11056. Can you tell the Commission, generally speaking, whether what has been termed the Manchester scare has had any effect on trades and manufactures such as yours with regard to making the manufacturers more careful in adopting a more stringent test?—I do not know about my neighbours, but I should think that naturally everyone would look into the question, as I have done. Although we did it before, we went even more narrowly into it since the scare, and I presume others have done the same thing. It is almost two years since the scare began, and I have been working in every direction to see whether the minutest traces can come in or be eliminated, and I do not see that we have altered or can alter one iota from what we were doing before.

11057. In fact, you have not changed the system you have always adopted in your business on account of the scare?—No. I suppose we have taken a few more precautions in the manner of making sure that no carboy could possibly be taken that had not been analysed; in that respect we have taken a few more precautions.

11058. As far as you are concerned, you do not think that, assuming the effect of this very serious occurrence in Manchester wore off by degrees, the consumer might suffer through some carelessness or laxity in the conduct of these manufactures?—Unless you got another careless manufacturer such as you had then. That is always possible; but so far as we are concerned the consumer would not suffer.

11059. At all events in your case it would not obtain?—Not in the slightest.

11060. Would you have any objection if it were in the power of an officer of a Government department, such as the Local Government Board, to visit your works?—An inspector does come down now and take samples of our invert sugar. We make a little invert for brewers, but we do a very small trade.

11061. Is that for the purpose of detecting any dangerous ingredients, or for Revenue purposes?—No; he gets it tested for arsenic.

11062. It is not for Revenue purposes?—I think it is entirely for arsenic, because it is only since the scare that he has done so.

11063. (*Dr. Whitelegge.*) Is it not since the sugar duty came on?—No, it is disconnected with that altogether. He comes down and takes a sample of what he finds in stock at our place, and says that he is going to test it for arsenic, and the next time he comes round he says: "I found that that sample was free," or "I found most minute traces," or something like that.

11064. (*Chairman.*) Can you make any suggestion to the Commission as to the source of arsenic occasionally found in West Indian brown sugar?—There are three or four possible sources. The likeliest I should say would be the use of chloride of tin. In order to get that special yellow colour the West Indian manufacturers largely use chloride of tin. It has the property of giving it the special colour that they want.

11065. You think that through that medium arsenic might easily be conveyed?—I think it is a very probable cause. We never use chloride of tin, and I have never tested it for arsenic; but I should think that was a very probable source. Tin is very often associated with arsenic; it is found associated with it.

11066. I suppose you cannot tell us what percentage of arsenic per pound might possibly be found in brown sugar?—I have tested a great many samples in one way or another, and I have found in one or two exceptional cases somewhere about 1-60th grain per pound.

11067. Would you say that that was an uncommon result?—Yes, I think that is uncommon.

11068. You think that is excessive, and avoidable?—Yes, decidedly so. It is more than one would look for, and I was surprised to find it.

11069. But you have actually found that quantity per pound?—Yes; but, on the other hand, I have found other West India sugars quite free.

11070. You have sent us a memorandum with regard to the possibility of fixing a limit to be applied equally to all food and drink. You say, "If a limit is applied equally to all food and drink it would greatly favour the brewer, who has been the cause of all the trouble,

as against the manufacturer of articles of much smaller possible consumption, and which have been hitherto above suspicion." Do you mean to say that if a limit were fixed you would wish to differentiate between food and beer according to the amount consumed?—Yes, and not only between food and beer, but between one food and another. I suppose that a man could take more beer than he could take of any one food. I put in my statement that a man might consume two gallons—I do not think that is extravagant in some cases.

11071. I have known cases where more was consumed than that?—I wanted to state it moderately. But if the limit were the same on a gallon of beer as it was on a pound of golden syrup—I take that because it is my own article—a man would be allowed to get from the brewer a far greater dose of arsenic than from me. Why should the brewer be put on better terms than I am? He has been the culprit in this case, and why should he be more leniently dealt with than other manufacturers who have not hitherto done any harm? That is my point of view.

11072. You do not think, surely, it would be a satisfactory outcome of the deliberations of a Commission like this if they were to go into a grave matter affecting consumers of food or drink on such a basis as that?—To differentiate?

11073. Yes?—Why not? Take extremes—take pepper or salt. You could not poison a man with arsenic in salt unless you had some extravagant quantity in it.

11074. (*Dr. Whitelegge.*) If I follow you clearly, your argument is that we ought to fix a very high limit in some foods, not by reason of the difficulty of keeping it out, but by reason of the small proportion in which it is used?—Yes; I contrasted golden syrup and beer. If you have the same limit for a pound of golden syrup as for a gallon of beer a man might get far more arsenic from the brewer than he would get from me.

11075. (*Chairman.*) Do not you think it would be a far safer principle to adopt to secure, as far as human ingenuity and skill can devise, that all articles of food or drink should be as free from arsenic as possible?—But there is no such thing as freedom from arsenic.

11076. As free as possible?—You must define what is "as free as possible." Then I want to point out this also, that supposing, for the sake of argument, you fix a very narrow limit, such as 1-140th grain per pound for all food, and supposing a pound of sugar was put in a grocer's window on such a day as this, how long would it take for 1-140th grain of arsenic to deposit in the smuts and smoke that are here to-day? Then a manufacturer would be found liable, and his goodwill destroyed through a thing that he had no control over. It would not take many hours in such an atmosphere as we have this morning to get 1-140th of a grain deposited in the smuts.

11077. (*Sir William Church.*) I understand that you have been manufacturing golden syrup for about 20 years?—We began to manufacture golden syrup in 1884.

11078. What did you understand by brimstone acid at that time?—Acid made from brimstone. We meant native brimstone, not sulphur from refuse works such as gas works.

11079. Is not comparatively little now made from Sicilian or natural brimstone?—I hardly think so. Every pound we get is made from Sicilian brimstone. Here is our last invoice. (*Handed in.*)

11080. Is it not the case that in the sulphuric acid trade a great deal of acid is sold as brimstone acid which is made from the refuse of gas works?—It may be so; but it is not in our case, because, as you see, it is native Sicilian brimstone. Since we started we have only dealt with two firms, Gibbs and Co., whose premises are two doors from us, were one of the firms, and I have gone in and seen the brimstone myself.

11081. Pearce is the other?—Yes. I have letter after letter from Pearce, saying that he guarantees it, and assuring us that it is made from brimstone, and that no pyrites is used.

11082. Is C.O.V. a particular brand?—No, that is concentrated oil of vitriol.

11083. From the very commencement of your making golden syrup you have had your acid tested?—Always.

11084. Do you keep your own analytical chemists?—We have a large staff of analytical chemists.

*Mr. C. Lyle.*  
21 Nov. 1902.

should allow  
for character  
of the food.

Food might  
get arsenic  
from dust.

Precautions  
before 1900.

Mr. C. Lyle.

21 Nov. 1902.

11085. And at that time, in 1884, did you specially test it for arsenic?—We always tested it for arsenic, and also tested it for specific gravity and purity, to see that we were getting the right quality.

11086. Even at that early stage you specifically tested it for arsenic?—Yes, we did.

11087. I suppose you just sampled a consignment, you did not test each separate carboy?—We took a sample of a great many carboys in each consignment. As a rule they came in lots of 30 carboys. Each load would be sampled, perhaps six or eight carboys in the load indiscriminately.

11088. And even at that early date you found very little contamination with arsenic?—Very little.

11089. Have you found, or have your chemists found, any greater difficulty in applying the Marsh-Berzelius test than in applying the Marsh test?—It is a much more difficult test to carry out well and scientifically.

11090. But have you found any practical difficulty?—No, we have found no practical difficulty if we have expert chemists; but it takes a long time, and it takes the services of two or three chemists regularly. We have two chemists who have been at this subject ever since this took place.

11091. Have your chemists ever found any difficulty in getting pure re-agents to work with?—Yes, there was some difficulty at first in getting them absolutely pure, but I think these difficulties are now got over.

11092. Do you mean at first, 20 years ago, or lately?—No. About 20 years ago we were only working with the Marsh test, and there was no difficulty in getting re-agents sufficiently delicate for that work; but when you come to the Marsh-Berzelius, it is more difficult.

11093. But still they have been able to satisfy themselves that they have got pure re-agents?—Yes, that has all been quite got over.

11094. The result of their work is singularly favourable as compared with other evidence we have had given us?—I think most chemists will now say that they can get clean re-agents.

11095. How frequently, in the course of these years, have you found specimens of acid which have exceeded those limits of arsenic which you have mentioned—one part in one million and one part in 500,000?—I think we have never returned any sulphuric acid within my recollection. But on one or two occasions we have returned phosphoric acid.

11096. And, notwithstanding that constant result, you have not relaxed your vigilance at all?—Not a bit, no, never.

11097. I may take it from you that, so far as your own experience goes, there is no difficulty in manufacturers on a large scale making use of the Marsh-Berzelius test?—There is only the difficulty of a considerable expense attached to it. If one were to test all one's products regularly by the Marsh-Berzelius test to see what they contained, I suppose we should need four or five experienced chemists doing nothing else but that.

11098. It takes a longer time; but I do not see quite what is the greater difficulty in using it than in using the ordinary Marsh test?—We have an experienced man with all the appliances that we can think of at work, and he cannot get through more than ten analyses per day. If he had to test everything in my factory during its different stages, and the final product, he could not do it all in a day; I am referring to his testing the final products of our own manufacture.

11099. (Chairman.) You mean he could not keep pace with the different processes going on?—Yes. We make ten or twelve different qualities, and there would be, perhaps, ten or twelve different boilings a day in each of those qualities.

11100. (Sir William Church.) But he would only have to test the materials from which it was made?—If there were a very narrow limit on the finished article, we could not afford to let any go out that was not tested.

11101. What other possible source of arsenic besides that which is in the materials could come into your manufacture?—I do not know of any other possible source, but still it would be so serious a business for any manufacturer to find the narrow limit exceeded that he could not afford to do it. To be safe he would have to test every lot himself. I certainly should. Consider: one

bad lot going out that exceeded, say, 1-140th of a grain and that is free, and does not contain a trace of arsenic, and if your sugar is free, and does not contain a trace of arsenic, how do you suppose the arsenic will get in unless you suggest it comes from the atmosphere?—It might come from the atmosphere, and it might also come from iron rust. Suppose some of your sugars got contaminated by iron rust, which is a very probable thing, you would have it in the iron, and you would exceed that limit right away.

11102. But how is that 1-140th to get in if you are using perfectly pure materials? If you test your acid, and that is free, and does not contain a trace of arsenic, and if your sugar is free, and does not contain a trace of arsenic, how do you suppose the arsenic will get in unless you suggest it comes from the atmosphere?—It might come from the atmosphere, and it might also come from iron rust. Suppose some of your sugars got contaminated by iron rust, which is a very probable thing, you would have it in the iron, and you would exceed that limit right away.

11103. Rust which gets into the sugar after it has been inverted?—Yes, and even after it is finally manufactured.

11104. Through passing through iron pipes?—It may be a rusted vessel, or a rusted pipe, or something of that kind. You are dealing with such a minute quantity that you must look out for every possible source. The quantity is so small that you can get it from the atmosphere, from smuts, and you can get it from iron rust, or you might get it from any dusty, dirty contamination.

11105. Therefore your contention is that it is impossible to get it absolutely pure?—Yes; at any rate, it is impossible to guarantee it unless you made the limit sufficiently wide to cover all those contingencies.

11106. You are rather pressing now for some standard limit to be fixed. I was inquiring rather with a view to its being excluded altogether, and I rather gather that in your trade you think that is almost an impossibility?—At present it is an impossibility for any manufacturer to guarantee any article, I do not care what it is, free from arsenic in the chemical sense. Such a thing does not exist.

11107. To go back again for one moment to the practical working of analyses, it appears to me that if your material is analysed, and is found free from arsenic when you commence to use it, that, practically speaking, there is no danger of any sensible amount of arsenic getting in in the course of manufacture?—But there lies the whole crux of the question: what is a sensible quantity? You would never get anything free from arsenic. If you say there must be none, then it is impossible.

11108. Granted that we do not get absolute purity, surely what I say is the case, that so long as you take care that your materials are free from arsenic?—When did I say that they are free from arsenic? They are never free.

11109. You have told us that all your sulphuric acid and all your sugar gives you no more than traces; you have told us to-day that sometimes you find none?—I would not say none—practically none.

11110. You said none, not practically none?—I do not think I said none.

11111. Yes, you said that in Jamaica sugar you found none?—I was speaking broadly there; but in the chemical sense you cannot say that anything is free from arsenic; and that is one reason, and my main reason, for saying in my memorandum that I want a limit fixed where a manufacturer can say it is free. Just at present no man can say it is free.

11112. You think that a limit of 1 in 500,000 need not be exceeded?—In acids, do you mean—in sulphuric acid?

11113. In your finished article?—Certainly not.

11114. One in a million, perhaps?—Yes; I never do exceed it, but I want a broad, wide limit, so as to avoid the necessity of having to test everything.

11115. But my point now is that I should like to know what you, as a practical manufacturer, think would be a working limit. Would one in two millions be practicable; or would one in one million be impracticable?—One in one million would be practicable, I think, for golden syrup—talking of that only. One in one million is quite practicable, but still I think it would compel me to analyse everything. I never have got anything approaching that in my syrups; but still, if that were the law that that limit must not be exceeded, to protect myself I must analyse everything.

11116. Then at the present time you do not analyse everything?—We analyse a great many here and there, but we do not analyse everything.

Mr. C. Lyle.

21 Nov. 1902.

Rejection of acid because of arsenic.

Expense of testing by Marsh-Berzelius.

Objection to constant testing of finished products.

Does not get 1 part arsenic in a million of golden syrup.

But official limit should be much more lax.

*Lyle.* 11117. Do you analyse all your finished products?—We analyse a great many of them, not all of them. We take surprise tests here and there, just at odd intervals, and test those.

11118. I suppose that before this arsenic scare—that is to say, previous to the last two or three years—the main object of the chemist you kept was to see that you produced a good finished article rather than to examine your materials?—Both. We buy all sugar upon analysis, and we therefore had a large staff. All the sugar trade is done upon analysis.

11119. But that is an analysis for the quality of the sugar?—Yes, but that compelled us to keep a chemist. When we did that, we also supervised all our departments with chemists, and we supervised all the acids, and so on, that we bought.

11120. The commercial chemists, if I may use such a term—that is to say, the chemists employed by commercial firms for their various purposes—although most competent chemists for those purposes, are not very competent chemists very often for analytical purposes, are they?—I can only speak for my head man. He is a Bachelor of Science.

11121. We understand a little behind that. The chemist who is engaged in one particular line of research, such as the commercial value of materials, does not have his mind directed to the analysis of impurities in the same way as a chemist who is employed rather in analysing materials for impurities?—I differ from you. I possess a fair amount of chemical knowledge myself, and from the very beginning, when we began to use acid, I consulted my chemist and said: "Now, before we use sulphuric acid what must we watch for?" He naturally said: "We must look for arsenic," and we did look for arsenic. We looked for lead; in fact, we looked for every possible contamination. We have examined, not once, but a hundred times, all round for all other things besides arsenic. We have by no means confined our attention to arsenic; we looked for everything that was likely to be injurious.

11122. That is a very wide term—that you looked for everything; you looked for the likely things?—We know we are doing a process that might bring in such contaminations.

11123. Any chemist would know that if he is using sulphuric acid he would be likely to meet with lead and arsenic?—Yes.

11124. Did you look for anything else?—Yes, I have searched again and again for all the different metals.

11125. Before this scare?—Yes, long before that.

11126. Before this Commission sat did you ever look for selenium?—No\*.

11127. Can you tell me of anything that you looked for besides lead and arsenic?—Yes. I have looked for oxalic acid and copper—at the moment that is all I can think of. We looked more to acids attacking our vessels than anything else. We have looked for zinc. Then when we knew there were special processes going on on the Continent we have looked for traces of these special things. We have also looked for barium.

11128. (*Dr. Whitelegge.*) I suppose you make all these analyses for two objects generally, for the safety of the public and for the reputation of your firm?—Yes.

11129. Would you think it safe to rely upon analysis of the final product only, without attempting any check analysis of the ingredients?—As a matter of fact, we begin by ascertaining that our ingredients are safe first.

11130. I follow that; but do you regard it as essential to look at the ingredients as well as the finished produce?—If one carefully looked at the finished product that would be sufficient, I think; but I think it would be the wrong end to begin upon, because if you found your product was bad you would not let it go out upon the market. Prevention is better than cure.

11131. In your own interests it is better to look at the ingredients?—Yes.

11132. Are your books kept in such a way that if by some mischance the check analyses made by your chemist were omitted, and if it were found that your finished product contained a considerable quantity of

arsenic, you could bring that home to a particular lot of sulphuric acid and to a particular guarantee that it was made with brimstone acid?—We could do that now, to a particular lot, but we could not always have done it.

11133. The system you now use would enable you to identify, in the event of any mischance in the finished product, the particular lot of ingredients that it was made from?—Yes.

11134. What would be your position in regard to the vendor of the acid if you had a complaint from your customers that arsenic had been found? I am assuming now that it missed detection in the tests—I do not say it is possible—I am putting a hypothetical case to you. I am assuming that if a particular lot of golden syrup containing arsenic were sent out, you would be able to identify it with the particular lot of acid. What would your position be in relation to the vendor of that acid?—I think I should have a claim upon him—I should expect that I had. It is more a legal question, which I am happy to say has never cropped up.

11135. I only wanted to know your opinion. You Effect of think that the guarantee amounts to something more guarantee than the power of returning the acid if it does not with acid. comply with that guarantee?—Yes, I think he is liable for the consequences.

11136. Do you consider that the system of check analyses is equally necessary in small works?—Certainly.

11137. Is there any difficulty in carrying it out in small works which does not arise in the case of a large firm like yours?—Only the expense.

11138. Is the expense greater relatively?—I should say it would be, decidedly.

11139. Are their consignments fewer or smaller?—The consignments would be smaller, and then a small works naturally could not maintain a large staff of chemists so well.

11140. There would be other work for the expert chemist to do in addition to that?—Yes, there would be such things to do in our case that there would not be in small works.

11141. You told us that an inspector visited your works occasionally and took samples which were tested for arsenic. Can you tell us whether that was an inspector of the Board of Inland Revenue?—I think it is an Excise inspector—yes, it is from the Excise authorities.

11142. I suppose your works are never visited by the inspectors of the local authority, the District Council?—With regard to this question?

11143. In any respect?—Only if we are putting up new buildings. They supervise the erection of new buildings.

11144. You are never visited for the purpose of the Sale of Food and Drugs Act?—No, I have never seen them.

11145. Would you consider it inconvenient if powers were given to local authorities to visit manufactories of food products and take samples?—It would be no great inconvenience if he simply limited himself to taking samples.

11146. You would not object to that?—I would not like it. I have nothing to hide. When I say that we are never visited for that purpose, I know, of course that samples are bought in grocers' shops.

11147. I am asking you whether you think it would be inconvenient that the officers of the local authority who now have power under the Sale of Food and Drugs Act to buy samples in shops, should have the same power to test the articles which are in bulk at the manufactories?—No, I would not look upon it as a great inconvenience, but I would be rather averse to it all the same.

11148. You have mentioned chloride of tin. Is that substance used in your works?—No.

11149. Can you tell us in what sort of proportion it is used?—No, I could only give you a very rough guess—it would be little more than a guess from memory, because we never have used it.

11150. Is it used to stain the sugar, or what?—They strive to get a yellow colour, a bloom, as they call it, and that is obtained by adding the tin to the sugar.

\* Since giving this answer my chemist has recalled to me that he did search specially for selenium, but found none.

*Mr. C. Lyle.*

21 Nov. 1902.

Use of  
chloride  
of tin to  
colour sugar

Mr. C. Lyle. 11151. Is the tin removed afterwards?—It passes through in the centrifugal machine, and goes into the syrups.

21 Nov. 1902.

11152. And remains in the syrups?—Yes.

11153. And no steps are taken to remove it from the syrups?—Finally these are molasses, which are distilled into rum.

Official limit of arsenic should be lax.

11154. There is one figure given in your memorandum which I think is rather important. You say: "This test reveals the presence of one part of arsenic in 1,000,000, and no sulphuric acid was ever used which showed more than one part in 500,000. As we use only one per cent. of acid to sugar, our very worst case would not therefore show more than 1-7142nd of a grain per lb. from this source." I do not want to go over the ground again, but I understand you to say that although from your sulphuric acid, which you regard as an important point of danger, and which you take every means to safeguard, you get not more than 1-7142nd of a grain per lb., still you think that for the finished product a standard of 1-140th would be too rigid, having regard to other possibilities?—Not that I think it will be there. I have never, as I have said, seen anything like 1-140th in the finished product, but I think if you make a limit, particularly if it is to be a penal limit, it would compel analysis of everything.

11155. Of every final product?—Yes, before we sent it out.

11156. (Chairman.) I suppose you are strongly of opinion, that the precautions which you use are necessary, generally speaking, for the trade?—Yes.

11157. Do you not think that there should be a careful analysis of each ingredient used, and of the finished product, not only for trade purposes to secure you against loss after you have prepared a material, but for the safety of the consumer?—Not necessarily of the finished product. I do not analyse every finished product; I do it, as I have said, occasionally here and there; but that is what I want to avoid having to do.

11158. You think security is best obtained by analysing at the initial stage of the manufacture, and dealing with each ingredient?—Yes.

Security depends on care with ingredients.

11159. Will you kindly tell us, roughly speaking, how many chemists are constantly employed in your business?—We must have a staff of from 25 to 30. When I talk of chemists, I ought to say that we have, for instance, one laboratory that is worked by girls. They, of course, are not trained chemists; they are trained to that special department and to the routine work.

11160. But they are part of the analytical staff in a sense?—Yes; we have an analytical staff of from 25 to 30.

Mr. R. HOWELL, called; and Examined.

Mr. R. Howell.

11161. (Chairman.) I believe you represent a London firm, do you not?—Yes, Messrs. Stevenson and Howell.

11162. Are you as large as any firm in your line of business?—Very nearly as large as any; perhaps there is one larger than ourselves.

Chemicals for food and drug purposes.

11163. Is the chief bulk of your business done for food purposes or for chemical and drugs?—The chief bulk of our business is for food purposes—indirectly for food purposes. Our business lies very largely with mineral water manufacturers and wholesale confectioners, supplying such things as essences, citric and tartaric acids—which we do not manufacture, but which we deal in very largely—and essential oils.

11164. You not only manufacture, but you purchase to sell again?—Yes. We manufacture principally essences and essential oils.

11165. You deal with a variety of chemical substances which are liable to contain arsenic in an impure state?—Yes—which were liable, I should say rather than are liable. I should think there is a good deal of difference in the last 12 months.

Greater precautions against arsenic lately.

11166. Has the difference in the last 12 months arisen on account of extra precautions taken since the occurrence in Manchester?—Yes, I think so very largely. In the first place, the tests for arsenic are very much more stringent than they used to be, and I think that now there is a demand for arsenic free substances, the manufacturers of such substances have found themselves fully equal to fulfil that demand.

11167. I suppose you deal in phosphoric acid?—I cannot say that we do not deal in phosphoric acid, because we do, but we do not supply it for dietetic purposes. If a man wants to use phosphoric acid for acidifying lemonade or aerated waters, we decline to supply him, and always have, not because we were afraid of its containing arsenic, but because we consider that the proper acidifying agent or material for aerated waters, and for other waters, is natural fruit acid.

11168. You think the process is wrong?—I may say that citric and tartaric acids are the acids which are generally used for the purposes.

11169. Do you supply phosphates of soda and other phosphates?—Phosphate of soda to a very small extent; I should hardly like to say that we supplied that for dietetic purposes.

11170. Boric acid?—That is supplied as a preservative generally.

11171. Sulphuric acid?—That is used for generating carbonic acid gas.

11172. Tartaric acid?—That is used for various purposes, chiefly as an acidifying agent in aerated waters and confectionery.

11173. And glycerine?—With regard to glycerine, until I had some conversation with Mr. Hammond Smith I was under the impression that glycerine was not used to any very great extent in confectionery, but he has told me that it is used very largely in cake making and biscuit making. We supply it to confectioners; they do not tell us what they are using it for, but I presume they use it for that purpose. As a rule, when any firm of confectioners use anything special in that way they keep it to themselves; they are not anxious to tell the people who supply them with it what they use it for.

11174. You were not generally aware as a trader, that it was used for this purpose until Mr. Hammond Smith informed you?—No. I think I may say that I was not aware what they used it for. I do not know that I ever gave the matter serious consideration. With us it is not a very big article; we do not sell large quantities to confectioners.

11175. Do you take any steps with regard to these various substances to secure their freedom from arsenic?—Yes. In the first place we get guarantees from the manufacturers, and, in the second place, we never make a contract on a sample for the supply of such an article as glycerine without submitting it for analysis to the firm of Helbing and Passmore, whom you may know. We do not even trust to our own chemist. If we make a contract we send a sample of everything round to this firm of analysts, with whom we have an arrangement, and they make an examination, and hand us a certificate.

11176. When you purchase any ingredients of this type, or when those who purchase from you do so, you take a sample out of the lot that is sent to you, and have it tested?—First of all we have that sample submitted. The makers, or the agents, or whoever it may be, that are selling to us submit a sample to us, which represents the bulk.

11177. In the same way they forward you a sample of the material?—That is so.

11178. Then the professional gentlemen supply you with a report as to whether it is free from arsenic or not?—Yes.

11179. That is the way you conduct your business?—Yes.

11180. When you talk of chemists, are they analytical chemists, or chemists with whom you are trading generally?—They are chemists engaged in conducting manufacturing operations in our place, and others who are making investigations with a view to finding out any improvements or anything new in our line of business.

11181. You mentioned whom you relied on to test in regard to freedom from arsenic; but in addition to that is there in any sense an analytical staff at your works?—

Mr. R. Howell.

No knowledge of purpose for which confectioners use glycerine.

Nature of precaution.

Tests made by firm.

Occasionally we rely upon our staff of chemists for examinations, not particularly with regard to arsenic, but with regard to lead in citric acid and tartaric acid, etc.

11182. And with regard to experiments connected with the trade?—Yes. But they are in no way safeguards to us. We do not regard them as safeguards to us for the purity of the goods. We regard Helbing and Passmore in that light—the analysts that we employ.

11183. Your sole reliance is on that one analysis in each case of a sample?—Are you speaking about the glycerine?

11184. Yes?—With regard to glycerine, I should say we get the guarantee from the manufacturers in the first place, which is a certain amount of safeguard; then in addition to that we submit the sample to Helbing and Passmore.

11185. But you rely in regard to all these substances more on your analytical test than you rely on a guarantee?—Yes, certainly. I should mention specifically three articles—glycerine, sulphuric acid, and glucose—which are the only three articles that I can find that we deal in that are likely to be really injurious, which are actually used as articles of food. It seems to me there is a good deal of difference between articles used for food purposes and articles not used for food purposes.

11186. Could you tell the Commission of any case in which you have given up trading with any particular firm with which you had been dealing in any of these substances, such as sulphuric acid, tartaric acid, or citric acid, on account of the detection of arsenic?—No.

11187. How many years have you been in this business?—Since 1881.

11188. And during that time, apart altogether from the occurrence at Manchester through the arsenical poisoning of beer, have you had any cause for alarm on analyses?—Never.

11189. I mean alarm, of course, in regard to the quantity of arsenic found in any substance?—No, never.

11190. Has your firm ever adopted anything like a limit of arsenic which you would consider admissible or otherwise for food purposes?—You could not compare a limit of arsenic in boric acid or metaspulphite of potash, which is largely used in brewing, and a limit of arsenic in glucose. There is no comparison between the two that I can see. For instance, we will say for the sake of argument that we find metaspulphite of potash contains 1-12th of a grain of arsenic to the pound, which is a large proportion. Three ounces of that metaspulphite of potash are used to the barrel of beer. That means in actual figures—I have not the figures in my head—something like 1-25,000th part of a grain of arsenic to the pint of beer, which is less than the Gutzeit or the Marsh test can detect. That has always seemed to me to be a very important point in connection with chemicals as applied to foods or drinks, so that we really find it rather difficult to establish a standard. The only standard that I know of is the B.P. standard, which, curiously enough, is only actually fixed in glycerine. In glycerine I believe the Gutzeit test is applied, and that really fixes, according to our calculations, the limit of arsenic in glycerine at about 1-200th part of a grain to the pound.

11191. You wish to make a kind of proportion sum of it—that where the quantity of a material which is used in the food is infinitesimal compared with others, that in that case you would allow with perfect confidence a larger amount of arsenic?—I would not, because I have never come across a sample of metaspulphite of potash containing that proportion of arsenic, and if it did we should have rejected it. We would reject boric acid containing that proportion of arsenic. At the same time it seems to me that up to 1-12th of a grain it really is not very material.

11192. Still, you would allow that what we should endeavour to obtain would be that every ingredient that is used, either in your trade or in any other, should be as free from arsenic as possible?—Most certainly.

11193. The point you have urged was merely incidental, was it not?—Yes. I do not wish to urge any point which means that arsenic should be passed in any way at all. I do not think it should be; I do not think it is necessary. I think that if a fixed limit of arsenic is insisted upon that it is easily arrived at.

11194. You were rather urging this—that there was a degree of danger in a much larger sense in one chemical than in another?—Yes; you would not compare glycerine, which is used more or less as an article of food, I believe, in biscuits and cakes, and also is very often given to children as medicine in equal parts with honey, with such things as boric acid, metaspulphites, and sulphites generally which are used in breweries.

11195. Are you often asked by your customers for a guarantee, or do you give a guarantee without being asked?—We never give a guarantee without being asked, but we give guarantees for those who ask for them. We are asked for guarantees for all sorts of absurd things which, of course, we are able to give.

11196. What special form do these guarantees take?—Guaranteed free from arsenic.

11197. Not free from any deleterious substance?—The citric and tartaric acids are guaranteed commercially free from lead.

11198. Do you usually sell to middlemen?—No, we sell generally direct to the manufacturers—very seldom to the middlemen at all.

11199. And you know generally for what specific purpose your chemicals are required?—Yes, as a rule we know. We give recipes with most of the things to show the manufacturer how they are to be used in the case of essences and citric and tartaric acids.

11200. Do you happen to know of any instance where chemical substances liable to contain arsenic, such as phosphoric acid, are sold under special trade names?—Yes, a great many.

11201. And thus the purchaser might have a wrong idea given him of the nature of the substances he is using. Can you give us any information with regard to that point?—I think there are any number of cases. For instance, there is "phospho-citric acid," which is sold to mineral-water makers. I do not know that that is a misleading name altogether, because it consists of about 96 per cent. of phosphoric acid and about 4 per cent. of citric acid. Then there is another acid which is sold in Manchester called "liquid tartaric acid," which, I believe, contains no tartaric acid at all, or, if so, only the same proportion as the citric acid in "phospho-citric" acid. Then there are such things as "cremaline" and "cream of tartar substitute"—any number of them. There is scarcely a house in the trade that has not fallen more or less into the temptation of making extra profit by selling these substitutes. There is another substitute which is largely used as a substitute for cream of tartar, bisulphate of potash.

11202. Can you point to any remedy for this state of things?—Yes; make it illegal to sell a chemical substance under a wrong name—any article sold for food under a wrong name or designation. The buyer does not know what it is—the buyer hardly knows what cream of tartar means.

11203. I have your catalogue here. What is the meaning of the analysts' statement on p. 32 when he speaks of colours as being "perfectly harmless for confectionery and for articles of food"—does that refer to absence from arsenic?—That is Mr. William Jago's report you are referring to, I presume? That refers to freedom from arsenic. It is his opinion that these colours are suitable for dietetic purposes.

11204. Does this statement apply to mineral colours such as bole armenia, which we found contained up to 1 grain of arsenic per pound?—No; it applies particularly to the colours which are enumerated in that list.

11205. Only to those?—Yes, practically to the series of aniline colours which are sold. Though aniline colours used to contain a considerable proportion of arsenic 10 years ago, one never, or very rarely, meets with arsenic at all in aniline colours at the present day, because the processes have improved so much.

11206. There has been a great improvement as regards the preparation of all these dyes?—Yes, a very great improvement.

11207. (Sir William Church.) I should like to ask some questions about these aniline colours, because I am under the impression that many of the aniline dyes are injurious, quite apart from their containing arsenic?—Yes, that is what the certificate particularly applies to.

11208. "For any aniline colours such as are certified harmless"?—Yes.

Mr.  
R. Howell.  
21 Nov. 1902.

Guarantees given to customers, if asked for.

Chemical substances liable to be arsenical sold under misleading names.

Form of guarantee with colours.

Mr.  
R. Howell.  
21 Nov. 1902.

11209. Therefore yours are submitted to Mr. Jago, so that the public may be protected from any which are likely to be hurtful?—Exactly.

11210. I imagine from your list that you supply brewers on a large scale?—Not on a large scale; we do supply brewers, but it is a very minor branch of our business.

11211. You are not yourselves manufacturers of tartaric acid?—No, we are not.

11212. You buy your tartaric acid, I understand, on guarantees?—Yes, we buy our tartaric acid on guarantees. We buy the best tartaric acid that we know of. As a matter of fact, we deal for tartaric acid and citric acid with a firm you will know very well, John Bennett Lawes.

11213. They are the largest makers?—Yes.

11214. As far as tartaric acid goes, you are middlemen?—Yes, as far as a great many of those things are concerned.

11215. Do you analyse it before you send it out yourselves?—We are constantly sending it over to Helbing and Passmore for examination, and other different makes of tartaric acid and citric acid, both for our own and for our customers' protection.

11216. With regard to citric acid, the same remark applies—you are not manufacturers?—No, we are not manufacturers.

11217. In the same way you test that before you send it out again?—I do not mean that we are always testing citric acid for arsenic. We cannot do that. We rely to a very great extent upon Messrs. Lawes' guarantee, and upon their reputation.

Tartaric acid rejected, but on account of lead.

11218. Have you often had to reject any tartaric acid?—Not from Lawes, but we have had to reject tartaric acid on account of its containing lead.

11219. But not arsenic?—Not arsenic, never. I think I may safely say that we have never found arsenic in either tartaric acid or citric acid.

11220. What quantity would have caused you to reject a consignment of tartaric or citric acid containing arsenic?—It is rather difficult for me to say.

11221. Do you pass it if it contains any lead?—I have never seen a tartaric acid or citric acid which is chemically free from lead, but so long as it passes the British Pharmacopoeia test we consider we are safe in sending it out. The British Pharmacopoeia is rather like the family Bible to the manufacturing chemist: I do not know whether it is as reliable.

11222. You do not sell large quantities of boric acid?—No, not large quantities, but we sell a reasonable amount.

11223. With regard to the other borax preparations which you sell, they are used very largely as preservatives in food, I suppose?—Yes, we sell a certain quantity of them, but not large quantities.

11224. Those you make yourselves?—No, we do not make borax or boric acid. We buy them on guarantee and analysis.

11225. I suppose you do not make glycine and those sort of things?—That is a patent thing, which to a great extent contains borax?—I am afraid I do not know it at all.

11226. It is a thing which is largely sold. What is the largest quantity of arsenic that you have passed in meta-sulphite of potash? You have told us that you did not think 1-12th of a grain in a barrel would hurt?—If it contained 1-1,000th part of a grain to the lb.—that is the limit of detection, is it not, of the Gutzeit test or the Marsh test?—we should consider that was not free from arsenic.

11227. Then directly either the Gutzeit test or the Marsh test, not the Marsh-Berzelius?—The Marsh-Berzelius, I mean.

11228. Directly they gave indications of arsenic you would reject it?—Yes, most certainly.

Purity attainable.

11229. Then it is feasible to get it pure?—Yes, I think it is quite feasible. It seems to me, as a working manufacturer or dealer or whatever I may be in connection with the chemical trade, that it all hinges upon the sulphuric acid, and that now it is quite easy to get sulphuric acid automatically free from arsenic, if one may use the term, with this new process—the catalytic process—the whole thing seems to me to turn upon that,

11230. (Dr. Whitelegge.) For the most part you buy and sell, do you not?—Yes, as far as articles likely to contain arsenic are concerned.

Mr.  
R. Howell.  
21 Nov. 1902.

11231. You make certain things, I believe?—As far as the things you gentlemen are particularly interested in are concerned, I should say we buy and sell most of them, as far as those things which are liable to contain arsenic are concerned.

11232. Food ingredients generally?—Yes.

11233. You store in bulk, I suppose?—Yes.

11234. When articles are stored, are they covered? We have been told that whatever precautions may be taken as regards ingredients, that arsenic deposited by soot from the air, and so on, has to be borne in mind as a material cause of contamination by arsenic. Is that your experience? And does your method of storage confirm that?—I will tell you what our method of storage is. Such things as boric acid, tartaric acid, and citric acid are put into large standard casks with a closely-fitting cover, and supposing 1 cwt. is wanted, the cover is taken off and the other cask in which the goods are to be sent out is filled, and then the cover is put on again.

11235. Do you store anything loosely?—Well, of course when the contents of a cask which may start by holding 10 cwts. are reduced to 2 cwts., it is more or less, loosely stored.

11236. (Chairman.) But it is still covered?—Yes.

11237. (Dr. Whitelegge.) Have you any experience in that way tending to show that there is material contamination from the air and smoke?—No, no experience whatever.

11238. Are your works visited by the Excise for any purpose?—Yes, we have an Excise officer there almost daily.

11239. On what footing does he come to you?—We ship large quantities of essences to various parts of the world—essences for making aerated waters, for flavouring aerated waters, and confectionery purposes.

11240. It is a question of rebate?—Yes. We hold certain licenses from the Inland Revenue—compounders' licenses, and dealers' licenses, and so on.

11241. But you are not visited by the officers of the local authority—the District Council officers?—No, unless we make ourselves a nuisance, or anything of that sort.

11242. They do not come to you for the purpose of the Sale of Food and Drugs Act, and take samples?—No.

11243. Would you object to their doing that?—Not in the least.

11244. You said that on ethical grounds you would not supply phosphoric acid to aerated water manufacturers?—Yes.

11245. Do you supply it for food purposes at all?—We supply it, we quote it in our price list as a matter of fact, and I think we make a particular remark. We say, "Phosphoric acid—concentrated, commercial, frequently sold under various misleading names as a substitute for tartaric and citric acids." We do that so that we may let the buyers know that these substitutes practically are phosphoric acid. I think we do the same thing with regard to bi-sulphate of potash, which we quote as "largely sold under very misleading titles as a substitute for cream of tartar."

11246. But you do sell it?—Yes. With regard to potash bi-sulphate, I do not think we ever sell any at all.

11247. It goes to your customer, who may use it for food?—We do not know. Phosphoric acid we sell largely to chemists and druggists, whose business is very varied. We do a considerable amount of business with blacking manufacturers and ink manufacturers, and we do not know in the least what particular buyers are coming for a certain article, so we put everything into the list.

11248. That being so, what is your practice with regard to phosphoric acid? Is that tested by your chemists for arsenic?—No, as a matter of fact, we rely upon the manufacturers for that.

11249. Then you obtain a guarantee with it?—Yes.

11250. A guarantee of freedom from arsenic?—I happen to have had two guarantees quite recently from two manufacturers—absolute freedom from arsenic.

Manufacturers' guarantee relied on in some cases.

11250. Do you sell Bole Armenia?—Yes, we do quote it.

11251. Can you say whether you make it?—No.

11252. It is a natural product more or less, is it not?—Yes.

11253. What is your practice with regard to arsenic in that?—It never occurred to me that it contained arsenic in any way.

11254. It is not examined by your chemist?—Not at all.

11255. I am afraid we have had evidence tending to show that it is necessary to look for it?—We must look to that at once—that is a drysalter's article rather.\*

11256. Is acid phosphate of lime one of your articles?—No, we do not sell that rather on principle, because that is used as a substitute for baking powder. We sell ordinary calcic phosphate, but that is more a pharmacopœial article.

\* Since my attendance I have drawn a sample of Armenian bole from our stock, and sent it to Messrs. Helbing and Passmore for analysis. I have since received their report that it is quite free from arsenic.

Mr. C. OVERBECK, called; and Examined.

11260. (Chairman.) I believe you come from Grimsby, do you not?—Yes.

11261. You invented a food called "Carnos"?—Yes.

11262. Can you briefly describe to the Commission what it is?—It is a meat extract substitute in which all the component parts are dissolved, and in which there is no solid matter. It is a meat extract not produced, as it were, from meat. I was led to the idea by finding out that yeast contained a meat basis, which is really the stimulant part of meat extracts; and it contained also a large quantity of hydro-carbons of a very nutritive nature, produced from glycogen, and so forth, which could be utilised as a food, and which would alone supply the form of an extract of meat, and at the same time would supply other constituents that meat extracts lack. The extract is rich in phosphate of potash, and consequently is in that way also valuable. The great point with me was this. I wished to make a meat extract which should be devoid of the shortcomings of extracts made from meat; I wished also to be able in doing so to make an extract not by chemical means, but as much as possible by natural means, in order that I could say that the substance was a natural substance and not a chemical product, as far as it would be possible to do so; and I think it bears out in its analysis what I claimed at the time for it. It may be condensed to a very thick syrup or practically solid. It is perfectly clear, having been filtered. Consequently, all substances in it are readily assimilable, and require no further digestion. The chemical part of the question is, of course, very complicated indeed, because in malt culms we have a lot of nitrogenous substances of a very nutritive character. One can give but a small quantity as food, because it is too feeding and too heating. These products are, I found, by digestion at a moderate temperature of, say, 120° or 130° F., considerably altered by the formation of peptones, and by the albuminoids being made more soluble. The peptase in the culms is also capable of acting upon certain nitrogenous matters in the yeast itself, when once the yeast cells have been broken up. Consequently, albuminoids which may be insoluble and not obtainable out of the yeast as such, on boiling and after having been converted, would become soluble and valuable and could be utilised. At the same time, the culms contain similar carbo-hydrate compounds, such as yeast contains, and the combination of the two would form a natural extract containing meat basis, carbo-hydrates, phosphates—all strengthening and fattening materials—as well as stimulants naturally produced without the actual employment of any meat.

11263. When did you first commence producing this nutritive form of food?—It is getting on for three years now; something like that. I should think it is not quite three years.

11264. You commenced to make it before this occurrence at Manchester with regard to the arsenical poisoning?—Yes.

4576.

11257. And if you sell that, it would be examined for arsenic in the ordinary way?—Yes; but the demand for that is very small.

11258. (Sir William Church.) With regard to phosphate of soda, do you sell it largely to confectioners as an ingredient of baking powders at times?—I can hardly tell you what use phosphate of soda is put to. I know that we buy at times perhaps a cwt.—it is a very small thing indeed, and it disappears gradually in the course of business. I do not know what is done with it.

11259. That is a substance which has been found occasionally very highly arsenical?—Of course, one knows of one very bad case of it indeed; but it is free from arsenic now, because I sent a sample of it over quite recently to Helbing and Passmore for examination, and we consider that when we get a certificate from people like Helbing and Passmore we are practically safe. I should say, if you would not mind my making a suggestion about that, that Dr. Passmore, of Helbing and Passmore, will give you more information on the subject of arsenic than any other chemist in London. I look upon him as quite the very best authority on any matter of that sort. I think his evidence would be very valuable to you if you would care to have it.

11265. Was "Carnos" sold in any quantity before this occurrence?—I cannot say in any quantity, because the company formed was a private company made up of friends of mine, to exploit and try the substance.

11266. A kind of syndicate?—Yes, with a very limited capital, and consequently we were not able to put it on the market on a large scale. We had to work with it on a small scale, and carefully to try and test the feeling and general taste of the public before risking any more upon it.

11267. Can you give us any indication as to how much was sold—what would a week's sale amount to; do you know the largest sale you had?—The largest sale would be perhaps not more than 40 lbs., I should think; but in the summer months, as with all the other extracts, it fell off completely.

11268. I suppose you are aware of the evidence that has been given before this Commission with regard to the possible contamination of malt culms with arsenic?—I am aware of the possible presence of arsenic in malt culms.

11269. Had you any suspicion of such a thing before the sittings of this Commission?—No, only since the scarce started in connection with the beer. I then at once thought of the culms.

11270. Have you taken any precaution to ascertain by analysis whether any of these ingredients that you used contain arsenic?—After it became public knowledge that these ingredients might contain it, or did contain it, I at once analysed the materials, and found the traces one would expect in these particular materials. At that time, not knowing how much might have been in any past brew, in order to prevent danger of any sort I recalled everything I possibly could, lest in any past brew, before I knew anything about it, there should be any contamination which might have occurred, and which might be deleterious.

11271. You called in all the ingredients you could possibly reach?—I called in all the "Carnos" made according to our books that I could possibly reach. Of course, it is quite certain that here and there a little may have been left; it was impossible to actually find out from the bottles, but we sent notices to all our customers that we were sending an improved extract out, and we should be glad to have their present samples back again.

11272. Have you taken any steps since to analyse the finished material of "Carnos"?—Whilst I was connected with "Carnos"—it is in liquidation at present—I examined several different lots. I took every precaution, chemically and mechanically, that suggested itself to me during the process which could possibly eliminate it.

11273. Can you give the Commission any results of the analyses?—The figures that I got varied very much; they were generally somewhere about 1-30th of a grain per lb. Then I considered that when one comes to think that in one ounce there are four large cupfuls of

R

Mr.  
R. Howell.

21 Nov. 1902.

Mr.  
C. Overbeck.

Samples called in on account of arsenic.

Arsenic in Carnos.

Mr.  
C. Overbeck.

21 Nov. 1902.

"Carnos," that that would work out at an exceedingly small amount in the substance. Of course, with all these things, it is very difficult to know what limit will be fixed as necessary with these different foods, and therefore I worked to eliminate everything I possibly could, bringing it down so low that I thought that, whatever inquiry would be made, the amount of substance that could possibly be taken at one time would be taken into account, and it would be seen that everything had been done to make it perfectly safe, and that it was so low as to be perfectly harmless; because really absolute freedom from arsenic in any commodity is simply a matter of the quantity taken for analysis.

11274. I have some analyses here of a sample of "Carnos" purchased through a local druggist in July, 1901, which contained 1-25th of a grain of arsenic per lb.; I have another sample given to Mr. Hammond Smith by yourself on November 9th, 1901, which produced 1-25th of a grain per lb., and another sample purchased through a local druggist on May 14th, 1902, which is said to have produced 1-6th of a grain of arsenic per lb. Those are serious quantities, are they not?—The 1-6th of a grain to me is a surprise, because that is very high indeed compared with any of the results I got when I made examinations while I was in connection with Carnos. I never allowed anything to pass at that. But even a sample containing 1-6th of a grain per lb. would work out at 1-300th of a grain in a cup of "Carnos," so that, even taken at that high figure—and I never had any "Carnos" which approached that figure—it would not be excessive on account of the amount of the substance used. Still, it is not at all a figure such as I came across at any time. I can only account for it in one way, namely, that it came from a brew made while the company was in liquidation, which I have not seen. That is all I can say about it. But there has been practically no sale for the last year since it has been in the hands of the liquidator.

Company in  
liquidation.

11275. Is it likely that the sale of "Carnos" will cease altogether?—I am very sorry to say I am afraid it will. It is a very great pity, from the value of the material itself.

Would pass  
1-25th grain  
per lb.

11276. Assuming that the company were not in liquidation, and that the sale was likely to increase, and there was likely to be a large consumption of it, surely some greater precautions ought to be taken as regards the materials used?—Certainly. Not a single material would be passed, and not a single batch of substance made would ever be passed, which would contain more than, say, 1-25th of a grain, which I think you will agree is very low.

11277. (Sir William Church.) What directed your attention in the first instance to this manufacture?—It is now quite 14 or 15 years ago since I first experimented in that direction, long before any of these yeast foods were known. It is about 15 years since I approached Armour's, in America, and asked them if they would consider it as a valuable substitute to mix with their meat extract. The correspondence went on for a certain time, but the business relations did not come off.

11278. It has been in your mind for some years. I do not know what your profession has been; I rather wanted to know how your mind became directed to it?—I am a brewer's chemist, but before I became a brewer's chemist I was at the University, with the idea of merely remaining at the University and merely studying. That was altered, and consequently I did far more chemistry than was ever required for the business.

11279. You have answered my question; I see now how your mind became directed to the subject. Of course, you had a certain amount of special knowledge as a brewer's chemist?—Yes; I had the commodity under my eyes. I saw there was a dreadful waste of the most valuable materials that we had in the brewery.

11280. Did it ever occur to you that there might be a possibility of danger in the use of those substances?—Not before.

11281. Although you are a brewer's chemist, you did not realise the existence of arsenic in malt?—Nobody did, I think. Of all the chemists I have met I have never heard of one who had guessed it.

11282. Before you put this food upon the market, did you take any steps to satisfy yourself of the wholesomeness of it?—When I made the substance itself, I tried it repeatedly on myself. I tried it also on animals, on dogs and cats, and it was so like meat that it struck me it would become a splendid substitute for it. I thought

if both cats and dogs were deceived in taste and flavour, and it agreed with them, and that they evidently liked it—

Mr.  
C. Overbeck.

21 Nov. 1902.

11283. I understand that you experimented on your own person, and experimented also on the persons of dogs and cats, and, finding it had no bad effect, you then thought you were justified in putting it on the market?—Yes.

11284. You took right and proper precautions. Do you think it is right that anybody should bring out a food stuff without his showing some authority that he is a person who is likely to have taken proper precautions that the food stuff he brings out is not harmful?—I should look upon that question in this sense. I had experimented so long, and knew the constituents of the stuff so well—

11285. I am asking you altogether apart from that. You have told me that you did take steps—that you experimented on cats and dogs, and yourself; but I ask you whether, as an inventor and a manufacturer, you think it is right that anybody should be able—as I believe they can at the present time—to bring out and advertise and place upon the market a food stuff without their being responsible to anybody that the food is not harmful?—I should say that they ought to have found out for themselves that it was not harmful before they put it upon the market, and that there was some value in it. The public is not easily misled to believe that a substance is valuable as a food product unless it is so.

11286. As a manufacturer, would you have any objection to manufacturers coming under the Sale of Food to samples and Drugs Act, and samples being taken out of your being taken factory?—I should not have the slightest objection to anything that could lend itself, in the first place, to satisfy any authority that everything was made from the purest materials obtainable, and in the cleanest and best manner, and also such an authority that I should know also would and could give the greatest help in saying that the process could not be improved upon. Anything that will improve the process, and help the public and the substance itself honestly and straightforwardly made, I do not think there is any objection to whatever. As it is, our works are always open to the Medical Officer of Health of the place, and have been from the very beginning.

11287. But not for the purpose of examination of the material you are producing, but to see that it is carried on under proper conditions?—Yes. I mean any local precaution that I could take to satisfy everybody that I was doing my best to make food in the best possible way. When Mr. Hammond Smith came, I was only too pleased to show him over and explain everything I possibly could in order that everybody should understand exactly the true bearings of the whole process.

11288. (Dr. Whitelegge.) When you were making the "Carnos," did you obtain your yeast and culms from manufacturers?—Yes.

11289. From brewers and maltsters?—I obtained my yeast from my own brewery.

11290. Are you a brewer?—I am manager of a brewery.

11291. Was any analysis made at any time for arsenic of the yeast that was used in manufacturing "Carnos"?—Yes, I found that the slightest trace of arsenic had been found in yeast. By the bye, I think I may say that the arsenic in yeast that has been given is not exactly inside the yeast cell, but may be superficial to some extent, for these reasons: When I found there was a certain amount of arsenic in the yeast, I used pressed yeast. It struck me at once, if that is so, I expect that yeast, being really more animal than plant, I could help it considerably by washing the yeast. In the original process I simply pressed my yeast and used it; after I had pressed my yeast dry, I passed a weak solution of soda water through the yeast, and washed it through in order that any superficial contamination on the yeast cells that might occur or might be present should be eliminated, and I really do think that that generally lowered the arsenic in the yeast itself, although one must never forget that no two batches of yeast from any brewery come out alike.

11292. At all events, you tested the yeast, and you would reject any that was found to contain a considerable quantity of arsenic?—Yes.

11293. When did you begin to do that?—The date I cannot give; I began it when I was associated with the

Mr. Overbeck. company—directly the arsenical poisoning scare commenced, when my eyes were opened to the fact that arsenic might be present in the yeast.

11294. Did you reject the yeast of any brew?—I never had to reject one; I never had any trouble in my own brewery with arsenic.

11295. What test did you use?—The hydrogen tests.

11296. The Marsh test?—Yes.

11297. With regard to the malt culms, did they come from your own works too?—No. I used really pale-malt culms. I wished the culms to be as pale as I possibly could get them on account of colouring matter, and so that the "Carnos" should not be traced to culms. Consequently I got them from a large maltster locally. I got their palest culms—that is to say, culms least fired. I found there were traces of arsenic discoverable upon culms in my original process where I digested the yeast and the culms together in the mash tun with water at the proper temperature. So that I now wash my culms first and press them. That I found helped considerably.

11298. Then you tested for arsenic?—Yes.

11299. Using the same process?—Yes.

11300. And if you found arsenic did you reject it?—I did not reject it then, because I have still further methods of eliminating it afterwards. When I found that in one or two batches the arsenic was too high I did not use any of the brew whatever.

11301. What do you mean by saying "too high"—what sort of standard?—When I found the darkening was considerable, then I knew it would be too high; I did not use any of it; it was thrown absolutely away.

11302. Otherwise what did you do with it?—After that I tried sulphuretted hydrogen solution in glycerine. In part of the process, when the warm liquid is being pumped up preparatory to boiling, this was mixed with it. In the original process I once filtered the finished product. Now I do not; I put the sulphuretted hydrogen in. The liquid was well boiled to 1060 degrees specific gravity, and then filtered, because I knew that I filtered the whole of the sulphide of arsenic together with the insoluble albuminoids off.

11303. But did you verify that by examining the filtrates?—Yes; I found out that I eliminated a lot of it, because I never got it so high after I used that process. Then I knew perfectly well that sulphuretted hydrogen must separate it, as I used a double fine filter. Some time after I did that I used polished copper plates, and I boiled them in the liquid to see if any darkening took place, because the "Carnos" is of an acid nature—there are various acids naturally produced in it, not chemically added. I found that when the plates were boiled they darkened considerably, but after the sulphuretted hydrogen had been added I could boil my plates for two or three hours and they did not perceptibly darken at all. Then I condensed my liquid in a vacuum condenser, and I bought another filter press and filtered it once more, and the perfectly clear filtrate that I obtained without a shade of precipitate gave the 1-30th of a grain, and then I thought I had gone as far as anybody could to eliminate it.

11304. But how did you get the 1-30th of a grain? Is it arsenic that has escaped the sulphuretted hydrogen, or what?—The quantity was so minute that I let it pass at that; I made no research to find if it was sulphide of arsenic—it must be sulphide of arsenic, because I always use a large excess of sulphuretted hydrogen; and I boiled it for so long that it was immaterial to me whether there was a small or large quantity in it.

11305. If you recommenced the manufacture of "Carnos," would you be content with your 1-30th of a grain of arsenic, and would you be content with the procedure described to us just now?—I think I should be justified in saying yes, considering the quantity of the substance that is used. A quarter of an ounce is the largest amount that you would use for a large cup. That is a very small quantity indeed, and works out lower per grain per pound than any malt that would be placed on the market.

11306. I do not doubt your calculation, but I do seriously doubt whether the public, if they knew, would accept the risk?—With 1-30th of a grain per pound?

11307. Yes?—Then the only thing, if that is the impression, would be that some other addition to the process must be tried in order to lower it still further.

Mr. NORRIS WALKER, called; and Examined.

11308-9. (Chairman.) I believe you are the manager, are you not, of Messrs. Castell and Brown, who are large jam makers, confectioners, and table syrup manufacturers of London?—Yes.

11310. I suppose you may be described as large wholesale dealers?—Wholesale confectioners and dealers.

11311. I suppose your firm sells a great quantity of golden syrup in the course of a year?—Yes, we get rid of a good lot of golden syrup.

11312. Is it made by your firm, or do you buy it from the manufacturers?—We buy it direct from the manufacturers, from the refiners.

11313. Have you any written agreement or undertaking with regard to this syrup when you purchase it that it shall be arsenic-free in every case?—Yes, it is guaranteed absolutely free from arsenic, and made from cane sugar only.

11314. Do you yourselves apply any test to this syrup?—No, we take the guarantee.

11315. You are satisfied with the guarantee?—Yes.

11316. Do you always employ the same manufacturer?—Yes, for the syrup.

11317. For how many years have you employed him?—I suppose they have supplied the firm for five or six years right off now.

11318. Can you show us any document or quote any document in the shape of a guarantee?—The guarantee is stamped on every invoice.

11319. It is merely stamped "This is arsenic-free"?—There is a rubber stamp and the signature of the firm guaranteeing the purity. I have some of the guarantees. These are the styles of guarantees we get from different people. (The guarantees were handed in.)

11320. These are only guarantees for colours used in confectionery, not for golden syrup?—Yes, colours and essences.

11321. Some of your golden syrup is sold as containing added glucose?—Yes, it is, but there is always a guarantee given with that by the firm—that is, by ourselves.

11322. You use glucose, of course, in confectionery?—Yes, in large quantities.

11323. You are aware of what happened in regard to glucose?—Yes, but we have a guarantee.

11324. You are aware of the notorious case in 1900?—Yes.

11325. With regard to analysis, do you employ an analyst at all?—We have not, but if there were any occasion to do so most decidedly we should.

11326. If there was any occasion?—If we had any doubt.

11327. How would you define an occasion of that kind—if you were urged to do it, or if you had any suspicion?—If we had any suspicion. But dealing with one firm continually for years, and getting their guarantee on the invoices or a written guarantee when we buy the stuff, we take it from the guarantee. They are firms of good standing, and I do not suppose they would dare to give a guarantee like that unless they were absolutely sure themselves.

11328. But still, if there were any accident, or any case of carelessness—in the best of firms there may be some cases of carelessness, may there not—do not you think you would be more secure if you analysed for yourselves?—It would certainly be a double warranty.

11329. What you urge is, that you have been connected with this business for many years, and for a long time have employed the same firm, with excellent results so far, and so long as you employ that firm you are satisfied from experience with their guarantees?—Yes.

11330. Supposing you changed the firm; in that case would you think it necessary to employ an analyst?—We

Mr. C. Overbeck.  
21 Nov. 1902.

Mr. N. Walker.  
Glucose likewise

No analysis considered necessary.

Mr.  
N. Walker.

21 Nov. 1902.

might do so in certain colours, but having found that the colours we are using suit our purpose, we should not think of changing.

11331. The general custom, I understand, of your firm in purchasing glycerine or colouring matters for confectionery or jam, or anything of that kind, is to rely upon the guarantee only?—With regard to glycerine, which you mentioned, we use very little indeed; I do not suppose we use 56lbs. in the course of a year.

11332. Of course you are aware of the liability of glycerine to contain arsenic?—Yes.

Glycerine  
not tested.

11333. And you do not test for that?—No, it is used in such minute quantities that it is hardly worth while.

11334. But still, if a minute quantity turned out dangerous or mischievous, there would be serious injury to the trade, would there not?—I am afraid that the quantity used is so very very small indeed that it really would not be noticeable.

11335. Is your practice as you have described it generally speaking, the practice of the trade at large?—Yes, taken generally, it is. They get the guarantee from the firms from which they buy, and are satisfied. But if there is any doubt about anything they would have it analysed; I should myself if I had any doubt about any of these things.

No objection  
to official  
samples  
being taken  
at factory.

11336. Would you object to an officer of any Government Department visiting the works of your firm from time to time to take a sample of the materials you are using?—No, I should welcome him.

11337. You would not think it inquisitorial or injurious to the business if such were done?—Not at all.

11338. In fact, you would look upon it as a kind of extra precaution?—That is so; I should not mind how often they took an analysis.

11339. Before this unhappy occurrence in Manchester were you and your firm generally aware of the danger of the presence of arsenic in these materials?—At that particular time I was not connected with the firm.

11340. You have only more recently been connected with it?—Yes. But still I used to handle a lot of the different ingredients used in confectionery for many years previous to that.

Manufact-  
urer will  
send an  
analysis if  
asked.

11341. From your own knowledge, have wholesale manufacturers taken greater precautions since these occurrences, or have they simply continued the system which they used before?—I think a precaution has been taken by these guarantees. I think nobody will buy unless they have a guarantee, and if necessary they will also produce an analysis. If we wanted the manufacturers to send an analysis of glucose, or syrup, or essences, or anything else, they would do so.

11342. In every case they would send you the analysis on which the guarantee is founded?—Yes, if we desired.

11343. That is always available to you?—Yes.

11344. (Sir William Church.) I suppose this system of having guarantees has only come in quite lately?—No, it has been in vogue for years; for some years, that is to say, anybody who is careful with what they are buying.

11345. Not subsequent to the alarm which arose from the arsenicated glucose of Bostock's?—No, I think not.

Mr. E. I. Pronk, called; and Examined.

Mr.  
E. I. Pronk.

11362. (Chairman.) You are connected with Messrs. Pronk, Davis and Co., who are large manufacturers and importers of colours of various kinds for food and for textile purposes?—Yes.

11363. As regards food, is your sale chiefly for confectionery purposes?—Yes, chiefly, and cakes, also for colouring sausages.

11364. Are you a purchaser of glycerine?—Yes.

11365. To a large amount?—Fairly so.

11366. You are aware of its liability to contain arsenic?—Yes.

Arsenic in  
colours.

11367. With regard to coal-tar colours, can you explain to the Commission how the liability of these colours to contain arsenic arises?—I should say it is owing to the arsenic being present in the materials from which the colours are manufactured. For instance, sulphuric acid being largely used in the manufacture, I dare say that the commercial article would generally contain arsenic.

due to  
sulphuric  
acid

11346. Before you were with Messrs. Castell and Brown, I suppose you were in the same sort of business?—Yes, I used to handle all the different essences and things before they were manufactured.

11347. And you were aware, therefore, that in the firm with which you were connected they used to require a guarantee?—I was the head of the firm myself, and I used to require guarantees.

11348. I only wanted to know whether it had been customary before the last three years to have these guarantees?—Yes, it has been customary.

11349. Those former guarantees did not in any way include arsenic?—No. They used to give a guarantee that the article supplied was pure; the word "arsenic" did not appear. I think there are several things which ought to be looked for, irrespective of arsenic, in the manufacture of certain things. I am almost afraid to say, but still I know for a fact that some of the manufacturers are not too careful about those things. For instance, cleanliness of their utensils. When they are using such things as natural acids, lemon, or anything of that sort, I myself have noticed very often that perhaps a pan which has been used for making lemon jelly overnight, in the morning has a thick sediment of verdigris on it. If that is not properly cleaned out and very carefully cleansed, and thoroughly washed, the next lot of jelly put into it would be absolutely poisonous.

11350. There is no doubt that care should be taken in the cleanliness of the utensils. Do you use much citric or tartaric acid in your trade?—We use a certain quantity.

11351. Is that bought under a guarantee?—Yes, it is bought under the guarantee of one of these firms, Stevenson and Howell.

11352. (Dr. Whitelegge.) Do you use American glucose?—Yes.

11353. In what way does that come to you? Who guarantees it?—It is guaranteed by the firm we buy it of in London.

11354. Have you any understanding with them how they arrive at the certainty of their guaranteed freedom from arsenic?—They have it analysed over here, I believe.

11355. And from them you receive an assurance in writing that it is free from arsenic?—Yes, on every invoice that they deliver.

11356. Do they distinguish it as American? Do you know it is American when you receive it?—Yes.

11357. The terms of the guarantee are the same, whether it comes to you from the manufacturer or from the importer?—We buy through the agent.

11358. Through the same agent in every case?—Yes.

11359. It is the agent's guarantee, not the manufacturer's?—Yes.

11360. Are your works visited by the Excise Officers for any purpose?—No.

11361. You do not come into touch with them?—No, there is nothing excisable on our premises.

Works not  
visited by  
Excise.

11368. Supposing the sulphuric acid could possibly be eliminated altogether, would there still be danger?—Yes, I should say that applies to most of the chemicals used in making aniline dyes.

11369. These brilliant dye colours?—Yes.

11370. There is some danger of arsenic from other chemicals?—I should say so.

11371. But the major danger would be if sulphuric acid was used?—Yes.

11372. Will you tell us which coal-tar colours are specially liable to contain arsenic?—At one time all anilines were made with arsenic.

11373. Do you mean directly?—Yes, arsenic was used in the manufacture of magenta, for instance, and soluble blue was made from magenta.

11374. When did the change occur in the trade, when arsenic was no longer used directly, but became incidentally mixed with the ingredients?—About 20 years ago a new process was invented for making magenta without the direct use of arsenic.

