down below which articles like beer should be considered pure. It should not be left to the individual officer, otherwise the traders and brewers will be continually harassed and worried.

10156. And the analyst of the future would work, according to your suggestion, with that fixed quantity before his mind's eye in making his report?—Yes.

10157. Putting samples on one side that are dangerous, and on the other side those which according to the standard are innocuous?—Yes, innocuous according to the law. Obviously you cannot leave that to the individual. Why should I, as public analyst, have the responsibility of condemning a sample on any particular quantity? My brother analysts might think me unreasonably severe or unreasonably lenient, and would appear as witnesses against me, and no case could be carried unless it was one of a gross description.

10158. In regard to fixing the precise quantity that would prove innocuous, whether to health or life, of course some dependence must be placed on the amount of beer that is consumed by any one individual. Is it not possible that in the case of a moderate drinker who only drank a moderate amount of beer during the day, an amount demanded by the work he was doing, it might be perfectly innocuous for him to take beer with a certain amount of arsenic in it, while to a regular toper, a man who drank large quantities a day, it might produce disease?—Yes, undoubtedly it would;

but I think the toper is just as much entitled to the protection of the State as the moderate man, and whatever limit is laid down, it should take into account, I will not say the most extreme cases, but most cases reasonably likely to occur.

10159. You think your minimum should secure the moderate drinker as well as the other?—It is really a medical question of what ought to be the minimum—a question of evidence as to what quantity has been known to produce ill effects. I am not a medical man, and cannot judge of that.

10160. You are still of opinion, are you not, that if we endeavour, by any suggestion we make, to secure absolute freedom from all arsenic in beer, we shall be beer from endeavouring to carry out what is entirely impossible?—You will be doing something absolutely impossible. In our state of civilisation, where coal is burnt—and all coal is arsenical—more or less arsenic must be everywhere. In every particle of coal-dust and ashes that fly about there is a trace of arsenic. How can you say that anything whatever can be absolutely free from arsenic? It is not possible.

10160\*. You think, within proper limits, we can get complete security?—I think so.

10161. (Sir William Church.) You said that one of the reasons why you thought anything of the nature of a blunt test should be rejected in favour of a more delicate one was the obtaining of results for comparison hereafter. Would you mind just developing that a little?—Supposing for the present the evidence is that beer with 1-100th of a grain per gallon is innocuous; but assuming at the same time it should be some day proved that a beer or a food with a less quantity has produced injurious effects, or might have something to do, as has been suggested, with certain diseases other than arsenical neuritis, then we would have no evidence whatever; whilst if we knew exactly, and had the means of ascertaining, how much beer does contain, and we had statistics at hand, I think we should have an accumulation of valuable material. Supposing that it should be found some day that 1-1000th of a grain has done some harm—

10162. That is what I gathered; but how would you suggest that these statistics should be obtained?—The analyst has his record of all analyses made; every brewer has a chemist, who knows exactly how much arsenic is in the materials.

10163. And those records should be kept by whom?—They are kept by every individual who makes the test, by the brewer, if you like. As a matter of fact, his books are available.

10164. If in the future, for instance, a question arose as to the wholesomeness of any particular beer from any particular brewery, you would be able, by consulting these books, to see whether that beer had 1-100th of a grain per gallon or 1-300th of a grain. In other words, you would have the brewer's chemist keep, not only a record of whether he has passed the beer as safe, but you would have a record of the actual quantity he found?—Quite so. I do not suggest for a moment that the brewer should be obliged to do it. Every reasonable and careful brewer does do that now. There should be no enactment about it.

10165. It comes to this—that the analysis should always indicate the amount of arsenic that the analytical chemist found present in any specimen of beer?—Yes.

10166. Not that he merely passes it as having less than 1-100th of a grain?—Quite so.

10167. (Professor Thorpe.) Two or three gentlemen who have appeared before us recently have impressed upon the Commission the desirability of prescribing for the use of the practical man, who need not necessarily have any chemical knowledge, a test which should safeguard him against using impure materials. Assuming the Commission saw the desirability of prescribing such a test, do you think that the Berzelius-Marsh test is a test which could be worked by a person of that order?—He must have some education and some drilling. I would rather that he should use the Marsh-Berzelius than the Reinsch, because he has to actually produce arsenic in a tube, and you can easily verify it; whilst he would require a large amount of judgment in ascertaining whether a certain piece of copper which has a deposit has its colour from arsenic or from other matter. I see no difficulty in

training a man in a works or brewery or malt-house to test the materials by the Marsh-Berzelius method, given pure materials.

10168. You think it does not demand a knowledge of chemical manipulative processes, and is not so recon-  
dite a process that an intelligent youth could not be trained to use it?—I think in a day, or two days, I would train any intelligent youth to do it.

Beer with  
less than  
1-100th grain  
easily obtain-  
able.

10169. You have had a very considerable experience in the analysis of beers?—Not quite so much of late. Do you mean as to arsenic?

10170. Yes?—I have tested a great many.

10171. I think you told us that in recent time your experience was that beer was gradually getting, I will not say arsenic-free, but that the arsenic was in extremely minute amounts?—Yes.

10172. That is the general average character of the beer, so far as you know, which is being produced?—Yes; beer and malt.

10173. The beer which has come under your hands is beer of that character?—Yes.

10174. You are rather guided, I understand, in your fixing of such a minimum amount as 1-100th of a grain by the circumstance that it is within your own experience that beers are regularly produced with even less quantities than that?—Yes.

10175. And, therefore, it would appear there is no practical difficulty to a brewer nowadays in insuring that degree of purity?—I believe not. I find all the beers now have that quantity, or a less. I do not know whether a larger amount may not be quite permissible; but I know practically this is a limit to which the brewer can work.

10176. Obviously there is no reason why, if such a limit can be secured with a reasonable degree of care, that limit should be raised?—I do not see any reason.

10177. No hardship is inflicted upon anybody?—We do not want to permit him to be slovenly, or say that he shall do anything which is not practical. And therefore I suggest a limit which I know can be practically reached.

10178. Is it those ideas which have led you to suggest the limit of 1-100th of a grain?—Yes; and one other—that the smallest quantity of arsenic which has been in beer to which injurious effects have been rightly or wrongly attributed was, I think, double the quantity. Therefore I think from that point of view I would be on the safe side.

Object of  
destroying  
organic  
matter.

10179. I think you told us on the last occasion you appeared here, that in your opinion the mere presence of the organic matter in the beer does not necessarily interfere with the recognition of the arsenic in beer?—No. In most cases the tests made, with and without destruction of the organic matter, give the same results, not in all.

10180. As a rule, the presence of the organic matter does not inhibit, as it were, the manifestation of the arsenic test?—No, it does not.

10181. And your only reason, therefore, in destroying the organic matter, in the case of having to take large quantities of beer, is not because the organic matter inhibited the formation of the arseniuretted hydrogen, but it was an inconvenient thing to have in the apparatus?—Yes; that is one reason.

Should be  
done if sul-  
phuric acid is  
used.

10182. It rendered the solution, I understand, vis-  
cous, and difficult to deal with?—Yes; there is a difference in the working of the process without destruction of organic matter, according to whether you use hydrochloric acid or sulphuric acid. When you use sulphuric acid it is better to destroy the organic matter.

10183. In the method prescribed by the Committee, does the examination of wort show any difficulty?—No.

10184. As you prepare your worts they are strongly acidulated, are not they?—I do not think so. We have made worts from sugar solutions, and so on, for testing.

10185. I am talking rather of malt worts?—I have not any experience of malt worts taken from the brewery. I believe my friend Mr. Chapman will have experience of that.

10186. (Dr. Whitelegge.) Do you think of 1-100th of a grain per gallon as being a standard for the guidance of the analyst or as the legal standard?—As a legal standard by which the analyst would have to be guided.

10187. You say that the intelligent operator ought to have the responsibility of passing or rejecting samples, knowing exactly how much arsenic is present. If the standard was fixed at 1-100th of a grain do you contemplate any further discretion for him than saying whether there was more or less than 1-100th?—I think so.

10188. What would that further discretion be?—I would myself not like to report against anything which is so little larger than 1-100th as to lie within the limits of experimental error.

10189. If you find 1-90th?—I would almost certainly, whatever the law might say, pass it. I would probably say 1-90th is so near to 1-100th that in my second experiment I might find 1-95th or 1-105th. Whatever limit the Commission or the law lays down, the operating analyst must have some discretion.

10190. Is it not the practice of analysts in giving certificates to local authorities to have some margin of that kind?—Plainly.

10191. The "discretion" only amounts to this, that you would not think it right to prosecute on anything only slightly exceeding a given standard, partly because it is so near, and also by reason of the experimental error which has to be taken into account?—Quite so.

10192. So that if we find 1-100th of a grain the lowest amount to be regarded as toxic, we must fix our legal standard at something considerably higher, must not we?—Do you mean more severe?

10193. Yes?—It would be a small matter. Whatever limit you may lay down, there will be some discretion of that kind. The 1-100th is so severe, I think, that you might well allow a small divergence from that.

10194. I only want to be clear that in practice it would not work out as a rigid exclusion of all beer containing as much as 1-100th?—I do not think it ought to, not for prosecution. Exclusion means, of course, criminal prosecution, I take it, and I would not like to take that responsibility. I would rather use this as a guide to the brewer, telling him he must work down to 1-100th, but I would not wish to clap him into gaol.

10195. You suggest that the analysts must decide whether the margin is or is not of that kind?—He has naturally nothing to do with the prosecutions, but supposing I found 1-90th, straining the regulations to some extent, I might report that as containing 1-100th. The Police Committee, or whoever it is who has to deal with those cases, decides what excess shall subject the offender to a prosecution.

10196. Do you adopt a practice of that kind in dealing with other foods?—Yes, certainly; there is a limit fixed by law for the strength of spirits, 25 per cent. under proof. If I find it 25.3 under proof, without any scruple whatever, I report that as being 25 under proof. It is so near to the limit of error that there would be no object served in straining the law in that way. A limit has been laid down by the Board of Agriculture as to the amount of water in butter, 16 per cent., a reasonable limit. If I find 16.1 or 16.2 I should not say a word about it.

10197. In what terms would you report in such a case?—That it complies with the law.

10198. Is that the practice amongst the analysts generally?—I believe so.

10199. Is there any understanding amongst public analysts as to the extent to which that discretion goes?—No.

10200. If that is the practice, does it need any special authority in the case of the suggested standard for beer?—No.

10201. If it is already the existing practice as regards water in butter, for example?—I do not know that it is an understood practice. I think every man who has to deal with a practical problem must allow some latitude for variation.

10202. In practice I agree with you that some such latitude is always allowed, and in my experience it has been allowed by the local authority and their legal advisers?—Supposing I found 16.01 or 16.001 of water in butter,

Mr.  
O. Hecker.  
13 June 1902.  
Analysts may  
allow margin  
in estimate.

and pass  
slight in-  
fringement  
of standard.

Mr.  
O. Hehner.

13 June 1902.

Organic  
matter of  
stale beer  
should be  
destroyed.

or as many O's as you like, would I, as the adviser of the local authority be justified in condemning such a sample, or would I be justified in expecting discretion from the local authority to know what all those O's mean? I, as an intelligent officer, must take the responsibility, and I do take that responsibility upon myself.

10203. I do not think we need discuss it in detail, but I suggest to you that there is an alternative, that instead of saying that it is within the standard limit, it would be possible to give the precise result as you found it with any advice to the local authority that might be proper, verbal or written advice?—Verbal and written advice is often resented by local authorities. They say it is my business to report. If it is a question of a slight deviation from the thing the labour involved would be great. I should have to make many tests instead of one, two, or three, on the average; I should have to go to endless trouble for no object whatever. If you said that 1-100th should be the limit, the officer must have some discretionary limit.

10204. He must read the 1-100th as meaning possibly 1-90th?—He must know best how near he can estimate it. Probably two men would have a different colorimetric limit of error. All these determinations, like the estimation of ammonia in water, are only correct, say, to 10 per cent.

10205. Then the decision of the analyst in regard to a given result, showing an apparent excess over the local standard, would depend upon his estimate of the accuracy of his own manipulation of that particular process?—Yes, every colorimetric process is so.

10206. Do the local authorities from whom you received samples continue to send you samples of beer now?—No, I do not think they do.

10207. You say very few now?—Very few from the local authorities.

10208. You told us when you were last here that you had met with arsenic in some other food substances?—Yes, quite lately I met arsenic in small quantities in sugar which had not been treated with acid at all. I have also met it in German beet sugar which had been obviously not treated with acid. These sugars are recovered from the lime or strontia compounds by carbonic acid, and if the carbonic acid is obtained from fuel which is arsenical, the sugar becomes arsenical. The sugar used for brewing or treacle making thus becomes slightly arsenical.

10209. Could you say how much was found in these samples of sugar?—I would not like to be definite, but it was about 1-100th of a grain per lb. I will look it up.

10210. Can you mention any other substances besides sugar in which you have lately found arsenic?—No, I cannot; in a good many mineral colours which go into confectionery I found it in some cases. I have lately found it in oxide of manganese, which is used for the same purpose.

10211. In considerable amount?—Yes, 1-10th of a gramme gave a very dense mirror.

Mr. ALFRED C. CHAPMAN, called; and Examined.

10226. (Chairman.) You are an analytical and consulting chemist practising in the City of London, a Fellow of the Institute of Chemistry, and one of the hon. secretaries of the Society of Public Analysts?—Yes.

10227. You formerly occupied for several years a position of senior Demonstrator of Applied Chemistry at University College, London; you are also a Fellow of the Chemical Societies of London and Berlin, and a member of various technical societies and institutes; you hold the position of analyst and scientific adviser to a number of well-known breweries in this country, and have for a period of more than 15 years devoted a very considerable amount of study and attention to brewing and the allied industries, both in their practical and in their scientific aspects?—That is so.

10228. In conjunction with Mr. Hehner, you represent the Society of Public Analysts before this Commission?—Yes, that is so. At the beginning of May, 1902, a letter was received from the Secretary to the Royal Commission, asking for information in regard to the

10212. With regard to the destruction of organic matter, I am not quite clear whether as regards beer you recommend that the organic matter should be destroyed if hydrochloric acid be used instead of sulphuric acid?—Not in fresh beer.

10213. You leave that as an alternative to the discretion of the analyst?—Yes.

10214. You do not find it makes any difference in practice?—Not when operating on fresh beer. If the beer gets very stale sometimes the arsenic does not seem to evolve in direct testing. Some time ago I tested a sample of beer which had been made up for the purpose of testing by the committee, and I could not find any arsenic after it had been some months old by direct testing, whilst my friend, Mr. Chapman, destroyed the organic matter of the same sample, and found what had been added. The arsenic had not gone as I had suspected.

10215. Was there frothing?—I do not think so.

10216. The destruction of the organic matter had another object in that case than the prevention of frothing?—Yes. It has an object in some cases when there is frothing; or if the direct marshing is impossible, you have to destroy it.

10217. But there are other reasons I understand?—If a beer had to be kept for some length of time for the purpose of a law case or a prosecution, I would destroy its organic matter if it has become a month or so old.

10218. As a matter of routine, frothing or no frothing?—Yes.

10219. (Professor Thorpe.) That is on account of the presence of possible moulds in the beer?—Quite so. I do not know what the explanation is. At that time I thought that the arsenic absolutely went away on keeping the beer, but I have no reason to think it does now. It becomes converted into a form which is not amenable to the test.

10220. (Dr. Whitelegge.) If due entirely to the action of a mould that would mean some volatilisation?—Not necessarily; only certain moulds evolve volatile arsenical compounds which have a powerful smell. I did not observe any such smell. I imagine that arsenic goes into an organic form, replaces a trace of the phosphorous, etc., in which it would not be discoverable without destruction.

10221. (Professor Thorpe.) In other words, I presume you mean that the mould secretes the arsenic very much as the yeast does?—Quite so—not secretes, assimilates it.

10222. I mean assimilates it?—Yes.

10223. Withdraws it from solution?—Yes.

10224. (Dr. Whitelegge.) You suggest that it not only withdraws it from solution, but converts it into organic forms?—I think so.

10225. So that you do not think of the oxidation of the organic matter as merely causing destruction of the yeast substance or the mould substance which hides the arsenic?—That might be one of the reasons, but it would also break down any organic arsenic compound, if there be any.

extent to which the method prescribed by the Joint Committee of the Society of Chemical Industry and of the Society of Public Analysts had been adopted, and with what results. For the purpose of obtaining this information, the Secretaries of the Society of Public Analysts were instructed to address a circular letter to all the members of the society, and on May 7th such a letter was sent out in the following terms:

Dear Sir,

The Secretary of the Royal Commission on Arsenical Poisoning has expressed the desire of the Commission to know to what extent the method of testing for, and estimating minute traces of, arsenic prescribed by the Joint Committee of the Society of Chemical Industry and of the Society of Public Analysts has been adopted, and with what results. We should feel obliged, therefore, if you would reply concisely and briefly to the questions contained on the appended slip, returning the same to us in the enclosed envelope at your earliest convenience.

Mr. A. C.  
Chapman.

Opinions of  
members  
obtained.

Mr. A. C.  
Chapman.  
13 June 1902.

A meeting of the society will be held on Wednesday, May 21st, at eight o'clock, at the Chemical Society's rooms, Burlington House, to discuss the details of the report, and it is hoped that you may find it convenient to be present.

We are, Dear Sir,

Yours faithfully,

EDWARD J. BEVAN } Hon. Secs.  
ALFRED C. CHAPMAN }

The questions alluded to in this letter were four in number, and were as follows:

- (1) Have you used this method, and if so, to what extent?
- (2) Have you found it advantageous, and do you consider it preferable to other methods?
- (3) Have you met with any, and if so, what, difficulties?
- (4) Have you any suggestions to offer with regard to the better working of the method?

Replies  
analysed.

To this letter 145 replies have been received. Below I give an analysis of these replies, which I think will supply the Commission with the information for which they have asked.

Total number of replies received	-	-	-	145
(a) Have not tried the method	-	-	-	55
(b) Have tried the method to a very limited extent, and do not care to express an opinion	-	-	-	12
(c) Prefer it to other methods, and are quite satisfied with it. Have experienced no particular difficulties, and make no suggestions	-	-	-	34
(d) Have tried the method, and consider it the best. Have met with difficulties, but do not make any suggestions	-	-	-	19
(e) Have tried the method, consider it the best, but suggest slight modifications of procedure	-	-	-	16
(f) Do not consider it preferable to other methods	-	-	-	6
(g) Doubtful	-	-	-	3
				- 145

In reference to (a) it must be remembered that very many of our members are engaged in work (e.g., metallurgical, mineral analysis, etc.) which does not render it necessary for them to test for minute traces of arsenic. This also, doubtless, accounts for the fact that a larger number of replies have not been received.

In regard to (c) I may add that of the 34, 16 tried the method extensively, 14 to a limited extent, while 4 give no information on this point.

Suggestions  
made.

The most common difficulty which those included under (d) have experienced has been that of obtaining pure acids and pure and sensitive zinc. Several, however, refer to the difficulty of obtaining uniform mirrors as well as the frothing in the case of certain organic liquids.

The suggestions made by the 16 members included in class (e) are, as a rule, of a very trivial character, and do not amount to anything more than a preference for a vertical to a horizontal chloride of calcium tube, to cotton-wool soaked in lead acetate solution rather than paper, or to some particular means for regulating the heating of the "combustion" tube. One member prefers an electrolytic method for the production of hydrogen, and a few others suggest the addition of cuprous chloride, a trace of a ferric salt, or a few drops of copper sulphate or of platinum chloride. In regard to the use of solutions of certain metallic salts for the purpose of facilitating the evolution of hydrogen, I may say that I have made a few experiments which I think throw light upon the retention of arsenic, which is generally recognised to result from this practice. These are briefly referred to below.

Objectors.

Of the members who are unfavourable, one prefers a modification of Gutzeit's method, one prefers his own modification of the Marsh-Berzelius method (which does not appear to differ in any essential point from that suggested by the joint committee), one condemns it in general terms, but adds that "in certain cases it is the best available method," whilst a fourth prefers Reinsch's method for qualitative work, and suggests

that "a standard gravimetric process should be substituted" for the Committee method. One member gives no reason for his objection to the process, whilst the sixth member says, "My slight experience leads me to prefer other methods," a preference which appears to be due to his difficulty in obtaining comparable mirrors. From the above analysis it will be seen that out of 75 members of the society who have had sufficient experience of the method to justify them in expressing an opinion, 69 (or 92 per cent.) consider it superior to other methods for the detection and estimation of minute traces of arsenic.

10229. You tell us that one member preferred an electrolytic method for the production of hydrogen? —Yes; and that is the gentleman to whom reference has been already made, the public analyst for Nottingham.

Mr. A. C.  
Chapman.  
13 June 1902.

10230. Have you examined his process?—I have not examined his process precisely as he carries it out, but I have made a number of experiments in connection with electrolytic methods, and my results have not been satisfactory.

10231. The public analyst in Nottingham did get satisfactory results?—So I presume; but I do not know to what extent he was able to detect traces of arsenic. I do not know what minute quantities he could detect, and with what degree of certainty. In fact, I have had no detailed account of the process as he carries it out, nor of his results.

10232. A slight account of his process has been handed to the Commission, and he considers it quite satisfactory; but he has not given any details as to the degree of minuteness to which the method is applicable. That method, if successful, has the great advantage of doing away with the zinc?—Doubtless.

10233. And also of being very simple—a much simpler affair in the cell containing the substance?—Possibly.

10234. And, if successful, less liable to error through uncertainty in respect to the zinc?—Quite so; but, of course, other errors may come in in that case, due to slight differences of conditions. It might be more difficult with a purely electrolytic method to regulate the conditions within the narrow limits found to be necessary for the success of the process. I can only speak from my own experiments, which have not been very numerous, but have not been very successful.

10235. It might be difficult, but it is possible that it might be ultimately found easy to regulate? It is quite possible.

10236. Your colleague, Mr. Hehner, had dealt, in his evidence, with various questions of analytical procedure about which we desired information. You have yourself made some experiments throwing some light on the question of the insensitiveness of certain samples of zinc?—I have. I was not the first to whom this occurred. It has been suggested a great many times that the question of the insensitiveness of zinc might be possibly due to the presence in the zinc of certain elements far removed from zinc, in the electro-chemical series, which might give rise to currents, which would be sufficient to cause the deposition of elementary arsenic, rather than its evolution, in the form of arseniuretted hydrogen. In order to ascertain whether there was, in fact, any foundation for this, or whether it could be experimentally demonstrated, I took some zinc which was highly sensitive—that is to say, which would with absolute certainty and ease show 1-500th of a milligramme of arsenious oxide—and spotted this sensitive zinc in places with metallic platinum by putting on platinum salt, or metallic silver, or metallic copper. I found that when the Marsh-Berzelius process was used with the spotted zinc, instead of the ordinary zinc, there was a reduction in the amount of arsenic obtained. The spotted zinc gave in each case appreciably smaller mirrors. I am not prepared to say the explanation I have suggested is the exact one, but, at any rate, those are the actual facts, and I think they are suggestive. I may just show you the tubes which illustrate that point. The first four were made with 1-200th of a milligramme, and the last three with 1-500th, and in that case you see the platinum has kept the whole of it back, while the copper has kept back very nearly the whole of it.

10237. In what quantity?—In about 30 or 40 cubic centimetres of liquid in the Marsh flask.

A. C. 10238. What would the 1-200th of a milligramme correspond to in respect to grains per gallon? In four cases you had 1-200th of a milligramme present in the solution?—Yes.

10239. How many cubic centimetres of solution in those cases?—About 40 cubic centimetres altogether—the total liquid in the flask.

10240. In the three cases of 1-500th of a milligramme, did you have about the same quantity of liquid?—Yes, about 40 or 50 cubic centimetres.

10241. Did you measure the quantity accurately?—No; it was about 50 cubic centimetres.

10242. The zinc spotted with platinum gives, perhaps, a rather fainter mirror compared with zinc spotted with silver?—Yes, less arsenic came out than with silver.

10243. When the zinc was spotted with copper the mirror was slightly stronger than when spotted with silver?—Possibly; but that, of course, would be probably within the limits of experimental error.

10244. You would scarcely reckon it a difference?—I should be scarcely inclined to call that a difference.

10245. Then the unspotted zinc gave a slightly stronger mirror than the others?—Yes.

10246. Those were all with 1-200th of a milligramme?—Yes.

10247. Now take the three cases of 1-500th of a milligramme. The zinc spotted with platinum and the zinc spotted with copper gave nearly equal mirrors?—This light is not very good, but I think you will find that the platinum-spotted mirror is less than the copper.

10248. The mirror produced when the zinc was spotted with platinum is very slightly stronger than when it was spotted with copper?—The top one is the platinum one, which is very nearly free—there is scarcely any mirror there.

on of  
e  
ay in-  
usi-  
s.  
10249. With unspotted zinc the mirror was stronger than either of the others?—Yes. May I be allowed to say one thing in reference to this, that the point of these experiments is rather to show the inadvisability of adopting the suggestion made by a few of our members who replied to our questions. It shows the inadvisability of adding either platinum chloride or copper sulphate or any other metallic salt to the Marsh flask for the purpose of increasing the evolution of the gas.

10250. I ventured to make the same suggestion to Mr. Hehner, and he gave an answer quite conformable to the effect you have mentioned. The behaviour of some samples of arsenic-free zinc seems to be capricious and uncertain?—That is so. I venture to think, possibly, that these experiments throw some light upon that behaviour.

10251. You think that these experiments show that the capriciousness may have been due to the presence of metallic and other impurities in the zinc?—I do.

10252. Do you think that those agents, setting up powerful galvanic currents locally, might suffice to cause arsenic to be deposited from solution in an elementary condition?—I think it possible.

10253. You are afraid that the pure electrolytic process, such as the public analyst at Nottingham followed, might be liable to that fault?—I think it quite likely.

10254. Did he give some evidence before your committee?—He was one of our members who replied to the circular letter which we sent out asking for information.

10255. Has his method been considered by the committee?—We have had no evidence with regard to his method put before us.

10256. He sent a mirror with the description of his method. You would consider that his method ought to be carefully examined and repeated?—Yes.

10257. It would be right to examine into it?—Most emphatically.

10258. And to repeat it, and find whether it does give the full strength of mirror that can be had by the zinc process?—Most certainly it ought to be inquired into.

10259. If it gives as strong a mirror with the same quantity of arsenic in the substance as the zinc process gives, then you would think it might be considered for adoption in preference to the zinc process?—Precisely, unless it happened to be much more laborious in execution.

10260. What proportion of public analysts are members of the Society of Public Analysts?—I cannot give you the exact number; but we have about 300 members, and of those 300 about 88, I believe, are public analysts.

10261. I see that out of 145 asked, 55 have not tried the method, and 12 have tried the method to a very limited extent, and do not care to express an opinion. Do these small numbers that have had experience with the method mean that public analysts largely use other methods, or does it mean that they are not getting beer to test?—I cannot answer that definitely; but I presume it means they are not getting beer to test. I think my friend, Mr. Hehner, gave some evidence on that point—that probably public analysts are not receiving so many samples now as formerly.

10262. What is your practice with regard to the destruction of organic matter?—I destroy the organic matter in all cases.

10263. Both in beer and in malt?—Both in beer and in malt.

10264. If you did not destroy the organic matter, would the Marsh process not work well?—No. I am accustomed to use sulphuric acid, and when using sulphuric acid the presence of organic matter does most certainly, as Mr. Hehner has said, prevent some of the arsenic from being obtained. It keeps it back.

10265. Then the sulphuric acid that you use in the process would not be sufficient to destroy the organic matter?—No; that is destroyed, first of all, by treatment with strong sulphuric acid and nitric acid.

10266. If the organic matter is not destroyed the Marsh-Berzelius test would be still applicable, but liable not to give such good results?—With sulphuric acid I should say it would not be applicable at all in very many cases. With hydrochloric acid, yes, in many cases.

10267. Where would the failure be?—The arsenic would not come out. I am speaking, of course, of very minute quantities.

10268. You consider that these very minute quantities are forcibly held by the organic compound, and do not come out in response to the Marsh test?—I do not know what the explanation is, but it certainly is a fact that using sulphuric acid in the presence of organic matter one does not get by any means the whole of the arsenic. In some cases one gets a very small proportion of it.

10269. But if the organic compounds are all thoroughly broken down, then the arsenic does respond to the Marsh test?—Yes.

10270. Do you know whether it is usual with analysts generally who use the Reinsch test to break down the organic matter, or do they not destroy the organic matter?—I cannot say what is the usual practice. I used the Reinsch method extensively at the time of the Manchester outbreak, and I did not destroy the organic matter. I Reinsched the beer directly.

10271. With the Reinsch it is not so necessary to destroy the organic matter?—I believe not. I think I should be right in saying that.

10272. As a brewer's chemist, you accept the committee's method as a good one?—Most certainly I do.

10273. But you would not be unwilling to see it improved, if a purely electrolytic method could improve it?—I should rejoice to see any improvement.

10274. What limit do you find it practicable to work to in respect of the quantity of arsenic per gallon?—In the case of beer I should say one could certainly detect 1-400th of a grain per gallon without working on an unduly large quantity.

10275. (Dr. Whitelegge.) Is that without concentration?—No, in this case it is concentrated. I should destroy the organic matter, and have a smaller volume of liquid.

Mr. A. C. Chapman.

13 June 1902.

Destroys organic matter both in beer and malt.

Uses sulphuric acid.

As brewer's chemist, accepts Committee's test.

Its delicacy.

Mr. A. C.  
Chapman.

13 June 1902.

Beer usually  
contains  
much less  
than 1-200th  
grain.

Official limit  
of 1-100th  
practicable  
for brewer.

Malt usually  
less than  
1-300th.

Glucose less  
than 1-300th

Official limit  
should be  
imposed on  
product, not  
on ingre-  
dients.

Replies from  
Society.

10276. (Chairman.) As advised by you, our brewers produce uniformly beer under 1-200th of a grain of arsenic per gallon?—I should say yes.

10277. You can so arrange with brewers that you advise that the beer shall not contain more than 1-200th of a grain per gallon?—I can say that of the very large proportion of the samples of beer submitted to me by private clients, the very great majority do not contain anything like 1-200th of a grain per gallon, but much less.

10278. Do you think a regulation that a beer shall not contain more than 1-200th of a grain per gallon would be workable, as a rule?—I think that would err on the side of being too severe.

10279. Would you think that a condition of not more than 1-100th of a grain per gallon would be too severe?—Not by any means.

10280. Would it be sufficiently severe?—That is purely a medical question. So far as the analytical procedure is concerned, it would not by any means be severe, nor as regards brewing practice would it be too severe. I cannot answer with regard to its possible effect on health.

10281. It would not be advisable from the brewers point of view to make the limit as far as 1-200th?—No.

10282. What minimum of impurity can you secure in the case of malt?—I had perhaps better answer that question by giving my own personal experience of the samples of malt submitted to me by maltsters. I should say that the very large majority contain less than 1-300th of a grain per lb. even now.

10283. Would you say, as Mr. Hehner said, that malt might be secured in practice with no more than 1-500th of a grain per lb.?—Yes. My own experience confirms that. I think Mr. Hehner was quite right.

10284. And that would not be too severe a regulation in respect to malt?—I think not.

10285. Do you ever find arsenic in glucose or invert sugar now?—In invert sugar very rarely indeed; in glucose occasionally in imported samples.

10286. How much do you sometimes find in glucose now?—As much as and not more than about 1-300th of a grain to the lb.

10287. Do you think that glucose might properly be required to contain not more than 1-300th of a grain per lb.?—Most certainly. 95 out of a 100 probably contain a great deal less than that.

10288. It would be quite a practicable and tolerable limit to say that glucose must not be used if it contains more than 1-300th of a grain per lb.?—I think so.

10289. Do you regard the purchase of malt and fuel on a guarantee that it does not contain more than a standard limit of arsenic to be a practicable and satisfactory proposal?—Provided a reasonable limit was adopted, I think it would be—I mean by that, providing the limit is not too severe.

10290. (Sir William Church.) Following up what Lord Kelvin has been just asking, are you in favour of having standards of purity for the materials from which beer is brewed, or only for the finished product?—I think it would be much simpler and more satisfactory if a limit were formally fixed for the finished product and not for the constituent materials.

10291. And that you think would be a perfectly sufficient safeguard for the public, and you would leave it to the brewer to see that he used pure materials?—Certainly.

10292. Without having any standard laid down by law?—Certainly.

10293. Might I ask you how many circulars you sent out?—We sent circulars to all the members of the society, about 300.

10294. I see you have received answers, pretty complete answers from 34, and from 19 who have also used it, and from 16 and 6—that amounts to 75. You say you think roughly from 80 to 90 of your members are public analysts?—That is so.

10295. So that probably you have received answers from 60 or 70 of your members who are engaged as public analysts?—Probably.

10296. Of course the large number of 55 who have not tried the method are probably men who are engaged in mineralogical and other work which has nothing to do with the production of beer?—Quite so.

10297. And probably they have not been in the habit of testing these organic substances for arsenic?—That is probably the explanation.

10298. So that we may take it really that the 75 answers you have received express pretty fully the views of those of your members who are engaged in public analytical work?—I think so.

10299. (Professor Thorpe.) I should like to have in some greater detail the experiments you made as to the effect of adding copper and platinum and silver?—May I tell you exactly what I did. I took the ordinary Marsh apparatus such as is described in the Report, and I then took some zinc, which I knew to be sensitive, which I knew whenever I added 1-500th of a milligramme of arsenious oxide would always produce a mirror which corresponded with that, and, therefore, the zinc did not retain any of the arsenic. I took some of the same zinc, and the same quantity, and put on to that with a sharp pointed rod very minute drops of some copper salt, or silver salt or platinum salt, and so got minute spots of the metal on the surface of the zinc. That was thoroughly washed and employed in another test precisely similar to the one that gave the 1-500th. Those tubes, which I think you have seen, show the amounts of arsenic, the depth of the mirror obtained, working with the zinc so spotted. Whereas 1-500th of a grain came out fully when nothing had been done to the zinc, when the zinc had been spotted with these metals less than 1-500th came out. Platinum exercised a greater inhibitory effect, and retained more of the arsenic than silver or copper. So noticeable is it that in the case of the 1-500th nothing came out at all with platinum. It was virtually blank.

10300. I think you gave us an explanation of what you imagined went on. You think the arsenic was deposited as arsenic on the copper?—I venture to think that is a possible explanation. I am making some experiments, in conjunction with my friend, Mr. Hehner, which may throw more light on the actual cause. I put these experiments forward for what they are worth, as showing the inadvisability of adding metallic salts to the Marsh apparatus for the purpose of increasing the flow of hydrogen.

10301. Do those comprehend all the experiments you have made?—Yes; of course, I have made other experiments than those represented by the tubes I have shown you. I have made two other series in the same way with similar results. One series which I did not purposely bring with me, give rather more striking results than those.

10302. The idea that copper might under certain circumstances act detrimentally would occur to anybody who investigated the method. It occurred, for example, to myself. Assuming I was using a substantial quantity of copper, and that I was operating in hydrochloric acid solution, and there was a substantial rise of temperature, I might be unknowingly Reinsch's solution?—Precisely.

10303. I wish to guard against the possibility of that error. I may say, however, that Mr. W. Thomson, of Manchester, who was examined here some little time ago, told us that he made a constant practice of adding copper salt to his materials. The only inhibiting metal to which he drew our attention was iron. He told us that for that reason he frequently found it impossible to use Brunner, Mond's zinc on account of the relatively large quantity of iron it contained. Certainly he led us to believe there was no detrimental effect exerted by copper in preventing the evolution of arseniuretted hydrogen. I may say that is rather our own experience in the laboratory. I did not really know that this question was going to come up, but I have brought down a series of tubes placed side by side, showing the effect of either adding or withholding copper sulphate to beer containing known quantities of arsenic, and certainly our general conclusion is that copper does not exercise any very serious detrimental effect, and certainly has, in the case of zinc with a high degree of purity, naturally a very considerable effect in promoting the evolution of hydrogen?—I think if you look at the tubes I have brought you will see that whilst platinum produces a very marked effect, copper produces only a very slight

Mr. A. C.  
Chapman.

13 June 1902.

Sensitive  
of zinc; eff  
of platinum  
and copper.

A. C. effect. I venture to think it is quite possible that the amount of effect produced would depend upon the distance of the zinc from the other element in the electrolytic series.

10304. The only tube which shows any departure happens to be one in which platinum chloride was selected, but as regards copper, which is the one all chemists are inclined to adopt, I venture to think the analytical evidence goes to show there is no very serious detrimental effect?—There is no serious effect, but probably there is an effect which is very slight.

10305. Have you made any examination of wort?—I have.

10306. By your methods?—Yes.

10307. I mean malt worts?—Yes.

10308. Or even raw grain worts?—Malt worts in a few cases.

10309. Do you find there is any special difficulty in treating those by what I may call the Committee's method?—None whatever. Of course I destroy the organic matter.

10310. Is that your invariable practice?—Yes.

10311. In that case you would have no difficulty. You have never made experiments without destroying the organic matter?—Not in the case of worts, but in the case of beers and malts or the extract of malts.

10312. What is your experience?—Using sulphuric acid, I could only get a portion of the arsenic that is obtained when I destroy the organic matter.

10313. Do you meet with any practical difficulties in the way of excessive frothing of the material?—In that case, no. By malt extracts I rather mean a liquid extract obtained by treating the whole malt with acid, the washing of the malt, as it were, not the mashing of it.

10314. Have you tried to make a malt wort as a brewer would make it, simulating the process of the mash-tun, and putting that wort into your apparatus?—I have never done that directly.

10315. Are you familiar with the interim report of the Commission?—Yes.

10316. You will perhaps remember that their recommendation was as to the Board of Inland Revenue, viz., that they recommended that the Board of Inland Revenue should possess and exercise powers to prescribe a test, and, if necessary, to enforce a penalty?—Yes.

10317. It has been suggested to the Committee which is engaged in carrying out the wish of the Commission that, as regards the penalty, it would be more satisfactory to everybody if that penalty were directed to the wort, that the wort should be that which took the offending brewer into court, not the finished beer. Do you see any difficulty about that?—No. Apart from the difficulty of analytical procedure, I see no reason why that should not be done.

10318. It is pointed out that it is eminently desirable, if you can, to stop a man at an early stage of his process. It is rather hard upon him to wait until the whole thing is completed before you pull him up. It would be more convenient to take him at some intermediate stage, and for all practical purposes would be as good as any other stage for carrying out the spirit of the law or regulation. Therefore it has been suggested to the Committee that the wort should be the thing to be examined, and the penalty, if necessary, should be inflicted upon the finding of the wort. As a practical man, do you see any objection to that?—Do the Committee suggest that the sample of wort should be taken before fermentation or towards the end of the fermentation? The Committee will doubtless have in their minds the removal of small quantities of arsenic by the yeast.

10319. The suggestion made to the Committee as regards the brewer was perhaps the hardest that could be devised, namely, that it should be taken before fermentation, immediately from the mash-tun, which is of course a much more stringent test than it would be after fermentation?—Certainly.

10320. You see no difficulties, as a practical man, in carrying out that suggestion, do you?—No; I see no difficulties.

10321. One additional reason that was put before us for taking the wort was that the brewer would be judged by a better representative sample of his output

than on any given sample of malt that might be picked up. There are obvious difficulties in sampling malt?—Quite so.

10322. If you take him upon the extract of the malt, you would probably get a better average specimen of his output?—That is quite true. I think it would be very difficult, and in some cases rather unfair to the brewer, to hold him responsible for quantities of arsenic found in the malts owing to the difficulty of getting homogeneous samples.

10323. But taking it from the wort largely minimises these difficulties?—Certainly it does.

10324. (Dr. Whittegg.) I want to ask a question on the point Dr. Thorpe has touched upon. You think it is not necessary to define any other standard than for wort or finished beer, as the case may be?—I do not think it would be necessary.

10325. You would not think it proper for a brewer to exercise any watch over his ingredients in terms of conforming or not conforming to a given standard that might be prescribed?—I think it would be certainly right and proper for every brewer to watch his materials, and I think every brewer worthy of the name would so watch his materials; but I do not think it would be necessary or wise to fix the standard for those materials.

10326. In what sense would you expect him to watch—to obtain a certificate of purity in any way?—I would suggest he should rather employ a chemist, or should obtain from the persons from whom he purchases his materials sufficient guarantees with regard to the purity of his materials. It would be in his own interest to do so. If by chance any sample of wort were found to show a large quantity of arsenic, that amount of wort would probably be lost to him, and it would be to his own advantage to see that the materials were sufficiently pure to give him wort within the limits prescribed by the Commission.

10327. It is necessary in his own interest, apart from the question of public health, that he should exclude arsenic from his ingredients?—As far as possible.

10328. Should he not have some sort of guide as to the amount of arsenic that should condemn these materials?—That, I presume, would be afforded to him both by experience and by the help of his scientific advisers.

10329. The suggestion has been made to us that 1-300th of a grain per lb. in the case of malt should be the standard?—I think that is not an unreasonable limit.

10330. Would you think it the duty of the brewer, in his own interest and in the public interest, to have malt not containing more than that?—I think so.

10331. In other words, he must watch over it under proper advice?—Precisely.

10332. Where are we placed by the suggestion that he shall be only taken into court on the finished beer or the wort? As I understand you now, he must still look to a certain standard, legal or otherwise, in the case of the ingredients?—Yes.

10333. Does the suggestion amount to anything more than that he shall not be prosecuted, however much arsenic the malt may contain, unless it leads to the production of wort containing more than the permissible limit in the case of beer?—That is what it amounts to.

10334. So that, as a matter of protecting the brewer from being harassed, your suggestion would be that he is expected to watch all these things, but if he fails as regards ingredients, however great that failure may be, he must not be prosecuted for it. It would come to that, would it not?—That is what it amounts to.

10335. Do you think there is very much gained by adopting that suggestion?—Certainly I think there would be if a reasonable limit were prescribed in connection with beer, which would be applicable to beer or to wort. The brewer himself would if, owing to carelessness or to some other cause, he used highly contaminated coal, be a loser pecuniarily. If a limit or limits were prescribed in reference to the materials used, then owing to the extreme difficulty of obtaining perfect samples in the case of malt and hops, he would be liable to prosecution in connection with the material, owing to the fact that it possibly had not been carefully sampled. In other words, he would be improperly, if I may use the expression, harassed

Mr. A. C. Chapman.

Brewers' control over ingredients.

Objection to official tests for ingredients.

Mr. A. C.  
Chapman.

13 June 1902.

Difficulty in  
sampling  
malt.

10336. I think you told us that it was easy to secure malt free from a greater proportion of arsenic than 1-300th of a grain per lb.—Yes, when properly sampled.

10337. Where does the harassing and injustice to the brewer come in if he is told that he is contravening the law if he uses a malt which, when properly sampled, contains more than 1-300th of a grain per lb.—Because the difficulty is to secure proper samples in the case of malt and hops. Experience has shown that, whilst in the majority of cases you can get a representative sample, yet there are other cases in which it is extremely difficult. The trace of arsenic which is deposited in the kilns may be deposited in an irregular manner or in one particular place where a current of air has brought down dust, and if by some extraordinary chance that particular lot was taken for analysis, then proceedings might be instituted against that brewer.

10338. But does not that tend to show that the method of sampling needs to be defined?—Probably it would; but I think it would be extremely difficult to procure a proper sample, say half a pound or a pound sample, from 5,000 to 10,000 quarters of malt.

10339. So that you would rather modify what you said as to the 1-300th of a grain, would not you? 1-300th of a grain would depend upon a rather academic method of sampling?—When I suggested 1-300th I had no idea that would be suggested as a legal limit. I was rather asked the question, I thought, whether it would be possible to work down to that, and I said, "Yes, it would be possible." I did not mention that quantity with any reference to a legally fixed limit.

10340. Now I understand you to say that if it became a legal limit it would be necessary to have defined conditions as to the method of sampling?—Most certainly it would.

Not in sam-  
pling glucose.

10341. In the case of glucose, is there any difficulty in sampling?—It is not by any means so great.

10342. Would you say it would not matter if a brewer used glucose containing however much arsenic, if the wort into which that glucose entered did not contain more than the prescribed limit? The difficulty of sampling vanishes here, does it not?—Yes.

10343. Ought the brewer to be at liberty to use an arsenical glucose, provided he does not produce an arsenical wort?—If a limit is fixed in connection with wort, I must confess I do not see how it would affect any single person, whether one of the materials employed contained 1-10th of a grain or 1-500th of a grain, provided that the amount of arsenic found in the finished product was below what would in the minds of this Commission be considered a safe limit.

10344. I think we agreed just now that it was the duty of the brewer to watch his ingredients?—Yes, in his own interests.

10345. And also in the interests of the public health, is it not?—Certainly.

10346. Then if he fails to exercise that watch over the ingredients—if it is the duty of the brewer to watch his ingredients—it is not quite immaterial if his precautions break down in respect to one of the ingredients. It must add more arsenic to the finished beer if an ingredient is allowed to contain arsenic in greater proportion than is absolutely necessary?—But, provided the finished product does not contain more than the Commission's safe limit, I do not see what the precise composition of the materials employed has to do with the case. The whole thing is simply this: If you suggest 1-100th of a grain in the finished beer as the safe limit, I say that so far as the public is concerned, I do not see it matters much what the composition of the materials may be. I merely gave expression to my opinion that brewers would, as intelligent and careful manufacturers, for their own satisfaction and protection, take steps to see that the articles with which they were supplied were reasonably and properly pure.

10347. I understand you now to accept the suggestion of Dr. Thorpe's Committee, and to say that it would not matter if the ingredients contained more than was necessary of arsenic provided that, when averaged and diluted in the finished material, the standard defined is not exceeded?—Yes, I think that is the meaning of Dr. Thorpe's suggestion.

10348. (Professor Thorpe.) I hope I shall not be misunderstood; it is not my suggestion?—I understood it was the suggestion brought forward by the Committee.

10349. (Dr. Whitledge.) Dr. Thorpe said just now that it was in a way making it more severe on the brewer, and at the same time arriving earlier at the detection of the arsenic if instead of examining the finished beer or fermented wort you went to the wort before fermentation?—It is safer for the brewer.

10350. And arrives at a conclusion earlier?—Yes.

10351. But you would not say that the same advantage arises in going still earlier into the ingredients?—I do not see that it does.

10352. You spoke of the difficulty of sampling as extending to the malt, but not extending, as I understood you, to the glucose and sugars?—Not to the same extent.

10353. In the case of coal, would you say the difficulty of sampling is considerable?—It is enormous.

Difficulty in  
sampling  
fuel.

10354. You advise brewers as to the selection of their fuels in addition to other points?—I do.

10355. Do you give them any advice as regards the use of fuel?—I do. In general terms my advice to them is to use the best selected anthracite. Coming to details, I recommend the anthracite from certain collieries which I have repeatedly tested, and know to be as free from arsenic as any anthracite ever is.

10356. Do you make any recommendations to them as regards certificates of freedom from arsenic to be obtained with the fuel?—No. I have very little confidence in such certificates.

Guarantee  
with fuel of  
little value.

10357. Do you advise them to send samples to you for analysis?—I do.

10358. What amount of sample do you ask them to send?—About 10 lbs. of coal.

10359. Is that picked?—Yes, picked under my instructions.

10360. By the brewer who sends it to you?—It is a sample taken by the brewer who sends it to me.

10361. It is freed from pyrites to a considerable extent?—No. I tell him to take large lumps representing as fairly as he can the truck load, or whatever it may happen to be, and to break these up into smaller lumps, and mix them up. Certainly not to take out a brassy or pyritic piece.

Advice as to  
selection of  
fuel.

10362. That is for the purpose of sending to you?—Yes.

10363. For the purpose of using it himself, do you recommend him to pick out any?—Yes, to reject any portion which is brassy in appearance or unusually heavy.

10364. Do you advise him to ask for it to be picked before it comes to him?—Yes, in all cases.

10365. And to pick it himself?—Yes, to take a fair sample for me, and to select for his own use. My report is against the sample.

10366. What would lead you to say that a given sample is too arsenical or to pass it?—I do not care to give figures, because coal varies very much. If you press the point I will give you a number, but I would rather not.

10367. Would you rather rely on the selection of the colliery and the careful examination and picking of the coal than on any certificate?—I should prefer to have both. I meant to say that the certificate which was sent out in a printed form by all colliery offices are things I attach comparatively little importance to; but the certificate I do attach importance to is that which is obtained by the scientific advisor to the firm in question, working on a sample taken as I have indicated. To that certificate I attach great importance.

10368. You heard Mr. Hehner's evidence?—Yes.

10369. I gathered from him that if you were working to 1-100th standard it would be necessary in deciding whether a given sample was to be returned as complying with that standard or not, to take into account the experimental errors?—I hold no public analyst appointment. Every analyst would use his own discretion.

Margin  
to 1-100th  
standard  
necessary in  
estimating  
by Com-  
mittee's test.

10370. You agree with Mr. Hehner that it is necessary to take into account experimental errors?—Certainly.

A. C. 10371. Can you say what range of experimental error you would consider to be proper in the case of the Joint Committee's test?—I think the example Mr. Hehner gave was a good one. With a limit of 1-100th of a grain working under the Sale of Foods and Drugs Act I should certainly hesitate to initiate proceedings if I found 1-90th. I should consider a figure such as that would come within the range of experimental error. It

might be 1-90th or 1-105th. If I found 1-50th I should obviously have no hesitation.

Mr. A. C. Chapman.

13 June 1902.

Professor DELEFINE called again.

10373. (Chairman.) I understand that you can give us some further evidence on a number of points relating to our inquiry?—Yes.

10374. You mention first a calculation of the amount of arsenic which could be introduced by brewing sugar? —Yes. I have calculated that glucose, such as the arsenical glucose No. 23 (Table IV. of Appendix to my previous evidence), might introduce as much as 2.1 grains of arsenic in 1 gallon of beer, supposing that only 5 per cent. of glucose had been used in brewing. That sample of glucose contained 6,000 parts of arsenic in 10,000,000 parts, or about 4.2 grains of arsenic per pound (according to estimation made for me by Dr. Coutts by means of my method). In order to find whether the above calculations gave an approximate idea of what actually takes place in brewing, I had some beer brewed in the laboratory, using as a malt substitute, glucose obtained from Brewery A, and which had been originally supplied by Bostock's. This glucose was collected a little later than Sample 23, but it had the same characters, and contained also 6,000 parts of arsenic per 10,000,000. It had been extensively used in Salford up to the day on which I discovered the danger connected with its use. The wort I had at my disposal contained distinctly less than 1 part of  $As_2O_3$  per 10,000,000 (i.e., less than 1/143 grain say about 1/200 grain per gallon), probably derived from malt. A quarter of a pound of glucose containing 4.2 grains of arsenious acid per pound added to this wort would, on the supposition that the whole arsenic contained in the sugar passed into the finished beer, be sufficient to introduce 1 grain of arsenic into a gallon of beer. But I have shown that yeast, even when it contains already a fair amount of arsenic, is capable of taking up a considerable amount of the poison, and I calculated that more than a  $\frac{1}{16}$  lb. of the glucose would be necessary to introduce 1 grain of arsenious acid in the finished beer. I had found that yeast containing 80 parts of arsenic per 10,000,000 parts was capable of removing 500 out of 1,000 parts of the arsenic contained in the arsenical wort, in the course of four days fermentation. The yeast at my disposal contained 66 parts of arsenic per 10,000,000. It was therefore probable that the yeast would remove rather more than half of the arsenic introduced into the wort by the glucose added to it. To secure the presence of 1 grain of arsenic in our finished beer it was therefore necessary to add about  $\frac{1}{16}$  lb. of the glucose in question to each gallon of wort. This was done, and the finished beer obtained after four days' fermentation was found on analysis to contain 130 parts of arsenic per 10,000,000 instead of the 140 parts which I desired to obtain (that is, 0.91 grain per gallon instead of 1 grain). Considering the difficulty in calculating exactly the amount of arsenic which the yeast would remove, the result was satisfactory, for it showed that arsenic can be introduced into the beer through arsenical glucose, and that the quantity of arsenic found by analysis in the finished beer may correspond very nearly to that introduced with the brewing sugar, allowance being made for the removal of a certain proportion of it by the yeast. This beer given to rats proved quite as noxious as other arsenical beers. No smell of cacodyl could be discovered during the fermentation, nor could any cacodyl be demonstrated by methods (for instance, treatment by hypophosphorous acid) which reveal even small quantities of that substance. This beer behaved exactly like other arsenical beers when tested by Reinsch's or Marsh's methods. This experiment therefore confirmed entirely the views I advanced in 1900 regarding the relations existing between the amount of arsenious acid in glucose and in arsenical beer.

the statements which I have previously made as to the methods I adopted for obtaining sublimate, so that there should be no doubt in your minds as to the precautions which I have taken to make the results comparable. I omitted to mention previously how I obtained sublimation tubes of a uniform size, a matter which is of great importance in the quantitative method which I have devised. Thin glass tubing with an average bore of 3 millimetres is used. In the first few experiments I found that although soft glass is often contaminated with arsenic, it could be still used for the purpose of making sublimation tubes. I took at first a considerable amount of trouble in getting thin tubing of hard glass, but my assistant found on trying soft tubing that it was possible to get very good results with them, and I ceased to trouble about the question of hard glass. This glass tubing is cut into pieces about  $2\frac{1}{2}$  long, each piece is then tested with a cylindrical steel rod, a little under 3mm. in diameter. All tubes which do not admit this rod are rejected. The selected tubes are then further tested by means of a brass plate with a circular opening measuring  $3\frac{1}{2}$ mm.  $\frac{1}{4}$  in diameter, and only those tubes which pass through that aperture are finally adopted. The tubes are then thoroughly cleansed. With these selected pieces of tubing minute test tubes measuring about  $1\frac{1}{4}$ in. in length are made. By this means sublimation tubes of uniform diameter and with walls of tolerably uniform thickness are obtained. It is essential in order to obtain good results that the tubes should be thoroughly cleaned. One almost always finds that there is a somewhat crystalline deposit coating the walls of these tubes, and this coating is capable of partial sublimation on heating. Whether it is arsenic one has to deal with or not is difficult to say, but there is no doubt that some minute crystalline bodies resembling crystals of arsenious acid are found inside these tubes when they are examined microscopically. The tubes are therefore thoroughly cleaned, first with distilled water, secondly with absolute alcohol, thirdly with ether after which they must be thoroughly dried and kept in a dry dustproof place. The cleaning of these tubes is a matter of very great difficulty. Simple washing will not do; it is necessary to use a kind of plug of cotton moistened with the fluids I have mentioned, and swab the inside of the tube very firmly. The small squares of copper (6 millimetres square) upon which the arsenic has been deposited are washed with pure absolute alcohol, pure ether, thoroughly dried, and cut into three narrow strips. The tube is gently warmed to drive off any moisture, the strips of copper are dropped into it, where they must lie side by side, and all reach the bottom of the tube. The tube is then heated by bringing it above the point of a very small flame. The copper may thus be heated to a dull red heat without the glass being deformed through softening. When arsenic is present a small sharply defined ring of crystals forms immediately beyond the copper. When the quantity of arsenious acid contained in 100 cc. of solution does not exceed 1/100 milligramme, the ring of crystals is invisible, or barely visible, to the naked eye, but when the amount exceeds 1/50 of a milligramme the ring is at once apparent when the tube is examined in suitable light. Any over heating is attended with a spreading of the sublimate which renders comparison between various sublimate difficult. It is, however, for each observer to conduct the sublimation in such a way as to obtain results which will be comparable amongst themselves. May I show you some sublimate obtained in this way with definite quantities of arsenic, in which it will be possible for you to see the differences in the sublimate obtained. The small pieces of copper which I use are of the same size, but minute differences do not have apparently any very great effect upon the results, because the arsenic is capable of depositing in various thicknesses on the metal. This is a sublimate containing 1 part in 10,000,000 of arsenious

acid, and cannot be seen very well with the naked eye, but is visible under the microscope. This other was obtained with 3 parts of arsenious acid to 10,000,000 parts of beer, and it is practically impossible to see it by transmitted light with the naked eye. When you come to 5 parts in 10,000,000 the sublimate can be easily seen, especially when the tube is placed against a dark surface and light is allowed to fall upon it in an oblique direction.

10376. These sublimate consist of arsenious oxide?—Yes.

10377. What is inside this small tube?—The sublimate which has been obtained from one of those pieces of copper.

10378. This is what might come from a piece of copper coated with arsenic like that we see?—Yes. I always use two pieces of copper, one for keeping or for control and one for sublimation. I have stated that I believe my standard sublimate are reliable, and that they keep long enough to be used in practical work. With regard to the first point, Dr. Coult, who was then my assistant, and myself have on three different occasions, at intervals exceeding six months, prepared sublimate from arsenic-free beer containing definite quantities of pure arsenious acid. The sublimate prepared at these intervals from solutions containing the same amount of arsenic have corresponded very closely. Sublimates obtained from 100cc. of beer containing 1-100th of a milligramme of arsenious acid have invariably been less abundant than sublimate prepared with 2-100th milligramme. With quantities exceeding 8 or 10 hundredths of a milligramme dissolved in the same quantity of fluid, the sublimate obtained were a little more variable. But, as I have pointed out before, my method is based on the appearances presented by sublimate obtained from minimal quantities of arsenic, because when the quantity of arsenic is small, the crystals composing the sublimate are almost uniform in size and pretty equally distributed. When larger quantities of arsenic are sublimated the appearance of the sublimate is frequently modified by the formation of larger crystals, which are not so uniformly distributed as the smaller crystals. In order to find out the limits within which estimations could be carried out by the comparison of sublimate, I have had a series of sublimate prepared from solutions containing respectively 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, and 20 hundredths of a milligramme of As. O<sub>3</sub> per 100 cc. of fluid. In each case only 100 cc. of fluid was used in applying the test. The coppers corresponding to the odd numbers were sublimated on one day, the other coppers corresponding to the even numbers were sublimated on a subsequent day. Dr. Coult and myself, independent of one another, arranged the sublimate in order of density, and we had no difficulty in arranging each group of sublimate in an order corresponding exactly to the quantities of arsenic which had been added to the fluid. This gave us two series in which there was a clear ascending scale, any degree being distinguishable from the degree above and the degree below it. Then we independently compared the two series of sublimate and found that up to 7-100 of a milligramme the two series were in perfect agreement. Above 7-100 mg. a difference of 1-100th of a milligramme could not always be appreciated. Thus it was not easy to determine which sublimate was the more abundant of the one prepared from 9-100 milligramme and from the one prepared from 10-100th. The difference between 8-100th and the 10-100th was, however, quite obvious. All through the two series the difference between the two adjacent degrees of the scale became slight when the quantities of arsenious acid exceeded 4 or 5 hundredths of a milligramme. On the other hand the difference between the degrees corresponding to 1, 3, 5, 7, 9, and 2, 4, 6, 8, 10 hundredths of a milligramme, respectively, were sufficiently clear to make it possible to determine whether a sublimate obtained from a solution of unknown strength belonged to one interval or another. The original sublimate prepared at the end of 1900, and corresponding to 1-100, 5-100, and 10-100 milligrammes, even after being preserved for six months, differed so little from the fresh sublimate that an error of more than 1-100 milligramme would have been difficult to make. With carefully prepared sublimate the error need not exceed 1-100 milligramme. I have, therefore, come to the conclusion that with care the method I have devised on the basis of Reinsch's process for the estimation of arsenious acid in beer should allow a careful observer to estimate quantities of arsenic vary-

ing from 1-100th to 1-10th of a milligramme in 100 cc. of beer with a possible error not exceeding 1-100th of a milligramme, or about 1-6,484 grain. As one gallon weighs about 4,536 grammes, the possible error in a gallon of beer would be equal to about 46-6,484 grain, or 1-141 grain when only 100 cc. of the unconcentrated fluid are used.

10379. Greater accuracy is obtained when the arsenic is 1-50th, or somewhat below 1-50th, grain per gallon than when it is above that quantity, is that so?—Yes. But it is easy to reduce the proportion of arsenic estimated by diluting the fluid. In order to ascertain whether the differences we had observed would be also apparent to other not specially trained observers, I took photographs of the sublimate corresponding to 1, 3, 5, 7, 9 milligrammes of arsenic, and then explained to my laboratory steward how the sublimate tubes had to be examined to compare one sublimate with another. I then gave him sublimate corresponding to 2, 4, 6, 8, 10 milligrammes, and asked him to photograph corresponding parts in each tube without further consultation with anyone. The photographs taken by him and by myself show that a person who had never attempted to apply this analytical method could recognise differences such as I have described. Both sets of photographs have been enlarged to make comparison easier. I have also had the first set of standards photographed to the same scale, to allow comparison between fresh standards and standards preserved for six months. These photographs show that the difference between the two sets is very slight. Certain appearance of the sublimate help in the comparison of quantities, thus when the sublimate corresponds to less than 3 or 4 hundredths of a milligramme, the crystals are very small, many are imperfectly formed (star-shaped), and between them one finds a large number of small drops (possibly of amorphous arsenious acid). When the quantity of arsenious acid exceeds 5 or 6 hundredths of a milligramme, large crystals, having usually the appearance of triangular plates, occur among the small crystals.

10380. You obtain the same results by estimations made after the material has been kept for some months?—Yes. I asked Dr. Coult to test on the 21st May, 1901, some of the original samples of beer which we had examined in December, 1900, and January, 1901. These samples had been kept at the ordinary temperature, and had become mouldy, the decomposed beer was, therefore, thoroughly shaken, so as to distribute the fungi equally all through the fluid. As the bottles in which the samples were kept were well corked, no serious loss of arsenic could have taken place even if a volatile arsenical product had been formed. The results of the first and second sets of estimations were as follows:—Beer B (Salford).—First test: 30 to 40; second test, about 38 per ten millions. Beer C (Salford).—First test: 30 to 40; second test, about 35 per ten millions. The beer brewed in the laboratory for experimental purposes was also tested, with the following results:—Laboratory-brewed beer, first test, 150; second test, about 130 or a little less, per ten millions. An interval of about two months had elapsed between the two tests.

10381. You have something to tell us with regard to the possible presence of organic compounds of arsenic in arsenical beer, and more especially of products belonging to the cacodyl group?—Yes. During the first few weeks of the investigation I came to the conclusion that the arsenical compounds present in arsenical beer had all the properties of arsenious acid or of arsenites, and I gave evidence to that effect before the Royal Commission in March, 1901. I have, nevertheless, made some experiments to test the accuracy of my views, and as some of these experiments were not completed when I gave my first evidence I wish now to give the results of my investigations. On the supposition that arsenic is in organic combination it may be surmised that either—

(a.) A loose compound is formed in the finished beer between the arsenious acid present in glucose, malt, or other brewing material, and some of the organic constituents of beer. Such a combination would be most likely to take place in the event of some insoluble precipitate being formed.

(b.) Some stable organo-metallic compound is produced under the influence of fermentation by the combination of arsenic with methyl, ethyl, or other alcohol radicles. In such a case one would expect some radicle belonging to the cacodyl series to be formed.

Applicable to  
beer after  
keeping.No evidence  
of cacodyl  
compounds in  
arsenical  
beer

With regard to the first supposition, I have already shown (5229) that there is no evidence of the presence of any insoluble arsenical product in arsenical beer. Arsenic is equally abundant in arsenical beer before and after filtration through porcelain.

10382. (*Professor Thorpe.*) When you speak of filtration through porcelain you mean "biscuit"?—Yes, a Chamberland bougie. I have also stated on the basis of numerous personal observations (5227) that arsenic is more easily deposited upon copper from solutions of arsenious acid in beer, than from solutions of arsenious acid in pure water. This does not show whether arsenious acid does or does not enter into some loose combination with the organic constituents of beer, but proves that if such a combination exists it does not interfere with the detection of arsenic.

As this point is of some practical importance I have thought it desirable to test the accuracy of my own observations by asking Dr. Coutts to estimate the amount of arsenic recoverable from solutions of known strength, made by dissolving a definite quantity of arsenious acid in water, beer, solutions of glucose, cane sugar, and sulphuric acid (the sulphuric acid being afterwards neutralised by ammonia). The quantity of arsenious acid added was in all cases five parts by weight to 10,000,000 parts by volume of the solvent. This quantity had been found on several occasions to be easily estimated when dissolved in arsenic-free beer. The sublimate obtained from the various solutions were compared with the standard beer sublimate. The results are shown in the following table:—

*Professor Delapine.*  
13 June 1902.  
Effect of different solutions on Reinsch deposit.