Mr.  
E. I. Pronk.

or to use of  
arsenic in  
manufacture

Mr. Pronk. 11375. Do you consider it easy in your trade to secure colours practically free from arsenic, or does that materially add to the cost of preparing them?—No, we find it perfectly easy now.

ing  
rs on  
base.

11376. You are perfectly confident as to that?—Yes; as a matter of fact we find that out of 100 lots of colour there may be one that contains a slight trace of arsenic.

11377. Of course, you want to secure your customers as much as possible, do you not?—Yes.

11378. Therefore I should like you to detail to the Commission, generally speaking, how you carry that out. For instance, I presume you have something like a certificate, have you not, that the colours are free from arsenic?—We know from past experience that certain colours are liable to contain a little arsenic, and therefore we do not recommend them for colouring articles of consumption; but we also know that other colours are generally free from arsenic and metallic poisons, and therefore we buy those in preference. We import, say, one bulk of 5 cwt. and have it analysed, and unless we can show that it is perfectly free from arsenic and metallic poisons we reject it.

11379. Apart from any guarantee which you may get from chemists or any process of analysis, you avoid all colours which experience shows might be dangerous in regard to food?—Just so.

tion of  
ical  
rs for  
pur-

11380. Do you mean to tell the Commission that as regards food you avoid all colours which experience has shown you are dangerous?—Yes.

11381. Do you think that supposing it were made obligatory in regard to manufacturers of confectionery, for instance, to buy only those colours which were free from arsenic, it would be a serious interference with trade, or impose much extra cost?—There would be no interference, there would be no extra cost, and it would be quite easy to do so.

11382. If that were done, you think that, so far as your trade is concerned, any danger from arsenical poisoning would be restricted to possibilities with regard to colours which were sold for textile purposes, apart from food consumption?—If I may make a suggestion, the only condition that would have to be attached to the use of aniline colours would be that only such colours are to be used that are not manufactured by the arsenical process.

11383. You think that that would give security?—That would give perfect security, except in so far as there may be some accidental traces of poisons in colours from sulphuric acid or other chemicals; but the quantity would be so small that it could not possibly be harmful.

ie in  
rmenia.

11384. Have you anything you can tell us with regard to bole armenia? Do you guarantee freedom from arsenic in such a case as that?—I should not guarantee it free from arsenic unless we had had it tested first. But personally I do not recommend bole armenia for colouring any articles of consumption.

11385. Is it used in your trade much for textile purposes?—No, it is not; it is used as a horse physic.

11386. Do you make use of any system of analysis in your trade?—No, we do not, except that we go to some good analysts.

made  
m.

11387. You go to them?—Yes, we go to good analysts for analyses; we do not do them ourselves.

11388. Do you analyse samples of the different colours that you purchase?—Yes. We analyse all colours we purchase for confectionery or for articles of consumption.

11389. When you say consumption, you mean when they are used for confectionery or food purposes?—Yes.

11390. You do not do so in regard to any colours that are used for textile purposes?—No, we do not.

11391. You do not think it necessary in that case?—No.

11392. But in regard to colours used for textile purposes, you advocate, as I understand it, that all colours which may possibly contain arsenic can easily be avoided?—Not for textile purposes.

11393. You mean for food purposes?—Yes, only for food purposes.

11394. For food purposes you think it very easy to get security by avoiding all colours which have been

proved possible to contain arsenic on analysis?—Yes, all colours that have been made under the old arsenical process.

Mr.  
E. I. Pronk.  
21 Nov. 1902.

11394\*. That is distinct from the position to-day. In regard to all colours which are used for confectionery or food, do you think the best security is through analysis?—Yes, as an extra precaution; although, as I said, all colours that are made by the non-arsenical process, if they contain any arsenic or metallic poisons, the amount would be so small as to be harmless. But still, as an extra precaution, we always have our colours analysed, so that we can give a clean bill.

11395. You have indicated the position you have taken up, and you define to us the difference between the old days, when arsenic was used in the production of these colours, and the system which you have adopted for the last 20 years, when that system has no longer prevailed; but can you tell us generally what the system prevalent amongst the trade is as regards security from the presence of arsenic in colours used in confectionery or food?—The supply of colours is in the hands of a comparatively small number of firms in England.

Small  
number of  
firms supply  
ing colours.

11396. I am aware of that?—For the purpose of colouring articles of consumption I may say there are only perhaps a dozen firms in England who supply such colours, and they buy them from a still smaller number of manufacturers. We, for instance, supply most of the wholesale firms who deal with confectioners.

11397. You think you are the largest dealers?—I should say we are. I do not want to mention any names, but many firms who are well known, and occupy more prominent positions than mine does, buy their colours from us, and we give them a guarantee that all the colours shall be free from arsenic and metallic poisons.

11398. The whole trade really is contracted within a narrow scope?—Yes.

11399. That being so, can you state that as regards the whole trade generally any precautions which are taken are on the same lines that you have detailed to us to-day?—Yes, I am sure they are.

Precautions  
are general.

11400. You say that from your own knowledge?—Yes, from my own knowledge. If you look up the advertisements of firms selling colours, you will find they all state they guarantee their colours free from arsenic and metallic poisons.

11401. I do not know whether you have read a report of Mr. Hammond Smith's, but in that report there is a reference to sausage makers and others who purchase mineral and other colours, without any security of purity, from middlemen who themselves know nothing of the purities of the colours they sell. Have you anything to say with regard to that?—No doubt it is so. But personally I do not sell much in the way of colouring matters for sausages, certainly not the ordinary thing which is sold, which is oxide of iron, and which I should say is not advisable to use for sausages.

Mineral  
colouring  
matters sold  
without  
knowledge of  
purity.

11402. Not advisable on the score of health?—Yes. I am not a chemist and not a doctor, but I should say that to add a large quantity of oxide of iron would be detrimental to the system. It might set up blood poisoning or irritation. Again, it is very difficult to obtain oxide of iron which is free from arsenic—we find it so.

11403. Is it your experience of oxide of iron that you find it very difficult to procure it without some arsenic in it?—Yes. It is possible, and we do obtain parcels free from poison, but most of them contain arsenic.

11404. Do you use very much of it?—We use a good deal.

11405. In what process in your business?—We sell it for colouring sausages:—making paints.

11406. Do you think it ought to be looked upon with suspicion?—Yes, I think it ought to be.

Objects to  
oxide of iron  
in food.

11407. (Sir William Church.) I rather gathered from what you said to the Chairman that a good many of these colouring matters you do not manufacture yourselves; for instance, you are only agents for aniline colours?—Just so.

11408. And it is those that you submit to analysis before you send them out to your customers?—That is so.

Mr.  
E. I. Proak.  
21 Nov. 1902.

11409. What colours do you principally make yourselves?—We do not make any ourselves. We mix a good many, but we do not manufacture them, except in so far as we make up paste colours with the colours we import.

11410. I suppose the colours that are used for foods are chiefly in connection with confectionery and sweetmeats; do you sell much colouring matters to agriculturists for cheese, butter, and such things?—We do not sell anilines for colouring butters, except one colour soluble in oil; there is a good deal of that used.

11411. For cheeses?—Yes. We also sell a good deal for colouring cakes; in fact, all cakes are coloured now with aniline colours.

11412. I suppose, practically speaking, these aniline colours have almost destroyed the use of vegetable colours for confectionery?—Yes, practically so; and, of course, I consider that aniline colours, if free from poison, are much better to use than vegetable colours.

11413. (Chairman.) Better for the consumer?—Yes.

11414. (Sir William Church.) Quite apart from their containing arsenic or any other poisonous mineral, aniline colours themselves, or some of them, are very prejudicial, are they not?—No, I think not; why should they be?

11415. I am not a sufficient chemist to say, but we have had it in evidence before the Commission that some of the aniline colours, quite apart from containing arsenic, are deleterious to animal life?—I do not think that has ever been proved. In fact, when complaints have been made, for instance about coloured garments setting up blood poisoning, it has always been proved that it was something else in the material that caused the mischief, some of the chemicals, most likely some of the mordant, but never the colouring.

11416. Of course, they are used in such infinitesimal quantities that probably it is rather a theoretical objection than a practical one, but the Commissioners on the use of Preservatives and Colouring Matters have distinctly given it as their opinion that some of these aniline dyes, apart from containing arsenic, are injurious?—I am not aware of it.

11417. What would be your objection to the vegetable colours?—Vegetable colours are exceedingly weak, and a large quantity must be used to produce a large effect. For instance, cochineal was used in confectionery, and to get a good colour one had to use a large percentage of it. Cochineal is an animal matter, but it is very seldom used as cochineal.

11418. Is there any known deleterious effect from cochineal?—Yes, it produces sickness if too much is taken inwardly.

11419. It is a very inert substance, is it not? It used to be used in medicines?—Yes, in very small quantities. But when it is used to get a deep colour in jams or in confectionery, you have to use such a lot that it is a different matter altogether. Then again, it is not used as cochineal. It is made into carmine, and then used as a cochineal. Carmine is made by certain chemical processes in which they use different chemicals, and possibly those chemicals may contain poisons. I have had samples of carmine analysed, and found traces of lead in them.

11420. Carmine was made, I think, by the action of acid upon cochineal, was not it?—No, there are different processes, but I think it is made with ammonia and starch.

11421. I suppose, as a rule, most vegetable colours have a very slight physiological action?—I do not know. Turmeric is used largely in pickles, for instance, and also for colouring confectionery. Turmeric is powdered very finely, more or less; sometimes not finely enough, in my opinion, and I should say that turmeric, if not fine, must be very deleterious to the system.

11422. As an irritant?—Yes, and of course it is used in medicines for that purpose.

11423. Is saffron still used for colouring confectionery?—No, it is too dear; it is not used now to any extent.

11424. (Dr. Whitelegge.) You distinguish, I understand, between the products which are going to be used for food and those which are not?—Yes.

11425. Do you always know which purpose they are destined for?—Yes.

11426. How do you know? By seeing the name of the firm to whom you are selling the goods?—Yes, and from the distinctive names of the colours.

11427. But how do you always know whether it is going to be used for textile purposes or for food?—supposing you received an order from a new customer?—I see your meaning now. Of course, where we supply dealers we very often ask the question: "For what purpose are the colours intended?" When we get orders from confectioners or similar trades we know what they are to be used for.

11428. But if you received an order from Manchester or from Leeds from a new customer, you would not at first know whether it was for food or for textile purposes?—We should, because it is unlikely that we should get an order straight away without a previous inquiry as to shade, quality, and price.

11429. Which would give you the clue?—Just so.

11430. You think you do know, as a matter of fact, which they are meant for?—I might say that we always do.

11431. And in the case of articles for food, you are careful to secure absence of arsenic?—Yes.

11432. In other colouring matters you do not think that necessary?—I do not, because I think the arsenic or metallic poisons would not be taken up by the textile fabrics; it would be run away in the water.

11433. When you sell to dealers as distinct from consumers, I understand that you make inquiries?—We always do.

11434. You said that certain colours were specially liable to contain arsenic, and that you did not recommend them for use in confectionery?—Yes.

11435. Can you tell us the names of some of those colours?—Arsenical magenta, blues, and various colours made from arsenical magenta base.

11436. You are referring more particularly to the use of arsenic in the manufacture of these things; there may be arsenic, even if arsenic is not intentionally used in the manufacturing, in some of the colours?—Yes, there may be accidental traces, but they would be very small.

11437. For example, do you know a colour called apple-green?—Yes.

11438. Is that liable to contain arsenic?—No.

11439. Not at all?—No.

11440. We have it on record that a sample lately examined did contain arsenic. You do not regard that colour as a dangerous colour; you would not consider it an improper colour to be used in confectionery?—Not at all; apple-green is always made up from a yellow and a blue; our analyses have never shown apple-green to be more likely than other colours to contain arsenic.\*

11441. What is your practice with regard to mineral colours? You spoke of bole armenia, which I understand you buy and sell?—Yes.

11442. Do you require any guarantee from the person from whom you receive it of, freedom from arsenic?—No.

11443. Do you make any analysis?—Yes.

11444. Do you find arsenic in bole Armenia?—Very often.

11445. What happens when you do find it?—We reject it, and sell it for making paint.

11446. Then, if you are selling bole armenia with any idea that it is going to be used for food, do you give a guarantee of freedom from arsenic?—Yes.

11447. Does that apply to other mineral colours?—Yes, as far as they are used for the purpose of colouring articles of consumption, but I hardly think there is anything besides oxide of iron in the way of mineral colours which we should care to sell.

\* Witness's attention having been drawn to the result of an analysis of a sample of apple green taken at a confectioner's, which was found to contain 1-12th grain arsenic to the pound, he has since written to the Commission that this quantity of arsenic would certainly be detected by the analyst employed by his firm and that (for food purposes) he would reject any bulk of colour containing more than 1 part of arsenic in 100,000 which is approximately limit of the test which his analysts employ.

ordered for  
food pur-  
poses.

11448. (Chairman.) Supposing you reject any colour as containing too much arsenic for food purposes, would you use it for textile purposes?—Yes.

11449. With regard to wall-papers, we have heard a complaint of the danger of colours in wall-papers. Have you anything like a limit of arsenic when selling colours which you know are to be used for wall-papers?—We take no guarantee, and we sell what we are asked for for wall-paper.

11450. Without any reference to the quantity of arsenic they may contain?—Yes.

11451. Since you have been in the trade, have you heard of any injury arising from wall-paper; have you ever come across that fact in the course of your trade?—No, I do not think I have.

11452. You have not made, in the course of your trade, any special reservation, or at least any difficulty in regard to the question of selling colours which are to be used for wall-paper?—No.

Mr. A. E. PALMER, called; and Examined.

11456. (Chairman.) I believe you are a large confectioner and cake manufacturer, carrying on business in Bristol?—Yes.

11457. You use various chemical substances, glycerine, glucose, and baking powders, in the process of making cakes?—Yes.

11458. I suppose you are aware, or at all events you have found out in the course of this inquiry from other sources, that these ingredients are liable to contain arsenic?—Yes, I understand that some of them are.

11459. Can you tell the Commissioners what safeguards, if any, you have adopted from time to time to secure that these substances are arsenic-free?—We have had them guaranteed as being pure from the manufacturers or merchants from whom we have bought them. I have the guarantees in my pocket from the various people. Taking glycerine first, this is the form of guarantee from Messrs. Lever Bros. (Handed in.)

11460. The guarantees are dated 1902. Has it been part of your practice to get these guarantees since you have been in business, or have you only taken it up lately?—The guarantee I have handed in refers to the last ton of glycerine we bought. We use only a little of it.

11461. You use little glycerine?—Very little in cakes.

11462. Have you always been aware since you have been in business that glycerine was liable to contain arsenic?—I cannot say I was until that scare.

11463. When did you first gain the information?—I think it was about the time of the arsenic scare. I had a conversation then with my doctor, and I asked him if he could tell me any things that he thought would be liable to contain arsenic that we were using in our goods, and he told me then he thought that glycerine might.

11464. From the very fact of your questioning him then, it appears that up to that time you were not aware of it?—I cannot say that I was. Of course, there is very little glycerine used in best-class goods; it is chiefly used in the cheaper grades of cake.

11465. Do you take any other precautions besides these guarantees such as you have handed in?—We send occasionally to the public analyst at Bristol.

11466. But you do not send a sample of all invoices?—Not of all the parcels that come in.

11467. You do it now and then?—Yes.

11468. But do not you classify the ingredients you use? Are you not aware that some are more liable to contain arsenic than others, for instance?—Taking that, for instance, I should think it would not. We do not buy in a competitive way goods such as that. With regard to all our chemicals and glucose and glycerine, we buy the best quality, and not the low-class forms, so that we expect to get a good and pure article.

11469. Do you use cream of tartar substitute?—No.

11470. Did not you at one time use it?—Not since Mr. Hammond Smith visited me.

11471. You did use a little previously?—Yes.

11453. I will just quote you a sentence from Mr. Hammond Smith's report. "Similarly with regard to the use of armenia bole and colouring matters of all kinds in meat preparations, I have been informed alike by a colour maker, a colour seller, and a colour user, that it is never the practice of the meat trade to require any guarantee of purity of the colours used, or to have the colours analysed. These colours are frequently procured at shops where sundry butchers' requisites are sold. At these shops the colour is obtained from middlemen without guarantee of purity." Can you give us any information with regard to that?—I should say that the middlemen who supplied them to the butchers would obtain their colours from third parties, who would be careful as to what they sell. I know we sell to several distributors in the meat market to whom we have given a guarantee.

11454. Middlemen?—Distributors, who sell to the middlemen.

11455. And you would give them a guarantee?—Yes.

11472. I believe Mr. Hammond Smith took a sample when he went to your works, and found that it contained some arsenic, did he not?—I gave him a sample of the cream powder when he visited our works, and he told me that he thought it was advisable not to use it, and I discontinued using it.

11473. But you use a considerable percentage, relatively speaking, of glycerine, of glycerine in the materials of which you make your cake—you use 1½ per cent. of glycerine in the materials, do you not?—No, I should say about ¼ lb. to 1 lb., that is what we are using in "medium rich" cakes. For cheaper cakes a slightly larger amount would be taken—1½ lbs. of glycerine to 100 lbs. of mixing. I cannot say what others are using.

11474. Are you satisfied with the precautions which you now take with reference to glycerine?—The guarantee is the only satisfaction we have; they say the glycerine is chemically pure.

11475. Occasionally, you say, you submit these samples to analysis?—Yes.

11476. That is your system as regards the guarantee?—Yes.

11477. Have you any other suggestion to make as to any further guarantee, or are you quite satisfied so far as the conduct of your business is concerned, that there is no danger to the consumer?—I should consider that if there is a percentage of arsenic which is allowed under the present test, it would be advisable to raise the test. If it is not pure enough, I should think the test ought to be raised.

11478. The standard should be raised?—Yes—that is in the interest of those firms who are not in a position to employ chemists of their own. If one employed chemists they would be analysing for impurities all the time.

11479. They would analyse a sample of everything bought in bulk?—Yes.

11480. (Sir William Church.) Do you use colouring matter at all in the manufacture of your goods?—Yes, a little.

11481. In ordering colouring matter, do you use any precautions as to the colours?—They are guaranteed as being absolutely pure under the Sale of Food and Drugs Act.

11482. Do you rely upon the guarantee of the firm which supplies them?—Yes.

11483. Do you chiefly use aniline colours or vegetable colours?—Vegetable colours, but it is very little that we use of them—only a little yellow, except in the case of icing sugar, when there is a little pink colour used in addition.

11484. Do you use turmeric?—No, the egg-yellow takes the place of that really.

11485. Nor cochineal?—No.

11486. In your opinion, the aniline colours, when guaranteed pure, are quite harmless?—The vegetable colours.

11487. You think they are the best?—Yes.

turer.

Mr. A. E.  
Palmer.  
Nov. 1902.

11488. Do you use vegetable colours, saffron?—No, we do not use that. It is egg-yellow, commercially termed. But I understand they are vegetable colours, not anilines.

11489. Is it usual in your trade to use chiefly vegetable colours?—I believe so. They are always advertised and sold at such.

11490. Of course you are not a sweetmeat maker?—No.

11491. Can you tell me anything about the use of baking powders—I suppose you use them a good deal?—We use cream of tartar, carbonate of soda, and a small proportion of tartaric acid in some goods, and carbonate of ammonia.

11492. Do you use phosphate of soda at all—is that mixed with the baking powders?—If you are referring to the substitute for cream of tartar, I have not used that since Mr. Hammond Smith was in Bristol, or soon after then.

11493. But it is used, or was once used?—I believe it is used now. It is advertised in all the trade journals: there are numerous substitutes.

11494. And I suppose in the same way with the baking powders, you rely upon the guarantee of the vendor?—If you are referring to baking powders, we mix our own powders.

11495. Do you take any steps for seeing that the ingredients are pure?—Yes.

11496. The materials that you use for making the baking powder you buy under guarantee in the same way that you do the colouring matters?—Yes.

(Secretary.) I have received a series of letters from Mr. Beach, Secretary of the Maltine Company. I understand the Commission do not wish Mr. Beach to be called at this stage, but that his letters should be printed as an appendix?—(Chairman.) Yes.

Mr. A. E.  
Palmer.  
21 Nov. 1902.

## TWENTY-EIGHTH DAY.

Friday, March 27th, 1903.

AT 1, CHAPEL PLACE.

PRESENT:

The Right Hon. LORD KELVIN IN THE CHAIR.

The Right Hon. Sir WILLIAM HART DYKE.  
Sir WILLIAM CHURCH.

Professor THORPE.  
Dr. WHITELEGGE.

Dr. BUCHANAN, Secretary.

Mr. J. LITHBY, called; and Examined.

Mr.  
J. Lithby.

27 Mar. 1903.

11497. (Chairman.) What is your position at the Local Government Board?—I am assistant secretary, in charge of the Public Health and Local Acts Department.

11498. Are the reports of the public analysts dealt with in your Department?—They are.

11499. What are the duties of the Local Government Board under the Sale of Food and Drugs Acts?—The only express duty of the Local Government Board, prior to the Act of 1899, was under Sections 10 and 19 of the Sale of Food and Drugs Act, 1875. Under Section 10 the appointments of Public Analysts made by the authorities specified in the section are subject to the Board's approval. The Board are empowered to require satisfactory proof of competency to be sent to them, and they may give their approval absolutely, or with modifications, as to the period of the appointment and removal, or otherwise. If local authorities fail to appoint public analysts as required by Section 10, the Local Government Board are empowered to require them to make the necessary appointment. Under Section 19 of the same Act, every analyst is required to report quarterly to the authority appointing him the number of articles analysed by him under the Act, during the foregoing quarter, and to specify the result of such analyses and the sum paid to him in respect thereof. Such report is to be presented at the next meeting of the authority appointing the analyst, and every such authority is required annually to transmit to the Local Government Board, at such time and in such form as the Board shall direct a certified copy of such quarterly report. I hand in a copy of the circular letter issued by the Local Government Board, specifying the form in which the quarterly reports are to be sent to them, together with a specimen form of analysts' quarterly report which the Board have suggested for use by public analysts.

It will be seen that the Board's functions under this Act, are extremely limited. As a matter of fact the reports which the Board receive are tabulated in the Department, communications are addressed to local

authorities who appear not to have adequately carried out the provisions of the Acts, suggestions are made to them from time to time as to what they should do, and remonstrances are addressed to them when they fail to do it. The Board have no compulsory powers in the matter. I may state that the subject of the administration of the Sale of Food and Drugs Acts, so far as the Local Government Board is concerned, was fully explained in the evidence of Mr. Preston Thomas before the select committee of the House of Commons on Food Products Adulteration in 1894—see page 1 of the evidence appended to the report (253 of 1894).

In 1899 an amending Act was passed by which the powers of the Local Government Board were enlarged, and powers were also given to the Board of Agriculture. Section 2 of the Act of 1899 provides as follows:—

(1) The Local Government Board may, in relation to any matter appearing to that Board to affect the general interest of the consumer, and the Board of Agriculture may, in relation to any matter appearing to that Board to affect the general interests of agriculture in the United Kingdom, direct an officer of the Board to procure for analysis samples of any article of food, and thereupon the officer shall have all the powers of procuring samples conferred by the Sale of Food and Drugs Acts, and those Acts shall apply as if the officer were an officer authorised to procure samples under the Sale of Food and Drugs Act, 1875, except that—

(a) The officer procuring the sample shall divide the same into four parts, and shall deal with three of such parts in the manner directed by Section 14 of the Sale of Food and Drugs Act, 1875, as amended by this Act, and shall send the fourth part to the Board, and—

(b) The fee for analysis shall be payable to the analyst by the local authority of the place where the sample is procured.

(2) The Board shall communicate the results of the analysis of any such sample to the local authority, and

Mr.  
J. Lithby.

27 Mar. 1903.

Additional  
powers of  
Local  
Government  
Board under  
Act of 1899.

Duties of  
Local  
Government  
Board under  
Sale of Food  
and Drugs  
Acts.

Extremely  
limited  
before Act  
of 1899.

thereupon there shall be the like duty and power on the part of the local authority to cause proceedings to be taken as if the local authority had caused the analysis to be made.

It will be seen that by this Section the Board are only empowered to act in relation to any matter appearing to them to affect the general interest of the consumer. They can only take samples and obtain analyses of them by the analyst employed by the local authority of the place where the sample is procured, just as the local authority itself could do. Beyond that, however, the Board's duty is limited to communicating the result of the analyses to the local authority, and it then becomes the duty of the local authority to cause proceedings to be taken as if they themselves had caused the analysis to be made.

Under Section 3 of the Act of 1899, if the Local Government Board, after communicating with the local authority, are of opinion that the local authority have failed to execute or enforce any of the provisions of the Sale of Food and Drugs Acts in relation to any article of food, and that their failure affects the general interest of the consumer, the Board may, by order, empower one of their officers to execute and enforce those provisions, or to procure the execution and enforcement thereof in relation to any article of food mentioned in the Order. Under this Section it will be seen that the Board can only act when they are satisfied that there has been default on the part of the local authority, and even then their action is limited to putting the Act in force with regard to the specific articles of food which may appear to the Board to require dealing with.

11500. Have the Local Government Board taken any action under the Act of 1899?—If by that question is meant "whether the Board have themselves directed one of their officers to procure samples," the answer is "No." The Act was passed on the 9th August, 1899; by Section 28 (2) it came into operation on the 1st January, 1900. The Board could have no information as to the working of the Act by local authorities until the reports of 1900 were received by them in January, 1901, and subsequent months. When these reports came to be tabulated it appeared that the total number of samples analysed in 1900 was 62,858, i.e., one to every 461 of the population in 1891, or nearly 19,000 in excess of the number of samples analysed in 1899.

In commenting in their annual Reports on the returns which the Board have received from public analysts, they have on more than one occasion expressed the opinion that at least one sample should be taken for every thousand of the population. This standard has in recent years been more than observed so far as the country generally is concerned, and having regard to the number of samples taken in 1900, it is clear that there was no ground for the intervention of the Local Government Board so far as the country generally was concerned. In their Annual Report for 1900-1 the Board remarked:—"In London one sample was analysed for every 312 persons, and in the provinces one for every 502. The increase is no doubt largely due to the fact that under the provisions of the new Act already referred to local authorities within the meaning of the Sale of Food and Drugs Acts now have a duty specifically passed upon them to carry out and enforce the provisions of the Act. During 1900 many local authorities have for the first time obtained samples for analysis, and many others have largely increased the number taken. We have communicated with the authorities of districts in which the work done under the Acts appears to us to be still insufficient, reminding them of their duty under the Act of 1899, and urging them to exercise the powers entrusted to them by the legislature for the repression of adulteration."

11501. You say that the increase was due to the fact that under the Act of 1899 local authorities now have a duty specifically cast upon them to carry out the provisions of the Sale of Food and Drugs Acts. Had they no such duty prior to 1899?—No. Prior to 1899, local authorities were merely empowered to carry out the provisions of the Acts. By Section 15 of the Act of 1875 it is provided as follows:—"Any medical officer of health, inspector of nuisances, or inspector of weights and measures, or any inspector of a market or any police constable under the direction and at the cost of the local authority appointing such officer, inspector, or constable, or charged with the execution of this Act, may procure any sample of food or drugs, and if he suspect the same to have been sold to him contrary to any provision of the Act, shall submit the same to

analysis," etc. It was within the power of the local authority to direct certain specified officers to take samples, but nowhere were they directly required to do so. By Section 3 of the Act of 1899, however, it is provided that it shall be the duty of every local authority entrusted with the execution of the laws relating to the Sale of Food and Drugs to appoint a public analyst, and put in force from time to time as occasion may arise, the powers with which they are invested, so as to provide proper security for the sale of food and drugs in a pure and genuine condition, and in particular to direct their officers to take samples for analysis.

11502. The statistics for the year 1901 would be received in January, 1902, would they not?—Yes.

11503. How do they compare with previous years?—The facts are set out in page cli. of the Board's Report for 1901-2. The total number of samples analysed in 1901 was 67,841, or nearly 5,000 in excess of the number taken in 1900. Commenting on these figures the Board state as follows:—

"This gives an average of one to every 479 of the population of 1901 for the whole country. In London one sample was analysed for every 291 persons, and in the provinces one for every 536 of the population. This increase, following on the very large increase noted in our last Report, is highly satisfactory. The following table shows that with the increase in the number of samples analysed in successive quinquennial periods there has been a considerable decrease in the rate of adulteration." I need not quote the table perhaps. The Report goes on to say:—"There are still a few districts in which the work done under the Acts is small in amount in comparison with the population, and in these cases we have communicated with the local authority, calling attention to their duty under Section 3 of the Sale of Food and Drugs Act, 1899, and urging them to take steps to carry out the Acts with efficiency in the future." That is all the action which the Board have thought it necessary to take up to the present time.

11504. Have you received the reports for the year 1902?—Most of the reports have now come in, and they are being tabulated at the present time. I am unable to say as yet what number of samples were analysed during the year 1902, or to what extent local authorities who were not carrying out the provisions of the Acts in 1900-1 have improved in this respect in the year 1902.

11505. What is the total number of authorities who appoint public analysts under the Sale of Food and Drugs Act?—According to the Board's report for 1901-2 the number of districts for which the Board had approved the appointment of public analysts was 231. The total number of public analysts in England and Wales at the end of that year was 126.

11506. What details are public analysts required to give in their reports to local authorities?—That is specified generally in Section 19 of the Act of 1875, which I have already quoted. They are to specify the result of each analysis, and the sum paid in respect thereof. The form which I have put in, which was issued by the Local Government Board for the guidance of public analysts, amplifies this a little. In the form the particulars asked for are:—

- (1) The nature of the article submitted for analysis;
- (2) Whether the sample was submitted to the analyst by an officer acting under the direction of a local authority under Section 13 of the Act, and if so, the name of such authority;
- (3) The result of analysis, showing whether the sample was genuine or adulterated, and if adulterated what was the nature and extent of the adulteration;
- (4) The sum paid in respect of the analysis; and
- (5) Observations.

I may add that it is the practice of the Board to enquire in what cases proceedings have been taken for offences against the Acts, and to ascertain where possible the amounts of the fines and costs which are inflicted by the magistrates. As a result of their examination of the figures supplied in regard to proceedings the Board and have communicated with the Home Office, and the Home Office have issued a circular to Justices, drawing their attention to the small fines imposed in many cases and suggesting whether it would not be desirable to increase the amount of fines in cases of a particularly bad kind.

Mr.  
J. Lithiby.  
27 Mar. 1903.

Local authorities now have specific duty of carrying out provisions of Sale of Food and Drugs Acts.

Number of local authorities appointing public analysts.

Terms of public analyst's report.

Local Government Board inquiries as to proceedings and penalties.

Mr.  
J. Lithiby.

27 Mar. 1903.

Samples under Acts must almost always be taken from retailer.

No public authority has general power of inspection or sampling at place where food is prepared.

Acts under which some power of inspection of food manufacture exists:—

11507. It is the fact, is it not, that under the Sale of Food and Drugs Acts a sample can only be purchased from some dealer in the finished product?—Practically that is so. Under the Act of 1879, Section 3, samples of milk might, however, be taken at railway stations, and by Section 14 of the Act of 1899, "The provisions of section three and section four of the Sale of Food and Drugs Act Amendment Act, 1879 (relating to the taking of samples of milk in course of delivery), shall apply to every other article of food. Provided that no samples shall be taken under this section except upon the request or with the consent of the purchaser or consignee."

11508. Has any administrative authority power to enter places where food is prepared, that is to say, food factories, with a view to ascertain whether there is any liability of the introduction of deleterious substances such as arsenic, in the case of particular food products?—Speaking generally, I do not think that any administrative authority has any such power. I do not know to what extent the officers of the Inland Revenue are empowered to enter malt houses with a view of examining malt in the process of manufacture; or stores or warehouses where sugars and sugar substitutes are kept. Certainly the local authorities under the Sale of Food and Drugs Acts have no such powers.

11509. Have the local authorities power to take samples of food ingredients, or of finished foods, at the factory?—I think not. If the factory is a place where the food products produced in it are sold by retail, the inspector of the local authority would be entitled to procure samples of the food for analysis. By Section 17 of the Act of 1875, "If any such officer, inspector or constable as before described shall apply to purchase any article of food or any drug exposed for sale or on sale by retail on any premises or in any shop or stores, and shall tender the price for the quantity which he shall require for the purpose of analysis, not being more than shall be reasonably requisite, and the person exposing the same for sale shall refuse to sell the same to such officer, inspector or constable, such person shall be liable to a penalty not exceeding ten pounds."

A question arose in 1894 as to how far an inspector is entitled when purchasing a sample for analysis to demand to be supplied out of a particular receptacle in the shop. Mr. Justice Bruce, in *Payne v. Hack*, 1894, 58 J.P. 165, said: "Without going so far as to say that an inspector is entitled to go into a shop and demand to have a sample out of any vessel he likes, I think that as he had already been supplied out of a particular bottle he was entitled to have a sample taken from that bottle."

The above section has been held by the Queen's Bench Division in Ireland to apply to wholesale dealers (*McHugh v. McGrath* 1894 2 Ir. R. 71).

By Section 5 of the Act of 1879, any street or open space of public resort comes within the meaning of Section 17 of the Act of 1875 and by Section 18 of the Act of 1899, notwithstanding anything in Section 17 of the Act of 1875, where any article of food is exposed for sale in any unopened tin or packet duly labelled, no person shall be required to sell it, except in the unopened tin or packet in which it is contained.

By Section 16 of the Act of 1899 "any person who wilfully obstructs or impedes any inspector in his duty, under the Sale of Food and Drugs Acts, or by any gratuity, bribe, promise, or other inducement, prevents or attempts to prevent the due execution by such inspector or officer of his duty under those Acts, is liable on summary conviction for the first offence to a fine not exceeding twenty pounds, for the second offence to a fine not exceeding fifty pounds, and for any subsequent offence to a fine not exceeding one hundred pounds."

These are the statutory provisions on the subject; practically they come to this—that the officers of the local authority are only entitled to take samples when they are exposed for sale, or when they are in a shop where people ordinarily go to purchase articles of the kind. The officer is not entitled to enter a factory which is merely used as a factory for the manufacture of food products. I have already drawn attention to the provisions with regard to taking samples in the course of delivery.

11510. What statutes other than the Sale of Food and Drugs Acts are there which empower local authorities to deal with articles of food which are not satisfactory?—There are other Acts which have some bearing on this question. There is the Bread Act of 1822, which relates to the sale of bread in London and its immediate

neighbourhood; and the Bread Act of 1836, which relates to the sale of bread outside the City of London and the liberties thereof, and beyond 10 miles of the Royal Exchange. These Acts contain very stringent provisions with regard to the adulteration of corn, meal, or flour, and the using of mixtures in the manufacture of bread. Section 11 of the Bread Act of 1836 provides as follows:

"It shall be lawful for any magistrate or magistrates, justice, or justices of the peace, within the limits of their respective jurisdictions, and also for any peace officer or officers authorised by warrant under the hand and seal of hands and seals of any such magistrate or magistrates, justice or justices (and which warrant any such magistrate or magistrates, justice or justices, is and are hereby empowered to grant), at reasonable times in the day time, to enter into any house, mill, shop, stall, bakehouse, bolting house, pastry warehouse, outhouse, or ground of or belonging to any miller, mealman, or baker, or other person who shall grind grain, or dress or bolt meal or flour, or make bread for reward or sale, beyond the limits aforesaid, and to search or examine whether any mixture or ingredient (not the genuine produce of the grain such meal or flour shall import or ought to be) shall have been mixed up with or put into any meal or flour in the possession of such miller, mealman, or baker, either in the grinding of any grain at the mill, or in the dressing, bolting, or manufacturing thereof, whereby the purity of any meal or flour is or shall be in anywise adulterated, or whether any mixture or ingredient other than is allowed by this Act shall have been mixed up with or put into any dough or bread of the possession of any such baker or other person, whereby any such dough or bread is or shall be in anywise adulterated, and also to search for any mixture or ingredient which may be intended to be used in or for any such adulteration or mixture; and if on any such search it shall appear that any such meal, flour, dough, or bread so found shall have been so adulterated by the person in whose possession it shall then be or any mixture or ingredient shall be found which shall seem to have been deposited there in order to be used in the adulteration of meal, flour, or bread, then and in every such case it shall be lawful for every such magistrate or magistrates, justice or justices of the peace, or officer or officers authorised as aforesaid respectively, within the limits of their respective jurisdictions, to seize and take any meal, flour, dough, or bread which shall be found in any such search, and deemed to have been adulterated, and all ingredients and mixtures which shall be found and deemed to have been used, or intended to be used, in or for any such adulteration as aforesaid; and such part thereof as shall be seized by any peace officer or officers authorised as aforesaid shall, with all convenient speed after seizure, be carried to the nearest resident magistrate or magistrates, justice or justices of the peace, within the limits of whose jurisdiction the same shall have been so seized; and if any magistrate or magistrates, justice or justices, who shall make any such seizure in pursuance of this Act, or to whom anything so seized under the authority of this Act shall be brought, shall adjudge that any such meal, flour, dough, or bread so seized shall have been adulterated by any mixture or ingredient put therein other than is allowed by this Act, or shall adjudge that any ingredient or mixture so found as aforesaid shall have been deposited or kept where so found for the purpose of adulterating meal, flour, or bread, then and in any such case every such magistrate or magistrates, justice or justices of the peace, is and are hereby required, within the limits of their respective jurisdictions, to dispose of the same as he or they, in his or their discretion, shall from time to time think proper."

Section 12 of the same Act imposes a heavy penalty if ingredients for the adulteration of meal or bread are found in any premises. It will be seen that this section gives special powers of searching the premises of millers, bakers, etc. I do not think that either the Act of 1822 or that of 1836 is much used. In the evidence taken in 1874 by the Select Committee on the Adulteration of Food Act, 1872, the Chairman of the Master Bakers' Protection Society was examined, and he stated (Q. 3864) that the Act was not then carried into force. I believe that is practically so now.

In the Customs and Inland Revenue Act, 1885, Section 8, there is a prohibition against the adulteration of Acts, beer by brewers for sale and dealers and retailers of beer. A local authority, however, would have no power to enforce the provisions of that section.

Under the Margarine Act every manufacturer of Margarine margarine within the United Kingdom of Great Britain Act, and Ireland is required to be registered by the local authority from time to time.

Section 10 of the Act provides as follows:—"Any officer authorised to take samples under the Sale of Food and Drugs Act, 1875, may, without going through the form of purchase provided by that Act but otherwise acting in all respects in accordance with the provisions of the existing Act as to dealing with samples, take for the purposes of analysis samples of any butter or any substitutes purporting to be butter which are exposed for sale, and are not marked margarine as provided by this Act, and any such substances not so marked shall be deemed to be exposed for sale as butter."

Under the sale of Horseflesh, etc., Regulation Act, 1889, Section 1, no person shall sell, offer, expose, or keep for sale any horseflesh for human food other than in a shop, stall or place over which there shall be at all times painted, posted, or placed in legible characters of specified length, during which such horseflesh is being offered or exposed for sale, a notice indicating that horseflesh is sold there. And under Section 3 "any medical officer of health, or inspector of nuisances, or other officer

Mr.

r. 1903.

of the local authority acting on the instruction of such authority, or appointed by such authority for the purposes of this Act, may at all reasonable times inspect or examine any meat which he has reason to believe to be horseflesh exposed for sale or deposited for the purposes of sale or of preparation for sale, and intended for human food in any place other than such shop, stall, or place as aforesaid, and if such meat appears to him to be horseflesh he may seize and carry away or cause to be seized and carried away the same in order to have the same dealt with by a Justice as provided in the Act.

mana-  
f food  
Public  
h Acts.

By Section 116 of the Public Health Act, 1875, any medical officer of health or inspector of nuisances may at all reasonable times inspect and examine any animal, carcase, meat, poultry, game, flesh, fish, fruit, vegetables, corn, bread, flour, or milk exposed for sale or deposited in any place for the purpose of sale or of preparation for sale, and intended for the food of man, the proof that the same was not exposed or deposited for any such purpose or was not intended for the food of man resting with the party charged, and if any such animal etc., etc., appears . . . . . to be diseased or unsound or unwholesome or unfit for the food of man, he may seize and carry away the same himself, or by an assistant, in order to have the same dealt with by a Justice. Section 117 gives power to the Justice to order the destruction of unsound meat, etc. Section 118 imposes a penalty for hindering the officer from inspecting meat, etc. Section 119 provides that on complaint made on oath by a medical officer of health or by an inspector of nuisances or other officer of a local authority any Justice may grant a warrant to any such officer to enter any building or part of a building in which such officer has reason for believing that there is kept or concealed any animal, carcase, meat, poultry, game, flesh, fish, fruit, vegetables, corn, bread, flour, or milk, which is intended for sale for the food of man, and is diseased, unsound, or unwholesome, or unfit for the food of man, and to search for, seize, and carry away any such animal or other article in order to have the same dealt with by a Justice under the provisions of this Act. The section also provides a penalty upon any person who obstructs any such officer in the performance of his duty under the warrant. It will be observed that under this section there is no penalty imposed for the mere concealment of the article. In order to render the party liable to penalty there must have been an exposure for sale or some such act as is made an offence by one of the previous sections.

Section 28 of the Public Health Acts Amendment Act, 1890, enacts as follows:—

(1) "Sections 116 to 119 of the Public Health Act, 1875 (relating to unsound meat) shall extend and apply to all articles intended for the food of man, sold or exposed for sale or deposited in any place for the purposes of sale or of preparation for sale within the district of any local authority."

(2) "A Justice may condemn any such article, and order it to be destroyed or disposed of as mentioned in Section 117 of the Public Health Act, 1875, if satisfied on complaint being made to him that such meat is diseased, unsound, unwholesome, or unfit for the food of man, although the same has not been seized as mentioned in Section 116 of the said Act." Corresponding provisions relating to London are contained in the London Public Health Act, 1891.

Under an old Act of 1776 relating to the adulteration of tea, an officer of Excise may obtain from justices special warrants for entering tea warehouses on proof on oath that he suspects that false leaves are there used for adulterating tea.

ets.

Provisions relating to the sale of food are contained in some local Acts. Thus, in the York Corporation Act, 1902, Section 64 enacts as follows:—

"Sections 116-118 of the Public Health Act 1875, as amended by Sec. 28 of the Public Health Acts Amendment Act, 1890, shall extend to authorise the inspection, examination, and search of any part or other vehicle or of any basket, sack, bag or parcel, whether open or closed, and the provisions of such sections shall apply accordingly."

Section 59 of the same Act provides as follows:—

(1) "Any person being a manufacturer of or merchant or dealer in ice cream or other similar commodity within the city who

(a) causes or permits ice cream or any similar commodity to be manufactured, sold, or stored, in any cellar or room in which there is an inlet or opening to a drain; or

(b) in the manufacture, sale, or storage of any such commodity does any act or anything likely to expose such commodity to infection or contamination or omits to take any proper precaution for the due protection of such commodity from infection or contamination; or

(c) omits on the outbreak of any infectious disease amongst persons employed in his business to give notice thereof to the medical officer;

4576.

shall be liable for every such offence to a penalty not exceeding forty shillings.

(2) In the event of any inmate of any building (any part of which is used for manufacture of ice cream or similar commodity) suffering from any infectious disease, the medical officer may seize and destroy all ice cream or similar commodity or materials for the manufacture of the same in such building, and the Corporation shall compensate the owner of the ice cream, commodity, or materials so destroyed."

This section relating to ice cream is contained in many local Acts in one form or another. Special powers of the kind are possessed by Liverpool, Manchester, Salford, Stockport, Halifax, Leamington, York, among other places.

11511. To what extent is it at present the practice of administrative authorities to seek and obtain information as to food products (including those of foreign origin), which through the process of manufacture are liable to contain deleterious substances such as arsenic, and which in consequence call for measures of precaution in the interests of public health?—I am afraid that I cannot give any exhaustive answer to this question. So far as the information in the possession of the Board goes, it would appear that local authorities confine themselves to procuring samples of such foods and drugs as are on sale in their districts, and do not trouble themselves with considerations as to how such articles are manufactured. I have already dealt with the question of the manufacture of ice cream; many towns have taken power to deal with this manufacture. Several Town Councils, e.g., Liverpool, Manchester, and Cardiff, have taken special steps to ascertain the quality of milk sold in their district by arranging for systematic bacteriological examination of the supply with a view of discovering tuberculous cows that may be supplying milk to their respective districts. In Liverpool also, bacteriological examinations have been made of various other articles of food, such as tinned meat, shell fish, etc.

11512. Has any authority power to condemn food products when at the factory and before consignment to the retailer, if it can show that such food products are liable to be deleterious to health?—Subject to what I have said above, I am not aware that any authority has any such power.

11513. To what extent has it been the practice of the Local Government Board to direct or advise local authorities under the Sale of Food and Drugs Act to take action regarding particular food products which it appears desirable to watch, either on account of special liability to fraudulent adulteration; or on account of liability to be contaminated by deleterious substances, for instance, arsenic?—On the occurrence of the arsenical beer poisoning epidemic the Board issued a circular (11th December, 1900), urging Councils of counties, boroughs, urban and rural districts to take for analysis samples of beer and other foods into whose composition glucose and other sugar substitutes entered. As a result thousands of samples were procured at the instance of local authorities, and examined by public analysts. I do not know whether a copy of that circular has been put in; I put in a copy now.

(The Circular was handed in.)

The Board have in their annual reports from time to time called attention to the prevalence of particular forms of adulteration which have been brought to their notice in the reports of public analysts. Copies of the Board's reports are sent to all sanitary authorities. It is also the practice to send to public analysts themselves that portion of the Board's annual report which relates especially to them and to their duties. As illustrating this practice I draw attention to the following Reports:—

1879-80, p. cxiii, under the heading of "Bread Making," the Board drew attention to a report which they had received from the chemists of the Inland Revenue Department, from which there seemed to be no doubt that some descriptions of flour especially that made from Egyptian wheat, contained appreciable quantities of clay, which could not be separated by the miller. It was pointed out with reference to this report that such tests should be used as would determine whether the alumina be present in an insoluble condition as it would be if derived from earthy matter, or in a soluble form, as it would be if existing as alum. In their report for 1880-1 the Board drew attention to the fact that in some so-called "unfermented wines" sold as temperance drinks, which profess to be composed of pure grape juice, were really mixtures of tartaric or salicylic acids, sugar, and flavouring matter. Some of these also contain a dangerous amount of copper, due probably to the manufacture having been carried on in vessels of which the acids had dissolved part of the metal.

In the Report for 1886-7 attention was drawn to a trade which had recently sprung up in the sale of "Poivrete," or "Pepperette," a substance which was made in Italy by grinding olive stones, and was sold in this country at about 1d. a pound, whereas the price of the pepper with which it was mixed was from 3d. to 1s. 6d. a pound.

In the Report for 1889-90 attention was drawn to a statement in the report of the public analyst for the parish of St. George, Hanover Square, to the effect that as there was no legal definition as to

the composition of sweets, the examination of them under the Act was confined to the search for poisonous colouring matters and flavouring materials, and for insoluble and indigestible constituents such as plaster of Paris and paraffin wax.

In the report for 1892-3 attention was called to a report made by public analysts for the West Riding of Yorkshire and Cheshire, to the effect that at that time a systematic attempt was being made to place on the English market imported butter containing an excess of water, and in some instances sophisticated with a small proportion of margarine difficult to detect and liable to escape recognition unless the butter be subjected to a very special examination. In the same Report, attention was drawn to the experience of the analyst for Cheshire with regard to the dyeing of sugar in order to make beet sugar pass as Demerara. The sugar was found to be dyed with what is called "Nicholson's blue," which is Triphenyl rosaniline sulphonic acid. In the same report, it was further pointed out that an imitation of lard which had recently been placed on the market under the name of "Lardine" had been found by the public analyst for Lancashire, to be made up either of beef fat or of the hard fat which remains when oleo-margarine is pressed out of beef fat. It was softened down by the addition of cottonseed or other cheap oil mixed with some preparation of hog fat, and prepared for market.

These are samples of the way in which the Board have utilised the experience which they have gained from the tabulation of the reports of public analysts. No duty of supplying this information has been imposed upon them. So far as I know, no information has been given to the Board with regard to the prevalence in food stuffs of such deleterious substances as arsenic prior to the occurrence of the epidemic of arsenic poisoning which is being enquired into by this Commission.

No organised system to guide local authorities in application of Sale of Food and Drugs Acts.

11514. Is there any machinery available for guiding local authorities under the Sale of Food and Drugs Acts as to the nature of samples which should be taken, and as to the character of the adulteration or contamination to be looked for? For example, is it a recognised duty of the public analyst or of medical officers of health to give advice of this kind?—I do not think there is any organised machinery of the kind referred to. The official publications of the Society of Public Analysts are full of learning connected with the profession of public analyst, and these organs have from time to time called attention to the introduction of new forms of adulteration. Public analysts are therefore in a position to learn from the experience of one another, and I take it that in the performance of their duties they do frequently advise the inspectors appointed to collect samples as to the samples which the inspector should procure. I cannot say whether analysts as a rule advise their inspectors in this way, I only know that some analysts do it. The Sale of Food and Drugs Acts do not impose upon public analysts or upon Medical Officers of Health the duty of giving such advice to the local authorities employing them. As regards Medical Officers of Health the Board's General Order of March 23rd, 1891, requires the Medical Officer of Health to inform himself as far as practicable respecting all influences affecting or threatening to affect injuriously the public health within his district, and to enquire into and ascertain by such means as are at his disposal the causes, origin, and distribution of disease in his district, and ascertain to what extent the same have depended on conditions capable of removal or mitigation; and he must be prepared to advise his authority on all these matters (Article 18 (1) (2) (4)). Hence in the event of there occurring any adulteration or impurity or contamination of some particular article of food prejudicially affecting the health of the district, it would be his duty to act under the regulations. The regulations also provide that subject to the instructions of the sanitary authority the Medical Officer of Health shall direct or superintend the work of the inspector of nuisances in the way and to the extent that the sanitary authority shall approve. Sub-Section 8, Article 18 (Duties) provides:

In any case in which it may appear to him to be necessary or advisable, or in which he shall be so directed by the Sanitary Authority, he shall himself inspect and examine any animal, carcass, meat, poultry, game, flesh, fish, fruit, vegetables, corn, bread, flour, or milk, and any other article to which the provisions of The Public Health Act, 1875, in this behalf apply, exposed for sale or deposited for the purpose of sale or of preparation for sale, and intended for the food of man, which is deemed to be diseased, or unsound, or unwholesome, or unfit for the food of man; and if he finds that such animal or article is diseased, or unsound, or unwholesome, or unfit for the food of man, he shall give such directions as may be necessary for causing the same to be dealt with by a Justice according to the provisions of the Statutes applicable to the case.\*

It is the duty of the Inspector of Nuisances under the

regulations relating to his work to procure and submit samples of food, drink, or drugs suspected to be adulterated. The regulation is in these terms:

"He shall from time to time, and forthwith upon complaint, visit and inspect the shops and places kept or used for the preparation or sale of butchers' meat, poultry, fish, fruit, vegetables, corn, bread, flour, milk, or any other article to which the provisions of the Public Health Act, 1875, in this behalf shall apply, and examine any animal, carcass, meat, poultry, game, flesh, fish, fruit, vegetables, corn, bread, flour, milk, or other article as aforesaid, which may be therein; and in case any such article appear to him to be intended for the food of man, and to be unfit for such food, he shall cause the same to be seized, and take such other proceedings as may be necessary in order to have the same dealt with by a Justice: Provided that in any case of doubt arising under this clause, he shall report the matter to the Medical Officer of Health, with the view of obtaining his advice thereon."

"He shall, when and as directed by the Sanitary Authority, procure and submit samples of food, drink or drugs suspected to be adulterated, to be analysed by the analyst appointed under the Sale of Food and Drugs Act 1875, and upon receiving a certificate stating that the articles of food, drink, or drugs are adulterated, cause a complaint to be made, and take the other proceedings prescribed by that Act."†

The Medical Officer of Health might thus be required by his local authority to direct the Inspector of Nuisances as to the nature of the samples to be procured by him for analysis.

Many county medical officers and many medical officers of districts as well as public analysts appear to give advice as to the nature of the samples which it is desirable should be procured for analysis. We know from the reports of Medical Officers of Health that before the Board's circular † suggesting that course was issued, many of them advised the taking of samples of various articles likely to contain arsenic.

11515. It would appear from the answer that you have given to the last question that it is not the express duty of anyone, except perhaps the Medical Officers of Health, to investigate the processes of manufacture of food products with a view to discover whether there is risk of introduction of poisonous or deleterious ingredients before the same is exposed for sale?—Except perhaps, the Medical Officers of Health, so far as I am aware that duty has not been imposed upon any person by law.

11516. Has your attention been called to the recommendation of the Departmental Committee on Food Preservatives and Colouring Matters respecting the appointment of a Court of Reference?—I have read the Report of that Committee, and I am familiar with their recommendations.

Suggested  
Court of  
Reference.

11517. Would it be practicable to prepare and publish a schedule of the preservatives or colouring matters which, after the necessary inquiry and experiment, might be regarded as likely to prove dangerous to the public health?—I think it would be possible to a certain extent, if a Court or Reference were established to settle precisely what preservatives are to be regarded as injurious and in what amounts, if any, they might be permitted to be used. The question, however, is a very difficult one. Who is to appoint the Court of Reference? What kind of body is it to be? Is it to be permanent or temporary? Are its decisions to be subject to appeal or not? These, and many other similar questions suggest themselves. Under the Sale of Food and Drugs Acts a sort of court of chemical appeal exists, consisting of the experienced chemists employed at the Government Laboratory. Attacks upon their decisions frequently have been made by other analysts of repute, their methods have been criticised, their decisions have been disputed, their knowledge has been impugned. No doubt this will all happen with regard to a Court of Reference such as was recommended by the Select Committee on Food Products Adulteration, and by the Departmental Committee on Food Preservatives. One difficulty in setting up such a Committee is to find a small number of men (and I take it the Committee must be small if it is to be effective) who will be competent to express on a variety of different questions opinions which will satisfy the scientific world generally. No doubt such a Committee, if it could be constructed,

\* Corresponding provisions to these are contained in the Board's General Order relating to London. That is a separate Order, but it practically contains, so far as this matter is concerned, the same provisions.

† 11 December, 1900.

Mr.  
J. Lithiby.

27 Mar. 1903.

would be of material service in setting at rest some of the vexed questions which are constantly arising in the administration of the Sale of Food and Drugs Acts. Whether such a Court will or will not be set up is a matter upon which I cannot now say more than this—that the question is under the consideration of the Local Government Board.

11518. Putting aside now the question of the appointment of a Court of Reference, can you say whether any administrative authority has at the present time power to prohibit particular processes of food manufacture; for example, kilning malt with gas coke or the use of particular ingredients in food, such as arsenical sulphuric acid?—No authority, as far as I am aware, has any such power. It is to be remembered, however, that in manufacturing food, as in manufacturing other articles of commerce, the manufacturer is responsible for the article he produces. Speaking generally, it is a rule of the common law that every dealer in provisions impliedly warrants them to be wholesome and fit for food. It was laid down as long ago as the reign of King Henry VI.—“If I come to a tavern to eat and drink and the taverner gives me meat and drink corrupted whereby I am made sick, an action lies against him without any express warranty because it is a warranty in law.” (Year Book 9, Henry VI, p. 53.)

There are, no doubt, limitations to a rule of this kind. Thus, even a vendor of food is not ordinarily liable for selling meat with a latent taint of which he was ignorant, and which he had no means of knowing, unless he gives a warrant that the meat is fit for human food.

11519. Would it be practicable to issue official memoranda or instructions to local authorities as to particular food products which through process of manufacture are liable to contain deleterious substances? What steps could be taken, for example, if it was decided to be necessary to protect the public against risk from arsenic to foods consisting largely of yeast?—It would be possible to take the same action in regard to any such matter as was taken by the Local Government Board in its circular of the 11th December, 1900; that is to say, it would be possible to warn local authorities that a certain dangerous ingredient had been found in a specific article of food, and to suggest to the authority that instructions should be given to its food inspector to procure samples of food of the kind in question, in order that the same might be submitted for examination to the public analyst. The difficulty in taking action of this kind in any case arises from the absence of knowledge on which to base the action. The Local Government Board have no staff whom they can employ in a roving enquiry to ascertain when any new element of danger may appear in an article of food. It would be altogether impracticable to enact, for instance, that no new article of food should be placed upon the market until its composition had been determined to the satisfaction of a Government Department. There must be some latitude to cooks and confectioners and other manufacturers of foods, artificial and otherwise, so as to enable them to prepare their respective goods for the market. You cannot give them a certificate of approval at the outset. You must, I think, be content with the responsibility that by law rests upon them of supplying a wholesome article. You might make their responsibility an absolute responsibility perhaps, though I think there would be difficulty in passing a proposal with that object through Parliament. I mean that it would be difficult to enact that the vendor of an article of food should be responsible for its wholesomeness if he did not know that it was unwholesome, and could not have ascertained that it was unwholesome by any reasonable action on his part. Parliament could, if it thought fit however, impose a liability on purveyors of food even to that extent. My suggestion is, that it would be unlikely or unwilling to do so.

11520. You have said in a previous answer “There are no doubt limitations to a rule of this kind. Thus even a vendor of food is not ordinarily liable for selling meat with a latent taint of which he was ignorant, and of which he had no means of knowing unless he gives a warranty that the meat is fit for human food.” Does that mean unless he gives a special warrant?—That is so.

11521. Does not the fact of him offering it for food imply that it is fit for food?—There was an actual decision of the Court. The facts which I have given came before the High Court, and they decided that on those facts the vendor was not liable unless he gave an express warranty, the reason being, I suppose, that

knowledge on his part could not be presumed. Of course, if it could be shown that the man knew that there was this taint, he would be liable, and if he could by the exercise of any reasonable action have discovered the taint, probably he would also be liable.

11522. That seems to mitigate somewhat the severity of the law in Henry VI.'s time, by which if the keeper of a tavern offers an article for food, and a person is made sick by it, the keeper of the tavern is responsible?—Yes, I think perhaps it does.

11523. There was a very bad case a few years ago, where people died from something they ate at a first-class London hotel?—Yes, there were several cases of illness among people staying at that hotel.

11524. Is the responsible head of the hotel not responsible for such a casualty, for such a disaster, as that?—That is a very difficult question to answer. You have two decisions given in the same book pointing in different directions. The answer would depend upon the facts of the particular case.

11525. (Professor Thorpe.) Did not an action arise out of this particular case at the hotel?—I believe there was an action.

11526. What was the result of that action?—As far as I know it is not reported.

11527. (Sir William Church.) Has there been any legal decision with regard to the poisoning caused through eating pies this year at Derby?—As far as I know, not by the High Court. Whether there has been any decision in any other Court I do not know. Of course an action would lie in the County Court.

11528. (Professor Thorpe.) There are a number of cases in which actions have been brought against the proprietors of restaurants by various people who stated they had been made ill by the food they had eaten at restaurants. The people have claimed their doctor's fees, and some compensation?—Whatever may be the result of cases of that kind, no action can be brought by a local authority in such cases. That would be only an action at Common Law for damages sustained by the person immediately injured. No action could be taken by a local authority with a view to prevent the sale of any such deleterious ingredient as may have been found in the substances complained of at a restaurant in those circumstances.

11529. Your point is, that it is a mere process of the civil law and civil recovery?—Yes, it is a civil remedy, and therefore it is inapplicable to the circumstances which the Commission have to consider.

11530. (Sir William Hart Dyke.) With regard to the general policy that has governed all these Food and Drugs Acts, it appears that Parliament has invariably shirked the main question of trying to strike at the root of these dangers from poisoning or from adulteration by not applying some efforts to detect deleterious substances before the finished article was presented to the customer?—Except to the extent that I have quoted from Statute Law, that is so.

11530\* Taking all these Food and Drugs Acts, they have all ended, have they not, in sampling?—Yes, sampling from goods exposed for sale or deposited for the purpose of sale.

11531. And therefore in many cases it may happen that the attention either of yourselves at the Local Government Board or the local authority is first drawn to the mischief that is going on by someone suffering severely through being poisoned, for instance, in what has been called the Manchester scare?—That is so.

11531\* You have been for many years at the Local Government Board, have you not?—Yes.

11532. How many years?—30 years.

11533. You have had a very practical experience with regard to all these matters, and have been serving a Department which has its eye on these dangers and difficulties. Speaking from your own personal experience, can you give the Commission any hint as to whether it would be safe to extend the provisions of the Sale of Food and Drugs Act further; for instance, with regard to giving powers to the officers of local authorities, whether representing the Board of Health or otherwise, to enter the manufactories, in fact, to examine articles which are about to be utilised for the purpose of food and drink?—I think there would be great difficulty in getting Parliament to consent to such powers. Parliament is jealous of giving a right of entry into private premises, where an Englishman is said to be in his

castle. If a man is selling anything, and the public have a right to go into his premises to buy, there is good ground for giving to an inspector the right of going in, and of demanding to purchase commodities which are there sold: but to give power to an inspector to go into what may be a private house for that purpose would be going further than Parliament has hitherto done. Then, if such powers were given, it is very difficult to see how they can be worked. Supposing the local inspector of food had a right to go into my house and enquire whether I was manufacturing any article of food for sale, is he to have a right of searching through my house? Is he to have a right of examining every food stuff or ingredient that may be manufactured into food, and if so, is he to take anything that he chooses, whether it is for sale or not, whether it is there for experiment or not? Is he to seize and take away anything and examine it? And supposing he takes it away and examines it, and ascertains that any particular ingredient is of a poisonous nature, how is he to be able to say that that was going to be used for food? Is he to charge me, the manufacturer of a food stuff, with an offence because I have on my premises an article which, if used for food, might be dangerous to a person consuming that food? I suggest these points as points of difficulty which would be found to arise if Parliament were to give power to enter and examine any ingredients that may happen to be found in a private house. With regard to those cases which I have quoted, take for instance, margarine, a more extended power is given to inspectors. Margarine is a substance that has been fraudulently sold for butter, and, in giving a vendor power to sell margarine in a condition which the ordinary public might not distinguish from butter, Parliament has accompanied that gift by the condition that the vendor shall be subject to somewhat extended powers of examination by the food inspector.

11534. There are special circumstances in regard to margarine, and its connection with butter, which enable Parliament to deal more stringently in that case than they generally do in regard to other manufactures?—That is so. I think that also applies to the case of the sale of horse-flesh. Horse-flesh has been fraudulently sold as ordinary meat; and in licensing houses where horse-flesh may be sold, the local authority may give that licence subject to certain conditions. There again, there are special circumstances which have enabled Parliament to give extended powers of entry and search which do not apply, I submit, in the case of ordinary food ingredients.

11535. Of course it is merely common sense to say that it is to the interest of the trader in every case to poison his customers as little as possible, but even if that is so, there must be danger, must there not? For instance, take the case of the manufacture of glucose, the terrible results of which were the cause of the forming of this Commission; and there must be other cases where carelessness of a gross nature, such as that, has resulted in great loss of life?—Yes.

11536. You agree, do you not, that some means ought to be devised, if possible, to prevent such a thing happening again?—I agree that it is desirable to apply a remedy, if a remedy can be found which is not worse than the offence.

11537. Will you tell us a little more with regard to the position that you, as the Central Department of the State, occupy with regard to the local authorities, not so much on the general health question, but more especially with regard to the taking of samples, which appears to be the chief and leading protection to the British public. You have referred to cases, have you not, where you analysed certain samples, and then sent the results of your labours to the local authorities. In what kind of case does that arise? Is it customary, when you find there is neglect on the part of the local authorities, for you to step in, or what is the precise relationship in that regard between yourselves and the local authorities?—The Board have no power to analyse samples themselves, and have never done so. We have no chemical officers working under the Sale of Food and Drugs Acts. We only get our knowledge from the reports that are sent to us under Section 19 of the Act of 1875. When we find in those reports any indication that may apparently be useful to public analysts generally, that is mentioned in the annual Report which the Board makes to Parliament, copies of which are sent to the local authorities. As I have already said, until the Act of 1899 was passed, the Board's position in the matter was a very small one. The Board had no powers whatever. The Act said that copies of certain

quarterly reports were to be sent to them. That was done, but there was nothing in any Act requiring the Board to take any action. These reports were originally received and tabulated, I think, in the year 1877, and from that time down to the present they have been tabulated, carefully examined, and letters have been frequently written to local authorities charged with the administration of the Acts. It has been pointed out to them that they should do more if they did not do enough, and generally the Board have done as much as they possibly could by exhortation, to get local authorities to put in force these Acts.

11538. This stimulating process goes on from headquarters as regards the local authorities, upon reports received by you?—Yes, that is so.