Reference.	Nature of Solution.	Quantity tested.	Proportion of arsenious acid introduced in 10,000,000.	Quantity estimated per 10,000,000.
M. 86	Arsenic free finished beer	100cc	5 parts	5 parts standard sublimate.
M. 89 (a)	Pure water	100cc	5 "	Under 1 part.
M. 89 (b)	2 grammes glucose in 100cc water	100cc	5 "	Over 5 parts. **
M. 89 (c)	2 grammes of saccharose in 100cc water	100cc	5 "	3 parts.
M. 16 (a)	Pure water	100cc	5 "	1 part.
M. 16 (b)	2 grammes of glucose in 100cc water	100cc	5 "	Over 5 parts. **
M. 16 (c)	8 grammes of glucose in 100cc water	100cc	5 "	Between 6 and 7 parts. **
M. 16 (d)	2 grammes of concentrated $H_2SO_4$ in 100cc of water neutralised by $NH_3$ .	100cc	5 "	Under 1 part.
M. 16 (e)	2 grammes of saccharose in 100cc of water	100cc	5 "	2 parts.

\*\* See paragraph next below.

In the first instance, M.86, the standard was identical with standards obtained from solutions of arsenious acid in beer on previous occasions. With regard to experiments 89 (b), 16 (b), and 16 (c), the abundance of the precipitate obtained from the glucose solution suggested that the glucose which has been used in those experiments might not be free from arsenic as had been supposed on the basis of tests made in the early parts of the investigation. A larger quantity of glucose was therefore tested again, and it was found that it actually contained enough arsenic to account for an excess of one part in 15,000,000 of solution when two grammes of glucose were added to 100cc. of water. This accounts for the difference between the sublimate obtained from arsenical beer solution and arsenical glucose solution. The presence of glucose (2 per cent.) favours the separation of arsenic to the same extent as that of the constituents of beer does. Cane sugar also favours precipitation, but not to the same degree as glucose. In the absence of organic matter the proportion of arsenic which is separated from an arsenical solution by Reinsch's process is comparatively small. The table shows clearly that when the quantitative method which I have based on Reinsch's qualitative test is used, standards must be prepared for each kind of solution used, or else arsenic-free beer or weak solutions of arsenic-free glucose must be used as solvents or diluents. I have from the beginning adopted the latter method. This was stated in my first report to the Salford Corporation, published in January, 1901. I suspect that some of the difficulties experienced by other workers have been due to a disregard to the facts which are indicated so clearly in the above table. I think also that the same results do not favour the view that arsenious acid forms with the beer ingredients a combination tending to make its detection by Reinsch's process difficult.

With regard to the more stable organo-metallic compounds belonging to the cacodyle series, things have not proved so simple. Solutions of cacodylate of sodium in beer or in water yielded variable results when tested by the Reinsch's or Marsh's process. Some-

times a small proportion of the arsenic present seemed to be revealed, but generally speaking the portion so detected bore no definite relation to the amount of cacodylate present. Solutions of cacodylate submitted to the action of sulphurous acid or permanganate of potash gave equally unsatisfactory results when tested afterwards by either of the above methods. It therefore seemed that if cacodylate of sodium was present in beer its presence could not be certainly revealed by the direct application of the Reinsch or Marsh methods. Cacodyle oxide or some gas having a cacodyle smell was undoubtedly set free during the application of the Marsh test, but if any arseniuretted hydrogen was produced, not enough of it was usually present to yield a good deposit of arsenic in the reduction tube. Under these circumstances it seemed to me that the only ready method available for distinguishing between the presence of cacodylates and other arsenical products which might be present in beer must be based upon the production of cacodyle oxide and the recognition of that gas by its smell. Cacodylic acid and cacodylates are easily decomposed by phosphorous acid. Moderately concentrated solutions of these substances, extracted by appropriate processes from the urine of animals poisoned with cacodylic acid, when boiled with phosphorous acid yield white vapours which have the characteristic odour of cacodyle. The process described by Rabuteau in 1882 being rather complicated, I thought of trying whether I could not obtain cacodyle oxide directly by the use of a still more powerful reducing agent, hypophosphorous acid. I found that the addition of about an equal part of hypophosphorous acid to cacodylate solution in beer and boiling of the two fluids together was sufficient to cause an escape of cacodyle or cacodyle oxide, which could be easily detected by the smell when there was at least one part of cacodylate of sodium in 100,000 parts of fluid. Therefore, having a test for detecting the presence of cacodylate of sodium and finding afterwards it was possible to detect so small a quantity as one grain of cacodylate of sodium in a gallon of beer, I applied the same test to a number of arsenical beers, and found that no smell of cacodyle could be recognised, from which I concluded that no

Tests for cacodyl in beer.

Professor  
Delepine.

13 June 1902.

material amount of cacodyle compounds was present. I have not relied upon my own sense of smell to recognise whether cacodyle was present or not, but I have asked a number of my assistants who were in the laboratory, five in all, to discriminate between fluids to which cacodylate of sodium had been or had not been added, and four out of the five were able to detect at once the tubes in which cacodyle oxide was present.

10383. Could you describe the method you have devised for the rapid detection of cacodylates in weak solutions?—I take 5cc. of dilute cacodylate of sodium, add from 2 to 5cc. of  $H_2PO_4$  solution, mix and boil for a few minutes. At the end of three or four minutes the smell of cacodyle should become distinct if there is at least 1-20th of a milligramme or more cacodyle in the 5cc. of fluid tested. The smell continues to increase in intensity for one hour or more, and is still quite distinct at the end of 24 hours and often longer. The presence of 1 grain of cacodylate of sodium in 1 gallon of beer can be detected by applying the test to 5cc. or 10cc. of beer. I tested in this way: first, many of the arsenical beers which had been sent to my laboratory; second, arsenical beer prepared in the laboratory from arsenical glucose; and, third, beer to which  $As_2O_3$  had been added in various quantities. In no case did I obtain any smell of cacodyle. On May 30th and 31st, 1901, I tested samples of beer to which cacodylate of sodium had been added to the amount of 1 grain per gallon, and samples of ordinary arsenical beer, and I asked several of my assistants, without giving them any information as to the nature of the fluid tested, to pick out of several tubes those in which they recognised the smell of cacodyle. Dr. Coutts, Dr. Moore, Dr. Sellers, Mr. Savatard recognised the tubes containing cacodylate beer without difficulty. Mr. Finney had some difficulty in recognising the difference on one occasion, but was able to detect it on another occasion. It seems therefore probable that five persons out of six would be able to detect the presence of small quantities of cacodylates by the test which I have just described. On the ground of these tests and of the physiological experiments elsewhere recorded, I feel justified in saying that there was no material amount of cacodylates in the arsenical beer which produced the Salford outbreak.

Action of  
yeasts and  
moulds on  
cacodylates.

10384. (Chairman.) Then as regards the action of moulds of various kinds on cacodylates. You have sent us an account of some experiments which may here be taken into our notes?—Yes, they are as follows:—Yeasts and moulds grow in solutions containing various proportions of cacodylates, and these salts are decomposed rapidly by some of these organisms. The decomposition is indicated by the cacodyle smell. The smell is possibly due to the generation of cacodyle and cacodyle oxide. Now if cacodylates had been present to any extent in the arsenical beer this should have been rendered evident by the generation of the smell of cacodyle, either during the ordinary process of fermentation or afterwards, as a result of the decomposition to which beer is liable when kept in bottles which have been opened (all the samples kept for one or two weeks in bottles which had been opened, partly emptied, and recorked became mouldy). I have stated previously (Question 5232) that I have not been able to detect any cacodylate smell in any of the samples of arsenical or non-arsenical beer which have been sent to me, or which I have purchased for analytical purposes. To ascertain how far this absence of smell could be relied upon as evidence of the absence of cacodyle, I devised two series of experiments. During the month of April, with Dr. Coutts' assistance, I tested the action of yeast on wort to which pure cacodylate of sodium had been added in such proportions that the solutions contained respectively as much metallic arsenic as would have been present in a 1 per 1,000, 1 per 10,000, and a 1 per 100,000 solutions of arsenious acid. The results of some of these experiments may be summarised as follows:—

Experiment 72.—1-1,000th wort solution of cacodylate, 3 grammes of brewer's yeast added to 250 cc. of the solution. A doubtful smell of cacodyle after 12 days,

and a distinct smell after 15 days. Fermentation slow. In this case unfortunately the solutions became contaminated, and the decomposition of the cacodylate of sodium seemed to be rather due to the presence of the *Penicillium glaucum* than to the action of the *Saccharomyces*. A very small quantity of arsenic could be revealed by Reinsch's process at any stage of this experiment, and the source of that arsenic was not certainly the cacodylate added to the wort.

Experiment 74a.—1-1,000th wort (sp. gr. 1055) solution of cacodylate treated as above. Fermentation slow, yeast fell to the bottom of vessel. After 13 days faint, doubtful smell of cacodyle. The fermentation was taking place slowly; after four days the specific gravity of the beer was 1031.

Experiment 74b.—1-10,000th wort solution of cacodylate treated as above. Fermentation brisk. Distinct smell of cacodyle after three days. After four days the specific gravity of the beer was 1021.

Experiment 74c.—1-100,000th wort solution of cacodylate treated as above. Fermentation active. After four days the specific gravity of the beer was 1018. Doubtful smell of cacodyle after three days, the same after 15 days.

Experiment 74d.—Wort without any cacodylate. Fermentation brisk, no cacodyle smell, specific gravity 1,019 after four days.

Experiment 81.—The 1-1,000th cacodylate wort of experiment 74 was divided into three parts.

(1) Left in original vessel, only a doubtful trace of cacodyle could be detected at the end of 18 days.

(2) Inoculated with sporing *Penicillium glaucum*. Three days after this inoculation the wort had a distinct smell of cacodyle; five days after inoculation the smell had become very strong.

(3) Inoculated with the white mycelium of the same *Penicillium*. Three days after inoculation smell of cacodyle distinct; five days after inoculation, smell more distinct.

From these experiments it seemed evident that cacodylate of sodium was easily decomposed by the *Penicillium glaucum*, and much more slowly by yeast, and that 1-1,000th solution of cacodylates interfered with the free growth of the yeast and mould experimented with.

In these experiments contamination by bacteria could not be prevented, brewers' yeast having purposely been used. During the months of May and June, 1901, I continued these experiments with the assistance of one of my pupils, Mr. Arthur Gill, and studied more specially the action of the *Penicillium glaucum* and *Aspergillus niger*. Pure cultures of the moulds were used to inseminate sterilised wort or sugar solution, to which various proportions of cacodylate of sodium had been added. The action of bacteria was therefore excluded, except in some cases where subsequent contaminations occurred. Careful note was taken of these cases. The results of these experiments are shortly recorded in the following summary, in which

A was the normal wort or solution of sugar.

B was the same wort or solution, to which cacodylate of sodium had been added in the proportion of 1-61 grammes of cacodylate to 100,000 cc. of wort; this solution contained about as much arsenic as if 1 gramme of  $As_2O_3$  had been added to the same volume.

C contained 1-61 grammes of cacodylate of sodium per 10,000 cc. (corresponding to 1 per 10,000 of  $As_2O_3$ ).

D contained 1-61 grammes of cacodylate per 1,000 cc. of solution (corresponding to 1 per 1,000 of  $As_2O_3$ ).

I. Wort inoculated with a few spores of *penicillium glaucum*, and kept at a temperature of 25°C.

Professor  
Delepine.

13 June 1902.

	Sp. gr. (19°C).	
A. - - - - -	1,053.4	
4th day.—Good normal growth - - - - -	1,053.5	No smell; resembling that of cacodyle.
8th day. Ditto - - - - -	1,050	- ditto - - - ditto.
13th day. Ditto - - - - -	1,041	- ditto - - - ditto.
After this date the growth had become contaminated owing to the repeated opening of the jar.		
	Sp. gr. (19°C).	
B. - - - - -	1,053.4	
4th day.—Growth more abundant than in A - - -	1,053	Slight cacodyle smell
8th day. Ditto - ditto - - -	1,043	Distinct smell.
13th day. Ditto - ditto - - -	1,038	- ditto.
After this day growth contaminated.		
C. - - - - -	1,053	
4th day.—Growth abundant; abnormal - - -	1,050	Strong cacodyle smell
8th day.—Growth yellowish; abundant - - -	1,046	- ditto - ditto.
13th day. Ditto - ditto Contamination	1,038	- ditto - ditto.
D. - - - - -	1,053.4	
4th day.—Growth scanty; abnormal - - -	1,050	Strong cacodyle smell.
8th day. Ditto - ditto - - -	1,047	- ditto - ditto.
13th day. Ditto - ditto yellow - - -	1,034	- ditto - ditto.

Although the smell of cacodyle is recorded here as having appeared only on the fourth day, I was able to distinguish it on the second and third days respectively in C and D. Mr. Gill, however, could not recognise the smell before the fourth day. In the event of fermentation being used for the purpose of detecting the

presence of cacodylates there would be great differences in the results obtained by various observers, as some persons have some difficulty in analysing a mixture of smells. In these experiments the smell of the wort and of the mould obscured that of cacodyle to a variable extent.

II. Wort inoculated with a few spores of *Aspergillus niger*, and kept at a temperature of 25°C.

	Sp. gr. (19°C).	
A. 4th day.—Good growth; spores fewer than in C -	1,051	No cacodyle smell.
8th day. - - - - -	1,047	- ditto - ditto
13th day. - - - - -	1,037.5	- ditto - ditto.
B. 4th day.—Good growth; chiefly mycelial - - -	1,050	Slight cacodyle smell.
8th day. Ditto - ditto - - -	1,044	- ditto - ditto.
13th day. Ditto - ditto - - -	1,037	- ditto - ditto.
C. 4th day.—Good growth; spores abundant - - -	1,052	Slight cacodyle smell.
8th day. Ditto - ditto - - -	1,043	- ditto - ditto.
13th day. Ditto - ditto - - -	1,033	- ditto - ditto.
D. 4th day.—Thin, wrinkled, yellowish mycelium -	1,053	Slight cacodyle smell.
8th day. Ditto - ditto - - -	1,050	- ditto - ditto.
13th day.—Contaminated with <i>penicillium</i> - - -	1,045	Strong cacodyle smell.

There was the same difficulty with regard to the recognition of the smell of cacodyle, as in the case of the experiments recorded in the previous table.

Action of moulds upon cacodylates in presence of a saccharose.

In the following experiments the wort was replaced by a cane sugar solution made as follows:—

	5th day - - -	- ditto	- - -	- ditto.
	6th day - - -	- ditto	- - -	†

This solution was distributed in jars, and quantities of cacodylate of sodium corresponding to those used in the wort experiments were added. Equal quantities of sterilised fluid were inoculated respectively with *Penicillium glaucum*, *Aspergillus niger*, and *Oidium lactis*. In the first set of experiments contaminations appeared early, the results were however in general agreement with those already recorded, I think it unnecessary to record them here. A second set of experiments yielded more satisfactory results, contamination having been successfully avoided for five or six days in every case. The results may be summarised as follows:—

Professor Delepine.	13 June 1902.	II. <i>Aspergillus niger</i> :—						Professor Delepine.	13 June 1902.
		A. Solution, no arsenic	1st day	Slight growth	-	-	No smell.		
			2nd day	Growth increased	-	-	Mouldy smell, strong		
			3rd day	Growth abundant	-	-	ditto.		
			4th day	ditto	-	-	ditto.		
			5th day	ditto	-	-	ditto.		
			6th day	ditto	-	-	ditto.		
		B. Solution	1st day	Slight growth	-	-	No smell.		
			2nd day	Growth more abundant	-	-	Mouldy smell.		
			3rd day	Growth almost equal to A. growth	-	-	Cacodylate smell, doubtful.		
			4th day	ditto	-	-	ditto.		
			5th day	ditto	-	-	ditto.		
			6th day	ditto	-	-	ditto.		
		C. Solution	1st day	Slight growth	-	-	No smell.		
			2nd day	Growth more abundant	-	-	Mouldy smell.		
			3rd day	Growth less than in B.	-	-	Cacodylate smell, slight.		
			4th day	ditto	-	-	ditto.		
			5th day	ditto	-	-	Cacodylate smell, doubtful.		
			6th day	ditto	-	-	?		
		D. Solution	1st day	Slight growth	-	-	No smell.		
			2nd day	ditto	-	-	Mouldy smell.		
			3rd day	Growth less than in C.	-	-	Cacodylate smell, slight.		
			4th day	ditto	-	-	Cacodylate smell, doubtful.		
			5th day	ditto	-	-	ditto.		
			6th day	ditto	-	-	Cacodylate smell, slight		

In these two groups of experiments, when the smell is given as doubtful, this means that Mr. Gill could not recognise it, but that I was able to distinguish it with some difficulty. Other observers sometimes were able to confirm my impression, sometimes they were not.

### III. *Oidium lactis*.

The experiments with this organism were conducted as those previously recorded. They yielded negative results, except with regard to the influence which the quantity of cacodylate had upon the amount of growth, this influence was of the same nature as in the case of other organisms. The smell of cacodylate was recognised on the fifth day in the 1/10,000 solution, but this culture was contaminated by bacteria.

### CONCLUSIONS.

The general outcome of all these observations may be stated as follows:—

1. The presence of cacodylate of sodium in a large amount (1.61 per 1,000) in wort or in sugar solution interfered materially with the growth of yeast, *Oidium lactis*, *Penicillium glaucum*, and *Aspergillus niger*. The *Penicillium glaucum* was, however, much less affected than the other organisms. The same amount of cacodylate in 10,000 parts of fluid was also usually detrimental though to a much less extent. In some cases, however, it seemed at first to stimulate vegetative activity.

The presence of the same amount of cacodylate in 100,000 parts of fluid had practically no effect upon the growth, except in the case of the *Penicillium glaucum*, which seemed for a time to thrive better in this cacodylate solution than in the normal fluid.

2. Brewers' yeast, *Penicillium glaucum* and *Aspergillus niger*, were capable of decomposing cacodylate of sodium, the presence of which was indicated by the production of a smell of cacodylate during the first few days of fermentation. The action of *Penicillium glaucum* was very much more intense than that of *Aspergillus niger* or yeast.

3. The presence of 1 grain of cacodylate of sodium in 1 gallon of beer was revealed by the production of cacodylate smell either during the ordinary fermentation of wort or during the decomposition of beer kept in bottles which had been opened and in which the fluid had become mouldy.

4. As no smell of cacodylate was detected in any of the samples of arsenical beer which I have examined, I am satisfied that none of these beers contained a material amount of cacodylate, and certainly not enough of that substance to produce any injurious effect. Direct and indirect evidence points therefore to the absence of cacodylates from the incriminated beer.

10385. Have comparisons of your results been made with those obtained by others using the Marsh method? —Some comparisons have been lately made; estimations by the Marsh test of the amount of arsenic pre-

sent in beer which had been sent to me for examination in Manchester. They were made by Mr. W. Thomson, a chemist in Manchester, who found that the quantity of arsenic that he could detect in certain beers in which I had found as much as 5 parts per 10,000,000 was, according to his own estimate by the Marsh method, about 1-10th part of what I had found. The discrepancy was rather important in this case, because a case of suspected arsenical poisoning had occurred in Manchester, and Dr. Niven had asked me to examine the urine of that patient to ascertain whether it was a case of arsenical poisoning or not. I found a comparatively large amount of arsenic in the urine, something like 6 parts per 10,000,000. It was suspected that the patient might be drinking arsenical beer; some samples of beer he was accustomed to drink were sent to me, and in that beer I found 5 parts per 10,000,000 of arsenic, which corresponds to about 1-28th of a grain of arsenious acid per gallon. Two chemists, Mr. Estcourt and Mr. Thomson, thought I had over-estimated the amount of arsenic, and asked me for a duplicate sample, which I provided them with, and they found that the amount of arsenious acid was very much smaller than what I had found.

10386. How much smaller?—I think the amount of arsenious acid found by Mr. Thomson was something like 1-200th or 1-250th of a grain per gallon. As I have used the same test for the last 18 months, and as my first results have been entirely confirmed in almost every detail by subsequent observers, I feel some confidence in the results which I have obtained.

10387. You have made a good deal of experimental investigation upon the action of arsenical beer and other arsenical solutions administered in large quantities to rats?—I have, and perhaps you will allow me to put the results before you in the form of a report.

(N.B.—This report and accompanying diagrams form Appendix No. 16.)

10388. (Sir William Hart-Dyke.) With regard to these rats, I should like to ask you as to your ideas of the influence of food in the case of an animal such as a rat receiving very small portions of arsenic. Have you formed any judgment you could give the Commission as to the effect of taking food in such cases? I notice in regard to these rats that you gave them very little food?—I found that so long as I gave a large amount of food to the rats under experiment, beer to which small quantities of arsenious acid had been added, or arsenical beer such as has been drunk in Manchester and Salford, had practically no effect upon them. They continued to increase in weight, and in fact they seemed to increase in weight more rapidly than animals not taking arsenic. This occurred only when the quantities of arsenious acid were below 1-6th or 1-7th of a grain per gallon. When the quantity of arsenious acid was very considerable, the bad effects of arsenic were at once evident, even when the animals were taking a large amount of food. I found that when the amount of arsenic exceeded one grain per gallon, and when the animals took at the same time food to the extent of about 10 per cent.

Large discrepancy in certain instances.

Cacodylate solution would evolve cacodylate on fermentation.

Comparison of Reinsch and Marsh estimations.

of their weight per day, the animals usually increased in weight, and appeared to thrive. But when the food was reduced to 5 per cent. of their own weight, they lost weight rapidly. Now, a normal rat taking food to about 5 per cent. of its own weight would remain either stationary or scarcely decrease in weight. I found that very much smaller quantities of arsenic were dangerous when the amount of food was reduced to 3.3 per cent. of the animals' weight, which is still proportionally a large quantity of food when we consider it in relation to man. For instance, ordinary bitter beer containing only 1-143 part of a grain of arsenious acid per gallon—given to a rat in the proportion which would represent 1 gallon a day to a man, continuously for several weeks, would produce bad effects if the animal was underfed, such an animal when only given a weight of food equal to 3 or 4 per cent. of its own weight would diminish in weight much more rapidly than an animal which was given beer entirely free from arsenic. So that although that small amount of arsenic would not kill the rat, still there would be evidence that its metabolism was not satisfactory. All this is illustrated by curves of weights which I have prepared from a considerable number of data. I have here the daily records of the weights of some 20 rats which were put under experiment in this way.

10389. I should like to press you rather as to what your deduction would be with regard to human beings?—Human beings are more readily affected by arsenic than rats. I found that the amount which was necessary to produce poisoning by arsenic in rats was proportionately at least four times the dose which was supposed to be capable of producing fatal results in man.

10390. (Professor Thorpe.) You mean the pro rata dose?—Yes, pro rata, the percentage to body weight. In recording my observations I have reduced all quantities to a body weight percentage. For equal body weight of man and rat a dose of arsenic which would be capable of producing death in a man would be quite incapable of producing the same result in a rat. It would be necessary to give to a rat four times as much arsenic to produce death, and death even then would occur later in a rat than in a man. That is speaking generally: the lethal dose of arsenic in man is not very easy to ascertain. One is obliged to take cases which have been recorded in which death has been attributed to certain doses of arsenic. The quantities regarded as being dangerous to man vary between 1-10th of a gramme to 2 grammes, and I have taken the largest dose as being one which was almost certain to be fatal to man.

10391. (Sir William Church.) I think the general outcome of your experiments with these rats is really that arsenic when taken by well-fed rats was not nearly so deleterious as when taken by underfed rats?—It did not appear to be deleterious at all for a time when given in small doses to well fed rats.

10392. But when given in large doses?—When given in large doses it became deleterious.

10393. Let me point it in another way. The well-fed rat took without deleterious effects a larger amount of arsenic than the ill-fed rat?—Yes.

10394. And you also found that the arsenic was better borne and tolerated when given with beer than when an aqueous solution was given?—Yes. There was a remarkable difference between the two things. Beer apparently seemed to act as food, so that a much larger quantity of arsenic could be given dissolved in beer than dissolved in water without bad effects.

10395. That to a certain extent I think you would say holds good in man?—I am certain of it.

10396. It is generally accepted, is it not, by the profession that arsenic when given medicinally should not be given on an empty stomach, and also that the diet should not be restricted?—Yes. That was this well-known fact which led me at first to believe that the special incidence of arsenical poisoning in the outbreak at Manchester and Salford might in great part be due to the condition of the patient affected by the poisoning.

10397. Therefore you would have no hesitation in saying that the worst fed portion of the population would be more likely to suffer from arsenical beer than the better fed?—Undoubtedly.

10398. And that may be one of the explanations of what puzzled me very much when we first began this enquiry: that the workers in several breweries did not suffer. They are generally in good circumstances, and

besides their beer they are well fed?—That would be the most probable explanation, and probably also the explanation why women suffered so much more than men.

10399. With regard to these experiments upon rats, the comparison of the amount of arsenic they took with their body weight does not seem to me to enable you to form any opinion with regard to what is an advantageous amount of arsenic for a man to take without prejudice to his health?—I have not found any case in which arsenic was clearly advantageous. I find that in all cases where arsenic has been given for some length of time there is evidence of its being detrimental in the end. In some cases when the rats were well fed arsenic caused a marked increase in weight, which was out of proportion to the amount of food taken. But when the animals were submitted to an alternation of high and low diet, those which were taking beer containing even a trace of arsenic suffered ultimately more than those which were taking no arsenic at all.

10400. I will put it in another way. These experiments have no bearing, as far as I can make out, on what would be a negligible quantity of arsenic for human beings to take. They do not advance our knowledge on that point at all?—The only point they seem to me to show is, that a quantity amounting to 1-100th of a grain of arsenious acid per gallon would certainly not be advisable to take for a great length of time, since in all the experiments which I have made on animals which are far more resistant than man, even that small quantity seemed to produce some detrimental effects. Therefore I should say that any quantity above 1-200th of a grain of arsenic per gallon of beer would be objectionable. I cannot say whether or not a smaller quantity would be objectionable also. See Diagram 5, Experiments 18 and 19 (Period A) two rats were taken, both of which were given only 5 per cent. of their body weight of food and 10 per cent. of their body weight of bitter beer, containing only one part of arsenious acid per 10 million. You will notice that both rats while taking that comparatively small quantity of food lost weight. Then comes period B. In both cases the arsenical beer was stopped, and lager beer free from arsenic was given, and both rats on the same amount of food began to increase in weight. On the 24th day, both rats were given the first beer (containing one part of arsenious acid per 10 millions), and both of them began to lose weight again, so that the two animals behaved exactly in the same way up to period D, which begins on the 30th day. On the 39th day rat 18 was given lager beer entirely free from arsenic, and rat 19 was given bitter beer containing one part of arsenious acid per 10,000,000. You will notice that rat 18 soon after began to increase in weight considerably, but rat 19 did not increase in weight to the same extent, and after a time its weight fell rapidly. It seemed to recover for a time, and then ultimately died, very much in the same way as if it had been suffering from some exhaustive disease. That was at the end of three months.

10401. The other one seems to have lost weight nearly as much before he met with an accidental death?—No, not if you take into account the original weight of the animal. In experiment 18 the animal was gaining weight extremely rapidly.

10402. The accident then happened?—Yes.

10403. He was not killed?—No.

10404. He lost weight after the accident?—Yes. If there had been only these two experiments I would have discarded them entirely, but I have other experiments with parallel periods, the animals always losing weight when taking bitter beer containing some arsenic, and gaining weight when not taking bitter beer, the food being exactly the same.

10405. With regard to the animal losing weight when taking the arsenical bitter beer, this rate was on what I should call low diet?—Yes, but most of them were on low diet for exactly the same period.

10406. But if it had been on full diet the arsenic might have agreed better?—It would have agreed better. But the diet was not so low as to produce detrimental effects by itself. When I found that both rats were losing weight considerably I put them on 8.5 per cent. of body weight of food. The increase in the amount of food was followed by a steady increase in weight in the animal who was not taking any arsenic, and a temporary rise in weight in the animal taking the slightly

arsenical beer, which was followed by a gradual fall leading to death. Other experiments show exactly the same thing. For instance, in diagram 2, experiment 6, you will find that at first the animal was taking bitter beer containing one part of arsenious acid per 10,000,000 (or 1-143rd part of a grain per gallon), and 10 per cent. of its own weight of food; its weight remained almost steady. After that the beer was stopped and replaced by water, and there was a slight gain of weight. The beer was resumed on the twenty-fourth day, the amount of food remaining 10 per cent., and there was an increase of weight, though not very considerable. Then the food was reduced to 3-3 per cent., and there was a steady fall of weight, which became so marked that I stopped the beer entirely to see whether the animal would recover. He was on the point of death. The weight had been reduced to 65 per cent. of the original weight, which I found indicated a fatal result in most cases. I replaced the slightly arsenical beer by lager beer, and was able to save that rat. The rise in weight afterwards was extremely slow, although the amount of food given was sufficient.

10407. On the ninety-third day you do not seem to have increased the food very much?—I left the rat for three days on 3-3 per cent. in order to see whether the difference in the beer would produce an improvement. During those three days the animal began to recover, before I had increased the amount of food. The replacement of the bitter beer by the lager beer was followed in this case, as in all the other cases, by a distinct improvement in the state of the animal.

10408. A reduction of solid food from 10 to 3 per cent. is very great?—It is, but 3 per cent. of the body weight corresponds to 4-2-10 lbs. of dry food to a man of average weight, which is a pretty large amount of food in itself. Ten per cent. of dry food to a man of average weight would be 14 lbs. a day, which is an enormous quantity.

10409. I should like to have your opinion as to whether you think these experiments in any way indicate what is a negligible quantity of arsenic for a man to take?—In my opinion they show that 1-150th part of a grain is not altogether negligible. Beyond that I would not like to go.

1-140th grain  
per gallon  
over long  
period detri-  
mental to  
rat.

10410. (Chairman.) Was there any possible benefit from the arsenic to the rats?—I did not get any evidence of any permanent benefit being derived from the addition of arsenic to the drink of the animals. I got apparent benefit for periods amounting to a month or so, but I did not find that a continuous use of arsenic for more than two or three weeks or a month was beneficial. On the other hand, I had perfectly clear evidence that an amount of arsenic equivalent to 1-140th of a grain per gallon was detrimental when the amount of food was insufficient.

Tolerance of  
arsenic.

10411. How do you account for a human being learning to take large quantities of arsenic by gradually increasing the dose?—That is a very difficult question. It is not everybody who is capable of getting accustomed to taking large quantities of arsenic. In certain countries, Styria for instance, where the habit of arsenic eating has been common for probably a considerable length of time, no doubt some people are capable of taking considerable quantities of arsenic without any bad effect.

10412. You admit that what we so often hear of with regard to Styrian peasants eating arsenic may be accepted as true?—I think the evidence which has been collected is so complete—although some exaggeration may have crept in in some statements—that there can be no doubt that it is a common practice there for people to take arsenic.

10413. In accustoming themselves to eating arsenic do they sometimes get poisoned?—There are cases on record where people in the habit of taking arsenic in this way have suffered. I do not speak of these things from my own personal knowledge, but only from what has been recorded in literature, and therefore I would not like to insist too much on the value of my statements, although as far as I am concerned I believe them to be correct.

10414. Might 1-100th grain per day be distinctly injurious to a human being?—That is my own conviction.

10415. Would 1 grain per day be unmistakably poisonous?—Yes; it would give rise to acute poisoning in

Question of  
negligible  
daily dose of  
arsenic.

most people—not in everybody. There are some people who might have acquired tolerance after taking the drug for a time. There is no drug the action of which is so uncertain as arsenic. Some people cannot bear the slightest trace of arsenic administered by the mouth. Even if used for the purpose of killing the pulp of teeth, arsenic may produce such intense nerve irritation that some people are not able to bear its action. Other people, on the contrary, are apparently capable of bearing large doses of arsenic taken by the mouth.

10416. 1-10th of a grain per day would be liable to produce serious results on human beings?—Yes, within a very short time. I am perfectly satisfied now that even 1-100th of a grain would not be safe, or, at any rate, that nothing above 1-100th of a grain would be safe to take as a daily dose for a considerable length of time.

10417. (Dr. Whitledge.) You say that the variation of susceptibility is greater in relation to arsenic than to most other drugs in man?—I may have put the statement too strongly; it is one of the drugs in which idiosyncrasy is of extraordinary importance.

10418. Would you extend that proposition to the rat?—I have no means of judging. I saw only one case in which I thought the rat was unusually quickly affected out of a series of 22 that I experimented upon. The rat to which I refer is the rat in experiment 7, in which I found that the presence of 10 per cent. of alcohol added to 1-7th of a grain per gallon of arsenious acid beer produced death extremely rapidly. That appeared not to be entirely explained by the addition of the alcohol, which seemed to have very little effect on the other rats.

Susceptibility of rats to arsenic.

10419. Were the rats all growing?—They were all rats which had not quite reached their full size, but they were nearly adults. They generally weighed above 150 grammes. The largest rats I had at the time weighed 200 grammes. I tried experiments on young rats, but I could not manage them. They would not take their food during the administration of arsenic well. Two young rats which I experimented upon died so rapidly that I did not venture to make more experiments of that kind for the time.

10420. Is it possible to say anything with regard to peripheral neuritis in connection with rats?—I found no clear evidence of these rats suffering from peripheral neuritis during life. They did not show any signs of unsteadiness of gait; they could stand on their hind legs quite well in the usual way, take hold of things with the front paws as normal rats do, and they could wash their faces. There was no sign whatever of paralysis. They had no loss of power over their limbs. In no case did I see any evidence of there being any difficulty in the performance of any of their movements. They took water with their paws very much like a human being, sucked their knuckles, and they had perfect control over their limbs. They sometimes looked drowsy, and were difficult to rouse, as was noticed in the case of patients suffering from arsenical poisoning. After death I could not find any clear evidence of the nerves being in a state of neuritis. In two or three cases the nerves were not quite normal. On the other hand, one of my pupils working at the central nervous organs found a large number of nerve cells in a state of more or less advanced degeneration, and this would account for the drowsy condition.\*

Evidence of neuritis in arsenicated rats indefinite.

10421. (Sir William Church.) Were those nerve cells in the spinal cord or in the brain?—Both. A certain proportion of the nerve cells were affected both in the brain and spinal cord. The degeneration was marked by breaking up the chromatophile elements. I have some photographs here of those nerve cells in various states of degeneration (photographs put in).

10422. (Dr. Whitledge.) It would be quite possible if the observations were continued longer with smaller doses of arsenic that something like peripheral neuritis might make its appearance?—Possibly, but I do not think there is much post-mortem evidence of unmistakable peripheral neuritis even in the human subject, that is to say, as a primary lesion. In the brains and spinal cords of patients dying from so-called peripheral neuritis which we have examined in the laboratory, it has seemed to me that the changes in the central nervous system were far more marked than those in the

\* As to this reply, however, see observations made in Appendix 16, on p. 191, below.

peripheral nervous system. Of course the peripheral nervous system is bound to be affected after a time if the central nervous system is affected.

10423. With regard to accumulation, in your summary you say "When arsenic is administered in large doses there seems to be no accumulation"—I have not put the sentence there quite correctly. I should have said there seems to be accumulation. What I have found is that when a very small amount of arsenic is administered daily there seems to be an accumulation. There is an accumulation, because one finds several days after the arsenic has been stopped that there may be in the body a larger amount of arsenic than the daily dose given. If one gives a very large dose of arsenic, the amount found in the tissues is always smaller than the amount given daily.

10424. Would you put it this way, that the absolute amount stored up in the body may be greater with the small doses than with the large doses?—No; what I want to say is that the body is apparently capable of storing up for a time a certain amount of arsenic. If small doses are given successively these may cumulate until the storage limit is reached. If, on the contrary, doses exceeding the maximum that can be stored up in the body are given, elimination of the excess apparently takes place rapidly, so that the amount of arsenic retained may be less than the amount given in a single dose.

10425. (Chairman.) In one case you mentioned a very large discrepancy between the quantitative estimate that Mr. Thomson made and your own result. I think you said Mr. William Thomson found 1-200th of a grain, and you found 1-30th of a grain?—Yes, about.

10426. Did you get any explanation of that discrepancy?—I could not find any explanation of the discrepancy. I supplied Mr. Thomson with the sample of beer, which I had tested myself. He wanted to try it, and he gave me his own estimate. He used Marsh's test, and I used Reinsch's test. That is the only difference. I mentioned this case because I was asked whether I was aware of any discrepancy between my results and those of other observers. This is the most striking discrepancy I am acquainted with.

10427. Have you had other cases in which there was a satisfactory and fair agreement between your test by the Reinsch methods and other tests by the Marsh method?—Generally speaking there has been a marked discrepancy from the first. Quite in the early part of the investigation in 1900-1 the estimates made in Manchester by chemists using Marsh's method often showed no arsenic whatever when I found a good deal by Reinsch's test. Later on, even during the months of January and February, 1901, after a period of experimentation, the results obtained by myself were generally higher than those obtained by chemists who were using Marsh's method. It is only lately that the same specimens happened to have been examined within my knowledge by a chemist whose experiences can be certainly relied upon. Mr. Thomson is a man in whom we have all confidence in Manchester, and I cannot account for the difference of results.

10428. Are you forced to the conclusion that the Marsh test is dangerous in not finding arsenic when the Reinsch method will find it?—I would not go as far as that. It is a matter of accident sometimes when the test does not give the same results. I would not venture to criticise the Marsh test, because I am not an expert chemist, but in my hands it has not yielded as good results as the Reinsch's test.

10429. Yet you have found very large discrepancies not confined to this single instance?—In the early part of the investigations there were very great discrepancies. Several analysts could not find any arsenic, or nothing more than traces of arsenic, when Dr. Coutts and myself were able to find by Reinsch's process material quantities of arsenic. At that time I think facts proved that I was correct in my estimations and conclusions.

10430. It was proved that you were right by independent tests?—Yes.

10431. By the Marsh tests?—Partly, and partly by the precipitation of sulphide. Professor Campbell Brown, of Liverpool, found very much the same quantities of arsenic by precipitation of sulphide, sometimes more than I have found, either in the same samples or in samples obtained from the same source. Professor Dixon in Manchester, also by precipitation of arsenic as sulphide, found very nearly the same quantities.

10432. He found it by the sulphide itself?—Yes.

10433. It is a very serious matter if it should turn out that one test should give seven times as much as another?—Yes. That discrepancy has existed before.

10434. And it is still the same?—Yes, and it will go on I think so long as different methods of applying each test are used.

10435. There can be no doubt that when the Marsh test is applied to a solution from which a previously measured quantity of arsenic has been taken out, and the liquor again tested, nothing is found. There seems to be no room for error there?—I think there is room for considerable error. First of all, you have to break up the organic matter, and that is not such an easy process as is generally supposed. Secondly, you have to prove that you have entirely reduced the arseniuretted hydrogen as it passes through the reduction tube. If some part escapes, of course you lose a portion of the arsenic, however completely arsenic may have been removed from the original substance.

10436. But we have heard that 1-200th put in expressly could be detected by the Marsh method. The test is repeated on the liquor which shows nothing, therefore the test has taken all the arsenic out?—Yes, but has the arsenic in the reduction tube been weighed?

10437. (Professor Thorpe.) The thing has been proved in another way. It was admitted to us in evidence by Dr. Luff that a solution of arsenious oxide, which was insensitive to the further action of copper, which would not give a Reinsch reaction, would nevertheless give a Marsh mirror?—I have done the same thing myself at the very beginning of my investigations, and have already explained that the accuracy of the Reinsch's process and of my quantitative method are not based on the complete precipitation of arsenic.

10438. We had it also in evidence from Mr. Hehner that he could not rely upon the Reinsch to a greater degree of sensitiveness than 1/50th of a grain. He thought that was its limit of delicacy. But he did not attach any definite limits in the case of the Marsh test. Both he and Mr. Chapman said there was no difficulty in picking up 1/200th of a grain?—There is no difficulty in picking up 1/200th of a grain by Reinsch's—you can even pick up 1/500th of a grain quite easily. But I do not advocate Reinsch's test because it is an absolutely perfect test; on the contrary, I quite grant it has great limitations, but these limitations are not more detrimental than those of the Marsh test. I have proved from the first that by Reinsch's process as usually applied only a portion of the arsenic present in the solution tested is precipitated. From the same fluid a precipitate of arsenic may be obtained in succession upon a great number of pieces of copper. Therefore I do not attach any importance to the entire precipitation of arsenic. My point is that if you place a certain quantity of beer in presence of hydrochloric acid and of a definite quantity of copper in a vessel of a definite capacity, under exactly the same conditions of heat, for a certain length of time, you can recover in that time a quantity of arsenic which is proportional to the whole amount of arsenic present, provided the amount of arsenic is not too large. I have used a very limited quantity of unconcentrated beer, and thus have purposely limited the delicacy of the test. If I wanted to obtain a more delicate test I should use four times as much beer. I might also reduce it by evaporation, and increase the delicacy of the test.

10439. (Professor Thorpe.) That could be done by any method?—(Re-written answer.) Yes; but I claim that by the method I use I can, without concentrating the beer, detect as small a quantity of arsenic as can be detected by the Marsh process after somewhat complicated operations. I have purposely limited the delicacy of the Reinsch's process by using only 100cc. of beer for my preliminary test, because I found that with this standard quantity of beer it was easy to detect and estimate 1-143rd grain of arsenious acid in 1 gallon of beer. It is therefore obvious that I could detect and estimate a very much smaller amount of arsenic by using a larger amount of beer. This I have already stated in my previous evidence. I wish also to point out that out of the two pieces of copper employed for each test, I sublimate one only. No doubt that by using special precautions the Marsh test can yield very good results, but, so far, I have not found that the results obtained by it were more satisfactory than my own. There is, however, one thing which seems to me difficult to under-

Professor  
Delepine.

13 June 1902.

stand, and that is the difference between the results obtained by Marsh's method and by Reinsch's process in the case to which I have previously alluded (10425). If the method I use is much less delicate than the Marsh's, how is it that I have been able to obtain from a sample of beer seven times as much arsenic as an expert chemist could by an improved Marsh process? If from a beer containing 1-200th grain of arsenious acid per gallon, according to the chemist, I can obtain repeatedly a sublimate which is five times more abundant than my smallest standard sublimate (which does not even indi-

cate the lowest limit I can reach), it follows that by my method I should be able to detect easily 1-1000th grain of arsenious acid per gallon; and as by my method only 100cc. of beer are sufficient to obtain a sublimate, the actual quantity of arsenic revealed by that method would on that supposition be 1-45000th of a grain, which is an absurdity. I am therefore led to believe that in the case in question the whole of the arsenic present in the beer was not revealed by the Marsh process, however completely it may have been removed from the material tested.

Professor  
Delepine.

## TWENTY-FIFTH DAY.

Friday, 20th June, 1902.

AT WESTMINSTER PALACE HOTEL.

PRESENT :

The Right Hon. Lord KELVIN (*Chairman*).

The Right Hon. Sir WILLIAM HAET-DYKE.  
Sir WILLIAM CHURCH.

Professor THORPE.  
Dr. WHITELEGGE.

Dr. BUCHANAN, *Secretary*.

Mr. ARTHUR R. LING, called; and Examined.

Mr.

A. R. Ling.

20 June 1902.

10440. Mr. B. E. R. Newlands and yourself have some evidence to give us regarding the presence of arsenic in fuel, and the mode of the treatment of fuel in respect of arsenic?—Yes.

10441. I believe Mr. Newlands is a past vice-president of the Institute of Chemistry and of the Society of Chemical Industry, and member of the Society of Public Analysts, etc.?—Yes.

10442. And you yourself are a Fellow of the Institute of Chemistry, member of the Society of Public Analysts, hon. local secretary of the London Section of the Society of Chemical Industry, and editor of the journal of the Federated Institute of Brewing?—I am.

10443. I believe both you and Mr. Newlands practise as analytical and consulting chemists in the City of London?—We do.

10444. Do you work together?—Yes, to a large extent in connection with brewing, especially myself.

10445. You have had a large experience with malting fuel?—Yes.

Arsenic in  
Malting fuel

10446. Have you ever, in that experience, met with a sample free from arsenic?—I can say confidently I have never met with a sample free from arsenic in the course of a very large experience with malting fuel.

10447. Never?—Never.

10448. Even a fuel expressly provided for malting?—No other fuel is referred to in this evidence except fuel obtained from maltings.

10449. And fuel such as has been used since the warning which was given a year ago?—Yes.

invariably  
present.

10450. Do you find that since the warning given a year ago the fuel that is used is still not free from arsenic?—I have never met with a fuel of any kind whatever free from arsenic.

Method of  
determining  
arsenic in  
fuel.

10451. How do you determine arsenic in fuel?—The method of determining arsenic in fuel is one which was described by Mr. Newlands and myself in a joint paper read before the Institute of Brewing on June 11th, 1901. It consists in burning a portion of the fuel and estimating the arsenic in the ash by the Marsh-Berzelius method, and in burning a second portion of the fuel mixed with a proportion of a base, such as lime, soda, or magnesia, and estimating the arsenic in the ash from that. The second determination gives the total arsenic, the first determination giving the arsenic fixed by the ash. The difference between the two gives the volatile arsenic.

10452. The second will be the sum of the two?—The difference between the total arsenic and the fixed arsenic will give the volatile arsenic.

10453. Do you consider that the second process gives the whole arsenic?—The second process gives the whole arsenic, as I have proved by numerous experiments with fuels and other organic substances, such as sugars and yeast, to which known quantities of arsenic have been added, and which have then been burnt in the same manner and the arsenic estimated.

10454. Do you consider that would be a good plan for finding the total arsenic in worts or in beer—to dry it and then burn it with an added base?—I do, I consider it a very good process indeed; in fact, it is one that the joint committee of the Society of Chemical Industry and of Public Analysts suggested as an alternative in cases in which destruction of the organic matter was necessary. They gave two processes, one the destruction of organic matter with nitric and sulphuric acid, and the other the burning with a base, as you have suggested.

10455. The Marsh-Berzelius method would be a simpler process for beer?—In the cases you refer to, the final test would be the Marsh-Berzelius method.

10456. The Marsh-Berzelius applied direct to the liquor suffices for most cases?—In my experience I have found that in the case of beer it gives reliable results when directly applied.

10457. So that the combustion method, although it would succeed, would be more elaborate but not more sure?—In my experience it is not necessary, but I am aware that some have contended that the arsenic is sometimes present in beer in a form in which it does not respond to the Marsh-Berzelius test. That has not been my experience. I ought to have said that I used hydrochloric acid when I worked with the direct Marsh test in beer. I believe that when sulphuric acid is used it is impossible to apply the Marsh test direct to beer with satisfactory results.

10458. I believe that Mr. Newlands has taken out a patent in connection with the process you have described, for the treatment of fuel with a base?—He has.

10459. Not a process for testing fuel?—Not for the purpose of testing fuel, but for the purpose of retaining the whole of the arsenic in the fixed condition in malting fuel.

Mr.

A. R. Ling.

20 June 1902.

fixed, and  
volatile.

10460. The object then is to burn the fuel by this method in the malting kiln?—Yes.

10461. Dr. McGowan has suggested some questions which we might put to you with reference to what you have told us. Have you definitely proved that the whole of the arsenic in fuel is retained by ignition with, say, sodium carbonate?—Yes, with any base such as lime, magnesia or sodium carbonate provided that the mixture be sufficiently intimate. Not only I, but several others have proved the same thing.

10462. I suppose you tried two cases—sodium carbonate in one case, and lime, ordinary quicklime, in the other?—Yes.

10463. Did the results agree in those two cases?—Yes.

10464. In the tables which you have handed in, the total arsenic determined in anthracite is, in some cases, equal in amount to the volatile arsenic determined?—Yes.

10465. May not this possibly indicate that some of the total arsenic has escaped estimation?—If that were so I cannot think that it was due to the arsenic not being retained by the base. It may be due to something we do not know of at the present time, some influence of certain substances on the Marsh-Berzelius method, but I am convinced that it is not to be ascribed to any fault in the non-retention of a portion of the arsenic by the base; because in the results I have brought forward I have always taken special care to intimately mix the fuel with a sufficiency of the base, and not only so, but, as I stated before, I have proved absolutely that when known quantities of arsenic are mixed with an organic substance and with a base and burnt the whole of the arsenic is retained.

10466. Must the fuel be very finely broken up for this process?—Yes; for the analytical process the finer the fuel is broken up the better. The more intimate will the admixture be. I should certainly advise that. My plan is to grind the sample for analysis in an agate mortar, and very often sift it.

10467. That would be too fine a powder to work in the malt kilns?—Just so. The only thing one can do on the technical scale is to coat the fuel with a base, such as lime wash, or to absorb a portion of solution of soda ash. One cannot expect to treat fuel with a large excess of a base such as you would in laboratory determinations.

10468. Have any experiments been made to prove that the fuel can be so treated with lime on a practical scale as to give no arsenic in the fumes when it is burnt in the kiln?—I have a large number of analyses here proving that malt dried with fuels so treated contains only negligible quantities of arsenic—generally 1-1000th of a grain per lb., or below.

10469. To return to the method of testing: what volume of liquid do you employ in the Marsh-Berzelius apparatus?—The volume of liquid employed is the same as that indicated in the report of the conjoint committee of the Society of Public Analysts and of Chemical Industry. I was one of the committee, and the method I adopt is in all cases the committee method.

10470. Does the volume used appreciably affect the depth of the mirror obtained?—I believe it does. But most of my experiments have been made with the size of flask recommended in the committee's report, and I have really very little experience except in the early days of the arsenic scare to prove that.

10471. You believe that not quite the same mirror would be obtained with a certain quantity of arsenic and 30 cubic centimetres of liquid as you would get with the same quantity of arsenic and 50 cubic centimetres of liquid?—I believe that would be the case.

10472. The mirror would be different?—I believe it would. I regard the quantitative Berzelius-Marsh test as a purely empirical one. Whatever apparatus I was working with I should make my set of standard mirrors for that apparatus, and then it would have no effect whatever upon the quantitative results, provided I used the mirrors obtained with the same apparatus that I was working in the actual analyses.

10473. So that if you were going to use 50 cubic centimetres of liquid in your test you would make your standards from the known quantity of arsenic put into the 50 cubic centimetres?—Yes, exactly.

4576.

10474. Would it be necessary to vary the amounts of lime used in the ignition for estimation of the total arsenic in the case of, say, 1 gramme or 10 grammes of fuel?—I should say decidedly yes, because in all cases an excess is employed. If I used ten times the amount of fuel I should use generally ten times the amount of base.

10475. What weight of base do you consider proper in proportion to the fuel?—I think, provided the mixture is intimate, 10 grammes of fuel require only 1 gramme of base. That is quite a sufficient excess—that is a very large excess indeed.

10476. (Sir William Hart-Dyke.) You use it *pro rata* according to the quantity?—Yes. I believe the amount recommended in the report of the joint committee is equal portions of a base and fuel. That is more than I employ; in fact, it is more than is necessary.

10477. (Chairman.) In the furnaces of the malt kilns the proportion of weight of lime to weight of fuel must be very small?—Very small indeed; in fact, 5 per cent. is the most we have experimented with; 5 per cent. of lime added in the form of a wash is found to be ample.

10478. Is that found quite sufficient to keep down all the arsenic?—Yes; provided, of course, that the fuels be not too arsenical. I have no experience with highly arsenical fuels, because I have not gone out of my way to get such fuels. I have simply analysed those fuels which came from maltsters. Although I have met with very bad samples of anthracite, I have had no fuels of the highly arsenical nature such as I have seen in published analyses—gas cokes, for instance. I do not know what would happen if one employed such highly arsenical fuels. Then, I take it, one would have to use more base.

10479. On extracting the ignited residue of ash and base with acid, may not some of the arsenic be in an insoluble form, such as sulphide?—That certainly is a point which occurred to me. As a matter of fact it is so. When one dissolves the ash of a coke, say in hydrochloric acid, a large volume of sulphuretted hydrogen is always evolved; but it must be remembered that even if sulphide of arsenic were formed I know from my own experience that it responds to the Marsh test as easily as arsenious oxide does, possibly because we are dealing with so large a dilution that the sulphide is in that dilution a soluble compound. I believe it to be.

10480. You do not feel quite sure, but it is possible that some of the arsenic may be converted to an insoluble form, such as sulphide, and be removed from the sphere of action of the Marsh test?—I think very likely some of it may exist as sulphide, but that will not be removed from the sphere of action because it will respond to the Marsh test. I do not admit that in the dilutions that we employ in the Marsh test arsenious sulphide is an insoluble compound; I believe it to be a soluble compound. I am speaking from memory, but I believe the solubility is something like one part in formed. 7,000,000, and we have usually a much greater dilution than that.

10481. Do you think it would be an improvement if the residue of your combustion was oxidised?—That is my practice at the present time. At first my results were obtained by heating the residue with an excess of hydrochloric acid at about 70°C. for a short time, allowing it to remain for about 12 hours, making up the volume, or using it direct as the case might be, introducing it into the Marsh apparatus on the following day. The method I have adopted recently is to heat with hydrochloric acid and a few drops of nitric acid until the whole of the sulphuretted hydrogen is destroyed. I heat it for a long time in that way, and allow it to stand for a number of hours. Before introducing it into the Marsh apparatus I add a little sulphurous acid to destroy any nitric acid present. I also have used bromine as an oxidising agent in the case of the residues of some cokes.

10482. Is bromine an oxidising agent?—Yes.

10483. How does bromine act as an oxidiser—where does the oxygen come from if you use bromine?—Bromine acts as an oxidiser in becoming converted into hydrobromic acid; it combines with the hydrogen from the water and thus liberates an atom of oxygen.

10484. After moistening your residue with nitric acid or otherwise treating it as you have described to oxidise it, do you evaporate it to dryness and re-ignite it?—No, I do not.

Mr.  
A. R. Ling.

lime to fuel  
on kiln.

Solubility of  
sulphide of  
arsenic

Residue is  
now oxidised.

Mr.  
A. R. Ling.  
27 June 1902.

10485. Do you take it in its moist state and put it into the Marsh apparatus?—Yes, I should consider it dangerous to evaporate in the case of small quantities of arsenic, because when the whole of the nitric acid is removed I believe that the hydrochloric acid might possibly act as a reducing agent, and volatilise a portion of the arsenic as chloride, especially in the presence of iron, because we have a well-known analytical process of determining arsenic by distilling with hydrochloric acid in the presence of iron salt.

Iron salts  
impairing  
Marsh  
estimations.

10486. Does the presence of, say, 1-10th of a grain of ferric iron in the Marsh apparatus prevent the formation of a mirror of quantitative accuracy?—I have no experience, or very little experience, of the addition of iron salts to the Marsh apparatus, but I have experience in the granulation of zinc with a salt of iron, in which it was found to considerably impair the sensitiveness of the zinc. By sensitiveness I mean the depth of the mirror formed with a known amount of arsenic. Some time ago I endeavoured to remove arsenic from arsenical zinc by various means, and one idea which suggested itself to me was to fuse the zinc, or endeavour to fuse it, with metallic chlorides, and among the metallic chlorides I chose for this purpose was ferric chloride. The method, I may say, was not successful. The zinc which I obtained contained a trace of iron, and it was so very insensitive that it would not show in the Marsh apparatus a mirror when 1-100th of a milligramme of arsenious oxide was introduced, whereas ordinary pure zinc free from arsenic—pure zinc—will show 1-1,000th of a milligramme.

10487. 1-1,000th of a milligramme in what quantity?—In the Marsh apparatus as recommended by the committee, say 100cc. of liquid.

10488. Does your answer apply equally to ferrous iron and ferric iron?—I am afraid I cannot give the Commission any evidence on the systematic addition of either ferrous iron or ferric iron to the Marsh apparatus; I cannot supplement what I have said in regard to iron in any way. I know it has been stated that the presence of a slight amount of iron in the zinc tends to increase the mirror; we have a statement in our report by Mr. Allen, of Sheffield, to that effect, but I have no evidence on that point.

10489. (Professor Thorpe.) May I point out that apparently there is a contradiction in terms—the iron in the Marsh apparatus is ferrous iron?—It must be ferrous iron, only of course the reduction of ferric iron which is in the insoluble state of ferric oxide, provided you have not dissolved it all up, may be a slow process, though there is an error involved in that in the first place, because you ought to dissolve it all up.

Unequal distribution of  
arsenic in  
anthracite.

10490. (Chairman.) Do you find that as regards arsenic different samples of anthracite are uniform?—I find that anthracite is anything but uniform. I believe that to present a great difficulty. One of the greatest difficulties met with in the analysis of anthracite *quod* arsenic is to obtain a uniform sample of a given bulk.

10491. Do you find it possible to obtain a representative sample of Welsh anthracite?—I find it possible to obtain fairly representative samples, but I have some figures which I can give the Commission illustrating the selection, or the attempt at selection, of average samples from the same bulk. Three samples, each of which may be described as average samples, were taken from the same bulk. No. 1 gave 1-30th of a grain of volatile arsenic per lb., and 1-333rd of a grain of fixed arsenic. No. 2 gave 1-50th of a grain of volatile arsenic per lb., and 1-50th of a grain of fixed arsenic. No. 3 gave 1-33rd of a grain of volatile arsenic per lb., and 1-33rd of a grain of fixed arsenic. From these samples some pieces containing slate were selected which contained very much larger quantities of arsenic; for instance,  $\frac{1}{4}$ th of a grain of volatile arsenic per lb. and  $\frac{1}{4}$ th of a grain of fixed arsenic. Perhaps I may show you these two samples, one of which is an average sample of the fuel used. You will see, if you look at the bad sample, that there are veins of slate running through it.

10492. I see no signs of pyrites?—There are none apparently; I have not observed any.

10493. If you chose a pyritic sample, the quantity of arsenic would be considerably greater?—I believe the chief source of arsenic in all coal is pyrites.

10494. And yet in these there are no pyrites to be seen?—I have also stated in my *précis* that slate is also a source of arsenic.

and in slaty  
specimens.

10495. (Professor Thorpe.) Do you mean that the slate *per se* is arsenical, or that pyrites is associated with the

slate?—I cannot say that. I find that slate in all cases, isolated from anthracite, contains arsenic. I have one case here in which  $1\frac{1}{2}$  grains per lb. of total arsenic were found in the slate.

10496. In the slate?—Yes.

10497. You have no evidence as to the form of combination?—No, I have not examined it under the microscope.

10498. (Chairman.) Have you tested pyrites, what we used to call slate diamond, and what percentage of arsenic did it contain?—I have tested for the purpose of this evidence several pieces of pyrites obtained from Welsh anthracite, and they contained the least arsenic of any pyrites I have examined. I have a piece here, for instance, in which I found 10 grains per lb. of arsenic. In other samples I have found less, for example, 7 grains of arsenic per lb.

Mr.  
A. R. Ling.  
20 June 1902.

10499. Have you sometimes found large pieces of pyrites embedded in the anthracite, such as slate diamond?—I have done.

10500. But you have not tested such a specimen by itself to see what proportion of pure pyrites it contains?—No; I should say that such a specimen as that would contain 90 per cent., or even more, of the pyrites.

10501. And that containing 10 grains per lb. gives you an idea of how much the pyrites itself contains?—Yes. Pyrites, I ought to say, from other coal contains very much larger quantities of arsenic than that, but from anthracite coal I have not found more, although I believe others have done so.

10502. Does pyrites occur in veins and sometimes in the middle of pieces of coal?—That is so, but I do not think the latter is often the case.

10503. Is it always possible to detect the presence of pyrites by the external appearance of the coal?—Certainly not. It is not always possible to detect arsenical contamination from the external appearance of the coal.

10504. The specimen that contains a quarter of a grain per pound of volatile arsenic and one-eighth of a grain of fixed arsenic shows no external signs of pyrites? It shows no external signs of pyrites, but it does show signs of the presence of slate, and such a specimen as that I should regard with the greatest suspicion.

10505. If these pieces were broken up much smaller, would pyrites be visible?—I have not found it visible.

10506. It may be so finely mixed with the anthracite as not to be perceptible to the naked eye?—I cannot say whether that sample contains pyrites or not. Its arsenic may be derived from pyrites, but I have no proof that it is.

10507. (Professor Thorpe.) Have no petrographic analyses of these materials been made in the same way that geologists make analyses, by slicing them up and looking at them through the microscope?—It is quite possible, I should imagine, to detect the minerals in a thin section by means of the polarising microscope.

10508. Have not you or the other analysts who have been working in this matter done that?—I am afraid that so many things have arisen on this question that we have not had time to do so; I can find no record of mineralogists having done such a thing. I quite agree that it should be done.

10509. (Chairman.) The chief source of arsenic in all coal is the pyrites or coal brasses?—Yes.

10510. Are these pyrites chiefly iron sulphide, or are they also copper sulphide?—I have found no copper whatever in coal brasses, although I believe the presence of copper is occasionally recorded in analyses of coal brasses.

10511. May pyrites occur not as brasses but as black pyrites mingled with the coal?—Certainly it may.

10512. Do you think it is probable that such black pyrites may form a very fine mechanical mixture?—That I believe to be the case.

10513. When pyrites occurs in high grade anthracite containing but little ash, is the greater portion of the arsenic volatilised on burning the anthracite?—That would be the case.

10514. Would it be the case if the anthracite had previously been treated with a base?—No. Provided a sufficiency of the base were used. If 5 per cent. of the base were used in practice, practically the whole could be kept back.

Pyrites in  
anthracite

10515. You tell us that the presence of coal brasses in anthracite has been long known, and that at one time it was regarded as one of the advantages of this fuel from a malting point of view?—That is so, on account of the sulphur it contained. The sulphur rises and comes into contact with the malt, and bleaches it to a certain extent, and those maltsters who liked pale malts attached importance to the presence of pyrites in the old days on that account. I have an extract dealing with the subject from an old book, called the "London and Country Brewer," published in the eighteenth century. The author there speaks of a certain brand of anthracite coal in which pyrites is found, which is distinctly favourable to the production of pale malts by reason, he says, of the sulphur it contains. In fact, so much sulphur does it contain that he states it was impossible to remain in a room in which it was being burnt.

10516. I have a distinct recollection of going through a malt kiln just a year ago in which anthracite, supposed to be of the very best quality for malting, was used, but I remember noticing on the floors a very decidedly pungent odour; was that sulphur?—Probably it was sulphur, but I could not say.

10517. That itself seems to prove that there must have been pyrites?—Yes.

10518. The charcoal could not have given anything like a pungent smell?—No, it could not.

10519. In walking over a malt floor during the process, is a pungent smell generally noticeable?—In cases in which the very best selected anthracites are used there certainly is not any noticeable odour, not as a rule.

10520. But hitherto that has been regarded as anything but an evil?—Yes, because, as I have explained, the sulphur bleaches the malt, and maltsters like to have as pale a malt as possible, other things being equal, and also want to please the eye of their customers.

10521. There was no suspicion of arsenic in connection with the material that gave that bleaching property?—In the old days, no. No one had any idea before the arsenic scare that malt contained arsenic, or was liable to contain arsenic.

10522. I see it is stated in the "London and Country Brewer" that no malting fuel "is so much in esteem as the golden streaked coal of Tenby, which is endowed with so much sulphur that in the ships that come from thence they can hardly bear the room it is burnt in, and at Bristol is sold for 8d. a bushel, where they are in no small concern for this sort of coal, because its great usefulness has of late encouraged them to dig so much out that their mines at this place are almost exhausted." Is it on record that there were any illnesses from drinking beer in those days?—I am not aware of any.

10523. But a good many people who consumed two or three gallons of beer a week may have been poisoned in virtue of that coal which was in so much request?—They may have been so.

10524. You have spoken of the difficulty of obtaining a representative sample of anthracite. Is that an argument against the possibility of accurately selecting samples sufficiently free from arsenic for malting purposes?—I think it is a strong argument against it; I would go further than that and say that even if it were possible to select a sample for analysis it would not be possible to ensure that the maltster every day of his work is making use of an average sample. As I have already stated, anthracite is so very variable in its composition, that one day he may be making use of a sample containing very much more than he was using another day, so that the analysis of an average sample would not help entirely, although it would be helpful.

10525. Even if a maltster's average anthracite was sufficiently free from arsenic he could not be sure that on some dates some tons would be used which would contain a dangerous amount of arsenic?—I would not go so far as to say dangerous, because I do not know what that means, but I would say that he could not ensure that his malts would not vary in the amount of arsenic they contained; he could not be sure that he was making use every day of an average sample.

10526. Has attention to fuel in your experience done much to reduce the amount of arsenic in malt?—I lately in think it has; in fact I am sure it has. When I first commenced to examine fuels for arsenic by the method I have described to you, in April or May of last year, one met with anthracite containing certainly larger quantities of arsenic than one does at the present time.