11539. And if you find there is anything like slackness, you put pressure on, so as to secure better local administration?—Yes.

11540. After this calamity from beer poisoning, you took steps, did you not, to procure something like a wholesale analysis?—Yes, we had the power given to us under the Act of 1899.

11541. You took advantage of that power?—We took advantage of that power to issue the circular which I have put in, asking local authorities to cause samples to be examined of the various ingredients in which arsenic might possibly be contained. Of course it is practicable to do that in any other similar case; the difficulty arises in knowing where to begin, or in what particular case such action is necessary.

11542. Mention has been made with regard to the report of this Committee on Food Products Adulteration, and to the recommendation of a specially constituted scientific body as a Court of Reference. In regard to that matter I should like you to give the Commission your views with reference to either the establishment of a Board of Reference such as that, or of some small expert Sub-Department of the Local Government Board?—I have said in my evidence in chief that I think it would be practicable to appoint such a Committee. There are many difficulties in the way, and when the question arose in the House of Commons during the passing of the Bill for the Sale of Food and Drugs Act, 1899, a motion was made by Sir Charles Cameron to insert a particular clause. That particular clause was opposed by Mr. Walter Long, who was then President of the Board of Agriculture, for certain reasons that he gave. That being so, I, as an officer of the Local Government Board, have some hesitation in expressing any view as to the establishment of a Court of Reference.

11543. But surely if Parliament is in difficulty with regard to the protection of the public in such a case as that which has occurred with regard to the wholesale beer poisoning—if Parliament can go no further than this process of sampling which now goes on; if Parliament is unable to suggest a further remedy—does not common-sense rather indicate that a kind of sub-committee of experts connected with a Board such as yours, watching any symptom of danger, carefully examining all reports that may be received—that a body like that, although Parliament has not given extended powers, might yet give an early note of warning in such a case as that which has occurred, which might have the effect of saving life, misery, and disaster?—If I may give my personal view in the matter, I think that the establishment of a Court of Reference such as was suggested might effect the end which the Commission have in view. It would be useful to ascertain from time to time when new chemical substances are employed as ingredients or as colouring matters, or as preservatives for food, whether there is likely to be any harm in the use of any such substance. If the question could be referred to a competent committee of experts, it would be practicable for something to be done to protect the public against the use of any such injurious ingredients. But one difficulty, if you have such a committee as was suggested by Sir Charles Cameron—I am speaking from memory—is this, that the committee would be irresponsible, and I doubt whether Parliament would agree to give to an irresponsible committee powers, practically legislative powers, which would enable the committee to say in regard to any particular article, "That article shall not be used in the composition of food." That power might, however, be given to a Government Department, because the chief of the Government Department would be responsible to Parliament, and any order that he might make in the matter would be subject to review in Parliament. The

Court of  
Reference

Relation of  
Local  
Government  
Board to  
administra-  
tion of Sale  
of Food and  
Drugs Acts.

Local Government Board have no officers who could do this, and it would be better, I should think, to suggest that a separate committee should report to the Local Government Board on the subject than that the Committee should make any order themselves. If, therefore, a Court of Reference were set up, with powers to examine any food ingredient that might be referred to them—we will say by the Board of Agriculture, or by the Board of Trade, or by the Local Government Board,—if powers were given to them to report on that article to the Government Department concerned, and that department were empowered to make an order on the subject, I think this would help to remedy the grievances which at present exist.

11544. You think that this body should have statutory powers, do you not? That is to say, it should be able to communicate at once to the local authorities where any mischief might be going on, in a factory or in other places, through the sale of any article manufactured in a particular way?—No, I should not suggest that they should have statutory powers.

11545. I am afraid I misunderstood you, then?—I suggest that they should report to a Government Department. The action which you suggest would be an administrative action. They should be merely a scientific body, declaring whether or not a specific article referred to them for report is or is not a dangerous ingredient. Assuming that that report were made to the Local Government Board, my suggestion is, that the Local Government Board would have the administrative power necessary to warn local authorities, and through them public analysts, as to the possibility that such an article might be used.

11546. I am glad you have made that clear. As far as the statutory power is concerned, that, of course, should be Departmental, should it not?—I think so.

11547. (Sir William Church.) There are one or two points I should like to refer to, which I did not quite follow. In answer to a question stating that it was not the express duty of anyone to investigate processes of manufacture of food products with a view to discover whether there is risk of introduction of poisonous or deleterious ingredients before the same is exposed for sale, you replied, "So far as I am aware that duty has not been imposed upon any person by law," and then you said, "Unless it came within the province of the Medical Officer of Health?"—The Medical Officer of Health's duty is what I read from the General Order relating to Medical Officers of Health. It is the duty of a Medical Officer of Health "To inform himself as far as practicable respecting all influences affecting or threatening to affect injuriously the public health within the district. He shall inquire into, and ascertain by such means as are at his disposal, the causes, origin, and distribution of diseases within the district, and ascertain to what extent the same may have depended on conditions capable of removal or mitigation." It may possibly be argued that in an instance like the beer poisoning cases in the North, it was the duty of the Medical Officer of Health, knowing that a death had occurred in some mysterious way, and that other similar deaths had followed it, to have investigated the causes and origin of the diseases which led to those deaths.

11548. That leads me to this: Supposing a Medical Officer of Health came to a conclusion, right or wrong, that certain cases of illness, we will say among children, arose from their consuming sweets made by a certain person: am I to understand from you that you think he would have the right of entry upon the premises to see what was going on on the premises where those sweets were made?—No; I am quite clear that he would not have any such right. I do not think, myself, it is the duty, in such a case as that, of the Medical Officer of Health under this Order to go to that extent.

11549. Supposing he went to his sanitary authority, would that sanitary authority have power to order their Inspector to go to those premises?—No. The only thing they could do would be to order their Inspector to take samples of those sweets at shops where those sweets were sold.

11550. That leads me to another point that I should like some information on. Supposing a person manufactures a food product of any sort or kind, sausages or patent meal, or whatever it may be, and sets up machinery for doing so in his own house; that machinery is inspected, and he is liable to see that it is properly guarded?—That is under the Factory Acts.

11551. But is not that a case where a man's castle is

invaded?—Yes, for the purpose of seeing that the worker is properly protected in the course of his work, but that is not intended to protect the public at all.

11552. Although there is no existing machinery now for seeing that the buyer is properly protected, do not you think that that is an analogous case? There would be no hardship in premises being inspected to see that the buyer was not prejudicially affected as well as the worker?—I submit that there is a difference in principle between an enactment authorising the inspection of premises to see that machinery on those premises may be safely used by factory workers, and one authorising the inspection of premises where food stuffs are manufactured with the object of taking away for analysis ingredients that may be found on the premises. In the latter case the object of the inspection is not to protect the workers but to protect the public.

11553. No doubt; but I do not see that there would be a greater infringement of the rights of the individual?—It is for the Commission to judge. My own view is that there is a difference between a case where machinery is used—dangerous machinery be it presumed—and a case where a man carries on, say, the making of bread without machinery in a private house.

11554. At the present moment, apparently, the law has never been repealed which applies to millers and bakers?—That is so.

11555. Therefore it would only be an extension of that to the premises of people who manufacture food products, of any sort?—That is so, and it was expressly because there was to that extent a precedent that I quoted the case to the Commission.

11556. Therefore, if you think there is this difficulty in obtaining the materials of which food products are made in the premises, you would also object to their being stopped on transit to those premises?—It is not that I should object.

11557. You think there would be difficulties in stopping them in transit to the premises?—I think the principles by which Parliament is usually guided in this case would apply. Parliament, so far as my observation of legislation is concerned, is very jealous of increasing the power of any local authority to enter private premises. One sees that in legislation generally.

11558. I think I understood you to say that milk in transit between the producer and the distributor may be stopped, and samples taken?—At railway stations.

11559. Only at railway stations?—Practically only at railway stations.

11560. Not on the road?—The object of that enactment was this. A great deal of milk is brought from the country by railway to London. Samples were taken at shops, and it was found that the milk was adulterated. The allegation was made that the milk had been adulterated before it reached the retail vendor's shop. Then an effort was made to protect the retailer by giving power to take samples at the railway station.

11561. That is a special case which you think is not applicable here?—That was extended by the Act of 1899 to all other articles, provided the consignee or the purchaser requested that such examination might be made. The object of that is again to protect the retailer against the wholesale vendor. The retailer says: "I sold the thing as I received it; the vendor to me must have been guilty; I have no means of ascertaining whether he was or not." Parliament says, "Then, at your request, you may during the transit of that article to you cause an examination to be made by the food inspector."

11562. Take a somewhat similar case. In the case of jam factories, is it not the fact that fruit going into those factories may be seized if it is found in a decomposing condition?—That has been done, no doubt.

11563. Under what power was that done?—That was done under the Public Health, London, Act. The fruit was, I suppose, deposited for sale, or for preparation for sale.

11564. Could not that Act be extended in such a way that samples of materials could be taken in the food factories?—I think it could.

11565. Could not it be so extended that it would be in the power of an Inspector to take a sample of sulphuric acid on its way to a glucose factory?—Once having established, in the ordinary course, that an article like glucose is likely to contain a poisonous ingredient, it

might be possible to schedule that particular article as a dangerous one which the Food Inspector might have special powers of examining.

11566. You mean, you would have no power to examine anything excepting scheduled articles?—You clearly could not examine under the Sale of Food and Drugs Act such an article as sulphuric acid except as a drug; it is not a food.

11567. (Professor Thorpe.) Anything which enters into the composition of a food is a food under the Act of 1899. To the extent to which oil of vitriol enters into the manufacture of food, or is ancillary to it, it is a food?—I do not know that sulphuric acid is an article that enters into the manufacture of food.

11568. (Sir William Church.) I would like to put this instance before you. We have had evidence given here that a man started a food factory—I do not know that he patented it—of a food which he made out of brewers' yeast, to a great extent, and malt culms. Could not power be extended so that those substances might be sampled upon the way to his factory?—It could, of course, be done.

11569. Would it be impossible, or do you think it would give rise to great difficulty, if some extension of power was given to the inspection of food factories, which are, of course, distinct from a private house in a village, where an old woman makes a few tarts to sell to children; would there be any objection, where anything in the nature of a wholesale factory is put up, to its being under Government inspection—it is under Government inspection for the Factory Act now?—Yes, for another purpose. I was thinking of the difficulty the Government Department would be in if it had such a responsibility cast upon it. If a Government Department is to be responsible practically for all the ingredients that enter into the composition of food it would want a very large staff to deal with the matter.

11570. But could it not be done by the Local Authority in the same way that now a sample of the finished product can be obtained from the retailer so the Local Authority's officer might have power to go into the factory and ask for samples of the material used in the production of the food?—Parliament could give such a power.

11571. That would not throw the greater amount of work, or not much work, upon the Central Board, the Local Government Board?—It would be practicable to give such a power to the officer of the Local Authority. My difficulty rather is to know how that would be worked in practice. An inspector of food would go into a factory and would take, we will say, sulphuric acid. It is known now that certain of those ingredients contain minute portions of arsenic. That was discovered, I presume, by accident.

11572. No, I do not think by accident?—My difficulty is, is there any known way of ascertaining whether or not a particular ingredient such, we will say, as sulphuric acid, contains a poison without examining that sample for every known poison, and using every known test that science is acquainted with.

11573. That applies to any analysis, the analysis of all food. The public analyst, for instance, who analyses milk, only analyses to see whether there is an undue amount of water in it; he does not analyse to see whether there is hydrocyanic acid in it. That applies to all analyses equally?—That is my point.

11574. An inspector might go into a food factory, take samples, and send them to the analyst of the body whom he represented, and say: "That is used in the production of food, does it contain anything which is obviously deleterious?" It might contain some unusual poisonous material, which would escape observation until some accident led to its discovery, and that is the case with all food?—That is so. It would no doubt be possible for Parliament to give such powers, but whether administratively those powers would result in the discovery, for instance, of such an ingredient as arsenic I very much doubt.

11575. But it would, at all events, give this protection to the public, that it would be known what the constituents of these prepared foods are. At the present moment, as far as I understand, it is open to anybody to set up a factory and turn out what he calls a food, or protein or give it what name he likes. Nobody knows in the least of what it is composed, and it would be a great safeguard to the public if a sanitary authority could investigate and know what those foods are?—It would be possible

to enact that a local authority should have the power of ascertaining the nature of the work that was carried on at any such factory as you suggest. Of course in patent processes—and some of those processes, I suppose, are patented—the patentee is obliged to disclose, before he gets his patent, what he puts into his commodity.

11576. That would be the guide for the analyst?—Perhaps there would be no greater difficulty in requiring that a man who sells an article of food should declare its ingredients than there is in requiring that a man who has a patented article should declare beforehand by a specification what that article contains, and how it is made.

11577. And it would be seen then whether he continued his manufacture under the terms of his patent?—Yes, the principle on which the declaration of the protection of a patented article rests is, I suppose, that others may sell it after a certain time has elapsed. The requirement of a declaration of the ingredients of manufactured food-stuffs might perhaps be defended as necessary to protect the public health.

11578. The Patent Office offers no opinion as to whether the food patented is likely to be wholesome or not?—No.

11579. But the Sanitary Authority would?—Yes.

11580. (Professor Thorpe.) I should like to have made a little clearer what your opinion is as to the exact limitations of the power of Medical Officers of Health. I will put a case to you which actually happened, and I should like to have your opinion as to whether the Medical Officer of Health went beyond his competency. A certain ingredient entering into the composition of beer was found to contain a large quantity of a noxious substance. It was found that this substance was compounded by a druggist who had, in addition to his retail establishment, a considerable manufacturing establishment, making articles to be distributed wholesale. The local authority was informed of the fact; their Medical Officer of Health went to this shop and asked to be given a sample. The person in the shop declared that he had no more of the article; he did not refuse to sell, because, had he refused to sell, he would at once have been amenable. But what he did say was, "I happen to have no more of the substance." The Medical Officer of Health had no means of knowing whether he had or had not, but he took it upon himself to go into the manufacturing premises, and actually took samples of various materials which entered into the composition of that material, and brought them away and had them examined. Do you think he acted *ultra vires*?—Certainly. I should think he would be liable to an action for trespass.

11581. When he was asked if he could do it, he himself expressed his own conviction that it was within his competency, and therefore he did it and took away the samples?

(Chairman.) Was he pulled up for doing it?

(Professor Thorpe.) No.

There is nothing like boldness in such a case. I should like to ask you whether the Medical Officer of Health had permission to go in. If he had permission to go in, and had permission to take these things, then no action would lie against him. If I go into a private house and say, "Will you give me a sample of that sugar and this jam," and samples are given to me accordingly, I have a right to take them away, but I have no right to demand those samples, nor had the Medical Officer of Health any right to demand to take those ingredients.

11582. To what extent it was an act of grace on the part of the proprietor to allow him to do those things I cannot really determine because I was not present; I only got the information second hand. The samples came to me, I may say, eventually, and were examined by me. We at the Inland Revenue set this action in motion; we could not do it ourselves, except through the Local Authority. The Local Authority, the Medical Officer of Health of the Sanitary Authority, in particular towns, does not seem to have any misgiving as to what he may do?—I am quite aware that sanitary officers are often welcome where they have no right, and are allowed to do things which by law they cannot claim to do. I think the case you have quoted must be such a case.

11583. Your point is that this man, unless he were allowed to do so, acted *ultra vires*?—I have no doubt about it.

11584. With reference to the numerical details you have given us as to the samples taken, was the great

Patent  
foods.

Powers of  
Medical  
Officers of  
Health at  
place of food  
manufacture

majority of these samples milks and butter?—That is so.

11585. They are not articles really into which any deleterious ingredient is likely to enter?—Not such an ingredient as arsenic.

11586. The object of taking those samples is to protect the consumer, in order to see that he gets milk which has the amount of fat in it and other nutritive ingredients as defined by the regulations of the Board of Agriculture?—That is so. The very considerable extension in the number of samples taken and examined during the year 1901 was no doubt due, to some extent, to the circular of the Local Government Board, and to the scare caused by the deaths and illnesses from beer poisoning. I have here an abstract of the reports of public analysts for the year 1901. If you wish, I will read the actual numbers that were examined and the various food stuffs, taken under the Sale of Food and Drugs Act.

11587. Of 100 samples of food analysed, what proportion were milk and what proportion were butter; is that given in the tabular return?—No, this is the percentage of adulteration.

11588. My point is this. Articles which are supposed to, or which may, contain deleterious ingredients are not very extensively sampled as compared with articles like milk and butter where the allegation is that the milk is watered or deprived of a little fat, or that the butter may be mixed with a certain amount of foreign fat which, of itself, is not noxious, but which merely constitutes a fraud upon the person?—That is true. In 1901 there were altogether 67,841 samples examined. Of these samples, 26,143 consisted of milk, 11,938 of butter, 5,068 spirits, 3,960 beer, 2,824 of confectionery and jams, 2,301 of drugs, 836 of sugar, 691 of mustard, 587 of flour, 530 bread, 463 tea, 52 wine, 1,883 coffee, 1,655 pepper, 1,374 lard, and 7,536 other articles.

11589. But the general effect of this is that these articles were examined not so much as containing possible deleterious articles as that they might be impoverished, or that they might be objects of a less valuable character than what they are represented to be: that was the reason they were taken, was it not?—I do not know to what extent value enters into the ideas of those who promote examination of food and drugs locally; the main idea is, are they or are they not sold in a pure state.

11590. Take the question of spirits?—The question of spirits mainly depends on whether the spirits are or are not watered unduly.

11591. Whether they are of the legal strength?—That is so.

11592. What is your impression that samples of lard are usually taken for? The question of whether or not lard contains water is one reason why the samples are taken. Another reason is whether it is in fact lard or not, whether it is not some other fat.

11593. Is it not rather the fact that it contains a small quantity of beef stearine?—That is what I mean by another fat.

11594. In the case of pepper, is not the real reason for taking samples to see whether it does not contain adventitious matters, such as olive stones, or an undue amount of sand, or something of that kind?—That is so. I do not suppose the Food Inspector considers very much whether the particular article he is going to sample is of greater or less value than it ought to be. He says, "My duty is to take samples of foods and drugs: I have taken so many samples of butter, now I will take some samples of jam, and see if Mr. So-and-so's goods are adulterated or not."

11595. With regard to jam, that perhaps is one of the very few things which are taken with a view of ascertaining whether there are deleterious ingredients. What is searched for in jam is an undue quantity of salicylic acid, which is, to some extent, an injurious constituent—to see whether a preservative of a somewhat deleterious character is not present. That is the main object of the jam analysis, together with finding out whether it may not be coloured with some deleterious colouring matter such as an aniline dye?—Or whether it does consist of the fruit it purports to contain; for instance whether marmalade is made of turnips or whether it is made from oranges.

11596. (Dr. Whitelegge.) I have a few figures showing the number of samples taken for the three years 1899, 1900, and 1901. You have given us some figures for

4576.

1901, including those for confectionery and beer. I suppose you would agree that a great deal of the increase in the number of the samples of those articles was due to what happened at Manchester, and to the circular of the Local Government Board?—I have no doubt that is so.

11597. I find, for instance, with regard to beer, that whereas only 239 samples were taken in 1899 they had risen in 1900 to 4,559 and in 1901 to 3,960. Then, for confectionery and jam the numbers were in the three consecutive years, 511, 1,547 and 2,824. Those you regard probably as more or less of a temporary increase?—Yes, I think so.

11598. Although the Board in its Annual Report expressed satisfaction at the considerable increase which has occurred in recent years, at the same time a very great deal of that increase is due to this one local circumstance?—And I think possibly also to the fact that the Act of 1899 for the first time imposes on local authorities the duty of sampling foods.

11599. The number of samples of coffee has not increased, and there is no increase in the number of samples of lard. Looking at these figures, it seems to me that the increase is mainly, at all events most conspicuously, in regard to those things that have to do with arsenic and the recent enquiry?—I quite agree.

11600. You have mentioned that the Board have no staff to make technical enquiry into these matters; some enquiry was made by the Board, I think, after the Manchester arsenic epidemic, was it not?—A medical rather than a chemical enquiry.

11601. There was no chemical enquiry made?—No chemical enquiry, so far as I know.

11602. I suppose no difficulties in regard to the right of entry arise in the case of Officers of the Board?—Facilities are generally given to the Officers of the Board over and above what they are entitled to demand.

11603. That is true throughout all the Government Departments; that is the general experience?—I think so.

11604. So that the difficulties you are anticipating with regard to inspection, the objection on the part of the manufacturer would extend to local inspection rather than to central inspection, I take it?—I think so.

11605. And that would be increased if the right of inspection of Local Officers extended not only to the officer of the district in which the factory was situated but to the officer of any district in which the goods produced in that factory were consumed?—Clearly. Under existing law, the officer of a District Council would have no right to go outside his district for the purpose of obtaining a sample. It was decided in the High Court quite recently, that an officer has no right to take a sample at a railway station outside his own district. So that if a retailer of milk in Kensington got the Kensington Inspector to go to St. Pancras and there examine a can of milk, the Inspector could not take proceedings in respect of the adulterated sample he might have got from that can of milk, because he is a Kensington Inspector, and the place of examination or delivery is St. Pancras.

11606. We have been considering this morning, the further question of power to take samples in a factory, which does not exist now. If that were given and exercised, I suppose you would say that the difficulty would be greater in the case of local inspection by sanitary officers than by Government inspection, and greater still if more than one local authority had the power to send its officers there?—I think that is so, judging from the experience which we have had in regard to the enquiries by Medical Officers of Health in cases of tuberculosis in cows supplying milk to distant towns. Some local Acts, for instance, have given power to the Medical Officer of Health of an urban district after certain formalities have been carried out, to go to the country place and examine the cows supplying the milk to the urban district. Rural District Councils have resented the invasion, as they call it, by the City Medical Officer of Health; they have resented the fact that power has been given to a distant officer to come into their district to examine into matters with which they are concerned.

11607. That is a power which has been given in many recent local Acts, has it not?—In several cases, yes, but it is still, I may say, a matter of Parliamentary fight. There is no general enactment to that effect.

Mr.  
J. Lithiby.  
27 Mar. 1903.

Increase in  
samples since  
1899 also due  
to arsenic  
question.

officers of  
Government  
Departments.

Objections to  
inspection of  
food factories  
by officers  
of local  
authorities.

Mr.  
J. Lithby.  
27 Mar. 1903.  
Present  
powers of  
Medical  
Officer of  
Health and  
local  
authority as  
to arsenical  
food.

11608. With regard to the power of the Medical Officer of Health, I should like to take a particular instance which has been before us of beer in breweries. The Medical Officer of Health in a town in which beer is brewed as well as consumed, has reason to suppose that beer manufactured in that brewery, and that certain ingredients which go into the beer, contain arsenic; I gather from what you told us, that you think he has no right of entry to that factory, that if he goes to that factory he could not demand samples under the Sale of Food and Drugs Act, because the sale is not by retail?—Because there is no sale at the factory.

11609. The retail difficulty does not arise in any action that might be open to him under the Public Health Acts; is not that so?—Yes.

11610. That is wholesale or retail indifferently?—It has been so held. But it must be a place of sale. The fact that a man sells sugar wholesale does not entitle me to go into his wholesale warehouse to take a sample unless, perhaps, people are in the habit of going to those premises to purchase articles. Sometimes this happens: a man has a retail shop, and there he sells goods. I go to that shop, and I claim to buy a pound of sugar. The food inspector may go to that shop and sample the sugar and other articles that he finds there, but that would not give him the right of going to a factory half a mile away or going to a warehouse half a mile away, and demanding to be served there from samples of sugar that he saw in that warehouse.

11611. I quite follow, under the Sale of Food and Drugs Act. But under the Public Health Act, I gather from you there would be no power for the Sanitary Inspector or the Medical Officer of Health to do anything in a brewery; he could not, for example, lay an embargo on a particular lot of glucose or finished beer, pending analysis?—He could not.

11612. As a matter of fact, as you have told us, a great deal is done beyond what the law requires: for instance, the brewers in many cases destroyed their beer. But as a matter of legal right that is your view?—Yes.

11613. I want now to take another case. The Medical Officer of Health or the Inspector goes to a retail beer shop and takes a sample of beer which, on the report of the analyst, is found to contain arsenic. Until he receives the report of the analyst he can do nothing under either Act, can he?—That is so.

11614. He can lay no embargo on the beer; he cannot seize the beer or do anything else?—That is so.

11615. So that when the report of the analyst comes, which is usually not for some little time, the beer may have gone, and there will be no responsibility in regard to it by those who sell it in the interim?—Presumably that is so.

11616. I am assuming that the analyst finds there is a considerable proportion of arsenic. The Local Authority take proceedings against the vendor. Must they necessarily take proceedings against the vendor in the first place, or could they go to the brewer if they think the brewer is responsible?—They could not go to the brewer.

11617. They must take proceedings against the vendor first?—Yes.

11618. If the vendor puts in a warranty, or something akin to a warranty, from the brewer, and it complies with the necessary conditions, he is entitled to his discharge on that score, is he not?—The retailer?

11619. Yes?—Yes.

11620. What is the position of the local authority as regards the brewer or the person who gives the warranty? What can they proceed against him for—for a false warranty?—No; they can only proceed against him under the Sale of Food and Drugs Acts, 1875 or 1879. They cannot bring anything in the nature of an action against the brewer, that is to say, a civil action for damages.

11621. Proceed against him for what—for selling beer which is contaminated with arsenic, or for giving a warranty saying the beer is free from arsenic when it is not?—The offence would be selling beer contrary to the provisions of that particular statute. The retailer is prosecuted for selling beer which is not of the nature, substance, and quality demanded. He makes a good defence, the defence of warranty; then the warrantor may be proceeded against, if the conditions of the statute can be complied with, but I do not think I can give any more detailed answer with regard to that question.

11622. I will not press that further?—I would like to point out to you that the requirements of the statutes are very exacting. You have to comply with those requirements literally, and several cases have broken down which have been taken against the warrantor. For instance, the proceeding must be taken within six months of the warranty being given, so that, although, I suppose, beer may be kept for two or three years—I do not know how long it is, in fact, kept—yet if the publican warranted a cask of beer, and the retailer did not sell any of it until more than six months after the warranty were given, that would be a bar against proceedings against the warrantor.

11623. In any case, it will be an essential to any further proceedings the local authority may take against the warrantor that he shall be proved to the satisfaction of the Court before which the case comes to have supplied beer containing arsenic; that will be part of the false warranty, or whatever it is called?—I do not know that I quite follow you there.

11624. Let me go one step further. When the case comes on against the warrantor later in the day, is he not entitled to plead some sort of grievance in that, although he is accused of having made and sold beer containing arsenic, he has not been allowed any of the protection which the Act provides so carefully for the retailer; he is not allowed a sample, he is not allowed the power of reference to the Government analyst, and he is not informed of it technically until later on, when he cannot make any counter analysis on his own account?—Yes, a defence of that kind would probably succeed.

11625. And a defence of that kind is usually set up, is it not?—Yes, I believe it is.

11626. Is there any power under the Sale of Food and Drugs Act to associate the warrantor with the retailer, where it is proposed to rely upon the warranty? It may be within your knowledge that in the Factory Acts there is power to do that. If an employer is summoned, and he says that not he, but some person in his employment is responsible, for instance, a foreman, he is allowed to require that that person be brought to the Court, so that, supposing an offence has been committed, one or other can be convicted. Is there anything of that kind under the Sale of Food and Drugs Act?—Perhaps I may be allowed to read section 25 of the Act of 1875. It says: "If the defendant in any prosecution under this Act prove, to the satisfaction of the Justices or Court, that he had purchased an article in question as the same in nature, substance, and quality as that demanded of him by the prosecutor, and with a written warranty to that effect, that he had no reason to believe at the time when he sold it that the article was otherwise, and that he sold it in the same state as when he purchased it, he shall be discharged from the prosecution, but shall be liable to pay the costs incurred by the prosecutor, unless he shall have given due notice to him that he will rely on the above defence." That was modified by the Act of 1899 in this way. Section 20 provides "A warranty or invoice shall not be available as a defence to any proceeding under the Sale of Food and Drugs Act unless the defendant has, within seven days after service of the summons, sent to the purchaser a copy of such warranty or invoice with a written notice stating that he intends to rely on the warranty or invoice, and specifying the name and address of the person from whom he received it, and has also sent a like notice of his intention to such person. (2) The person by whom such warranty or invoice is alleged to have been given, shall be entitled to appear at the hearing, and to give evidence, and the Court may, if it thinks fit, adjourn the hearing to enable him to do so. (3) A warranty or invoice given by a person resident outside the United Kingdom shall not be available as a defence to any proceeding under the Sale of Food and Drugs Act, unless the defendant proves that he had taken reasonable steps to ascertain, and did, in fact, believe in the accuracy of the statement contained in the warranty or invoice." Some other provisions follow, and then sub-section 6 is to this effect: "Every person who, in respect to an article of food or drug sold by him as principal or agent, gives to the purchaser a false warranty in writing, shall be liable, on summary conviction, for the first offence, to a fine not exceeding £20, for the second offence to a fine not exceeding £50, and for any subsequent offence to a fine not exceeding £100, unless he proves to the satisfaction of the Court that when he gave the warranty he had reason to believe that the statements or descriptions contained therein were

1903. true." That last part slightly modifies the law as it was under the Act of 1875. Under the Act of 1875, he had to prove "That he had no reason to believe at the time when he sold it that the article was otherwise." Under the Act of 1899 he is liable, "unless he proves to the satisfaction of the Court that when he gave the warranty he had reason to believe that the statements or descriptions contained therein were true." In principle, there is a considerable difference between those two positions; in practice I do not think there is much, because it was almost impossible for the prosecution to prove under the Act of 1875 that the vendor "had no reason to believe," and now, under the Act of 1899, it is very easy for the vendor to prove that when he gave the warranty "he had reason to believe that the statements or descriptions contained therein were true." He only has to go into the box and say so, whereas, for the other side to bring contradicting evidence is, as you see, almost impossible. Therefore, although there is a difference in principle between those two provisions, the advantage to the prosecutor is not great.

11627. Supposing the person who is summoned on the false warranty could prove that the arsenic came in through some ingredient, respecting which he had a warranty from some other person outside, that would be amply sufficient to discharge him, so far as that Court was concerned, would it not?—I should think so.

11628. And under that Act, at all events, the local authority could not follow up the further warranty at all.—Certainly not.

11629. I want to ask one or two further questions about the reports of the analysts. They are quarterly reports, are they not?—Yes.

11630. Why are they quarterly, instead of annual; is any point gained by that?—I do not know why the Act of 1875 required them to be made quarterly, but, as a matter of fact, it does. These reports are required to be sent in every quarter to the local authority, and then, once a year, the four quarterly reports of the preceding year are sent to the Local Government Board. So that the local authority would have its reports of work done, we will say, from January to Lady Day, presented to it in April, but it would not reach the Local Government Board until the following January.

11631. Those four together make up the annual report?—Yes.

11632. The Board have laid down certain standards for reports of analysts; you gave us the particulars that are asked for now?—Yes. The Act itself simply authorises the Board to provide a form in which the reports shall be sent to the Board. That form was prescribed in the letter which I have put in. It is the fact that the reports made by the public analysts in 1877 and the early years of the operation of the Act of 1875 were on no common basis. It was impossible to accurately tabulate those reports, and for that reason the Local Government Board suggested the form which I have put in. They suggested it, they did not prescribe it.

11633. But, practically, there is a substantial acceptance of it by analysts?—It has been generally accepted, nobody has disputed it. I point that out, because my suggestion is that there is a difference between prescribing and suggesting.

11634. There is no suggestion made of a statement of what was looked for in the case of any particular sample?—None.

11635. For example, looking at the number of samples of beer taken six or seven years ago, and looking at those for last year, we should find an enormous increase, but in one case they would be examined for things in general?—For salt, mainly.

11636. And the recent ones would be examined for arsenic, but in neither case would the fact of the substance for which the search was made be stated?—That is so.

11637. Has any attempt been made by the Board to differentiate in a particular instance of this kind? It has been suggested that analysts might say how much arsenic they found in a sample of beer; would that appear naturally in the report itself?—The practice of analysts varies. Many analysts give the actual results of their analyses. Some say, "Genuine," or "Adulterated," and nothing more.

11638. The word "genuine" is usual?—It is.

4576.

11639. That means that whatever the foreign substances, be they many or few, that the analyst has looked for, he has not found them?—Quite so.

11640. So that "genuine" five years ago would be consistent with a high proportion of arsenic in beer?—That may very well be.

11641. With regard to the number of samples taken, they have increased, and I think it is perhaps very largely in consequence of the arsenic question. But is not there a further consideration? Is it not important to look beyond the mere number? Is it not important to look, also, to the kind of samples taken? For example, in an agricultural district—or, perhaps, rather, in a borough—there might be a large proportion of milk samples taken, while it may be that other branches equally necessary are left aside?—It may be.

11642. The Board have not reminded local authorities of default in particular kinds of sampling?—The Board have no information on which to base pressure on local authorities with regard to particular articles.

11643. But you exercise pressure, do you not? If you find the gross numbers fall below a certain proportion of population, in such a case you do send a reminder to the local authority, do you not?—In such a case we write to the local authority, inviting their attention to the provisions of the Act, and since 1900 we have pointed out the requirements of the Act of 1899; but we have no information at present which would enable us to say: "You ought to examine butter, or you ought to examine lard, or you ought to examine any particular substance."

11644. I quite follow you; but if the reports of the analysts show that a particular local authority had not taken a single sample of milk, would that be a thing which the Board would attend to?—That we should leave now to the Board of Agriculture. I may state that the Board of Agriculture are sending inspectors round, or have been sending inspectors round, to point out to local authorities their duty under the Act of 1899, and to induce them to take samples with regard to agricultural produce.

11645. That is shown in the number of analyses here; the milk samples have gone up from 21,964 in 1899, to 26,143 in 1901?—That is, no doubt, due to the action taken by the Board of Agriculture. The Commission will remember that this Act of 1899 was introduced, not by the President of the Local Government Board, but by the President of the Board of Agriculture.

11646. The annual report of the Board is sent to the local authority, I think you told us?—Yes.

11647. And portions of it to the Public Analyst?—Yes.

11648. Is it sent to the Medical Officer of Health?—No, the report itself is not sent to the Medical Officer of Health.

11649. He would seem to be a person interested as usually directing the collection of samples?—Yes, but it would be almost impracticable to supply every officer concerned. The report is sent to the local authority, and it is available to the Medical Officer of Health, if he chooses to ask for it; but a copy is not sent to him personally from the Board.

11650. (Sir William Hart Dyke.) You mentioned that it was the practice of the Board now and again to schedule articles. Under what Act does that process take place?—My suggestion was that it might be done if a Court of Reference were established. Then if it were found, we will say, that arsenic is conveyed into certain classes of food by means of glucose, a schedule might be made of the articles on which the Court of Reference had adjudicated as likely to contain arsenic, and an order might be made in reference to those by the Local Government Board, or by whatever Government Department the Acts were administered.

11651. That in itself would be a safeguard for the future; at all events, apart from any administrative action, it would be a very strong warning indeed that such and such a thing had been barred?—Yes. Might I put it in this way: Boric acid is largely used as a preservative. If there were a Court of Reference, that Court may say  $x$  grains of boric acid could be safely used in a gallon, we will say, of milk. My suggestion is that it might be made possible for a Government Department—say, the Board of Agriculture—to issue an order under which any excess of boric acid in a gallon of milk beyond  $x$  amount would be an offence.

Mr.  
J. Litchby

27 Mar. 1903.

Local Government Board have no information on which to base pressure on local authorities with regard to particular articles.

Recent increase in milk samples under Sale of Food and Drugs Acts due to pressure by Board of Agriculture.

Court of Reference and schedules of deleterious articles of food.

Mr.  
J. Lithiby.  
27 Mar. 1903.  
Actions  
which might  
be taken on  
such  
schedules.

11652. If Parliament were asked, do you think it would be likely they would consent to such a thing as this—to extend the action of the Sale of Food and Drugs Act farther, and empower the officers of local authorities to enter factories where the articles scheduled in the way you now denote, were being made? For instance, take glucose. Would it be possible by Act of Parliament to extend the action of the Sale of Food and Drugs Act merely to articles which were thus proved to be dangerous. For instance, I will put this case to you. Supposing it were the outcome of this Commission that in all places where glucose was manufactured there should be a right of entry at all times as a safeguard—not a universal power to enter all factories or manufactories or breweries, but wherever glucose was manufactured there should be a right of entry at all times for the protection of the public. What do you say to

that?—It would be practicable. I think an analogous case would be the right of entry which is given to the inspectors of the Local Government Board under the Alkali Acts in reference to certain scheduled processes. The processes are scheduled, and the inspectors at all reasonable times are entitled to go into the works and see the processes that are being carried on. The object under the Alkali Acts is to prevent nuisance arising from the process.

Mr.  
J. Lithiby.  
27 Mar. 1903.

11653. Do you not think it might be possible to legislate in that restricted sense only, whereas if you were to legislate in the general sense, and give right of entry in every possible case for every possible manufactory, there might be very great difficulties and great opposition?—I think a proposal limited in that way would be more likely to succeed in Parliament.

Professor  
Thorpe.

Professor THORPE, called; and Examined.

Professor  
Thorpe.

Report of  
Depart-  
mental Com-  
mittee of  
Board of  
Inland  
Revenue on  
Arsenic in  
Beer In-  
gredients,  
&c.

Methods of  
testing re-  
commended:

electrolytic  
method and  
its advan-  
tages:

zinc and  
acid method.

Purity and  
sensitiveness  
of zinc.

(Professor Thorpe.) I shall be glad to answer any question you may wish to put to me respecting the report of the Inland Revenue Committee on Arsenic in Beer Ingredients. (Appendix 21), page 208, below.

11654. (Chairman.) We have had advance copies of that report. We understand that it is not yet formally presented to us, but that it is to be presented by Sir Henry Primrose, the Chairman of the Board of Inland Revenue, at the next meeting?—Yes.

11655. The report relates, does it not, to methods of testing, and describes the system which has been worked out at the Government Laboratory, and which has been found satisfactory by the Committee?—Yes.

11656. The electrolytic method is described in detail, is it not, and is preferred for reasons stated at page 12 of the report?—Yes.

11657. In particular, it gives more uniform deposits, and it does not necessitate the preliminary destruction of organic matter; that, no doubt, has been checked by a series of experiments?—Yes.

11658. You find there is strong evidence, I believe, that that statement is correct—that it does not necessitate the preliminary destruction of organic matter?—Not as regards some of the things—as regards beer and wort, for example.

11659. Have experiments been made in your laboratory to prove that statement?—Yes; and also in the laboratories of the other gentlemen who have signed the report.

11660. I believe the alternative method, with zinc and acid, is also described in detail in the report?—Yes.

11661. With a few modifications, does it accord with the Marsh Berzelius test?—It is the Marsh Berzelius test.

11662. With the Marsh Berzelius test formulated by the Conjoint Committee of Societies of Public Analysts and of Chemical Industry, as to which we have had evidence?—It was adopted by them, yes. Of course, it is a very old method.

11663. They did not adopt the electrolytic method?—They knew nothing about the electrolytic method.

11664. I believe the advantages and the drawbacks of the zinc and acid method are stated on page 17 of the report?—Yes.

11665. Have you anything to add to that?—No, I think that practically summarises all our knowledge.

11666. What is the ordinary range of experimental error in the case of the zinc and acid method—for instance, would it always distinguish with certainty a difference of .002 milligramme?—The zinc and acid method is, of the two methods, the most uncertain in its action. The electrolytic method is practically uniform in its action, and, of course, obviates the use of zinc. Zinc, in the first instance, is a metal which it is very difficult to obtain pure. All commercial samples of zinc contain greater or less quantities of arsenic and of certain other metals, notably iron, which has the extraordinary property of inhibiting the formation of arseniuretted hydrogen. A small quantity of iron mixed with the zinc or present with the zinc will prevent the formation of arseniuretted hydrogen when small quantities of arsenious oxide

are actually added to it, so that no sample of zinc can be taken into use by an operator unless he has first assured himself that it contains no arsenic, and, next, until he has assured himself that when arsenic is added to that zinc it will actually form arseniuretted hydrogen. Those conditions are not always possible to secure, and a great number of samples of zinc have, as a matter of practice, to be tested before one is found that will satisfy those conditions. That is one fundamental difficulty connected with the use of the zinc and acid method when you have to detect very small quantities of arsenic—I mean arsenic of the order of 1-100th of a grain of arsenious oxide to the gallon of beer. The amount which we suggest to be used in the case of beer is 25 cubic centimetres of the beer.

11667. Do you find the Marsh-Berzelius test, which was at all events considered to be the best test until this inquiry was made, decidedly uncertain for estimating such small quantities as 1-100th of a grain per gallon?—I should not, perhaps, put it quite so strongly as that. Of course, when an operator has satisfied himself that his zinc is both pure and sensitive, as we call it, then the method is pretty certain in its indications.

11668. But you would not consider it safe that anyone should use it without having satisfied himself by special experiment that his zinc is correct?—That is absolutely a *sine qua non*—that is the first step he must take.

11669. If an analyst was giving evidence as to results, you would ask him: "What steps did you take to make sure that the zinc was correct?"—Yes, he would have to show that he had made special experiments to that effect.

11670. Has it been usual that analysts have taken what they purchase as chemically pure zinc, without themselves ascertaining that it was correct?—No, I do not think so. I think they have all, by a preliminary test, ascertained that the zinc could be used, but it is comparatively recently that it has been discovered that small quantities of foreign metals will inhibit the formation of arseniuretted hydrogen.

11671. But until a year or two ago a careful analytical chemist would have been entitled to consider that pure zinc was safe and sufficient for this test, would he not?—Do you mean what was called pure zinc by the seller of the thing?

11672. That which would be admitted into an accurate scientific laboratory as pure zinc?—No. Of course, the Marsh method has long been employed in toxicological investigations, and it has been absolutely necessary for the toxicological chemist, before he made use of the zinc, for the purpose of detecting the presence of arsenic, we will say, in the contents of a stomach, or whatever it may be, to assure himself that the zinc he has been using is proper to be taken into use; but I am afraid he has not been aware of the fact that although the zinc may show no evidence of arsenic, that is to say, he may not be able to get any arsenical mirror from it, he has not been alive to the fact that there may be associated with the zinc certain metals which would actually prevent the formation of arseniuretted hydrogen. That is a fact which has practically come out in this inquiry.

Professor Thorpe. 11673. The zinc which had been actually used and applied by the analysts in making analytical tests might be deceptive in not giving a mirror when there was arsenic?—Certainly.

11674. And that was not known two years ago?—It was not known.

11675. Is the Committee satisfied that the tests, as described, can be satisfactorily arranged to any required degree of delicacy by varying the quantity of substance examined?—We prescribe an invariable and uniform quantity of substance to be examined—a uniform amount.

11676. Do you not recommend different quantities of the substance to make sure that they discriminate different quantities?—No, we employ of every particular ingredient which is to be examined a prescribed amount. For example, we say of each particular ingredient how much shall be taken.

11677. In the table given in the report, an illustration is given showing a delicacy of 1-720th of a grain per lb., using 10 grammes of malt, and a delicacy of 1-360th grain per lb., using five grammes of glucose; is that so?—I may illustrate that by these standards, which have been prepared in accordance with prescribed tests. (*The standards were produced.*) Here, for example, are the series of standards which have been prepared in accordance with the electrolytic method for wort, where we take 25 cubic centimetres of the wort, and add to that known quantities of arsenious oxide, and these are the mirrors which are obtained corresponding to the known quantities of arsenious oxide which have been added.

11678. I notice there are some for 1-180th grain per gallon, and some for 1-90th grain per gallon; the mirror in the case of 1-180th looks rather more distributed than in the case of the 1-90th?—It is possible there may be in that particular instance. In these cases we are getting to the disappearing limit of accuracy of the method (*indicated*). It is not sensitive on account of the amount taken; it will not pick up any arsenic less than that in those materials.

11679-80. When the method begins to fail by losing sensitiveness with 25 cubic centimetres, if you take 50 cubic centimetres would the method then show the quantity more definitely?—Certainly; you have doubled the arsenic present.

11681. When you come almost to the limit of perceptibility would you recommend a larger quantity of the liquor or substance to be taken?—If there is any object in so doing. Of course, you must bear in mind that these tests have been devised with a view to the eventual prescription of warranties and guarantees on the part of the sellers of these articles.

11682. This in every case is metallic arsenic?—Yes. You will see that the amounts obtained by the zinc and acid method are substantially of the same intensity as those which are obtained by the electrolytic method, but on the whole they do not tend to be quite so uniform in their density. Personally I prefer the electrolytic method, and it is the one which we constantly make use of in the Government Laboratory now, because of course, we have a supply of current readily available. But we have worked out the zinc and acid method, because that is a method which probably will be more generally available to the brewer who may not always be able to obtain a supply of current.

11683. As electric lighting is coming so much more into use, do not you think both brewers and public analysts will feel less and less difficulty in applying the electrolytic method?—I should imagine so. Certainly for judicial proceedings I should much prefer that the electrolytic method was the one used. The reasons for saying that are given in the report, because there is much less of the personal equation in the electrolytic method than in the other one. The thing is automatic, it works itself, and the results of two analysts are very much more directly comparable; there is less discrepancy possible.

11684. As a rule, is it possible, if you are given one of these tubes, to say, after comparing it with other tubes, whether it is 1-72nd of 1-52nd, or something like that?—That is our practice. They are all made according to the prescribed manner, and when the assistant gets a deposit he simply finds which particular mirror it most nearly corresponds with.

11685. Are these tubes given out to people to use, or

are these simply specimens?—These are what we ourselves use in the Government Laboratory now.

11686. You carry the specimens to be examined along from one to another of the standards to see which it agrees with?—Quite so.

11687. You have a number of different cards containing mirrors in series for the same specified material; if you compare the different cards with one another they agree very nearly?—They do. My own belief is that it does not very much matter which particular card you take, but inasmuch as the method is strictly comparable, we have made standards for every single ingredient of beer; but, as you see, there is no great difference between them.

11688. When the zinc and acid method is used, you take a card in which the mirrors have been formed by the zinc and acid method?—Yes.

11689. For the different substances tested, is your Committee of opinion that the safest plan is to make standard mirrors for each substance?—I think so.

11690. One standard mirror when the substance tested is glucose, and another standard mirror when the substance tested is invert sugar?—Yes, or malt, or hops.

11691. With regard to fuel, what method has been employed?—The methods of fuel analysis have had to be very carefully worked out in the laboratory. We found that on the whole the most convenient method for determining the amount of arsenic in fuel is by an arrangement which is figured at the end of the report, which in principle is very simple. It consists in taking the powdered coal, or coke, placing it in a hard glass tube, such as I have here (*produced*). We take about 10 grammes of the fuel, and distribute it by a very simple method along the tube. Then we gently warm it, and burn it in a current of oxygen gas. The fuel takes fire, and goes on burning itself; it is only necessary to apply a little extraneous heat after you have once started the combustion. Provided the current of oxygen is sufficiently regulated, no organic volatile matter escapes combustion; eventually the whole of the coke is burned away, and the ash is left deposited in the tube. A certain small proportion of the arsenic, usually about in the proportion of 3 to 7—it varies with the character of the fuel and the nature of the ash—volatilises, is swept forward, and is caught in the little collecting arrangement which contains a very dilute solution of hydrochloric acid or sulphuric acid. If we are using the Marsh test to discover the amount of arsenic we use hydrochloric acid. If we are going to submit it to electrolysis we use dilute sulphuric acid. Then we determine the amount of arsenic which is left in the ash by the method which is described in detail in the report, and the volatilised arsenic is also determined by the direct addition to the Marsh apparatus, or by submitting the solution to electrolysis.

11692. In what form is it volatilised?—Arsenious oxide.

11693. At what temperature does arsenious oxide volatilise?—At a relatively low temperature; it is one of those curious things which, under the ordinary tension of the air, volatilises without previous fusion.

11694. Like camphor?—Yes. You can chase arsenious oxide from one side of a bottle to another; it is easily volatilised at a comparatively low temperature. One advantage we claim for this method is that it gives the seller and the user of fuel some idea as to the eventual distribution of arsenic in the fuel. I am about to publish a considerable number of determinations which have been made in the laboratory upon fuels which have been actually collected from maltsters, and various specimens of oven coke and gas coke which have hitherto been used. As far as the inquiry has gone, it shows, as I have stated generally, that not more than 30 or 35 per cent. of the arsenic present is volatilised.

11695. 70 per cent. remains in the ash?—Yes.

11696. Is there any evidence that the proportion of arsenic volatilised in this way would correspond to the proportion volatilised under conditions of slow burning in the open fire of a kiln?—As a question of volatilisation, I think yes, but as a case of mechanical distribution of dust by the action of strong currents of air which are going through the kiln, it is not. You will

its relation to volatilisation on the kiln fire.

Professor  
Thorpe.

27 Mar. 1903.

have the dust mechanically swept forward and deposited upon the damp grain.

11697. Some of the ash is swept out of the tube?—No ash will go out. I understood you to ask me if it corresponded to what would obtain in practice in kilning, and I say not quite.

11698. In the kiln there is more of the ash carried off?—Yes.

11699. Is there any evidence that the proportion of arsenic actually volatilised in this experimental method would correspond to the proportion volatilised under conditions of slow burning in the open fire of a kiln?—I should think it would; I do not see why it should not; there is no *a priori* reason why it should not.

11700. Would the burning in a current of oxygen be at a higher temperature?—No, not necessarily. Of course, the heat given out is not more than the chemical combination would effect.

11701. Can you say whether there is any approximately fixed proportion between the volatile and the fixed arsenic determined by the test?—No, it varies very considerably. I have not the numbers here, but in some experiments that were made the amount of volatilised arsenic is as little as 10 per cent. of the total quantity of the arsenic which has been there, and in other cases it has been as high as 30 or 35 per cent. That entirely depends upon the nature of the ash. If the ash is highly ferruginous the proportion retained is very considerably greater.

11702. Have you any further information or experiments to describe besides those we find in the report?—No, I have nothing to say beyond what is there. The report contains none of the experimental facts upon which the conclusions are drawn. We have tested this method, for example, by adding known quantities of arsenical pyrites to fuel. We have mixed very small and gradually-increasing quantities of arsenical pyrites, and we have assured ourselves that we actually do capture the arsenic which we have added to the coal in the form of arsenical iron pyrites. All facts of that kind are not given in the report, which is a mere summary of the conclusions at which we have arrived. Nor does the report indicate the large amount of experimental work which has been done. It has involved in the aggregate thousands of determinations.

11703. The tests for fuel must include an examination of the ash as well as of the volatilised part?—I think it ought to, in order that the complete history of the thing should be known.

11704. There is no such approximate proportion between the volatilised and the non-volatilised part as to allow you to extract sufficient information merely from examining one or the other?—I think not.

11705. How is the ash tested? Is it dissolved in sulphuric acid?—That is described in detail here. It consists practically in dissolving the ash in strong hydrochloric acid, to which there is added a small quantity of bromine. Oxide of iron which has been strongly heated dissolves with very great slowness in the mineral acids, but its solution is very greatly accelerated if there is free chlorine, or bromine, or iodine, or any free halogen. In fact, as a matter of practice, the only way in which the iron does dissolve is by the formation of the free halogen from the acid, and so, to accelerate the solution, we add a small quantity of bromine to it, and in that way, in the course of a very short time, we get the ash into solution.

11706. (Sir William Church.) Is it not the case that the colour of these standard mirrors fades by the action of light?—That is said to be so, but I have no absolute experience about it. Of course, as a matter of practice, we keep them in the dark.

11707. At all events, they do not fade sufficiently rapidly for it to be a source of error?—I do not think so to any considerable extent. The greater number of these standards I have brought with me were made 15 or 18 months ago, but some of them have been made within the last six weeks, and I am unable to perceive any substantial difference between those made a few weeks ago and those made 15 or 18 months ago. It is true they are kept in this little case in the dark.

11708. (Chairman.) Have you any tubes that have been kept for years?—Yes.

11709. And they do not seem to show any signs of fading?—No, but they have been kept mainly in the dark. There are here a great many tubes which have

been obtained in the course of our ordinary routine work.

11710. (Sir William Church.) I only wanted to know whether there was any likelihood of it being a source of error to any amount?—I do not think so.

11711. (Chairman.) Some of these tubes have not the same metallic appearance as the other mirrors; some of them are very black?—When they get very dense they get black. They are all brown when we get amounts such as we have here, but with an intense deposit they get very thick and metallic-looking.

11712. When it is very thick and black is it still metallic arsenic?—Yes, it is arsenium.

11713. (Dr. Whitelegge.) In that combustion tube a large proportion of the arsenic remains, and about 30 per cent. goes forward?—It may do.

11714. That which goes forward is arsenious oxide, is it not?—Yes.

11715. Is any of that which remains behind arsenious oxide not in combination?—No.

11716. It remains behind because it is in combination with something else?—Mainly with iron and the like.

11717. Which would make it difficult of solubility in any ordinary media?—It would not be soluble in the water which was used for mashing the malt. Non-volatile arsenic.

11718. So that if it were, in practice, by a very violent draught, to be carried forward and got mixed with the malt, it would still be different in kind from that which was being carried forward in the experimental tube?—Certainly.

11719. And would not be soluble under conditions of brewing. You regard that as, not being harmful in any practical sense?—It is not harmful.

11720. I notice in this report the Committee do not attempt any statement of what the standards should be for administrative purposes?—No. Report does not recommend what standards should be fixed.

11721. They only describe the tests by which the actual amount can be judged?—That is so.

11722. The chairman touched on that point in the questions he put. In the table in the report different quantities are specified to be taken for analysis, are they not?—Different quantities of the several ingredients.

11723. For instance, one gramme of chemicals, five grammes of hops, caramel, yeast, or other substances, 10 grammes of malt fuel or sulphur, and 25 cubic centimetres of wort, beer, or other liquid?—Yes. Quantities of different materials prescribed for testing.

11724. What was the underlying idea in taking those different quantities. Was it for the convenience of analysis or was it in the proportion in which those are likely to be present in beer?—I may explain shortly what was the guiding principle which we adopted. We had evidence as the result of a large number of analyses which we made on beers which were obtained from various parts of the country that it was possible by attention on the part of the brewer to secure purity. It was possible for him to obtain beers which contained arsenic in no greater amount than 1-100th grain per gallon. We had many examples of such beers.

11725. In the finished beer?—Yes. Therefore we came to the conclusion there was no reason why beer should contain more than 1-100th grain of arsenic, and we devised a test, and so arranged the conditions of the experiment that quantities larger than 1-100th grain should be perceptible.

11726. In the beer?—Yes, in the beer and in the wort, because practically, short of the amount which the yeast with-draws from the wort, you may say that all the arsenic which is in the wort will go into the finished beer. As a matter of fact, worts as a rule probably contain slightly more arsenic than the finished beer, because we have learned that the yeast to some extent secretes it, and also the hops, which are frequently sulphured. When those sulphured hops are boiled with the arsenicated wort the sulphur combines with a certain amount of the arsenic, and no doubt a small quantity is with-drawn in that manner. We came to the conclusion that that was the ideal, so to say, to which we might strive to attain, the ideal being really secured for us by the efforts of brewers who had done their best by arranging their plant and taking the very best advice they could, and improving their scrubbing machinery as regards malt, and paying attention to the cleanliness of their vats, and doing what they could to prevent the possibility of arsenic occurring. I am referring to the action of the large brewers whom we knew had taken these

steps, and with whom we were in touch in the course of this inquiry. That practically was what was fairly attainable by brewers with the best appliances, and working under the best conditions, and paying due attention to those conditions. Therefore, so to speak, that was the working basis upon which we started—we arranged the tests as regards their stringency so that they should capture any arsenic which was higher than 1-100th grain per gallon of wort or of beer.

11727. Assuming that the whole of the arsenic going into that wort or beer came from the particular ingredient in question?—I was going on to say that when we had, so to speak, fixed our ideal standard with reference to beer, we then had regard to the amounts of the particular ingredients which would be used to make that beer, and we then took such an amount of the several ingredients—the malt, glucose, invert sugar, and the other ingredients—that by no possibility, supposing they passed our test, could an amount as great as 1-100th of a grain per gallon be in the beer.

11728. If you are examining the glucose you think of a standard for glucose such that if no arsenic is added except through glucose the limit would be 1-100th?—As regards glucose, the amount of glucose which we recommended to be tested, and on which we based our tests, was so large that the beer might be considered as wholly derived from glucose. That is the amount we prescribed. If a sample of glucose passes our test the amount of arsenic either in the wort or in the finished beer is certainly less than 1-100th grain per gallon.

11729. I am afraid I do not quite follow that. What proportion is the glucose to the beer? Can you give me a comparative figure?—Do you mean what is actually in use now.

11730. Yes?—Perhaps 25 or up to 30 per cent.

11731. Then if you are aiming at excluding anything worse than 1-100th grain of arsenic from beer, how would you work that out in terms of the glucose? Would you say that the glucose being 25 or 30 per cent., you must allow a proportionately severe test for arsenic in it?—We have enormously increased the severity of the test as applied to glucose, because we prescribe that such an amount of glucose should be employed for the test as would be present in 25 cubic centimetres of beer or wort, assuming that nothing else but glucose had been used to make that wort or beer. We have enormously increased the stringency as regards the test on glucose.

11732. Naturally; the test on the glucose would have to be more stringent than the test on the beer. But supposing, for example, that each of the ingredients of

a beer came up to the limit of arsenic which you have in your mind for those ingredients, would that yield a beer containing more than 1-100th grain per gallon?—No. By the application of the tests to the individual ingredients of beer, assuming that those individual ingredients passed these tests, by no possibility could you have as much as 1-100th grain in the finished beer.

11733. Even if they all contributed as much as your tests allow?—Yes.

11734. Then you have taken as your basis a calculation of that kind, and you have not attempted to bring down the exclusion of arsenic to the furthest possible point? You had regard to the arsenic in the finished product?—Yes, we first of all had regard to the arsenic in the finished product, and then we tried to get rid of the further quantity of arsenic by increasing the stringency of the test on the individual ingredients.

11735. Does it not follow from that that you would not think it necessary to say that an individual ingredient must be as free from arsenic as practicable if it is only a small ingredient? If you have regard to the proportion in which it would be present in the beer, it must follow that you are less severe upon the ingredients which are used in smaller proportion?—No, that is not so. As a matter of fact, we have no regard to the proportions in which some particular things may be present. For example, if you turn to the chemicals, there are certain alkaline solutions which are used to revivify or what is called regenerate the beer. They are used in very small quantities, but we have been as stringent with them as regards their purity as would be the case of a substance which is used to a large extent in beer. We have not apportioned the degree of stringency to the relative proportions of the quantity used. We thoroughly discussed that. If it is practicable for a man to secure practical freedom from arsenic in such a material as carbonate of potash, it is no answer to us that because he used such a material in only a very small quantity the obligation to furnish that thing free from arsenic should be less stringent than in the case of the maltster.

11736. Then, substantially, these different quantities are taken for the convenience of chemical analysis, are they not?—Partly that; but, of course, with some regard, especially in the case of glucose and other things, to the amounts in which they may enter into the composition of the beer.

11737. That does come in?—To a certain extent, of course.

(Professor Thorpe here exhibited and described to the other members of the Commission the various apparatus and mirrors above referred to.)

Official limit  
should be  
governed by  
purity attainable  
rather than  
by quantity  
used in beer.

Dr. THOMAS M. LEGGE, Medical Inspector of Factories, Home Office, called; and Examined.

Thomas  
Legge.  
r. 1903.

11738. (Chairman.) You have handed in a statement with regard to the symptoms met with in industrial poisoning by arsenic; may we take that as your evidence on the subject?—Yes.

(Statement appears below at end of witness's evidence.)

11739. Have you inquired into several cases of arsenical poisoning arising in the course of employment?—Yes, a certain number; but the number reported is not large.

Question  
arises  
as to  
Home Office.

11740. Is the Home Office informed of all such cases?—No; I could not say it is informed of all. Medical practitioners are required by Section 73 of the Factory and Workshops Act, 1901, to report cases occurring in their practice if contracted in factories and workshops to the Chief Inspector of Factories, but I cannot say that the requirements of the section are known to every medical practitioner throughout the country. But wherever arsenical poisoning is common—where, for instance, there is a factory in which arsenical preparations are made—it would be known.

11741. You consider the cases reported to the Home Office are fair samples of the whole?—Yes, I do.

Cases  
reported.

11742. Will not the cases which are reported be rather extreme cases? Will they not probably be worse than many cases which are not reported?—That is so, but the medical practitioner must be the judge of what arsenical poisoning is, and what stage it reaches before he notifies it.

11743. There must be many cases in which there is evidence of arsenical poisoning, but only to a slight

degree?—Yes, evidence of the effects of arsenic, which might not amount to arsenical poisoning.

11744. By poisoning, do you mean death by poisoning?—No; symptoms of such severity as to keep them away from work. They may have slight symptoms of the effects of arsenic without being absent from work at all; in fact, the majority of them would have that, I should say.

11745. And those would not be reported?—No.

11746. You have seen cases that have not been reported, and seen their progress?—Yes.

11747. Poisoning by arseniuretted hydrogen is rare, is it not?—Yes.

Dr. Thomas  
M. Legge.

Arseniuretted  
hydrogen  
poisoning.

11748. But it has occurred, has it not, in certain instances where hydrogen was being evolved during a manufacturing process in which hydrochloric acid was used that was highly arsenical?—Yes. In a manufactory of bleaching powder there were three cases, with two deaths; in a chemical works for making zinc chloride there were 13 cases, with one death; and in a galvanising iron works there were seven cases, without a fatal result.

11749. Were those all due to arseniuretted hydrogen?—They were believed to be due to arseniuretted hydrogen. The symptoms in the galvanising iron factory were much slighter than in the others, and the evidence was not so strong there, although the symptoms pointed more to arseniuretted hydrogen than to anything else.

11750. But there was no death in that instance?—

Dr. Thomas  
M. Legge.

27 Mar. 1903.

its symp-  
toms.

Poisoning  
from ex-  
posure to  
arsenical  
dust.

Symptoms  
are of local  
irritation;  
neuritis rare.

Arsenic in  
dust  
probably  
insoluble.

Arsenic in  
green tapers.

That is so; it involved absence from work in most of the cases for about three weeks. The cases were severe to that extent.

11751. Broadly speaking, what are the symptoms of such poisoning?—The typical symptom is coppery jaundice, which develops in the course of from 24 to 48 hours, and hæmoglobinuria.

11752. Poisoning of that kind has almost nothing in common with the symptoms of chronic poisoning due to arsenic in beer?—There is practically no resemblance at all. Arseniuretted hydrogen poisoning acts powerfully in destroying the red blood cells.

11753. Poisoning among workers exposed to arsenical dust arises occasionally, does it not, in factories of emerald green and sheep dips, and also among men in Cornwall who roast arsenical ore to obtain arsenic?—Yes; the symptoms in all those cases are very much alike—irritation of the skin and mucous membranes, without, as a rule, symptoms of paralysis or neuritis. They are local symptoms.

11754. The symptoms are not felt acutely, and there is not much pain?—No; it causes very considerable discomfort, but it does not undermine the health in the same way, for instance, that persons exposed to salts of lead suffer.

11755. When the sufferer gets over the attack is he the worse for it, or does he get quite well again?—He gets quite well.

11756. There is nothing cumulative in the system?—Nothing, as far as we can judge, except that they do get pigmentation of the skin undoubtedly. This is the notification received of a case from an emerald green works only three weeks ago. (Document handed in.)

11757. What is emerald green?—Aceto-arsenite of copper.

11758. It is not the same as Scheele's green?—I think it is. The paper I have handed in is quite typical of the cases notified from these emerald green works, but it is more severe than many of them.

11759. How does the poison obtain access to the workmen—from dust?—Yes, from very fine dust indeed.

11760. From inhaling dust?—From the dust alighting on the skin, and also from such dust as gets on the fingers being rubbed on the face and other parts.

11761. Is an abrasion injurious?—I should say that it is. I think the dust generally lodges in a crack, and there acts as an escharotic. The eczema is most prominent round the corners of the nose, the ears, the eyes, and the mouth.

11762. Can you suggest any reason for the difference that is presented between this poisoning and the poisoning from arsenicated beer?—Except that in beer the arsenic would be in solution.

11763. The substances that you speak of in the dust are not commonly called soluble?—I should say not.

11764. Is emerald green soluble?—I do not quite know what the solubility of it is. It dissolves entirely in an excess of alkali and in acids.

11765. But not in pure water?—I should say not.

11766. Can you say, approximately, how many works there are where emerald or Paris green and sheep-dips are made?—There are about three factories in which emerald green is made on any scale, and perhaps 10 in which sheep-dip is made.