10527. In the early part of 1901 did you meet with samples of malt containing 1-50th to 1-25th of a grain per pound?—That is so. Those samples were obtained from the maltsters, and it is probable they were all coke dried.

10528. (Sir William Hart-Dyke.) Gas coke?—Probably gas coke.

10529. (Chairman.) Do you mean that anthracite had been used in the malting and gas coke in drying the malt?—No, I mean that in the samples containing these very large quantities of arsenic, coke had been used throughout for drying; but that was in the early days of the arsenic inquiry.

10530. At the present time what amount of arsenic may be frequently found in malt?—In malts dried with anthracite or said to be dried with anthracite, we seldom find more than 1-300th of a grain per pound. I should say that in samples which come to us without our knowing how they have been treated it is rare to find more than 1-150th of a grain of arsenic per pound of malt.

10531. With selected anthracite containing 1-25th of a grain of volatile arsenic per pound, you account for as much as 1-150th of a grain per pound in the malt?—Arsenic in There is a possibility of the malt containing as much anthracite as that, assuming the whole of the volatile arsenic which may reached it, but this is simply a calculation.

10532. If a portion of the volatile arsenic was fixed, by lime for instance, then it could not give as much as 1-150th of a grain per pound of malt?—It would not, in my experience.

10533. Is chemical analysis practically successful as a means of control when applied to the fuel used in malting?—I think not, I believe it affords a very valuable help, but I do not think its indications can be taken as final for the reason I have just stated—that it is very difficult to obtain an average sample, and impossible to ensure that the maltster is always making use of an average sample.

10534. In respect of statutory requirements in regard to malting fuel or anthracite, would it be practicable that the statutory requirement should be that the anthracite uniformly should contain less than a certain amount of arsenic?—I think it might be valuable to fix a standard of some kind, but I think it should be a very lax standard, for the reason I have just stated.

10535. (Sir William Hart-Dyke.) You mean that a large margin should be allowed?—Yes, with a large margin I think it would be helpful.

10536. (Chairman.) Do you suggest any statutory requirement as to the amount of arsenic allowable per pound of anthracite?—I have handed in several analyses of samples of anthracite, and I think it may be judged from the values obtained with these samples what can be done by selection, and what amount of arsenic, volatile and fixed, may be expected in the best samples.

Mr.  
A. R. Ling.  
23 June 1902.

Mr.  
A. K. Ling.  
20 June 1902.

The analytical results handed in were as follows :—

## ANALYTICAL RESULTS.

Mr.  
A. R. Ling.  
20 June 1902.

All the fuels referred to in the following tables were obtained from maltings :—

## I.—ARSENIC IN WELSH ANTHRACITE.

Good Samples :			I.	II.	III.	IV.	V.	VI.	VII.
Volatile arsenic	-	Grain per lb.	1-30th	Nil	1-23rd	1-50th	Nil	Nil	1-140th
Fixed	"	"	1-333rd	1-24th	1-14th	1-50th	1-24th	1-14th	1-70th
			VIII.	IX.	X.	XI.	XII.	XIII.	XIV.
Volatile arsenic	-	Grain per lb.	Nil	1-33rd	Nil	1-140th	1-110th	1-70th	1-140th
Fixed	"	"	1-52nd	1-33rd	1-50th	1-20th	1-70th	1-70th	1-11th
			XV.	XVI.	XVII.	XVIII.	XIX.	XX.	XXI.
Volatile arsenic	-	Grain per lb.	1-35th	1-70th	1-140th	1-110th	1-50th	1-1000th	1-24th
Fixed	"	"	1-35th	1-70th	1-28th	1-35th	1-70th	1-55th	1-9th
Bad Samples :			I.	II.	III.	IV.

## IV.—ARSENIC IN MALTS DRIED WITH TREATED AND UNTREATED FUEL.

Mr. J. L. BAKER'S Results (see Journal of Federated Institutes of Brewing, 1901, p. 329).

Fuel employed.							Arsenic in Malt.
							Grain per lb.
Coke alone	-	-	-	-	-	-	1-220th
Coke and 5% of milk of lime	-	-	-	-	-	-	1-600th
Coke and 5% of slaked lime	-	-	-	-	-	-	Nil
Coke alone	-	-	-	-	-	-	1-245th
Coke and 5% of slaked lime	-	-	-	-	-	-	Nil
Anthracite alone	-	-	-	-	-	-	1-300th
Anthracite and 5% of lime	-	-	-	-	-	-	Nil

N.B.—Mr. Baker regards any sample containing less than 1-750th grain per lb. as free from arsenic.

Ling.

Mr  
A. R. Ling  
20 June 1902

V.—ARSENIC IN MALTS DRIED WITH LIMED COKE—AMOUNT OF ARSENIC IN THE COKE UNKNOWN. INSTRUCTIONS GIVEN, BUT NO PERSONAL SUPERVISION EXERCISED.

## OUR OWN ANALYSES.

Arsenic - - - Grain per lb.	I.	II.	III.	IV.	V.
	1-350th	1-500th	1-200th	1-370th	1-300th
" - - - " "	VI.	VII.	VIII.	IX.	X.
	1-480th	1-290th	1-500th	1-600th	1-250th

VI.—ARSENIC IN MALTS DRIED OFF WITH GAS COKE (TREATED AND UNTREATED) AND WITH ANTHRACITE.

## ANALYSES OF THE FUELS

<i>Gas Coke (untreated):</i>					
Volatile arsenic	-	-	-	-	Grain per lb.

## FURTHER SERIES OF MALTS DRIED DURING MAY, 1902.

Mr.  
A. R. Ling.  
20 June 1902.

Mr.  
A. R. Ling.  
20 June 1902.

Fuel employed.		Arsenic.
		Grain per lb.
Half anthracite	- - - - -	1-360th
Half limed coke	- - - - -	1-700th
Half anthracite	- - - - -	1-1000th
Half limed coke	- - - - -	1-1000th
All limed coke	- - - - -	1-1000th
All limed coke	- - - - -	1-1000th
Half anthracite	- - - - -	1-1000th
Half limed coke	- - - - -	1-1000th
Half anthracite	- - - - -	1-1000th
Half limed coke	- - - - -	1-1000th

The anthracite and coke were the same as used in the previous series.

10537. In bad samples of anthracite you found arsenic in a volatile condition equal to one-quarter of a grain per lb. ?—I have found as much as one and one-third grains per lb.

Bad samples  
of anthracite.

10538. You have found volatile arsenic equal to one and one-third of a grain per lb. ?—That is so. Of course, these should be out of the question entirely. They would never come forward with the control now exercised. This  $1\frac{1}{3}$  grain per lb. is simply stated as an actual fact, but such a sample would, I believe, be refused at once, because it obviously contained pyrites.

10539. But in the eighteenth century such specimens would be preferred for malting?—Apparently so from the statement I have quoted.

Arsenic in  
coke.

10540. Coke is a more homogeneous material than anthracite, is it not?—It certainly is. It is much easier to sample coke than anthracite.

10541. But as a rule coke contains more arsenic than the best anthracite?—That is so.

10542. Oven coke contains less, however, than gas coke?—The best oven coke certainly contains less than gas coke. It is perfectly possible I believe by selection of the coal before coking to obtain oven coke as pure, as regards arsenic, as the best anthracite.

10543. You have found samples of oven coke containing as much as one-seventh of a grain per lb. of volatile arsenic?—I have.

10544. In other specimens of oven coke you found practically the whole of the arsenic has been in a fixed condition?—That is so.

10545. Have you found how much arsenic there was in the fixed condition?—In a fixed condition in specimens containing no volatile arsenic I found in two cases 1-20th of a grain per lb.

10546. And of volatile arsenic?—There was none in those two cases.

10547. The largest and the smallest amounts of volatile arsenic in gas coke were  $\frac{1}{4}$  grain per lb. and 1-25th grain per lb. ?—Yes.

10548. Does that apply to the largest and smallest?—Yes, in the samples which have come under my notice of gas coke used for malting.

10549. It is generally asserted that gas coke is more arsenical than oven coke; is that probably the case?—That is probably the case.

All samples  
from malt-  
ings.

10550. The samples you examined were obtained from maltings?—All the analyses given here are of fuels from maltings.

10551. Fuels that have been to some extent selected?—Yes, that would be presumably the case.

10552. Since the warnings of a year ago?—I should take it that they had really to some extent been selected, otherwise they would have been more arsenical.

10553. You have something to tell us about malt dried with treated coke and with anthracite untreated?—I have a series of systematic experiments with malt dried with fuel, untreated and treated anthracite, and treated coke, that is to say, treated with a base.

10554. (Sir William Hart-Dyke.) How treated?—Treated with 5 per cent. of lime, for example.

Advantage of  
liming fuel.

10555. (Chairman.) Five per cent. of powdered lime mixed with the fuel?—Slaked lime. If I may give the Commission some of the numbers obtained, I will do

so. The last series (No. VII.) will be the most instructive, because I know everything about these. I have analysed both the anthracite and the coke. The anthracite contained 1-50th of a grain of volatile arsenic and 1-100th of fixed arsenic; the coke contained 1-55th of a grain of volatile arsenic, and 1-21 of a grain of fixed arsenic. The fuel employed was a mixture of limed coke and unlimed anthracite, or entirely limed coke. When I speak of limed coke in this case I mean this coke treated with 5 per cent. of lime in the form of cream. In one case, in which half limed coke and half anthracite were employed, 1-570th of a grain per lb. of arsenic was found in the malt, whereas when all limed coke was employed 1-1,400th of a grain was found in the malt.

10556. What do you mean by half limed?—The fuel consisted of half coke treated with lime and half anthracite untreated.

10557. Half of it treated and half untreated?—Anthracite untreated mixed with the same weight of coke treated.

10558. (Sir William Hart-Dyke.) That would weaken the remedy by 50 per cent., would it not? You have a portion, one-half subjected to the treatment and the other half not and then you mix the two things together?—Yes, the object of these experiments was to show that treated coke is a better fuel than untreated anthracite. If you will look down the numbers given you will see that the arsenic is the greater the larger the proportion of untreated anthracite present. In the experiments with treated coke alone the malts contained less arsenic than where anthracite was present untreated.

10559. (Chairman.) The treatment is by milk of lime; how is that brought to bear upon the coke? Is it all dried with coke? You say, for instance, 5 per cent.; is that 5 per cent. of lime?—Yes.

10560. It is not 5 per cent. of the milk of lime?—No, 5 per cent. of the lime made into milk of lime.

10561. It is dried on the coke?—The coke is broken into moderately small pieces, such as the maltster uses for his firing. The lime is slaked first of all and then mixed with water into a cream, and the cream added to the fuel, and the fuel shovelled together. Or the lime is simply slaked with sufficient water, by which it falls to powder, and then also shovelled together with the fuel. That is the general mode of treatment; in fact, it is with the milk of lime treated in the way I have described that these experiments have been conducted, and 5 per cent. of lime to 95 per cent. of fuel was the proportion used.

How added

10562. If the coke were merely dropped into a vat of milk of lime and taken out again, would that be satisfactory treatment?—Yes. In fact, I have found in former experiments that a very small amount of lime is effective, that very good results can be obtained by simply saturating coke with lime water. This was stated in the paper read by Mr. Newlands and myself before the Institute of Brewing.

10563. Saturating the coke would bring the lime water all through the body of the coke?—Yes.

10564. Anthracite could not be treated in that way?—It could not. We found that coke drenched with lime water led to a malt containing 1-300th of a grain per lb., and in another case gas coke containing about 1-25th of a grain volatile arsenic per lb. was used, it was

drenched with lime water, and the malt dried with it contained 1-400th; so that a very small quantity of lime suffices apparently.

10565. How is the coke dried after being treated with milk of lime?—Simply allowed to dry on the floors.

10566. Without heat?—Yes. There is a small amount of evaporation when placed upon the furnace, but that is nothing.

10567. But treatment of anthracite will not be so easy, because the milk of lime will not adhere to the anthracite?—That is so. My idea is this, that good selection, coupled with chemical analysis of anthracite, and in conjunction with basic treatment, should give the best result. It should, in fact, enable you to be certain of obtaining a malt containing probably less than 1-500th of a grain per lb. of arsenic. I think the treatment of anthracite with a base gets over the difficulty the maltster has in not employing an average sample every day. I do not mean to suggest using a fuel containing so high a proportion of arsenic as 1-4th of a grain per lb., or anything of that kind, but I think selection combined with basic treatment should prove successful.

10568. From what you have told us, it seems that coke, either gas coke or oven coke, treated with milk of lime, may be safer than well-selected anthracite without treatment?—That is my contention. I think the malt analyses I have given bear on this point most strongly.

10569. Do you consider that it would be safe to allow gas coke or oven coke, whichever is cheaper, to be used, provided the treatment was applied?—I do not consider that gas coke should be used indiscriminately. I think, provided proper selection be carried out, in conjunction with the control which can be afforded by chemical analysis of a sample taken from the bulk, the maltster should be at liberty to use treated oven coke or even treated gas coke.

10570. Do you believe that malt is sometimes contaminated with dust carried up mechanically from the furnace or from elsewhere?—I do. It has been stated by many authorities on the subject that that is the case, but I consider that any contamination caused by this dust can be practically ignored.

10571. The amount of it you consider to be very small?—The amount is very small, although the dust itself may contain large quantities of arsenic. I have found in the dust taken from the spreader three to five grains of arsenic per lb. The spreader is the arrangement placed over the furnace.

10572. If much of that dust gets on the malt it will make a large contamination?—I have it on good authority that 1 lb. of this dust can be caught from about 10 cwt. of coal, by an arrangement placed between the kiln floor and the furnace, and assuming the largest amount of arsenic I have found in this dust, five grains per lb., reckoning one part by weight of fuel to five parts of malt, this would lead to the contamination of 1-1,120th grain arsenic per lb. of malt.

10573. If all the dust got in?—Yes, and it is not likely to all get in.

10574. (Sir William Hart-Dyke.) You act as analyst, do you not, for a large number of brewing firms?—I act as analyst for some brewing firms. I act as adviser, too.

10575. Of course you are aware of all the circumstances attending what is called the Manchester scare?—Yes.

10576. In pursuing your avocation of an analyst, have you lately found traces of arsenic in any glucose you have examined?—I have, and that rather bears upon the question of controlling things by analysis, because although I have found on an average that glucose contains negligible quantities of arsenic, only recently I discovered in a sample of foreign glucose, either American or German, I cannot say which, as much as 1-12th of a grain per lb.

10577. Was that very lately?—The week before last, I think.

10578. Discovering that, you are rather led to the conclusion that this system of analysis must be very vigorously pursued?—Yes. I do not think it would be at all safe nowadays not to test for arsenic. Everything connected with brewing is tested for arsenic by analysts, I think.

4576.

10579. When you speak of the necessity of controlling by analysis, I should like you to explain what you refer to. Do you refer to a system whereby each brewer's firm should have its own analyst, and analyse all materials carefully before they are put into the beer, or some controlling power of the Government Department?—I mean at the present time every brewer is in duty bound, knowing what he does, to have all his samples tested by an analyst.

10580. Do you think if that were done it would be sufficient guarantee to the consumer?—I do not. I think some Government steps ought to be taken to control the purity. In the meantime I should think the brewer is probably in his own interest taking steps to have all his materials analysed.

10581. You would recognise in the case of the brewer and the maltster that the result of this scare might subside?—That is what I am afraid of.

10582. And there might be a relapse again into carelessness?—I think that is very likely to happen, and unless some official means are taken for the control of the purity of materials I am very much afraid that things will relapse into a lax state.

10583. You quoted in an earlier part of your evidence the result of careful analysis of some anthracite, which showed a good deal of arsenic. Could you tell the Commission where that anthracite came from?—I am afraid I cannot tell the Commission that.

10584. Cannot you tell us what part of the world it came from?—It came from Wales; they are all Welsh anthracites.

10585. Did it come from collieries which would be, generally speaking, sending anthracite to those maltsters who were using it?—Yes. They were all well-known collieries. What I could do, if the Commission desires it, is to confer with Dr. McGowan, and let him see my notes, and show him exactly where it did come from privately. That might perhaps be helpful to the Commission.

10586. But they were not samples taken from a maltster's establishment?—They were all taken from a maltster's establishment; none of them were taken at the pit's mouth.

10587. They were specimens liable to be put into use?—Yes, they were all being used, everyone of them.

10588. Would you be satisfied with any very careful examination of fuel, whether anthracite, gas coke, or oven coke, without the use of this system which you have been detailing to us—the application of a base such as lime?—No.

10589. Assuming you were in the malting trade at the present moment, and were aware that a very heavy penalty might attach to you in the case of finding any treatment of arsenic in your malt, would you tell the Commission as with lime concisely as you can how you would secure yourself?—I should not be satisfied by the control afforded by analysis only. I think it would be unsafe on account of the difficulty of sampling the fuel. I do not think the selection method in conjunction with analysis would be a sufficient guarantee. My conviction is that in connection with basic treatment it would.

10590. Do you know enough of Mr. Newlands to include him in the belief that the real security is the application of some treatment through lime or soda?—Yes, our investigations demonstrate that. These investigations have now been continued for considerably more than twelve months, and neither from my own results nor from those of other people who have tried the process have I any other than favourable evidence.

10591. I think you were urging just now, were you not, that in the case of anthracite the fuel should be carefully sampled and examined before it is used, with the addition also of the basic treatment?—That is so.

10592. Is that because the application of the basic treatment is more difficult in the case of anthracite by its not being such an absorbent as coke?—Not on account of that alone. It would apply to all fuels. I am of opinion that the selection of fuel should still be practised even though the basic method were used. I have no experiments to give the Commission in which very bad fuels have been treated by the basic process.

10593. You mentioned that, "The method has, we believe, come into general use, and it has been recommended by the Joint Arsenic Committee of the Society

Mr.  
A. R. Ling.  
June 1902.

Precautions  
against  
arsenic will  
get lax unless  
official control.

Selection of  
fuel plus  
penalty

Mr. A. R. Ling. 20 June 1902. of Chemical Industry and the Society of Public Analysts." Will you kindly explain by whom this has been recommended?—I refer there to the method of analysing fuels.

10594. Apart from the system of treating by the maltster?—Quite apart. I referred to the analytical process because the same principle underlies both, the principle Mr. Newlands first pointed out, that arsenic could be retained on a technical scale.

10595. During all this period you have been analysing fuels in general use by maltsters?—Yes.

Malts will get more arsenical unless official control.

10596. You say further on, "At the present time it is rare to find more arsenic than 1-150th grain per lb. of malt." Will you kindly account for this? Is it your opinion that if a general test were applied throughout all the malting establishments this would be the result?—I do not think so. I think at the present time that things are very much better than they would be after this scare has entirely subsided. A certain amount of selection is now being used, but still one finds occasionally malts containing 1-150th of a grain per lb., or even more. Such cases are rare. I think they would be very much more common when this scare has entirely subsided unless some precautionary means are taken.

10597. You think that in two or three years' time, if nothing more were done or suggested, the examination of fuel going on now would then cease?—I do. I think it is highly probable.

10598. You are aware that we have had many witnesses here who practically condemn the use of gas-coke altogether?—Yes.

10599. They suggested that the chief security in the future for the maltster is giving up the use of gas-coke?—I have heard that.

10600. With regard to anthracite, are you aware there has been a general recommendation on the part of many witnesses as to the use of anthracite being far more secure?—Yes, and I agree with them that it is more secure than the use of gas-coke, but I do not agree that it is absolutely secure.

10601. Not secure *per se*?—I do not think so.

10602. How many samples, roughly speaking, do you think you and Mr. Newlands have analysed of anthracite?—I cannot say; I should think 50 or 60 about; more than that perhaps, at all events many more than are given in my précis. Those are analyses carried out by myself.

10603. Do these specimens of anthracite that you have examined come from different maltsters in all parts of the country, or only from the North or the South?—They come from the North, from the South, and from the Midlands. The North, as far as Lancashire. There are none further North than Lancashire.

10604. (Sir William Church.) Besides the great attention you have paid to the fuel, have you paid any attention to the quality of the malt for brewing purposes?—I am continually analysing malt for brewing purposes.

10605. What is your opinion as to the necessity of the fumes passing through the malt?—I have very little to say upon that matter, because I can only tell you that it is stated by certain practical brewers that it is absolutely necessary to dry malt in contact with the fumes of the furnace. Whether that be the case or not I am not able to say.

Fumes may not be essential for malt.

10606. Could you state your view to the Commissioners? Do you think that is likely to be true? Brewers may be very conservative people. We have had one witness here who said that the best malt he ever made was made without contact with the fumes?—I am inclined to think there is a great deal of prejudice in the matter, but I should not like to state that definitely, because so many brewers hold the opinion that it is necessary for the flavour of the beer. Although I can detect the flavour of the fumes in malt, I cannot go so far as to detect whether the malt used for making beer has been dried in contact or not in contact with the fumes.

10607. You see no reasons why the fumes should come in contact with malt?—I see no scientific reason why the fumes should not be entirely excluded.

Malting without time.

10608. Have you paid any attention to the various kilns which have been proposed? I have lately seen several plans and patents for kilns in which the fumes do not come into contact with the malt?—I cannot say I have seen any of them at work, but I

am aware of the existence of various patents, and I am also aware that in the Continental system of malting the malt is entirely dried out of contact with the fumes, and in some pneumatic systems of malting, systems by which the malt is made in a drum.

10609. Malt for lager beer is made in drums, is it not?—Not entirely. The amount of malt for lager beer made by the drum system is now on the increase; but the drum system has not found entire favour in this country.

10610. Drums are used for roasting the malt?—For the kilning. In some systems they are used instead of the ordinary malt kiln, that is to say, the grain is not only germinated in the drum, but the malt dried and cured (kilned) in the drum.

10611. I am only asking you very generally, of course, because you are not prepared to give such detailed evidence as you have given about fuel, but you see no objection to experiments being made on a large scale to see whether it is necessary that the fumes should pass through the malt?—I see none whatever. In fact, I am inclined to the view that it is not necessary. At the same time I do not feel prepared to assert in the face of many practical men who are apparently unprejudiced men, that it is not necessary to pass the fumes through the malt. From the scientific point of view there is no reason why it should be done.

10612. You see no practical difficulty in the arrangement of kilns by some system of heat radiators above the furnace heating the air to pass through the malt without direct connection with the fumes?—There are very many ways in which it could be done, but I do think it would be rather unfair to maltsters to compel them perhaps to pull down their existing kilns and build up fresh ones simply on that ground, if the same thing could be effected by other means with existing plant.

10613. That would not apply to new kilns?—No, provided there was no objection to excluding the furnace gases.

10614. (Professor Thorpe.) Have you had any experience of the use of briquettes in malting?—Never.

Briquette contains base.

10615. Do you know if briquettes are used at all?—I have heard recently that briquettes have been made up and used, but I have had no experience with them.

10616. In the manufacture of those briquettes, was any basic material incorporated?—I have been told that has been done quite recently, that briquettes have been manufactured with basic material.

10617. Are you in a position to say where the experiment has been carried out?—I do not know.

10618. And you do not know the results?—No. I should imagine very good results would accrue.

10619. Of course briquettes are made practically from powdered coal?—Yes.

10620. They would be made from materials from which presumably a large quantity of pyrites would be sifted out, and therefore, you would start with a material containing a relatively small quantity of arsenic?—You would.

10621. That would be a precaution?—Yes; even that, or the coking of coal in the presence of lime would be certainly a very good way of applying the basic treatment.

Oven coke with lime.

10622. The coking of coal in the oven in the presence of lime you mean?—Yes.

10623. That is not a practical measure in the manufacture of coal gas. The coke is the residue, and you would not advise a gas manufacturer to put lime in his oven?—It could not be done in the case of gas coke, as it would have such an influence on the products, and especially upon the tar.

10624. You would not ask the gas manufacturer to lime his fuel?—Certainly not.

10625. Would you advise in the ordinary coke oven that lime should be introduced?—I see no reason why it should not.

10626. Would it have any detrimental effect?—I see none.

10627. If a maltster were to come to you, with your knowledge of the present condition of things, asking your advice as to what character of fuel he ought to use, what would you say to him?—I should advise him to use limed coke, previously selected and analysed; in fact,

Select fuel and treatment.

that is done at the present time. I am doing that particularly in one case, in which all the malt dried has been dried with limed fuel for more than twelve months.

10628. What character of coke have you advised him to select?—Oven coke.

10629. You advised him to select oven coke, and add lime water to it?—Milk of lime.

10630. In the manner you have described?—Yes.

10631. You have done that because you think that is the safest procedure you think he can adopt?—Yes.

10632. Was that sample of glucose which you analysed a few days ago, and which you found to contain that relatively large quantity of arsenic, German or American glucose?—I expect it was American; I am not certain.

10633. Was it liquid or solid glucose?—Liquid glucose.

10634. Was it used for brewing?—Yes; it was sent me from a brewery.

10635. Was it a fairly colourless glucose?—It was a glucose which had not been decolorised by sulphurous acid.

10636. That was the object of my question?—Because it was employed for brewing. I generally advise the use of samples which have not been decolorised, because the sulphurous acid has an influence on the flavour of the beer which the brewer does not like. Therefore the arsenic was in no way due to sulphurous acid. What it was due to I am not aware.

10637. Turning to the analytical evidence you gave the Commission, you pointed out that your practice was to use hydrochloric acid in preference to sulphuric acid in generating the hydrogen in the Marsh apparatus?—That is so.

10638. I think you stated you preferred the use of hydrochloric acid because you had reason to believe the sulphuric acid rather tended to retain arsenic within the apparatus, and that you did not get the same mirror in the case of sulphuric acid that you did in the case of hydrochloric acid?—I have not stated that to-day, but that was my belief some time ago—that the mirrors were not so large with sulphuric acid as with hydrochloric acid. It has been observed by others that that is the case. What I stated was that in the case of beers, when sulphuric acid was used direct, it had been observed that it is impossible to use sulphuric acid direct, because the arsenical mirror is not so intense as when hydrochloric acid is used. When sulphuric acid is used it has been found necessary to destroy the organic matter in the case of beer.

10639. What is your explanation of that?—I do not know the reason. I have no explanation to offer.

10640. Is it the organic matter of the beer which retains the arsenic?—That I cannot say at all.

10641. Is it possible that there is any reduction of arsenic to sulphide of arsenic which does not form arseniuretted hydrogen?—I think arsenic sulphide does form arseniuretted hydrogen.

10642. Have you any experimental evidence for that?—I have added arsenious sulphide to the Marsh apparatus, and have obtained a mirror.

10643. Do you know whether the mirror you have obtained is equivalent to the amount of sulphide of arsenic?—That I do not recollect at the moment.

10644. Anyhow, it is interesting to know you have directly added sulphide of arsenic, and that has been reduced to arseniuretted hydrogen?—Yes. I believe in the dilution we use, arsenious sulphide is a soluble compound.

10645. We all know arsenious sulphide is not absolutely insoluble. If the whole of the arsenic was reduced to arsenic sulphide, the amount of fluid in the apparatus is sufficiently large to keep it in solution, and, therefore, in solution it would be reduced by zinc into the form of arseniuretted hydrogen?—May I go back a little further, and say I have experimental evidence, that when one adds a proportional amount of arsenious sulphide to the apparatus the true arsenic mirror, other things being equal, is formed proportionate to the amount of arsenic. I had forgotten it for the moment. I have done so many experiments in this arsenic testing, that one is apt to forget some of them.

10646. Salts of iron in the apparatus, whether they are introduced directly or introduced inadvertently in the zinc, seem to have some power of keeping back the arsenic, that is to say, retaining it in the flask, and in preventing its evolution as arseniuretted hydrogen?—That is so in my experience in the case of zinc containing iron—zinc which has been granulated with ferric chloride is insensitive. It has failed to detect 1-100th of a milligramme of arsenic added to the apparatus.

10647. Applying that fact to your method for the determination of arsenic in fuel, of course there is in many cases a considerable quantity of iron in the ash, and obviously if there is much pyrites there would be *pro tanto* a relatively large quantity of iron. What would be the effect of that iron in the apparatus, or even on the method of treatment for retaining arsenic?—It might be to give low results. These analyses are compared with the standards in pure water, so that it may be my results are low, especially in the case of gas coles, which sometimes contain large quantities of iron.

10648. That is to say, you might really not be estimating the amount of arsenic which was actually in the flask owing to the presence of iron?—Quite so.

10649. But even if that were the case, and no doubt it would be the case, still, looking at it from the practical point of view, not much harm would result, inasmuch as that arsenic would be retained in the process of burning the fuel. The same operation which retains the arsenic in your flask would retain it in the fuel when burnt?—As the basic treatment is practically carried out there is no doubt it would.

10650. But the iron there would exercise a specific action in preventing the arsenic from being volatilised?—I do not know what the action of the iron is in that case.

10651. Is it not a fact that it does?—Yes, but whether it precipitates it or not I do not know.

10652. In other words, the bane contains its antidote?—I do not think we can compare what happens in the Marsh apparatus in the presence of a liquid and what happens in a high temperature in the dry state.

10653. I am talking of the high temperature in the dry state. If you roast arsenical material with oxide of iron you retain arsenic?—I believe it is retained by oxide of iron as by any other base. But I have pointed that out, I think, in my evidence, that when pyrites occurs in high grade anthracite containing but little ash, the greater part of the arsenic is volatilised during the burning. That is a fact. I found the arsenic in pyrites is practically all volatile.

10654. Do not you think that the iron which is associated in the pyrites tends to retain any arsenic?—It does to some extent, but not to a very great extent, because it does not become oxide of iron until practically the whole of the arsenic has volatilised.

10655. When the fuel is being burned, of course, the process of oxidation is going forward, and the arsenic oxide may be evolved before there is sufficient ferric oxide formed?—That is my theory.

10656. Did you ever analyse samples of spent pyrites?—No. I have analysed pyrites in the laboratory, and determined the fixed and volatile arsenic. Of course, I should have got a spent pyrites in those laboratory experiments, but I have not examined a sample of spent pyrites from vitriol works.

10657. You are aware that spent pyrites may be highly arsenical?—Yes.

10658. They may contain a large proportion of the arsenic?—Yes, they must.

10659. That is proof, of course, that the oxide of iron does act in that direction?—Yes, it is.\*

10660. (Dr. Whitelegge.) Does this process you have described to us add materially to the cost of preparing malt?—Not at all. Lime is a very cheap substance, and I believe that the patent royalty is a penny a quarter of malt. It also enables the maltster to use cheaper fuel.

10661. With careful picking over, which I understand will be necessary in the case of anthracite on account Handpicking of pyrites, would it be possible to remove the slate of anthracite, which you have also described as being arsenical?—I think that slaty portions could be detected.

\* Note by witness.—It will be remembered, however, that arsenic is obtained from pyrites on a technical scale by volatilising it out by heating.

Mr.

iron impair-  
ing Marsh  
estimations.

Royalty on  
lining pro-  
cess.

Mr.  
A. R. Ling.  
20 June 1902

10662. You showed us two samples, one of which is slaty?—The slate is so interwoven with the carbon of the coal, it would be very difficult.

10663. In practice would the picking over for the removal of pyrites from anthracite cover the greater part of the slate?—It would cover the greater part of the impurities generally; but you can only get to a certain point with picking.

10664. It is not so easy to remove slate by picking over as it is to remove the pyrites?—The large quantities of pyrites, the visible pyrites.

10665. In the case of the black pyrites to which you referred, I understand that is disseminated in the substance of the fuel, and cannot be separated very well by picking?—That is so.

10666. I understood you to tell us that in addition to the selection of fuel and to picking over, in the case of pyrites you would rely to some extent upon analysis?—Certainly.

10667. But you pointed out difficulties in the selection of samples, and you think if it could be fixed in sufficiently broad terms some sort of a standard would be useful?—I do.

10668. I should like to know exactly in what light you are thinking of a standard. Are you prepared to suggest a figure?—I hardly think I am prepared to suggest a figure. I have brought forward a number of careful analyses, but I think that the actual figure had better be left over for the present.

10669. Still you think a figure could be fixed such as would guide you in advising your clients, and which might be defined in general terms?—I do.

10670. But you are not prepared to define it now?—No.

10671. I do not want to press you about the particular figure, but in working at a conclusion on a given sample of fuel sent to you, and on which you have to advise the maltster, do you look to the total arsenic or to the volatile arsenic?—I look to the volatile arsenic first of all, but I also look to some extent to the total arsenic. I never ignore the total arsenic.

10672. You do not regard the fixed arsenic as being negligible?—Certainly not.

10673. In what way do you think of the fixed arsenic as gaining access to the malt?—I do not altogether think of the fixed arsenic. I look at the total arsenic. It is necessary in order to arrive at the total arsenic to estimate the fixed arsenic. I do not think the fixed arsenic has any practical significance, but I do think the total arsenic has, because the conditions of burning, if the fuel is untreated, may be such that the volatile arsenic may be greater, as Dr. Thorpe has brought out, in some cases than in others.

10674. Leaving aside the volatile arsenic, the only part that remains of the total arsenic is the fixed arsenic. The total arsenic is made up entirely of fixed and volatile?—Yes.

10675. If the fixed arsenic is a negligible quantity, what is learned by looking at the total arsenic rather than the volatile alone?—I mean that the total arsenic is necessary. It is necessary, in the first place, as has been contended by a great many people, to regard the total arsenic. It may be to some extent a matter of conditions how exactly it is differentiated into fixed and volatile—conditions of burning.

10676. Temperature?—That may be the case.

10677. (Professor Thorpe.) What you really mean is that the proportion of fixed arsenic is not constant; it may vary with circumstances?—Yes. That is my reason for looking at the present time at the total arsenic, and for not ignoring the total arsenic.

10678. It is not constant even in a given sample?—It may be. It is constant in so far as our laboratory method is concerned, but that does not imply that the laboratory method and the practice are analogous.

10679. (Dr. Whitelegge.) You would attach primary importance to the volatile arsenic, and some importance to that which passed as fixed in the particular experiment?—Yes.

10680. Turning now to malt, does the difficulty of which you have told us in sampling fuel apply to malt? Is it easy to obtain a uniform sample?—No.

10681. Have you given any directions as to the taking of samples to be submitted to you?—Yes. I always direct that samples shall be taken from every portion of the kiln, bulked together, and then divided.

10682. But still, subject to careful sampling, you think that the standard figure can be fixed?—I do. I think it is much easier to obtain a uniform sample of malt, despite the fact that the arsenic is not equally distributed all over the kiln. It is easier to obtain an average sample of malt than it is of coal.

10683. I think you told us it was rare to find more than 1-150th grain of arsenic in malt now?—Yes.

10684. And that it is commercially practicable in the way you describe to make sure that the malt prepared in a proper manner should not contain more than 1-300th?—That is the case. That is my contention. In the experiments I have personally supervised I have never found as much as 1-300th, although that is, in my opinion, an amount which can be ignored.

10685. An amount which could be ignored; you mean it is not likely to be injurious to health?—That I would not say. I am thinking now of a 1-100th of a grain per gallon limit in beer. If 1-300th grain per lb. were present in the malt this would correspond with 1-150th of a grain per gallon in the beer.

10686. I have been rather pursuing it from the other side. As the result of experience now, and while the memory of the Manchester trouble is still recent, the maltsters are turning out malt that rarely contains more than 1-150th. You are satisfied that with improvement in treatment, it can be kept within 1-300th as the limit?—I am sure it could.

10687. So that there would be no hardship, in your view, in telling a brewer he is not to allow more than 1-300th of a grain of arsenic in his malt?—I think it is perfectly possible to do that, not by analysis alone, but by analysis combined with treatment and selection.

10688. I do not think that you have given us one part of the evidence in your supplementary proof. You refer to Mr. J. L. Baker, who says that the longer the interval since the cleaning of the malt kiln, the larger the amount of arsenic found in the malt?—That Mr. Baker assures me is the case. I have not noticed it myself, but his duty is to systematically examine the out-turn of several large maltings. His entire duty is in connection with maltsters and brewers, and he tells me that, from a given malting, as the season advances so the amount of arsenic goes up, other things being equal, and the same fuel being used. I think that is an interesting observation. He tells me he can bring before the Commission a large number of analyses bearing on that point.

10689. Do you advise maltsters as to the cleaning of the malt kiln?—I do. It was one of the first things I did, after the arsenic scare, to advise maltsters to clean their kilns.

10690. Do you advise them as to frequency of cleaning?—I do.

10691. Will you tell us how often you consider it is necessary on an average?—I think if a malt kiln is brushed down thoroughly twice during the season, it is sufficient. I think it should be cleaned after every operation to some extent.

10692. But thorough cleansing twice in the season?—Yes.

10693. (Chairman.) I have a letter here from Mr. Increase Baker referring to the increase of arsenious acid in arsenic in malts as the season progresses. What do you understand by that?—He means that, provided the malt kilns have not been cleaned, as the season progresses the malts contain a larger amount of arsenic when the same fuels are used.

10694. As the season progresses from the time of cleaning?—He means to say, first of all, portions of the malt kiln are to some extent absorbent of the arsenic, and as they become saturated with arsenic, so to speak, they become less and less absorbent, and more reaches the malt.

10695. When the kiln is cleaned is that done away with?—Apparently so.

10696. Is there a regular cleaning at definite seasons, spring cleaning, or cleaning several times a year?—I am afraid that was not done as often as it ought to have been until the arsenical scare arose, but I can only speak for those maltsters I advise.

10697. Can you explain the chemical or physical difference between volatile and a non-volatile arsenic of which you have been speaking?—The non-volatile arsenic is the amount retained in the ash of the fuel. The volatile arsenic is the amount which rises as gas. It may be in any form, probably as arsenious oxide.

Mr.  
A. R. Ling.  
20 June 1902

Malt with less than 1-300th grain easily obtainable.

Cleansing of malt kilns.

Increase of arsenic in malts as the season progresses.

Cause of arsenic being separable into volatile and non-volatile.

Any standard test for fuel should be of volatile and of total arsenic.

Sampling malt.

10698. How is the difference that makes some of the arsenic volatile and other not volatile to be explained?—I suppose it is to be explained by the nature of the inorganic constituents of the fuel, whether or not they are basic, alkaline.

10699. Is there such a difference between the arsenic in malts? Do you find volatile and non-volatile arsenic in the malts?—No. I have never tried; it has no significance.

10700. At present there has been no research or chemical investigation to discover the cause of the difference; what chemical combination the volatile arsenic is in, and what chemical combination the non-volatile part is in?—I take it the non-volatile portion is that which is held back by the basic substance of the fuel, the substances which result when the coal is burned.

10701. (Professor Thorpe.) In what form is the arsenic retained in association with the basic material?—The arsenic is retained in association with the basic material as sodium arsenate or calcium arsenate, which is a compound non-volatile at the highest temperature of the blowpipe.

10702. (Chairman.) And the volatile part is arsenite?—Probably arsenious oxide. It may be oxidised to arsenic oxide also to some extent as it rises. It may be sulphide of arsenic too.

10703. (Professor Thorpe.) The arsenic is partly fixed and partly volatile. That which is fixed is retained by virtue of being arsenate either of calcium, iron, lime, or some other basic substance, and that is non-volatile; that which goes away is probably almost entirely arsenious oxide. I say that because the actual crystals of arsenious oxide are often found in deposit on the plates, and have been found on the grain itself?—Exactly.

10704. There is, however, a certain quantity even of the fixed arsenic which gets on the malt by the mechanical deposition of the dust, very finely divided dust swept forward in the air current and lodged on the grain. The consequence is that when you treat malt with water the arsenious oxide goes into solution, and the merely mechanical portion carried up, and otherwise fixed, is left behind?—That is so.

10705. (Chairman.) Fixed arsenic in the malt or beer, if there was any, is still amenable to the Marsh test?—Yes.

10706. (Professor Thorpe.) Yes; it would be dissolved by the acid of the apparatus?—That is so.

10707. It would be evolved as arseniuretted hydrogen?—Yes.

10708. (Chairman.) It is certain that that fixed arsenic does not escape the Marsh test?—Yes.

10709. (Professor Thorpe.) You asked me just now, my Lord, a question as to the formation of pyrites. The explanation of how pyrites is formed in the deposit of coal

was worked out by Bischof many years ago in his essays on Chemical Geology. In the water with which the vegetable matter is soaked, you have carbonate of iron dissolved in carbonic acid contained in the water, and you have also in the water various soluble salts, e.g., sulphate of lime and sulphate of magnesia. In the chemical transformation of the woody fibre into coal the sulphates are reduced to sulphides. They react upon the dissolved carbonate of iron held in solution by the carbonic acid, and you have a precipitation of black sulphide of iron. You see that in every ditch, where you see black mud: the blackness of the mud is partly due to the presence of black sulphide of iron.

(Chairman.) That black pyrites is a sulphide of iron?

(Professor Thorpe.) Yes; sulphide of iron is black when sufficiently finely divided.

(Chairman.) Pure sulphide of iron is black without charcoal at all?

(Professor Thorpe.) Yes; it has nothing to do with charcoal.

(Chairman.) There is also a yellow sulphide, is there not?

(Professor Thorpe.) In process of time the black sulphide becomes gradually crystallised. That has nothing to do with the absorption of arsenic—arsenic may or may not be there. The occurrence of the arsenic is purely fortuitous; arsenic is not necessarily there. If the material contains arsenic, then, by virtue of the extraordinary selective power which iron salts have for arsenic, the arsenic is retained in the pyrites and crystallises with it. When the amount of arsenic gets, as in some cases, sufficiently large it associates itself with sulphide of iron, and you get a definite molecular combination of arsenic and sulphide of iron.

(Chairman.) Is there a definite chemical ratio?

(Professor Thorpe.) Yes, a definite ratio capable of being expressed by a chemical formula— $\text{FeS}_2 \cdot \text{FeAs}_2$ .

(Chairman.) Is there a large proportion of sulphide of arsenic in such cases.

(Professor Thorpe.) Yes.

(Chairman.) Does it affect the crystalline form?

(Professor Thorpe.) Very slightly. You can tell at once that it is the double compound.

(Chairman.) What is the name?

(Professor Thorpe.) Mispickel is the mineralogical name given to this definite product.

Mispickel.

(Chairman.) When the black sulphide of iron crystallises it becomes pale yellow, does it not?

(Professor Thorpe.) Yes.

(Chairman.) Has it the same chemical composition?

(Professor Thorpe.) Just the same, ferric sulphide— $\text{FeS}_2$ . It has the same composition in the black as in the brassy condition, when it is known as marcasite.

And marcasite.

Mr. E. S. BEAVEN, called; and Examined.

10709. (Chairman.) You have been engaged in the management of maltings for 25 years, I think?—Yes.

10710. And you have had opportunities of acquiring experience of the working of a considerable number of different types of malt kilns, both of old and of recent construction?—That is so.

10711. You tell us you have lately been studying the question of the relation of the structure of kilns to the question of arsenic in malt. In this from time to time you have received considerable assistance from Dr. J. M. H. Munro, the Professor of Chemistry at the College of Agriculture, Downton?—That is so.

10712. Dr. Munro had for some years special experience in the subject of arsenic from a prolonged investigation on the effects of fumes escaping from smelting works in South Wales?—That is so.

10713. Do you consider that the access of solid particles to the malt is a considerable factor—the dust carried up?—I am under the impression that if arsenic is present it would be in a solid form, or would be more likely to be in the solid form. The temperature of the malt kiln is usually under 200deg. F., and there-

fore if any arsenic were present in the furnace gases it would be condensed before the furnace gases reached the malt which was being dried.

Mr. E. S. Beaven.

10714. Do you consider that the volatilised matter in the fumes cannot contain much arsenic?—I think it cannot contain much when it reaches the malt, because the temperature is then very little above 200deg. F.

10715. The proportion of contaminating dust in the malt will vary, and the proportions of arsenic in such dust will also vary, according to the differences in the velocity of construction of the kiln?—Yes. The quantity of dust which reaches the malt will be minute, according to my experience.

Construction of kiln and velocity of construction of the kiln?—Yes. The quantity of dust which reaches the malt will be minute, according to my experience.

10716. According to the construction of the kiln there would be more or less arsenical dust reaching the malt?—I think that the construction of the kiln will operate indirectly, but that the most direct factor is the velocity of the furnace gases.

10717. The interposition of baffle plates or other surfaces which effect condensation of arsenic and mechanically keep back the dust would have a good effect, would

Mr. E. S.  
Beaven.

20 June 1902.

it not?—I should prefer the expression screens or filters to baffle plates. I do not quite know what is meant by baffle plates, but I think they would be useful.

10718. Something not to be used as a filter, but something which would cause the dust to be deposited on the plate. But you think a filter better than a baffle plate?—I prefer a perforated structure.

10719. You say that one important factor is the velocity of the hot air and accompanying gases from the fire, which is sometimes very high. For instance, in the case of tall kilns with several floors?—I have no experience with kilns of several floors.

10720. Is there only one floor in a kiln?—In the majority of kilns there is only one drying floor. Kilns are constructed with two drying floors, and sometimes three, but I have had no experience with such kilns. The floors which I refer to in my proof are not drying floors, but working floors. There has been recently a tendency to build maltings higher than they were formerly built. The old method of building maltings before much machinery was used was to build two working floors, germinating floors, one above the other. Generally then the kiln was on a level or somewhat above the third floor. That would carry it to a height of perhaps 15 or 18 feet from the ground.

10721. From the furnace?—Yes.

10722. (Sir William Hart-Dyke.) What is the space between the two working floors?—Eight feet, perhaps.

10723. (Chairman.) Does a man walk about on each floor and turn the malt?—Yes. Recently there has been a tendency, in order to economise space, to build more floors, and many maltings have been built with four germinating floors, one above the other. The kiln in these newer maltings is frequently, not in all cases, at a higher elevation above the furnace.

10724. How does the velocity compare in the two cases of one floor or several working floors? Is the velocity of the fumes nearly the same in the two cases?—When the drying floor is a great height above the furnace it is much easier to obtain a great velocity in the furnace gases.

10725. You obtain your hot air through the ascensional hydrostatic pressure?—Yes. I do not think it is always the case that velocities are higher, but I think they would tend to be higher in high kilns, but they would not necessarily be higher.

10726. The malt is carried from the germinating floors to the drying floors?—That is so.

10727. It is never dried on the germinating floor?—Never in my experience.

10728. The germinating floor is always on one level. There may be several levels, but the germination is the same on the different levels?—That is so.

10729. What do you call the working floor?—What we call in technical language the working floor is the germinating floor.

10730. Where there are several working floors, is the malt dried all on one floor?—I am only acquainted with kilns with one drying floor in which the malt is dried on one perforated floor. Kilns are constructed in which there are two perforated floors, one above the other, but I am not acquainted with the working of such kilns.

10731. In those kilns the fumes would pass through the lower floor and then through the upper floor?—Yes.

10732. And there are kilns with as many as two drying floors, and sometimes three?—Yes.

10733. Do you think that the arrest of arsenic can be effected by reducing the velocity of the gases leaving the fire?—Yes, provided a considerable proportion of the air be heated before admixture with the furnace gases. That, I believe, is accomplished in some high kilns at present. Not all the air derives its heat directly from the furnace, but some heat is communicated to the air which is used for drying the malt indirectly. In other words, there are channels through which a considerable volume of heated air passes without coming into contact with the furnace at all.

10734. So that a large part of the drying is done by air which has not been through the fire at all?—That is so.

10735. Do you think the whole drying of the malt might be done by heating the air in tubes or by plates without passing it through the fire at all?—I have no doubt that if the end in view is simply to reduce the moisture content to a certain point that might be done.

10736. And is not all that is wanted to dry the malt to a proper degree to grind it and prepare it for the commencement of the brewing?—I am not a brewer, and I find that most brewers think not. I imagine that the product would not be the same.

10737. What would be the difference?—I should suppose that the fuel gases have some antiseptic properties.

10738. Supposing that you could get absolutely pure carbon for fuel, would the result be good; would you like a little peat reek along with it?—I think not.

10739. Do you think that pure charcoal for the fuel, setting aside the question of expense, would give the best results?—I imagine there would be no antiseptic value in the fumes from pure charcoal.

10740. What ingredients might give antiseptic value—sulphur?—Yes.

10741. It used to be considered in the year 1742 that sulphur in the fumes passing through the malt in drying was useful as bleaching the malt and giving a fine colour to the beer?—I do not think any importance is attached to that at present.

10742. Is there any other idea about antiseptic property than that which sulphur could give?—I imagine there are other volatile bodies in fuel gases other than sulphur.

10743. Has arsenic, for instance, a fine antiseptic property?—I have no knowledge, but I imagine not.

10744. It has been stated in evidence before us that the flavour of the beer would not be satisfactory if the malt were dried with pure hot air?—I am not a brewer, and I do not know whether that would be so. No reason occurs to me, except that I have already said that there may be, and I think probably there are, some antiseptic properties in furnace gases.

10745. It would be very different with different fuels. For instance, gas coke, oven coke, anthracite, and pure carbon would all have different qualities in respect to any supposed antiseptic substances?—I imagine the pure carbon would have none.

10746. But all forms of impure carbons would have some of that supposed antiseptic quality?—I suggest it is possible; I have no evidence on the point.

10747. Have you any reason to believe that there is a different antiseptic or other quality in the fumes of gas coke, oven coke, or anthracite?—No, I have no evidence.

10748. So that practically you do not feel convinced that pure hot air might not have as good an effect as the fumes from those three different kinds of fuel that are practically used?—No. I am quite open to conviction. I have no strong opinion. I suggest that flavour is a thing which is unaccountable to a great extent. I do not know whether it would be out of place to relate an opinion that was once expressed to me with regard to the difference between Scotch and Irish whisky. I was once going through one of the largest distilleries in Dublin, and I asked the manager if he would explain to me what the difference between Scotch and Irish whisky was. He pulled a very long face, and said in a very solemn manner, "That is a very important question, but I think it is a question you had better not ask me." My impression was that he did not know, and that it is not an accountable difference. There may be just as much difference, which we are not able to account for, between the product of drying by pure air and with gases containing matters derived from fuel.

10749. One difference that seems possible would be the difference between hot pure air and hot carbonic acid, carbonic oxide, and air?—Yes; but I cannot imagine anything would be due to the difference between hot carbonic acid and air.

10750. Or carbonic oxide and air?—I cannot imagine any difference.

10751. Can you imagine anything that is common to the three kinds of fuel, oven coke, gas coke, and anthracite, that would give a flavour to the malt?—I think some flavour is given.

10752. Would it be different between gas coke, oven coke, and anthracite?—It is slightly different. I think I could tell myself the difference, although I am not sure, between the malt which was dried with coke and one which was dried with anthracite. I do not know why, but some brewers prefer the flavour of malt which is dried with coke, and others prefer the flavour of malt which is dried with anthracite.

Mr. E. S.  
Beaven.

20 June 1902.

Fumes  
believed to  
be essential  
for flavour.

E. S. 10753. Chemists cannot test the difference which  
Beaven. accounts for the different flavours?—No. There may be  
June 1902. difference of flavours impossible of analytical estimation.

10754. It seems difficult to imagine that there is a subtle flavouring matter in anthracite and in gas coke and oven coke, and that it is the same in those different substances, and that there would not be anything of the kind in pure charcoal?—I admit the difficulty of understanding or explaining it, but I suggest very respectfully that it is no more difficult of explanation than is the difference between many other flavours to which the public attach importance, such, for instance, as the difference between the flavour of Scotch and Irish whiskey.

10755. In Scotch whiskey there is a great deal of the peat reek flavour which is not done away with in the distillation?—It is extremely difficult to say how it gets into the whiskey.

10756. The malt is dried with peat mixed with fuel?—I am told that is often not so. I am not acquainted with the process, and therefore have no evidence.

10757. You have heard the name of peat reek as giving a flavour to whiskey?—Yes.

10758. That is from the use of peat; but that may be a thing of the past. There may be little peat used now?—I am told that it is not used generally.

10759. (Professor Thorpe.) I believe it is used?—It may be. I have no personal knowledge.

10760. You say you cannot conceive there should be a possible explanation of any difference, but I may point out to you that there is a fundamental difference in fuel, such as coal, coke, and charcoal. It is not a mere question of hot air. All coal contains a considerable quantity of nitrogen, and when the coal is heated the nitrogen is evolved as pyridine, picoline, and bases of that character. These nitrogenous bases are present in an extremely small quantity, but they have the most penetrating smell, and even a piece of paper brought into the atmosphere of three or four drops is impregnated. There are specific flavours which are practically almost imperceptible when you afterwards try to assess them, so to speak, as actual entities. It certainly is so in the case of whiskey. Matured whiskey contains an extremely small quantity of furfural, an aldehyde, present in whiskey to a very small extent, especially in matured whiskey. Whiskey that is deprived of the last traces of furfural is unmerchantable?—No doubt.

10761. (Chairman.) There may be a difference between pure air and fumes, in that the pure air has oxygen and the fumes comparatively little oxygen. Could that affect the germinated grain in the drying malting?

(Professor Thorpe.) In fumes there is any amount of oxygen?—There is something distinctly recognisable in the fumes which come from malt. As between, say, anthracite and oven coke there is a distinct difference in the fumes recognisable to the senses. They are very distinctly recognisable by the smell, and I think it is highly probable that they communicate some different flavours to the malts. Indeed, the aroma of the malt dried with different materials differs. I think the difference is quite comparable to the differences between Scotch and Irish whiskey. I do not mean that it is similar to either, but the difference is comparable. I suggest that it is just as probable that these differences have something to do with the character of the ultimate product, as in the case of whiskey.

10762. (Chairman.) You think there may be a perceptible difference in the flavour of beer according to whether anthracite, gas coke, or oven coke has been used in the malting?—Yes.

10763. Whatever flavouring essence there is one would expect it to be very different in the case of oven coke and anthracite?—I am not competent enough to say how far one would expect it to be very different. I speak from experience that it is somewhat different, but I suggest that it is undoubtedly very different from what would be obtained by pure hot air.

(Chairman.) Would charcoal have a very definite smell?

(Professor Thorpe.) It depends on the charcoal. One form of charcoal will give a kind of fume that another form of charcoal will not. The fume that comes from oak charcoal is very different to that which comes from dog-wood charcoal.

(Witness.) Until recent years, and I believe even now, in the manufacture of one or two special types of stout, wood is still used in the drying of the malt.

10764. (Chairman.) Uncharred wood?—Usually I believe beechwood or oak faggots or billets. I am not sure what wood is generally used. I have not used it myself.

10765. That gives a very decided flavouring to the malt and the beer?—Yes, and it is used with that object.

10766. It may be a very agreeable and wholesome flavour?—Yes.

10767. (Professor Thorpe.) The point is that it is used with that object?—Yes. It is used with the object of giving a particular flavour. There is a brewery with which I was acquainted which until recently used it, and as far as I know it is used now.

10768. (Chairman.) That is a most important statement with regard to the knowledge we are wishing to elicit. Coming back to what Dr. Thorpe has said with reference to nitrogen in anthracite and other coal, is not that nitrogen driven off altogether in the coking?—(Professor Thorpe.) Very largely. To that I ascribe the difference that Mr. Beaven has pointed out, that he can differentiate between malt dried with anthracite and that dried with coke?—I could sometimes do it. I do not suggest that anyone could do it infallibly.

10769. The fact is that it is so. In the tar derived from the coke, those things are obtained. There would be less of the flavour generating substance in the coke than there would be in the anthracite that contains the nitrogen?—Yes.

10770. (Chairman.) According to that, it would seem that while there still might be flavouring essences when coke, whether oven coke or gas coke, was used, there would be less of flavouring essences with these cokes than with anthracite?—Probably.

(Professor Thorpe.) There is that probability. I merely put forward this in answer to your difficulty, that it was mentally inconceivable to you how such a thing might occur. I pointed out that there is the fact of the nitrogenous constituents to be reckoned with. I have no evidence whatever that these nitrogenous materials are to be found in malt. That is not the point.

(Chairman.) My view, which is probably not correct, was that cokes are a near approach to pure carbon, and an approach in which volatile organic matter would probably have been destroyed, but from what Dr. Thorpe now tells us it seems that even a process of coking is not sufficient to destroy some of those subtle flavouring materials.

(Professor Thorpe.) The coke still contains nitrogen.

(Witness.) I believe the extent to which cokes are burnt also varies very much. I believe it is common sometimes to burn oven cokes in ovens for as long as three days. I believe that gas cokes, on the other hand, are only burned for a very short time, sometimes six or eight hours, and that oven cokes are burned with the access of a limited quantity of air to the oven, which I believe is not present in gas ovens. I suggest, still with much diffidence, that even those factors might make some difference to the flavouring material.

10771. You consider it important to cut off the furnace gases when the fires are stirred?—Some dust in all kilns rises from the fires when they are stirred. I think it is a cleanly thing to do to fit a swing valve to keep that dust out of the hot air chamber. It does not necessarily follow that it finds its way through the drying floor, but I think as a safeguard, and as a measure of cleanliness, it is a desirable thing to cut off the furnace gases and check the velocity of the furnace gases by closing the aperture which leads from the furnace into the chamber at the time when the fire is stirred, when there is such an aperture.

10772. (Sir William Hart-Dyke.) What happens if this precaution is used?—Nothing.

10773. The furnace fumes do not ascend?—No. The fire burns temporarily with less vigour.

10774. They are practically destroyed by this process you mention?—The current of air is stopped.

10775. If you do not stop this current of air, you say in the passage of the air there would be certain particles which might go through the perforated floor and affect

Mr. E. S.  
Beaven.  
20 June 1902.

Mr. E. S.  
Beaven.

29 June 1902.

the malt?—It is an undoubted fact that some dust when the fires are stirred goes forward. I think it is desirable as a matter of cleanliness to prevent that. It is such an easy thing to do.

10776. What happens to this dust?—It collects within the distributing chamber.

10777. And would be deleterious would it not, unless it were removed?—I do not suggest that any appreciable quantity of it reaches the drying floor, but I suggest as a matter of precaution, it is desirable to keep it out of even the distributing chambers.

10778. (Professor Thorpe.) You mean keep it within the furnace?—Yes. It goes down with the ashes: when the fire is stirred, instead of the dust flying forward, it simply goes through the fire-bars.

10779. (Chairman.) There is a great deal of dust mixed with the air during the stirring, which, if you give it a few minutes, will settle into the fire again?—Quite so.

10780. Cleaning out the furnace would involve sweeping away the dust?—Yes.

10781. The dust is cleared away at certain times?—That is so.

Use of screens  
for filtering  
and condens-  
ing arsenic.

10782. You suggest also that the interposition of screens kept below 300 deg. F. which act both as filters and condensers of volatile matter would be useful?—I find it in practice very useful.

10783. Why do you fix upon 300 deg. F.?—Because I believe that at that temperature arsenical matter, if present, will be at any rate largely condensed.

10784. You believe that arsenical matter cannot be carried up in practically deleterious quantity in air at a temperature of less than 200 or 300 deg. F.?—That is my impression.

10785. (Professor Thorpe.) Arsenious oxide requires a much higher temperature than that to volatilise it?—I presume so.

10786. (Chairman.) You point out that the fumes as they go through the drying floor are essentially at so low a temperature that they would not carry volatile arsenic, and that the chief way that arsenic does get into the malt is in the form of dust?—That appears to me to be so.

10787. That is a very important conclusion. You would also treat the filters you interpose with lime, in order to fix the arsenic. Do you think that is important?—I have found that a certain amount of arsenic—not a large amount, because I use fuels, anthracites, that contain only a very small amount, a negligible amount—but I have found that of that small amount some is arrested in combination with lime, when lime is placed near the furnaces, and when the furnace gases are at a high temperature, and when also there is a supply of water vapour, or of the elements of water somewhat greater than that which is contained in the furnace gases themselves.

Use of lime  
to intercept  
arsenic.

10788. But those filters that you propose to be kept at a temperature below 300 deg. F., would not want time?—No, I do not think lime would be of any service.

10789. But you would place lime in the hotter filters below those?—Yes. I have done that. I have passed the furnace gases, in a kiln which has been fitted with a filter of this description, at a high temperature through lime, and I find that the lime absorbs a substantial proportion of the small quantity of arsenic which is present in the anthracite coal which was used.

10790. How do you place the lime, in powder or small lumps?—I have tried many different ways, and I am still uncertain as to the best method of using lime, and I am still endeavouring to find out the best method.

10791. Do you know Newlands' patent?—I do.

10792. Did you hear the evidence given by the last witness?—Yes.

10793. Have you any experience of the efficacy of lime or other bases on the fuel itself?—Mr. Newlands and myself have been in constant communication. I think that my plan is in effect the same as Mr. Newlands'. It is to bring the products of combustion at a high temperature in contact with an active base for the purpose of fixing arsenic in a non-volatile form.

10794. Have you experimented at all upon the lime you have used in that way in keeping it for a considerable time to see whether arsenic is caught by it?—Yes, it is. I have made a good number of estimations in my

own laboratory, and they have been made for me by others; as to the arsenic which is taken up by lime so placed.

10795. Do you find it corresponds to the quantity of arsenic which may be supposed to be volatilised from the fuel in the fire?—That is very difficult. It is difficult to make such a comparison, because it is practically impossible to know how much there was in the fuel. I have some experimental results, but I regard these results as preliminary, and I should give them with much hesitation, because I regard them as requiring to be confirmed. I think you would say that this is a matter in which it is necessary to proceed with caution, and in which it would be very foolish to draw conclusions on insufficient premises. All results of this kind need to be carefully established before they are given with any confidence as results, but I have no doubt of the general proposition which I have made, that when lime is placed in the path of furnace gases from anthracite some arsenic is absorbed, if there is also the supply of a certain amount of water vapour or of the elements of water at the same time. I have a model of an apparatus at the office of the Commission which I think would illustrate the point.

10796. We will take the opportunity of looking at it afterwards. In the meantime, is there anything more you can give, whether the results of preliminary experiments or otherwise, bearing on what you have just told us and confirming it?—I have got a book full of results, but I would rather confirm them. I will, however, give you some if you wish.

10797. We should be very glad to have some?—They are to be understood as preliminary results, and I will not guarantee their accuracy. From the consumption of 2,000 lbs. of anthracite I recovered 1,290 grammes of furnace dust, in the filter as I call this lime apparatus, and in the condensing curtains together, which is equal to 15 per cent. of the coal, or 3 lbs. per ton of coal. In that, and in the lime which was used in the filter, I estimated that there was arsenious oxide equal to 1-60th of a grain per lb. of the coal.

10798. Of the coal originally used?—Yes, or 1-400th of a grain in the malt which was dried.

10799. That is, if all that powder had gone into the malt?—Yes; but I do not suggest, or suppose, or believe for a single moment, that any considerable proportion of that would have reached the malt. If it had not been arrested just where it was it would have mainly, almost wholly, I think, have been collected in the distributing chamber of the kiln as dust.

10800. Did you hear Mr. Ling's statement in evidence that very little of the arsenic found in malt can be due to dust?—Yes; I understood he meant very little comparatively.

10801. There is definitely a certain amount of arsenic found in the malt?—Not in all malt.

10802. The arsenic that is frequently found in the malt, according to Mr. Ling's judgment, could not have come to the malt from the dust, but your view is that it could not have come in any other shape than dust?—If condensed matter is also included in the term "dust."

10803. Certainly it is?—Then I would not say it could not, because I believe that where a body has a condensation point of a certain degree of temperature, it may be possible that some condensation fails to take place just at that particular point, but with that proviso I think it is extremely improbable that other than extremely small quantities of arsenic could reach malt as volatile arsenious oxide.

10804. Did you notice the observation and experiment on which Mr. Ling founded his conclusion?—I did not.

10805. Could you explain the opinion given by Mr. Ling? He said, "I have it on reliable authority that for every 10 cwt. of coal used, 1 lb. of dust may be caught by an arrangement placed between the furnace and the kiln. Assuming this dust to contain 5 grains of arsenic per lb. and reckoning one part by weight of fuel to five parts of malt, if the whole of this dust reached the malt it would only contaminate it to the extent of 5 grains of arsenic per 50 cwt. of malt, or 1-1,200th grain per lb."—That I think is quite right.

10806. Do you think then that there must have been a considerably larger portion of dust that may have reached the malt not caught in the arrangement described by Mr. Ling there? Far and away larger quantities than the amount mentioned have been found in malt?—No doubt.

Mr. E. S.  
Beaven.

29 June 1902.

Quantity of  
dust from  
burning  
anthracite  
intercepted  
on screens,  
&c.

Such dust  
would con-  
tribute very  
little arsenic  
to malt.

E. S.  
ren.  
e 1902.

10807. He has it on reliable authority that for every 10 cwt. of coal used 1 lb. of dust may be caught?—Yes, 1 or 1½ lbs.