11767. What is emerald green used for chiefly?—As an insecticide.

11768. Not for a pigment?—To some extent, but far more largely as an insecticide. I do not think it is used in the manufacture of wall paper now.

11769. These two wax tapers (produced) are said to contain 5·32 per cent. of arsenious acid, of white arsenic. Do you think these are made with emerald green?—I should think it is quite likely.

11770. Is emerald green used in ordinary green wax tapers?—I was not aware that it was.

11771. There is a prodigious proportion of arsenic in these wax tapers?—Yes.

11772. These tapers have been sent by an excellent chemist (Mr. William Thomson, of the Royal Institution Laboratory, Manchester), who says that the quantity of arsenic tri-oxide in each has been tested, and that he has found it to amount to 5·32 per cent. of the whole weight

of the tapers?—It is used to some extent as a pigment still.

11773. These tapers would be very dangerous things on a Christmas tree, or anything of that kind; a great deal would get into the air if they were burned?—Yes.

11774. Is there any evidence that heavy drinkers are more affected than other workers by industrial arsenical poisoning?—None whatever, I should say; I have no evidence on that point.

11775. I notice you state "Emerald or Paris green." Is that the same thing?—I believe it is exactly the same thing.

11776. You do not know what substances are now coloured with emerald green?—No, beyond that it is used as a pigment. I have seen it used in railway wagon works for painting crests, and I have seen it used at Woolwich Arsenal in painting.

11777. And in paint shops is emerald green used as a pigment?—They make a little of it.

11778. Does sheep-dip contain arsenious acid?—Yes, arsenic sulphide and free arsenious acid.

11779. Can you say whether the workmen suffer more in making sheep-dip or in making emerald green?—Much greater in emerald green, I should say. In the manufacture of sheep-dip a peculiar condition of erosion of the septum of the nose is brought about.

11780. I see you say that the men do not know that they have had perforation?—All do not know. The perforation is similar to that found very commonly among men working in factories where bi-chromate of potash is packed.

11781. Does bi-chromate of potash act as a poison similar to arsenic?—It does, very largely, in the same way, creating sores on the skin, especially where the bi-chromate gets into cracks or folds in the skin.

11782. Those perforations will cause permanent destruction of that part?—Quite, but it is limited. It does not involve the whole of the septum of the nose, so that there is not much disfigurement in the cases where it has occurred.

11783. Have you personally examined into the state of health of men employed in roasting arsenical ore to recover arsenic?—Superficially only.

11784. Has this ever been made the subject of expert medical inquiry?—Not of expert medical inquiry, but the conditions of work have been carefully gone into in a report by Mr. Gould, the late Deputy Chief Inspector of factories, and Mr. Martin, one of the Inspectors of Mines.

11785. Where are the arsenic mines chiefly?—In Cornwall.

11786. Is it got from pitch-blende?—I think the ore there is called mundic.

11787. (Sir William Hart Dyke.) This small schedule that you have given us in your précis of cases covers the three years, 1900, 1901, and 1902; have you extracted that from the Home Office report?—Yes; they are summarised every year by myself in my annual report to the Chief Inspector.

11788. What is the scope of this schedule?—It represents the cases which have been reported under Section 73 of the Factory and Workshop Act.

11789. Throughout England and Wales?—Throughout the whole of the United Kingdom.

11790. These are the total cases that have come under your cognisance?—Yes.

11791. I see that in 1900 there were 14 cases in chemical works and three deaths, but that in the two succeeding years there was not a single case nor a single death. Can you explain that?—The whole of these cases occurred in two chemical works, and they were all due to the same cause—the evolution of arseniuretted hydrogen in the vat affecting a group of men all working together.

11792. Was that due to any carelessness on the part of those conducting the works, or was it the result of a new process?—In the factory where there were ten cases, they were pouring rather impure hydrochloric acid on to zinc in a large open vat in the open air, in order that the fumes might get away completely, but in order to protect the men against rain and bad weather they had put a little lean-to roof close by for them to take shelter under, and on the particular

hydrogen  
poisoning.

Thomas Legge. day in question—it was a sultry day—the lean-to roof seems to have caught the fumes and kept them there, and the men who were working anywhere near that shelter suffered.

11793. It was an accidental circumstance, then, owing to this lean-to roof being put up?—Very largely. It would have been possible for the firm before that to have made arrangements for carrying away the fumes into a tall chimney.

11794. Do you consider that the present machinery of inspection at the Home Office is sufficient to safeguard these workers in factories and elsewhere?—I should say so.

11795. There is no evidence before your mind at this moment that would lead you to advocate any amendment of the law, and any further protection than that now afforded?—No, I should say not.

11796. (Sir William Church.) Can you tell me whether emerald green and Paris green are the same? I thought they were distinct?—I believe they are the same, but I could not be positive on the point.

11797. What number of men do you think are employed in the colour industry where arsenical pigments are made?—I should not think there are more than two to three hundred.

11798. In London?—In the whole of England. There are not more than two or three hundred coming into contact with these arsenical colours. In this particular factory, where most of the cases have occurred, the work is so arranged that the men do not come into contact with the emerald green more frequently than for one day once or twice a week.

11799. (Chairman.) Where are those factories?—This particular factory is in the north of London.

11800. Is emerald green sold as a finished product, as a powder?—Yes, to be mixed with oil for paint, or, I suppose, to be mixed with water and sprayed on to the roots of trees.

11801. (Sir William Church.) Assuming that it is the same as Paris green, it is really made for an insecticide?—Yes, I believe great quantities of it are exported to America for destroying the Colorado beetle.

11802. There is a great deal used in England, too, in fruit gardens, for dressing apple and other fruit trees?—Yes, that is so.

11803. I see that very few of these workers suffer from the ordinary effects of arsenic, such as diarrhoea?—Very few.

11804. Or abdominal pain?—I think that is probably to be accounted for by the alternation of work—that it is considered so unpleasant in its effects that they do not work at it for many days together.

11805. What are they working at in the interval?—They are packing other powders and paints.

11806. Lead paints?—Sometimes.

11807. Have you personal experience of the arsenic workers in Cornwall?—I have visited there once.

11808. With regard to these eczematous eruptions that occur in paint workers, are they similar to the ones in Cornwall, are they of the acute form?—Just the same. The only thing is that in Cornwall the workers seem to get a larger local ulcer than they do in these paint and colour works, but I do not suppose the powder is so fine.

11809. I see that in the list you have given only one amongst 25 is stated to have had pigmentation, and that person had no other symptom whatever?—Yes.

11810. How do you know what the character of it was?—I remember distinctly that it was round the eyes very markedly in that particular case. It was the case of a woman who had been a forewoman at the works for several years.

11811. But pigmentation round the eye in a woman is a very common thing?—Yes, coupled with anaemia.

11812. With or without anaemia, but especially with anaemia. Pigmentation from poisoning through beer is so very marked and quite different from the pigmentation that you get in other cases?—I was examining these people more with a view to seeing the eczematous condition, and I was not paying very much attention to pigmentation then, but it was sufficiently great in her case to specially draw attention to it.

11813. It may not have been arsenical?—It may not.

11814. Apparently none of the others had marked pigmentation. There is nothing said about pigmentation in this report in regard to Cornwall?—No.

11815. Any more than there is of neuritis?—But if you look at the symptoms in these sheep-dip cases you will see that almost everyone had very marked pigmentation, and I think it is quite likely that if one's attention had been more specially directed to the point of pigmentation one would have got evidence among them.

11816. One would have expected that in these people who handle it keratosis would happen?—Yes.

11817. That does not seem to be mentioned in either report?—Do you think it would after employment for only six weeks? The duration of employment of these women is put down here, and it is very short. You must remember that the article is only made during the six winter months. It is never made in the summer.

11818. (Chairman.) Are these cases chiefly women?—Those you are looking at are all women, but in the report I have handed in to-day they are mostly men.

11819. (Sir William Church.) Do you get any cases of arseniuretted hydrogen poisoning?—We have had no cases this year.

11820. I suppose they are all quite exceptional?—Yes. The symptoms are so little known that it is quite likely a case or two occurs which we do not hear of.

11821. (Chairman.) Why does the manufacture only take place in the winter months?—Because the demand for it is not sufficiently great to make it necessary to manufacture it all the year round.

11822. (Dr. Whitelegge.) You do not think the pigmentation is a local result?—No, not at all.

11823. You take that as a constitutional effect of the arsenic?—Yes.

11824. From what we have heard, the keratosis comes on rather late—it is a late manifestation of peripheral neuritis. You have not seen or heard much of peripheral neuritis in arsenic workers?—No.

11825. You cannot tell us anything about the arsenic affection of workers in mines?—No.

11826. It would be outside your official province? You have not heard of it?—I have heard of the severity of bronchitis amongst the Cornish miners.

11827. All the cases reported under the Factory Act would come to your knowledge?—Yes.

11828. You were saying that some cases would be so slight as not to be brought to light in that way, and that they would not prevent a man going on with his work. But that would not affect the reportability of the cases, would it? It is not like the reportability of an accident, which depends on absence from work?—No, it depends entirely on the view taken by the medical practitioner.

11829. It depends on whether it impresses the practitioner as being of sufficient importance to be called arsenical poisoning?—Yes.

11830. But arsenical poisoning, however slight, and even if it did not require absence from work, would still be reportable?—Yes, if the medical practitioner believed that it was so.

11831. Without any condition as to the absence from work?—Yes. But at the same time I must say that of the men examined at the sheep-dip works, with one exception, none were reportable cases.

11832. Why?—Because I do not think that they constitute arsenical poisoning. In my opinion they would not be so.

11833. I only want to make it clear that we are not to understand that absence from work is essential for reporting arsenical poisoning?—No.

11834. Do you know anything as to the condition of the hair in these cases? We have had some interesting evidence—I do not know how far it has been published—as to the finding of arsenic in the hair of persons constitutionally affected by it?—I thought of getting some hair, but it seemed to me that it would be difficult, in view of the very fine powdery state of both the sheep-dip and the emerald green, to get it out of the hair.

11835. Still, it would be interesting, as showing the constitutional effect?—Yes.

11836. It is a fact, is it not, that this requirement of notification of arsenical poisoning has been in force since 1895?—Yes.

Cases reported to Home Office

*Dr. Thomas M. Legge.* 11837. But that prior to the dates given here—I think the first is 1900—the statistics were not as well organised as they have been later under your charge?—That is so. There was only one case which was known to have occurred before.

11838. You have right of entry to all factories and workshops, have you not?—Yes.

11839. Do you meet with any difficulty—is your right challenged?—No.

11840. Do you have to go to places where you have

not any statutory power of entry?—Such, for instance, Dr. Thomas M. Legge, as warehouses.

11841. They would come under the Act, and you would have power of entry there? Take industries carried on at home?—Yes, I have visited some of those.

11842. Have you found any difficulty in gaining admission there?—No, but I have had to show my authority on one or two occasions.

11843. You have to prove that you are a Government official, and then there is no difficulty?—Yes.

*The following is the Statement handed in by Dr. Legge.*

#### SYMPTOMS MET WITH IN INDUSTRIAL POISONING BY ARSENIC.

The Chief Inspector of Factories receives information of cases of arsenical poisoning in accordance with the requirement of section 73 of the Factory and Workshop Act, 1901, which is as follows:—

"Every medical practitioner attending on or called in to visit a patient whom he believes to be suffering from lead, phosphorous, arsenical, or mercurial poisoning, or anthrax, contracted in any factory or workshop, shall (unless the notice required by this sub-section has been previously sent) send to the Chief Inspector of Factories at the Home Office, London, a notice stating the name and full postal address of the patient and the disease from which, in the opinion of the medical practitioner, the patient is suffering, and shall be entitled, in respect of every notice sent in pursuance of this section, to a fee of two shillings and sixpence, to be paid as part of the expenses incurred by the Secretary of State in the execution of this Act.

"Written notice of every case of lead, phosphorous, or arsenical, or mercurial poisoning, or anthrax, occurring in a factory or workshop, shall forthwith be sent to the inspector, and to the certifying surgeon

for the district; and the provisions of this Act, with respect to accidents, shall apply to any such case in like manner as to any such accident as is mentioned in those provisions."

The notifications thus received cannot represent all the cases which occur—they are samples distributed over various industries, and are useful in suggesting lines of inquiry, and indicating the direction in which remedial measures are necessary.

The requirement of the section quoted, which dates from the Factory and Workshop Act of 1895, is still not universally known to medical practitioners, as industrial poisoning of the kinds specified is usually an accident in their professional life, and not like scarlet fever, etc., an incident. No absolute definition of arsenical poisoning is possible, and each practitioner in reporting what he believes arsenical poisoning to be must form his own standard.

One case only of arsenical poisoning was reported between the years 1895-1899, viz., in the manufacture of paints and colours in 1895. The number since then has been as follows:—

	1900.				1901.				1902.			
	Cases.		Deaths.		Cases.		Deaths.		Cases.		Deaths.	
	M.	F.	M.	F.	M.	F.	M.	F.	M.	F.	M.	F.
Paints and Colours . . . . .	—	6	—	—	3	—	—	—	4	1	—	—
Chemical Works . . . . .	14	—	3	—	—	—	—	—	—	—	—	—
Galvanising . . . . .	—	—	—	—	7	—	—	—	—	—	—	—
Paper Hanger . . . . .	1	—	—	—	—	—	—	—	—	—	—	—
Brass Polisher . . . . .	—	1	—	—	—	—	—	—	—	—	—	—
Flowers . . . . .	—	—	—	—	1	—	—	—	—	—	—	—
Copper Extraction . . . . .	—	—	—	—	—	—	—	—	1	—	—	—

I have little doubt that the cases reported in a paper-hanger and brass-polisher were not due to their employment, but were probably due to arsenic in beer. No arsenic was found on analysis either in the wallpaper, which the man had been chiefly engaged in hanging, or in the composition used in the brass-polishing. In the latter case, which occurred in Birmingham, in June, 1900, the certifying surgeon definitely stated his opinion that the symptoms were due to alcoholism.

Industrial arsenical poisoning usually occurs in two forms: (1) from the inhalation of arseniuretted hydrogen gas, and (2) from inhalation of, or contact with, the dust of salts of arsenic. In the latter case there is direct manipulation of the salts, while in the former the toxic arsenical agent is present as an impurity in the substances used for one purpose or another, and the workman is, therefore, usually quite ignorant of its presence.

The symptoms from these two sources bear no resemblance to one another. The first exerts a destructive influence upon the red blood corpuscles, the second acts as a local irritant, or escharotic on the skin and mucous membrane. Neither gives rise as a general rule to neuritis or paralysis.

#### (1).—ARSENIURETTED HYDROGEN POISONING.

The cases which have come under my notice number 20, with three deaths—13 in 1899 and seven in 1900. The source of the poisoning in each case was believed to be impure hydrochloric acid.

The cases occurred in three works (a) in the manufacture of bleaching powder (three cases with two deaths), (b) in the manufacture of zinc chloride (15 cases with one death), and (c) in galvanising iron (seven cases without fatal issue).

In addition to these which may be said, strictly speaking, to have been contracted in factories and workshops, mention should be made of the following, recorded by Layet\* :—

(i.) Nine persons (1876) engaged in a silver mine in pouring hydrochloric acid on to argentiferous zinc to extract the silver were attacked, and three died. Arsenic was found in all the organs analysed.

(ii.) Four Italians, vendors of coloured india-rubber balloons for children, after filling them with hydrogen gas, obtained from commercial sulphuric acid and common granulated zinc, were attacked, and one died. The room in which they carried out the operations is

\* L'Hygiène Industrielle. Paris, 1897, pp. 495-497.

Dr. Thomas  
M. Legge.

Mar. 1903.

described as having had a cubic capacity of about 700ft., and to have been ventilated only by a broken window-pane.

(iii.) The deaths of two aeronauts from the escape of gas from balloons.

Other sources of arseniuretted hydrogen poisoning, which have been described by Layet, but of which I have no knowledge, are:

(i.) The manufacture of aniline colours by the action of arsenious acid on aniline oil. I believe this process is now discontinued.

(ii.) The manufacture of cobalt.

The train of symptoms resulting from the inhalation of the gas are characteristic:—

In the course of a few hours there is shivering, followed by weakness, headache, vomiting, rapid weak pulse, and collapse. After some eight to ten hours, and later, the destructive action of the gas on the red blood cells shows itself in haemoglobinuria, and in very severe cases anuria. After twenty-four hours jaundice appears, and usually becomes of an intense coppery hue. Death may occur within twenty-four hours, but in the majority of cases is delayed until the lapse of a week or more. Recovery in the mild cases is slow.

I append particulars of the cases which have come under my own notice (see pp. 457-566 of the Annual Report of the Chief Inspector of Factories for the year 1900, and p. 234 of the same for 1901), and of others of which I have been able to find record. Reference is there made to the work of Dr. Dixon Mann and Dr. Gray Clegg\* which summarises much of our knowledge on this subject. They describe in detail the pathological changes observed in two fatal cases.

In discussing the nature of the icteric hue of the conjunctiva and skin they conclude that, although the rapid occurrence of this symptom after the appearance of free haemoglobin in the blood plasma gives support to the view that the jaundice is of haematogenous origin, the weight of evidence is in favour of the liver being concerned in the "production of jaundice in all cases, even in those in which, owing to destruction of, or injury sustained by, the red corpuscle, free haemoglobin is present in the general vascular system."

Almost all the cases of arseniuretted hydrogen poisoning contracted in factories or workshops appear to have been due to work which has been carried on in confined spaces, or under conditions in which the means for the removal of the gases evolved were inadequate, and the remedy, therefore, is obvious.

## (2).—POISONING BY SALTS OF ARSENIC.

The principal industries giving rise to lesions from this source which have come under my notice are: (1) The extraction of arsenic; (2) the manufacture of Paris or emerald green; and, (3) the manufacture of sheep dip.

Poisoning from the use of Scheele's green in the manufacture of wall-papers or of artificial flowers, is not now believed to occur, as other pigments have been substituted for it. Other industries in which arsenious acid is used, and in which injurious cutaneous effects have been noted (although I have no personal knowledge of them) are—the preservation of hides and skins, the use of caustic potash and arsenious acid as a depilatory in tanneries, and its use in dye works.

(1.) *Extraction of Arsenic*:—Arsenical ore (mundic) is roasted and the arsenic thus volatilised is deposited in flues from which it is collected and again roasted and again deposited in flues. The white arsenic thus obtained is ground in a covered-in machine, and while being ground it is automatically packed in barrels, thus obviating dust.

The symptoms among the workers are eczema, and the development of ulcers where the skin has been broken. I have no doubt that pigmentation would be observed if looked for.

The precautions taken in addition to those mentioned are the provision of overalls, respirators (handkerchiefs), washing accommodation, baths, and protection of abraded surfaces.

The subject of alleged injury to health, as carried on in this industry in Devon and Cornwall, has recently been made the subject of inquiry and report by Mr. Gould, late Deputy-Chief Inspector of Factories, and Mr. Martin, Inspector of Mines.

(2.) *The Manufacture of Emerald Green and Paris Green*:—I have seen the manufacture on any scale carried on in one factory only. All the reported cases (four in male workers and seven in females) occurred there. The lesions are marked, but limited to the cutaneous, catarrhal, and gastro-intestinal types. In the extracts from the Annual Report of the Chief Inspector of Factories for the year 1900, I give the symptoms noted among the female workers. The manufacture takes place only in the winter months, and appears to depend largely on the prevalence of the insect pests which these insecticides are used to destroy.

The conditions of work in this factory were made the subject of Home Office inquiry in 1893, in consequence of publicity given to the alleged injury caused to the workers.

The process of manufacture consists essentially in dissolving sulphate of copper in water. To this is added a solution of arsenite of soda, made by boiling arsenious acid in a solution of soda. Acetic acid is added to this. The precipitate of emerald green so formed is well-washed in water. Thus far the workers run no risk, as there is no exposure to dust. By means of cloth filters the water is removed, and the clay-like mass is dried in a stove. The dried material is emptied into a hopper, in which operation dust is created (now minimised by a fan draught). The colour is next mixed in a revolving enclosed cylinder-sieve, and finally packed in small cases, which are placed under hoods connected with a fan draught. The powder is extremely light and fine, and "flies" readily.

Precautionary measures adopted in processes involving exposure to arsenical dust, in addition to the fans (which are, of course, the chief), are overall suits and head coverings, respirators, washing accommodation, and baths, alternation of employment (no man being allowed to work more than one day in seven). Periodical medical examination once a week has been instituted since 1899.

(3.) *Manufacture of Sheep Dip*:—The manufacture is carried on in about ten factories and workshops, of which I have recently visited four. I append the result of the superficial examination of 18 men employed in the largest of them. Perforation of the septum of the nose had not been mentioned to me in any of the factories visited as one of the effects of the employment. On the condition of No. 12 being noted, I was informed that they were the symptoms which would be presented by nine out of ten persons on commencing work. None of the men examined confessed to injury to health from their employment. Sheep dip is an arsenite of soda containing arsenic sulphate and free arsenious acid. The process of packing gives rise to considerable dust.

Precautionary measures taken are to cover over the grinding mills and sieves. In two factories the finely ground material is conveyed to the packing benches by means of a continuous worm. Overalls, head coverings, and respirators (of cotton wool, and held in place, as shown in the diagram opposite p. 41 in Mr. Gould's Report) are habitually worn by workers exposed to dust. Washing accommodation is provided, and in some factories baths also. Machinery for carrying out grinding and packing automatically is to be installed in the principal factory shortly.

The perforation of the septum of the nose is similar to that which occurs to workers in bichromate factories. A portion only is attacked—the anterior, and inferior margins remain free, and thus rigidity of the parts is maintained and deformity absent. Necrosis of the central portion is accounted for by the fact that the mucous membrane covering it is adherent, forming the perichondrium, and is far less vascular than the mucous membrane lining the rest of the nasal fossae. It is the seat of election for the dust to alight upon, and once the mucous membrane is destroyed, the blood supply to the cartilage is cut off, and necrosis ensues. The morbid process is ushered in by sneezing, and the ordinary symptoms of nasal catarrh. Pain accompanying it appears to be very slight, and it is certain that many of the men were unaware of the perforation.

Ulcers on the hands, as intense as those frequently found among bichromate workers, were not observed. Workers, however, do require to protect abrasions, as there is a tendency for them to ulcerate if dust gets

\* Medical Chronicle, Vol. III. (New Series), p. 161, 1895.

† Report forwarded to Commission

Dr. Thomas  
M. Legge.

27 Mar. 1903.

to them. Occasionally the scars of such ulcers were noted—more commonly, perhaps, on the hands of those engaged in the extraction of arsenic than in the others. Slight conjunctivitis is common. The throat is markedly congested, but the symptoms of hoarseness so noticeable in workers in emerald green is much less common in those handling sheep dip. Pigmentation was most characteristic around the eyes, and on the temples, neck, chest, and in the armpits. It appears to get less pronounced after many years' work. Affections of the nails and hair were not observed.

History of definite gastro-intestinal, or of nervous affections was not forthcoming.

Arsenious acid enters as an ingredient into the composition of enamels—especially of those used in the manufacture of enamelled copper letters. Several analyses of these have been made in the Government Laboratory, which show that lead is present to the extent of about 40 per cent., and arsenic from 5 to 8 per cent. I have examined many workers exposed to the dust, and while evidence of lead absorption is abundant, I have not had my attention drawn to symptoms attributable to the deleterious action of arsenic.

Dr. Thomas  
M. Legge.

M. L. J. Gge.  
27 Mar. 1903.

# TWENTY-NINTH DAY.

Friday, 3rd April 1903.

AT 1, CHAPEL PLACE.

PRESENT:

The Right Hon. LORD KELVIN in the Chair.

The Right Hon. Sir WILLIAM HART DYKE,  
Sir WILLIAM CHURCH.

Professor THORPE.  
Dr. WHITELEGGE.

Dr. BUCHANAN, *Secretary*.

Sir HENRY PRIMROSE, re-called; and Examined.

Sir H.  
Primrose.

Action taken  
by Board of  
Inland  
Revenue  
since former  
evidence.

11844. (*Chairman*.) I believe we are to have information from you as to the action taken by the Board of Inland Revenue since the date of your last appearance before the Royal Commission on May 3rd, 1901?—Yes. The next stage was the issue of the interim report of the Commission, which was presented in July, 1901. The last paragraph of your interim report, No. 34, was one which specially interested the Board of Inland Revenue. The paragraph says:—

"(34) To this end we recommend that the Board of Inland Revenue should possess and should exercise powers to specify in detail individual ingredients of beer which are liable from their origin or mode of preparation to be contaminated by arsenic, to prescribe for every such ingredient, and for the different materials used in their preparation, an adequate test which should ensure their freedom from arsenic, and to prohibit, under penalty, the use in a brewery of any material which infringes the prescribed test."

We at once considered that. The first thing which we had to determine was whether the Board of Inland Revenue did or did not possess the necessary powers. We were advised that we did not possess those powers, and thereupon we wrote to the Treasury drawing their attention to this recommendation, saying that we concurred in it, but that as we did not possess the necessary powers legislation would be necessary in order to enable us to carry it out. We suggested that, pending legislation, which certainly could not take place immediately, we might be doing a good deal towards getting things in order, so that when any Bill was passed we should have the necessary machinery in order; more especially in regard to determining what materials used in the preparation of beer ought to be scheduled for testing, and, further, what the test should be which those scheduled materials and ingredients should pass. The Treasury intimated their concurrence in that, but said that they wished to do something immediately, seeing that legislation might be delayed for a considerable time, probably until the presentation of the final report of the Commission. They informed us that they proposed to issue an Order under the Revenue Act of 1888 prohibiting the use in brewing of glucose or of invert sugar containing arsenic. That Order was issued in October, 1901, and simply prohibited the use in the manufacture and preparation for sale of beer of any glucose or invert sugar containing arsenic. That would give us power to seize any beer in which such materials were used, and impose a penalty of £50 upon any brewer who used it. We drew the attention of the trade to that Order in a circular of November 14th, in

which we urged that, pending any further Orders, they should, at any rate, always insist upon a warranty with such articles, and we pointed out that any brewer who accepted materials of that class without a warranty would incur considerable responsibility. We further said that we should exercise much greater stringency in supervision in any case where we knew that a brewer did not require that warranty. I have already sent copies of that circular and of that Order to you, but I am not quite sure whether they have been printed, so I will hand in these.

Prohibition under Section 5 of the Customs and Inland Revenue Act, 1888, of the use in Beer of certain substances.

Whereas it appears to the satisfaction of the Lords Commissioners of His Majesty's Treasury that glucose containing arsenic and invert sugar containing arsenic are substances which are capable of being used in the manufacture and preparation for sale of beer, and that the said substances are of a noxious and detrimental nature.

Now the said Lords Commissioners, under the power conferred upon them by Section 5 of the Customs and Inland Revenue Act, 1888, do hereby prohibit the use in the manufacture and preparation for sale of beer of any glucose or invert sugar containing arsenic.

Dated this 10th day of October, 1901.

N.B.—A penalty of £50 is imposed by the said Section for any breach of this prohibition.

W. H. FISHER.  
H. T. ANSTRUTHER.

Notice to Brewers of Beer for sale, and Makers and Vendors of Glucose and Invert Sugar.

5352-01 E

Inland Revenue Office,  
Somerset House,  
London, W.C.  
November 14th, 1901.

The Commissioners of Inland Revenue desire to invite the attention of brewers of beer for sale and makers and vendors of glucose and invert sugar to the notice which was published in the "London Gazette" of the 15th ultimo, and of which a copy is subjoined. By this

Issue of  
Treasury  
Order pro-  
hibiting use  
of arsenical  
glucose and  
invert sugar  
in prepara-  
tion of beer.

Sir E.  
Primrose.

notice the use in the manufacture and preparation for sale of beer of any glucose or invert sugar containing arsenic is prohibited.

The Commissioners are aware that precautionary measures have already been taken by brewers and by makers of glucose and invert sugar in this country, and they also understand that, in many instances, the delivery of these goods is accompanied by an invoice which contains a written warranty that they are free from arsenic.

The Commissioners hope that brewers will in no case accept delivery of glucose or invert sugar unless accompanied by such a warranty, and they think it well to intimate that the absence of such a warranty must materially increase the responsibility of a brewer, and must of necessity lead to greater stringency of supervision on the part of the Board's officers.

The object of His Majesty's Government in causing this notice to be issued is to ensure as stringent precautions against the introduction of arsenic into beer as are possible in the present state of the law, and of scientific knowledge as represented by the first report of the Royal Commission on Arsenical Poisoning.

In that report the Royal Commission recommended that the Board of Inland Revenue should possess and should exercise powers to specify in detail individual ingredients of beer which are liable, from their origin, or mode of preparation, to be contaminated by arsenic; to provide for every such ingredient, and for the different materials used in their preparation, an adequate test which would ensure their freedom from arsenic; and to prohibit, under penalty, the use in a brewery of any material which infringes the prescribed test; and the Board of Inland Revenue take this opportunity of informing you that they are engaged in considering the fuller measures that may be necessary to carry out these recommendations, or so much of them as His Majesty's Government may eventually decide to adopt.

The Board have reason to believe that the recommendations of the Royal Commission will meet with the approval generally of the trades concerned, and they trust they may count on receiving from their members co-operation and assistance in framing the details of any system that may be devised for carrying them into effect.

J. B. MEERS, Secretary.

(The copies were handed in.)

Then the next step was to issue instructions to our officers with reference to this Order. Those instructions dealt with what samples they were to take. The order was that they were to take one sample of finished glucose and one of invert sugar per month from each maker of these articles for examination as to the presence of arsenic. We have power to do that as regards glucose. As regards invert sugar, I think it has to be done, more or less, with the consent of the makers, but, inasmuch as invert sugar-makers and glucose-makers are commonly one and the same people, no difficulty has arisen in that connection. Then, as regards brewers, we ordered that one sample a month of the glucose or invert sugar should be taken from them, but only from such brewers as are known to receive imported brewing sugars without a warranty of freedom from arsenic. Having sampled freely at the factories, we did not consider it was necessary to take so many samples from the brewers, except in the case of imported sugar, where they did not accept a warranty. Those samples have been regularly taken in accordance with those orders, sent to the Government Laboratory, and there analysed. I hand in copies of our instructions.

Circular to Supervisors.

5352-01 E.

Inland Revenue,  
Somerset House,  
London, W.C.

November 14th, 1901.

Sir,

The Board direct me to acquaint you that they have prepared a notice for issue to brewers of beer for sale and makers and vendors of glucose and invert sugar, calling attention to the prohibition of the use in the manufacture and preparation for sale of beer of any glucose or invert sugar containing arsenic; and I am to instruct you to cause a copy of the notice to be served without delay upon every trader concerned in your district.

The necessary supply of the notices should be obtained from the Controllor of Stamps and Stores by application in the usual manner.

Further instructions as regards the taking of samples will be issued in due course.

I am, Sir,

Your obedient servant.

J. B. MEERS, Secretary.

Extract from Instructions.

#### 12. Samples of Glucose and Invert Sugar.

In connection with the recent prohibition of the use in the manufacture and preparation for sale of beer of any glucose or invert sugar containing arsenic, the Board direct that one sample of finished glucose and one of invert sugar, per month, be specially taken from each maker of these articles, for examination for the presence of arsenic.

As regards brewers, it will be sufficient to take (in addition to the samples of materials at present taken for testing their brewing value) a sample, monthly, of glucose or invert sugar from such brewers only as are known to receive imported sugars without a warranty of freedom from arsenic.

The samples should be taken and forwarded to the Government Laboratory in accordance with the regulations for sampling contained in the general instructions. The general label form 77-1 should be used, and the name of the maker and the words "To be tested for arsenic" inserted thereon, as well as in the advice letter. In the case of samples sent from breweries, the name of the importer or merchant, in addition to that of the brewer, should be given.

11845. (Sir William Hart Dyke.) That monthly taking of samples only takes place in those cases where the material is imported?—Yes; in regard to breweries, we should only take samples of the imported sugar, as a rule, because we have already sampled all the British factories, and, therefore, it did not seem necessary to take many samples from the breweries.

11846. But after the issue of this Order you have full powers to do so?—Yes, we certainly could do so.

11847. Your powers are full enough in regard to taking these samples monthly, when and where you like in the breweries?—Yes. I will now state the results of the sampling carried out in conformity with the above orders:—

(1) *Makers of Glucose and Invert Sugar.*—From these 185 samples of glucose and 224 samples of invert sugar have been taken. Of the 185 samples of glucose, 92 have been found free from arsenic, while 93 showed traces in no case exceeding 1-250th grain of arsenious oxide per lb. Of the invert sugar, 94 samples proved free; 127 contained less than 1-250th grain per lb.; while three contained more. In no case did the arsenious oxide exceed 1-100th grain per lb.

(2) *Breweries.*—The number of samples taken, and the results of analysis, are shown in tabular form, as follows:—

Samples obtained from brewers using imported glucose if no warranty as to arsenic.

Results of sampling.

at British sugar factories;

and at breweries.

H. 11848. (*Chairman.*) I notice you have not confined  
yourself to taking samples merely of glucose; you  
have taken samples of malt, maize, and rice, and other  
1903. ingredients used in brewing?—Yes.

11849. But the Order of the 14th November, 1901,  
mentions only glucose and invert sugar?—That is so.

11850. But in virtue of this Order, you have taken  
also samples of other ingredients?—Yes; because under  
our general powers we have power to take samples of  
any material that is used in brewing. I have handed  
in two tables. The first table shows the number of  
samples taken, and classifies them according to the  
quantity of arsenic found to be present in them. Those  
that have been discovered to be entirely free from ar-  
senic are shown in the first column, where it will be seen  
that there are 677 absolutely free out of a total of 1,225.  
Those in the second column are those which, though  
not absolutely free, contain arsenic in quantities less  
than 1-250th grain per lb., which would be equivalent  
to 1-100th grain per gallon of beer. That accounts for  
another 507 of the total of 1,225. The third column,  
which totals to 41 altogether, are those samples in  
which arsenic was found to a greater extent than  
1-250th grain per lb. The samples in the first, which  
are absolutely free, and the samples in the second  
column we may regard, I think, as negligible. The  
only interest which attaches to the table is to the 41  
samples in the third column. Then Table 2 gives a  
complete list of the 41 samples, with the quantities of  
arsenic found. It will be seen that the first 20 or so are  
all small. In all the cases in Table 2 where malt was  
found to contain arsenic to the quantity named, we  
always drew the attention of the brewers to that fact,  
and warned them that the malt was not such as ought  
to be used. I think in no case have we found any re-  
luctance on the part of the brewers to recognise and  
accept our advice—in fact, they have, as a rule, thanked  
us for drawing their attention to it, and I think in  
every case we have been satisfied that the malt has  
not been used after they received our notice.

11851. I see the greatest quantity amounted to  
1-50th grain per lb.?—Yes.

11852. How much would that amount to per gallon  
of beer?—About 1-20th. That is much the worst case.  
I have brought with me a certain number of papers,  
which show exactly what we did. We drew the brewers  
attention to this matter, and this was their reply:—

"We thank you for your letter of the 16th inst., re  
malt, and beg to state we have only 1qr. 6 bushels of  
that especial malt, which has been sent to the stables  
for horse food, and will on no account be used in  
the brewery."

Probably, Professor Thorpe will remember that in this  
particular case the brewers sent samples to their own  
chemist, who gave rather a different result.

11853. (*Professor Thorpe.*) I do not remember about  
the different result. I know they did, as a matter of  
fact, have it analysed again, but I do not quite know  
with what result?—I do not attach much importance  
to it, because we cannot be quite sure that the sample  
was taken in the same way, or that the same quantity  
was tested.

11854. (*Dr. Whitelegge.*) Was the control analysis  
made after the Government laboratory examination?—  
Yes. The report of the brewery chemist is dated March  
3rd, 1903, whereas the laboratory report is dated the  
12th February, 1903, so that the brewery analysis was  
made nearly three weeks afterwards.

11855. (*Chairman.*) In the particular case, where so  
much as 1-50th grain of arsenic per lb. was found in  
the malt, was the origin of the malt traced?—No, not in  
that case; but there are several cases in which it was.  
In this case they did not mention where they got the  
malt.

11856. It was taken in a brewery?—Yes; but there  
is nothing said as to where it was obtained. Then,  
immediately below the malt samples, we give the  
samples of articles, of which many were submitted to  
us for permission to use. Among them are regenera-  
tors and malto-peptones. The latter, I suppose, is a  
yeast food. You will notice that there are three cases  
of malto-peptones; in all those cases we refused to  
allow the material to be used at all, and none of it, I  
think, was used, because they would have to obtain our  
sanction to its use before they could use it. In the  
first instance, they sent it up to us, and we informed

them that it was not fit for use, and that they must  
not use it, so that none of it, as a matter of fact, would  
get into beer.

11857. What is malto-peptone, and what is it used  
for?—It is used as a yeast food—I do not know what it  
is composed of.

11858. Is it not used in brewing?—It is not used  
directly in brewing.

11859. Was this sample taken in the brewery?—Yes,  
all these samples were taken in the brewery.

11860. Did the brewers intend to sell it for other  
purposes than brewing?—No; they sent it up to us  
with an application to be allowed to use it. I think I  
have the correspondence in one case, which will show  
you exactly how the subject was dealt with.

11861. (*Sir William Hart Dyke.*) With regard to you  
prohibiting the use of this malto-peptone, have you  
full powers to prohibit the use of such an article?—  
Yes; there are materials of a kind that a brewer may  
only use with our permission under the ordinary law.

11862. (*Chairman.*) Was it for the purpose of brew-  
ing that the brewers wished to use the malto-peptone?  
—Yes, it was. This is a schedule of the samples sent.  
Two samples of malt, two samples of sugar, one sample  
of grain, and one sample of malto-peptone. Perhaps  
Professor Thorpe knows, but I believe we have sanc-  
tioned the use of the malto-peptone in a general way.

11863. (*Professor Thorpe.*) Yes?—Then it is not a new  
thing? When I said that none of these might be used,  
I should not have referred to malto-peptone; I was  
thinking of the next one on the table, the peptomide.  
But in this case they sent up malto-peptone with other  
samples, and we informed them that they should be  
acquainted with the presence of arsenic in excess in  
the malto-peptone, with a view to its immediate discon-  
tinuance in use and its removal, and the result should  
be stated. This is their answer:

"January 14th. We are obliged for your letter,  
and have at once communicated with the makers.  
In the meantime, we have stopped using it, and had  
it all removed from the brewery premises."

11864. (*Sir William Hart Dyke.*) Would that prohi-  
bition in regard to this particular firm stay there, or  
extend to the trade generally?—It would only refer to  
this particular specimen.

11865. Not to the use of the article, generally, in the  
trade?—No.

(*Professor Thorpe.*) Some malto-peptones are quite  
right.

(*Chairman.*) What is malto-peptone? Is it a substi-  
tute for malt?

(*Professor Thorpe.*) It is not a substance actually used  
in brewing; that is to say, in the conversion of the  
starchy matter of the grain to alcohol; it is used merely  
as a food for the yeast.

(*Chairman.*) How much of it would get into the beer?

(*Professor Thorpe.*) Very little, probably none.

(*Chairman.*) A small quantity would be used in con-  
nection with a large quantity of yeast?

(*Professor Thorpe.*) Yes. It consists mainly of soluble  
phosphate associated with nitrogenous matter.

(*Chairman.*) Has it anything to do with digestion?  
Peptone is something digestive?

(*Professor Thorpe.*) It is not peptone in that sense;  
it is simply a name given to the ingredient by the trade.

(*Chairman.*) What is the substantial value of it in  
connection with yeast?

(*Professor Thorpe.*) It is a sort of concentrated food  
which is given to the yeast to cause it to grow and  
multiply more rapidly than it otherwise would.

11866. (*Chairman.*) (*To the Witness.*) At all events,  
the use of these specimens was forbidden?—Yes, those  
particular things, and in every case they were at once  
removed.

11867. I notice there is another new name here—pep-  
tomide?—I think that is a preparation of the same  
kind. In that case we prohibited its use by the brewer,  
and we informed the maker also.

11868. Can Professor Thorpe tell us whether the use  
of this malto-peptone and peptomide are new-fangled  
methods in breweries?

Sir H.  
Primrose.

3 April 1903.

Sir H.  
Primrose.

3 April 1903.

(Professor Thorpe.) No, they are pretty old now.

(Chairman.) But new names have been given to them?

(Professor Thorpe.) They are names given to these preparations of yeast food. Peptomide is somewhat similar to malto-peptone, but is prepared, I believe, from yeast; they are proprietary articles.

(Chairman.) Are they old things to which new names have been given?

(Professor Thorpe.) I should think they have been used for some years past; for 15 or 20 years, certainly. They are scheduled in the report, which Sir Henry Primrose will refer to, as ingredients or materials which are liable to contain arsenic.

Arsenic in  
beer "re-  
generator";

11869. (Chairman.) (To the Witness.) I notice there is a "regenerator" in the list which seems to be very rich in arsenic?—Yes. That, I think, is used for improving beer that has turned sour, or has been returned as sour. The regenerator is used with the object of seeing whether they cannot work it up in any way so as to make it fit for consumption. You will notice there are two cases in the list where the quantity was 3-10th. of a grain and 7-10th of a grain.

11870. (Chairman.) What is a regenerator?

(Professor Thorpe.) It is a very crude carbonate of potash, which is used to neutralise the acetic acid which is in the beer.

(Witness.) In the second case in which that large quantity of arsenic occurred in the regenerator we intimated to the brewer that we could not allow him to use it, and we also sent a letter to the people who had made it, warning them of the quantity of arsenic that it contained. We did that last December, but I cannot find that we have heard from them since.

(Professor Thorpe.) I can supply the members of the Commission with the facts of that case, if you have not them on the papers. The makers of that article, on receiving the letter from the Board, came to see me about it, and gave me the history of the whole thing. The material came from France, and they threw it back upon the persons who sold it to them.

in "beer  
softening"  
material;

(Chairman.) I notice there is a "beer-softening material" which contains 7-10th of a grain of arsenic per lb.

(Professor Thorpe.) That is used for softening the water.

11871. (Chairman.) Is that prohibited?

(Witness.) That would be prohibited. I have not the actual facts of the case here, but I fancy that would be one of the articles which they would ask us to be allowed to use.

11872. It would depend on what quantity of it was used as to how far it might poison the beer. If a very small quantity was used in a large quantity of beer it might possibly not cause the beer to be injurious to health?—Probably that would be the case—that only a very small quantity would be used for softening the water.

11873. For softening the water before commencing the mash?—Yes.

in glucose;

11874. Then the results of the analyses of samples of glucose, colouring solution, and caramel are given. In the case of glucose, I see that one sample contained 1-120th of a grain; that is about twice the 1-250th in the other cases?—Yes. In both the cases of glucose mentioned in Table 2 we warned the brewer. We instructed our officer to inform the brewer that the samples of glucose contained more arsenic than should be present, and instructed him to call the traders' attention to the laboratory certificate of analysis. The report received was: "Trader informed of the analysis; use of this glucose discontinued."

in colouring  
solution;

11875. I notice that the sample of colouring solution contained 1-40th grain of arsenic per lb. Was any order made with reference to that?—A very small portion of that would be used in a barrel of beer.

11876. So that probably that would not add 1-200th of a grain to the beer itself?—I should think not.

11877. Was that allowed to pass because it was a very small quantity?—I think in all the cases given in this table it may be taken that we have practically stopped the use of the particular material.

(Professor Thorpe.) I should like to make that quite clear. Because a substance is only used in a small

quantity, we have never considered that a sufficient excuse for the use of arsenicated material.

Sir H.  
Primrose.

3 April 1903.

11878. (Chairman.) It appears from Table 2 that the samples of caramel were largely arsenicated; they contain  $\frac{1}{4}$  and 1-5th of a grain of arsenic per lb.?—Yes. In both those cases we informed the people that the substance was absolutely inadmissible for use in brewing.

11879. Then I notice there is a "hop compo" containing  $\frac{1}{4}$  grain of arsenic per lb.?—Yes. That was rather a remarkable case, because not only arsenic, but antimony in a very large quantity was present—25 grains per lb. We immediately sent an inspector down to the counter- place to thoroughly investigate the facts, and it proved to be the result of an accident. The material was made by a chemist, who also made horse powders—powders that are given to horses to make their coats shine—and he had apparently used the vessel in which he had been making the horse powders for making this hop compo.

in "hop  
compo."

11880. (Sir William Church.) Do you know what hop compo consists of?—I suppose it was a hop substitute. I have the particulars of that case, I think.

(Professor Thorpe.) I can supply you with the particulars, if you would like to know them. It consists of a large proportion of hops.

(Sir William Church.) The question I want to know is: did it contain hops?

(Professor Thorpe.) Yes, with a considerable proportion of an astringent bitter, chiretta, and tannic acid.

(Sir William Church.) I only wanted to know whether "hop compound" really did contain hops at all. I suppose it is probably made of inferior hops, which have lost their flavour, and then flavoured with another bitter.

(Professor Thorpe.) I know nothing about the quality of the hops.

(Sir William Church.) You did not estimate the amount of lupuline?

11881. (Chairman.) Is there any legal way of applying severe punishment for such a fearful piece of carelessness as preparing an ingredient for brewers in a vessel that has been used for arsenic and not washed?—The law does not give our Board any power. I do not know what power the local authority might have. Also, I do not know whether, under the laws relating to chemists, there can be any punishment for such a thing as that. When we sent our inspector we told him to at once put himself in communication with the officer of the local sanitary authority, because we felt we had no particular power to deal with it, and that our business was to set them to work to examine into it.

11882. Was the person who made this mistake a manufacturing chemist supplying materials to a brewery?—Not, I think, on a large scale. I will see what the report of our inspector actually was.

11883. (Sir William Church.) The chemist would only be liable to a civil action by anybody who was damaged by using improperly prepared material?—That, I should imagine, would be the case. This is what our inspector reported: 18 parts of hop, 12 parts powdered chiretta, three parts tannic acid. The following certificate had been given by Mr. Norman Tate, of Liverpool, dated 30th November, 1882: "I hereby certify that I have made a careful examination of A.B. Hop Composition, and find it to be composed of vegetable matter capable of imparting to malt liquors an agreeable bitter flavour, and of good keeping qualities. There is nothing of an injurious character present. I consider this compound to be a good tonic bitter, possessed of properties which render it an excellent substitute for hops in the brewing of ales and other malt liquors." Apparently, the sales in 1883 were upwards of 150. The purchasers were either brewers in a small way or agents. No name of any importance appears in the list. In the following year the sales fell off considerably, and the decline was still more marked in subsequent years, until on the 29th April, 1896, the credit sales appear to have ceased altogether. Since then a few ready-money sales of small quantities have been effected, but of them no record has been kept. Therefore, of late years it has been very little used. Since hops have been cheap there is no particular inducement to use it.

11884. Was that particular hop composition tested in February, 1903?—That is so.

11885. Was that a residue of an original composition, or has it been made up at different times from 1887

11887. till 1903 in small quantities?—Yes; only in small quantities, I gather.

11886. Was it made by the same maker who made it originally?—Yes. He says the firm is highly respectable, and does a good business, but, apparently, largely in veterinary medicines of various kinds, and it was that which produced the accident. When they were first told of it they said they could not conceive how it happened. It was only on going into the details of their business that it was brought out pretty clearly that that was what had happened—that they had used the same vessel for this stuff that they had used for some of their veterinary compositions.

11887. That accident occurred in the establishment of the manufacturing chemist who sold it?—Yes.

(Professor Thorpe.) I should like to add that the arsenic was an impurity of the antimony. Arsenic, presumably, is not present in the hops or in the chiretta, or in the tannic acid.

(Chairman.) It presumably came in with the antimony?

(Professor Thorpe.) Yes. Arsenic is a very frequent concomitant of antimony. Most antimonial preparations contain small quantities of arsenic.

11888. (Chairman.) Have you heard of the case of a manufacturing chemist in London who very nearly caused the death of a son of Mr. Ludwig Mond by making a mistake in his factory through putting in arsenic powder instead of another white powder?—Yes. I seem to have seen something about it in the papers.

11889. I do not know whether an inquiry was held at the time, or whether there was any question of taking steps to prevent such an accident?—That would hardly come within our province.

11890. Knowing what the present state of legislation is, does it appear to you that some protective legislation is wanted to diminish the liability of such accidents?—I do not really feel able to speak about that. My impression is that there is already sufficient responsibility imposed upon chemists. They have to be properly qualified, and I suppose they have to take the consequence of any mistakes they make.

11891. And the mistakes their workmen make?—Yes.

11892. (Dr. Whitelegge.) Do you refer to the pharmaceutical chemists or chemists in the broader sense?—Pharmaceutical chemists.

11893. The manufacturer to whom you are referring was a pharmaceutical chemist?—Yes, he was. I do not know whether Dr. Thorpe heard anything more from the medical officer of health in that particular case.

(Professor Thorpe.) No.

11894. (Sir William Hart-Dyke.) In regard to the question of forbidding the use of these articles, as you have done, in brewing, will you tell us about what percentage of arsenic you take as dangerous?—I think, according to this classification here, we should not draw the attention of the brewer to a less quantity of arsenic than 1-250th grain per pound, or 1-100th grain per gallon.

11895. Speaking generally, that would be about the percentage?—Yes.

11896. Do you think there should be a fixed standard of the amount of arsenic which would cause danger to the consumer?—I do not know that I am very well qualified to speak about that. I should like, if I may say so, first of all to finish my evidence, and then hand in the report of this Committee on Tests, copies of which I have already furnished to the Secretary. The idea of the committee was to enable the Commission to form a judgment as to what should be said upon a point of that kind. The table on page 11 of the report gives certain graduated rates of arsenical contamination, and it would be open to the Commission to select some one or other of the degrees in that table as a standard for the tests to be officially prescribed.

11897. This report which you have handed in is for the purpose of assisting the Commission in coming to some conclusion as to a standard?—Yes.

11898. And you think it would be well for them to do so?—That is what the Board are hoping the Commission will do.

11899. Do you think if that were done on the authority of the Commission it would be of assistance to the Board in future in carrying out their duties of protecting the public from danger?—Yes.

11900. In your notice of November 14th to the brewers you mention, do you not, that your Board have been considering fuller measures which might be necessary?—Yes.

11901. And you indicate, do you not, what direction you think those measures should take?—That was intended to refer to the recommendation of this Commission that we should possess and exercise certain powers. That merely refers to the fact that we were considering whether we should take steps to obtain from Parliament those powers.

11902. The powers which we indicated in the first report of the Commission?—Yes.

11903. I think the Chairman put a question to you with regard to whether you should not possess some punitive power—for instance, in cases of gross carelessness, whether it would not be better that you should be able to signalise your authority more emphatically by having some power of punishment in such cases?—I do not think it would be easy to give us powers in reference to the makers of materials. Our powers, I think, ought to be limited to dealing with the brewers and the brewing trade rather than that we should go outside.

11904. In fact, you would not like, as regards administration—that is, the protection of the Revenue—to go outside your original sphere of duty?—No.

11905. You rather indicated, I think, when you first gave evidence before us, when you were pressed on the matter, that there would be a difficulty in dealing with this question?—Yes.

11906. I think you were rather afraid, were you not, that there would be grave difficulty in trying to go outside your duties as laid down by Parliament, if you were to go in for a crusade for the protection of the public against poisoning? I think you said another Department had better do that?—I think the view of the Board has always been that we should limit ourselves as closely as possible to what is our special duty, namely, collecting the revenue; but I admitted on the last occasion when I gave evidence, if I remember right, that inasmuch as the collection of the revenue creates a certain machinery, it might be usefully used for the protection of the public health in this matter, and that within reasonable limits I thought the Board ought to accept certain responsibility in that direction.

11907. Speaking generally, do you think what you have done already is about as far as you ought to go for the absolute protection of the public?—I think it is.

11908. I am not criticising what you have done—I think your Department have done a great deal—but do you think you have gone as far as you ought?—I think we have gone as far as we ought or as far as we can with the existing law. But I am quite in favour of amending the law so as to give the power that is contemplated in the first report of this Commission, of enabling us to require brewers to see that they use no ingredients or no materials that do not satisfy a certain test, and that having considered the report of this Tests Committee, and on the advice of this Commission we should then say that no ingredients should be used that would not pass such and such a standard in this table.

11909. That would be giving you much greater powers of administration, would it not?—Yes.

11910. It would be extending the supervision which you now exercise to a much greater power of administration?—It would give us this power, that in the event of our discovering materials in a brewery which did not satisfy the required test, it would enable us to lay our hands upon them. Our position now as regards malt is this, that however badly contaminated it may be, we have no power to do anything except to tell the brewer that if he uses it he uses it at his own risk, and in a bad case we should do as we did in one of the cases mentioned in the table, where the malt was very seriously contaminated—warn the brewer that he must not on any account use it, and unless he guaranteed that he did not, and satisfied our officer that he did not, we should communicate with the medical officer for the district, and then of course he would run the risk of having his beer sampled in the public-house.

11911. All the larger breweries have their own analysts, have they not?—Yes, I believe nearly all of them have.

11912. And therefore a letter such as yours of November 14th would have a great effect, would it not, amongst all the brewers in forcing them to take the greatest possible care in regard to their tests?—Yes. I think we

Action by  
Board of  
Inland  
Revenue as  
to arsenic  
and relation  
to revenue  
questions.

Sir H.  
Primrose.

3 April 1903.

have every reason to be sure that the brewers themselves would really welcome legislation and intervention on our part of that kind. It is to their interests to be protected from the risks of such another occurrence as took place two or three years ago.

11913. You are aware, perhaps, that under the Sale of Food and Drugs Act there is no power of doing what you are able to do in your own Department—there is no power of entry for the purpose of examining materials in the process of manufacture?—No.

11914. Either in food or in the case of a brewery?—Yes.

11915. But you are aware of the fact that the Sale of Food and Drugs Act gives the power of testing samples of the finished material?—Yes.

11916. Therefore, as regards yourselves and the Local Government Board, you have a power which very much exceeds anything which the Local Government Board possess under the Sale of Food and Drugs Act?—Yes, that is so.

11917. You have full power to test every one of those articles as you have done in this case, and although you have no punitive power, you can give a severe warning to the brewer in regard to the use of the articles?—Yes, we have a right to take a sample of any article in a brewery that is used in the manufacture of beer, and to test it.

11918. It may be outside the scope of your Department, but I should like to ask you a question on this point. You have had some experience in dealing with this question, but, of course, you are restricted to the brewing trade, I apprehend?—Yes.

11919. Do you think it would be a good thing to extend the powers of the Sale of Food and Drugs Act, so as to give the power of examining samples and of entry to the premises of manufacturers to the Local Government Board?—That is rather a big question. My personal opinion would be that if it were established that there was any real necessity for it, then I think perhaps it ought to be done, but I think it ought to be fully established that there is in particular cases such a risk to the public health that some sort of Government intervention and control is necessary.

11920. You think it would be a rather hazardous step to take unless there was some very obvious danger as regards poisoning or injury to the public health?—Yes.

11921. And that that should be well established first before we ought to ask Parliament to grant such an amendment to the Sale of Food and Drugs Act as would give a right of entry to premises at all times?—I do. After all, the difficulties of determination are very considerable. The consequences of a mistake, say, on the part of an analyst who condemned something on insufficient grounds, might cause very serious loss and great inconvenience.

11922. I suppose you have had much greater facilities placed at your disposal in dealing with brewers and others connected with the trade in the last year or two, after what has been termed the Manchester scare?—Yes.

11923. And you have found in several cases that the trade have been very anxious to meet you in every way, and give you every information and facility?—Yes, that is most marked.

11924. (Sir William Church.) Taking these two tables and leaving malt out of consideration, is there any reason that you see why the other substances should not always be absolutely arsenic free; these are things which the Revenue have allowed to be used in beer, in addition to what are the proper and normal constituents of beer?—Yes.

11925. Is there any objection whatever to it being laid down that any of these substitutes, whether they be yeast foods, or hop substitutes, or preservatives, should all be arsenic free?—I think not, with possibly one exception, and that is glucose. I think, from the method of its manufacture, a trace of arsenic would very often appear, and that to get it absolutely free would be extremely difficult, quite as difficult as, say, with malt. I suppose that with malt a very slight change in the fuel used and so on would produce a trace of arsenic in the malt. In the same way it is my impression that from the method of the manufacture of glucose faint traces of arsenic might be found in a very large number of cases; that is to say, if you insisted upon absolute freedom from arsenic in glucose

you might have to reject very large quantities of that article which are really perfectly safe and harmless.

11926. According to Table 1, only two samples of glucose contained more than 1-250th of a grain of arsenic per lb.?—That is so; but you see that a very considerable quantity, 130, did contain traces.

11927. But what is your opinion with regard to the other substances which are used in smaller quantities, and which are not necessary really in the production of beer?—I do not see any objection to insisting upon absolute freedom in their case. There is also this to be said, that they are used in very small quantities.

11928. That does not matter. It seems to me that in regard to peptomides and regenerators and beer softeners and colouring solutions and hop compounds, there is no reason why it should not be laid down that if used at all they should be absolutely arsenic free?—No, I see no reason either.

11929. Passing away from those ingredients, and considering the glucose and malt together, seeing that such a very large percentage of the materials that you have examined would give less than 1-100th of a grain per gallon in the finished beer, would there be any hardship in laying down 1-100th of a grain as the standard, so that allowing, as is going to be suggested to us to-day, a 25 per cent. margin for error by the analytical chemist, any beer in which 1-75th of a grain of arsenic per gallon was found, would necessarily be condemned?—I should say not. I think with these figures one would say that would not be an excessively exacting test.

11930. At all events, you say there would be no difficulty in brewers working to a standard of 1-50th of a grain per gallon?—No, certainly not.

11931. And you do not think there would be any real interference with the trade in making them work to a standard of 1-100th of a grain per gallon?—No. I think, looking to the very small proportion of the 1,200 odd samples that we have taken, which are, I think, very representative of the general materials used, and looking at the very small proportion of those that have, as a matter of fact, been found to contain arsenic equal to 1-100th of a grain per gallon, there would be no hardship in fixing that as a standard.

11932. Whether it gets in through the malt or through the glucose seems to me to be immaterial so long as your finished beer is harmless?—Yes.

11933. I suppose you would lay down as your standard for glucose a more stringent test than for beer. Glucose, I take it, is a substance that you can keep under observation much easier than you can malt?—Certainly.

11934. And, therefore, you might have a more stringent and more constant examination of glucose than of malt, and it would be desirable that the amount of arsenic that was allowed in glucose should be smaller than the amount which was allowed in malt?—It seems to me that you might have the same standard when converted into grains per gallon.

11935. I was proposing that you should have a still more stringent standard for glucose. Supposing 25 per cent. of glucose was used in brewing, I was proposing that it should contain, say, not more than would give 1-500th of a grain of arsenic per gallon in the beer?—I do not quite see it. Of course, as regards the use of glucose for other purposes than beer, it may be another question. As regards beer, would there be any particular object in fixing a higher standard for glucose than for malt with reference to the quantity of arsenic that would appear in the beer?

11936. There is no need for glucose to contain arsenic. Although it is likely to contain traces of arsenic, as we see from the table, there is rather a larger proportion which is returned as arsenic free than as containing arsenic?—That is so.

11937. And, therefore, as it is a substance over which you can easily keep a close inspection, why should there not be a fairly stringent test for it?—That is a point which may be worth considering. Looking to the insidiousness of arsenic, and to the difficulty of absolutely keeping it out from such an article as glucose, I think it would be rather hard upon the glucose makers to impose too stringent a test. I am rather inclined to think, as far as dealing with beer is concerned, it would be better to consider a standard with reference to wort or beer than with reference to the material.

11938. I am afraid I have not got the references.

Certain  
brewing  
ingredients  
might be  
required to  
be free from  
arsenic.

Sir H.  
Primrose.

3 April 1903.

No hardship  
in requiring  
a "standard"  
of  $\frac{1}{100}$  grain  
per gallon  
in beer.

Stringency  
of "standards"  
for glucose  
and malt.

but I think we have had evidence from glucose makers that there would be no difficulty in manufacturing glucose so that it would not contain more than an infinitesimal part of arsenic?—If that were so, I should see no objection at all. I am speaking without knowledge of what would be an unduly severe test on glucose makers.

11939. Do you think that if it were laid down that all beers containing more than, we will say, 1-75th or 1-50th of a grain of arsenic per gallon in the finished article should be destroyed or condemned, that that would impose any insuperable difficulty on the brewer?—No, I do not suppose it would.

11940. (*Dr. Whitelegge*.) I understand that the Committee's report is intended to prescribe certain tests, is it not?—Yes.

11941. Have you understood that in the sense of prescribing methods of analysis as distinct from prescribing standards?—Yes. I understand that the Committee recommend that particular method of analysis. I do not know whether it would be necessary to make it imperative, but I should think it would be better to require that the standard should be with reference to the method of analysis—that the standard should be understood to include the method of analysis as recommended in this report.

11942. But, given the methods of analysis which the Committee recommend, do you regard their report as proposing the standards?—Do I understand this as recommending the standards?

11943. Yes?—I understand the report to leave that open for further consideration. It gives the material for fixing a standard, but does not itself recommend any definite standard.

11944. Then, if I follow you rightly, you think the Commission should now consider standards upon which the Board of Inland Revenue might work?—Yes. What the Board are hoping is that the Commission, taking this Committee's report, will give some indication as to the scale of tests in the table on page 11 of that report, and suggest some one at which we might draw the line, and say that anything that would not pass it must be prohibited and not allowed to be used.

11945. The table on page 11 specifies different quantities of different groups of substances to be taken for analysis?—Yes.

11946. For example, 10 grammes of malt are suggested, but only 5 grammes of sugar; do you regard that as a suggestion that there should be a more lenient standard for the one than for the other?—No. I am afraid I am not sufficiently acquainted with the scientific part of the subject, but I understood that as merely representing convenient quantities.

11947. For the convenience of analysis?—Yes.

11948. But consistently with the general assumption that arsenic ought to be kept out as far as possible? I think you told us, in regard to the individual cases that have come under the notice of the Board, the smallness of proportions in finished beer should not be accepted as an excuse for a large percentage of arsenic in the ingredient?—No. I think we should have power to deal with the ingredients to the extent of being able to stop their use. I believe the brewing interests would prefer that for the purpose of legal proceedings there should be some stage in the process of manufacture taken as the point at which analysis should be made, preferably the wort stage. But, apart from the question of proceedings in the way of prosecution, I think we ought to be able to lay our hands, so to speak, upon articles that were largely contaminated with arsenic, and order them not to be used.

11949. Make it penal to use them?—Yes.

11950. Which would not be altogether consistent with an exclusive standard for wort or finished beer?—No, I should not have a wholly exclusive standard. As a matter of fact, I do not think there would be any real question of proceeding on the materials, because I cannot conceive that a brewer who was informed that certain materials were seriously contaminated would care to go on with them.

11951. In reference to malt and chemicals, the legal position is the same as it was before the Order of 1901 was issued?—Yes, the Order of 1901 only affected glucose and invert sugar.

11952. I understand that was an Order of the Treasury, not the Board of Inland Revenue?—It was an Order of the Treasury under the Revenue Act of 1888.

11953. If the Treasury had thought fit, I suppose there was no legal reason against going further and specifying other ingredients, such as malt?—No. I cannot myself see, if it was right to prohibit glucose or invert sugar, why you should not equally have prohibited malt. As a matter of fact, I think the reason why nothing was said about malt was that first of all not nearly as much was known then as is known now as regards the extent to which malt is capable of being contaminated with arsenic; and in the second place it was perhaps going too far; it was, in other words, imposing on brewers a task that was pre-eminently a difficult one of determining how and when and what things were contaminated. It would have applied to the whole of their materials.

11954. Have the officers of the Board of Inland Revenue power to enter the premises of maltsters for sale?—No, not maltsters.

11955. The tables which you have given us state the seriousness of the arsenic contained to two degrees; first, as I follow it, where the proportion of arsenic which it would impart to beer does not exceed 1-100th of a grain per gallon?—Yes.

11956. And the other in which it does exceed that proportion?—Yes.

11957. I suppose that is adopted as a standard in a general way only, and it proceeds on the assumption that there is no other arsenic added to the beer?—Yes.

11958. So that if we had arsenic contributed to the same beer by different ingredients, the finished beer would contain far more than the 1-100th that the other ingredients might yield?—That no doubt might be so.

(*Professor Thorpe*.) Would you mind repeating the question; I did not hear it thoroughly?

(*Dr. Whitelegge*.) The finished beer might and must contain more than 1-100th of a grain if each of several ingredients were contributing at the rate of 1-100th of a grain.

(*Professor Thorpe*.) It depends on the amounts used. I should like to point out with reference to that question exactly how these particular quantities in the Committee's report which were selected for testing were selected by the members of the Committee. I may remind the Commission that the general principle on which we went was that it had been proved that beer made with due attention to carefulness on the part of the brewer could contain and did contain less than 1-100th of a grain per gallon of arsenic. There seemed to be, therefore, no particular reason why a sample of beer should contain more, because it had been proved to us, by the analysis of a large number of samples, that a great many of them did contain less. Having determined that a sample of beer need not contain more, when manufactured with ordinary attention to care in the selection of materials, we then proceeded to lay down convenient amounts of the several ingredients, such that none of them when used in very much larger quantity than they conceivably could be used would contribute arsenic to the beer to the extent of 1-100th of a grain. The quantities of malt, for example, taken for the test, the quantities of invert sugar taken for the test, the proportion of hops taken for the test, the proportion of chemicals which may be used, preservatives, and so forth, are always far larger than would be present in a gallon of beer containing 1-100th of a grain of arsenic, so that, as a matter of fact, the individual tests applied to the ingredients are far more rigorous than they are either to the wort or to the finished beer. What I mean is, assuming that every one of these ingredients passed its test, then it is inconceivable that the beer should contain an amount of arsenic up to 1-100th of a grain.

(*Dr. Whitelegge*.) Even if all contained a little arsenic and were added together?

(*Professor Thorpe*.) Yes; the finished beer or the wort would not contain as much as 1-100th of a grain.

11959. (*Sir William Hart Dyke*.) Is there any evidence that guarantees given by importers of glucose, or attached to their agents, can be relied on as a safeguard?—I do not know that we have any positive evidence on that point. Some of the manufacturers of glucose, certainly the largest manufacturer of glucose, has a well equipped laboratory and very competent chemists, and I should imagine that any guarantee given by him would be very trustworthy. I do not know to what extent other glucose manufacturers may do the same.

(*Professor Thorpe*.) I think you may inform the Com-

mission that there are only seven or eight manufacturers of glucose, and that they all have chemists.

11960. (Sir William Hart Dyke.) I do not know whether you are aware of the fact that we have had evidence as to the way in which American glucose may be guaranteed. For instance, one witness states at Question 8794: "The merchant does not have it analysed, but he guarantees it in that guarantee to the broker. The broker does not have it analysed, but he guarantees it on the merchant's guarantee to the consumer. So that they guarantee a thing of which they have no personal knowledge whatever." I did not know whether you were aware of that?—No.

No drawback  
claimed on  
arsenical  
beer since  
1901.

11961. Have you any knowledge in regard to the destruction of beer since 1901; have any brewers claimed rebate on account of beer which they found contained too much arsenic and consequently had destroyed?—I do not recall any cases of that kind; in fact, I cannot recall any case since the Manchester scare in which we have had an application. I think in one of the cases on that list a certain amount of the beer was destroyed, but they did not make any claim for the duty.

Court of  
Reference.

11962. We have had various recommendations regarding the establishment of a scientific court of reference to determine standards of purity in foods and food

ingredients; do you think it would be an advantage to the Board of Inland Revenue, in cases where health questions were involved, to have such a body to refer to?—I do not feel that we ourselves are in need of such a body; I think we are satisfied with our own staff.

11963. With reference to the precautions which you have taken in the last year or two, has that involved any addition to your staff?—No.

11964. You have been able to carry it out without any addition to the staff?—I do not think we have had to add to Dr. Thorpe's staff.

11965. (Professor Thorpe.) No, not in consequence of this?—We certainly have not added to the Excise staff.

11966. (Sir William Hart Dyke.) Of course, if you had larger powers thrown upon you of administration that might involve an increase in your staff?—I do not think so, if we did not go beyond what the Commission has already recommended; I do not think it would add seriously to our work. After all, it only means taking a certain amount of samples.

11967. You have machinery there; that is the great point?—Yes, we have the machinery, and the mere existence of the machinery would probably prevent any great mischief.

Mr. ALFRED HENRY ALLEN, called; and Examined.

Mr. A. H.  
Allen.

11968. (Chairman.) You are an analytical and consulting chemist, and have been in practice in Sheffield for upwards of 30 years?—I have.

11969. You are a Fellow of the Institute of Chemistry, a Past-President of the Society of Public Analysts, and now a Vice-President, and you are Public Analyst for the West Riding of Yorkshire, the City of Sheffield, and several smaller boroughs?—I am.

11970. You have had an extensive experience in the analysis of articles purchased under the Sale of Food and Drugs Act, and have, within the last few years, analysed numerous samples of beer, with the object of detecting contamination by arsenic?—Yes. In many instances arsenic has proved to be present. The maximum quantity I have met with has been about one grain per gallon. In many instances the proportion of arsenic was very small, frequently under 1-1000th of a grain per gallon, expressed in terms of arsenious oxide. In some other cases arsenic was detected, but the quantity must have been much smaller than that. I am prepared to detail, or, at any rate, to outline the method I used for examination, if it is of interest to the Commission, but otherwise it is on record. I do not know that I need trouble the Commission with the details of the process, unless Professor Thorpe desires it.

11971. Was the maximum quantity of one grain of arsenic per gallon found in the beer in which Bostock's sugars were used?—I do not know the origin of all the beers that came to me; they came to me under the Sale of Food and Drugs Act with numbers, and I have no means of tracing their origin.

11972. (Professor Thorpe.) From the local authorities?—Yes. There is no doubt that in some cases arsenic was present in the malt used, as we know it is apt to be on the outside of the malt; and in other instances I know that the brewers were customers of Bostock's, and that the beers must have been derived from Bostock's stock, but I know nothing about some other cases.

11973. (Chairman.) Ordinarily, at present, is the amount of arsenic in beer under 1-1000th of a grain per gallon?—Since attention has been directed to the matter, the brewers and maltsters have been more careful, and it is much less than that, as a rule; in fact, I constantly report that I am unable to find any trace of arsenic. Since the trouble arose, brewers and maltsters have frequently sent samples to me privately to know whether they are free from arsenic, and the majority of them now show no arsenic reaction. Of course, if you took a sufficient quantity, I have no doubt you would obtain evidence of the presence of extremely minute quantities of arsenic, but I am speaking from a practical point of view; the amounts are below 1-1000th of a grain per gallon—quite insignificant.

11974. Could you tell it was below 1-1000th of a grain per gallon; do you discriminate between 1-300th and 1-1000th of a grain?—I can get indications, giving quantities roughly down to 1-700th of a grain. If it is some-

thing less than that, I talk of it as a 1-1000th of a grain, more or less.

11975. What process of analysis have you employed?—I formerly employed a process of determination based on precipitation of the arsenic on metallic copper, as in Reinsch's process, resolution of the arsenical deposit by an oxidising agent, and distillation of the solution thus obtained with fuming hydrochloric acid and a reducing agent. The distillate contained all the arsenic in the form of arsenious oxide, and its amount was determined after neutralisation by titration with a very weak solution of iodine. The results by this process were very satisfactory, and I repeatedly proved the method to be capable of giving accurate results. I had, however, the disadvantage of requiring the use of a considerable quantity of beer, not less than 500cc. being requisite, and twice this quantity being desirable. Hence, at the time I employed this process, it became necessary to make small purchases of beer, with a view of ascertaining if arsenic were present; and then to purchase large quantities, at least one gallon, for the purpose of a quantitative determination, on which a certificate could be based. I have now abandoned the above process in favour of the Marsh-Berzelius method, employed with certain precautions. I think this process the best at present known, or, at any rate, it is the best known to me, for dealing with minute quantities of arsenic, and it has the advantage of being available with a very small quantity of beer. The results are only approximate, but this fact being recognised, they are sufficiently exact for practical purposes.

11976. I believe you were one of the members of the Joint Committee of Public Analysts and Chemical Industry?—I was.

11977. So that you have now had considerable experience of the working of the tests?—Yes. In other words, I was in the minority in using a modified Reinsch process; for a long time I could not succeed well with the Marsh-Berzelius process, but ultimately, with certain precautions, which I thought and think essential, I got excellent results, and have never had a bad result since. So that I have modified my opinion. I always regarded the process I used to employ as clumsy, and requiring an undesirably large quantity of beer; but now I can get good results, more satisfactory results, and, I think, quite as accurate results, by the Marsh-Berzelius process with quite small quantities of beer.

11978. Do you get as satisfactory results by the Marsh-Berzelius process with small quantities of beer as you formerly got with large quantities by the Reinsch method?—Yes.

11979. As satisfactory?—As satisfactory.

11980. And as approximately accurate?—Yes, accurate enough for our purposes.

11981. Do you approve of prescribing any process of analysis officially?—No. I deprecate the official pre-

Sir  
H. Primrose.  
3 April 1903.

Mr. A. H.  
Allen.

Use of  
Marsh-  
Berzelius  
method.

Arsenic in  
beer now  
brewed often  
below  
1-700th or  
1-1000th  
grain per  
gallon.

A. H. Ten. 1903. description of any process of analysis, however excellent, as being practically fatal to improvement in the future. Having in view the fact that the Marsh-Berzelius process is an arbitrary one, in which exact attention to details is essential, the personal equation in its employment is considerable. On this account, if any limit of arsenic is recommended by the Commission, it is desirable to leave a margin for unavoidable differences in the analytical results. Thus, should it be the opinion of the Commission that 1-100th of a grain of arsenious oxide per gallon of beer is the maximum amount which should be tolerated, the official limit recommended should not be less than 1-125th grain, thus allowing 20 per cent. of the total for divergencies.

11982. (Chairman.) You say the official limit recommended should not be less than 1-125th of a grain; should not that be not greater than 1-125th?—No, it is less; in other words, they should prescribe that the amount of arsenic should not exceed 1-125th, and, therefore, the limit should not be less than 1-125th.

11983. What principle do you follow in reporting on samples of beer?—In reporting on samples of beer, I am in the habit of stating that "the sample contains a material quantity of arsenic, I estimate the proportion of arsenic present at . . ." In the event of very small quantities of arsenic being found, I state that "A minute trace of arsenic was present, but the quantity was too small to enable any determination to be made." There are such things as very zealous authorities anxious to secure absolute purity of food and drugs, and sometimes one finds it desirable to certify in such a manner as to show that the quantity of arsenic is very minute; and, therefore, although one is bound to say one finds it, yet, if no determination can be made, it practically precludes any possibility of proceedings, and that is the reason why I have adopted these two alternative forms of statement in my certificates.

11984. When you estimate the proportion present at so much, do you mean to say it is less than, not greater than?—No; I give the result as obtained by the Marsh-Berzelius process.

11985. You estimate it?—I ascertain by analysis the proportion present at so much.

11986. Supposing it was so small as 1-250th of a grain, what would you say?—I should not have said that the quantity was a material quantity. If it were less than 1-250th, or down to that, I should, under usual circumstances, report that there was a minute trace present and avoid giving a figure.

11987. You say a minute trace present; by that, you would mean less than how much?—I think it would depend upon who I was reporting to, whether I was reporting to a sanitary authority or whether I was reporting to a brewer. In giving a certificate which a brewer can use, you want to inform him that there is arsenic there, and that he must take care; you want to convey to him that there is a trace in it, but it is so small that you cannot ascertain the quantity. That relieves his mind; but, at the same time, it makes him careful. But in the case of the sanitary authority, I should go a little further, and say the proportion was not more than a certain quantity. I have gone down to 1-500th of a grain, and 1-700th of a grain. I should state the actual figure to a sanitary authority, but, seeing that it is also said to be minute, that, of course, precludes practically any possibility of proceedings. Sometimes proceedings are apt to be initiated under the Sale of Food and Drugs Act, not on beer, but on other things on which the public analyst is not in any sense consulted, and on which they might have taken other steps to call the attention of the vendor rather than by actual prosecution, and one has to word one's certificate in such a manner as to be a guide to the local authority. In some parts of the Kingdom the inspector will proceed on any certificate which he thinks bears a construction that the article is not absolutely pure, and is not so well advised as he might be if he had to send all the offenders before a Committee, including the medical officer, and so on, who would be able to form a more decided opinion, and act, perhaps, with greater discretion. I have no doubt Dr. Whitelegge will appreciate what I mean in that way.

(Dr. Whitelegge.) Fully.

11988. With regard to articles of food other than beer, have you made any investigation?—Yes; but I have little to say, beyond what is probably already fully known to the Commission. I have strong reasons for believing that arsenical contamination has been due to

other sources than Bostock's products and malt. Thus, I found a sample of confectioners' glucose syrup, of American manufacture, to be strongly arsenical. That was not Bostock's; and the man wanted to know at the time whether there was arsenic in the syrup. He said: "Is my glucose right?" He brought it to me to analyse, and it was very strongly arsenical.

11989. (Sir William Hart Dyke.) Was there much of a percentage?—I do not remember that I determined the percentage, but it was very strongly arsenical indeed, comparable, I have no doubt, to Bostock's samples; and I told him he must not use it.

11990. (Chairman.) Was that glucose syrup imported from America?—Yes. It is used by confectioners.

11991. I understand that you have not found arsenic in any samples of jam or marmalade?—No.

11992. Glucose is used in making jam and marmalade?—Yes. We used to think that marmalade was made with sugar and oranges, but the Lord Chief Justice holds that you can put in glucose, and practically anything else. There is no definition of marmalade.

11993. How is the flavour of marmalade given?—I think it is given by the oranges chiefly. As I understand, the old-fashioned way of making orange marmalade was with oranges and sugar; but the ordinary sugar—cane sugar—is now in part replaced by glucose; and the manufacturers say it keeps better because it is less likely to candy—the cane sugar is more liable to crystallise out, and that some people think objectionable. There may, therefore, be a good practical reason for partially replacing it with glucose. I am not in any way objecting to the use of glucose in that manner, only we have not got a definition, and we suffer so much in practice under the Sale of Food and Drugs Act from the want of an accurate definition of such articles as marmalade.

11994. Is glucose as wholesome as cane sugar in marmalade?—It is equally a heat-producing food, and it is equally wholesome in the ordinary sense, provided it has no arsenic in it. I do not see that glucose is in any way a worse food than cane sugar. To certain invalids glucose would be more objectionable than cane sugar, but we are not proposing to legislate for special invalid cases. I do not object to glucose, if by glucose we mean inverted cane sugar or something which is strictly dextrose; but there are varieties of brewers' glucose on the market which contain a large quantity of dextrin and indefinite substances, the nature of which is still a matter of dispute, and I do not like introducing indefinite substances into food.

11995. Does "right-handed" and "left-handed" discriminate between cane sugar and glucose?—No, not quite. If you invert cane sugar by an acid or other means, it splits up into a mixture of dextrose or dextro-rotatory glucose and levulose or levo-rotatory glucose in equal parts. That mixture is a thing which would be produced gradually by the action of an acid, perhaps, in the boiling of the marmalade; but, while you should not use previously inverted sugar, it may be desirable that cane sugar should become inverted in the preparation of the marmalade. I do not see any objection, from a physiological point of view, to the use of glucose, if by glucose you mean this invert sugar; but if you mean glucose such as is produced largely and employed in the manufacture of beer by the treatment of starch and starch-containing products with acids, then the products are different; you have no levulose formed, but you have maltose formed, besides dextro-glucose, dextrin (a gummy substance of intermediate character), and more or less indefinite products, which we should like to know more about.

11996. Do you consider that even the best glucose is not so wholesome as cane sugar or as inverted cane sugar?—I should not like to say it is not so wholesome. I say we do not know all we should like about the glucose made from starch. We have certainly no evidence of ordinary glucose being injurious; the evidence is purely presumptive.

11997. Have you found arsenic in borax?—Yes.

11998. And in glycerine?—As a rule, there is no arsenic in glycerine. I have had hundreds of samples of glycerine pass through my hands, and I think in only two or three have I found any arsenic. In one there was 1-20th of a grain per lb. 1-20th of a grain in a pound of glycerine is a very different thing from the 20th of a grain in a pound of sugar, because you do not

Mr. A. H.

Allen.

3 April 1903.

Arsenic in confectioners' glucose.

Arsenic in borax; in glycerine, but rarely.

Mr. A. H.  
Allen.  
3 April 1903.

take glycerine by the pound as a food, as a rule. Some people may take glycerine internally, but the quantity taken internally is generally very small, and, therefore, the 20th of a grain of arsenic in a lb. of glycerine is perhaps, after all, comparable to a tenth of that amount in a pound of sugar. But, still, there is no reason why the arsenic should be there, and I think we should aim in practice at getting food products as free from notably injurious substances like arsenic as we can.

11999. Can glycerine be called a food product, or is it, technically, a drug?—A drug is defined by the Sale of Foods and Drugs Act as a medicine for internal or external use by human beings. Carbolic soap is a drug in that sense. Glycerine is used as a drug, but it is also used in food. There are various preparations for invalids in which glycerine is used. In diabetic foods they employ glycerine as a sweetening agent instead of sugar. It is distinctly used as a food, and under particular circumstances might form a very essential part of food.

12000. (Professor Thorpe.) The modern definition of a food is anything that enters into the composition of a food, is it not?—Yes. It has been extended, in consequence of Mr. Justice Hawkins' view that baking powder was not an article of food.

12001. In the Act of 1899 food is specifically defined, is it not?—Yes. According to that Act, it is specifically anything used in the manufacture of food.

12002. As a food?—Therefore, tea-leaves would come under the definition, though you do not consume them.

12003. Glycerine jujubes, of course, would be a food?—Yes—or a drug; it does not matter which.

12004. (Sir William Church.) Glycerine is put into a large number of cakes by confectioners to keep them moist, is it not?—I have learnt that from Dr. Hammond Smith's evidence. I did not know it before, but, of course, I accept it at once.

12005. (Chairman.) You consider the Sale of Food and Drugs Act, as at present interpreted and administered, does not afford a sufficient check on the introduction of deleterious substances?—I do, and for the following reasons. The authorities administering the Adulteration Acts have but imperfect knowledge as to the particular foods liable to be contaminated, and of the particular deleterious substances liable to be contained in such foods, and the public analyst is not systematically consulted as to the kind of samples which require investigation, nor is he generally cognisant of any systematic effort which may be made by the authorities. The samples sent to the analyst are distinguished merely by numbers. He reports the result of the analysis, and generally hears nothing officially as to any proceedings which may be taken. He may find reports in the newspapers if he keeps a very careful eye on them. He may, by writing to the inspector, learn what happened in respect to a certain sample. In many instances they are extremely remiss in informing the analyst of anything that has occurred. The public analyst is often in possession of the requisite knowledge with respect to substances liable to contain objectionable matters, but new forms of sophistication are continually being devised with the express purpose of escaping the public analyst, and it cannot be expected that all objectionable additions, whether accidentally or purposely introduced, can come within his knowledge. It is further, of course, out of the question to make an exhaustive examination of every sample submitted on the offchance or unlikely event of some unknown impurity being present. There seems to be an idea among the public that a public analyst has to make an absolutely exhaustive examination for every poison (and for every other substance not poisonous) of every article that comes to him. To us, of course, such a view is ridiculous; but the view is held, and sometimes public analysts have been accused of neglecting their duties, or executing them in a very perfunctory manner, because they have not gone out of their way to look for things which were not expected to be present. I am afraid I must plead that in the case of arsenic in beer. I never thought there was arsenic in beer until this Bostock case arose. I only had a sample of beer under very special circumstances, because we could not report on beer, as there was no definition of beer saying what it was to be made from, and unless you actually found something injurious there was no means of getting at the offender. Certainly it never occurred to me that people would use arsenical glucose, and therefore that arsenic would be found in beer, and I was equally ignorant of the now

well-known fact that malt is liable to contain arsenic. I confess I was wholly ignorant on the subject.

12006. (Sir William Church.) You only investigated beer for salt and water, and things like those?—That was so; and then the idea about salt being used as an adulterant died out, and the authorities said: "It is no use sending samples of beer. Really there is nothing to be done with them. We cannot prosecute for either one thing or the other, even for hop substitutes. What is the use, therefore, of knowing that beer contains these things if it is held that they are not illegal?" Therefore until the arsenic question arose I do not think I had half a dozen samples of beer a year from all my authorities, and then if I had been asked I should have recommended them not to send them.

12007. In years gone by had you never had beer sent you to investigate for things like *cocculus indicus* and drugs of that sort that were said to be put into beer?—Under the Sale of Food and Drugs Act they do not send you the beer for special investigation or for investigation for a particular purpose. I receive a sample of beer, and I have to report whether it is "genuine." Many years ago I met with a beer taken under the Sale of Food and Drugs Act, of which a public analyst sent me a sample. It was before the days that Somerset House was made referee, so it is a long while since. I distinctly confirmed his conclusion that there was tobacco in the beer. I got very distinct evidence of it. I have looked in former days for *cocculus indicus*, and I have never found it. At one time I was actively interested in hop substitutes, and did find those, but nothing came of it. Of recent years I have never looked for such things as *cocculus* in beer, nor do I believe that they are used. In those days, when there were private brewers, and every little country publican at a public roadside house could brew his beer as he liked and from what he liked, there was a tendency to put in these things. Brewers' druggists went round and said, "Put in this, that, and the other, and it will do your beer good." But in these days, when the beer is almost invariably brewed in large breweries, where large quantities are made, and where the Excise officers are always around, and would spot a bag of anything wrong in the corner, I do not think that such things are used at all. Brewers are only too anxious to make a good, honest beer. They may say they make it cheaper from malt substitutes than from malt, but that we have had out before. My impression is that they are anxious to make a good article, and that we get a much better article than we did in the old times. I do not believe in these injurious substances being used on the sly. They cannot be used on the sly under present conditions.

12008. (Chairman.) In your opinion, any additional information respecting the liability of impurities, such as arsenic to get into articles of food would be welcomed, but I understand that past experience does not encourage you to believe that any central or local authority could be entrusted with the duties of collecting information?—That is so. The authorities are busy. The only officer they have whom they could consult, apart from the public analyst—who very often is at a distance, and is not present at their committee meetings—is the medical officer of health, and in some cases he is a busy man, with a great deal to attend to, and perhaps a private practice. In other cases, where the sanitary authority is a large one, he devotes his whole time to his duties, of which the purchase of samples under the Sale of Food and Drugs Act is a very limited part, and although he would be pleased in most circumstances to act on any hint or suggestion conveyed to him by the public analyst, it does not occur to him spontaneously that a thing wants looking into; and the authority are only advised by him. We really want to be better in touch with the sanitary authorities. One of the difficulties at present existing is that public analysts for different districts do not see each other's reports, and are not officially aware of the results of analyses in other distant parts of the country. In Sheffield I have, as an act of courtesy, a copy of the quarterly reports sent to me bound up with the Council Minutes, and I have it for my own satisfaction. In the West Riding I have a copy sent to me in the same way, and if I asked for them I could get two or three more copies; I do not think I could in Sheffield, because the quarterly reports there are included as part of a big volume. I never see my reports to the smaller boroughs; I suppose they send them up regularly to the Local Government Board—I have no doubt they do, as a

rule—but some of the authorities habitually lose them and ask me for copies. Ultimately they go up, but I do not see them, and I do not see other public analysts' reports. There are one or two cases where it seems to be the practice to publish a large number of copies in pamphlet form, and then the public analyst sends it to a few of his friends, but he cannot send it to everybody in the country, even if he has a list. The most complete list of public analysts was that in connection with the Sale of Food and Drugs Act handed in in evidence by Mr. Thomas to the Committee on Food Products Adulteration; but it was erroneous in several important particulars as to fees and terms of appointment; so even the Government have not got the particulars. Then, the annual report of the Local Government Board appears very tardily, and only summarises the adulterations met with in such a manner as to detract very much from its value. In other words, we learn only from the Local Government Board report—published, perhaps, a year or so after its nominal date—that Mr. So-and-So, of such a town, has found something as an adulterant. That is all we know about it. Of course, there is a certain amount of co-operation among public analysts—we have our Society's meetings, and so on, and there a good deal of chat goes on as to the way these things are done; but it would be very much better if the annual reports of public analysts, if not their quarterly reports, were published formally. Remember, the annual report is not a formal report—the law requires a quarterly report; but the annual report is a statement which the authorities are glad to have, because it enables them to see once a year what has been done, instead of wading through quarterly returns. A public analyst is under no legal obligation to furnish an annual report, although the local authority may like it.

12009. But he is under a legal obligation to furnish a quarterly report?—Yes.

12010. Could not the summarising in the quarterly report be thoroughly satisfactory instead of unsatisfactory, as you find it now, and so dispense with an annual report?—The quarterly report should be as full as it can conveniently be made, and I would suggest that it should be part of the regulations that it should be printed in sufficient numbers to enable the Local Government Board to send it round to all the other analysts, so that we might know what others are doing. Personally, I find that my annual report in the West Riding gives me an opportunity of commenting upon defects in the working of the Act, which opportunity I have not in the quarterly reports. We are tied down formally in a quarterly report more than we are in an annual report, I think.

12011. (Sir William Hart-Dyke.) You are speaking here of the provisions of the Food and Drugs Act?—I am speaking of the working of the Adulteration Acts, which term also includes the Margarine Act, and so on. I should be sorry not to have an opportunity of making an annual report. At the same time the quarterly report is the formal one which we are bound to make. You see sometimes a quarterly report is limited to a comparatively small number of samples, and you get a better purview really of the condition of affairs at the end of the year than you do at the end of the quarter. As a matter of fact, it has been my practice in the quarterly report to give a slight description of all adulterated samples, and to say the rest were genuine, and in reference to anything which has been specially interesting, I have generally paraphrased the wording of my certificate. In the annual report I give a table, which takes a very considerable time to compile, stating the number of samples of each particular kind examined during the year and their source, as there are a large number of sanitary authorities existing in the West Riding, each one of which is liable to send me samples. That makes the annual report a very troublesome one, and I am very glad I have not to give a quarterly report to these little sanitary authorities, who send, perhaps, half a dozen samples of milk a year. It would be a nuisance to have to make quarterly reports to them; but they are all included in the West Riding report. I do not grudge the trouble of compiling the statistics, because I think they are useful and valuable, and I should be sorry to be told, "Well, you must put everything you want to put in into the quarterly report," because, as I say, you do not get that general purview of the subject which you are able to get after a longer period.

4576.

12012. What is your view as to the analytical control in the case of arsenic and kindred impurities in foods?—I hold that the analytical control of the quality of food may be exercised more readily over the ingredients of a food than over the finished product, but the Sale of Food and Drugs Acts give no power to the local authorities to take samples or otherwise deal with food constituents at a factory where such ingredients are not on sale. For instance, in reference to this beer question, if local authorities, when Bostock's had their trouble, had had the power to go to other glucose manufacturers and say, "I demand some of your glucose," they would have been able to see at once whether other glucose manufacturers had got into the same trouble, or what kind of stuff they were distributing to their customers; but the process actually came to be this—that it was the finished beer that had to be examined, instead of preventing the arsenic from going into the beer, as the brewers would have been most anxious to do—the beer was finished, and then they had to run it down the gutters in some cases, or, as happened in one instance within my knowledge, put it aside till the scare was over, and then distribute it.

12013. When a retailer is prosecuted is there a difficulty in reaching the manufacturer?—Yes. First of all, the prosecution of the retailer often involves a distinct hardship. He is not always the man who is really to blame, and he has to defend himself under disagreeable circumstances. This is going a little away from the beer question, but in the case of many very well-known foods, and also in cases of arsenical impurity, the retailer is not responsible, really, for what he sells. The foods are very often done up in tins. Take the case of condensed milk. The importer, or the manufacturer, or the creamery man—the merchant—often puts on the can containing the condensed milk a grossly misleading statement as to its composition and misleading directions as to the use of the contents. For instance, in some cases they prescribe that these condensed milks shall be diluted with seven to ten parts of water for general use, and with 12 to 15 parts of water for babies. Now, there is no condensed milk in the market which is condensed to less than one-third of its original measure, so that to bring it to its original strength you should not put more than two parts of water, and then you would have the original strength. But these condensed milks which are preserved with sugar would be then of the thickness of thick cream, or even of treacle, and intolerably sweet, so that nobody could use them in tea unless they were very fond of sugar; and as for the baby using them, it is out of the question. Then, when the article is diluted to such an extent that the baby can tolerate it, you have got to fill its stomach with a lot of water; that is, give it very dilute milk indeed—deluged with sugar, which is a food, but, at the same time, you do not get the nitrogenous food or the fat. The result is that the directions on the tin, I consider, lead to the semi-starvation of children fed on condensed milk, where it is sweetened milk. Where it is unsweetened, a much more moderate dilution can be practised; but I do think it is a shame to lead people by label to suppose that they can get a good, wholesome milk of the original quality by adding a large quantity of water, even up to 14 parts, as is directed in a notable case. In any case, wherever you go beyond three parts, you have dilution of the original milk. Concentrated foods for invalids are also often very grossly misdescribed, but no means exist for local authorities proceeding against the prime offenders, since the sale of the article to the retailer takes place outside the district. I am not quite sure that I am strictly right about that, as I think it is possible perhaps that you might catch them at the railway station as they came in, in the same way as you can the milk; but the whole thing is eminently impracticable.

12014. (Sir William Hart-Dyke.) The manufacturer is in one district and the retailer in another district; that is your point?—Yes. That brings one really to the question of the warranty. A few weeks ago a man was summoned in Sheffield for selling adulterated milk. He pleaded that it was warranted as genuine, and he said he got the warranty from Liverpool. The Corporation summoned the Liverpool man who supplied him with that warranty and that milk, and it was argued for the defence—"You have nothing to do with us; we did it in Liverpool, and you cannot prosecute us in Sheffield for what we did in Liverpool." The stipendiary magistrate is taking time to consider this legal point, admitting

Mr. A. H. Allen.

3 April 1903.

Sale of Food and Drugs Acts give no power over ingredients where they are not on sale.

Penalties of Sale of Food and Drugs Acts do not reach the person responsible for the adulteration, &c.

Misleading descriptions of food, e.g., condensed milk.

Difficulty in reaching the manufacturer.

Mr. A. H. Allen.

3 April 1903.

Objections to prosecution of mere retailer.

that the law on the subject is somewhat intricate. Local authorities will not take proceedings unless they see their way clear. To have a case like that lost does very much harm, because every other adulterator says: "I have only to get the article and a warranty from a distance, and then they cannot touch him." The warranty is doing a most serious amount of harm in that way. The law, whatever it implies, does not distinctly say that the manufacturer or the merchant can be prosecuted at the same court where the retailer was originally brought up, and, therefore, it makes it impracticable. I will take the case of invalid foods as an instance. Some of these patent foods, which are grossly misdescribed, are sold in tins—they are closed preparations, and the retailing grocer or druggist does not know what is in them. He sells them over the counter for what they are stated to be. Yet if you want to prosecute, you have got to prosecute that innocent man, and then if he says, "I simply bought it from the wholesale man, and he described it on his invoice as being so and so," you cannot then summon the man from London down to Sheffield, because it is a different district, and the sale did not occur in Sheffield, but in London. At any rate that is the difficulty we are continually meeting with. There is a glaring case, which I think I mentioned to a previous Committee, of a patent invalid's food, described as containing over 80 per cent. of nitrogenous constituents. It was made chiefly of milk sugar, and wheat flour; it was worth perhaps twopenny, and they charged 3s. 6d. for it. But that is not the point; let them charge what they like, but they should not misdescribe it. It was purposely misdescribed on an enamelled label, and they sold it largely. The Sale of Food and Drugs Act does not touch that kind of fraud. We want to have the power of summoning the wholesale man at the local police court; he is the man who really is at the bottom of it.

12015. (*Professor Thorpe*.) Why does not the Sale of Food and Drugs Act touch that particular case? It is not of the nature, substance, and quality demanded as by the label?—The wholesale man in Liverpool says, "You cannot summon me at Sheffield for an offence committed at Liverpool; I gave the false warranty in Liverpool, but you have nothing to do with that in Sheffield."

12016. (*Sir William Hart Dyke*.) That is a point of jurisdiction, rather?—It is, but at the same time it is one of the practical difficulties we suffer from. The warranties go from one man to another until they ultimately warrant them out of the kingdom, of course.

12017. (*Dr. Whitledge*.) You have not had a hostile decision on that, have you?—We have not had a hostile decision, but there have been more than several instances where our authorities have not prosecuted, because they know the man has practically a warranty from a distance, and they say, "Well, we had better withdraw the case."

12018. (*Professor Thorpe*.) Take London, for example; surely there have been one or two cases in which the man giving the warranty has been attached to the prosecution, although he is outside the particular district controlled by the analyst who brought the original charge?—I do not know how far that would affect London; but I would point out a somewhat similar thing which occurred recently, where milk was taken to the analyst for the wrong district, and the case was dismissed because he was the wrong man to take it to, as the offence had been committed outside his district.

12019. I know that case. On the other hand, as a set-off against that, there have been one or two cases of adulterated butter, for example, when a particular analyst—we will say the Kensington analyst—has brought a charge against a certain retailer for the sale of butter which, in his opinion, is adulterated, and the man has pleaded, "No; I got this butter as pure, and under a warranty," and the court has attached the warrantor to the case, and conviction has followed, but nevertheless the warrantor has been outside the district of the particular analyst who brought the original charge?—That, I would suggest, shows that there is a difference in practice, and that the law is not clear on the subject. The Sheffield stipendiary is now taking time to consider the legal question whether the Sheffield authorities can take action against a person in Liverpool for a false warranty. That question was distinctly raised by the solicitor for the defence, who argued that the Sheffield stipendiary had

no jurisdiction at all. The same difficulty has arisen before, and has within my knowledge prevented local authorities from taking action, because of the obscurity of the law on that point.

12020. (*Chairman*.) Is the absence of legalised limits as to the amount of impurity allowed in food objectionable, in your opinion?—Yes; it causes much trouble in practice, and many failures of justice. The limit of strength in the case of spirits has operated very satisfactorily, but no limitation exists as to the amount of deleterious impurity allowable in such liquors. In fact, the whole question as to which of the subsidiary constituents of spirit are deleterious, and to what relative extent, is very uncertain, and would require lengthy investigation by experts before any legal limits could be fixed. The whole subject is highly complex, and its investigation does not come within the public analyst's duty, who, could he succeed in isolating the constituents which he might suspect to be injurious, is at once crippled by the Vivisection Act, which would prevent him administering a dose to a mouse to see whether it had any ill-effect. It is a thing which has not literally come to the point so far, but it is one of those things which would tell whenever he was required to express any opinion; and really it is important, because at present the examination of spirits under the Sale of Food and Drugs Act is limited practically to ascertaining the alcoholic strength, with the exception that I always look for sugar and for acids, which have been alleged to have been used, but which I have never found in the course of a quarter of a century's experience and many thousands of samples.

12021. Water is the only adulterating material which is permitted, is it not?—Water is the only adulterating material which can be looked for under the circumstances under which samples are examined under the Sale of Food and Drugs Act. In the absence of any definition of spirits—of brandy, whiskey, rum, and so on—it would be quite impracticable to say it was not rum or it was not whiskey, except in a very special case. I have only recently certified on a sample which was labelled "Liqueur Rum," and on another which was labelled "Liqueur Brandy." They contained only a trace of alcohol, 20 per cent. of sugar, and flavouring matters, and yet they were sold as liqueur rum and liqueur brandy. That is so absolutely outside trade practice that I do not think there can be much doubt about a conviction ensuing under the Sale of Food and Drugs Act; but at the same time, with those very special and remarkable exceptions, it is only a question of strength. I may remind the Commission that in London the publican systematically evades the Act by putting up in his bar a notice, "All spirits sold here are diluted, but not below half-proof strength"; that is to say, he says everything here is adulterated, but is not adulterated to bring it below 50 under proof, whereas the legal limit for whiskey, rum, and brandy is 25 under proof, and for gin 35 degrees under proof. He goes beyond that, admits it, and by means of a label or an announcement he can sell any dilution he likes.

12022. In respect to the sale of whiskey, rum, and brandy, you say the publican may give notice that it is diluted?—Yes.

12023. And he does?—He does so habitually.

12024. Is he within his legal rights in doing that?—A prosecution fails if you prosecute him, because he immediately says, "It was up in the bar parlour; I had a notice there, and I had it up in the bar." I would respectfully suggest that if you frequented London public houses you would find that notice was very general. The publican says: "All spirits sold here are diluted, but not below half-proof strength." That means not below 50 under proof, whereas the Act says you must not sell it below 25 under proof unless you sell it as a mixture.

12025. (*Sir William Hart Dyke*.) That is without a notice?—Yes; but that notice is not understood by the frequenters of the bar, and it is perhaps not seen, and the law is evaded. It has been suggested that those licensed houses which exhibit such a notice should have their licence objected to in future, but there are so many other reasons now given for objecting to licenses that I do not know that it would hold water.

12026. (*Chairman*.) Do you not think that practice

Mr. A. E. Allen.

3 April 1903.

Need for "standard" and definition under Sale of Food and Drugs Acts.

Evasion of Sale of Food and Drugs Acts by means of notices.

\* Since this evidence was given the Sheffield stipendiary has dismissed the summons on the ground of warranty, but without reference to the point of locality of proceedings.

H of diluting these spirits is rather to be encouraged?—No.

1903 12027. Providing notice is given, and providing he does not cheat the people by charging them more than he has a right to do?—I do not think the people understand the nature of the notice.

12028. (Sir William Hart-Dyke.) If you ask for a glass of gin, you may get gin and water?—Yes. As a strict teetotaler put it, I think they would be very much better without the spirit; but I do object to publicans selling water at the price of whiskey.

12029. (Professor Thorpe.) What you say is the constant practice in public-houses in respect to spirits is a growing practice in refreshment rooms in the case of milk; even refreshment contractors in railway stations put up a notice to the effect that "The milk sold in this establishment is diluted"; that is so, is it not?—Yes. They do that now on some railways. In the refreshment-rooms there is a notice to the effect that "In order to avoid any trouble under the Sale of Food and Drugs Act we beg to announce that all milk sold here is diluted," or "is not guaranteed to be genuine."

12030. (Chairman.) They do not say how much?—No. As a fact it is not diluted. They sell the genuine milk, but they want to protect themselves from annoyance.

12031. (Sir William Church.) What you do object to is that these diluted spirits are sold at the price that undiluted spirits should be sold at; and that does not seem to be right; it might be desirable that spirits should be sold weaker than they are, but then they should be charged less; that is your view?—I would rather put the water to it myself to the extent I wanted it. I think that some of these practical objections would be met if it were made part of the duty of local sanitary authorities to put the Merchandise Marks Act in operation in the same manner that they are entrusted with the taking of samples under the Sale of Food and Drugs Acts. At present it is no one's duty to put the Merchandise Marks Act into operation, and the sanitary authorities and the police consider it beyond the scope of their present duties. The other day the Danish Government representative brought an action at Leeds under the Merchandise Marks Act against a buttermilk for selling as Danish butter what was of Finnish origin, and got a penalty of £238. If it had been under the Sale of Food and Drugs Act in Sheffield, even if the man had been convicted, 10s. would have been as much as the man would have been fined.

12032. (Chairman.) How was this penalty of £238 arrived at?—I do not know how it was added up, but the Merchandise Marks Act gives very much heavier fines, and the practice is better—at any rate it is much more easy to obtain convictions under that Act than it is under the Sale of Food and Drugs Act. I do not think the warranty comes in except as a question of false warranty—he misdescribes his goods. Those instances I mentioned to you of invalid foods could be proceeded against under the Merchandise Marks Act if it were made the business of the local authorities to take action; but they say: "We have nothing to do with it, and we should be considered to be going outside our province if we were to touch the Merchandise Marks Act." The result is that it is useless. It should be made by law part of their duty to take proceedings, where they thought desirable, for false warranty and false descriptions, such as are practised now, and for which there is no penalty. Practically under the Sale of Food and Drugs Act you may misdescribe the article to any extent on a label, but that would not be the case under the Merchandise Marks Act.

12033. Do you think a Court of Reference whose duty it should be to recommend standards or limits would be valuable?—Yes, I should welcome a Court of Reference to recommend standards or limits and to formulate definitions. Such a Court would be valuable if properly constituted and endowed, but unless thoroughly representative, so as to have the confidence of all interests concerned, its appointment would be disastrous. As a matter of fact, the Society of Public Analysts suggested that a long time ago, and the Select Committee on Food Products Adulteration which sat in 1894-5 and 1896 practically adopted the suggestion, and thought a Board of Reference would be desirable, on which all large interests should be represented. Nothing, however, was done by the Government, and it has been omitted from the modifications of the Act which have since been made.

4576

12034. Do you consider that the Sale of Food and Drugs Acts are in a satisfactory or an unsatisfactory condition?—In many respects I think they are in an eminently unsatisfactory condition. The Government, the judges, and the magistrates alike combine by their actions and decisions to encourage adulteration. I do not, of course, mean intentionally, but that is the practical effect of it. As an instance of the condition of the Acts, in the case of *Mason v. Cowdray* (Q.B.D. 1900, p. 419) six twopenny bottles of camphorated oil were purchased, and two of these were left with the vendor, two sent to the analyst, and two retained by the inspector. It was pleaded that there had not been a proper division into three as required by the Act, and that to send two complete bottles out of the six samples to each of the different people concerned was not right—they ought to have divided up a single bottle. In his decision Mr. Justice Ridley said it did not matter that the sample purchased was a small article. Six bottles were six articles. The appellant bought six bottles, and did not divide any of them. In that case the attention of the Local Government Board was drawn to the circumstance, and they replied that there had been a paper recently published saying that it was possible to ascertain the amount of camphor in camphorated oil with as little as one-sixth of an ounce—I have the correspondence here if it would interest you—and therefore it was not impracticable to divide the contents of one of these little twopenny bottles into three and submit it for analysis. The adviser to the Local Government Board did not take into account the fact that penny bottles were sold as well as twopenny bottles. The public analyst would always wish to repeat his analysis; in each case he would want another quantity. He is expected to report upon, and does habitually report upon, not simply the amount of camphor, but whether the oil present is wholly olive oil, as it ought to be, or is a mineral oil or is cotton seed oil, or some other oil. He cannot do that with only one-sixth of an ounce to work on. The same principle applies to pills, lozenges, sweets, and each blue and white packet of sedlitz powder. The decision means this: that if you buy pills, each pill is a separate article, and so you have got to divide that pill into three, and send one portion to the analyst, and so on. The result is that in the West Riding (where they were anxious to go into these matters, and did send to be analysed such things as bismuth lozenges, which very often contain only half the proper quantity of bismuth, and other things of this sort) every part of the Act to which this decision has applied has fallen through absolutely. It is no use buying samples and then having such a decision as this brought against one. It is deplorable that a large class of articles are not capable of being touched in consequence of such a decision. I mention that as one of the working troubles of a public analyst, not that it matters to the public analyst personally, except as a zealous officer. He, as a public analyst, is only too glad not to be bothered with this. The sanitary authorities who would like to do their duty cannot proceed against people who are misdescribing lozenges and so on because of such a decision.

12035. (Sir William Hart-Dyke.) I think you have told us that almost immediately after what has been termed the scare and loss of life owing to the Bostock case, a great change for the better took place as regards the samples which you had to analyse?—Of course, at the time one received from brewers and also from sanitary authorities various beers containing more or less arsenic, but the brewers were most anxious to avoid anything of that sort, as it was a most serious matter to them, and they had never meant it, and so they righted matters, most of them perfectly honestly, by destroying the beer which was contaminated with arsenic. There were exceptions in the case of people who put such beer aside until they could sell it off gradually.

12036. Even up to this date I presume you would admit that the brewers are most anxious in every way to take every step for security?—Yes, undoubtedly.

12037. But supposing in process of time more careless methods supervene, you would wish, would you not, for something to fall back upon for the complete security of the consumer?—Yes; I think the beer should be habitually looked into, so as to be quite certain there has been no relapse. Of course, we must recognise that the Bostock arsenical contamination was not intentional. I do not call it an accident, because it was worse than an accident, but nobody meant to put

Mr. A. H. Allen.

3 April 1903.

Directions in which Sale of Food and Drugs Acts are unsatisfactory.

Precautions against arsenic may become lax if no adequate official control.

Mr. A. H.  
Allen.

3 April 1903.

arsenic in the beer, and it has been such an experience to brewers all round that they will be very careful in the future. But there are some of them who do not realise that, and, as I say, I know an instance where it was arranged to pass off highly arsenical beer when people were not so actively on the look-out for it.

12038. You suggest that public analysts should see more of each other—that they should meet oftener and compare notes in their various reports?—Yes, I do. Of course, spontaneously they do that; we meet once a month as a Society; but then those go who like, and you must remember Great Britain is a large island, and that Ireland is also included in our membership. The United Kingdom is too large for all our members to come to London every month for a meeting. What I suggested was that machinery should be contrived by which they should be made aware of, and could judge, others' work in certain directions. If a man has got anything of considerable interest, he may bring it before his brother analysts at his Society; but that does not apply to the everyday work he is doing—how he has found three samples of such and such a thing to be adulterated. It may or may not be of purely local interest, but at any rate other analysts never know of it until they see in the Local Government report, which is published very tardily, that some public analyst has found something adulterated in an unusual or unique manner.

12039. I suppose you compare, do you not, your different systems and methods of analysis?—Undoubtedly we do, and a very great good has come from collaboration and consultation, from rubbing shoulders together like that; and I think it is very highly appreciated. But you must remember that that is simply informal, and that there is no official machinery for our making these things known to each other.

Margin to be allowed for unavoidable differences in analysis.

12040. You have informed us that, supposing that standard were fixed, whether it be 1-100th grain per gallon or whatever it might be, you consider that a margin of 20 per cent. should be allowed to cover the difference of analysis; that you have given to us as your opinion, but are you able to say that that would be about the general opinion of practised analysts?—I have not consulted them actually on that point, but I think so. In other words, we should be dealing in the Marsh-Berzelius process, with an arbitrary process, with a certain amount of personal equation in it—dealing with the depth of colour of the arsenic mirror, on glass; and I can quite understand that two analysts, working on the same beer, could obtain one, we will say, the 100th of a grain per gallon, and the other the 80th of a grain per gallon. That is a difference of 20 per cent. I can imagine making that difference myself at intervals of a few weeks. Therefore we must not expect different analysts to work more closely than oneself. The process is only approximate; it is quite good enough for practical purposes if it will tell you whether it is an 80th or whether it is a 100th of a grain; but I should not like to have a limit fixed, and then find that the amount of arsenic had exceeded that limit slightly, and that we were bound to report the beer as containing an excessive quantity of arsenic when it might, after all, be only a question of the personal equation. I would rather fix the official limit a little lower.

12041. If it became a question of penalising the manufacturer, of course, you would admit that the more nearly you can approach accuracy in the analysis the better, surely?—Undoubtedly. The best method of analysis is that which is most accurate; but there must always be a margin left. Supposing you go and fix the 100th of a grain officially, and supposing I were to find not the 100th of a grain, but rather more—the 90th of a grain—should I say that I am going to condemn this? It is within the limits of error, and it is not good enough to take into court, with a wholesome fear of the Government Laboratory before our eyes. The personal equation might cause a variation to that extent.

Arsenic in confectioners' glucose.

12042. You have mentioned the case of American glucose which you analysed and found strongly arsenical; have you examined many samples of glucose since that period?—Not of confectioners' liquid glucose. That was a liquid preparation used by confectioners.

12043. You have not found other samples of glucose equally contaminated with arsenic since that?—My experience of American glucose, I think, is limited to that one sample, at any rate so far as I know their origin. One does not get to learn the origin in many instances. I may say, from some independent source—I cannot remember at the moment how I know, but it is within my

knowledge—that a good deal of the American glucose is arsenical.

12044. You have heard that by report?—It is by correspondence with a chemist-friend in America, I think. I dare say I could ascertain where I got the information from, but I do not remember and cannot tell you at the moment.

12045. As an analyst of very long experience, may I ask you this general question: Do you think from your experience that there is sufficient danger to the public at present existing in confectionery, or in all other articles of food, apart altogether from the brewing trade, to suggest that there should be a strengthening of the Food and Drugs Act in order to protect the public?—From arsenic.

12046. Yes, from arsenic?—I think it would be well if you could deal with the manufacture of the food product rather than the actual food. You see, where it is not on sale the inspector has no right of entry.

12047. Would you like to see that done?—I should like to see that done, and I should like to see these things habitually and systematically examined. We have got our eyes open now, and I think the local authorities will many of them be alive to it; but you must remember that many of the smaller local authorities consist of members whose sons and brothers-in-law, and so on, are the tradesmen of the town.

12048. (Dr. Whitledge.) Are there any standing official instructions available, let us say, for a new medical officer of health or a new inspector, as to the range and amount of samples to be taken?—I do not know of anything of the sort. Of course, we have the old pious opinion of the Local Government Board that there should be at least one sample per annum per 1,000 persons. I think that has been modified since.

12049. I gather that the Local Government Board had taken rather a stringent view of this?—Yes. I think the Board of Agriculture have expressed the same opinion.

12050. That would be as to the number of samples?—Yes.

12051. Has anything been laid down officially for the guidance of the officers concerned as to the bulk of a given sample?—Take the case of my own experience. In the West Riding of Yorkshire I was asked, in the time, I think, of the previous medical officer of health, to say what amounts I should require for analysis (which, of course, would be at least one-third of the total quantity purchased), so as to make out a list for the inspectors of the kind of articles which could be advantageously purchased and the amounts they were to purchase. Those were the printed instructions which the inspectors were given, and those have been modified from time to time.

Official instructions to nature samples to be taken.

12052. They were for the West Riding only?—Certainly. I should say that is the best way, because another analyst might have his own particular ideas based on his own particular methods of analysing, and might say, "I require so much of a sample," whereas I might find it desirable to have double that quantity or half that quantity, according to the way I worked. I would rather the inspectors were instructed to purchase what I thought desirable, or, rather, three times as much as I required, than to have it laid down formally from the Local Government Board. For instance, it has been held by one of the Government Departments, I do not know which, that all samples should be put into stoppered bottles. Of course, that is a provision which could not have been very practical. In the first place, a stoppered bottle would require to be tied up and sealed, and you might have to do that in a gale of wind, which is not an easy thing to do. Then a stoppered bottle is not so tight as a corked bottle under many circumstances. Certainly in the case of spirits and milk, I would rather have them contained in a well-corked bottle than in a stoppered bottle. In practice what we do is to use a corked bottle and to seal the cork properly, and put a label on the bottle, and enclose that in an envelope having only one aperture, which itself is sealed on the outside. That does not prevent tampering, however; we have had cases of tampering with samples of a very serious kind sometimes.

12053. Is it within your experience that in the absence of any definite instructions, local or general, inexperienced officers of the local authorities send samples which are inadequate for the purpose?—Yes; sometimes too small an amount is sent. We had, as

Mr. A. H.  
Allen.

3 April 1903.

Advocates control over food manufacturer.

H. I say, in the case of beer, to take small samples with the view of seeing whether there was any arsenic there, and of then getting a larger sample with all the formalities of the Act for a more complete examination, but that difficulty has been overcome since the adoption of the Marsh-Berzelius process, by which we can work with much less. Then, of course, you must remember that the beers examined of recent years were examined only for arsenic, and not with a view of making an examination for anything else. We have nothing to do with whether it is all malt or whether the bitters are all hops, or anything else. We are not in the habit of finding definitely deleterious matters in beer except arsenic, and therefore recent examination has been limited to that, in the same way that the examination of spirits has been limited practically to water.

12054. You have suggested that more might be done in the way of utilising the reports of public analysts; would there be any difficulty in doing that without any legislation? If, for example, the central authority had an expert adviser, would it not be practicable to summarise the reports annually in such a way that the information contained in them could be made available for all public analysts and for the public at large?—Yes, I think that would be quite practicable. As a fact, if it were made my business to do it, and I were an official adviser of the Local Government Board, knowing what would be important and interesting to my brother analysts, I think I could write a valuable and interesting resumé of the work done by them.

12055. Would that not be better than circulating the whole of the reports of each analyst?—I think it would be more practicable. What I suggested in examination-in-chief does imply a lot of waste paper, there is no doubt.

12056. You have said, I think with reference to the suggestion of a Court of Reference, that it would be good if all interests were adequately represented?—Yes.

12057. Would that mean interests in every branch of manufacture concerned, or do you mean that in addition to the official element and the scientific element there should be a representation of the manufacturing interest?—Without entering into details, my idea had been that, broadly speaking, the interests chiefly concerned should be represented; for instance, we ought, as a permanent member, to have the chief chemist of the Government Laboratory. Naturally a representative of the public analysts, if not nominated from among themselves, should be nominated by the Local Government Board—in fact, I would suggest a public analyst nominated by the Local Government Board and another one nominated by themselves, the Society of Public Analysts.

12058. My main point is that you do not consider that every branch of manufacture should be individually represented?—No.

12059. That would not be practicable?—I think the agricultural interests, the Dairy Farmers' Association, or whatever it is that represents milk, might very properly be represented. I can understand the Chamber of Commerce being represented, and certainly the Pharmaceutical Society, or preferably druggists and pharmacists generally. You must remember that the Pharmaceutical Society does not by any means include all or even the majority of pharmacists; it is only a society which consists of a fraction of the practising pharmacists. The pharmacists ought to be represented, no doubt.

12060. The main interests should be?—Yes.

12061. Would you suggest in addition to other functions that such a board should have power to define articles to be used as food—marmalade, I think, was an instance mentioned?—Yes. They could do a great deal for of good work. At present the public analyst is crippled because there are no definite limits as to how far accidental impurities can be tolerated, and that makes it very difficult indeed. The result is that the local authorities say, "We cannot proceed upon this; here is 3 per cent. of sand in so-and-so"—it is probably shop-sweepings—"but if we take that into court the magistrate will say that the vendor would not adulterate for the sake of 3 per cent. extra profit." They take that view, whether it be reasonable or not, and the result is that proceedings are not taken against that man. The chances are that if there are 3 per cent. of what analysts call sand in an article, that means a good deal more of extraneous matter, which proves the really bad quality of the article. But such cases as that are allowed to go through for want of a guide.

12062. Would it strengthen the hands of the local authorities in a case of reliance on a warranty for defence if the person alleged to give the warranty could be associated compulsorily in the same hearing and in the same case?—I should think that would be a very valuable provision. If a man was going to plead a warranty and gave a notice to that effect, the warrantor should be associated with him in the prosecution, so that the case could be heard at the original court where the retailer was summoned, and the whole case could be decided—whether he had given a false warranty or not. As I have pointed out, it is very questionable as to whether you have a legal right to summon a warrantor at a distance to the particular district police-court. It is held by some magistrates, at any rate, that the 28 days' limit must be accepted, and that you have got to take proceedings (because that is a new proceeding) against the warrantor within 28 days from the original purchase of the sample. This is very often quite impracticable. Perhaps the original summons is heard, we will say 20 days after it was issued—if it comes on as soon as that it is a wonder—they have to give a fortnight's notice, first of all, before it goes into court; but we will assume that to be the commencement of the proceedings. Then perhaps there is an adjournment—for perfectly legitimate reasons—bringing it to five weeks; and then the twenty-eight days' limit has expired, and you cannot proceed against the guarantor.

12063. If you are bound by the 28 days, that is so. I gather you are of opinion that the local authority ought to have more power to visit a factory where foods are manufactured?—Yes, I think that if they had had the opportunity of visiting glucose manufacturers in connection with this beer disaster, they would have been able to stop it, instead of its being innocently introduced into beer by the brewers and then their getting into trouble afterwards.

12064. Do you think that only the local authority for the district in which the glucose manufacturer is situated should have the right to do so?—I should not like to say that, because the local authority might never exercise the power.

12065. But there would be a practical difficulty, would there not, in giving a roving commission to every local authority?—The question is whether, arsenic being so important, it would not be well to have a travelling inspector looking always into the question of arsenic and its sources.

12066. To deal with arsenic as a particular case?—Yes. Local authorities are very difficult to move, and the Food and Drugs Acts Inspector has got his own work to do, and he does not want to be bothered with extra work. I should be almost inclined to think, as it is so very important, that a special official might be appointed, who would then, I presume, submit the samples to the local analyst.

12067. I gather that your general opinion is that in beer there is no real justification for the presence of arsenic in any quantity above the 100th of a grain per gallon?—I think the 100th of a grain per gallon will cover all unavoidable traces of arsenic. As a matter of fact in practice they contain much less than that, but it is a question for the Commission to consider how far they are to be bound down to absolutely exclude these minute traces.

12068. I only wanted to have the benefit of your experience in the examination of beer samples. Your opinion would be that there would be no hardship in tying down the brewer to turn out a beer containing not more than the 100th of a grain per gallon?—I do not think there would be any hardship at present. Now he does it habitually, and is anxious to have as little arsenic as possible.

12069. We have not had quite a definite suggestion in reference to the food products; speaking broadly, are there any food products of the solid kind which could not fairly be tied down similarly to a limit of the 100th of a grain per lb?—That is a difficult question to answer. I have in mind a case within my own knowledge which I think the Commission will have an opportunity of hearing about from a brother analyst—I do not know that I am at liberty to mention it. It is a case where a substance has been added as colouring matter to a mixed food product—an artificial food product—this colouring matter being perfectly unknown to contain a large quantity of arsenic; but it does contain very material quantities of arsenic, and therefore has contaminated the food product. A colouring matter might

Mr. A. H. Allen.

Question of attaching warrantor to prosecution.

Beer should be well below 1-100th grain per gallon limit.

Mr.  
A. H. Allen.  
3 April 1903.

contain a trace of arsenic, and you have no right to consider it as the 100th of a grain per lb., which is a very minute dose in a colouring matter, seeing that when it has entered the food product it only constitutes a very small quantity of the food product. I think it would be infinitesimal then. There is no evidence that this particular food has done any harm, but it was being made with a highly arsenical colouring matter.

12070. My question was rather directed to the food product, and not to the ingredient; the case you mention is one of an ingredient?—Yes.

12071. I suppose you would say, would you not, in advising a manufacturer, that he must keep out arsenic as far as possible, however small may be the proportion in which that colouring matter is going into the food?—Yes; and the manufacturer in this case, being advised and now having become aware, is taking the very greatest care that he does not introduce any arsenic, because if he went to an ordinary analyst and he found arsenic, that analyst would be perfectly right to report that it was present. An inspector would have been the manufacturer's best friend practically; the merchant's attention would have been called to the source of the impurity, and it would never have gone into general distribution. He would have been told, "That colouring matter that you are using is unfit for use in food, and undesirable for use in food."

12072. (Professor Thorpe.) I see—and I quite understand why—that you deprecate anything like the use of official methods being prescribed. I do not know whether you are aware of the interim report of the Commission; have you read that?—No, I have not had the opportunity.

12073. It has been published and circulated. There the Commission recommended that "the Board of Inland Revenue should possess and should exercise powers to specify in detail individual ingredients of beer which are liable from their origin or mode of preparation to be contaminated by arsenic, to prescribe for every such ingredient and for the different materials used in their preparation an adequate test which should ensure their freedom from arsenic, and to prohibit under penalty the use in a brewery of any material which infringes the prescribed test." The recommendation in Paragraph 34 was really directed to this, and it runs as follows:—"We are of opinion that by requiring the brewer to produce satisfactory evidence (whether in the form of a guarantee from the vendor or as the result of analysis by the brewer's chemist, stating in such terms as the Board of Inland Revenue may determine) that the prescribed tests have been applied to all the ingredients of beer at

the brewery which have been specified as liable to contain arsenic, and that by the examination of samples in the Government Laboratory an immediate and effective safeguard to the public with regard to arsenic in beer can be secured." Of course, that contemplates that the Board of Inland Revenue should have certain punitive powers given to them for an infraction of those provisions. I do not understand how it would be possible in a court of law to secure convictions unless the warranties and guarantees were given in accordance with a method laid down?—In other words, you mean that it must be invoiced or guaranteed to pass certain tests, just as in commercial matters benzol is sold as being 90 per cent. benzol according to a specified test?

12074. Yes!—That implies that if you are going to guarantee it, you must prescribe the method of testing—I think that almost follows—or a method giving concordant results.

12075. There you introduce a difficulty, and you will see at once the difficulty that is introduced—namely, that you may have a conflict of evidence. The analyst, for example, may be able to bring rebutting evidence that a thing is below the standard which is prescribed, whatever that standard may be. You see that introduces a difficulty in giving effective power to the Board of Inland Revenue in the case of infractions of the warranty?—Take the matter personally. I can conceive that I might individually be clever enough to invent some process which in my hands gave me accurate and superior results to the prescribed method; I should be perfectly justified in using that method for my own purposes, but if I should be thinking of condemning a sample, I should say, "Well, it must show that result by the official test, and, therefore, I should be bound by the official test in reporting; but for my own convenience I might use another one which I had found to give comparable results." I do not like to be tied down only to use a certain method when a better might be invented; but, certainly, if you are going to specify it, it must be on the basis of an official test in the same manner that we at present say that milk must contain 8.5 per cent. of non-fatty solids and 3 per cent. of fat, although the time may come when those really will not be the best criteria of genuine milk.

12076. That is not quite the point, is it? In this particular case, inasmuch as we are dealing with very minimal quantities of material, the particular way in which those have been arrived at is all-important?—Very important as an arbitrary test.

12077. Your statement perhaps is subject to the qualification you now make?—Yes, I think that is so.

Mr.  
A. H. Allen.  
3 April 1903.

Guarantees should have reference to prescribed tests or methods

Dr. J. A. Voelcker.

Dr. JOHN AUGUSTUS VOELCKER, called; and Examined.

Dr. J. A. Voelcker.

Taking up of arsenic by farm crops. Experiments at Woburn.

12378. (Chairman.) I believe you have devoted yourself very much to the application of chemistry to agriculture?—I have.

12079. You are able to give us evidence, that I am sure we shall find very interesting, regarding the taking up of arsenic by farm crops?—Yes.

12080. You have made experiments at the Woburn experimental station of the Royal Agricultural Society of England, I believe?—I have.

12081. Were those experiments made in the year 1901?—Yes.

12082. Were those experiments made for the purpose of inquiring into arsenic in connection with this Commission?—They were not originally instituted in connection with the inquiry of this Commission. As the question of the contamination of food products with arsenic was raised, I thought it desirable to institute experiments on the question with regard to farm crops, principally because of the assertion that had been made in some quarters as to farm crops, and particularly barley, being contaminated with arsenic through the use of artificial manures. It was with that object that I instituted the experiments at the Royal Agricultural Society's farm.

12083. Had you previously had occasion to consider the question of possible danger to food in consequence of arsenic having been contained in the manure or in the soil?—I had previously for a number of years often been called upon, for instance, to test different commercial samples of superphosphate for the possible presence of arsenic, and I also had at intervals submitted to me roots and grain which had been grown with super-

phosphate, for the purpose of ascertaining whether they contained any appreciable quantity of arsenic.

12084. Was that before this Commission came into existence?—It was before this Commission opened.

12085. You were alive then to the importance of the question?—I was alive to the importance of the question, and to the possibility of arsenic being introduced in that way, but, having no definite experiments that I could rely upon, I thought it advisable that a society, such as the Royal Agricultural Society, might very well carry out trials with respect to this.

12086. I understand that those experiments conducted in 1901 were conducted with crops grown on a sandy loam?—The soil of Woburn happens to be a sandy loam; at the same time the farm comprises three different kinds of soil varying somewhat in respect of heaviness. One field is a very light soil; another one, which is mentioned in my epitome as being Warren Field, is a distinctly heavy soil; and a third one is intermediate.

12087. How do you distinguish a heavy soil from a light soil?—As a matter of fact, the geological formation alters exactly at our farm. We have one portion of the farm on the Lower Greensand, and another portion on the Oxford clay. The one field that I have called here Lansome Field is on the Lower Greensand. The Lansome Field is the light soil, and the Warren Field is the heavy soil.

12088. On the Lansome Field, with a crop reared in the ordinary way, you examined eight plots, a quarter of an acre each, I think, and we have the results of these and your other experiments in this epitome?—Yes.

Crops.

J. A.  
Vodeker.Dr. J. A.  
Vodeker.

11903. EPITOME of EXPERIMENTS conducted at the Woburn Experimental Station of the Royal Agricultural Society of England in 1901. 3 April 1903.

Soil—A sandy soil.  
Crops.—Barley, Swedes, Mangels.  
Pot-culture experiments on Barley.  
Analyses made by Mr. Otto Hehner.

I. Barley.—Lansome Field. Crops reaped in ordinary way. Eight plots, one quarter acre each, treated as follows :—

	Manures per Acre.	Arsenic in Crop.	
		Grain.	Straw.
			Grains per lb.
Plot 1 - -	Without manure - - - - -	None.	'006
Plot 2 - -	3 cwt. Superphosphate made with arsenic-free acid - - -	"	'007
Plot 3 - -	3 cwt. Superphosphate containing '01 per cent. arsenic - -	"	'006
Plot 4 - -	3 cwt. Superphosphate containing '03 per cent. arsenic - -	"	'004
Plot 5 - -	3 cwt. Superphosphate containing '03 per cent. arsenic - -	"	'004
(duplicate of 4.)			
Plot 6 - -	3 cwt. Superphosphate containing '01 per cent. arsenic - -	"	'005
(duplicate of 3.)			
Plot 7 - -	5 cwt. Superphosphate containing '01 per cent. arsenic - -	"	'004
Plot 8 - -	5 cwt. Superphosphate containing '03 per cent. arsenic - -	"	'004

II. Pot-culture experiment on Barley.—The straw being cut off when crop was ripe, and not allowed to lie on soil (as in the field).

	Arsenic in Barley Straw.
	Grains per lb.
Barley manured at rate of 3 cwt. per acre of superphosphate containing '50 per cent. arsenic - - - - -	'007

III. Swedes.—Road Piece Field. Crop gathered in ordinary way; leaves left lying on ground; bulbs topped and tailed, and stored in heaps on land; bulbs cleaned and washed before analysed; leaves not washed.

Six plots (each duplicated) manured as follows :—

	Manures per Acre.	Arsenic in Crop.	
		Bulbs.	Leaves.
			Grains per lb. in dried leaves.
Plot 1 - -	Without manure - - - - -	None.	—
Plot 2 - -	3 cwt. Superphosphate made with arsenic-free acid - - -	"	—
Plot 3 - -	3 cwt. Superphosphate containing '01 per cent. arsenic - -	"	'02
Plot 4 - -	5 cwt. Superphosphate containing '01 per cent. arsenic - -	"	—
Plot 5 - -	3 cwt. Superphosphate containing '03 per cent. arsenic - -	"	—
Plot 6 - -	5 cwt. Superphosphate containing '03 per cent. arsenic - -	"	—

Dr. J. A.  
Voelcker.

IV. Leaves of Swedes and Mangels, after cleaning and washing (to remove attaching soil, &c.). Crops under ordinary cultivation.

Dr. J. A.  
Voelcker.

3 April 1903.

3 April 1903.

	Swede Leaves.		Mangel Leaves.
	Warren Field.	Great Hill.	Warren Field.
Arsenic.—Grains per lb. of dried leaves	·004	·002	·002

V. Soil.—Tested for arsenic (in air-dried soil).

	Warren Field.	Great Hill.
Arsenic.—Grains per lb.	·02	·014

Results.

Barley.

12039. What were the results of treating the plots in different ways?—In Plot No. 1, without manure there was no arsenic in the grain; in the straw there were 0·006 grains per lb. In Plot No. 2, which was manured with 3cwt. per acre of superphosphate made with arsenic-free acid, there was no arsenic in the grain, but there was 0·007 grains per lb. in the straw. In Plot No. 3, manured with 3cwt. of superphosphate containing 0·01 per cent. of arsenic, there was no arsenic in the grain, but 0·006 grains per lb. in the straw. In Plot No. 4, manured with 3cwt. of superphosphate containing 0·03 per cent. of arsenic, there was no arsenic in the grain, but 0·004 grains per lb. in the straw. In Plot No. 5 (duplicate of No. 4), manured with 3cwt. of superphosphate containing 0·03 per cent. of arsenic, there was no arsenic in the grain, but 0·004 grains per lb. in the straw. In Plot No. 6 (duplicate of No. 3), manured with 3cwt. of superphosphate containing 0·01 per cent. of arsenic, there was no arsenic in the grain, but 0·005 grains per lb. in the straw. In Plot No. 7, manured with 5cwt. of superphosphate containing 0·01 per cent. of arsenic, there was no arsenic in the grain, but 0·004 grains per lb. in the straw. In Plot No. 8, manured with 5cwt. of superphosphate, containing 0·03 per cent. of arsenic, there was no arsenic in the grain, but 0·004 grains per lb. in the straw. The practical result of that is that when barley was grown upon this soil and treated in different ways with superphosphate of the ordinary kind which the farmer would purchase, and in the quantity that he would ordinarily use, the grain being reaped and threshed in the ordinary way, it was practically free from arsenic altogether.

No arsenic in grain.

Traces in straw.

12090. The grain was practically free in every case?—Yes.

12091. But the straw showed traces?—The straw, on the contrary, showed small quantities of arsenic.

12092. I see more arsenic was shown on Plot No. 1 than on Plots 4 and 5?—The differences are not more than would be due to experimental error.

12093. Plot No. 1 was without manure, you say?—There was no added superphosphate in Plot No. 1, but there was as much as 5 cwt. per acre used in Nos. 7 and 8.

Quantities of superphosphate used: per cent. of arsenic; and controls.

12094. I see you had either 3 cwt. or 5 cwt. of superphosphates?—I took those two quantities because they would very well indicate respectively a moderate and an extreme quantity of superphosphate that a farmer would use for the cultivation of barley; 3cwt. per acre is an ordinary quantity; it is the quantity that we should use ourselves on this very land, and to grow this particular crop. Five cwt. is an extreme quantity; it may be used in some parts of the country, but it is very seldom that that quantity would be exceeded. Similarly, with regard to the quantity of arsenic contained in the manures used, the figures are taken from determinations of arsenic that I have made in a number of commercial samples that have been sent to me for the last ten years or so for the purpose of testing the amount of arsenic present in them. I desired in this case to take, first of all, the natural land without any super-

phosphate—that is, Plot No. 1. In the second case I took the ordinary dressing of superphosphate, but it was a superphosphate made with sulphuric acid which was chemically free from arsenic. This superphosphate was made for me purposely by a chemical manufacturer; it was a small lot made for the purpose of this particular experiment. You may take the arsenic obtained here as that which has come out of the soil, subsequent analyses showing the soil of this field, as of other fields, to contain a certain quantity of arsenic.

12095. When the superphosphate was made with arsenic-free acid, may we assume that the superphosphate so made was free from arsenic?—I do not think that it is quite fair to assume that. I doubt myself whether it is possible in any factory to make a superphosphate free from arsenic and to keep it free from arsenic. I should believe that the very presence of the atmosphere in the manufactory and the dust flying about will be enough to cause a perceptible amount of arsenic to be found even in the superphosphate that had been made originally with pure acid. In fact, I subsequently tested this very sample, and I could not say it was perfectly free from arsenic.

12096. You tested the superphosphate and found traces of arsenic in it, do you say?—Yes.

12097. Though it was made with acid free from arsenic?—Quite so.

12098. Then there can be no doubt that in Plot No. 8 there was much more arsenic in the soil than there was in Plot No. 1; it was the same soil which in the first place was without manure and in the second had 5 cwt. of superphosphate containing 0·03 per cent. of arsenic?—There would be from five to six times as much as in No. 1.

12099. And yet there is less arsenic in the straw?—Yet there is less in the straw; but the whole of these figures are within experimental error.

12100. The whole amount in the straw is so small that you do not consider these results inconsistent with the data as to manure; they simply show that in every case the arsenic was very small?—Yes.

12101. It is rather remarkable that the more arsenic there is in the manure, the less there is in the straw—one of your results brings that out, of course, on the very small figures?—It shows that with an increase of arsenic in the superphosphate you do not necessarily get an increase in the arsenic taken out. A subsequent experiment shows that in very great measure the amount of arsenic recorded in the figures which I have given is really an accidental mechanical admixture.

12102. Due to the dust and soil upon the straw?—Much of the. Quite so. It is to that rather than to any actual differences in regard to absorption that I attribute the figures here given. arsenic due to adherent soil, &c.

12103. Then to what do you attribute the arsenic in the straw in the case of Plot No. 1, for example, which was without any manure at all; there must be some arsenic in the soil?—There is arsenic in the soil, and I

J. A. Laker. confirmed that by analysis of the soil. You will find the analysis given under heading V., in my epitome.

12104. That may have been the result of manuring with superphosphate in previous years?—It may have been that, but personally I believe that you will not get any soil in which you do not find about that amount of arsenic—any soil, for instance, that contains pyrites is pretty sure to contain arsenic.

12105. Have you examined many soils independently of this farm for arsenic?—No, I have not, because the question had not arisen before; but I have done so lately, and I have never been able to find one that did not give some signs of arsenic.

12106. Is there any arsenic in coprolites, for instance?—There is pretty sure to be arsenic there.

12107. They are largely used for manure, I believe?—Not now; they were formerly, but the coprolite industry is quite worked out now in this country.

12108. Why has it been given up?—The coprolites are not rich enough, and it does not pay. The principal sources of the raw materials of superphosphate manufacture are the Florida phosphates and the Algerian phosphates, and others, which are very much richer than coprolites; coprolites would only contain from 48 to 60 per cent. of phosphate of lime, whereas these other phosphates will contain something like 80 per cent. The difference of working cost has so much altered that it makes it unprofitable to work the coprolite beds any more. It is in these coprolite beds, and where you have iron associated with the coprolites, that you would expect to find the iron pyrites, and consequently a considerable amount of arsenic.

12109. What is the chief object of these manures; is it to introduce phosphorous?—Yes.

12110. And nothing else?—Nothing else. The superphosphate is simply to be regarded as a means of giving phosphate to the crops.

12111. So far as your experiments go there is very little absorption from the soil into the grain?—Very little. I am not able at the present time to discriminate entirely between what may be mechanically attaching and what may pass into the tissues of the plant; but I am prepared so far to say that in the firm parts and the matured parts of the plant, such as the grain, the arsenic is not taken up, whereas in the greener parts, such as the leaves and the stalk, it is quite possible that there may be a certain amount. I am fully of opinion that where results have been recorded as giving in straw or leaves a certain amount of arsenic, to a great extent, this is due to the mechanical attraction of particles of soil or manure which contain arsenic.

12112. The outside of the leaves being soiled with the soil—dirtied with the soil?—Quite so. For instance, a barley crop in a field will be cut off close to the ground, but the whole straw will be splashed up with bits of the soil when the rain comes, and bits of manure may subsequently be thrown up. Also in the ordinary processes of threshing and cleaning the grain, there is a great deal of dust flying about which may contain small quantities of arsenic. It is quite reasonable to suppose that the softer parts of the plants, such as the leaves and the straw, will more easily take it up mechanically than will the hard grain.

12113. Would it be a merely surface layer which could be washed off the leaves, or do you think it gets in at the surface, and is soaked into the leaves?—I am not prepared to say that in the case of the straw and the green parts of the plant it is entirely a surface attraction; but I am prepared to say that if you take a crop of barley, for instance, with its straw, and reap it in the ordinary way, and lay it on the soil, you will have a good deal more arsenic than if you grow it under conditions where it does not lie on the soil and is not subject to the mechanical additions that it would get in that way.

12114. Then I understand you made experiments on the pot culture of barley; the straw being cut off when the barley was ripe, and not allowed to lie on the soil (as in the field)?—Those experiments were carried out as being supplementary to the field experiments. Our object at Woburn is to carry on scientific experiments side by side with practical ones, and in a question like this, when I was considering the absorption of arsenic by plants, I thought it was very desirable in the first place to carry out experiments in just the same way and on the same scale as the ordinary farmer would adopt. Therefore the figures given with regard to the

field experiments are on exact practical lines. I supplemented these by carrying out other experiments on plants grown on the small scale—pot culture experiments. In one of these I grew barley with a superphosphate to which not merely the arsenic natural to the commercial acid was attached, but to which arsenic in excess, and in large excess, was added.

12115. That is Experiment II.—0.50 per cent. of arsenic?—Yes. I reaped the crop here; but you would not in such a case get the same amount of mechanical attraction from the soil that you would in the fields, because the straw when reaped was taken straight away. You will find that although the quantity of arsenic supplied was 50 times as much as in the case of plot 3, yet the amount of arsenic in the straw was not much more than in the case of plot 3.

12116. Just the same as in the case of the superphosphate made with arsenic-free acid and used on plot No. 2?—Yes, just the same.

12117. Is that not a very large amount of arsenic to be in a superphosphate?—That is an altogether extreme quantity. Such an amount would never come forward in practice.

12118. Have you any evidence as to whether that interfered with the health of the plant?—I have some very clear evidence about that, which I will be happy to lay before you. These results are not given in the summary, but since preparing the latter, I have been able to put my notes together with regard to this further point. I had no less than 11 different sets of pot-culture experiments, where the soil of one of these ordinary fields was used, and where I treated the barley plant in different ways. In the first case I used no superphosphate at all. In the second case I used 3 cwt. per acre of superphosphate free from arsenic. In the third case 3 cwt. of superphosphate with 0.01 per cent. of arsenic, and so on, with varying quantities up to 3 cwt. per acre of superphosphate containing .05 per cent. of arsenic, which figure, according to my experience, is the highest that one meets with ordinarily in commerce. After that I added arsenic in excess directly as arsenious oxide, and the next series contained 3 cwt. of arsenic-free superphosphate per acre, to which I added 0.15 per cent. of arsenic as arsenious acid. In the next series there was 3 cwt. of superphosphate, with .30 per cent. of added arsenic, and in the next 3 cwt. of superphosphate, with .50 per cent. of added arsenic. The remaining series consisted of soaking the seed directly in solutions of arsenic. I used arsenious acid, and dissolved it with a weak caustic soda solution so as to get it into solution. Having done that, the soda solution was almost neutralised with acid, remaining slightly alkaline; and that was added to the ordinary superphosphate. I had different sets containing the following amounts:—Seeds soaked for 30 minutes in .15 grammes of arsenic in 100 cubic centimetres of water; that is, .15 per cent. In the next set the seeds were soaked for 30 minutes in .30 per cent. In the next the seeds were soaked for 30 minutes in .50 per cent; and in the last the seeds were soaked for 30 minutes in a 1.0 per cent. solution. I kept observation on those different lots, and it was only with the last lot—the seed when it was soaked in a 1 per cent. solution of arsenic—that germination was at all affected. I have here a record of the dates at which the different plants appeared, and so far as the germination of the seed was concerned there was practically no effect until you got above a strength of half per cent. of arsenic used in a solution.

12119. So the weaker solutions applied for the length of time you mention did not exercise any perceptible effect?—The weaker solutions had no effect in preventing or in retarding the germination.

12120. Then I understand you experimented on swedes?—Yes. The reason of my taking that crop was that it has often been asserted that a crop such as swedes might do harm eventually to people, because the swedes might be eaten off by sheep, the sheep might return the arsenic to the land in their droppings, and as it is a common practice, especially in our part of the country, to grow barley after swedes, so the arsenic might be carried on perhaps into the people who ate the mutton, or into the barley which was grown subsequent to the roots. Therefore I thought it well to experiment with the swede crop also. Very much the same series of practical experiments was carried out as with barley, viz., on quarter-acre plots of land. Plot 1 was without manure; on plot 2 there was 3 cwt. per acre of superphosphate made with arsenic-free acid;

Dr. J. A. Voelcker.

Only two specimens of soil tested for arsenic.

experiments 7 and 8. I should think that in Mr. Angell's experiments a good deal was due to the fact that he did not destroy the organic matter.

12159. (Chairman.) That, you think, may have made a difference in his estimations?—Yes, I think it affected the estimations.

12160. In reference to the soils which you tested for arsenic, did you test a large number of the specimens of Warren Field and of the Great Hill Field?—No; there were not a large number.

12161. I see there is just one result given in each

case, namely, '02 of arsenic in grains per lb. for Warren Field, and '014 for Great Hill?—I was saying just now that there are very few determinations made by modern and exact methods of the amount of arsenic in soils.

12162. Those two are a small number of tests?—That is all.

12163. Just two individual tests, were they?—Two individual tests. I made these because of finding arsenic in the leaves. I should not have thought of the arsenic being in the soil had it not been for the quantity found on the leaves.

Dr. J. A. Voecker.

3 April 1903.

## APPENDIX 16

## PROF. DELEPINE'S RAT EXPERIMENTS

EXPERIMENTAL INVESTIGATION INTO THE EFFECT OF VARIOUS SUBSTANCES ON THE  
MOTOR ACTIVITY OF RATS

By Prof. Delepine, University of Paris

The purpose of the following experiments was to determine the effect of various substances on the motor activity of rats. The substances tested were: (1) Cocaine, (2) Amphetamine, (3) Ephedrine, (4) Adrenaline, (5) Atropine, (6) Morphine, (7) Chloroform, (8) Ether, (9) Chloralhydrate, (10) Potassium bromide, (11) Sodium chloride, (12) Calcium chloride, (13) Magnesium chloride, (14) Zinc chloride, (15) Iron chloride, (16) Copper chloride, (17) Silver chloride, (18) Lead chloride, (19) Barium chloride, (20) Strontium chloride, (21) Potassium nitrate, (22) Sodium nitrate, (23) Calcium nitrate, (24) Magnesium nitrate, (25) Zinc nitrate, (26) Iron nitrate, (27) Copper nitrate, (28) Silver nitrate, (29) Lead nitrate, (30) Barium nitrate, (31) Strontium nitrate, (32) Potassium sulphate, (33) Sodium sulphate, (34) Calcium sulphate, (35) Magnesium sulphate, (36) Zinc sulphate, (37) Iron sulphate, (38) Copper sulphate, (39) Silver sulphate, (40) Lead sulphate, (41) Barium sulphate, (42) Strontium sulphate, (43) Potassium carbonate, (44) Sodium carbonate, (45) Calcium carbonate, (46) Magnesium carbonate, (47) Zinc carbonate, (48) Iron carbonate, (49) Copper carbonate, (50) Silver carbonate, (51) Lead carbonate, (52) Barium carbonate, (53) Strontium carbonate, (54) Potassium bicarbonate, (55) Sodium bicarbonate, (56) Calcium bicarbonate, (57) Magnesium bicarbonate, (58) Zinc bicarbonate, (59) Iron bicarbonate, (60) Copper bicarbonate, (61) Silver bicarbonate, (62) Lead bicarbonate, (63) Barium bicarbonate, (64) Strontium bicarbonate, (65) Potassium phosphate, (66) Sodium phosphate, (67) Calcium phosphate, (68) Magnesium phosphate, (69) Zinc phosphate, (70) Iron phosphate, (71) Copper phosphate, (72) Silver phosphate, (73) Lead phosphate, (74) Barium phosphate, (75) Strontium phosphate, (76) Potassium acetate, (77) Sodium acetate, (78) Calcium acetate, (79) Magnesium acetate, (80) Zinc acetate, (81) Iron acetate, (82) Copper acetate, (83) Silver acetate, (84) Lead acetate, (85) Barium acetate, (86) Strontium acetate, (87) Potassium formate, (88) Sodium formate, (89) Calcium formate, (90) Magnesium formate, (91) Zinc formate, (92) Iron formate, (93) Copper formate, (94) Silver formate, (95) Lead formate, (96) Barium formate, (97) Strontium formate, (98) Potassium oxalate, (99) Sodium oxalate, (100) Calcium oxalate, (101) Magnesium oxalate, (102) Zinc oxalate, (103) Iron oxalate, (104) Copper oxalate, (105) Silver oxalate, (106) Lead oxalate, (107) Barium oxalate, (108) Strontium oxalate, (109) Potassium citrate, (110) Sodium citrate, (111) Calcium citrate, (112) Magnesium citrate, (113) Zinc citrate, (114) Iron citrate, (115) Copper citrate, (116) Silver citrate, (117) Lead citrate, (118) Barium citrate, (119) Strontium citrate, (120) Potassium tartrate, (121) Sodium tartrate, (122) Calcium tartrate, (123) Magnesium tartrate, (124) Zinc tartrate, (125) Iron tartrate, (126) Copper tartrate, (127) Silver tartrate, (128) Lead tartrate, (129) Barium tartrate, (130) Strontium tartrate, (131) Potassium succinate, (132) Sodium succinate, (133) Calcium succinate, (134) Magnesium succinate, (135) Zinc succinate, (136) Iron succinate, (137) Copper succinate, (138) Silver succinate, (139) Lead succinate, (140) Barium succinate, (141) Strontium succinate, (142) Potassium malate, (143) Sodium malate, (144) Calcium malate, (145) Magnesium malate, (146) Zinc malate, (147) Iron malate, (148) Copper malate, (149) Silver malate, (150) Lead malate, (151) Barium malate, (152) Strontium malate, (153) Potassium fumarate, (154) Sodium fumarate, (155) Calcium fumarate, (156) Magnesium fumarate, (157) Zinc fumarate, (158) Iron fumarate, (159) Copper fumarate, (160) Silver fumarate, (161) Lead fumarate, (162) Barium fumarate, (163) Strontium fumarate, (164) Potassium pyruvate, (165) Sodium pyruvate, (166) Calcium pyruvate, (167) Magnesium pyruvate, (168) Zinc pyruvate, (169) Iron pyruvate, (170) Copper pyruvate, (171) Silver pyruvate, (172) Lead pyruvate, (173) Barium pyruvate, (174) Strontium pyruvate, (175) Potassium lactate, (176) Sodium lactate, (177) Calcium lactate, (178) Magnesium lactate, (179) Zinc lactate, (180) Iron lactate, (181) Copper lactate, (182) Silver lactate, (183) Lead lactate, (184) Barium lactate, (185) Strontium lactate, (186) Potassium gluconate, (187) Sodium gluconate, (188) Calcium gluconate, (189) Magnesium gluconate, (190) Zinc gluconate, (191) Iron gluconate, (192) Copper gluconate, (193) ## APPENDIX 16.

Appendix 16.

## PROF. DELÉPINE'S RAT EXPERIMENTS.

## EXPERIMENTAL INVESTIGATION UPON THE ACTION OF ARSENICAL BEER AND OTHER ARSENICAL SOLUTIONS ADMINISTERED IN LARGE QUANTITIES TO RATS.

*Handed in by Professor S. Delépine, 13 June 1902.*

The objects of this investigation were to ascertain :—

1. Whether the presence of arsenious acid in beer could account for the changes observed in persons who had consumed arsenical beer.

2. Whether it was necessary to assume that a compound more poisonous than arsenious acid was present in arsenical beer.

3. Whether the presence of organic compounds of arsenic such as cacodylates could account better for the effects of arsenical beer than the presence of arsenious acid.

4. Whether the quantities of arsenic found in beer by chemical analysis were sufficient to account for the effects produced by arsenical beer.

5. Whether the presence of alcohol in such amounts as are usually present in beer so favour the pathogenic action of arsenic as to render minute doses of that poison exceptionally noxious.

6. Whether concurrent influences, such as insufficient diet, could account (as I had surmised) for the different effects of arsenical beer upon different individuals.

Rats were specially suitable for the experiments, because they take beer and weak watery solutions of alcohol and arsenious acid very readily, and can adapt themselves to considerable variations in their diet.

They are less affected by arsenic than man and many other mammals.

In man doses of arsenious acid varying between 0.1 gramme and 2 grammes have been stated to produce death (Lachèse, Tardieu, Orfila).

A dose of 2 grammes to a man of moderate weight i.e., weighing about 65,000 grammes, is equivalent to a dose of 0.003 grammes per 100 grammes body weight. Rouyer has found that arsenious acid or arsenites administered to dogs by the mouth was fatal in doses of 0.006 grammes per 100 grammes body weight (a dose of 0.015 grammes of arsenate of soda is necessary to produce the same result). Such a dose usually produces death in twenty-four or forty-eight hours. In rats I have found that a much larger dose was necessary to produce death in four and five days when administered by the mouth. A single dose of 0.012 per cent. of body weight produced the death of a rat weighing 135 grammes in four days. Two doses each of 0.006 grammes per cent. of body weight administered to another rat weighing 141 grammes produced death in five days from the giving of the first dose. From these results it would appear that the lethal dose of arsenious acid administered by the mouth may be for rats at least twice greater than the lethal dose for dogs, and four times greater than the lethal dose for man. (See General Table (I.) of Results, Experiments 16 and 17.) These figures are necessarily only approximate, especially with regard to man, but they are none the less useful in forming an opinion upon the value of the results obtained in experiments on rats. Thus, in trying to estimate the probable effects of certain quantities of arsenical beer upon man, I have thought it desirable to administer to a certain number of rats solutions containing at least four times more arsenic than I had found in the most contaminated beers examined by me during the outbreak. I have, however, also used doses smaller than those actually taken by many beer drinkers.

Most of the beers I have examined contained less than 2 grains of arsenic per gallon. In one case I have found over 1½ grains of arsenic per gallon. The largest quantity of arsenious acid I gave to rats for ordinary experimental purposes was 7 grains per gallon, the fluid being given at the rate of 1 gallon a day for a man weighing 140lbs. The quantity of beer taken by sufferers has frequently exceeded 1 and 2 gallons daily, i.e., 7.14 per cent. to 14.28 per cent. of the weight of a man weighing 140lbs. I have administered the arsenical beer or solutions in quantities equivalent to 8 per cent. or 16 per cent. of the body weight of the experimental animals. The slight excess being allowed as a compensation for accidental unnoticed losses.

The experiments were conducted in sets. In each set a certain number of rats were placed under conditions absolutely identical. All the cages were of the same size and shape, placed side by side in the same part of the room, so as to be at the same temperature and receive the same amount of light. All the rats were fed at the same hour in the morning, and were weighed just before being fed. A certain number of experiments were always carried out simultaneously, these groups of experiments constituting what I call a set. The various sets were started at short intervals from each other, but care was taken to make the general conditions in the various sets as similar as possible.

To test the action of the arsenic and alcohol it was necessary to submit the animals to variations in the feeding. (The victims of the arsenic epidemic belonged chiefly to a class liable to great irregularities in their diet.) During certain periods of each set of experiments these variations were identical for the various animals composing the set. It is upon those "comparable periods" that conclusions must be chiefly based. The comparable periods in all cases extended over one month, and in several sets over seven or eight weeks.

In considering the results of each set of experiments, it will be necessary to analyse the results obtained, first, during the whole time the animal was under observation (see Diagrams and Table I.); second, during each special period characterised by the administration of a special amount of food (see Diagrams); third, during the comparable groups of periods (Diagrams and Table II.). To make all the results comparable all the quantities have been reduced to a percentage of the weight of the animal at the beginning of each experiment and at the beginning of each special group of periods composing the comparable periods.

Definite quantities of food and drink were daily measured and weighed, but it sometimes happened that the rats did not take the whole supply. When any food or fluid was left over at the end of twenty-four hours this was carefully weighed before a new supply of food was given. I have, therefore, distinguished in the record of results between the amount of food and drink given and those taken. All the figures recorded have been calculated on the basis of the food and drink actually taken. In the diagrams the amounts given are indicated as well as the amounts left over (except when the difference was trifling). The amounts left over were generally indications of a bad state of health or of a dislike for certain solutions (watery solutions were usually not so well taken as beer).

The description of each set of experiments will indicate the special object of that experiment.\*

\* In Table I. a synoptical summary of quantities given during the whole course of the experiments and of the gross results will be found. In Table II. a similar summary relating to comparable groups of periods. In the diagrams 1 to 6 detailed records of daily variation will be found. In these tables and diagrams the same numbers and letters of reference as those given in the text have been used. Although daily records have been kept in all the experiments, I have found it advisable to record in the diagrams the average results of consecutive periods of three days. In this way the curves have been equalised and the irregularities produced by micturition and defecation reduced to a minimum. For shortness sake the word arsenic is frequently used here as synonymous with arsenious acid. The word arsenicum is used to designate metallic arsenic.

Condition of the experiments.

Mode of feeding. Comparable periods.

Analysis of results.

Estimation of the amount of food and drink taken by the experimental rats.

## Appendix 16.

## A. ALTERATIONS OBSERVED DURING THE LIFE OF ANIMALS EXPERIMENTED UPON.

First set of experiments.

First Set of Experiments.—This consisted of five experiments, one of which had to be discarded at the end of one month. A pregnancy of the animal, which had not been noticed at the onset, caused alterations in weight which vitiated the results. The four other rats were given respectively:—

Experiment 1.—Salford arsenical beer containing 25 parts of arsenic per 10 million parts, or about  $\frac{1}{4}$  grain per gallon. The amount given daily was about 16 per cent. of the body weight (corresponding to over 2 gallons for a man weighing 140lbs.), amount of alcohol about 5 per cent.

Experiment 2.—Watery solution of arsenious acid containing 20 parts of  $As_2O_3$  per 10 million (or about 1-7th grain per gallon). Amount given daily, 8 per cent. of body weight (corresponding to over 1 gallon for a man weighing 140lbs.). No alcohol.

Experiment 3.—Salford arsenical beer to which arsenious acid was added so as to make the total amount of arsenic equal to 1,000 parts per 10 million, or about 7 grains per gallon. Amount given daily, 8 per cent. of body weight (corresponding to over 1 gallon for a man weighing 140lbs.); amount of alcohol, about 5 per cent.

Experiment 4.—Watery solution of arsenious acid containing 1,000 parts of  $As_2O_3$  per 10 million (or about 7 grains per gallon); amount given daily, 8 per cent. of body weight (over 1 gallon for a man 140lbs. in weight); no alcohol.

The changes observed during the various periods of the experiment were as follows:—

Period A.—Duration, 36 days; food, oats and dry bread; amount, 14 per cent. of body weight (except in Experiment 3, in which food was 10 per cent. of body weight). In all cases but No. 4 there was a rapid increase of weight. This increase was very sudden and considerable in Experiment 3, and more gradual in Experiment 1.

Period B.—Duration, 9 days; food reduced to 3-3 per cent. of body weight (dry bread only). Great and rapid loss of weight in all cases. Rats 1 and 2, which received moderate doses of arsenic, may be compared. The loss of weight was much more marked in 2 than in 1, although rat 1 was drinking beer containing 1-6th grain of arsenic per gallon at the rate of over 2 gallons per day, and rat 2 a watery solution containing 1-7th grain of arsenic per gallon at the rate of over 1 gallon per day. The watery solution seemed therefore to be more detrimental than the arsenical beer.

In 3 and 4 the dose of arsenic was much above that found in ordinary arsenical beer. The loss of weight was not sensibly greater than in 1 and 2. Rat 4 did not usually take the whole of the watery solution given to it.

Period C.—Duration, 9 days; food increased to 5 per cent. of body weight (dry bread only). This caused a diminution in the rate of loss of weight except in 4.

This effect was most marked in rats 1 and 3, both of which were taking beer. It was more marked in rat 3 than in rat 2, although rat 3 was taking a much larger amount of arsenic than rat 2. Rats 2 and 4 did not take the whole of the watery solution given to them.

Period D.—Duration, 9 days; arsenical fluids replaced by pure water; food increased to 10 per cent. (dry bread). Considerable increase in weight of animal 1. Distinct increase, but less considerable, of animals 2 and 4. No marked effect in animal 3.

Period E.—Duration, 15 days; arsenical fluids resumed at the same rate as before Period D; food reduced to 5 per cent. (dry bread). A slight gain in weight was observed in the case of 1. All the other animals remained stationary; 2 and 4 left much of the watery solution given to them.

Period F.—Duration 12 days; experiment interrupted by the death of 2, 3, and 4; food reduced to 3-3 per cent. (dry bread). Marked loss of weight in all cases. The loss was slighter in 1 than in 2, 3, and 4. In 2 and 3 the loss was considerable. In 4 it was less marked owing probably to the animal being already considerably emaciated at the end of period E. Rat 3 died 11 days, rat 2 12 days, and rat 4 13 days after the beginning of this period. They all died suddenly, apparently from failure of the heart, or of the respiratory muscles. Rats 2 and 4 left much of the watery solution given to them.

Period G was a continuation of period F in the case of the surviving animal No. 1. This animal, kept on

the same low diet for another 12 days, after a further slight loss of weight, maintained its weight for six days.

Period H.—Duration, 18 days; the arsenical beer was replaced by arsenic-free lager beer; and the food (dry bread) increased to 10 per cent. This was followed by a slight increase in weight, but after 12 days the animal began to lose flesh again. The animal, which had taken its food and drink well up to this date, began to leave a considerable portion of both untouched.

Period I.—Duration, 12 days; lager beer replaced by water; food (dry bread) remaining 10 per cent. For 6 days the rate of loss by weight remained the same as in the previous period, but when the weight had been reduced to about 80 per cent. of the original weight the fall ceased. Some food and drink left.

Period K.—Duration, 12 days; water replaced by lager beer; food the same as in I. No sensible effect observed. The animal took the beer better than water, but did not eat the whole of its food, although it took more food than in the two preceding periods.

The stoppage of the arsenical beer was apparently followed by a marked disorder of health, manifested by a disinclination to take food and drink, which had been well taken up to then, and a marked loss of weight. This animal was then killed.

Results during the group of periods selected for comparisons. Composed of part of period A, whole of periods B, C, D, E, and part of period F, during which the animals were submitted to the same conditions except with regard to the administration of experimental fluid.

Total duration of selected period, 60 days.

(See detailed account of quantities of arsenic and alcohol taken daily in Table II.)

1. Salford arsenical beer, 2 gallons daily; average daily loss of weight, 0-20 per cent.

2. Watery solution containing a little less arsenious acid than the Salford beer, 1 gallon of solution daily; quantity of arsenic taken daily less than half that taken by No. 1; average daily loss of weight, 0-62 per cent.

3. Salford arsenical beer with arsenious acid added up to 7 grains per gallon i.e., containing 40 times as much arsenic as the original Salford beer; average daily loss of weight, 0-62 per cent.

4. Watery solution of arsenious acid containing 7 grains of arsenious acid per gallon (i.e., the same quantity as in Experiment 3); average daily loss of weight, 0-83 per cent.

This first set of experiments seemed to indicate that—

(1) Solutions of arsenious acid in water acted in the same way as arsenical beer.

(2) That arsenical beer was less injurious than watery solutions of arsenic of the same strength.

(3) That when an animal was well fed the presence of a small quantity of arsenic did not affect its health seriously for a time.

(4) That doses of arsenic, much greater than those found in arsenical beer capable of causing symptoms of chronic arsenical poisoning, might be taken for about one month without causing death, but that death was liable to occur suddenly at the end of such a period.

(5) That after arsenical beer had been taken for a period of over three months the sudden stoppage of that fluid might be attended with disturbance of health causing serious loss of weight.

The correctness of these provisional conclusions was tested in the following set of experiments:—

Second Set of Experiments.—Three rats were given the following fluids in daily quantities, uniformly equivalent to 8 per cent. of their body weight (corresponding to over 1 gallon for a man 140lbs. in weight).

Experiment 6.—Ordinary bitter beer, containing a trace of arsenic, always less than one part in 10 million (i.e., less than 1-143rd grain per gallon); pure ethylic alcohol was added to the beer to bring the percentage of alcohol up to 10 per cent. (by weight), so as to make the beer distinctly richer in alcohol than beer in ordinary use.

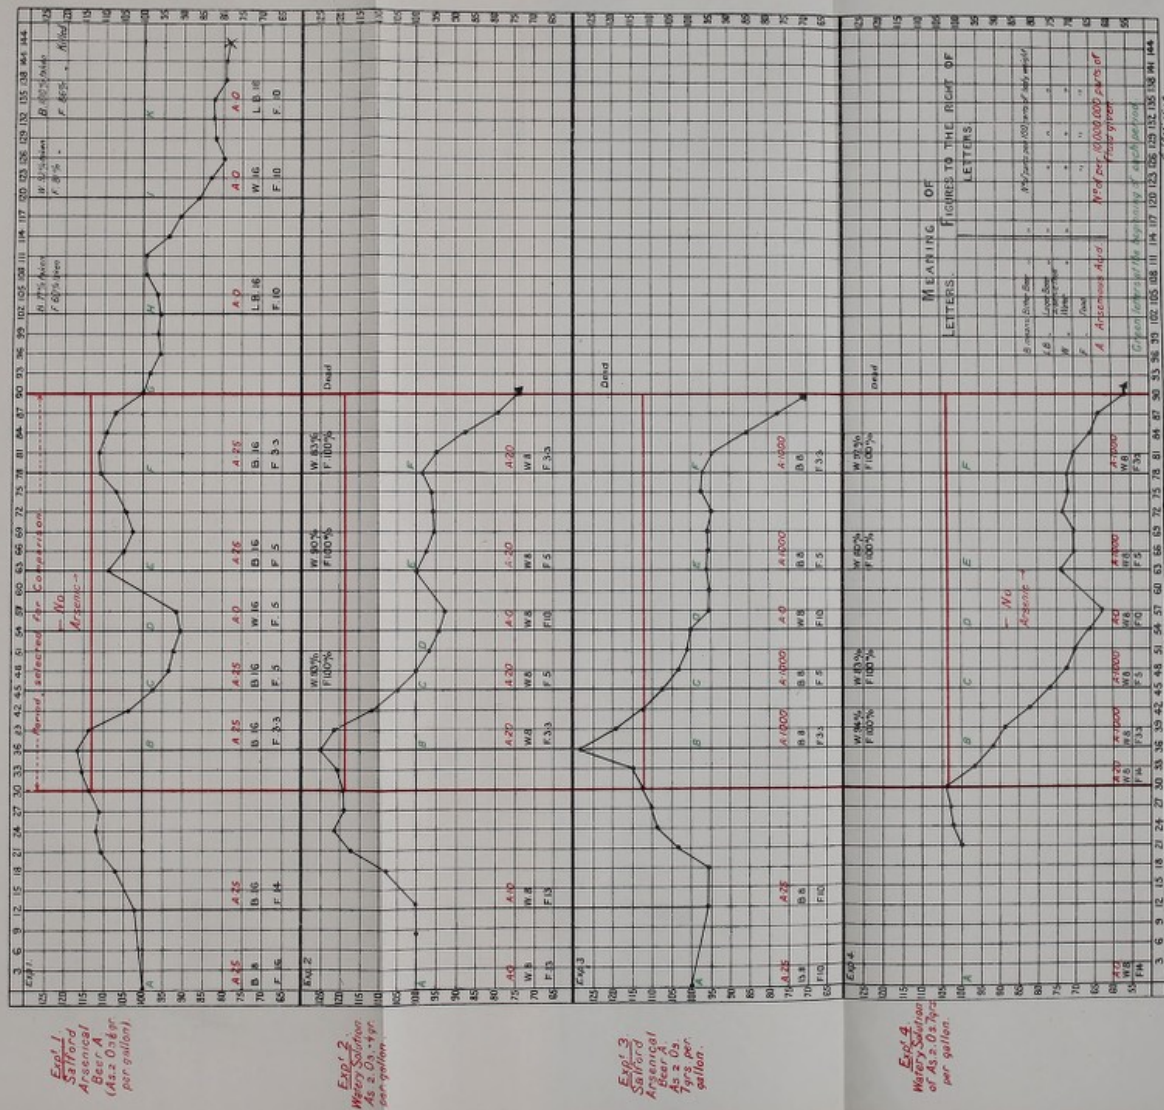

Experiment 7.—Ordinary bitter beer, containing a trace of arsenic (same as that used in Experiment 6), to which arsenious acid was added so as to bring the pro-

General results of first set of experiments. Provisional conclusions.

Second set of experiments.

SET 1. Action of Sulfuric Arsenical Beer to which Arsenious Acid has been added, and of Arsenical Solutions (water) in which Arsenic was in the same proportions as in the other fluids.

DIAGRAM 1.

The original weight of each animal is reduced to 100 and the subsequent weights are given in proportion to an original weight of 100 grammes. The black vertical lines indicate the beginning of each period of the experiment, each one of such periods is characterised by the amount of fluid and sometimes the kind & quantity of fluid given.

The vertical red lines indicate the beginning & the end of the group of periods selected for comparison.

The horizontal red lines indicate the weight of the animal at the beginning of the group of periods selected for comparison.

The figures in the columns on the right and left of the diagrams indicate the number of days of the experiment.

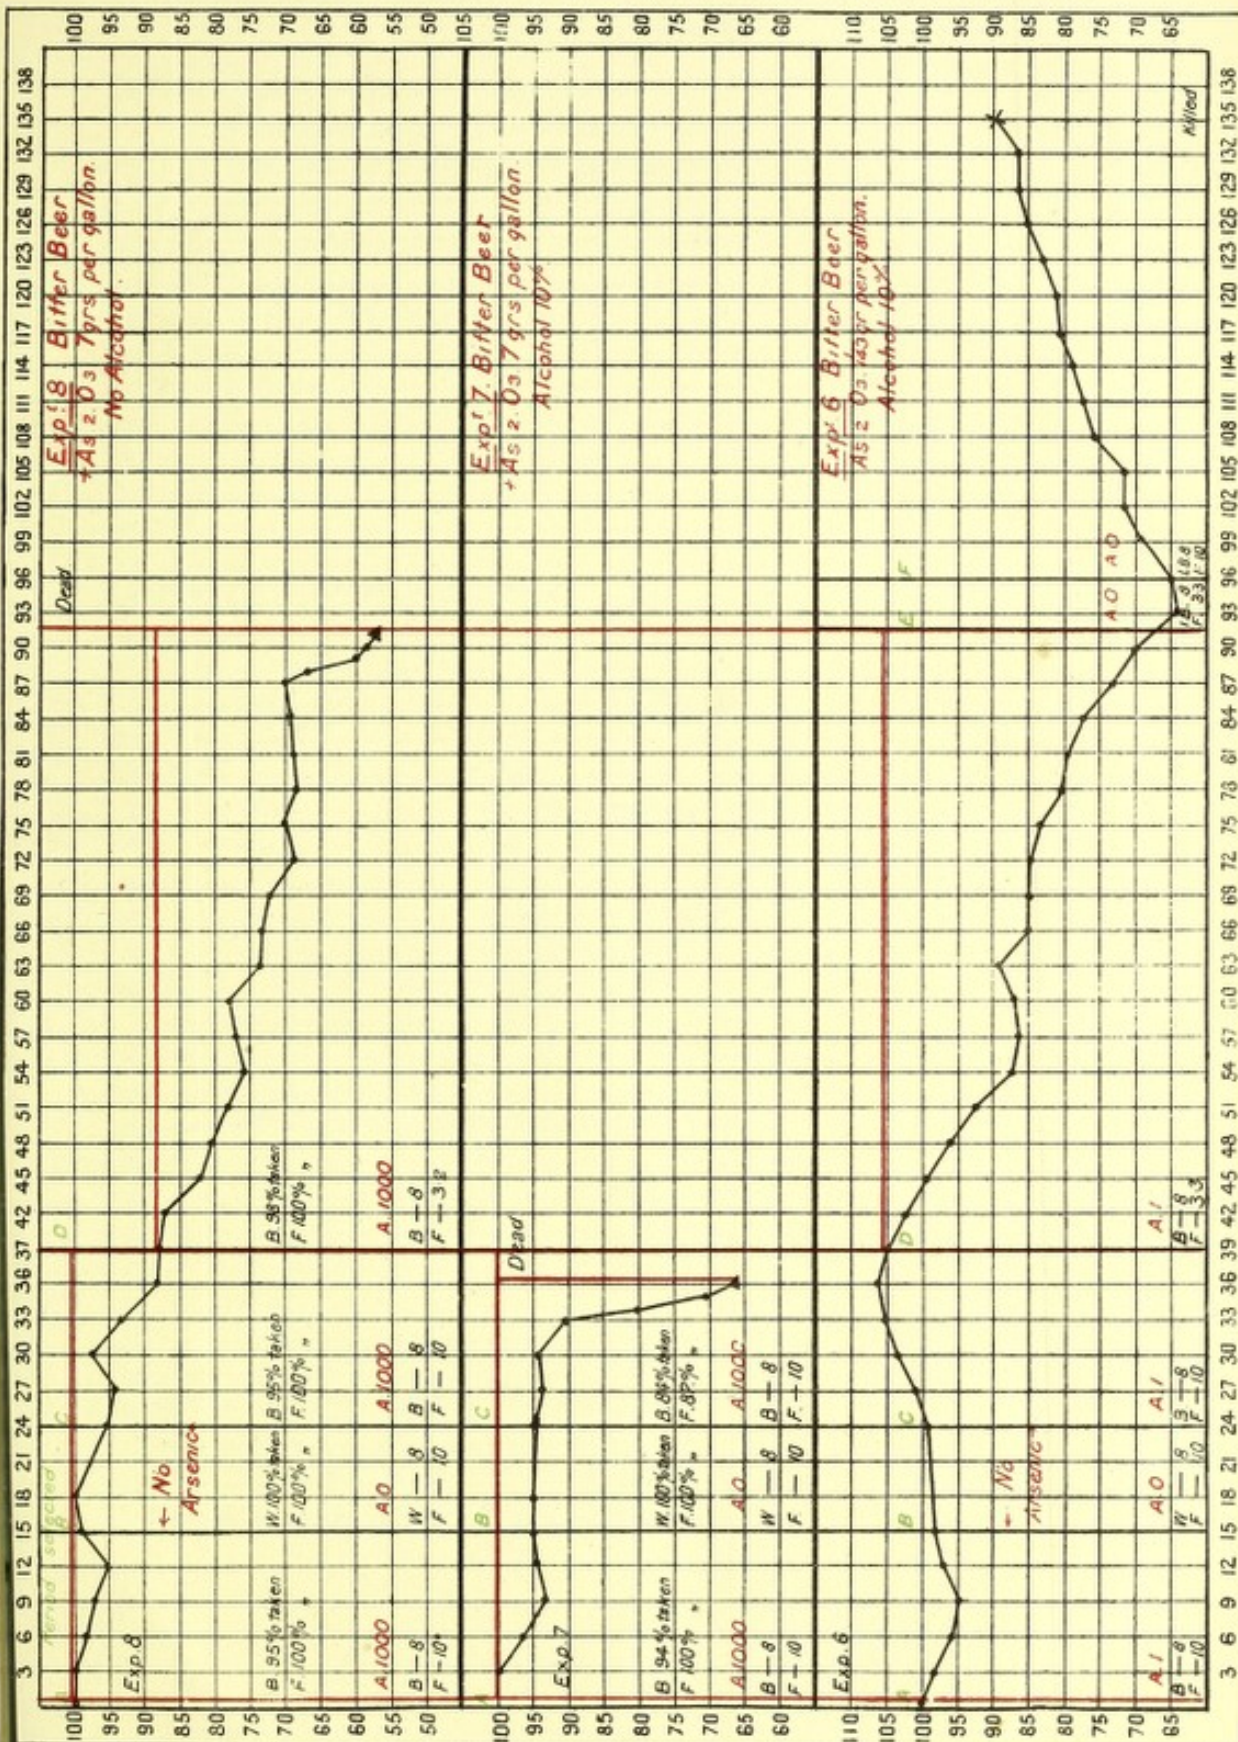

The percentages given near the top line of each diagram indicate the amount of fluid and food taken when the whole of what had been given was not taken.

The figures near the bottom line of each diagram indicate the amount of fluid and food given daily.

DIAGRAM 2.

SET II. *Action of Beer with a trace of Arsenic and 10% Alcohol; of the same beer to which a large amount of Arsenic had been added; & of the same beer containing as much Arsenic as in the last case but from which Alcohol had been driven off.*

Weller & Graham Ltd Litho. London.

portion of arsenic up to 1,000 parts in 10 million (i.e., about 7 grains per gallon); pure ethylic alcohol added so as to bring the percentage of alcohol up to 10 per cent., as in the previous case.

**Experiment 8.**—Ordinary bitter beer (the same as in the two previous experiments), heated in saturated steam so as to drive off the bulk of the alcohol without concentrating the beer. To this practically alcohol free beer, arsenious acid was added up to 1,000 parts in 10 millions (i.e., about 7 grains per gallon).

The changes observed during the various periods of the experiments were as follows:—

**Period A.**—Duration 15 days. Administration of the three beers begun at once. Food, 10 per cent. of body weight. After an initial loss of weight, rats 6 and 8 recovered entirely, in 7 a loss of weight amounting to about 4 per cent. of the original weight was observed. All the animals took their food and drink well.

**Period B.**—Duration 9 days. Beer replaced by an equal amount of water. Food, 10 per cent. of body weight. Slight gain in rat 6; slight loss in rat 7; marked loss (over 4 per cent.), in rat 8. The replacement of arsenical beer by arsenic free water did not seem to have a beneficial effect in any of the cases.

**Period C.**—Duration 15 days. Beer resumed. Food, 10 per cent. of body weight. Marked increase of weight in rat 6 (about 7 per cent.); great loss of weight in rat 7. This rat died 12 days after the beginning of the period, its weight being reduced to 67 per cent. of the original weight; marked loss of weight in rat 8. Thus, the beer containing a large amount of arsenic, plus a marked excess of alcohol, appeared to cause death sooner than the beer containing an equal amount of arsenic; but no alcohol.

**Period D.**—Duration 52 days. (Only 6 and 8 remain). Beer as before; food reduced to 3·3 per cent. Marked steady loss of weight in both cases. Rat 6 was reduced to 68 per cent. of its original weight; rat 8 was reduced to 57 per cent. of its original weight, and then died suddenly at the end of the period. The only animal surviving was, therefore, rat 6, which was taking beer containing a trace of arsenic and 10 per cent. of alcohol.

**Period E.**—Duration 5 days. To find out whether the reduction in the amount of food was alone responsible for the loss of weight the bitter beer was replaced by lager beer, the amount of food remaining the same. During the first three days the fall of weight continued, then the weight began to rise again.

**Period F.**—Duration 39 days. To ascertain whether the animal had been permanently injured by the low feeding and the drinking of bitter beer, with a trace of arsenic, the administration of lager beer was continued, and the amount of food raised to 10 per cent. This was followed by a steady increase in weight. The animal was killed when its weight had risen again to 90 per cent. of the original weight, and it looked again apparently quite well.

Selected comparable periods corresponding to A, B, and C. Total duration of this period 39 days (36 in the case of rat 8). (See detailed account in Table II). Rat 6: Bitter beer containing a trace of arsenic and 10 per cent. of alcohol, over one gallon taken daily; average daily gain in weight, 0·11 per cent. Rat 7: Bitter beer, containing 7 grains of arsenic per gallon, and 10 per cent. of alcohol; over 1 gallon taken daily; average daily loss of weight, 0·90 per cent. Rat 8: Bitter beer, containing 7 grains of arsenic per gallon, and deprived of its alcohol, over 1 gallon taken daily; average daily loss of weight, 0·30 per cent.

The outcome of this set of experiments seems to be that arsenical beer, containing only a trace of arsenic, even in presence of an amount of alcohol above the average, is not very injurious to the health so long as a large amount of food is taken. The presence of a large amount of arsenic is clearly injurious, whether alcohol is present or not, but the presence of a large amount of alcohol seemed in this case to precipitate the fatal issue. The loss of weight in Experiment 7 was greater than in Experiment 3 (first set), in which the same amount of arsenic was administered in beer containing only 5 per cent. of alcohol. As in the first set of experiments, I observed that the replacement of the arsenical beer by pure water is not always attended with a beneficial result. The animals 7 and 8

died suddenly, in the same way as the animals of the Appendix 16. first set died.

**Third Set of Experiments.**—This consisted of three experiments, one of which (No. 11) is a control experiment, comparable both with this and other sets of experiments. (Experiment 12 in the 6th set is another control of the same kind, and differs from 11 by the amount of food given.) Three rats were given the following fluids in daily quantities, uniformly equivalent to 8 per cent. of their body weight (corresponding to over 1 gallon for a man 140lbs. in weight).

**Experiment 9.**—Beer brewed in the laboratory from arsenic-free malt and hops, part of the malt being replaced by arsenical glucose obtained from Bostock's so as to introduce about 1 grain of arsenious acid per gallon of beer. At the end of the process there were found 130 parts of arsenious acid per 10 million parts of beer (or 0·91 grains per gallon), the amount of alcohol being 5·31 per cent. by weight 6·63 per cent. by volume).

**Experiment 10.**—Cacodylate of sodium dissolved in arsenic free beer or water, so as to make the proportion of arsenicum per gallon equal to that in Experiment 9 ( $\text{As}_2\text{O}_3 = 198$ — $\text{Na Kd O}_2 = 160$ ). That is to say, 210 parts of cacodylate were added to each 10 million parts of fluid, giving a quantity about 1·47 grain per gallon).

**Experiment 11.**—Water or arsenic free beer (lager beer). The changes observed during the various periods were as follows:—

**Period A.**—Duration, 12 days; food, 10 per cent. of body weight; water, 8 per cent. of body weight. Slight loss of weight in rat 9. Distinct, but moderate, increase of weight in rats 10 and 11.

**Period B.**—Duration, 9 days; administration of experimental fluids mentioned above, quantity 8 per cent. of body weight; food, 8 per cent. of body weight. Rat 9, slight loss of weight. Rat 10, considerable increase of weight. Rat 11, slight increase of weight.

**Period C.**—Duration, 48 days; experimental fluid given in the same quantities as in the previous period; food, reduced to 3·3 per cent. of body weight. Rat 9, steady and considerable loss of weight, amounting to 45 per cent. of original weight. The animal died suddenly at the end of the period. Rat 10 (nine days after the beginning of this period, the cacodylate of sodium which had previously been given dissolved in water, was given dissolved in lager beer, to make experiment 10 comparable with experiment 9). So long as the watery solution was given there was a rapid loss of weight, but as this followed a previous rapid increase, the weight of the animal did not fall below the original weight.

(C 1.) Soon after the water had been replaced by beer the loss of weight ceased to be manifest, and at the end of the period (although the diet had been insufficient) the loss was only about 7 per cent. of the original weight. Rat 11: This animal was given water for the first 9 days, to allow comparison to be made between experiments 10 and 11. As in 11, a considerable loss of weight was observed.

Arsenic free lager beer was then given instead of water, and as in the previous case, this prevented a further loss of weight.

(C 2.) To ascertain whether the beneficial action was really due to the administration of beer 25 days later the lager beer was again replaced by water; this was followed by a rapid loss of weight.

The results obtained during this period seem to show:—

1st. That the arsenical beer brewed in the laboratory and deriving its arsenic from arsenical glucose, and containing no more arsenic than beer found on the market during the epidemic, was very noxious.

2nd. That solutions of cacodylate of sodium in water and in beer, behaved much in the same way as water and beer free from arsenic. The presence of cacodylate of sodium seemed even to have a beneficial effect.

3rd. That an animal receiving an insufficient diet kept its weight better when given arsenic free beer than when given water to drink. The beer in such cases apparently acted as food.

**Period D.**—Duration, 6 days; food, the same as during the previous period (3·3 per cent.). Rat 10: Lager beer solutions of cacodylate of sodium replaced by watery solutions of the same strength. Loss of weight equal to about 4 per cent. of original weight. Rat 11: Water replaced by lager beer. Gain of weight about 2 per cent.

Summary of results obtained during period C. of third set of experiments.

Appendix 16. of original weight. These results confirm those observed during period C as regard the action of cacodylate of sodium and of arsenic free beer.

Period E.—Duration, 19 days; food increased to 10 per cent; fluids continued as in period D. Rat 10: Rapid increase in weight; at the end of this period the weight of the animal was 108 per cent. of the original weight. The rat was then killed. Rat 11: Very rapid increase in weight. At the end of the period the weight of the animal was about 106 per cent. of its original weight. It was then killed.

These results show that after being on an insufficient diet for 54 days, and losing weight, an animal taking a large quantity of cacodylate of sodium, recovered its weight as well as an animal having received no arsenical fluid, when put on an abundant diet.

Selected comparable groups of periods, corresponding to A, B, and C. Total duration, 60 days; food insufficient during greater part of period.

Experiment 9.—Laboratory beer, containing 0.91 grain of arsenious acid per gallon, arsenic derived from arsenical glucose. Average dose taken over 1 gallon per diem. Daily loss of weight, 0.76 per cent. of original weight.

Experiment 10.—Cacodylate of sodium dissolved in water or beer, 1.47 grains per gallon, average dose taken over 1 gallon per diem. Daily loss of weight, 0.22 per cent. of original weight.

Experiment 11.—Water or arsenic-free beer, average dose taken daily, over 1 gallon. Daily loss of weight, 0.45 per cent.

This set of experiments showed that beer containing arsenic derived from arsenical glucose, used as a malt substitute in brewing, was apparently as injurious as finished beer to which pure arsenious acid had been added. Cacodylate of sodium had apparently no bad effect, and seemed even to be beneficial. Beer free from arsenic, and containing a small amount of alcohol, was distinctly beneficial, and apparently acted as a food.

Fourth set of experiments.—This consisted of experiments on 2 rats which were kept under observation for over two months. These experiments had for object to compare the effects of watery solutions of pure ethylic alcohol, and of watery solutions of pure arsenious acid, in which the alcohol and arsenic were present in quantities similar to those found in arsenical beer. Opportunity was also taken to observe the effects of isolation of the animals, and of the addition of some animal food to the vegetable diet given in the course of all the other experiments.

Period A (Experiments 14 and 15).—Duration, 6 days. Both animals were left for 6 days among other rats supplied with an unlimited amount of oats and water. Both rats exhibited considerable daily variations of weight, but at the end of the period had not gained more than most of the isolated rats supplied with 8 or 10 per cent. of their weight of food.

Period B.—The two rats were then isolated, and the amount of food reduced to 10 per cent.; the weight remained stationary for three days.

Period C.—A part of the bread was then replaced by an equal amount of cheese (bread 8 per cent., cheese 2 per cent. of the body weight). At the end of 9 days both animals had considerably increased in weight.

Period D.—The actual experiment was then begun. Experiment 14.—This rat was given a watery solution of arsenious acid (containing  $\frac{1}{2}$  grain of the poison to the gallon) at the rate of over 1 gallon a day.

Experiment 15.—This rat was given a watery solution of pure ethylic alcohol (containing 5 per cent. of alcohol) at the rate of over 1 gallon a day. The food remained the same as in the previous period (bread and cheese). In both cases the weight of the animal continued to increase, but not so regularly as before the administration of arsenic or alcohol.

Period E.—Duration, 6 days; the same quantity of food was given, but the cheese was stopped. The same solutions were given. In both cases the weight continued to increase for a short time, then it fell slightly.

Period F.—Duration, 6 days; the same fluids being given, the food was reduced to 3 per cent. (a quantity insufficient to maintain the weight under ordinary circumstances). This was followed by a rapid loss of weight, more rapid in the case of the rat taking arsenic than in the case of the rat taking alcohol. The weight of both rats was still above their original weight.

Period G.—Duration, 33 days; the same quantity of

food was given, and in Experiment 14 the watery solution of arsenic was continued as before. In Experiment 15 arsenious acid was added to the alcoholic solution, so as to cause the rat to take, in addition to the alcohol, the same amount of arsenic as was taken by rat 14. At the end of the period rat 14 (taking arsenic alone) had lost during the period about 35 per cent. of its original weight, whilst rat 15 (taking both alcohol and arsenic) had lost during the same period about 18 per cent. of its original weight. At that time the weight of rat 14 was less than 90 per cent. of its original weight (70 days previously), whilst the weight of rat 15 was over 98 per cent. of its original weight (70 days previously).

Period H.—Duration, 12 days; the food was continued as before.

Experiment 14.—Alcohol was added to the arsenical solution; this seemed at first to have a beneficial effect, but the weight began again to fall rapidly, and the animal died suddenly at the end of the period.

Experiment 15.—The alcohol solution was replaced by a watery solution of arsenic of the same strength as before, but without alcohol. The rat began immediately to lose weight much more rapidly than before, and at the end of 12 days had lost nearly 20 per cent. of its original weight.

The chief outcome of this set of experiments was that General alcohol when given in small doses together with arsenic does not seem to intensify the bad effects of the latter; there is, on the contrary, an indication that alcohol retards the action of arsenic. During the preliminary stages of the experiment rat 14 increased in weight more rapidly than rat 15, and yet at the end of the experiment rat 14 had lost weight to a greater extent than rat 15, which was taking arsenic along with alcohol.

Fifth Set of Experiments.—These experiments had for object to determine the lethal dose of arsenious acid when the poison was taken under the conditions of the previous experiments. The results have already been discussed at the beginning of this summary, and are also given in Tables I. and II.

Sixth Set of Experiments.—These experiments had for object to control some of the previous experiments. I had been impressed with the fact that rats generally kept in better health and required less food to maintain their weight when lager beer was administered than when ordinary bitter beer or even water was given to them. In order to ascertain whether this conclusion was correct, I took two rats and gave them each a daily amount of food equal to 5 per cent. of their body weight, i.e., quantity barely sufficient to keep their weight constant when no other drink than water was given to them. I then gave them both for short periods either lager beer or bitter beer at the rate of over 1 gallon daily. Finally I gave one of the rats only lager beer and the other rat only bitter beer for a considerable period. The lager beer contained no arsenic, and about 5 per cent. of alcohol.

The bitter beer contained a trace of arsenic, always less than 1.145rd per gallon (probably never more than 1.200 or 1.250 judging from the sublimate obtained); it contained 6 per cent. of alcohol.

The results obtained may be summed up as follows:—

Period A.—Duration ten days.

Bitter beer, 10 per cent., food 5 per cent.

Experiment 18.—Loss about 15 grammes (out of 145 grammes).

Experiment 19.—Loss about 14 grammes (out of 159 grammes).

Period B.—Duration 14 days.

Lager beer 10 per cent., food 5 per cent.

Experiment 18.—Gain about 5 grammes (upon 130 grammes).

Experiment 19.—Gain about 2 grammes (upon 145 grammes).

Period C.—Duration 15 days.

Bitter beer ten per cent., food 5 per cent.

Experiment 18.—Loss about 10 grammes (out of 135 grammes).

Experiment 19.—Loss about 6 grammes (out of 147 grammes).

Period D.—Duration six days.

Experiment 18.—Lager beer 10 per cent., food 5 per cent.; loss 8 grammes (out of 125 grammes).

General results of third set of experiments. Provisional conclusions.

Fourth set of experiments.

General results of fourth set of experiments and provisional conclusions.

Fifth set.

Sixth set.

Experiment 19.—Bitter beer 10 per cent., food 5 per cent.; loss 11 grammes (out of 141).

Period E.—Duration 45 days.

Beer 10 per cent., food 8.5 per cent.

Experiment 18.—Lager beer; gain 23 grammes (upon 117 grammes).

Experiment 19.—Bitter beer; loss 19 grammes (upon 130 grammes), death.

After this period the rat 18 continued to increase in weight for several days, but then became suddenly ill, would not take its food, and died 105 days after the beginning of the experiment. The illness was entirely different from that observed in rats dying from the effects of arsenic, the animal refusing to take its food and drink, whilst the arsenical rats although they frequently left variable amounts of food and drink, usually ate up to the last day and died suddenly. Death in this case was due to an accidental illness, which began at a time when the animal was rapidly increasing in weight.

This set of experiments confirmed my impression that bitter beer drunk at the time of the outbreak in Salford and in Manchester was less wholesome than lager beer imported from Munich.

Whether this difference was attributable to the small trace of arsenic present in the beer, or the difference between the products of high and low fermentation, I am not prepared yet to say, but my general impression is that beer brewed at a low temperature is more wholesome than beer brewed at a high temperature. It is also to be noticed that the bitter beer used in this set of experiments was beer which would have passed easily the test recommended by the Brewers' Commission.

Seventh Set of Experiments.—For purposes of comparison I have brought together four experiments carried out previously in my laboratory by Dr. Kerr, and which had for object to ascertain the effect of the administration of large doses of pure ethylic alcohol, on the liver.

Experiment 20 (xxii.).—A rat weighing 180 grammes was given daily 10 per cent. of its body weight of dry food, and 3.2 per cent. of a 25 per cent. solution of pure ethylic alcohol,

or about 0.80 per cent. of its body weight of absolute alcohol. Appendix A  
The fluid was given by the mouth.

During the first 6 days it lost about 27 per cent. of its weight, but began to gain flesh again. On the 52nd day the loss had been reduced to 16 per cent.

Experiment 21 (xxvii.).—A rat weighing 150 grammes was given daily 10 per cent. of its body weight of dry food and 2.7 per cent. of its body weight of a 20 per cent. watery solution of pure ethylic alcohol (0.54 per cent. of body weight in absolute alcohol). This fluid was injected into the rectum.

After an initial diminution, the weight increased again. Sixty-nine days after the beginning of the experiment, when the animal was killed, its weight was only 6 per cent. lower than the original weight.

Experiment 22 (III.).—Rat weighing 150 grammes. Experiment conducted as in the previous case (daily dose of absolute alcohol 0.51 per cent. of body weight). The animal was killed 69 days after the beginning of the experiment; the loss of weight was about 30 per cent. of the original weight.

Experiment 23 (V.).—Rat weighing 154 grammes. Experiment conducted as in the two previous cases (daily dose of absolute alcohol 0.35 per cent. of body weight). This animal did not bear the administration of the alcohol well, and died on the 63rd day, there being a loss of 45 per cent. of the original weight.

Summary of the Results of the 7th Set of Experiments.—Summary.

These animals showed frequent evidences of intoxication, so that the administration of a fluid containing 20 or 25 per cent. of absolute alcohol, produced effects which were not observed in rats to which an equal amount of alcohol was given in a more diluted state. The effects of alcohol were also more variable than those of arsenic. Two of the rats appeared to recover gradually from the first effects of alcohol, and to regain weight; two other rats continued to lose weight from the first. Only one of the four died, and that animal seemed from the first to be very sensitive to the action of alcohol; possibly it was not in a good state of health at the beginning of the experiment. To insure the rapid passage of the alcohol into the circulation, the alcohol solution was in three out of the four cases injected into the rectum; this caused intestinal irritation, which complicated the action of alcohol. Owing to this disturbing element, experiment 20 is the only experiment in this set which is quite comparable with the experiments on arsenic.

## B. ESTIMATION OF THE AMOUNT OF ARSENIC PRESENT AT THE TIME OF DEATH IN THE TISSUES OF RATS WHICH HAD BEEN TAKING ARSENICAL FLUIDS.

After the death of most of the rats used in these experiments a post-mortem examination was made. The stomach and intestines were removed in all cases, as well as portions of the lungs, a part of the liver, both kidneys, a small part of the spinal column, and spinal cord, the diaphragm, a portion of the muscles, nerves, and bones, of one of the extremities. These parts were kept for microscopical and microchemical examination. The remainder of the body was then used for chemical estimation.

In some cases these remains were entirely reduced to pulp, care being taken to avoid accidental contamination, and this pulp was then macerated either in water or in 20 per cent. hydrochloric acid for 24 or 48 hours, the quantity of fluid being brought at the end of that time up to 50 cc., 100 cc., or 150 cc. (according to the quantity of material), either by the addition of 20 per cent. of hydrochloric acid, when dilute acid had been used from the first (which was generally the case), or by the addition of pure hydrochloric acid up to 20 per cent. of the whole amount of fluid used, when pure water had been used as a macerating fluid.

The mixture was then treated according to the method which I have devised for estimating the amount of arsenic in beer on the basis of Reinsch's process. In other cases the skin was separated from the other tissues, and the amount of arsenic in it was estimated in the same way.

In another group of cases a square patch of skin was removed from the back of the animal, the hair was then removed from that patch, and the arsenic estimated separately in the hairless skin, and in the hair. The skin of the back was selected for that purpose as being the least exposed to accidental contamination from the food and drink taken by the animal. In

one case the amount of arsenic present in the liver was also estimated. All the parts used were weighed so as to make it possible to calculate roughly the amount of arsenic in the whole body. For several reasons I did not entertain great hopes of obtaining accurate results; at the time the analyses had to be made I had not been able to determine how far the amount of arsenic separated by Reinsch's process from fluids containing blood, hair, muscles, etc., would bear a ratio to the total amount of arsenic present in these parts comparable to that which I had determined in the case of beer. The beer standard had therefore to be used. Then, owing to the difficulty of boiling fluids containing a large amount of proteid substances, Dr. Coutts, who carried out the estimations for me, had to vary the proportion of the dilute acid to the matter analysed. This must, to a certain extent, have influenced the proportion of arsenic precipitated upon the copper. Thirdly, the sublimate obtained in several cases were less abundant than my lowest standard (1—10,000,000) sublimate, so that we were deprived of means of accurate comparison. This was due to the very small amount of material available in some cases.

For all these reasons it is obvious that the quantities which are recorded in Table 1 are not strictly comparable with those obtained in connection with the beer, moreover, they are not exactly comparable among themselves.

It has appeared to me, however, that, imperfect as they are, the figures obtained would be more useful than a mere statement that arsenic had been found to be chemical present or absent. Notwithstanding all their defects these estimations revealed clearly the fact that the amount of arsenic present in the body after death bore some relation to the amount of arsenic taken during life. Summary of results of chemical estimations.

## Appendix 16.

CALCULATED Amount of Arsenic found in the Body after Death, compared with the Amount of Arsenic given during Life.

Experiment.	Total Amount of Arsenic given during Life per cent. of body weight. As As <sub>2</sub> O <sub>3</sub> .	Amount of Arsenic taken Daily per cent. of body weight. As As <sub>2</sub> O <sub>3</sub> .	Apparent Total Amount of Arsenic* found P.M. in the body, Estimated in As <sub>2</sub> O <sub>3</sub> .	Weight of Animals P.M.

15	0.0031950	0.0000710	0.0000749	77	- ditto - - - ditto.
16	0.0120000	—	0.0008050	125	Death two days after second dose of arsenic.
18	0.0000240	0.0000010	Trace	115	Lager beer taken up to time of death.
19	0.0000740	0.0000010	Trace	111	Bitter beer stopped 50 days before death.

\* All the analyses upon which I have based the calculations in this column are based upon the estimations made for me in my laboratory by Dr. Coult's, the method which I have devised for estimating the amount of arsenic in beer being used in every case. The figures given in the first two columns are practically accurate since they represent the exact amount of arsenic given to the rats, except in the case of experiments 1, 6, 18, and 19, in which the amount of arsenic present in the beer was also ascertained by my method.

† Since making the above experiments I have examined again lager beer from the same source as that from which I obtained the beer used in these experiments and have found distinct traces of arsenic in some of the samples.

Evidence of accumulation of arsenic in the tissues.

Usually the amount calculated for the whole body was below that of one daily dose administered during life. But when the daily dose was less than 0.00007 grammes (per cent of body weight) the amount estimated to be present P.M. was more or less in excess of the daily dose. The smaller the dose the more marked this excess seemed to be. Two interpretations may be given to this; either this excess is evidence of experimental error, or else it indicates that arsenic when administered in small doses can accumulate up to a certain point in the tissues.

Experiment 11 seems to support the first view, for this rat had taken during life only water and beer which appeared to be quite free from arsenic, and yet after death a recognisable trace of arsenic was discovered in the tissues. It is, however, possible that although it was impossible to detect arsenic in the fluids given to the rat, there were nevertheless very minute quantities of the poison which could not be detected in the quantities used for analysis. Admitting that the figure 0.000006 indicates the result of some experimental error which may have tainted all the other estimates, it will be noticed that such an error would not explain the excess found in Experiments 6, 14, and 15.

Limitation of accumulation. Saturation of tissues.

The evidence, therefore, as far as it goes, seems to indicate that arsenic may accumulate in the tissues up to a certain point. That the tissues are not capable to retain more than a certain amount of arsenic seems also to be indicated by the fact that whenever large doses of arsenic were administered, even up to the time of death,

the amount of arsenic found in the body after death was invariably smaller than the amount of arsenic given daily. These results seem to indicate that arsenic forms some kind of compound with tissue elements.

Another interesting fact is brought out by these estimations. Arsenic was found in the tissues of two rats which had ceased to take arsenic for more than 40 days before death. In experiment 1 the amount found was nearly equal to a daily dose. In experiment 6 the amount of arsenic found was 16 times greater than a single daily dose. The daily dose in this case was exceedingly small.

To account for these results it is almost necessary to suppose that arsenic enters into combination with some of the constituents of protoplasm.

When large doses are given it is probable that a portion of the arsenic passes out of the body with the faeces, and that portion of what passes into general circulation not being retained by the tissues is excreted by the skin, liver, kidneys, and other glands. This view is supported by actual observation in the human subject. I made several attempts to collect the urine and faeces of rats taking arsenical fluids, but I was not successful in devising a plan excluding the possibility of contamination of the excreta with the fluid administered to the animals.

With regard to the localisation of arsenic in the tissues, I have not been able to make many observations, but the results summed up in the following table are suggestive:—

AMOUNT of Arsenic in parts per 10,000,000.

Experiment.	Body with part of Skin.	Body without Skin.	Skin and Hair.	Skin without Hair.	Hair alone.	Liver.
1	—	3 to 4	10 ?	—	18 ?	—
2	—	—	—	15	25 ?	—
3	—	—	—	21	300 ?	—
4	—	—	—	10	900 ?	—
6	1	—	—	—	—	—
7	4	—	23	—	—	6 ?
8	40	—	—	5 ?	30 ?	—
9	—	1 ?	—	6-8	8 ?	—
10	2.5 ?	—	—	—	—	—
11	0.25 ?	—	—	—	—	—
14	10 to 15	—	80	—	—	—
15	—	10	5 to 8	—	—	—
16	Over 68	—	—	—	—	—

Note.—(?) indicates that the estimation were subject to more experimental fallacies than usual.

In Experiments 3 and 4 the rats were taking large doses of arsenic, and it is probable that their skin had more than once been wetted by the fluid given to the animals to drink.

On the whole the results confirm those of other observers with regard to the special tendency which arsenic has to accumulate in the skin, and more especially in the hair.

The amount of arsenic found in the body of the rats taking small doses of arsenic corresponds to the amount we found in some of the organs of patients that had died from the effects of arsenical beer (the same method of analysis having been used).

### C. LESIONS FOUND AFTER DEATH IN RATS WHICH HAD BEEN TAKING VARIOUS FLUIDS CONTAINING DIFFERENT PROPORTIONS OF ARSENIC. COMPARISON OF THESE LESIONS WITH THOSE OBSERVED IN PERSONS WHO HAD DIED FROM THE EFFECTS OF ARSENICAL BEER.

I have previously (Questions 5303 to 5315) alluded to some of the changes which have been observed in persons that had died from arsenical poisoning resulting from the consumption of beer\* :—

Among the changes, some were, in my opinion, evidences of the action of deteriorating influences, such as imperfect feeding and disease (more especially tuberculosis). Another group of lesions seemed to me to be special and common to the majority of cases of arsenical poisoning, and consequently to be attributable to the action of arsenic.

Among these lesions the most important were—first, degeneration of the more specialised tissues, such as glandular epithelium, muscular and nervous tissues (these degenerations lead to wasting and perturbation of functional activities); second, irritation and increased proliferative activity of the less specialised tissues, such as connective tissues and certain epithelial tissues (these changes lead to fibrosis, keratosis, pigmentation, etc.).

(See my evidence in Vol. I. of Commission's Minutes.)

In order to acquire more information than we possess at present on these points I have arranged for investigations to be carried out with the material collected for me chiefly by Dr. Moore, assistant lecturer in my department at Owen's College. Several of my pupils have undertaken at my request to investigate in detail the changes observed in various organs. I have already related the general changes observed by Dr. F. C. Moore in the autopsies which he conducted (see Table X.). Dr. J. C. Muir has completed an investigation on the blood and bone marrow of many cases; he has given an excellent account of his work. Dr. W. F. Jackson has completed a research on the changes occurring in the kidneys. He has found that congestion, some degeneration of epithelium, and possibly in some cases accumulation of melanin in some of the secreting cells might be attributed to the action of arsenic. Dr. Reginald Lawrence has carried out an examination of the nerve centres, which brings out the fact that nerve cells are invariably affected by arsenic, and are the seat of degenerative processes. The investigations relating to the liver, lungs, skin, lymphatic glands, muscles, and fat are not yet complete. If desired to do so, I will submit the reports which are at present available. I may say generally, on the basis of my own preliminary examinations, that the following changes were of common occurrence among the victims of arsenical beer :—

1. General hyperæmia, most noticeable in the lungs, glands, muscles, and nerve centres.
2. Considerable degeneration and wasting of some of the muscles examined.
3. Albuminous and fatty degeneration of the cardiac muscle, patchy and often slight.
4. More or less complete disappearance of fat from some of the cells of fatty tissue.
5. Albuminous and fatty degenerations of glandular epithelium, specially well marked in the liver.
6. Degeneration of nerve tissues most marked in the nerve cells of the cerebral cortex and the spinal cord.

#### Ref. No.

107	-	Thyroid Body	less than 5 in 10,000,000
124	-	Bones	about 4 in 10,000,000
125	-	Spleen	about 1 to 2 in 10,000,000
126	-	Thyroid Body	about 7 to 8 in 10,000,000

The material at my disposal did not allow me to push the comparison further.

Generally speaking, the results of the estimation of arsenic in the experimental rats confirm the view that based on arsenical beer, such as was drunk during the outbreak, acted in the same way as solutions of arsenious acid containing about the same quantities of arsenic as those which I had estimated to be present in that beer. Watery solutions of arsenious acid appeared, however, to be more toxic than beer containing the same amount of arsenic.

Appendix 16.

Conclusions  
based on  
chemical  
examina-  
tion.

The terminal nerves seemed also to be affected in a few cases, but I am not certain whether the changes were attributable to arsenic or to some other causes; in several cases no clear evidence of degeneration of peripheral nerves could be found.

7. Over production of melanin in the deep layers of the epidermis, accumulation of melanin or of an allied pigment in the lymphatics of the true skin, in lymphatic glands, in some connective tissue cells, and possibly in some glands—e.g., the liver and kidney. In the present state of our knowledge it is not however quite possible to determine whether a pigment resembling melanin is certainly melanin without further investigation.

8. Sometimes there was over-production of cutaneous epithelium, also keratosis, and of fibrous tissue in some of the organs, which were also the seat of degenerative processes. With regard to the latter change, it was generally difficult to exclude the possible influence of other causes.

The post-mortem examinations which I have made of the rats used in the experiments which have been previously related, have yielded very similar results. In fact, with one exception, the changes observed in the various organs and tissues have been of the same nature as those found in the human subject; but with regard to pigmentation, I have obtained no result. I expected this difference, for all my experimental rats were albino rats; the absence of pigmentation in these cases is an additional confirmation of the theory which I have formulated many years ago regarding the origin of melanin. At the time when I started my experiments I tried to obtain some tame grey rats, but I was not able to get any. It would have been impossible to conduct carefully systematic experiments with wild rats. A detailed account of these pathological investigations is not yet ready, and would not in its present state add materially to the value of the evidence which I have already obtained.

There remain in my mind no doubts regarding the similarity between the lesions observed in the bodies of patients who have died of the effects of arsenical beer, and the lesions observed in the carcasses of rats to which solutions of arsenious acid in water or in beer had been given, over periods varying from 30 days to 90 days. Several of these cases had not taken proportionately more arsenious acid than the human victim. The mode of death in both cases was usually sudden, as if due to cardiac failure, or failure of the respiratory muscles. It is also noticeable that when small quantities of arsenic were given, a fatal result did not usually occur before the end of three months, and that slow recovery was possible at the end of that time.

The experiments on rats had also the object of determining whether arsenious acid in beer was more poisonous than arsenious acid dissolved in water. The changes of weight observed in animals taking equal amounts of arsenious acid dissolved in beer or in water, had already shown that arsenious acid dissolved in water seems to be more injurious than arsenious acid dissolved in beer; the post-mortem examinations confirmed this view, for the degenerative changes were most marked in rats taking watery solutions of arsenious acid.

Changes  
observed in  
rats.

Watery

acid com-  
pared with  
arsenical  
beer.

\* It must be remembered that most of these patients were also suffering from other illnesses, the majority of them were tuberculous. In some there was some pyrexia.

## Appendix 13.

## Influence of alcohol.

Alcohol up to the amount usually present in beer did not seem to affect the rats unfavourably, but the addition of alcohol up to 10 per cent. of the total fluid seemed in one case to have a detrimental effect. The bad effects obtained with strong solutions of alcohol, even in moderate quantities, indicated that dilution has an important influence upon the results.

## Action of cacodylate of sodium.

With regard to the possible presence of arsines in arsenical beer, cacodylates seemed to me to be among the most noxious arsines\* which could reasonably be expected to be present in beer, the results obtained in the only case in which cacodylate of sodium was administered were so much in accordance with what was known before of the physiological action of this salt that I did not think it necessary to multiply experiments. Far from having a detrimental effect during periods comparable to those of the Salford epidemic, cacodylate of

sodium seemed to have a beneficial effect even when administered in large doses, the animal treated with cacodylate of sodium bore better the effects of low diet than a control animal taking no arsenic at all. Another rat receiving as much arsenicum, in the form of arsenious acid as the cacodylate rat became, on the contrary, seriously ill under the same collateral experimental conditions. The post-mortem state of organs agreed with the symptoms during life. In the rat receiving arsenious acid, and which died in consequence, the usual degenerative changes were observed, and the fat of the fatty tissue had disappeared entirely from one of the parts where it is usually found. The cacodylate rat, on the contrary, was apparently quite well when killed; its organs had a normal appearance, and there was the usual amount of fat under the skin and in other situations.

## D. GENERAL SUMMARY OF EXPERIMENTAL RESULTS.

## (D.) General summary of experimental results.

In all the experiments from which these conclusions are drawn, the animals were taking arsenical fluid at a rate which corresponded to over one gallon for a man weighing 140 lbs.

1. Beer to which had been attributed several human cases of arsenical poisoning during the 1900-1901 outbreak at Salford, produced in rats lesions characteristic of arsenical poisoning. The quantity of beer necessary to produce this result was not proportionally larger than the quantity taken by a great number of the persons attacked. (Experiment 1, also Table I., in Appendix to my previous evidence in Vol. I.:—Beer A, B, C, 71, 72, IX.)

2. The same effects may be produced by the administration of beer containing the same amount of arsenic introduced by the use in brewing of glucose obtained from Messrs. Bostock's factory (Experiment 9).

3. Similar effects, but more rapid and intense, can be produced by watery solutions of arsenious acid containing the same amount of arsenicum as arsenical beer brewed from arsenical glucose (Experiments 2 and 14).

4. Beer containing traces of arsenic introduced by the use of badly prepared malt does not produce effects approaching those produced by arsenical glucose beer; there is, nevertheless, some evidence to show that even the smaller quantities of arsenic introduced by arsenical malt may have a detrimental effect. (Experiment 6 and 19 and Table II. Malt, in Appendix to my evidence in Vol. I., see Malts 83, 84, 87, 89, 90, 91, 92, 97, 98.)

5. Beer to which arsenious acid has been added so as to make the proportion of arsenic about four times greater than that present in badly contaminated samples of original arsenical beer (so as to make the dose administered to rats comparable to the doses taken by beer drinkers) invariably produced chronic arsenical poisoning, fatal in less than three months from the beginning of the administration (Experiments 3, 7 and 8.)

6. Solutions of arsenious acid in water, containing the same quantity of arsenic as the beer referred to in Sec. 5, acted in the same way, but more rapidly and intensely. (Experiment 4.)

7. Solutions of arsenious acid in water, containing from 70 to 140 times more arsenic than had been found in the most arsenical beer examined in the laboratory, produced acute arsenical poisoning. (Experiments 16 and 17.)

8. The presence of from 5 to 6 per cent. of ethylic alcohol in the arsenical fluid did not seem to have a material influence upon the action of the arsenic. (Experiments 1, 3, 14, and 15.)

9. The presence of 10 per cent. ethylic alcohol seemed in one experiment to have a detrimental effect, but,

judging by the bad effects of alcohol alone, administered in 20 and 25 per cent. dilutions, it seems likely that the effects of alcohol are superadded to those of arsenic, and unlikely that the toxicity of arsenic is exalted by the presence of alcohol. (Experiments 6, 7, 8, 20, 21, 22, 23.)

The quantity of alcohol present in ordinary bitter beer does not seem to have materially influenced the course of the outbreak.

10. The administration of large doses of cacodylate of sodium dissolved either in beer or in water does not produce deleterious effects comparable to those produced by arsenical beer.†

11. As long as growing rats received a large amount of food (7 to 10 per cent. of their body weight) the presence of a small amount of arsenic in their drink did not appear to have any detrimental effect; on the contrary, the rate of weight increment seemed to be increased. By reducing the amount of feed to a quantity barely sufficient to maintain a normal rate of increment (3 to 5 per cent. of their body weight), rats taking even a minute quantity of arsenic were liable to an abnormally rapid loss of weight, and soon became ill.

12. When the amount of arsenious acid reached the proportion of 7 grains per gallon, the effects of arsenic were not much influenced by the amount of food taken, and after a few days even the complete stoppage of arsenic did not bring about a rapid improvement in the condition of the animal. The reverse was true when small doses of arsenic were taken.

13. The effects of arsenical beer were evident for days after the administration of the fluid had ceased. In one case the replacement of moderately arsenical beer by arsenic-free fluids was followed by an aggravation in the state of the animal (Experiment 1). Rat No. 1 had taken arsenical beer containing 1-6th grain of arsenious acid per gallon almost daily for 102 days. When it died 42 days later there was still a considerable amount of arsenic in its tissues.

14. The tissues are capable of retaining a certain amount of arsenic, and my experiments indicate that, even when very small doses of arsenic are administered, the poison may accumulate until a certain limit is reached. When arsenic is administered in large doses there seems to be no proportional accumulation, because the amount of arsenic retained by the tissues is usually less than the amount administered in one dose.

I wish to give this last conclusion with some reserve, as I feel that it should be tested by more accurate analyses than those which have so far been carried out in my laboratory. I think, however, that, imperfect as they are, the results indicate clearly the conclusions to which I have arrived.

(See table of calculated amount of arsenic found in the body after death, given above.)

\* The action of various combinations of arsenic with alcohol radicals has been studied by several physiologists (a summary of these results is given by E. Wertheimer in "Richey's Dictionnaire de Physiologie," 1895, p. 701). Cacodylic acid has been shown to be toxic by Lebahn, H. Schulz, Rabuteau. The action of cacodylic acid resembles that of arsenical compounds generally, but this compound is much less poisonous than arsenious acid. Schulz, Schroetter, and Rabuteau have also studied the action of other organic compounds of arsenic, and have found them less poisonous than arsenious acid. (In discussing the lesions produced by arsenic in man and rat, I have mentioned only those changes which have allowed me to recognise identity of action; the above statements do not deal with the pathology of arsenical poisoning; I do not intend to give an account of that part of my inquiry before the examination of all the material at my disposal has been completed. I may, however, submit, if desired to do so, photographs illustrating some of the lesions already observed.)

† Although the matter is comparatively irrelevant, it is worth noting, 1st, that cacodylate of sodium seemed to have a distinctly beneficial action; 2nd, that beer appeared to act as a food, and that in ill-fed animals the toxic effects of arsenic were to a certain extent reduced by the other constituents of beer.

## E. GENERAL CONCLUSIONS OF EXPERIMENTAL INVESTIGATIONS.

Appendix 16.

1st. The 1900-1901 outbreak was due to the presence of arsenious acid in the beer drunk by the victims.

2nd. The presence of an amount ( $\frac{1}{3}$  to 2 grains per gallon) of arsenious acid capable of producing such an outbreak can only be accounted for by the use of arsenical glucose or invert sugar as malt substitutes.

3rd. The presence of smaller quantities ( $\frac{1}{15}$  to  $\frac{1}{25}$  grain per gallon) of arsenious acid, such as may be due to the use of badly prepared malt, though seldom dangerous to the same extent, is capable of producing injurious effects in ill-fed or weak individuals. I am therefore of opinion that the amount of any food or drink, which may be taken daily by any consumer, should never contain more than  $\frac{1}{15}$  grain of arsenic (estimated as  $As_2O_3$ ). I would even prefer to see the amount of arsenic allowable daily reduced to  $\frac{1}{25}$  grain.

4th. Bad feeding and other deteriorating influences are sufficient to account for the special incidence of cases of poisoning among classes of people liable to these influences.

(Conclusions 1 and 2 are in perfect agreement with those I gave to Dr. Tattersall on the 27th of November, 1900. Conclusions 3 and 4 are based on observations which were made during the following month, and were partly communicated to the members of the Royal Commission over one year ago (March, 1901). These conclusions have been further confirmed by experimental work extending over the greater part of the year. Finally, when I speak of arsenious acid as being present in beer, I do not wish to convey the idea that some loose compound may not be formed between arsenious acid and some of the constituents of beer. Arsenious acid in watery solutions can be easily detected by the Marsh's test, without previous treatment of the solution, but a solution of arsenious acid in beer does not give the same results. This might be said to indicate the existence of some loose organic combination, but such an inference would be purely hypothetical. What is absolutely clear is that the poisonous action of beer containing arsenic resembles closely that of arsenious acid or arsenites, and not that of arsines.

S. DELEPINE.

## FURTHER NOTE AS TO DEVELOPMENT OF PARALYSIS IN RATS RECEIVING ARSENIC.

Sent to the Commission by Professor Delépine, January, 1902.

With reference to my answer to Dr. Whitelegge in (Q. 10420), I wish now to add that at the time when I gave this evidence I had only begun experiments upon the action of larger doses of arsenic than those given in beer or water. In the new set of experiments, the arsenic was administered with the food, and the average daily doses were at least three times larger than the doses given in any of the previous experiments (except the experiments on acute poisoning, Set V.). The total amount of arsenic taken by each one of the rats in the new series was larger than that taken by any of the

previous rats (including those which had taken acutely poisonous doses). In three of the rats of the new series (Series VII.) which lived more than three or four weeks, symptoms of chronic arsenicism, similar to those observed in arsenical beer drinkers, were observed. See appended Table IV., which is a summary of observations made partly by myself and partly by Drs. Butterworth and Melling under my direction.

It is probable that when smaller doses of arsenic were used, the paralytic symptoms were too slight to be clearly recognisable in an animal such as the rat.

TABLE IV.

Set VII. Later set of experiments, arsenic being administered with food, and the dose made at least three times larger than the largest dose administered in beer or water in the previous sets of experiments I. to VI.:

No. of experiment.	Original weight of guinea pig.	Average weight of food per cent. of body weight. Daily quantity taken.	Average daily dose of arsenic, per cent. of body weight.	Duration of experiment.	Daily average loss per cent. of body weight.	Remarks and symptoms of arsenicism evidenced during life.
	Grammes.	Grammes.	Grammes.	Days.	Grammes.	
1172 A	290	6.3	0.0023	38	1.8	(Some daily doses rose to 0.0055 gramme per cent. just before death). Paralysis of extensor muscles of front paws (position of paws similar to that of hand in wrist-drop) marked conjunctival hyperemia, oedema of eyelids.
1286 A	180	7.	0.0024*	45	0.86	Daily doses rose occasionally above 0.004 gramme per cent. Extensive paralysis of front paws, conjunctivitis.
1286 B	133	8.3	0.0024*	21	0.10	Daily doses amounting to 0.004 gramme per cent. were given for five consecutive days up to the third day previous to death. Extensive paralysis of front paws, conjunctivitis, oedema of hind limbs and tail.

These animals exhibited in addition the swelling of nasal mucous membrane, drowsiness, unsteady gait at times, redness of plantar skin, which had also been observed in nearly all the rats previously experimented upon to which much smaller doses had been given.

\* A dose of 0.0024 gramme per cent. would correspond to one of 1.5 gramme to a man weighing 63,300 grammes, or a little less than 140 lbs. Such a dose would be rapidly poisonous for a man.

## Appendix 16.

REMARK.—In interpreting the results it must be remembered that a healthy rat not fully grown and given only water to drink almost always loses weight when the amount of dry food given to it falls below 4 per cent. of the body weight. It may maintain its weight when given 5 or 6 per cent. of food, it gains weight when the amount of food reaches 10 per cent. Experiments 12 to 13, which were made on very young rats, were discarded because the animals never took their food and drink well and regularly. Experiments on very young rats had to be entirely abandoned on that account.

80	80	69	— 0.34	Slow illness, chronic poisoning.	Whole body	Trace.	—

⊗ These figures have no absolute value and are not even quite comparable. Those results which are most doubtful have been indicated by queries.

N.B.—All the quantities given, except the original weight of the rats and the proportion of arsenic in the fluid administered, are expressed in terms of the weight of the body. The weight of the body having been reduced to a uniform weight of 100 grammes (the young white rats weighed usually from 100 to 150 grammes, the fully-grown ones from 200 to 300 grammes). Knowing that a man of average weight weighs about 140 lbs. or 63,364 grammes, it is easy to obtain an idea of what a man would have to eat or drink in order to take quantities comparable to those taken by the rats: in the same way the amount of arsenic, loss of weight, &c., may be calculated. The weight of a gallon of beer is  $\frac{1}{4}$ th part of that of a man weighing 140 lbs. or 7.14 per cent. A glance at this table will show that the quantity of beer given to the rats was generally 8 per cent. of the body weight, corresponding therefore to more than 1 gallon for a man 140 lbs. in weight.

## APPENDIX 17.

## 1900 EPIDEMIC AND 1901 BIRTH RATE.

MEMORANDUM sent to the Commission by Mr. J. Niven, M.A., M.B., Medical Officer of Health of Manchester, 11th July 1902.

ON THE APPARENT RELATION BETWEEN THE OUTBREAK OF ARSENICAL POISONING IN MANCHESTER IN THE YEAR 1900 AND THE DROP IN THE BIRTH RATE IN 1901.

The birth rate of Manchester for the year 1901 was 28.7 per 1,000, showing a decrease of 3.66 per 1,000 on the birth rate for the year 1900. So marked a decrease on the birth rate of a population of 546,000 persons seemed to require an explanation. Yet there appeared to be nothing in the state of trade to account for it, nor did the figures relating to pauperism indicate any marked increase of distress. There was, it is true, a slight decrease in the birth rate for the whole country in 1901 as compared with 1900 equal to 0.4 per 1,000, but the difference is so great as to show that what occurred in Manchester was not part of the general decline in the birth rate.

On reflecting over the more likely explanations it appeared to me to be possible that it was due to the outburst of arsenical poisoning in the year 1900. If this were so, a drop in the birth rate should also have occurred for Salford and Liverpool, both of which towns suffered considerably. The drop in Salford was found to be 4.2 per 1,000, in Liverpool 1.42 per 1,000.

The detailed figures are:—

BIRTH RATES, CORRECTED IN ACCORDANCE WITH THE CENSUS FIGURES.

	Manchester.	Salford.	Liverpool.
1898	32.70	34.9	33.21
1899	32.63	34.1	33.32
1900	32.38	33.3	33.45
1901	28.72	29.1	32.03

Now the outburst of poisoning was practically confined to the second half of 1900, and was much more severe in the fourth than in the third quarter. Hence the effect upon the birth rate should be most marked in the third quarter of 1901, though observable in the second and fourth; in the fourth because the arsenical poisoning was not over in 1900, though its causes might be.

Such is in fact the case. The following are the recorded birth rates, in quarters, for the three towns, to which are added, for comparison, the corresponding birth rates for 1899 and 1900:—

MANCHESTER BIRTH RATES, IN QUARTERS AS RECORDED.

	1899.	1900.	1901.
First quarter	32.2	33.8	30.3
Second "	33.9	33.0	28.9
Third "	32.3	32.7	25.7
Fourth "	30.8	28.4	29.8

SALFORD BIRTH RATES, IN QUARTERS AS RECORDED.

	1899.	1900.	1901.
First quarter	33.8	35.3	31.2
Second "	34.3	34.2	28.0
Third "	33.5	32.1	25.8
Fourth "	33.9	31.1	31.6

LIVERPOOL BIRTH RATES, IN QUARTERS AS RECORDED.

	1899.	1900.	1901.
First quarter	35.3	38.4	36.2
Second "	35.6	35.3	32.1
Third "	35.9	36.2	31.2
Fourth "	35.4	34.0	31.7

The anticipated differences in quarters is very well marked in Manchester and Salford, but in Liverpool the drop is more evenly distributed than in Manchester and Salford, though the distribution of the decrease is very much the same.

The same changes are not uniformly observed in smaller places visited by arsenical poisoning, but that is scarcely to be expected, as in a small place the workmen affected being few are more easily replaced.

Heywood was perhaps the district most severely visited along with Manchester and Salford, and here the birth rate was 3.2 per 1,000 less in 1901 than in 1900, while the greatest drop occurs in the third quarter.

Now, if the above be the true explanation of the drop in the birth rate, then—

(1.) On the removal of the disturbing cause, the birth rates should resume their previous amounts.

(2.) Other towns whether connected with Manchester and Liverpool or not, but free from arsenical poisoning, should not show corresponding changes in the birth rate.

(3.) The arsenical poisoning was due to the consumption of cheap beers, and we know generally the parts of the city where most of the mischief was done, which were generally the poorest parts. The decrease in the birth rate should be greatest in those parts of the city.

As regards the resumption of their former magnitude by the birth rates, these were in the first quarter of 1902 for—

Manchester.	Salford.	Liverpool.
34.6	35.2	35.6

To see whether a corresponding drop in the birth rate occurred in other towns, let us take the large towns connected with Manchester and Liverpool, namely,

Blackburn, Bolton, Preston, and Oldham, the first three of which were very little affected; inland seats of industry—Birmingham, Leeds, Sheffield, Nottingham, Leicester; seaports—Hull, London, Portsmouth, Cardiff.

If we record their birth rates in quarters we see that there is nothing corresponding to the depression of the birth rate in the third quarter of 1901 in Manchester, Salford, and Liverpool, except in Oldham.

It should be noted that the town populations on which each year's quarterly birth rates have been calculated are in each instance the "estimated populations" for the year, reckoned before the 1901 census figures were available.

If the object were to compare the annual birth rates

of one town with another it would be needful to begin by making new estimates of the populations in the years in question, taking account of the 1901 census. But, for the purpose of studying the variations in the birth rate quarter by quarter in a given town, the more readily available "estimated population" for the year may be considered sufficient.

It will be seen that the quarterly birth rates in Oldham follow the same course in 1901 as do those of Manchester, Salford, and Liverpool. Now there was a certain amount of arsenical poisoning in Oldham though it is not believed to have been extensive. Whether the figures for Oldham are accidental, or indicate that there was more arsenical poisoning than was supposed, I have no means of saying.

London	30.8	29.6	28.6	28.4	1899
	30.4	28.7	28.6	26.6	1900
	29.5	28.8	28.9	28.0	1901
Portsmouth	27.0	25.9	26.4	25.3	1899
	27.9	26.4	24.2	24.3	1900
	26.8	27.1	28.2	27.9	1901
Cardiff	29.5	28.9	28.4	27.8	1899
	27.4	26.8	26.9	26.2	1900
	26.4	31.9	32.4	29.6	1901
Birmingham	34.9	25.5	34.0	32.8	1899
	34.9	34.0	32.6	29.4	1900
	32.6	32.2	32.2	31.2	1901
Leicester	29.1	31.1	28.8	28.7	1899
	28.8	29.2	29.1	25.7	1900
	27.6	30.9	28.1	28.0	1901
Nottingham	28.0	30.9	29.4	27.5	1899
	29.4	28.2	29.1	24.2	1900
	29.0	28.3	24.9	26.8	1901
Bolton	31.8	30.3	28.5	29.0	1899
	28.9	30.2	29.5	27.5	1900
	27.5	28.2	27.8	26.9	1901
Blackburn	28.6	27.1	26.9	25.5	1899
	27.2	26.2	25.3	22.0	1900
	24.7	28.5	26.5	24.3	1901
Leeds	29.7	32.1	30.6	30.0	1899
	30.7	30.7	31.2	29.2	1900
	28.7	30.9	30.0	30.0	1901
Sheffield	35.2	34.1	33.5	35.1	1899
	36.1	33.5	33.5	33.5	1900
	35.6	32.1	32.4	33.1	1901
Hull	33.4	35.1	34.6	33.7	1899
	35.0	31.8	33.7	31.0	1900
	33.7	33.1	34.0	32.1	1901
Newcastle	32.3	31.4	31.2	30.7	1899
	32.3	30.7	30.2	28.5	1900
	29.3	32.4	33.1	30.4	1901
Preston	30.8	30.9	30.0	28.5	1899
	32.0	29.6	28.3	26.0	1900
	31.8	32.2	30.1	27.6	1901
Oldham	25.2	24.9	24.1	25.1	1899
	24.4	23.4	24.7	24.0	1900
	25.6	23.9	22.6	26.4	1901

On the other hand, there is a tendency towards a minimum in the birth rate in the fourth quarter of the year in all these towns. It will be seen that the same tendency is observable in the birth rates for Manchester, Salford, and Liverpool. The relation in 1901 is therefore unusual, and the fact of its occurrence in all three towns is thus a striking one.

It is not a single one of these towns was the difference between the highest quarterly birth rate and the birth rate in the third quarter in any of the three years nearly

equal to the difference between the highest quarterly birth rate in 1901 and the birth rate in the third quarter of the same year in any one of the three towns, Manchester, Salford, or Liverpool.

The decrease of the birth rate in 1901 as compared with the mean birth rate for 1891-1900 in the three main divisions of the city of Manchester, and in each sanitary district of the city, also the relation to the birth rate in 1900, is shown in the following table:—

## Appendix 17.

DISTRICT.	Mean Birth Rate, 1891-1900.	Birth Rate, 1900.	Birth Rate, 1901.	Decrease or Increase in 1901 as compared with the Mean Birth Rate, 1891-1900.	Change in 1901 as compared with the Birth Rate, 1900.
City of Manchester . . . . .	33.09	32.38	28.72	- 4.37	- 3.65
Manchester Township . . . . .	35.51	33.84	29.08	- 6.43	- 5.46
Northern Districts . . . . .	32.06	32.37	29.17	- 2.39	- 2.79
Southern Districts . . . . .	32.39	31.57	27.86	- 4.51	- 3.71
Ancoats . . . . .	37.98	36.88	31.75	- 6.23	- 5.13
Central . . . . .	30.78	28.56	23.66	- 7.12	- 4.90
St. George's . . . . .	36.35	34.29	29.79	- 6.56	- 4.50
Cheetham . . . . .	31.72	31.28	31.55	- 0.17	+ 0.27
Crumpsall . . . . .	24.68	24.20	24.40	- 0.28	+ 0.20
Blackley . . . . .	27.17	25.48	24.56	- 2.61	- 0.92
Harpurhey . . . . .	35.11	35.61	31.62	- 4.09	- 4.59
Moston . . . . .	27.30	31.76	30.26	+ 2.96	- 1.50
Newton . . . . .	30.59	29.10	25.84	- 4.75	- 3.26
Bradford . . . . .	38.19	38.63	34.25	- 3.84	- 4.28
Beswick . . . . .	37.97	38.72	32.52	- 5.45	- 6.20
Clayton . . . . .	29.62	36.38	19.52	+ 0.90	- 5.86
Ardwick . . . . .	34.72	35.96	30.88	- 3.84	- 5.08
Openshaw . . . . .	36.18	35.88	31.18	- 5.00	- 4.70
West Gorton . . . . .	36.25	36.73	29.67	- 6.58	- 7.06
Rusholme . . . . .	25.73	25.69	30.80	+ 5.13	+ 5.17
Chorlton-on-Medlock . . . . .	26.99	24.51	21.02	- 5.97	- 3.49
Hulme . . . . .	34.65	33.40	28.84	- 5.81	- 4.56

On comparing these diminutions in the birth rate in 1901 with the figures for the death rate in union workhouses, we find that in the larger divisions of the city there is a correspondence between the magnitude of the diminution and the figure indicating poverty. This is not very close, however, for the individual districts.

On the other hand, all the individual districts in which the diminution is large are known to have been markedly affected by arsenical poisoning.

In Cheetham, the Jewish district, where there was very little arsenical poisoning, there is an increase in the birth rate.

In Rusholme, where there was but little, there is a marked increase. In the district of Moston also there was little or no arsenical poisoning.

The following districts we know to have been severely visited, viz., Ancoats, Central, St. George's, Harpurhey, Newton, Bradford, Beswick, Ardwick, Openshaw, West Gorton, Chorlton-on-Medlock, and Hulme.

So far then as these figures go, they support the view that the diminution of the birth rate in Manchester was due to the outburst of arsenical poisoning.

## LIME FILTERS IN MALT KILNS.

MEMORANDUM RECEIVED FROM MR. E. S. BEAVEN, OF WARMINSTER, IN SUPPLEMENT TO HIS EVIDENCE ON JUNE 20th, 1902.

(Received June 23rd, 1903.)

In evidence before the Commission I stated that there were various methods by which the access of arsenic to malt with the furnace gases during drying might be prevented or reduced to negligible quantities. The methods which I stated to be practicable were:—

1. By reducing the velocity of the gases leaving the fire and by providing for a considerable proportion of the air to be heated before admixture with the furnace gases.
2. By treating the fuel with basic material with a view to fixation of arsenic in the furnace ash.
3. By cutting off the furnace gases when the fires are stirred.
4. By bringing the furnace gases into contact with basic material at a high temperature in an apparatus capable of being repeatedly cleansed.
5. By arresting furnace dust and uncondensed matter escaping the previous operations by means of curtains which, if so placed as to be kept below 350 F., act both as filters and as condensers of volatile matter.

I stated that I had used these methods as safeguards only, and with anthracite of good quality, and that I could not offer any evidence as to the application of the methods to other fuels, such as gas coke, which was not used for drying malt in the district with which I was acquainted.

The following questions were put to me:—

10813. Have you tried your lime filter with fuel containing larger quantities of arsenic?—I have not, except absolutely experimentally, from which I have no results I can quote.

10814. Do you intend to continue your researches on the subject?—I do.

10815. The Chairman will be grateful to you if you will communicate the results of further experiments, particularly with the object of finding out whether or not the distinctly arsenical fuel, fuel with more arsenic in it than that which we consider admissible, does give volatilised arsenic, which is removed by your process of a basic filter applied hot, or by condensation on the colder screens?—I will do what is possible experimentally.

I accordingly obtained recently from the North of England Gas Coke in sufficient quantity for experiment.

I have forwarded to the Secretary a model of a malt kiln and furnace fitted with a basic filter similar to that in which the experiments to be described have been made.

The furnace itself is of a type common to many kilns, but the furnace gases, instead of passing directly, as is usual, into the distributing chamber, pass through a sloping grating which forms part of the structure of the furnace, and immediately come in contact with basic material. The basic material is arranged in a filtering chamber so as to be supported by this grating. The chamber is filled from above with irregular pieces of limestone to a depth of about 2 feet. The limestone immediately in contact with the grating is almost immediately converted into lime by the furnace gases, and from time to time some of the lime falls through the grating, and this is replaced from above with fresh material.

As compared with other malt kiln furnaces the volume and velocity of the furnace gases is much reduced, but their temperature is much higher than in the absence of the filter. The material in the lower part of the furnace is maintained at red heat, and the temperature, determined by a pyrometer, of the furnace gases leaving the filter usually exceeds 700 F. I have found no evidence of any re-volatilisation of arrested arsenic at the tem-

peratures which are reached in the filter. As the temperature required for drying varies from 100 to 200 F. it is necessary and also economical to dilute the furnace gases with considerable volumes of cold air. This is taken up through channels surrounding the filtering chamber, and is indirectly heated in passing through these channels. In fact, with such arrangements or with modifications of them, it is obvious that by far the largest part of the air which is used is to some extent heated without contact with the fuel, and I find in practice that the consumption of fuel is less than in the same kilns without the filter.

The velocity and volume of the furnace gases passing through the filter have been repeatedly measured, and I find that a velocity of less than 50 feet per minute through the filter is quite sufficient where the superficial area of the filter is of suitable dimension.

The volume of air corresponding to this is more than sufficient for consumption of the fuel, and is very much less than the volume which usually passes through and over the fire in existing malt kilns.

The filtering material, in addition to arresting volatile arsenic, arrests in the lower strata particles of ash, invariably in my experience containing ferric oxide, and this dust at the temperature of the filter is capable, as I have already pointed out, of absorbing arsenic. I do not find that after some weeks of continuous use any sensible quantity of dust escapes from the filter, even when the material is not renewed, as it easily may be when necessary. I have, however, in all cases fitted above the filter dust arresting curtains of woven wire, provided with hanging gutters for receiving dust, and by these means the further passage of dust is prevented. A small quantity of volatile matter sometimes escapes complete arrest or combustion, both in the fire and in the filter, and this is condensed or collected upon the curtains.

Where coke is used which is considered to contain such quantity of arsenic as would be capable of showing an appreciable percentage in the malt, it is desirable, as an additional safeguard, to saturate it with lime water or thin milk of lime before burning. I find that to accomplish this it is necessary, not merely to put milk of lime or lime water over the fuel, but to immerse the coke in the fluid for about two hours. In this time the lime completely penetrates the coke. There is no doubt that this method fixes to some extent what might otherwise be volatile arsenic, but the fact that with the coke with which I have experimented there was, even after such liming of the fuel, some arsenic collected in the filter shows that with such cokes the filter is desirable.

Samples of a number of successive kiln loads of malt dried with the gas coke referred to have been examined and reported on to me as follows:—

- |        |   |
|--------|---|
| No. 1. | Free, or below 1-700 gr. per lb. arsenic. |
| No. 2. | do. do.                                   |
| No. 3. | About 1-500 gr. per lb. arsenic.          |
| No. 4. | Free, or below 1-700 gr. per lb. arsenic. |
| No. 5. | do. do.                                   |
| No. 6. | do. do.                                   |

The coke was reported to contain  $\frac{1}{2}$  grain per lb. of arsenious oxide, and it is evident, therefore, that all but a very small fraction of the total quantity was either not volatilised or was arrested. I think it probable that even better results might, if necessary, be obtained by using more filtering material provided the structure of the kiln permits of a deeper filter being used without too greatly restricting the draught of the fire.

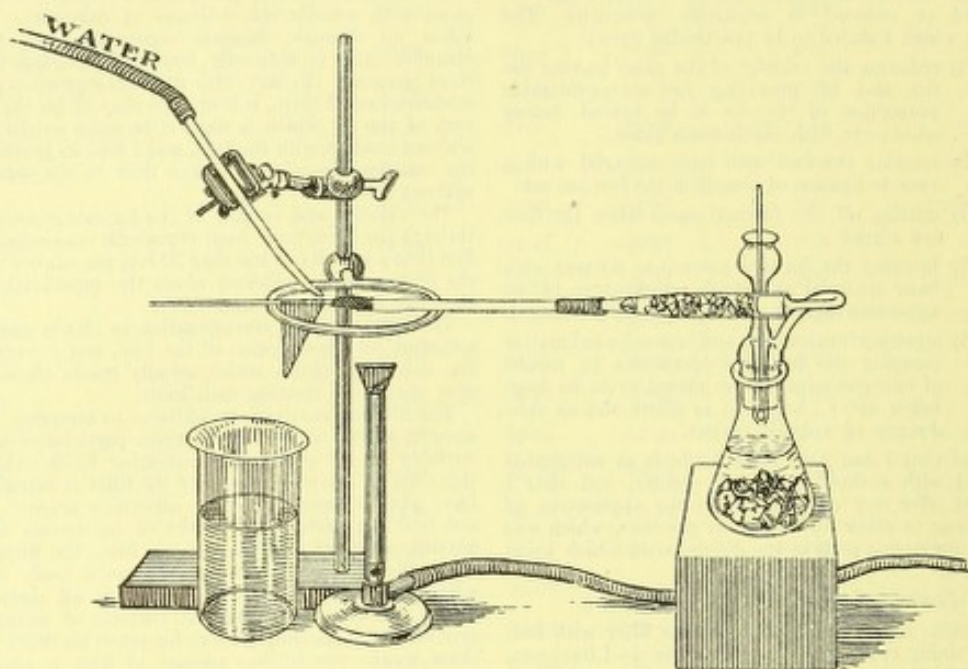

Samples corresponding to the above experiments are at the disposal of the Commission.

E. S. BEAVEN.

## BREWERS' EXPERT COMMITTEE'S FINAL REPORT.

## FINAL REPORT OF THE COMMISSION OF EXPERTS APPOINTED BY THE MANCHESTER BREWERS' ASSOCIATION.

Handed in by Mr. Gordon Salomon, 9th May, 1902.

TO THE MANCHESTER BREWERS' CENTRAL ASSOCIATION,  
MANCHESTER.

Gentlemen.—The investigations rendered necessary by the results of the preliminary examination of brewing materials employed in Manchester and its district are now complete.

In all, 663 samples have been analysed for the purpose of the inquiry.

The effective manner in which the brewers carried out our previous recommendations speedily resulted in the beer brewed in Manchester being free from arsenic, and analyses of recent date clearly prove that Manchester beer is now fully as pure as any beer produced in the United Kingdom in respect of its freedom from even infinitesimal quantities of arsenic.

## PRELIMINARY REMARKS.

The analyses and investigations that we have made prove finally and conclusively that the presence of arsenic in injurious quantities in the Manchester beer was in all cases due to the sugars manufactured by Messrs. Bostock and Co., Limited, and that such sugars derived their contamination exclusively from the employment in their manufacture of arsenicated sulphuric acid, supplied by Messrs. Nicholson and Co., Limited, of Leeds. No other cause of contamination to which the presence of arsenic in the observed quantities can be attributed has been discovered by us, nor is one believed to have been possible.

The first suspicion as to Bostock's sugar being the cause of the widespread poisoning dates from about the 21st November, 1900, and its employment in or about Manchester was discontinued by December 1st, 1900. Nevertheless arsenic continued to be found in smaller quantities in brewings both in Manchester and in many other parts of the United Kingdom. It was the discovery that such minute quantities of arsenic commonly existed in beer obtained from widely different sources that has necessitated the long and detailed investigations referred to in this Report, without which we have felt that we could not fulfil our task. For although these traces of arsenic in beer (of which the presence was hitherto quite unsuspected) cannot be said to be directly poisonous, and are, perhaps, not even injurious to the human system, it is extremely desirable that they should be eliminated if it be possible.

## ANALYSES OF BEERS.

One hundred and sixty samples of beer have been analysed by us for the purpose of this enquiry. These samples were collected from all parts of the country, between November 22nd, 1900, and the end of February, 1901, the larger proportion, however, being derived from Manchester and the surrounding district.

Of these 160 samples, 84 were found to be quite free from arsenic when examined by the Reinsch test. The remaining 76 samples were found to contain arsenic\* in amounts ranging from one and 1-10th grain to 1-400th of a grain per gallon of beer.

Of the 76 samples found to contain arsenic, 53 were traced to have been brewed with Bostock's sugar, and represented brewings previous to December 1st, 1900. Of these 53 samples, 27 contained more than 1-20th of a grain of arsenic per gallon, a quantity which must be regarded as dangerous. Of these 53 samples, 37 were brewed in Manchester and district, and 16 were obtained from other parts of the country where Bostock's sugar had been used.

The remaining 23 samples, which were not brewed from Bostock's sugar, were found to contain quantities

of arsenic ranging from 1-30th to 1-400th of a grain per gallon of beer. Of these, 21 contained less than 1-70th of a grain per gallon.

In our opinion these very small quantities were in every case derived from the malt. The sample containing approximately 1-30th grain per gallon was clearly proved to be an all malt beer. Such also was the case in respect of a sample containing approximately 1-70th grain per gallon.

It appeared, therefore, that (excluding those brewed from Bostock's sugar) 20·8 per cent. of the samples examined contained arsenic derived from sources independent of the special source of contamination to which the outbreak must be attributed. This result necessitated a searching examination of all materials employed in brewing, in order to ascertain definitely whether or not arsenic was to be found in them, which would account for the presence of these appreciable though small quantities in the beers.

We shall now proceed to give the results of this examination, arranging it for the sake of convenience under the headings of the materials examined.

## BREWING SUGARS.

One hundred and thirty samples of brewing sugars were analysed, made up as follows:—

Glucose	-	-	-	-	63
Invert Sugar	-	-	-	-	53
Raw and purified Sugar	-	-	-	-	11
Caramels	-	-	-	-	3
					130

## GLUCOSE.

Eight samples of glucose were proved to have been made by Messrs. Bostock and Co., Limited, and were probably delivered to breweries between September and November, 1900. All contained arsenic in quantities ranging from 0·027 per cent. to 0·075 per cent.

The remaining 55 samples were independently obtained from brewing sugar factories, merchants, agents, brokers, and breweries, and represented normal output and deliveries, both British and foreign, of all such goods employed in brewing in this country.

Of these 55 samples, five were ascertained to have been made by different makers previous to the contamination of Manchester beer by arsenic. They were found to be free from arsenic, with the exception of one which contained an infinitesimal quantity, approximately about 1-600th of a grain per lb.

The employment of even so large a proportion as 20 per cent. of this latter glucose for brewing purposes would have introduced an amount of arsenic into beer almost incapable of detection, and certainly negligible.

The remaining 50 samples were all found to be free from arsenic by the Reinsch test.

## INVERT SUGARS.

Six samples were made by Messrs. Bostock and Co., Limited, and were probably delivered into breweries between September and November, 1900. These samples all contained arsenic, ranging in amounts from 0·021 per cent. to 0·067 per cent.

The remaining 47 samples represented every known manufacture, and were independently obtained as in the case of the samples of glucose.

Of these, five were ascertained to have been manufactured previous to the detection of arsenic by the Reinsch test.

Wherever the quantity of arsenic is referred to in this report it is estimated as arsenious oxide.

Appendix 19. The remaining 42 samples were also found to be free from arsenic by the Reinsch test.

#### RAW AND PURIFIED SUGARS USED IN BREWING.

These were all quite free from arsenic.

#### CARAMELS.

These were all quite free from arsenic.

Many other samples of caramel were analysed by some of the members of the Commission, independently of this investigation, and were found to be free from arsenic.

#### MALT ADJUNCTS.

Thirty-seven samples of malt adjuncts, *i.e.*, of different forms of starch to be used with malt in brewing, were submitted to analysis. As in the case of the brewing sugars these were independently obtained.

The samples were made up as follows:—

Rice—consisting of cleansed broken rice, cleansed whole rice, grits, flaked grits, flaked and gelatinised rice, all representing current deliveries to brewers	10
Maize—consisting of Danubian and American corn, flaked maize manufactured in England, American imported flaked maize, gelatinised maize and maize meal, also representing current deliveries to brewers	24
Sago Flour—taken at Messrs. Bostock's Works	1
Tapioca Flour—ditto	1
Torrefied Barley	1
	37

Not one of these samples revealed a trace of arsenic when examined by the Reinsch test, and there is nothing in their method of growth, composition, or mode of manufacture for brewing purposes, to suggest the possibility of arsenical contamination.

#### HOPS.

Eleven typical samples representing English and foreign growths were submitted to analysis.

They were all found to be free from arsenic.

Nevertheless there exists the possibility of minute quantities of arsenic being present in hops, and we are aware that such traces have been found to exist in hops by analysts of authority. It is conceivable, but extremely improbable, that they are introduced with the sulphur employed when the hops are upon the poles, but they are much more likely to be derived from the fuel and brimstone employed for kilning operations in the Oast houses.

The quantity of arsenic thereby introduced into beer must in any case be infinitesimal.

#### PRESERVATIVES, WATER HARDENING MATERIALS, ETC.

Sixteen samples, independently collected and representing materials in current use, were submitted to analysis.

Of these, five were found to contain arsenic. Four of them respectively contained arsenic approximately amounting to 1-300th, 1-300th, 1-700th, and 1-200th grains per pound of material.

The quantity of material used per barrel of beer being in all cases extremely small, the arsenic introduced into beer from such sources would be infinitesimal.

The fifth sample above referred to contained approximately 3-5ths of a grain of arsenic per pound of material. The amount present distinctly showed gross negligence in manufacture, but the proportion of the preservative in question employed in brewing is so small per barrel that the amount of arsenic introduced into beer by its use would also be infinitesimal. We believe that this material is not in use in Manchester or the surrounding district.

Eleven samples were quite free from arsenic.

#### FININGS.

Six samples as used for clarifying beer throughout the country were submitted to analysis. They were all found to be free from arsenic.

#### YEAST.

Nineteen samples of yeast produced in Manchester breweries, at or about the time of the outbreak, were submitted to analysis.

Of these, 10 contained arsenic in quantity ranging approximately from  $\frac{1}{4}$ th grain to 1-200th grain per pound of pressed yeast.

Analyses made during February last proved that the Manchester yeast had been freed from arsenic, and may to-day be regarded as quite pure. This statement applies even to those breweries in Manchester in which Bostock's sugars had previously been employed.

The extremely interesting discovery has been made that if arsenic be present in worts, yeast will take up a very considerable proportion of it. It would be rash to hazard the prediction as to whether this is due to mere mechanical absorption, or to any physiological or chemico-physiological action as between the arsenic and the yeast. The fact remains, however, that in a brewery in which only minute quantities of arsenic are to be found in the brewing materials, much more definite quantities of arsenic are to be found in the yeast.

#### BARLEY.

Fourteen samples of typical malting barley, grown in different parts of the country, were submitted to analysis. In every case 50 grammes of material was operated upon.

Five samples out of the 14 contained minute quantities of arsenic.

One sample of unkilned barley contained approximately 1-400th grain of arsenic per pound.

A sample of Lincolnshire barley, certified as non-kiln dried, was submitted to analysis and found to be free from arsenic.

The same barley after kiln drying, *i.e.*, previous to malting, was found to yield a very distinct mirror of arsenic by the Marsh test, and to contain approximately 1-200th of a grain of arsenic per pound. In this case the slight contamination of the barley had been undoubtedly derived from the fuel used for kiln drying.

Another sample of barley not previously kiln-dried yielded a very minute mirror of arsenic by the Marsh test, as well as distinct evidence of the presence of arsenic by the Reinsch test. It contained approximately 1-700th of a grain of arsenic per pound. This same specimen of barley was afterwards kiln-dried, and upon examination was found to contain approximately 1-400th of a grain of arsenic per pound.

The above two sets of analyses are instructive, as showing the proportion of arsenical contamination which can be derived from the kiln drying of barley.

One of the samples above referred to, namely, that which yielded approximately 1-200th of a grain of arsenic per pound, was steeped in cold water for sixty hours, and again tested. The mirror obtained was distinctly smaller, and the amount of arsenic was estimated at approximately 1-250th grain of arsenic per pound.

The remaining 10 samples were quite free from arsenic.

The question of the source of the contamination of barley before it had been subjected to any manufacturing process naturally presented itself, and accordingly two samples of super-phosphate manure employed for root crop growth were examined. They were furnished by one of the members of your Association. One of these samples contained a mere trace of arsenic. The other sample was heavily charged with arsenic.

A sample of urine, obtained from a ewe, one of several that had died after feeding off roots grown on land manured with these super-phosphates, was also furnished for examination. It was found to contain a small amount of arsenic, but the quantity operated upon was of necessity very small, and no quantitative estimation was possible.

From these results there can be no doubt that barley is liable to take up very minute quantities of arsenic when grown upon land manured with arsenicated fertilisers.

#### MALTS.

One hundred and thirty-eight samples of malt, fairly representing the malt made and used throughout the country, were obtained from independent sources, and submitted to analysis.

Of these one sample contained approximately 1-39th gram of arsenic per pound.

Six contained approximately 1-50th of a grain of arsenic per pound.

One contained approximately 1-80th of a grain of arsenic per pound.

The remainder contained from 1-100th to 1-300th of a grain of arsenic per pound.

Ninety-seven samples were found free from arsenic by the Reinsch test.

Those samples which contained arsenic were mainly derived from maltings situated in the Midlands and the Northern Counties. The products of the Southern and Eastern Counties exhibited remarkable freedom from arsenic.

The malt containing these traces of arsenic when brewed would, in all probability, impart only a minute quantity of arsenic to the beer, having regard to the removal of arsenic effected by yeast; and it is probable that such traces have existed for many years past. There can, however, be no doubt that it is quite practicable wholly to avoid this contamination, and no better evidence could be given in support of this statement than by reference to the malts supplied to-day to the breweries in and around Manchester, which are remarkably free from arsenic.

The importance of thoroughly examining this arsenical contamination of malt led us to examine two products of the malting process not used in brewing, viz., malt-culms, and kiln dust, as well as the coal and coke used in malting.

#### MALT-CULMS.

Forty samples were submitted to analysis, 50 grammes being in each case operated upon.

Of these, 24 were found to contain arsenic. Of these, seven approximately contained at least one grain of arsenic to the pound. The remainder varied from this quantity to 1-300th of a grain to the pound.

It was noticeable as in the case of the malts that the great majority of the samples of culms containing arsenic (and particularly of those containing large amounts) were obtained from maltings in the Midlands and the Northern Counties. The Southern and Eastern Counties' culms were particularly free from arsenic. But cases occurred where the malt had been free from arsenic but the culms from the same maltings were contaminated. It was evident, therefore, that this contamination-affected culms to a much greater degree than the malt itself.

#### KILN DUST.

Twenty samples obtained from maltings from which malt and culms had been furnished were submitted to analysis.

Of these, 18 contained arsenic.

Of these, seven contained approximately between one and two grains of arsenic per pound.

The remainder contained arsenic in quantities diminishing to 1-300th of a grain per pound.

It is to be noted that in the case of kiln dust coming from maltings where the culms were free from arsenic, the kiln dust contained it in nearly every case, and the large quantities of arsenic above alluded to were in every case derived from those maltings which had yielded arsenic-loaded culms. It is therefore apparent that the kiln dust contains more arsenic than culms, and the culms vastly more than the malt.

It should not be forgotten in connection with the desirability of preventing the presence of arsenic in malt and its bye-products, that the culms are largely used for feeding purposes, and are given to sheep and stock as they are produced. Their price has averaged for the last three years about 65s. per ton. They are worth between 70s. and 80s. per ton at the maltings in the winter season, and drop to 50s. or 60s. per ton in the spring.

#### MALTING COAL.

Nineteen samples of malt anthracite, independently obtained from various maltings throughout the country, were submitted to analysis.

Of these, two only contained arsenic in minute traces. The others were free from arsenic.

#### COKE.

Twelve samples of coke independently obtained and used in maltings in different parts of the country were submitted to analysis. Of these ten contained notable quantities of arsenic, and two were free from arsenic. Of the latter, one came from Scotland, and the other from Yorkshire. The contaminated samples of coke included both gas coke and oven coke.

The amount of arsenic present in these samples of coke was amply sufficient to account for the observations made in respect of the arsenical contamination of the kiln dust, the culms, and the malt above alluded to.

#### CASK SHAVINGS.

In order to test whether contamination by arsenic could be imparted to beer by the use of casks which had previously been used for arsenicated beer, we thought it advisable to examine some cask shavings.

Eleven samples taken from casks known to have contained highly contaminated beer were submitted to analysis. They were all found to be free from arsenic.

Proof was thus furnished that the washing to which the casks had been subjected had effectually removed all contamination, and that there was no retention of arsenic by the wood. The shavings were from the interior surface of the cask, and were also deeply cut from beneath the interior surface.

Summing up the above results, it is clear that the most frequent source of arsenical contamination in beer is the use of malt which has been kiln-dried or malted with improper fuel containing arsenic. At the same time the experience of the late outbreak has shown that precautions must be taken against the presence of arsenic in brewing sugars and other materials (except perhaps malt adjuncts) on account of the serious consequences of any carelessness in manufacture which might introduce arsenic. Accordingly we have considered what steps should in future be taken by brewers to protect themselves from any repetition of the recent disasters.

#### RECOMMENDATIONS.

We recommend that brewers should make it a rule to require a written guarantee of freedom from arsenic with all purchases of brewing materials of every kind.

In addition to this we recommend that brewers should from time to time test the purity of their beer in respect of arsenic. The fact that yeast has a special affinity for arsenic affords an excellent method of demonstrating the purity of the materials used. If the yeast be tested for arsenic, it will readily show whether the wort is contaminated, for it will be many times richer in arsenic than the wort itself. It thus forms an excellent indicator of the presence of arsenic.

In addition to frequent testing of the yeast, it would be advisable for the brewers to take control tests from time to time of their brewing sugars, finings, and other materials. But in addition to these tests, and of the general guarantee above referred to, we recommend that in the case of brewing sugars, malt and hops, special guarantees should be required as follows:—

#### BREWING SUGARS.

Brewers should demand from the manufacturers—

(1) A written guarantee that the brewing sugar is free from arsenic, and that a bulk sample representing each specific delivery has been analysed and certified by a competent analyst to be pure and to contain no trace of poisonous metal.

(2) The acid employed, whether sulphuric acid made from brimstone or pyrites, or hydrochloric acid as the case may be, should be guaranteed by the manufacturer to be free from all arsenic. The brewer should exact the production of such guarantee by the brewing sugar manufacturer at his demand.

(3) The manufacturer of brewing sugar should undertake, notwithstanding such guarantee, to have each delivery of such acid suitably tested at his own works by a competent analyst for the presence of arsenic.

(4) If yeast be employed, as it occasionally is, for the purpose of inverting cane sugar, it should, on account of its peculiar liability to absorb arsenic, be tested for this metal previous to use.

Appendix 19. (5) As an additional safeguard, brewers would do well to insist upon a minimum Brewer's Extract for invert sugars of 72 lbs. per 2 cwt., and a maximum amount of mineral matter not exceeding 2 per cent. upon the total composition of the invert sugar.

Notwithstanding the absence of arsenic in the samples of caramel which have been examined by us, it cannot be denied that the method of manufacture of caramel, and the fact that it is employed for imparting colour to beer (as well as spirits, sauces, and many other food stuffs), admits of the possibility, although remote, of the introduction of arsenic in very small quantities into beer, and therefore although the amount of arsenic that could be so introduced would be infinitesimal, the brewer is recommended to obtain from the manufacturer a guarantee that the caramel has been tested and found to be free from arsenic.

#### HOPS.

The brewer should demand that the hop merchant should obtain from the factor, who in turn would obtain it from the grower, a guarantee that none but the purest "flowers" were used upon the poles, and that the fuel and brimstone employed for drying were free from arsenic.

#### MALT.

It has been mentioned that when malt is contaminated with arsenic the malt culms and kiln dust contain a much larger proportion of arsenic than the malt itself. This is accounted for by the fact that when the green malt is loaded on to the kiln, and subsequently during the kilning, the physical structure of the culms renders them particularly liable to absorb any arsenious vapour that may be carried through the malt as the result of combustion of contaminated fuel, and that this liability is increased by the fact that from their position relative to the malt they are more exposed to the heated air.

The importance of this is shown by the fact that although the proportion by weight of culms to malt is only about 2 per cent., yet the amount of arsenic contained in the culms is vastly in excess of that to be found in the malt.

The same remark applies with greater emphasis to the kiln dust, which is produced to an extent varying from a little over half per cent. up to nearly 2 per cent. by weight of the malt. It is, however, not used as cattle food, but is sold as manure (principally for root crops), and fetches between 30s. and 40s. per ton at the maltings.

Our investigations have shown that the contamination of malt culms and kiln dust is chiefly due to the use of coke, and especially of gas coke.

Enquiries made of the principal maltsters in England have elicited the practically unanimous opinion that there is no necessity whatever to employ gas coke in the preparation of malt. Nor, indeed, is there any real necessity to employ coke at all for purposes of malting.

If the use of coke were dispensed with a good many malt kilns would have to be structurally modified, but the brewer would not fail to appreciate the benefit of such alterations.

The price of good malting anthracite has recently advanced, and may be taken to range this season from 32s. to 36s. per ton delivered at the maltings.

Gas coke varies from 18s. to 20s. per ton, and contract prices are lower than this.

This price does not in all cases include carriage to the maltings.

Washed coke is about 38s. per ton, but the price varies considerably.

When coke is used it is usual to employ all coal for the first two days, a mixture of two-thirds coal and one-third coke on the following day, and half coal and half coke on the finishing day. The object is stated to be to secure higher temperatures. The prices quoted in respect of gas coke, however, show that there is another object for its employment, and it is to be observed that it is mainly maltsters for sale that largely use gas coke.

It might be necessary to use a small proportion of coke in the drying of amber malt, but in such case it would certainly be advisable to employ coke made from hand picked and washed coal, and not gas coke.

We recommend therefore—

(1) That the maltster be required to give a guarantee to the brewer that he does not employ gas coke in the preparation of his malt.

(2) That the malt culms be regularly tested for the presence of arsenic.

(3) If the culms be found to contain noticeable quantities of arsenic, that the kiln dust be at once removed, and the fuel employed be further examined for arsenic.

(4) That wherever possible, the best anthracite be employed for malting purposes.

#### SELENIUM.

The contaminated sugars supplied by Messrs. Bostock, as well as the contaminated acid used by them, have been tested by Dr. Stevenson, Mr. Gordon Salamon, and Dr. Luff, to ascertain whether selenium was present, but they have found none.

#### THE TESTING OF BEER FOR ARSENIC.

We have now examined all the possible sources of arsenic in beer, and have pointed out the precautions necessary in each case. If such precautions be taken we believe that the beer will be brewed free from arsenic, and at no substantial increase of cost. And in view of the desire of the brewers that the beer supplied to the public should be free from all suspicion of containing arsenic, we recommend that the following should in future be adopted as the standard test and should be regularly applied. It is more stringent than the one recommended in our former report, but it is not too delicate for the standard of purity to which, in our opinion, the beer should attain.

This test (Reinsch) should be performed as follows:—

Take 200 c.c. of the beer in a porcelain evaporating dish, acidulate with 1 c.c. of pure concentrated hydrochloric acid, and evaporate till the volume of liquid is reduced to one-half. Then add a further 15 c.c. of the hydrochloric acid, and insert a piece of pure burnished copper foil, a quarter of an inch by half an inch in size, and keep the solution gently simmering for an hour, replacing the evaporated liquor from time to time by distilled water. If at the end of an hour the copper remains bright and red, the beer is arsenic-free.

If a deposit is obtained on the copper, the foil should be removed, washed successively with water, alcohol, and ether, dried at a temperature not exceeding 100° C., and subjected to slow sublimation in a thin reduction tube, not less than two inches long and having an internal diameter of 0.15 inch, the upper portion of which should be warmed before the sublimation begins. For the purpose of the sublimation a small spirit lamp flame should be used. If any sublimate is obtained, it must be examined under a magnifying power of about 200 diameters. Any sublimate which does not show well-marked octahedral or tetrahedral crystals is not to be considered arsenical. Mere blackening of the copper, or deposit thereon, does not demonstrate the presence of arsenic.

The addition of oxidising agents to decompose sulphites, and the use of reducing agents to decompose possible arsenates, is not recommended, as such a procedure is, in our opinion, unnecessary in the testing of beer, and introduces sources of error.

In all cases where the presence of arsenic is ascertained by this test, it is then desirable to estimate the amount by means of the Marsh test, which, although not giving an accurate quantitative determination, will, when properly applied, give an approximate estimation of the amount of arsenic present.

When arsenic is detected by the above test its quantity is best determined by the process of Marsh (Marsh-Berzelius), which should be performed as follows:—

The beer—preferably 50 c.c.—is acidulated by the addition of 1 c.c. of pure concentrated hydrochloric acid, and gently boiled in a porcelain evaporating dish for a few minutes till frothing nearly ceases, cooled, and gradually introduced into a Marsh apparatus of 200 c.c. capacity, which is already giving off a gentle stream of pure hydrogen gas, evolved from pure zinc and diluted hydrochloric acid. The purity of the evolved gas is first tested by ascertaining that it yields no mirror after

15 minutes, when it has been passed through a drying tube charged with successive layers of cotton wool, lead carbonate, and spongy calcium chloride, and then heated to dull redness in a narrow glass tube drawn out to a capillary size just beyond the point of heating. The open point of the tube at which the gas escapes should be turned upwards at right angles, so that the amount of issuing gas can be regulated by seeing that when lighted the flame of the burning gas is just perceptible. The beer is introduced by means of a straight thistle funnel provided with a stop-cock, so that the admission of liquid into the apparatus can be regulated without introducing air. From time to time a little pure concentrated hydrochloric acid is also introduced, so as to maintain the uniform evolution of gas.

The blank experiment having shown no mirror in the heated tube at the end of 15 minutes, the experiment is continued for half an hour after the commencement of the introduction of the beer. The arsenical mirror thus obtained is then compared with standard mirrors obtained by treating known quantities of arsenious oxide dissolved in water with the addition of pure hydrochloric acid under precisely similar conditions as to generation of gas, and the quantity of

arsenic present is thus judged with great approximate accuracy. The mirror may subsequently be converted into crystals of arsenious oxide by sealing off the portion of the tube containing the mirror at each end by means of a blowpipe, and then gently heating the tube, by which means the mirror is volatilised, oxidised, and converted into crystals of the oxide. The mirrors obtained should be small, the comparison of small mirrors yielding more accurate results than where large mirrors are compared.

We believe that if the recommendations contained in this report are carried out the brewer will send out beer free from arsenic, and the public health will be amply safeguarded.

## APPENDIX 20.

## "JOINT COMMITTEE'S" REPORT.

## REPORT OF THE JOINT COMMITTEE OF SOCIETIES OF CHEMICAL INDUSTRY AND PUBLIC ANALYSTS ON THE DETECTION AND APPROXIMATE ESTIMATION OF MINUTE QUANTITIES OF ARSENIC IN BEER, BREWING MATERIALS, FOOD-STUFFS, AND FUELS.

*Handed in by Mr. Otto Hehner and Mr. Chapman, 13 June, 1902.*

The joint committee of the Society of Chemical Industry, and of the Society of Public Analysts, appointed in March, 1901, and consisting of Messrs. Otto Hehner (chairman), Alfred H. Allen, Alfred C. Chapman, C. Estcourt, David Howard, Arthur R. Ling,\* Drs. Rudolph Messel, and Leonard T. Thorne, reports as follows:—

After an examination of various methods, the committee recommend that of Marsh-Berzelius.

## MATERIALS REQUIRED.

**Hydrochloric Acid**—The purest hydrochloric acid obtainable is very rarely free from arsenic. To the "pure" acid, as purchased for analysis, diluted with distilled water to a specific gravity of 1.10, sufficient bromine is added to colour it strongly yellow (about 5 c.c. per litre); sulphurous acid, either gaseous or in aqueous solution, is then added *in excess*, and the mixture is allowed to stand for at least twelve hours. Or hydrobromic acid and sulphurous acid may be used. The acid is then boiled till about one-fifth has evaporated, and the residue can either be used direct, or may be distilled, the whole of the arsenic having volatilised with the first portion.

**Sulphuric Acid**—This is more frequently obtainable arsenic-free than hydrochloric acid. If not procurable, to about half a litre of sulphuric acid, "pure for analysis," a few grammes of sodium chloride are added and the mixture distilled from a non-tubulated glass retort, the first portion of about 50 c.c. being rejected. For the purpose of the test to be described, one volume of the distilled acid is diluted with four volumes of water.†

**Nitric acid** can, as a rule, be obtained free from arsenic without much difficulty, the pure redistilled acid being used. This should be tested by evaporating 20 c.c. in a porcelain dish, which should then be washed out with dilute acid, and tested as described in this report.

The purified acids should be prepared as required, and should not be stored for any length of time. If this be unavoidable, however, Jena flasks are to be preferred, since most bottle glass is liable to communicate traces of arsenic.

**Zinc**—Arsenic-free zinc is obtainable from chemical dealers. It should be regranulated by melting it and pouring it from some height into cold water.‡

**Lime**—Caustic lime, even when made from marble, is not always free from arsenic. A selection must, therefore, be made from various samples. If pure lime is not obtainable, magnesia may equally well be used, and can more readily be obtained of sufficient purity.

**Calcium Chloride**—This salt often contains arsenic, and before being used as a drying agent must be freed from the volatilisable part of the impurity by moistening it with strong hydrochloric acid, fusing, and regranulating.

## APPARATUS.

A bottle or flask, holding about 200 c.c. (for frothing materials preferably wider at top than bottom), is fitted with a doubly-bored cork, india-rubber stopper or with a ground-in glass connection, carrying a tapped funnel holding about 50 c.c. and an exit tube. The latter is connected with a drying tube contain-

ing, first, a roll of blotting paper soaked in lead acetate solution and dried, or a layer of cotton wool prepared in a similar way, then a wad of cotton-wool, then a layer of granulated calcium chloride, and finally a thick wad of cotton-wool. To this tube is fitted a hard glass tube, drawn out as shown in the figure, and of such external diameter that at the place where the arsenic-mirror is to be expected the tube just passes through a No. 13 Birmingham wire gauge (corresponding with 0.092 inch). The exact size is not material, but all tubes used for standards and tests should be as nearly as practicable of the same diameter. A good Bunsen flame is used to heat the hard glass tube close to the constriction. About one inch of tube, including the shoulder, ought to be red-hot. A piece of moderately fine copper gauze (about one inch square) wrapped round the portion of the tube to be heated assists in insuring an equal distribution heat.

## MODE OF TESTING.

About 20 grammes of zinc are placed in the bottle, and washed with water to clean the surface, as particles of dust may contain arsenic; all parts of the apparatus are connected, and a sufficient quantity of acid (prepared as previously described) allowed to flow from the funnel, so as to cause a fairly brisk evolution of hydrogen. When the hydrogen flame—which during the heating of the tube should be kept at as uniform a height as possible (about a quarter of an inch)—burns with a round, not pointed tip, all air has been removed from the apparatus. The Bunsen burner should then be placed under the hard glass tube as described, and more acid (10 to 20 c.c. is generally enough) run in as required. With good materials no trace of a mirror is obtained within half an hour. Great care must be taken that when additions of acid are made to the zinc no bubble of air is introduced, since in presence of air the arsenic mirror may become black and unevenly distributed, whilst it is brown when the experiment has been properly conducted.

Should the blank experiment not be satisfactory it must be ascertained by changing the materials methodically, whether the fault lies with the acid, zinc, other materials, or with the apparatus.

**Preparation of Standard Mirrors**—When a satisfactory blank experiment has been obtained a series of standard mirrors must be prepared under the following conditions:—

A hydrochloric acid solution of arsenious oxide, containing in each cubic centimetre 0.001 milligramme  $As_2O_3$ , is prepared by diluting a stronger solution with distilled water. Two c.c. of this solution (equal to 0.002 milligramme of arsenious oxide) are introduced into the apparatus, a new tube having been joined to the drying tube. If the zinc is sensitive, a distinct brown mirror is obtained after twenty minutes. It is important to note that some "pure" zinc is, from a cause at present unknown, not sufficiently sensitive; that is to say, the addition of minute quantities of arsenic produces no mirror. The portion of the tube containing the mirror should be sealed off while still filled with hydrogen; in contact with air the mirrors gradually fade. Mirrors are now similarly made with 0.004, 0.006, 0.008, and 0.01 milligramme of arsenious oxide. With a little practice it is easy to obtain the deposits of arsenic neatly and equally distributed. The standard mirrors, properly marked,

\* Mr. Ling also acted as secretary.

† Mr. A. H. Allen holds it to be essential, both for a regular evolution of hydrogen and for the formation of uniformly deposited brown-coloured mirrors, that the zinc should contain a trace of iron.

‡ A diagram of a suitable form of apparatus is given in "The Analyst," February, 1902.

are mounted on a white card or porcelain slip. It is to be understood that the first stage of every test must be a blank of at least twenty minutes.

Hydrochloric acid is somewhat more sensitive than sulphuric acid—that is to say, it gives rather denser mirrors with minute quantities of arsenic. If, for one reason or another, sulphuric acid is preferred by the operator, he must make a set of standard mirrors with sulphuric acid, and use these for comparison.

Organic materials, such as beer, yeast, etc., cannot be tested, when sulphuric acid is used, without destruction of the organic matter, whilst, as a rule, they can be directly tested with hydrochloric acid. However, many materials are met with in which it is preferable to destroy the organic matter.

#### PROCEDURE WITHOUT DESTRUCTION OF ORGANIC MATTER.

The apparatus is started, and a blank experiment allowed to go on for twenty minutes. If no trace of a deposit is obtained, 10 c.c. of the liquid to be tested and about 10 c.c. of hydrochloric acid are put into the funnel, and slowly introduced into the bottle without air-bubbles. Some materials (beers, for example) are apt to froth, hence the necessity for slow introduction. If after about ten minutes no mirror appears, another 10 c.c. of the liquid, with 10 c.c. of hydrochloric acid, are added, and the experiment continued for fifteen to twenty minutes, acid being from time to time added as may appear necessary.

**Malt.**—Fifty grammes of the malt are placed in a 400 c.c. separator funnel furnished with a stopcock; 50 c.c. of hydrochloric acid, prepared as described, and 50 c.c. of water are warmed to about 50° C., and poured on the malt. The whole is then allowed to digest for fifteen to twenty minutes, with frequent agitation, and the acid then allowed to run off by the stopcock. About 60 c.c. of the acid liquor is thus obtained, of which every 20 c.c. contains the arsenic from 10 grammes of the malt.

**Hops.**—Twenty grammes of hops are digested with 100 c.c. of dilute hydrochloric acid (one volume of the purified acid to one volume of water) at about 50° C. for half an hour, 50 c.c. of the strained-off liquid being used for the test.

**Sugar and other brewing materials** are dissolved in water, 10 c.c. of acid added, and the solution tested direct, operating upon from 10 to 20 grammes of material.

#### DESTRUCTION OF ORGANIC MATTER.

(a) **Acid Method.**—Ten grammes of the substance to be placed in a 3½-inch porcelain crucible, and covered with pure redistilled nitric acid (about 10 to 15 c.c.). The whole is then heated on a sand-bath until the evolution of brown fumes ceases. Three c.c. of concentrated arsenic-free sulphuric acid are then added, and the heating continued till the mass just begins to char, when a further quantity of 5 c.c. of nitric acid is added. The heating is now continued till all the acid is expelled, leaving in the crucible a black, nearly dry, charred mass. The crucible is about half filled with water and a few c.c. of hydrochloric acid, of dilute sulphuric acid, run in (according as the one or the other is to be used in the Marsh apparatus), the whole being allowed to extract for about half an hour on a water-bath. It is then filtered into a porcelain basin, the charred mass washed with hot water, and the filtrate concentrated down to about 10 c.c., which is allowed to cool, and is then ready for the test. It is essential that the mass should be thoroughly charred, and that the solution, when filtered, should be colourless.

In the case of beer, 10 to 20 c.c. are evaporated to dryness on a water-bath, and the residue oxidized as above stated.

**Hops.**—10 c.c. of pure nitric acid and 5 c.c. of concentrated sulphuric acid are mixed in a 3½-inch porcelain crucible, and the hops are then added in small portions at a time, each quantity being thoroughly disintegrated by pressure under the acid with a glass rod, a further quantity of 5 c.c. of nitric acid being added when about half the hops have been

thus introduced. The crucible with its contents is then cautiously warmed so as to avoid frothing over. When the evolution of dense red fumes ceases the heating is increased, and the acids are evaporated on a sand-bath, and the dry charred mass extracted with dilute acid, filtered, concentrated, and introduced into the Marsh apparatus in the ordinary way. It may be noted that with many English hops of relatively fine texture the addition of the second quantity of nitric acid above recommended is unnecessary.

When, owing to the presence of larger quantities of arsenic, smaller amounts of substance—e.g., 0.5 gramme to 2 grammes—are taken, the quantities of acids recommended above may, of course, be reduced.

(b) **Basic Method.**—The materials are mixed with pure lime or magnesia (1 gramme for 20 c.c. of beer), dried and incinerated. For sugars or other solid materials about half their weight of base is employed. The ash is dissolved in hydrochloric acid, and the solution tested. This method is not recommended for hops.

Of coal or other fuel, after careful sampling, two portions of 1 gramme each are weighed. One portion is incinerated in a platinum dish in a muffle, and the hydrochloric acid extract of the ash tested for "non-volatile arsenic." The other is intimately mixed with 1 gramme of lime or magnesia and also incinerated. The hydrochloric acid extract of the latter gives the "total arsenic," the difference between the two determinations being the "volatile arsenic." It may in some cases be found that the above-mentioned quantity of fuel gives a mirror too dense to be measured. When this is the case the hydrochloric acid extract is diluted to a determinate volume and an aliquot portion taken.

**Sulphites.**—The sulphurous acid must be oxidized by bromine, the excess of the latter being removed by heating.

The committee have convinced themselves that arsenic in both states of oxidation can be detected and estimated by the procedure described.

As an additional precaution a fresh tube should always be substituted for that containing the mirror, and the experiment continued for a further period of 15 minutes. Should a second mirror be formed, the quantity of arsenic with which it corresponds is to be added to that shown by the first.

It must be understood that the tests are only approximate, and that mirrors corresponding with less than 0.003 milligramme of arsenious oxide in the quantity of materials taken cannot be safely relied upon. When a mirror has been obtained, a duplicate test should always be made to preclude error by accidental contamination.

The proof that the mirrors are arsenical is obtained as follows:—The narrow portion of the tube containing the mirror (which should not be denser than that produced by 0.01 milligramme of arsenious oxide) is cut off, the hydrogen replaced by air, and the ends sealed up. The tube, held in the tongs, is then heated by drawing it repeatedly through the flame of a Bunsen lamp until the mirror has disappeared. On cooling, minute crystals of arsenious oxide deposit, the sparkling of which can be seen with the naked eye, if the tube be held before a luminous flame, and which can be readily identified under the microscope by their crystalline form.

This test, as recommended, is one of such extreme delicacy, that with quantities of 20 grammes (or 20 c.c.) it will give an indication of the presence of 0.000015 per cent. (or one part in 7,000,000) of arsenious oxide. This would represent with solids  $\frac{1}{100000}$  grain per pound with liquids  $\frac{1}{100000}$  grain per gallon. It must be understood that the committee do not suggest any limits for traces of arsenic which may be regarded as negligible; but they desire to express the opinion that limits should officially be fixed by the Royal Commission or otherwise. This could be easily effected by prescribing the amounts of solids and liquids respectively to be taken for the test, and the minimum mirror to be recognised.

## APPENDIX 21.

## REPORT OF THE INLAND REVENUE DEPARTMENTAL COMMITTEE.

Handed in by Sir HENRY PRIMROSE, April 3, 1905.

REPORT OF THE COMMITTEE APPOINTED BY THE COMMISSIONERS OF INLAND REVENUE TO SPECIFY THE INGREDIENTS OF BEER, AND THE MATERIALS USED IN THEIR PREPARATION WHICH ARE LIABLE TO BE CONTAMINATED BY ARSENIC, AND TO PRESCRIBE TESTS BY WHICH THEIR FREEDOM FROM ARSENIC MAY BE ASCERTAINED.

To the Honourable the Commissioners of Inland Revenue.

Gentlemen,—The Committee charged by the Board of Inland Revenue—in conformity with the recommendation of the Royal Commission appointed to inquire into Arsenical Poisoning from the consumption of Beer—to specify in detail individual ingredients of beer which are liable from their origin or mode of preparation to be contaminated by arsenic, and to prescribe for such ingredients and for the different materials used in their preparation adequate tests which should ensure their freedom from arsenic, beg to report as follows:—

Glucose and invert sugar are ingredients of beer, and it has been established that these sugars may become contaminated by arsenic if mineral acids containing arsenic have been used in their preparation.

"Priming" and caramel, if made from such contaminated sugars, may also be contaminated by arsenic. Other ingredients used by the brewer, if made by the agency of impure sulphuric or hydrochloric acid, may likewise become contaminated by arsenic.

It has been further established that malt may become contaminated by arsenic if the fuel used in its preparation contains arsenic.

Hops are also liable to contain arsenic if they have been sprayed with arsenical preparations, or if they have been "sulphured" with impure sulphur, or if the fuel used in drying them is arsenical.

In an appendix to this report we specify in detail (1) the individual ingredients of beer which are liable from their origin or mode of preparation to be contaminated by arsenic; (2) the materials used in the preparation of such ingredients which are liable to contain arsenic.

Broadly speaking, all the ingredients of beer liable to contain arsenic are comprised under the main groups of (1) malt; (2) malt substitutes (prepared sugar, caramel, and malt extract); (3) hops and hop substitutes; (4) yeast and yeast foods; (5) chemicals employed as cleaning and preservative agents; and (6) finings.

The materials used in the preparation of the ingredients of beer which are liable to contain arsenic are, as already stated, mainly the common mineral acids, and especially sulphuric acid and hydrochloric acid, sulphur, and fuel.

All the evidence we have been able to collect appears to indicate that the arsenic which may be present in the ingredients of beer is in the form of the oxides of arsenic, either free or combined. A study of the behaviour of solutions derived from these ingredients as regards their deportment towards chemical re-agents serves to substantiate this conclusion.

The task entrusted to the Committee was to prescribe tests whereby arsenic, if present, might be readily and certainly detected, and, if necessary, its amount determined, in any of the members of these groups of substances.

Although the recommendation of the Royal Commission above referred to makes no explicit reference to a test for arsenic in beer, as distinguished from its ingredients and the materials which may have been used in their preparation, we have considered that the question of the application of such a test to beer might be regarded as coming within the terms of our reference.

We have, therefore, given attention to the methods of detecting the presence and determining the amounts of arsenic in (1) malt; (2) malt substitutes; (3) wort; (4) hops and hop substitutes; (5) beer; (6) yeast and yeast foods; (7) chemicals; (8) finings; (9) fuel.

Of the various methods which have been suggested from time to time for the detection and estimation of the relatively small quantities of arsenic which may be present in beer and the ingredients of beer, or in

the materials which may be used in their preparation, we are of opinion that those methods which depend upon the conversion of the arsenic into arseniuretted hydrogen, and the subsequent deposition of the arsenic in the elementary form by heating the gas, are, on the whole, to be preferred.

The arseniuretted hydrogen may be formed in practice by the action of so-called "nascent" hydrogen upon the arsenic present. The hydrogen may be evolved either electrolytically or through the agency of dilute hydrochloric acid upon zinc admixed with or containing such an amount of copper or other suitable metal as to give rise to a sufficiently rapid evolution of the gas.

The amount of the arsenic deposited by heating the arseniuretted hydrogen so formed is then determined by comparison with deposits obtained in precisely the same manner from wort, beer, malt extracts, sugar solutions, etc., containing known quantities of arsenic.

## 1.—ELECTROLYTIC METHOD.

An electrolytic method for detecting arsenic appears to have been first suggested by the late Professor Bloxam, of King's College (Quarterly Journal of Chemical Society, Vol. XIII., 1861, pp. 12 and 338), but in its original form it had several disadvantages which have prevented it from being generally adopted by chemists. Modifications of it have been made by Mr. Trotman, Mr. Bevan, and others. The process has been carefully investigated in the Government Laboratory, and in the form now described it is easy of application, and is capable of giving trustworthy results with a comparatively small expenditure of time and trouble.

The apparatus employed in the electrolytic method is seen in plan and elevation in Figures 1 to 4, drawn to scale.

It consists of the following parts:—

1. A glass vessel A, provided with a ground glass stopper and connections B, and calcium chloride drying tube C.
2. A porous cell D.
3. A glass vessel E.
4. A cooling vessel F.
5. A hard glass constricted tube G.
6. A small Bunsen burner H.

The glass vessel A forms with the porous vessel D the inner cell for the cathode where the hydrogen and arseniuretted hydrogen are produced on passing the electric current. The vessel A is open at the bottom and fitted at the top with the ground glass stopper B, through which is passed to a point just below the neck of the vessel the stem of the tapered funnel. The glass stopper also carries the gas exit tube on which is a bulb. The tube is bent as shown in the drawing, and is connected by grinding with the drying tube C. Through the glass cap is fused a stout platinum wire for making the connection on the outside with the current, and within the vessel with the electrode.

The inner electrode, forming the cathode, is of sheet platinum and cone-shaped, with several perforations. It is suspended from a hook made on the end of the wire passing through the glass stopper, and is adjusted so that when the stopper is inserted in the vessel the lower edge of the electrode is 1 mm. above the bottom of the vessel A. It is then securely attached to the wire by closing the hook.

The porous vessel D is larger by 3 to 3 mm. in diameter and in depth than the cylindrical portion of the glass vessel A. As seen in the figure, A rests by means of its bulged-out shoulder upon the upper edge of D. The

porous vessel is of unglazed highly silicious ware—of the composition employed for the well-known biscuit filters, first made by Dr. Pukal—and is from 1 to 1.5 mm. in thickness.

The cell for the anode consists of the stout vessel E upon the flat bottom of which the porous vessel D, containing the glass vessel A, stands. The anode consists of a band of platinum 2 cm. broad passing loosely round the porous cell, and connected with the current by means of a stout platinum wire. The liquid in the vessel E should be kept below 50°C., and the vessel E is therefore placed in a larger dish F containing cold water.

The drying tube C is packed as follows:—A plug of cotton wool is first inserted, and then pure granulated anhydrous calcium chloride,\* in pieces about the size of small shot or malt grains, for a length of 5 cm. Another loose plug of cotton wool is placed upon the calcium chloride, followed by a roll of lead acetate paper. This is prepared by soaking filter paper in a cold saturated solution of lead acetate and then drying the paper in air. The paper is cut into strips about 1 cm. broad, and rolled into a coil fitting loosely in the tube. A small spiral coil of lead acetate paper is also placed within the enlarged end of the exit tube to which the calcium chloride tube is attached.

To the other end of the drying tube there is fixed by means of a short piece of unvulcanised rubber tubing the hard glass constricted tube in which the arsenic is to be deposited. The ends of the drying tube and the hard glass tube should be in close contact beneath the rubber. To make one of these tubes a piece of Jena glass tubing having an external diameter of 5 mm. and an internal diameter of 3.5 mm. is cleaned by successive treatment with acid, water, and alcohol, and dried. It is then held in the blow-pipe flame, so that a portion of the tube about 2 cm. in length and 5 cm. from the end of the tube is thoroughly softened, when the heated portion is drawn out to a length of 7 to 8 cm., and having at a distance of 1 cm. from the shoulder of the tube an external diameter of 2 mm.—a size which should be maintained as nearly as possible throughout the length of the constricted part. The tube is cut off near the end of the drawn-out portion, the last 1 cm. of which is turned up at right angles. The hard glass tube is supported in a horizontal position when attached to the drying tube of the apparatus, by resting in the slots on the upper edge of the cone which surrounds the flame of the small Bunsen burner. A piece of platinum gauze about 2 cm. square is wrapped round the hard glass tube at the point where it is to be heated by the Bunsen flame.

The small Bunsen burner has a circular base 12 mm. high, and its tube is 6 cm. in height, and 5 mm. in internal diameter. The upper portion of the tube is threaded, and carries a gallery upon which rests a copper cone. The upper edge of the cone contains two slots to receive the hard glass tube.

The apparatus, when worked in the manner to be described, has an apparent resistance of 1.4 ohms, the potential difference between the ends of the wires of the poles being 7 volts with a current of 5 amperes. This strength of current gives about 40 cb.c. of hydrogen in a minute, which furnishes a steady flame about 2 mm. in height, and is the strength of current recommended to be used for the purposes of the test. To effect the reduction of the intensity of the main laboratory supply, which is the most convenient source of the current, a rheostat of incandescent lamps may be employed. The lamps are arranged parallel with each other, but in series with the apparatus, and according to the current desired, lamps of different candle power may be inserted. An ampere meter is included in the circuit.

The apparatus may be arranged for the simultaneous execution of a number of tests. By suitable construction on the charging board, the electric current passes through the solutions arranged in series, and any of these may be brought into or cut out of the circuit as desired. The current is brought to the required strength—4.5 to 5 amperes—by the introduction in the rheostat of lamps of the requisite power according to the number of tests to be carried out simultaneously. A diagram illustrating the method employed for this purpose is shown in Fig. 5.

\* Where a series of experiments is carried out with the same apparatus, the calcium chloride should be renewed from time to time, say, after three or four experiments.

† The lime water, lime, magnesia, and potassium metabisulphite are tested as to their freedom from arsenic by the method described under "Chemicals."

The sulphuric acid solution employed in the apparatus is prepared by mixing one volume of pure concentrated sulphuric acid with seven volumes of water. It must, of course, be tested to ascertain its freedom from arsenic before it is used.

Certain of the solutions to be tested are very liable to froth when introduced into the apparatus. This inconvenience may be obviated by adding one or two cubic centimetres of rectified amyl alcohol (b.p. 128°—132°C.) to the acidulated liquid undergoing electrolysis.

Before describing the application of the test, it will be convenient to give in detail the methods to be followed in preparing the extracts or solutions of the various substances in such a form and in such an amount as to render them suitable for testing.

(1) **MALT.**—Unground malt may readily be examined for arsenic by washing the malt with warm dilute acid, and testing the acid extract; but this method is inconvenient in the case of a ground or crushed malt, as there are difficulties in obtaining a suitable extract. A ground malt is therefore incinerated in presence of lime and magnesia, and the solution of the ash tested. Direct experiment has shown that deposits of arsenic obtained after treatment of an unground malt with dilute acid are equal in intensity to those obtained by the basic method of treatment of the same malt. The two methods are as follows:—

*Basic Method for Ground Malt.*—10 grams of the ground malt are transferred to a porcelain, or preferably a platinum, dish about 3 in. in diameter, 30 cb.c. of arsenic-free lime water† are added, and the dish heated over a small Bunsen flame for a few minutes. About 0.5 gram of arsenic-free magnesia or lime is then added, and thoroughly mixed with the contents of the dish, the heating of which is continued until the organic matter is completely charred. The dish is then placed in a muffle furnace, or over a low Bunsen flame, and heated at a dull red heat until practically all the carbon is burnt off. When cold the ash is moistened with water, and 20 cb.c. of the dilute sulphuric acid added. The dish is warmed, and the contents transferred to a 4 oz. flask. About half a gram of potassium metabisulphite is added, and the solution boiled until free from sulphurous acid. After cooling, the solution is ready to be tested.

*Acid Method for Unground Malt.*—40 grams of malt are transferred to a wide-mouthed stoppered bottle, 40 cb.c. of the dilute sulphuric acid, and 60 cb.c. of water, are mixed together, raised to a temperature of 50° C., and added to the malt. The bottle is shaken at intervals during 20 minutes, and the liquid poured off. Twenty-five cb.c., representing 10 grams of malt, are transferred to a small flask, half a gram of potassium metabisulphite added, and the solution boiled until free from sulphurous acid. When cold the solution is used for the test.

(2) **MALT SUBSTITUTES** (Glucose, Invert Sugar, Caramel, etc.).—Five grams are weighed in a small flask, and dissolved in 20 cb.c. of water. Half a gram of potassium metabisulphite and 5 cb.c. of the dilute sulphuric acid are then added and the solution boiled until free from sulphurous acid. When cold it is ready for adding to the electrolytic apparatus.

(3) **WORT.**—Direct experiments have shown that when using the electrolytic apparatus it is unnecessary to destroy the organic matter of the wort. All the arsenic which may be present is evolved as arseniuretted hydrogen.

For the test, 25 cb.c. of the wort are placed in a small flask, half a gram of potassium metabisulphite and 5 cb.c. of the dilute sulphuric acid are added, and the solution boiled until free from sulphurous acid. When cold the solution is used for the test.

(4) **HOPS AND HOP SUBSTITUTES.**—Five grams of the substance, ground if necessary in a mortar, are placed in a platinum dish treated with lime and magnesia and incinerated, and the examination for arsenic carried out in the same manner as described in connection with ground malt.

(5) **BEER.**—Direct experiments have shown that when the electrolytic apparatus is used it is unnecessary to

Appendix 21. destroy the organic matter of the beer. All the arsenic which may be present is evolved as arseniuretted hydrogen.

Twenty-five c.c. of beer are placed in a small flask, half a grain of potassium metabisulphite and 5 c.c. of dilute sulphuric acid added, and the solution boiled until free from sulphurous acid. The cold solution is used for the test.

(6) YEAST AND YEAST FOODS.—Five grains are introduced into a flask and gently warmed with 20 c.c. of water. Half a gram of potassium metabisulphite and 5 c.c. of dilute sulphuric acid are then added and the contents of the flask boiled until free from sulphurous acid. The cold solution is used for the test.

Of liquid yeast foods 25 c.c. are taken, and the solution boiled, after the addition of potassium metabisulphite and sulphuric acid, until free from sulphurous acid.

#### (7) CHEMICALS:—

(a) Sulphites.—Of solid sulphites 1 gram is dissolved in 25 c.c. of water in a small flask. Five c.c. of dilute sulphuric acid are added and the solution boiled until free from sulphurous acid. The cold solution is used for the test.

Of solutions of sulphites 25 c.c. are taken and boiled in like manner after the addition of 5 c.c. of dilute sulphuric acid. The liquid is tested by the addition of a little more sulphuric acid to ascertain if the whole of the sulphite has been decomposed.

(b) Acids.—Sulphuric Acid.—Five c.c. are diluted with 20 c.c. of water, half a gram of potassium metabisulphite added, and the solution boiled to expel sulphurous acid. When cold the solution is used for the test.

Hydrochloric Acid.—Five c.c. are placed in a porcelain dish, and diluted with about 5 c.c. of water. Five c.c. of pure nitric acid (Sp. Gr. 1.4) and 2 c.c. of pure concentrated sulphuric acid are then added, the dish placed on a sandbath, and the liquid evaporated until the sulphuric acid fumes. The dish is removed, and when cold about 20 c.c. of water and half a gram of potassium metabisulphite added. The solution is transferred to a flask and heated until free from sulphurous acid, and then tested.

(c) Sulphur.—Ten grams are taken, and the examination for arsenic carried out in the manner described under Fuel (see below). Owing to the readiness with which sulphur sublimes, the temperature to which the hard glass tube is heated should be as low as possible consistent with the burning of the sulphur, and the empty portion of the hard glass tube, next to the bent and drawn out end, should not be heated until the sulphur in the other part of the tube has been burnt. The liquid in the absorption tube is boiled to expel sulphurous acid, and any sulphur or other solid substance which may have passed into the absorption tube in the process of combustion is rendered soluble and in suitable condition for addition to the electrolytic apparatus by the method described for treating the ash of fuel.

(d) Other Chemicals.—Of solids 1 gram is taken and dissolved in 25 c.c. of water. Of liquids 25 c.c. are taken. In either case, if the solution is alkaline it must be neutralised by the addition of dilute sulphuric acid. To the neutral liquid half a gram of potassium metabisulphite and 5 c.c. of dilute sulphuric acid are added, and the solution boiled until free from sulphurous acid. The cold solution is used for the test.

(8) FININGS.—Five grams are weighed out in a flask, 20 c.c. of water added, and gently warmed to effect solution. If sulphurous acid or a sulphite is present, 5 c.c. of the dilute sulphuric acid are added, and the solution boiled until free from sulphurous acid.

If no sulphurous acid is present in the finings, half a gram of potassium metabisulphite is added to the solution prepared as above, together with 5 c.c. of the dilute sulphuric acid, and the solution boiled to expel sulphurous acid, and then tested.

(9) FUEL.—A piece of hard glass tube A, about 60 c.m. long, is drawn out and the drawn out portion bent, as seen in Figure 6. Ten grams of the finely-powdered sample of fuel are then introduced into the tube in such manner that it occupies about 30 c.m. of the length of the tube, leaving about 6 c.m. of the tube next to the bent and drawn out portion empty. A convenient method of introducing the fuel is to distribute it along a stout glazed cardboard trough or gutter which can readily be inserted in the tube held in a horizontal position, and with the bent portion pointing vertically upwards. On turning the tube round through 180°, so that the bent portion points downwards, the powdered coal falls from the gutter and is loosely distributed along the length of the tube, when the cardboard gutter may be withdrawn. The drawn out portion of the tube is then connected with the absorption apparatus B containing dilute sulphuric acid. A convenient form of apparatus consists of a modified de Koninck absorption tube, the straight limb of which contains glass beads or short lengths of thin glass tubing so as to offer a considerable wetted surface to the passage of the gaseous products of combustion. The hard glass tube A is placed in an ordinary combustion furnace and connected with a supply of oxygen. The burners of the furnace beneath the empty portion of the tube are first lighted, a rapid current of oxygen passing meanwhile through the apparatus. The powdered fuel is then heated at the place where the stream of oxygen first strikes it. As soon as the combustion has started, very little external heat will be required, and the coal or coke gradually burns away without the formation of soot or tarry products. The whole operation is under perfect control, and is finished in from two to three hours, depending upon the nature of the fuel. The ash is left in a loose pulverulent form, and is readily detached from the tube. The arsenic present in the fuel will be found partly in the ash and partly in the constricted end of the hard glass tube and in the liquid in the absorption apparatus.

To determine the amount of arsenic retained by the ash, this is shaken out into a Wurtz flask A of about 100 c.c. capacity, which is then attached, best by grinding, as shown in Figure 7, to a small reflux condenser B, connected with a flask C of about 70 c.c. capacity, containing about 10 c.c. of pure, i.e., arsenic-free hydrochloric acid of Sp. Gr. 1.1. Into the flask A containing the coal-ash 25 c.c. of arsenic-free hydrochloric acid containing 0.25 c.c. of bromine are added by means of the ground-in tap funnel D. In practice it is convenient to prepare a stock of brominated hydrochloric acid by adding 1 c.c. of bromine to each 100 c.c. of acid of Sp. Gr. 1.1. The flask is then heated and the liquid maintained in gentle ebullition for about two hours. After cooling, about a gram of potassium metabisulphite is added, and the liquid again heated until the free bromine disappears. The solution is filtered from the suspended silica, which, together with the small filter, is washed with the acid contained in the small flask C. Unless the silica is removed the solution is apt to boil irregularly, and it is difficult to distil it properly. The filtered solution is returned to the distilling flask, still connected with the reflux condenser, and boiled to expel the sulphurous acid. The condenser is then reversed and the liquid distilled into the small flask C, the distillation being continued until the residue in the flask A is syrupy, when a further addition of 10 c.c. of hydrochloric acid is made to the residue and the solution again distilled. The total distillate is made up to 100 c.c. and an aliquot portion taken for testing. This is transferred to a small porcelain dish, 5 c.c. of pure nitric acid (Sp. Gr. 1.4) and 2 c.c. of pure concentrated sulphuric acid are added, and the solution evaporated until fumes of sulphuric acid are freely evolved. The dish is cooled, and the liquid diluted with about 20 c.c. of water and transferred to a small flask. Half a gram of potassium metabisulphite is added, and the solution boiled until free from sulphurous acid, and when cold used for the test.

To determine the amount of arsenic which is volatilised in the combustion of the fuel, the acid in the absorption tube is poured into a small beaker, and the absorption tube rinsed with a small quantity of water. The end of the hard glass tube is then well washed by repeatedly drawing the liquid in the small beaker into it. Finally, the hard glass tube is rinsed out with a little more acid, and the whole of the solution and washings made up to 50 c.c. Of this 25 c.c. are taken and used directly for the test.

## MODE OF WORKING.

The electrolytic apparatus, as already described, is arranged for the test, and the test carried out in the following manner. The cells, electrodes, and glass vessel A with the cap, funnel, and exit tube, are thoroughly cleaned and rinsed with distilled water. The porous vessel D containing the vessel A is placed in E, which is surrounded by cold water contained in the glass dish F. The calcium chloride tube C, which has been packed in the manner described, is fitted on the ground glass connection. The hard glass tube G is attached by the rubber connection to the drying tube, so that the bent portion at the end is in an upright position, and the platinum gauze is so arranged on the tube that it just overhangs the shoulder. The small Bunsen burner H is placed beneath the tube which rests in the slots on the upper edge of the cone in such a position that when lighted the flame will heat about 2 cm. of the tube just before the constriction commences.

The connections with the battery wires are made by means of binding screws in such a manner that the current will pass from the vessel E to the cell D; 30 c.c. of dilute sulphuric acid are then poured into E, containing the anode, and 20 c.c. of dilute acid are also run into the cell D by means of the stoppered funnel B, the stem of which must be left full of liquid.

When all the connections are complete, and the acid has been added, the current is switched on and the time noted. At the end of 10 minutes the apparatus is practically free from air, and the issuing hydrogen may be lighted. At the same time the Bunsen burner is lighted and the flame carefully adjusted so that the small piece of platinum gauze is maintained at a red heat throughout the experiment. The heating of the tube during the passing of the gas is continued for 15 minutes, and if during that time no brown ring or deposit of arsenic has been formed in the constricted tube (best seen by holding a white card beneath the tube) the apparatus and the acid may be considered free from arsenic and suitable for the application of the test. Two c.c. of amyl alcohol are then run into the inner cell D by means of the tapped funnel B. This is at once followed by the addition of the solution to be tested prepared as described, 5 c.c. of water being used for rinsing out the containing vessel. No air must be admitted, and the stem of the funnel must be left full of liquid. If arsenic is present in the added liquid a deposit begins to form in the narrow tube, in the course of a few minutes, at a point between 1 cm. and 2 cm. from the heated shoulder. At the end of 30 minutes the whole of the arsenic, except in very extreme cases, will have been deposited in the tube, which is now sealed up while full of hydrogen. This is effected in the following manner. The stopper of the funnel is opened and a small pointed flame is at once directed against the narrow tube at a point 3 cm. from the deposit, between the deposit and the turned up end of the tube, which is meanwhile held by a pair of forceps. The tube at once collapses, and the end is drawn off. The electric current is at the same time disconnected, and then the tube is similarly heated and drawn off just below the shoulder. The deposit of arsenic must on no account be heated by the flame during the sealing of the tube. The short tube, about 4 cm. long, containing the arsenic deposit, may then be mounted on white card for reference.

Of course, if the deposit of arsenic thus obtained should be so considerable as to prevent accurate comparison with the standard deposits, the experiment must be repeated upon a smaller quantity of the substance.

**Preparation of the Standard Deposits.**—Although there is good reason to believe that the amount of arsenic deposited is in no wise affected by the nature of the substance with which the arsenic may be associated—0.01 mgm. of arsenic in beer, for example, giving a deposit of equal intensity with the same quantity of arsenic in malt—nevertheless, as the quantitative estimation is based on comparison, it is expedient to make use of deposits prepared by the addition of known amounts of arsenic to arsenic-free specimens of each class of substance. By so proceeding, all doubts which may arise from differences in manipulation, or concerning the possible effect of differences in the nature and composition of the substances on the formation of the

deposit are obviated. Thus, for example, in the case of hops and malt, although the final solution to be tested is substantially an acid solution of alkaline earths containing a minute quantity of arsenic, nevertheless as the malt and hops behave somewhat differently on incineration, and themselves contain different amounts of inorganic matter, it is advisable to make the standards by which malt and hops are to be compared directly from these substances.

The preparation of a solution of arsenic of definite strength, for this purpose, must be carefully carried out. Pure, resublimed arsenious oxide is ground to a fine powder in an agate mortar, and dried at 100° C. 0.1 gram is accurately weighed on a watch glass, and transferred to a litre flask by washing it down a funnel placed in the neck of the flask with one or two c.c. of pure concentrated hydrochloric acid. The liquid must not be heated. When the solution is complete, it is diluted to one litre with distilled water, and thoroughly mixed. Each cubic centimetre of this solution (conveniently called A) contains 0.001 gram, or 0.1 mgm. of arsenious oxide. Of this solution 100 c.c. are carefully measured and transferred to another litre flask, and diluted with water to 1 litre. This solution (conveniently called B) contains in each c.c. 0.0001 gram or 0.1 mgm. of arsenious oxide.

**Malt.**—It is first necessary to obtain a malt free from arsenic. In certain of our experiments malt of this character was obtained by drying green malt by means of steam heat. In others a malt was used which had been dried in cylinders and out of contact with the fumes of fuel. The absence of arsenic in the reagents to be employed must also be ascertained by carrying out a control experiment with the malt, in all respects similar to the actual experiment, but without the addition of arsenic.

Ten grams of arsenic-free malt, previously ground in a mortar, are placed in a porcelain or preferably a platinum dish, and 0.2 c.c. of standard arsenic solution B, containing 0.02 mgm. of arsenious oxide, is added from a sufficiently narrow burette.\* The whole is then treated in the manner described in connection with the examination of malt, by the basic method (page 6). Similar deposits are obtained for 0.04, 0.06, 0.08, 0.10, 0.12, 0.14, 0.16 and 0.18 mgm. respectively.

**Hops and Hop Substitutes.**—A similar series of standards for hops and hop substitutes is prepared by taking five grams of hops, previously ascertained to be free from arsenic, adding definite amounts of the standard arsenic solution, and carrying out the method of examination as described in connection with hops.

**Wort and Beer.**—A series of standards is prepared for each of these, by adding to 25 c.c. of the measured liquid definite amounts of the standard arsenic solution B, the liquid being treated in the manner described in connection with the test for wort and beer.

A series of standard deposits is also made for each of the following groups of substances—malt substitutes (glucose and invert sugar), yeast and yeast foods, and chemicals.

**Fuel.**—With regard to the standards for fuel, it has been shown by direct experiments that all the arsenic which may be present in fuel is obtained, according to the method described, partly in the hydrochloric acid distillate from the solution of the ash, and partly in the solution containing the arsenic volatilised during combustion; and the amount of arsenic in fuel may be accurately estimated by a comparison of the arsenic deposits obtained from testing the fuel in the prescribed manner with the standards employed in the case of chemicals.

The following table gives the amounts of arsenic, represented by the various standard deposits, converted into grains per pound, or per gallon, or per cwt., according to the nature and amount of the substance tested. In the case of malt the amount of arsenic in grains per pound is converted into its equivalent in grains per gallon of beer on the assumption that a gallon of beer of the standard gravity 1.055 is produced from 2½ lbs. of malt.

\* The burette used in our experiments had an internal diameter of 7 mm., and one cubic centimetre occupied a length of 20 mm.

## Appendix 21.

## Arsenic Deposits obtained from

Standard As <sub>4</sub> O <sub>6</sub> Solution.	10 grams Malt.		25 cke. of Wort, Beer, or other Liquid.	5 grains of Hops, Sugar, Caramel, Yeast, or other substance.	1 gram of Chemicals.	10 grains of Fuel or Sulphur.
Mgm.	Grains per lb.	Equal to Grains per Gallon of Beer.	Grains per Gallon.	Grains per lb.	Grains per lb.	Grains per cwt.
002	$\frac{1}{114}$	$\frac{1}{369}$	$\frac{1}{156}$	$\frac{1}{369}$	$\frac{1}{72}$	15
004	$\frac{1}{569}$	$\frac{1}{154}$	$\frac{1}{79}$	$\frac{1}{185}$	$\frac{1}{36}$	31
006	$\frac{1}{345}$	$\frac{1}{103}$	$\frac{1}{49}$	$\frac{1}{129}$	$\frac{1}{24}$	46
008	$\frac{1}{190}$	$\frac{1}{77}$	$\frac{1}{45}$	$\frac{1}{99}$	$\frac{1}{18}$	62
010	$\frac{1}{144}$	$\frac{1}{62}$	$\frac{1}{36}$	$\frac{1}{72}$	$\frac{1}{14}$	77
012	$\frac{1}{129}$	$\frac{1}{54}$	$\frac{1}{30}$	$\frac{1}{69}$	$\frac{1}{12}$	93
014	$\frac{1}{105}$	$\frac{1}{44}$	$\frac{1}{26}$	$\frac{1}{51}$	$\frac{1}{10}$	109
016	$\frac{1}{99}$	$\frac{1}{39}$	$\frac{1}{23}$	$\frac{1}{45}$	$\frac{1}{9}$	124
018	$\frac{1}{80}$	$\frac{1}{34}$	$\frac{1}{20}$	$\frac{1}{40}$	$\frac{1}{8}$	140

The advantages of the electrolytic method are that:—

1. It obviates the use of zinc.
2. It is simple in execution, is under perfect control, and may be carried out under such conditions that the results obtained by different operators are strictly comparable, inasmuch as with a current-strength of fair regularity the evolution of the gas is practically constant and uniform.
3. The whole of the solution to be tested for arsenic may be added to the apparatus at once, so that during the whole time of testing the arsenic is under the influence of the "nascent" hydrogen.
4. It has been established that such amounts of arsenic as are present in beer or its ingredients are evolved as arseniuretted hydrogen during the 30 minutes occupied by the test. The nature of the material associated with the arsenic is found to exercise no inhibiting effect on the formation and evolution of the arseniuretted hydrogen. Beer and aqueous extracts of malts and worts may be added directly to the electrolytic apparatus without previous destruction of the organic matter as required by the zinc and acid process.
5. The deposits obtained are more uniform in character than those furnished by the zinc and acid method, and admit therefore of more accurate quantitative comparison.
6. The process allows of the simultaneous execution of a number of estimations of arsenic, depending upon the arrangement of the rheostat.

The disadvantages of the methods are:—

1. The initial cost of the apparatus as compared with that employed in the zinc and acid method.
2. That it can only be applied when an electric current of sufficient intensity is available.

## II.—ZINC AND ACID METHOD.

In the method in which zinc is employed as a means of generating hydrogen, the apparatus may conveniently take the form represented in Figures 8 to 10, which are drawn to scale.

The flask A is fitted with the ground glass stopper B through which passes the stem of a funnel furnished with a stop-cock. The stopper also carries the exit tube on which is a bulb, and which is bent twice at right angles, and connected by grinding with the calcium chloride drying tube C. The hard glass tube in which the arsenic is to be deposited is connected with the dry-

ing tube C in the manner already described. The drying tube, hard glass tube, and Bunsen burner, are, in fact, precisely similar to those used with the electrolytic apparatus.

The materials required are zinc, hydrochloric acid, fuming nitric acid and copper sulphate.

**Zinc.**—Arsenic is frequently present in zinc. Hence it must be ascertained that the zinc is free from arsenic before it is made use of in the test. It has also been established that some varieties of commercial zinc, owing to the presence of small quantities of iron, will not furnish a deposit of arsenic when small quantities of arsenic are added to the solution in the hydrogen generating flask. It is therefore necessary, before any tests can be carried out with a particular sample of zinc, to ascertain, firstly, if it is free from arsenic, and secondly, if it yields a normal arsenic deposit from a solution containing a known amount of arsenious oxide when used in the prescribed manner.

Before use in the apparatus the zinc must be granulated. The outer surface of the block of metal is cleaned first by scraping, and then by treatment with hydrochloric acid, after which it is thoroughly washed with water. The zinc, in pieces of a suitable size, is next melted in a Cornish, Hessian, or porcelain crucible in a muffle or other furnace. When the zinc is just melted, or even when some portion of the zinc in the crucible still remains in an unmelted condition, the molten metal is poured in drops from a height of about four feet into cold water contained in a clean vessel. It is then dried, and preserved in a stoppered bottle.

**Hydrochloric Acid.**—Hydrochloric acid, unless specially purified, generally contains sufficient arsenic to render its application for the purpose of the test useless. Several methods have been suggested for freeing it from arsenic. The plan proposed by the Joint Committee of Public Analysts and of the Society of Chemical Industry (Jour. Soc. Ch. Ind., Vol. XXI., 1902, 49-96; Analyst, Vol. XXVII., 1902, 210), and that published by Dr. Thorne (Proc. Chem. Soc., Vol. XVIII., No. 252, p. 118) have been tested in the Government Laboratory and found to be efficient.

The hydrochloric acid used in the test has a specific gravity of 1.1.

**Fuming Nitric Acid.**—This re-agent is the pure re-distilled nitric acid of specific gravity 1.4 into which oxides of nitrogen have been passed. The nitrous fumes are conveniently generated by the action of nitric acid on starch.

**Copper Sulphate.**—A 2 per cent. aqueous solution of crystallised copper sulphate is made. Its freedom from arsenic must be ascertained before its use in the test.

## Preparation of the substances to be tested.

(1) **MALT.**—The statements made in connection with the examination of malt by the electrolytic process are applicable to the examination of malt by the zinc and acid process. Direct experiment has shown that the amount of arsenic in unground malt may be estimated either by washing the whole malt with warm dilute hydrochloric acid, or by grinding the malt and examining it by the method for ground malt.

The two methods are:—

**Basic Method for Ground Malt.**—10 grams of the ground malt are placed in a porcelain, or preferably a platinum, dish, about 3 inches in diameter, and mixed with 30 cb.c. of lime water and 0.5 gram of magnesia or lime.\* The whole is then dried and incinerated in the manner described in connection with the electrolytic process. The ash is moistened with water, dissolved in 10 cb.c. of pure hydrochloric acid (Sp. Gr. 1.1), and the solution added to the hydrogen generating flask.

**Acid Method for Unground Malt.**—40 grams of malt are transferred to a wide-mouthed stoppered bottle. 40 cb.c. of hydrochloric acid of specific gravity 1.1 and 60 cb.c. of water are mixed together, raised to a temperature of 50°C., and added to the malt. The bottle is shaken at intervals during twenty minutes, and the liquid poured off. 25 cb.c., representing 10 grams of malt, are taken for the test.

(2) **MALT SUBSTITUTES.**—(a) **Glucose, Invert Sugar.**—5 grams are weighed in a beaker, and dissolved in 20 cb.c. of water. To the solution 10 cb.c. of hydrochloric acid are added, and it is then ready for the test. The amount of sulphurous acid which may be present, even in a bleached glucose, exerts no inhibiting action on the formation of the arsenic deposits.

The examination of the solutions of these substances may also be carried out by one or other of the methods described in connection with wort.

(b.) **Caramel, Malt Extracts.**—Solutions of caramel and of certain malt extracts, when brought in contact with the zinc and acid, are apt to "froth" inconveniently. They occasionally so retard the action that it becomes difficult or impossible to ensure that the arseniuretted hydrogen is being generated. In these cases the 5 grams of the substance should be treated by one or other of the methods described under wort.

(3) **WORT.**—It has been established in the case of a malt infusion containing arsenic, and brought in contact with zinc and hydrochloric acid, that the formation of arseniuretted hydrogen is interfered with to such an extent that small quantities of arsenic may escape observation. If, however, the maltose, dextrin, and albuminoid matter contained in the infusion are destroyed, no difficulty is met with in detecting the arsenic.

The destruction of these substances may be effected by incineration with lime and magnesia, or by treatment with fuming nitric acid.

**Basic Method.**—To 25 cb.c. of the wort, contained in a porcelain or, preferably, platinum dish about three inches in diameter, are added 20 cb.c. of arsenic-free lime water, and 0.5 gram of magnesia. Or 0.5 gram of pure lime may be used in place of the lime water and magnesia. The mixed wort and lime solution must give a decided alkaline reaction to litmus paper. The dish is placed over a low flame, and the liquid evaporated to dryness. The residue is charred and finally heated until the organic matter is destroyed. This may be carried out over a Bunsen flame, or in a muffle furnace heated to dull redness. The ash is moistened with water, and dissolved in 10 cb.c. of the purified hydrochloric acid (Sp. Gr. 1.1). The solution is added to the generating flask.

**Acid Method.**—25 cb.c. of the wort are put into a 100 cb.c. round-bottomed Jena flask and evaporated to a thick syrup on a sand bath. The syrup is cooled, and 5 or 6 cb.c. of the fuming nitric acid added, the mixture is then very gently warmed until the reaction starts. Care must be taken to moderate it if necessary by immersing the flask in cold water. The flask is then replaced on the hot sand bath and heated until the greater part of the nitric acid has been driven off. To the residue 1 or 2 cb.c. of fuming nitric acid are added, and the flask heated as before to expel the greater portion of the acid. This operation is repeated until a total of

about 10 cb.c. of fuming nitric acid has been added. The contents of the flask are finally heated until there is no further evolution of brown fumes. When cold the resulting brownish-yellow crystalline mass is dissolved in 10 cb.c. of hydrochloric acid, diluted with an equal bulk of water, and the solution transferred to the apparatus.

(4) **HOPS AND HOP SUBSTITUTES.**—Five grams of the substance previously powdered are heated in a porcelain or, preferably, platinum dish with lime water and magnesia, dried and incinerated in the manner described in connection with the electrolytic process. The ash is moistened with water, dissolved in 10 cb.c. of hydrochloric acid, and the solution added to the generating flask.

(5) **BEER.**—It has been established that no arsenic is lost in the course of fermentation, except that which may be secreted by yeast, or which may be precipitated, as, for example, by the agency of sulphured hops; nor is the arsenic converted, as has been surmised, into cacodylic acid. If any other organic combination of arsenic is formed it is broken up by analytical treatment in such manner that the arsenic may be recovered.

Many finished beers, especially those of low gravity containing arsenious or arsenic oxide will readily yield the arsenic as arseniuretted hydrogen when introduced directly into the apparatus. Experiments have been made on beers containing known quantities of added arsenious oxide, and the resultant deposits are practically equal in intensity to those furnished by aqueous solutions containing similar quantities of arsenic.

Certain of these beers, however, even after boiling, froth to such an extent as to make it difficult to work with them.

Other beers, especially those containing large quantities of dextrinous matter, behave, as regards the formation of arseniuretted hydrogen, like a malt infusion.

As it is desirable that a uniform procedure should be adopted in the case of beer in regard to the destruction of the organic matter as a preliminary to testing for arsenic by the zinc and acid method, we recommend that the beer should be treated like wort, the dextrin and albuminoid matter being destroyed by treatment with fuming nitric acid or by incineration with lime and magnesia.

For the test, 25 cb.c. of the beer are taken and treated as described under wort.

(6) **YEAST AND YEAST FOODS.**—Five grams of a solid or syrup, or 25 cb.c. of a liquid substance, are taken, and the examination carried out by one or other of the methods described in connection with wort.

(7) **CHEMICALS:—**

(a.) **Sulphites.**—Of solid sulphites 1 gram is transferred to a 4oz. flask, and dissolved in 20 cb.c. of water. Five cb.c. of the purified hydrochloric acid (Sp. Gr. 1.1) are added, and the flask placed over wire gauze on the iron ring of a retort stand. In the neck of the flask is placed the glass condensing tube (Fig. 9) 2ft. in length, and having two bulbs about 2in. from the lower end. The tube rests by the lower bulb on the mouth of the flask, and is held in position by a clamp attached to the stand. The liquid is raised to the boiling point, and maintained in gentle ebullition until it is free from sulphurous acid. When cold the solution is added to the apparatus.

Of solutions of sulphites 25 cb.c. are placed in the flask, 5 cb.c. of the hydrochloric acid added, and the solution boiled as above.

The solution must be tested by the addition of a little more hydrochloric acid to ascertain if the whole of the sulphite has been decomposed, and, before adding to the apparatus, the total amount of hydrochloric acid added to the solution must be made up to about 10 cb.c.

(b.) **Acids.**—**Sulphuric Acid.**—5 cb.c. are mixed with 20 cb.c. of water. When cold the solution is ready for the test.

**Hydrochloric acid.**—5 cb.c. are mixed with 20 cb.c. of water and added to the apparatus.

\* The lime water, lime and magnesia, are tested as to their freedom from arsenic by the method described under "Chemicals."

## Appendix 21.

(c.) Sulphur.—10 grams are taken and the examination for arsenic carried out in the manner already described in connection with the electrolytic process.

(d.) Other Chemicals.—Of solids, 1 gram is dissolved in a mixture of 25 cb.c. of water and 10 cb.c. of hydrochloric acid (Sp. Gr. 1.1).

Of solutions, 25 cb.c. are taken and mixed with 10 cb.c. of hydrochloric acid.

If the solution to be tested has an alkaline reaction, care must be taken that there is an excess of acid before its addition to the flask.

(8) FININGS.—Five grams are taken, and the examination carried out by one or other of the methods described in connection with wort.

(9) FUEL.—The examination of fuel for arsenic is carried out in the manner described in connection with the electrolytic method, except that hydrochloric acid is used in the absorption tube instead of sulphuric acid.

For the arsenic in the ash of the fuel, the hydrochloric acid distillate is made up to 100 cb.c. and an aliquot portion taken for the test.

For the arsenic volatilised during the combustion, the acid in the absorption tube and the acid washings of the end of the combustion tube are made up to 50 cb.c. and 25 cb.c. taken for the test.

## MODE OF WORKING.

Ten grams of granulated zinc are placed in the flask A and covered with 15 cb.c. of distilled water, to which are added 5 cb.c. of hydrochloric acid. After a minute or two it is thoroughly washed and covered with 15 cb.c. of a 2 per cent. copper sulphate solution, which is allowed to act for about 10 minutes, when the copper-zinc couple produced is repeatedly washed with water.

The flask is then fitted with the stopper B carrying the funnel and exit tube; the drying tube C packed with calcium chloride, and lead acetate paper is fixed on the ground glass end of the exit tube, and the hard glass constricted tube is attached by the caoutchouc connection to the end of the drying tube. The Bunsen burner is also placed in position so that the hard glass tube rests in the slots on the upper edge of the cone of the burner, and in such a position that the flame will heat about 2 cm. of the tube just before the constriction commences. Around this heated part of the tube a piece of platinum gauze is placed.

When all the connections have been made, about 10 cb.c. of hydrochloric acid (Sp. Gr. 1.1) are gradually added. At the end of 10 minutes the apparatus will be practically free from air, and the issuing hydrogen may be lighted. At the same time the Bunsen burner is also lighted, and the heating of the hard glass tube so regulated that the piece of platinum gauze is maintained at a red heat. Then, during 20 minutes, a further quantity of 10 cb.c. of hydrochloric acid is added. The hydrogen flame should be from 2 to 3 mm. in height, and the acid is to be added throughout the experiment so as to secure this. During the 20 minutes' heating of the tube a deposit of arsenic, best seen by holding a white card beneath the tube, will be formed if the zinc or acid is not arsenic free. In such a case the experiment must be discontinued, the flask washed out, and fresh materials employed.

When the materials are thus proved to be free from arsenic, the solution to be tested is gradually run in, so that its addition to the generating flask is spread over a period not exceeding 15 minutes, and the hydrogen flame is maintained at a height of 2 to 3 mm. When the whole of the solution has been added, the generation of the hydrogen is continued for another 15 minutes at least by the addition, as required, of more hydrochloric acid. For that purpose from 10 to 15 cb.c. are needed.

*Preparation of the Standard Deposits.*—The standard deposits with which the arsenic deposits from tested substances are to be compared must be prepared by the use of a specimen of each kind of substance containing known amounts of arsenious oxide. The quantity of substance taken, and the manner of preparing the solution or extract, must be the same as described under the test for that substance. Every care should be taken that the period of time over which the solution is added, the size of the hydrogen flame, the mode and duration of heating of the glass tube, and the amount of acid used, should be the same in the preparation of the series of standard deposits as in the carrying out of the actual test.

The preparation of the standard arsenic solution has been described in connection with the electrolytic method.

The amounts of arsenic obtained by comparison of deposits may be converted into grains per lb., or per gallon, or per cwt., by means of the table already given.

It will be seen that this process, which has come to be known as the Marsh-Berzelius method, is similar in principle to that recommended by a Joint Committee of the Society of Public Analysts, and of the Society of Chemical Industry, an account of which has already appeared in a number of scientific and technical journals (*Jour. Soc. Ch. Ind.*, Vol. XXI., 1902, 94-96).

The method now described differs from that of the Joint