10808. Do you consider that in these data of Mr. Ling the dust caught was exceptionally free from arsenic?—No. I have no reason to suppose it is exceptionally free. I have never had any acquaintance with fuels with any large proportion of arsenic in them. I should think that is about normal as far as I am aware, and it corresponds with my own experience.

10809. That would give what we are considering practically free from arsenic, only 1-1,120th of a grain per lb., which is generally considered to be so small a quantity that it could not produce any injurious effect?—That is one of my contentions.

10810. Then in cases in which the malt has as much as 1-100th of a grain of arsenic, there should be far more arsenic in the powder caught above the furnace?—Or some abnormal conditions under which a far larger proportion than usual of the dust reached the malt.

10811. But if the whole dust reached the malt, Mr. Ling contended it would only give 1-1,120th of a grain per lb.?—It has been always a great mystery to me where these quantities come from which have been quoted as being present in malt.

used  
might  
inter-

10812. Do you think that a considerable amount of volatilised arsenic may have been passed through, over and above this dust described by Mr. Ling in the statement I have read?—I am wholly unable to account for the presence of material quantities of arsenic in malt. I have had no experience of such quantities. I do not think I can give any explanation.

10813. Have you tried your lime filter with fuel containing larger quantities of arsenic?—I have not, except absolutely experimentally, from which I have no results I can quote.

10814. Do you intend to continue your researches on the subject?—I do.

10815. The Commission will be grateful to you if you communicate the results of further experiments, particularly with the object of finding whether or not the distinctly arsenical fuel, fuel with more arsenic in it than that which we consider as admissible, does give volatilised arsenic which is removed by your process of a basic filter applied hot, or by condensation on the colder screens?—I will do what is possible experimentally.

its  
ision.

10816. I think we may see how, without suspecting the accuracy of anything put before us by Mr. Ling or yourself, the dust might be carried in an exceedingly subtle form. You hold that the arsenical vapour is essentially condensed to dust before the fumes reach the temperature of the drying floor. That may be. But all the arsenic may be there as dust, and yet be thoroughly carried up with the fumes just as if it were gas. Dust if fine enough is carried with air just as thoroughly as if it were gas?—Quite so.

10817. Your process would consist in passing the fumes through a hot basic filter, and leaving the filter at a temperature somewhat near that of the drying floor?—No, it would leave the basic filter at a higher temperature, and there would be condensing curtains above that where the gases would be mixed with a considerable volume of cold air entering from cold air inlets, and where the temperature would be reduced to approximately 300deg.

ime.

10818. You think that the thoroughly volatilised fumes, if hot enough, will act upon the lime in such a way as to leave the arsenic in the lime, and the fumes go out still hot?—Yes, two things being provided: that the mass of filtering material and the quantity of filtering material in relation to the total volume of air going through be sufficient. A thin layer will not accomplish much. Therefore there must be a considerable body or mass of basic material for the gases to come in contact with.

10819. Would it be a layer a foot thick, for instance?—I would not like to commit myself.

10820. An inch thick would be quite insufficient?—Quite.

10821. A foot might be sufficient?—It might be sufficient. I believe from my experiments, provided also that there is the presence of the elements of water.

10822. How are those supplied?—Those are supplied partly by what is contained in the products of combustion.

bustion, but I think this is not sufficient. In the apparatus of which I have made a trial I place a vessel under the basic filter, and I use it not only for the purpose of conveying a small quantity of water vapour or the elements of water at a high temperature to the basic filter, but also as a washing vessel for cleansing the filter.

10823. The filter is at a high temperature?—Yes.

10824. You cannot wash that with water?—Yes.

10825. It is at a temperature far above the boiling point of water?—Yes.

10826. How could you wash it with water?—Do you pour water down through it?—I can demonstrate it to you if you will allow me to show you the model. It is a comparatively simple structure. It is a mechanical arrangement by which the filter is simply immersed into a washing vessel.

10827. Sunk down temporarily; immersed, cooled, and brought up again?—Yes. It has been objected that the water is objectionable, that you are giving the furnace more work to do to drive off that amount of water and the water in the malt. That is so, but the quantity of water is absolutely negligible in relation to the quantity of malt. For instance, in a comparatively small kiln the quantity of water which would be driven off the malt would be ten tons of water in four days. The quantity of water which it would be necessary to use in connection with this apparatus might be 100lbs. or 200lbs.

10828. How often would this washing be performed?—As often as necessary—every day or every hour; it could be performed with the greatest facility.

10829. How often have you done the washing in practice?—In practice once every four days.

10830. That would not give sufficient of the material of water?—No; but there is water permanently underneath permeating through, dry steam.

10831. Water is evaporating under your lime filter?—That is so. I wish to add that the character of the arrested matter will depend on the temperature, but the quantity of it will depend upon the velocity.

10832. The velocity of the fumes upwards?—Yes, but I wish to explain that what is important is not their velocity when they leave the fire, but the velocity when they pass through the malt, and the velocity is much smaller than is commonly supposed. I believe there is a common idea that volumes of air are taken through the malt at great velocities. That is not the case. The theoretical velocity which is required, and which I have demonstrated by means of laboratory appliances, is less than two feet per minute.

10833. (Sir William Hart-Dyke.) You have had very considerable experience in the malting trade in all its bearings?—I have.

10834. You have been amongst maltsters constantly for the last 20 or 25 years?—Yes. I cannot pretend to have any authority to speak on behalf of maltsters generally.

10835. I am not asking that, but as your general experience you have had the advantage of hearing their views, and you know a great deal of the ins and outs of the trade?—Yes.

10836. You are also a practical maltster yourself?—Yes.

10837. I should like to ask you one question with regard to a question put to you by the Chairman as to altering the malting system by a process of pure air. The question arose as to matter of taste. It is rather an important matter, is not it, as regards the brewing interest?—I think it is a very important matter. I think it would need very strong compulsion indeed by some superior authority to induce brewers and maltsters to give up their system.

10838. It is quite possible that if a new system was introduced such as this, brewers might be at very considerable loss by having their beer sent back by customers who rejected it?—It is quite conceivable.

10839. Without really going very closely into this matter of taste, it is perfectly obvious, is it not, that the consumer of beer is very quick indeed at discerning anything fresh in the beer, that the slightest possible change is sure to be detected?—There is no doubt about that.

10840. I notice you state here that you "believe, therefore, that it will be found possible to provide in

Mr. E. S.  
Beaven.

20 June 1902.

Mr. E. S.  
Beaven.

20 June 1902.

Dilution of  
furnace gases  
with air.

several distinct ways for the effectual arrest of arsenical matter in malt kilns without having recourse to indirect drying, the indirect drying being the other process?—Yes.

10841. You mention one or two processes which you think will be thorough and effectual. The first is by reducing the velocity of gas leaving the fire and providing for a considerable proportion of the air to be heated before admixture with the furnace gases, and you said, with regard to that, that this will require in most existing kilns considerable structural alteration?—I think it is a point which may be borne in mind in the building of new kilns, that it would not be a difficult matter to provide. I am aware of some kilns which have already some device of that kind. That is obviously a matter of the structure of the kiln.

10842. If all maltsters were forced to make this change in existing buildings and existing apparatus it would be rather a serious charge on their business?—Yes, very.

10843. Then we come to the proposal which you have heard a good deal about from Mr. Ling with reference to the treating the fuel with a basic material with a view to the fixation of the arsenic in a non-volatile form. With regard to that, I think you suggested a different process from that Mr. Ling put before us?—I suggest that the process is practically the same, and that it is quite the same as to its effects. What happens is that the products of combustion are brought into combination with basic matter in both cases.

10844. (Chairman.) Hotter in Mr. Ling's case than in the process you suggest?—Yes; but by placing the basic matter immediately over the fire the temperature might conceivably be as high in the filter.

10845. (Sir William Hart-Dyke.) I presume there is a process of experiment on in reference to this matter?—Yes.

10846. And is likely to proceed for some months?—Yes. It has been going on for some time.

10847. I should like you to tell the Commission whether it is not a fact that in either case the cost of what you have suggested would be really very small?—Comparatively small.

10848. Have you any idea of what your system—how much per quarter of malt the expense would be?—The total expense would be 2d. or 3d. a quarter—roughly—at a guess.

Cost of  
applying his  
system.

10849. Have you any doubt in your mind, if these experiments proceed for some months and a conclusion is reached as to the best process to be adopted for this basic treatment, that security for the drinker of beer in future will be assured by some such process as this?—I have no doubt that the complete security of the consumer can be secured, but I must be allowed to say that I think the consumer already has security. I am unable from my experience to understand how it is possible for any quantity which could possibly be considered deleterious to be present.

10850. Can you tell us the number of analyses you have made for the detection of arsenic in malt?—I have only made the experiments during the last two years.

10851. Since this occurrence at Manchester?—Certainly. One never supposed before that that there was any arsenic. I have with me records of 385 determinations, not all upon malts—upon malts and furnace products. That is exclusive of a large number of preliminary matters. Those are done by the Marsh-Berzelius process, and they are exclusive of a large number which were done by processes suggested earlier.

10852. You expressed surprise just now at some of these statements placed before us as to the quantity of arsenious oxide found in malt?—Yes.

10853. You express this surprise after your experience. During the two years you have been analysing you have not found these results yourself?—I may say that the results which have been reported to me by professional analysts—I am not a professional analyst—lead me to the same conclusion.

10854. You "desire to say you are of opinion that the malts hitherto produced in this country have been free from arsenic in any other than such minute quantities as there is no evidence to show have been prejudicial"?—That is my opinion.

10855. (Chairman.) There is a large amount of evidence of ordinary malts having considerable quan-

ties of arsenic. We have had a good deal of evidence that there is a certainly dangerous amount of arsenic in a considerable number of malts?—I think the conditions must be quite abnormal in some respects I have no experience of and cannot account for. I cannot give evidence about what I know nothing.

10856. (Sir William Hart-Dyke.) You are strongly of opinion that onerous restrictions such as would materially interfere with trade should not be imposed?—I am.

10857. You do not consider them at all necessary?—I do not think onerous restrictions should be imposed.

10858. (Professor Thorpe.) You obviously consider that some degree of restriction should be imposed, that something should be done to meet the difficulty raised by arsenic in malt. We cannot let things go on exactly as they were. What have you to say to that?—I think that is rather a matter for the Commission than for any individual.

10859. You have given a great deal of attention to this matter, certainly more than any individual member of the Commission. You have been at it continuously for two years. Would you give the Commission the benefit of your own conclusions on that point?—I must say that I think with regard to malt the public mind has been unnecessarily alarmed.

10860. But if it is the fact, and we believe it is the fact, that now and again—I do not say on a very considerable scale—but now and again we meet with quantities of malt which contained arsenic to a deleterious extent, and proved to be a deleterious extent, surely that is a condition of things which calls for some dealing with—that you must admit, do you not?—Yes; if the amounts have been proved to be deleterious, I think it is a state of things which ought to be rectified.

10861. Cannot you, in the light of your experience in treating malts, give the Commission the benefit of your own experience, and say what is the best way of meeting this condition of things? What should be done? If you were in our place, what would you recommend should be done?—That is an exceedingly difficult question.

10862. I suppose it is capable of being answered, is it not?—I cannot say that I have approached the matter from that point of view.

10863. Well, I present that point of view now to you. What would you recommend us to do? My object is simply to get the benefit of your knowledge and experience on this point?—I do not think that a standard test for malts to which malts should conform would be objected to. I mean a test which would have the effect of providing that no arsenical malt should be used—that is, with deleterious quantities.

10864. Do you think that would not be objected to?—I think that would not be objected to, provided the test were not an academical one and the quantity were not an academical one. I look on some of these minute quantities here as academical quantities, not quantities at all—something for which we want some other word than the word quantity.

10865. I quite gather your meaning. You say that you think the trade in general would not object to the imposition of certain limits of the amount of arsenic which should be contained in the malt?—I have no kind of authority to speak on behalf of the trade.

10866. But that is the impression you seek to convey to us. You have reason to hope, at all events, that they would not object to it?—I do not think I should be personally put to any inconvenience by the imposition of a reasonable test applied to malt.

10867. A reasonable test with a reasonable limitation?—Yes.

10868. We will separate the two things; never mind the test for the moment. What do you think would be a reasonable limitation?—I do not know. I think that is a medical question.

10869. Looking at it from the point of view of practice, of what can be obtained by ordinary care without any degree of difficulty, what is a reasonable amount, without the imposition of onerous conditions, or great constructional alterations, or anything out of the common?—I do not think that with anthracite coals, or with good oven coals even—I cannot say with regard to gas coals—I doubt if malts would be produced, except under extremely abnormal conditions, containing more than 1-200th of a grain to the lb., and 1-200th of a grain is an extremely small quantity.

Mr. E. S.  
Beaven.

20 June 1902.

Severe official  
restrictions  
on arsenic in  
malt not  
needed.

E. S. 10870. That would be 1-100th of a grain per gallon of  
beer?—About the same.

1902. 10871. In other words, it comes to this then, that no  
beer ought to be sold containing more than 1-100th of a  
grain per gallon. That is a practical condition even  
now. Is that your point? Such conditions you know  
would secure the beer with not more than 1-100th of a  
grain per gallon?—You mean contributed by malt?

10872. Contributed by malt. Assuming the beer to  
be a whole malt beer?—Yes, that would be so.

10873. That you think is a reasonable degree of limita-  
tion to ask for?—There are other questions which arise,  
when I am asked a question of that kind, especially the  
question of the analytical methods which are employed.  
If too severe a test is imposed it becomes immediately  
within what I believe to be the error of experiment of  
the Marsh-Berzelius process. I believe the unavoidable  
error of experiment of the Marsh-Berzelius process is not  
inconsiderable in relation to such small quantities as  
have been suggested. I foresee the possibility of great  
difficulties, and, perhaps, some contentions arising.

10874. If I have gathered your meaning correctly, you  
wish us to believe that when we impose a limit, if we do  
impose a limit, that the limit should have some refer-  
ence to the nature of the analytical method involved?—  
Yes.

10875. But, assuming that the analytical method in-  
volved were of a character to actually, without much  
reasonable doubt, indicate 1-100th of a grain, what is  
your point then—assuming that the analytical method  
were all right? I do not see exactly how the question  
of the analytical method comes in, because we have as-  
sumed that the analytical method is valid, and there  
ought to be no question about that?—In dealing with  
these extremely small quantities, these practically in-  
tangible quantities, I do not know how any person who  
is not both a chemist and a medical man of experience  
can possibly have an opinion. I do not come within  
that category, and, therefore, I venture to think that I  
have not sufficient grounds to form an opinion.

10876. I have not asked you anything with relation to  
the medical side of the matter. I am asking you, as a  
practical man, having tested hundreds of samples of  
malt, what you find is in practice a more or less attain-  
able limit as regards arsenic?—With the Marsh Berze-  
lius process as it was recommended by the Committee  
of the Society of Public Analysts, or preferably carried  
out, because of the question of solubility of arsenic, with  
the extract of an equivalent quantity of malt, I should  
say that the quantity which I have already indicated  
would not be reached where good fuel was used, except  
under abnormal conditions. But I have only a limited  
experience with regard to fuels, and whether larger  
quantities than these would be reached with other fuels,  
and whether larger quantities than these are still per-  
ceptible quantities I cannot say.

10877. Let us confine ourselves to your own experi-  
ence?—I am confining myself to my own experience.

10878. From your experience, when you use fuel of  
good quality, and when you pay attention to the clean-  
liness of your kilns, and take all the other neces-  
sary precautions which now your experience has taught  
you to regard as desirable, what is the amount of arsenic  
which you still find that your malts contain?—I did not  
understand your question in that way. The malts I  
have been concerned with have not been reported to  
contain as large a quantity as I have just mentioned.

10879. What have they been reported to contain?  
Have they been reported to contain 1-300th of a grain  
per lb.?—No malt has been reported to contain that.

10880. Not so high as that?—No.

10881. Something between 1-500th and 1-300th of a  
grain is what they may under normal conditions con-  
tain; is that so? It is a magnitude of that order,  
something between 1-500th and 1-300th of a grain per  
lb. You would not be surprised if they contained some-  
thing of that character?—I should not; and I consider,  
as I have indicated before, that these are intangible  
quantities within or very near the limits of error of  
estimation.

10882. But you would be surprised if they contained  
a much larger quantity?—Yes. I do not think  
they would contain a larger quantity except under ex-  
ceptional circumstances.

10883. Is there anything in your procedure which is  
exceptional? Is there anything you do which any prac-

tical man could not equally well perform?—On the  
other hand, I am under considerable disadvantages in  
some respects.

10884. Do you mean the disadvantages tell against  
you in the reduction of the amount of arsenic?—No; I  
should not say that. I simply refer to personal dis-  
advantages.

10885. What I want to get from you, if I can, is, ought  
not your brother maltsters to conform to the same  
standard of efficiency that you have reached?—I am not  
competent to speak for my brother maltsters; I have  
no title to speak for them. I would rather not be  
pressed to speak on behalf of others, but I have every  
reason to believe they take as much care as I endeavour  
to in the matter.

10886. I will not press you. I only wanted to gather  
what your individual experience is, and I wished to  
generalise from that. I want to make use of the ac-  
cumulated experience, you possess, and generalise from  
that with the view of finding what is a reasonable prac-  
tical limitation?—I think it must depend upon the  
quality of the fuel which is being used more than upon  
any other factor, and I doubt if, say, in districts where  
practically only coke is available—I am fortunate not  
to be in such a district—

10887. Do you mean gas coke or coke of any kind?—  
Coke of any kind.

10888. But you yourself regard oven coke as being  
very much on a par with anthracite?—Some oven cokes,  
but I imagine there is great variation in cokes, both gas  
cokes and oven cokes. From analyses which I have  
seen I imagine that there is great difference in the  
character of cokes.

10889. But the differences are not wider than in the  
case of anthracite?—I should think that they were.

10890. That is your experience?—Not from my ex-  
perience, but from published reports. I think that a  
limit should be imposed with great care unless it is  
clearly shown that that limit is necessary in the interest  
of the public health, because there is, so far as I am  
aware, no evidence that the malts which have been pro-  
duced, and the beers which have been consumed in this  
country from time immemorial, have been other than  
perfectly wholesome, and because there is no evidence  
that the present methods of producing those malts and  
beers are any worse than they have been. I think that  
is the practical aspect of the question which the Com-  
mission ought to consider. I am sure that is how the  
matter will appeal to most outsiders.

10891. (Chairman.) You feel that it is necessary the  
malt should be tested for arsenic before the brewers use  
it?—I have seen no evidence which is convincing to my  
mind that any malts have contained a sufficient amount  
of arsenic to be injurious.

10892. But we have absolute evidence of some malt  
containing as much as 1-20th of a grain of arsenic per lb.  
or more. How are the brewers to know whether the  
malt contains 1-20th or 1-100th or 1-300th or less than  
1-500th of a grain, unless they test it?—I think that  
brewers will for their own protection for a long time  
to come be extremely careful with regard to the malts  
which they use. I have not a doubt that maltsters will  
be equally careful with regard to the fuels which they  
use, and with regard to their processes of drying in the  
light of what has transpired.

10893. (Professor Thorpe.) What is to keep them up  
to the mark, unless it is by the imposition of something  
like a limit—how is the public to be made secure?

10894. (Chairman.) We have had some evidence of  
malts made since the warning was given a year and a  
half ago—recently made malts—containing as much as  
1-10th of a grain to the lb., many containing 1-20th of  
a grain to the lb., and many specimens containing 1-30th,  
1-40th, etc.?—I do not think such amounts ought to  
occur with proper methods.

10895. Of a large number examined we have many  
containing 1-40th, 40 containing 1-60th of a grain, 32  
containing 1-100th of a grain, and so on. There must  
be some security against such amounts of arsenic being  
in the malt that is used?—Yes.

10896. You told us that in some modern processes of  
malting a considerable proportion of the air is brought  
to the drying floors not through the furnace?—That is  
fumes with so, in almost all kilns; a large proportion.  
air.

Mr. E. S.  
Beaven.

20 June 1902.

*Mr. E. S. Beaven.*  
20 June 1902. 10897. Modern kilns?—Yes, and in almost all kilns I would go as far as to say a considerable proportion of the air that comes in contact with the malt does not come in contact with the furnace.

10898. Could you have said that two years ago as well as now?—Yes.

10899. The air that does not go through the furnace is heated how?—It dilutes the air that does go through the furnace.

10900. There is no air expressly heated for the purpose introduced in modern kilns?—There is in a certain kiln which to my knowledge has been recently built.

10901. Within this past year?—The particular kilns to which I refer have been built within the last two years.

10902. In the kilns you refer to, a considerable proportion of the air is heated and introduced to the floors, not through the furnace?—To a certain extent.

10903. To a temperature high enough for drying the

malt?—In the earlier stages—when the temperature is not required to be high. I have not had actual experience of those kilns.

10904. Have you any reason to say that most probably that malt would be less satisfactory in flavour than malt dried by fumes which have come through the floors?—I have no reason to suppose it would be less satisfactory, but I cannot say, as I have not seen the malt dried in that way. I have seen one or two samples of malt which have been dried by air alone. I have considered those malts to be somewhat deficient in what I, as a maltster, call flavour.

10905. From your own examination?—From my own tasting of them, but I have not seen a sufficient number of samples to form an opinion.

10906-10. So that there is really not any large body of evidence against drying malt solely by pure air?—I do not think there is any large body of evidence, but I think, as I have said before, there is a strong general opinion that the flavour would be different.

*Mr. E. S. Beaven.*  
20 June 1902.

## TWENTY-SIXTH DAY.

Friday, 31st October, 1902.

AT 1, CHAPEL PLACE.

PRESENT :

The Right Hon. Lord KELVIN (*Chairman*).

The Right Hon. Sir WILLIAM HART DYKE.  
Sir WILLIAM CHURCH.

Professor THORPE.  
Dr. WHITELEGGE.

Dr. BUCHANAN, *Secretary*.

Mr. H. HAMMOND SMITH, re-called; and Examined.

*Mr. H. H. Smith.*  
31 Oct. 1902. 10911. (*Chairman*.) With regard to your Report, on arsenic in various articles of food (Appendix 24) which is before us, will you in a general way tell us how the inquiries there referred to were carried out?—They were mainly carried out by direct inquiries from the manufacturers, and, in addition, as far as I could, I made use of the men who were actually working at the works to find out as much as I could about the different ways in which the manufactures were carried on. I did not confine my inquiries to a single representative of the firm. I very often went round with the manager or foreman, and consulted the chemist of the works, where there was one.

10912. (*Sir William Church*.) I do not know whether this is the proper time to mention it, but I would like to ask you about the use in food of Pharmacopoeial preparations, as, perhaps, some of the statements in your report may be brought to the notice of the Pharmacopoeial Committee of the General Medical Council. Is it the case that a good many of the manufacturers of food products rely upon getting pharmacopoeial acid, pharmacopoeial glycerine, and other substances, and that they do not think it necessary, if they get what are sold to them as pharmacopoeial preparations, to test them any further themselves?—At a number of the works I refer to, a manufacturer—using glycerine for an example—takes the precaution of obtaining a pharmacopoeial preparation, or else he orders "glycerine suitable for food purposes," and then gets supplied with glycerine which passes the test of the British Pharmacopoeia. I should say that, as a rule, he is quite content not to have the glycerine tested himself. Of course, there are some who do not ask for pharmacopoeial preparations, or for any other evidence of suitability for food purposes. I have lately corresponded with a medical man in Pontefract who is well acquainted with the manufacture of liquorice there. I asked him whether glycerine is used in

making liquorice sweets, and he replied that it is, but that "good glycerine" would be too expensive to use for the purpose. That probably is an illustration of the use of a substance that does not conform to the pharmacopoeial tests. Of some substances, such as borax, the pharmacopoeial quality would hardly ever be ordered when it is required for food.

10913. The question suggested by your report is whether, when pharmacopoeial preparations are used, the official tests of the Pharmacopoeia afford a sufficient safeguard against arsenic?—I am not quite sure that they do altogether. In some substances liable to contain arsenic, boric acid for example, arsenium is not mentioned as a contamination to be looked for. Then, again, the pharmacopoeial tests require that "no arsenium" shall be present by certain tests. These tests are merely qualitative, and I am not sure how much arsenic they might pass. For example, I lately sent to Dr. McGowan a sample of acid phosphate of lime, used as a constituent of baking powder, and he reports 0.84 grain, or nearly 1 grain of arsenic per lb. in it. It is possible, though unlikely, that a merely qualitative test might not detect even as much arsenic as this.

10914. (*Professor Thorpe*.) Is acid phosphate of lime a pharmacopoeial preparation?—It was bought through a chemist.

10915. Through a wholesale druggist?—Yes. I see you are right; calcium phosphate is a pharmacopoeial preparation, but not the acid phosphate.

10916. (*Sir William Church*.) I gather from your report that if the attention of the Pharmacopoeial Committee were called to the question of arsenic in pharmacopoeial substances used in foods, the chief of these substances would be sulphuric acid, hydrochloric acid, phosphoric acid, tartaric acid, citric acid, borax and boric acid, and glycerine?—Yes. Glycerine is an

*Mr. H. H. Smith.*  
31 Oct. 1902.

B.P. requirements are uncertain as to safeguards against arsenic.

Pharmacopoeial substances in foods.

Mr. Smith. exception, because in that case a quantitative limit of arsenic is fixed by a special test in the British Pharmacopoeia. But it has been pointed out to me often by chemists that this test is not very stringent, and you have before you in the appendix to my report the observations which Professor Campbell Brown has made on the subject. I might add that one analytical chemist whom I saw, and who had lately been going into the question, was so much impressed with the occurrence of arsenic in glycerine that he urged that a large number of glycerines should be collected by the Commission and analysed for arsenic.

10917. (Chairman.) Would it be desirable that the manufacturers should be encouraged to ask for pharmacopoeial glycerine, and for the pharmacopoeial quality of any particular ingredient, and that if they got that they could be sure they had been efficiently tested?—I think it would be of great assistance to the manufacturers who use these substances.

10918. Would it be right, in that case, that the manufacturers should take that as being a sufficient guarantee, without testing it themselves?—It would be an additional advantage if they did test it, and where a manufacturer uses a considerable quantity of an ingredient like sulphuric acid or glycerine, I do not think he ought to neglect the precaution of testing systematically himself. In practice a golden syrup maker, using a considerable quantity of sulphuric acid, usually, and quite rightly, relies on his own testing. But in any case, what is suggested would be useful, as there would then be some form of standard to go by if the drug they were using could be required to comply with the official tests. I think the tests might, as Sir William Church suggests, be looked over again, and altered if it is found that there is any serious doubt about their significance in respect of arsenic.

10919. (Sir William Church.) There is another substance to which you refer in your report which I do not think is actually pharmacopoeial, but which is used a great deal in the treatment of disease, namely, lanoline. It is largely used in ointments?—Yes. It was quite by accident that I came across the fact that lanoline had been used in a food preparation. It was employed at a sugar refinery to prevent the sugar boiling over too rapidly.

10920. (Chairman.) What is lanoline?—

10921. (Sir William Church.) It is a grease that is obtained from the wool of sheep, and all the sheep dips, or most of them, contain arsenic. This lanoline has been found in one or more instances to contain a high percentage of arsenic. Would you think it desirable that chemists' attention should be drawn to the possibility of arsenic in lanoline?—I should.

10922. (Sir William Hart-Dyke.) I suppose you wish to insist, do you not, that certain foods may contain dangerous quantities of arsenic unless great care is taken in their manufacture?—Yes.

10923. Do you think much danger is likely to arise from actual ignorance of the manufacturer as to the properties of some of the ingredients he uses?—Yes; so many of the manufacturers do not know anything of the dangers that exist. For instance, I think very few of them know of the danger of arsenic getting in by way of glycerine. It is not wilfulness on their part, it is simply that they do not know anything about it.

10924. If they knew more about these ingredients the alarm it would create would at once make them more careful?—It would make some of them more careful; but some of them are very ignorant men.

10925. Can you suggest any expedient whereby manufacturers, both those who have been long in the trade and those who have only come in lately, could be informed of the dangers which exist in these ingredients? Would it be of any use for a Government Department, upon the information which you have placed before the Commission, to issue a schedule or a list of dangerous articles and ingredients?—I do not see why those foods that may contain dangerous substances should not be scheduled, just as much as a dangerous trade in a factory is scheduled by the Home Office; or there might be a schedule of ingredients which are liable to be dangerous, and the manufacturers told of the risk they incur by using them.

10926. Do you think there is any difficulty in any careful manufacturer, who is aware of these dangers, turning out food free from arsenic?—I do not see any difficulty in their turning out food entirely free from

arsenic. All these articles which are liable to introduce arsenic into food can be obtained practically arsenic free.

10927. And you do not think that in the manufactories, where these processes are going on, any material extra cost would be incurred by protecting the public?—I do not think it would cause any great increase in the cost, because the quantities used are very small.

10928. Can you tell us if any official safeguard exists to-day against the careless manufacturer, whether British or foreign, and, if so, what?—I am not an expert in legislation. So far as I understand it, there is no safeguard as to the ingredients the manufacturer uses. What safeguard there is, consists in taking samples under the Food and Drugs Act. The Commission themselves indicated in their interim report, that this control over the finished article has not in the past proved very efficient.

10929. You think, that in some cases, the safeguards, under the Food and Drugs Act, are unreliable, because they come too late, as it were?—Not only that, but I am not sure that they are quite reliable, as regards the kind of samples that are taken. Take cakes, for instance. I have never heard of cakes being examined by the public analysts. It may have been done, but I have never heard of it. The public analyst has certain things that he analyses regularly—milks, butters, peppers, and that sort of thing—and the inspector goes on, in a more or less routine way, collecting substances recognised as likely to be adulterated or diluted, in order that the vendor may make more profit; but, I doubt if many of these substances that are mentioned in this report are examined very often, or at all, for arsenic.

10930. But some foods are now being tested by the public analysts; is not that for the security of the public?—So far as arsenic is concerned, I should think the number of foods so tested is small. In the returns made by the public analysts to the Commission last year, it was evident, that just after the Manchester epidemic, a large number of foods, particularly those containing glucose, had been tested in many districts, but I do not think that public analysts are now doing much in the way of testing food for arsenic. I have had several conversations with the public analysts I have met in the course of my inquiry, and I have been rather struck by this.

10931. So far as your investigations have gone, do they lead you to think, that with regard to public analysts, a great deal more protection might be afforded, if analyses for deleterious substances were proceeded with on a much larger scale than at present?—Yes, I think it would.

10932. If the analysis of the actual food itself is not proceeded with, might not this occur, that some new method of manufacture, or some new ingredient might be used, and that might lead to danger; some new chemical process might be carried on, which would be dangerous, which might, as it were, slip in as something new, and in that case danger might arise?—Yes. It seems to me also desirable, that the manufacturer of such a food should, in some way, be liable to inspection of some sort, which would show whether there is any risk in his methods.

10933. That would tend rather to the examination of the method of manufacture, and to the analysis of every possibly injurious ingredient, rather than to analyses directed to the finished product?—Yes. I do not profess to have gone into the administrative question. I think there might be some control through the ingredients. You might, for instance, have a dangerous food schedule.

10934. With regard to imported food-stuffs—food, drinks, confectionery, and other matters—in that case, I presume, the only possible safeguard is examination and test of the finished product?—Yes, I do not see how you can do it in any other way.

10935. That is the sole protection, is it not?—I do not see any other. That question is very important. I had no idea, until I looked into it that such a large quantity of the kind of finished foods, which have been dealt with in this report, are imported into this country. For example, take these malted foods from America. I can get no information first-hand, of what these foods are malted with. Some of the agents tell me, that in America, they are always malted over anthracite. But, again, on the other hand, I have been told, with regard to a lot of the foods made in the West of America, that the anthracite would be so very expensive, that it could

Official safeguards against arsenic in ingredients.

and in finished foods, insufficient.

er often  
nt of  
om  
e in  
ients.

Possible inspection of food manufacturer.

Mr. H. H. Smith. 31 Oct. 1902. not possibly be used as a malt fuel. Then there are all the different meat foods, and the foods made from caseins, prepared by the use of different acids. They come over from America, manufactured ready for use, and you have no safeguard as to what acid they are using in America.

10936. But, with regard to all home-products and manufactures, you are strongly of opinion, that analyses should take place of each ingredient used, where it is liable to be contaminated by arsenic?—I certainly think it would be a great safeguard.

10937. You think, that should be urged upon all manufacturers?—I think it would be the greatest safeguard the public could have, if it were done.

10938. You have suggested another safeguard, namely, that there might be some schedule of all these dangerous ingredients, and that all manufacturers shall have it placed before them?—I think so, certainly.

Demand for official limits for arsenic in food; 10939. Do you think it is essential, before further action is taken in the matter, that there should be some agreement as to the quantity of arsenic, which would be enough to condemn any food as injurious to health?—I think it would be of great assistance to the manufacturer. At many of the places I have been to, I have been asked that question: "Is there going to be a standard for these things?" Of course, I said I could not say, but I think it would be of great assistance if the manufacturer knew that he must keep well below some definite limit of arsenic in his product.

10940. They want really to know, in effect, what security means?—Yes.

10941. And that would be of considerable assistance to them in dealing with all ingredients?—Yes.

10942. Tests would be applied to see that there was not above a certain quantity of poisonous matter in any ingredient?—Yes.

10943. (Dr. Whitdegge.) When you speak of the demands for standards from the different manufacturers, I suppose, that that was not only a demand for a standard of what was likely to be injurious to health, but a demand for a standard of the particular amount they could work to?—Yes, especially as regards ingredients. If they got more arsenic than that, it would be sufficient to condemn the article, so that they could not use it.

principle on which such limits should be fixed. 10944. There is a reference to that under "coloured foods" in your report, repeating rather what Mr. Hehner told us. I think it is rather remarkable to find that Mr. Goodfellow takes the attitude described here. He passes very considerable quantities of arsenic, presumably avoidable quantities, in consideration of the fact, that in those uses of colours which are known to him, the arsenic would be so diluted as to be harmless. I suppose, the standards which manufacturers in general are asking for, would not be standards of that sort?—The colour which Mr. Goodfellow has alluded to here, is a dry colour, which is imported into this country before it is made up into the paste, which the confectioner uses, but those were his words. He said: "I can assure you, that you will be surprised to hear what a large amount of arsenic I pass in these colours, because I know so little will eventually get into the finished article."

10945. We have your recommendation now, based on your interview with a number of manufacturers, that there should be a standard, or standards available, for manufacturers of foods?—Yes.

10946. You agree with that?—Yes.

10947. But you do not contemplate a standard of the sort adopted by Mr. Goodfellow in this instance, do you?—I have so little information about the colours, that it would be a difficult thing for me to say what the basis of a standard in colours should be. I am informed by Mr. Pronk, who belongs to a large firm of colour-makers, that it is quite possible to send out these colours, arsenic free, and that, when he is sending colours to food manufacturers, he always ascertains that those colours are arsenic free. When he finds that a colour contains arsenic, he rejects it as not being proper for food, and it is put on one side for textile manufacturers.

10948. But, would you think, that if an ingredient of food is used in a small quantity in the preparation of food, it is immaterial whether the amount of arsenic be kept down to the lowest possible limits or not?—I think it is most important that it should be kept down to the lowest possible limits, and, if possible, avoided altogether. In the colours I mentioned, the arsenic can be reduced to an extremely small proportion, or obviated

altogether. Here is the whole list of colours which are used in confectionery, which are reported as arsenic-free. They are all analysed before they are sent out.

10949. Does it not follow, that if a very small proportion be used, the additional cost (if any) to the manufacturer using it must be necessarily relatively small?—I suppose so, if he used a small quantity.

10950. (Sir William Church.) I should like to ask one question here. I am under the impression, that at the present time there is no Department, either governmental or municipal, that exercises any control over the private individual who sets up a manufactory of food-stuffs. He is not responsible to any one?—I believe he is not.

10951. For instance, you give an example here of Mr. Overbeck, who starts a new food, made to a large extent from malt culms. In starting that business, and putting his ware upon the market, he is not responsible to anyone, he is only responsible if his finished products are found to be deleterious, under the Food and Drugs Acts?—I believe that is so.

10952. Do you think it would be possible, that anybody, setting up a manufactory of food-stuffs, should have to give notice to any public authority?—Merely as a personal opinion, I cannot see why he should not. You protect a man from working in a dangerous trade, you impose special regulations for him; you protect a boy working in a factory, by seeing that the machinery is all properly enclosed, you protect him further by having him examined by a doctor before he is allowed to work in that factory; but any man may make any food for the man or boy to eat, and unless it is found deleterious by the public analyst, he can go on eating it until an accident occurs. That is the way the question has struck me during the time I have been inquiring into it. There are certain precautions taken, of course; for instance, the sanitary inspector finding diseased meat on sale. But there is nothing done about treacle or cakes, or anything like that. The case of Mr. Overbeck is a very good example.

10953. As a matter of practice, you have been inquiring into these things. Would it not be impossible to maintain control in any way over the production of food stuffs, because many food stuffs are produced in small quantities by private individuals, and then placed on the market. A man who opens a factory is not really in a different position from the woman who makes a few pots of jam, which she sells on the market?—Yes; but most of the foods that we have been talking of here are made in rather large quantities in large factories. It does not follow, of course, that because they are large places their precautions are adequate. Take, for instance, a table syrup maker whom I saw the other day. He buys his glucose, and he buys the invert sugar that he makes his table syrup from. He sells some of this invert sugar as "golden syrup," and he sells another quality as "golden syrup mixed with glucose." But he has no idea where that invert sugar comes from, he has no idea what acid has been used in its manufacture; he knows nothing about his glucose. He has never had either of them analysed, and he has never had either of them tested. That manufacturer is one of the largest men in London, so that you may very possibly have an accident arising out of his ignorance of the materials that he is selling.

10954. (Chairman.) Where does he buy his glucose?—He gets it on the market, through merchants. He buys a large quantity at once. Take a man, again, who makes gingerbread nuts. At one place I visited they make the best gingerbread nuts with golden syrup; I know about the manufacture of this syrup, and it is a very good one. But another and cheaper golden syrup is used for the commoner article by the same manufacturer, and he knows nothing whatever of its origin or manufacture.

10955. (Sir William Church.) You do not think that the mere examination of the finished product, as it is turned out, is a sufficient safeguard?—I do not think it is a sufficient safeguard, unless an enormous number of foods were analysed.

10956. I gather that in your view a municipal or Government inspector should have power to enter any factory and take samples of any material which is used in the product of the factory?—I do not venture to suggest who should be the authority.

10957. Without saying who it should be, you would grant to some persons the right to enter these factories

Mr. H. H. Smith. 31 Oct. 1902.

No official control over a new food manufactory.

Official control at factory.

fr. and demand that they should be allowed to look at the books with reference to the ingredients which might be harmful?—Yes, I had that in my mind.

10958. (Chairman.) At present municipal inspectors under the Food and Drugs Act are entitled to enter any shops, large or small, in which food is sold?—I believe they may enter any retail shop.

10959. But there is no power for doing that in a factory?—My impression is that there is no such power.

10960. (Sir William Church.) Do you see any practical objection to an extension in some way of the Act that there should be some public authority—I am not saying who it should be at the present moment—who should have the right to go into a factory of food products for the purpose we are discussing?—My impression is that the large manufacturers would rather welcome it. Perhaps I am going a little too far in saying that, but they would not object to it. As to the small manufacturer, you have to deal with an ignorant man, who is using things which he had no idea were dangerous.

10960\*. That would be all the more reason why you should have the power to deal with him?—Quite so.

10961. (Professor Thorpe.) You are suggesting, in effect, an extension of the provisions of the Food and Drugs Act to meet the case of the manufacturers, as well as the retail tradesmen. If this were done, and the machinery already set up by these Acts utilised, the authority charged with the execution of the new powers would be the local authority, subject to supervision by the Local Government Board?—Yes, that would be so.

10962. There is something in that direction already as regards margarine in the amended Margarine Act. Premises in which margarine is manufactured must be registered by the local authority, and that gives them a right of entry. Every manufacturer or wholesale dealer in margarine must keep a register, and this register must be open to the inspector of the Board of Agriculture?—I did not know that, but it is evidently an important point.

10963. (Dr. Whitelegge.) Margarine, of course, is a food substance and nothing else; it is often manufactured in a place where nothing but margarine is made, and there is no question about its destination for food. If you were considering foods generally, and still more if you were considering food ingredients, you would frequently have a case where the destination of the finished product might be food, or it might not. For example, take the manufacture of glucose. We have been told that there are several other destinations for glucose which have nothing to do with food whatever. I am not objecting to the suggestion of inspection, but this might be a more complicated case?—Yes; there would be many points to be worked out.

10964. (Chairman.) In the first section of your report, with regard to coal-tar colouring matters containing arsenic, have you, since making the report, received any information as to the quantities of arsenic found in them?—I took a sample of green colouring matter called apple green, and sent it to Dr. McGowan. He reports approximately one-twelfth of a grain of arsenic per lb. in it.

10965. Was this used for colouring food?—Yes. I took it at a confectioner's.

10966. Are there other poisonous colours used in confectionery besides those which may contain arsenic?—Some of the mineral colouring matters, I think, are poisonous, but I have not been much into the question.

(Professor Thorpe.) Certain coal-tar colours, which are free from arsenic, are quite as dangerous as if they contained considerable quantities of arsenic.

(Chairman.) And are such liable to be used by confectioners?

(Professor Thorpe.) Yes; that came out in evidence before the Departmental Committee on Food Preservatives and Colouring Matters.

10967. (Dr. Whitelegge.) It would be very convenient if we could have some evidence as to the prices of the sulphuric acid prepared in different ways. That is referred to in Section I.?—You mean the addition it might make to the price?

10968. Yes. For instance, brimstone acid, acid prepared from recovered sulphur, or by the synthetic process?—I am afraid I cannot give that straight off.

10969. Perhaps you would kindly add that. Similarly, in Section I., with regard to borax and boric acid, you speak of de-arsenicating process increasing the

price £5 per ton. It would be rather useful, again, if we knew what that increase was on?—I do not know more than this; whatever the market price of the commercial boric acid is at the time, the price of the purified substance is so much more. I will give an example of the price if I can obtain it.

10970. (Chairman.) Can you give a summary of the chief ingredients liable to contain arsenic, which seem to require the attention of the manufacturer?—Provisionally, I would say that the chief are:—Sulphuric acid, hydrochloric acid, phosphoric acid and phosphates, tartaric and citric acids, borax and boric acid, glycerine, glucose, invert sugar, caramel, colouring matters, and malt.

10971. In part of section 2 you deal with the risks of arsenic in golden syrup. Did not Bostock at one time make a golden syrup?—They did. I should like to refer to the visit I paid to Bostock's manufactory, where they had been trying to invert cane sugar to make table syrup. They added sulphuric acid to cane sugar, flavoured it with essences, and sent it out in tins to grocers. Luckily for the public, they failed in their process. They inverted too much, the syrup went solid, and was returned to them by the grocers. I got a sample of the returned stock, which I found on their premises, and sent it to Dr. McGowan. He at first reported that he had got such a black mirror with the syrup that he could not really estimate the amount of arsenic. I lately asked him to repeat the test, and he has taken a very small quantity, and he returns approximately one grain of arsenic per lb. of the table syrup.

10972. That was enough to cause wholesale poisoning?—Yes. But, luckily, nothing beyond a few specimen tins ever went on the market.

10973. (Sir William Hart-Dyke.) What is the date of this occurrence—was this after the Manchester scare, or quite lately?—The manufacture of this table syrup had been undertaken in 1900, not long before the detection of arsenic in the brewing sugars. I found the tins of this syrup when I visited the works on the 24th May, 1901.

10974. (Chairman.) A child taking a few spoonfuls of that would have a poisonous dose?—I should think it would make him very ill.

10975. Was a quantity of that syrup in stock ready to go out?—There were 14 tons in stock. It was in tins packed in small square boxes, two dozen tins in a box. They were all ready, with their labels on. Some had already been sent out, but they had been returned, because, luckily, they had got solid, and could not be sold as syrup.

10976. And through that accident it was returned to the makers?—Yes.

10977. And after it was returned, it was found to be poisonous to the extent of the amount of arsenic you have mentioned?—Yes. That is the report I have now received. After my visit to Bostock's it was all burned.

10978. (Dr. Whitelegge.) What were they doing with it when you found it there?—They had it in a big room in the warehouse. Mr. Williamson, who represented Messrs. Bostocks, had told the Commission that there were 700 tons of their glucose there, and I went up directly afterwards to look at this glucose, and on my way to see this at the factory, I walked through the room where the cases were.

10979. Were they not destroying it on their own initiative?—No.

10980. Nor had they examined it for arsenic?—Not until after my visit.

10981. (Professor Thorpe.) That means that Bostocks were practically using the same sulphuric acid for the inversion of ordinary sugar that they had been using for the manufacture of glucose?—Yes.

10982. They had been using Nicholson's acid?—Yes.

(Chairman.) What has become of the rest of Bostock's stock and of the firm's action against Nicholson?

(Secretary.) Mr. Hammond Smith has just stated that the contaminated table syrup was burned. Bostock's glucose has been sold with very stringent precautions to textile manufacturers, an undertaking being given by each person purchasing it that he proposed to use what he bought solely for the purpose of his own business and for matters unconnected with food, and that he would not part with the glucose to anybody else. Bostock's invert sugar has been sold to blacking makers with similar precautions. These steps were taken in all sales after the end of May of last year. They were really the outcome of the evidence which was given in

Mr.  
H. H. Smith.

the Commission by Mr. Williamson, of the correspondence which ensued between the Commission and the liquidators, and of the representations which I was instructed by the Commission to make to the Local Government Board. My colleague, Dr. Darra Mair, was sent by the Board to make local inquiry. He saw the liquidators and their representatives, and pointed out to them that the Commission and the Local Government Board were not satisfied with what had been done, and told them what precautions were essential if the stock was to be sold at all. I understand that the whole of the stock had been disposed of in the way I have said by the beginning of this year, after Dr. Mair's visit. The liquidators undertook that particulars of each separate sale should be reported to the Commission as it took place, and I have sent copies of all reports to the Local Government Board. So that we know what the destination of the stock has been, and I think we can be satisfied with the precautions to secure that none of it has had any chance to get into food since the date of Dr. Mair's visit.

10983. Is Bostock's manufactory going on still?

(Secretary.) No, I believe the machinery has been sold by the liquidators. With regard to the action between Bostock and Nicholson, about which you asked, I cannot give you any definite information. It has not been withdrawn.

Boron  
preservatives  
in milk.

10984. Borax and boric acid are still largely used for preserving milk and butter?—(Witness.) I was told at the factory of the Consolidated Borax Company that its largest use is as a preservative for bacon and ham, and that sort of thing. But notwithstanding the recommendation of the Preservatives Committee, the prosecutions lately based upon the use of preservatives in milk show that borax preservatives are still being used. Last July, for instance, there was a prosecution for 112 grains per gallon in milk.

10985. That was a prosecution under the law as being an adulteration?—I presume so.

(Professor Thorpe.) These prosecutions are always brought under the same clause of the Act, namely, that a thing is not of the nature, substance, and quality demanded by the purchaser; in this case because it contained boracic acid. They are generally now successful.

10986. (Dr. Whitelegge.) In Section III. of your report it is said that samples of coffee have been sent to Dr. McGowan, and the same observation is made in other cases. Have you any further results of these analyses?—I have a few which have been sent in since the report was written, but I have not received the analyses of coffee yet.

10987. The results will be added when they are sent in?—Yes. I understand that a complete list of samples which Dr. McGowan is examining will be prepared when the results are complete.

Grilled foods.

10988. (Chairman.) With regard to the subject of food exposed to the products of combustion, and the use of fire for cooking, have you examined a mutton chop or a beefsteak which have been cooked over the fire?—I have not had any chops or steaks examined. I went to examine some of the grills in the big grill rooms in London. The mode of construction of the fireplace led me to think that while chops and steaks received the heat from the coals, the actual product of combustion was drawn through the back of the grill and passed up the chimney.

10989. With the old method of cooking mutton chops and beef steaks over the fire, if there was arsenic in the fuel one would think it would come in contact with the steak. Have any experiments been made as to this?—No, I do not think so. I have made none.

10990. Do you think there is reason to believe that arsenic to a perceptible degree could get into a beef steak cooked over an ordinary fire?—Not to any dangerous degree. I would refer to the amount of arsenic which we obtained on bladders. The figures are given in Section III. These bladders were exposed for a fairly long time.

10991. Exposed to the fumes?—Yes.

10992. I see the greatest amount of arsenic is about 1-140th grain to a pound of skin?—Yes, after they had been 18 hours exposed to the fumes of coke. So there is not a great deal of arsenic gets on.

10993. That perhaps answers my question sufficiently?—The food was really exposed to the fumes coming directly from the fire, which was in a brazier containing coke, placed directly under the bladders. The bladders are hung on rods above the coke, raised tier on tier. When I took the samples I always took

some samples from the bottom of the tier closest to the coke, and some from the top tier to the highest elevation. But you even see in the lowest tier there is not a great quantity of arsenic deposited on the bladder.

Mr.  
H. H. Smith.  
31 Oct. 1902.

10994. As the bladder is cool, if it is put into the fumes for the purpose of being dried it is then more liable to get a deposit of arsenic than if it was hot?—The bladder is put on wet, and, I suppose, any arsenic which came off the coke would on that account be more liable to be deposited on the bladder.

10995. (Dr. Whitelegge.) Do you know if the attention of any public body abroad has been given to the danger of arsenic in chicory?—I do not think so. It has never been mentioned to me by any chicory roasters whom I have seen in England. I have some works on the preparation of chicory abroad, but I cannot find anything about arsenic in them.

Arsenic in  
chicory.

10996. There is no attempt at public control of it?—As far as I am aware, none.

10997. (Sir William Church.) I should like to ask a question with regard to the table in Section IV. which is not quite clear. I think it should have something added. These fowls when bought were stated to weigh 14oz. When the experiments began they weighed 26oz. Just so. They were kept until they were ready for fattening.

Fattening  
fowls with  
arsenic.

10998. I think it will be just as well to put that in. This fact is also remarkable, although it is not a large enough experiment to draw deductions from. Two of the fowls which were fed on arsenic, Nos. 4 and 5, if you will add up the totals, increased in weight very much in the same ratio as the two which were not fed on arsenic. But another two, Nos. 3 and 6, both cockerels and fed with arsenic, increased much faster than the control birds. I think it would make the table complete if the total weights at the time they were killed were added at the end?—I will see that that is done. The curious part as to what you mention is that the birds got on to what you might call a killing weight very much faster when they were taking arsenic than when they were not. I tried it again, though not so fully, this year. I kept a lot of chickens on arsenic this year, and it is very curious how quickly they got to their killing weight. They got to it a month sooner.

10999. Exactly. The arsenic birds increased more rapidly—I do not say much more rapidly, as the results seem very irregular?—They seemed to get rapidly up to a certain weight, and afterwards not to increase, whereas the control birds went on increasing.

11000. The really important thing about your experiments is that the arsenic appeared ultimately in the feathers and not in the flesh?—Yes, and they showed, too, that fowls can tolerate arsenic if the fattener administers it. Mr. Tegetmeier, when I saw him, would not have it, but my poultry friends all have a suspicion of it. It is given at the end to increase their weight very rapidly. The birds are got to their full weight quicker.

Arsenic in  
fowls' feathers.

11001. (Chairman.) That is interesting information as to the elimination of arsenic by the feathers. As a practical matter, do any of the producers of fowls get tempted to use arsenic by knowing that the fowls increase in weight?—I think they must know it, but my information is very meagre on the point, because directly you mention the word arsenic you get no more information. I was talking to one of these fowl fatteners on the subject about this time last year, and he would not tell me whether he used anything but ordinary fat and milk. Directly I asked him, "Do you use any chemical additions to your food?" he began to talk about how many eggs his fowls would lay in a year. He would talk on anything except the subject of fowl fattening.

11002. Was this a professional man?—Yes, a professional fowl fattener.

11003. Do you think he used arsenic?—I am unable to say. He would not tell me.

11004. Did you ask him?—At last I had to put it plainly. He said, "No, I do not know anything about it." But I did not believe him, because I am certain, from one or two things I have heard, that arsenic is used. But I cannot get the information direct. I tried to get some of their food, but I did not manage it.

11005. Did you make the acquaintance of any other people in the trade?—Yes, I tried to get it through some friends, who are also poultry breeders. I got them to go down and try to see these people who fatten fowls in Surrey, but they could not get to know; they would not tell them anything.

Mr. Smith. 11006. (Dr. Whitelegge.) In what part of the feathers was the arsenic found? In what part of a given feather? —I do not know. I think the whole of the feather was taken for analysis.

11007. In the case of a hair there is some reason to believe that it is not distributed over the whole length, but that it goes into the growing part. There may be some unequal distribution in the case of a feather corresponding to that?—There might be, but I have no experiments as to that.

11008. (Chairman.) Can you make any addition to what you say on the subject of enamels in Section 4? —Since I wrote that report I have received a little more information on the subject from Mr. Albert Smith, who is an analytical chemist in the North of London. He discovered for himself, while using some enamelled pots for chemical purposes, that the solution he took out of those pots contained arsenic. He then tried boiling plain water with some soda in it in the pots, and he found he got arsenic in his solution. He then tried whether the constituent parts of the solutions which he put into the pots had been free from arsenic, and he found that they were free. Then he analysed the enamel of the pots, and found that in one instance he got 0.46 per cent. of arsenious oxide in the enamel, and in another instance he had 2.03 of arsenious oxide per cent. in the enamel. The point is of some importance, as these experiments rather show that the food cooked in an enamelled pot containing arsenic in its enamel might become contaminated by arsenic possibly to a dangerous extent.

11009. You say he boiled some water in the enamelled pot with soda?—Yes.

11010. And he took arsenic out of the enamel?—Yes.

11011. Would pure water take arsenic out of the enamel?—I do not know. I may say that Mr. Albert Smith thought that the pots were a cheap Belgian ware. I have made some inquiries among English manufacturers of enamel, and they tell me that for cooking utensils they never use arsenic now, and that they thought I might take it as a matter of certainty that no arsenic is used in the manufacture of enamelled hardware in England for cooking purposes.

11012. (Dr. Whitelegge.) It is within the experience of my Department that the use of arsenic in the manufacture of enamelled metal hollow-ware has decreased very much. We placed the manufacturers under regulations to obviate industrial poisoning, and in order to escape the regulations they gave up the use of arsenic?—That was exactly what they told me. They said it was to avoid being placed in the category of the dangerous trades that they gave it up, although they might possibly make a better enamel with it.

11013. (Professor Thorpe.) Is there any reason to believe that enamel which is better or cheaper by virtue of containing arsenic is allowed to come into this country from Belgium or Germany or other places in competition with the English manufacturer?—I have only the statement of Mr. Albert Smith.

11014. There is no check on the importation of these things at present?—I believe not.

11015. (Sir William Church.) Does this enamel come in as enamel, or is it that the hardware comes in already enamelled?—No; in the articles in question the enamelled pots themselves were imported. It is possible, of course, that enamel may be imported as such, but I do not know if this is the case.

11016. (Chairman.) Have any analyses for arsenic been made of the enamels taken from pots?—I have got together a large number of samples of both English and foreign hardware for that purpose, and they are ready for examination by Dr. McGowan.

(Dr. Whitelegge.) Dr. Thorpe has made a certain number of analyses for the Home Office, and these results can be supplied if the Commission wish to have them.

(Chairman.) Is arsenic found in them?

(Professor Thorpe.) Very little now. It is the rarest possible thing that we find arsenic in them now.

(Sir William Hart Dyke.) And negligible when you do find it.

(Professor Thorpe.) Practically so.

(Dr. Whitelegge.) Would it be difficult to obtain some cheap Belgian enamelled goods?

(Witness.) The difficulty with enamelled hardware is to get anything authentic as to their origin. They are sent out without a trade-mark, and you cannot tell exactly where they are made. These enamelled pots that Mr. Albert Smith spoke of had no distinctive mark on them. I have been told that there is an enamel made in America which contains arsenic, and is sold as mottled enamel, but I have no particulars with regard to it.

11017. (Dr. Whitelegge.) It comes over as enamel?—No; the ware about which I have been told comes over finished.

11018. (Chairman.) The statement of Mr. Cochrane mentioned in your report is rather remarkable. Is it probable that similar experience has occurred to others?—Mr. Cochrane is a retired ironmonger, and he came and volunteered that statement to me. He suggested that enamelled hardware should be examined for arsenic on account of a wholesale case of poisoning that occurred, as he believed, from some hardware he had sold. He was asked to supply a hotel in London with some copper saucepans in a hurry. They had a rush of people in, and as he had no copper saucepans in stock, he said, "If you will use these enamelled saucepans for to-night, I will send you the copper ones in the morning." They used them, and everybody in the hotel who had food out of these enamelled saucepans was taken ill.

11019. (Sir William Church.) Was that the occurrence at Lincoln's Inn?—No; an earlier case than that. This was several years ago, at a hotel in Bryanston Street.

11020. (Dr. Whitelegge.) Did he say enough about the nature of the illness to make it point to arsenic? There are other things than arsenic which might conceivably be dissolved from the enamel?—No; I cannot say that it was fully proved on the facts he gave me.

11021. (Chairman.) Were the enamels that Mr. Cochrane described English enamels?—These pans were supplied to the hotel some years ago, and they were English enamels. But it was some years ago when they were made, and at that time I believe they did use arsenic in English enamels.

11022. Does the risk of arsenic getting into food only hold when the article is new?—That is what might perhaps be expected—that the newer it is, if there is arsenic in it, the more likely you are to get it out.

11023. Would it be safe after it had been used and washed a great many times? Might not a little extra heat at some time make the enamel scale off?—I am not prepared to say, but I should suppose it would come off more readily when it was first used than afterwards.

11024. (Chairman.) In this summary at the end of your report, what does "brewed temperance beverages" mean? Does that mean fermented beverages?—I meant brewed temperance beverages, such as ginger-beer and non-alcoholic beer.

11025. It is really a fermenting?—Yes; the drinks to which I refer here were brewed and fermented. In relation to that I may say that some of these brewed temperance beverages are brewed from brewers' invert sugar. The beer that they brew up in Manchester, called "Best British Beer," for instance, is brewed from invert sugar. They told me they did not use malt, but malt substitute; but when I went to see what it was, it was simply brewers' invert sugar.

11026. Was that a temperance beverage, or was it a beer?—It was a temperance beverage. The amount of alcohol was kept below the regulation amount. Of course, an essence of hops was added to it to make it taste like beer.

11027. (Professor Thorpe.) I may make a remark here which bears on the discussion we had on a previous section. In reference to what is said here, that the manufacturers use precautions to secure freedom of tartaric acid and citric acid from lead, that was due to the action of local authorities, or, rather, the public analysts, in bringing actions into court in the case of mineral water and soda water contaminated with small quantities of lead. It was when the manufacturers found they were liable under the Food and Drugs Acts, and some of them were rather heavily fined, that they stipulated that the materials they used should be pure?—Yes; no doubt that was the case.

Mr. H. H. Smith  
31 Oct. 1902.  
Difficulty in identifying origin of ware.

Brewed temperance beverages.

# TWENTY-SEVENTH DAY.

Friday, 21st November 1902.

AT 1, CHAPEL PLACE.

PRESENT:

The Right Hon. Sir WILLIAM HART-DYKE (*Chairman*).

Sir WILLIAM CHURCH.

Dr. WHITELEGGE.

Dr. BUCHANAN, *Secretary*.

Mr. C. LYLE, called; and Examined.

Mr. C. Lyle. 11028. (*Chairman*.) You are connected with the firm of Messrs. Abram Lyle and Sons, sugar refiners and golden syrup makers?—Yes.

11029. I believe your business is in London?—Yes.

11030. How many years have you been established there?—We started building our factory in 1881; we started to manufacture sugar in 1883.

11031. I suppose you may be said to be in a large way of business?—Yes, ours is the second largest in the kingdom. Mr. Tate's, I think, is the largest.

11032. You necessarily use, do you not, sulphuric acid in the manufacture of your golden syrup?—Yes. If you are referring simply to golden syrup I may say that I am by far the largest maker of golden syrup in the kingdom; I was referring before to general sugar work.

Always known that golden syrup liable to be arsenical. 11033. I believe that from the very commencement of your business you have been aware of the liability of golden syrup to become dangerously contaminated with arsenic if proper care is not taken; you have been alive to that from the very first?—Yes.

11034. And you have been conducting your business on the principle that, with this danger attending it, you must use the utmost care with regard to the materials used, in order that the manufacture shall be free from arsenic?—Yes, from the very first we have tested every carboy we ever had for arsenic ourselves, besides having bought it as brimstone-made acid.

Precautions taken. 11035. I think Mr. Hammond Smith in his evidence has given us some details of the precautions that you have been in the habit of using to safeguard yourselves?—Yes, he was good enough to show me what he had said about us, and it is quite correct.

Sulphuric acid must contain less than 2 parts per million. 11036. With regard to the amount of contamination, have you any difficulty in obtaining a sulphuric acid containing no more arsenic than one part in a million, that would be about 1-140th of a grain per lb. I think that is the limit of your test?—We subject it to a test which reveals one part in a million, and sometimes, but not frequently, we get it to show one part in 500,000. If it does that we reject it—we do not reject it, but we caution the manufacturer. If it were more than one in half-a-million we should certainly reject it. But from brimstone-made acid we never have had more than 1 in 500,000; we have rarely had it as much as that.

11037. At any rate, you have never gone above that amount of arsenic in the acid?—That is so.

11038. You are confident about that?—Quite.

11039. You also use phosphoric acid, do you not?—Yes, to a very small extent.

11040. But you do use it at times?—Yes.

11041. Are you obliged to use it, or is it a matter of choice?—It is not a necessity, but it is part of our process to use it; we think there is an advantage in using it.

Phosphoric acid also. 11042. Have you any difficulty in obtaining phosphoric acid with similar freedom from arsenic?—No, we have no difficulty, but I think phosphoric acid more frequently comes nearer the limit.

11043. You think there is a distinction between the two?—I think that phosphoric acid is a little more apt to contain arsenic.

11044. It is more liable to contain arsenic than the sulphuric acid?—Yes, I think so. Still it may be got, and we do get it free—not absolutely free, but to show not more than the quantity I mentioned, 1 in 500,000.

11045. With regard to the application of tests, would you consider it essential that you should make tests in both cases, whether in sulphuric acid or in phosphoric acid, totally irrespective of any guarantee that was given by the firm from whom you purchased the article?—Yes.

11046. You would depend solely on a guarantee?—No, certainly not.

11047. In the conduct of your business have you been in the habit of applying tests?—Always.

11048. Totally irrespective of any guarantee given you?—Yes, we trusted to our own tests, not to the guarantee, although we had the guarantee as well.

11049. Do you have a guarantee in every case?—We have a guarantee that it is made from brimstone. We could have bought guaranteed acid which had been made from pyrites and treated to remove arsenic, but we did not think that as safe as buying brimstone acid.

11050. You thought that safer?—Yes. The other when carefully prepared is all right and very pure, but there is always the liability to some error or accident.

11051-2. With regard to your manufacture in general, do you know if there is any general standard of purity for sulphuric acid or phosphoric acid which can be said to be applied by all manufacturers of the class of products made by your firm?—There is none recognised. Up to the time of this arsenic scare people were content if the Marsh test alone was used. If no arsenic was revealed by the Marsh test it was considered to be sufficiently delicate without going to the Berzelius in addition. If the product showed nothing by the Marsh test it was considered sufficiently free for all practical purposes.

11053. What has happened since this unfortunate occurrence at Manchester?—We still use the Marsh test in the old way, but besides that we have the Marsh-Berzelius, with which we check the other.

11054. You superadd the other in every case?—Yes, in every case of phosphoric acid and sulphuric acid. I may say that we have tested the Marsh-Berzelius against the Marsh, and it is from those tests that we find we can detect from the Marsh test alone one part in one million, whereas by the Marsh-Berzelius we can detect one part in 20 millions. In fact, with regard to the Marsh-Berzelius test as applied by chemists nowadays, I do not know whether there would be any limit.

11055. Do you think there would be any advantage in having a kind of fixed standard of purity as regards these two substances, sulphuric acid and phosphoric acid, which would give an indication to all those engaged in manufactures such as yours that anything below that standard should not be used?—There would be no harm done in fixing a limit if it was a sufficiently

Mr. C. Lyle. 21 Nov. 1902.

Mere guarantee with acid insufficient.

Brimstone acid used.

Tests applied.

Question of official limit for sulphuric acid used in food.

*Lyle.* wide one. We have always been careful not to exceed one part in 500,000, but if you look at the figures that I give in my memorandum I think you could very safely allow a great deal more.
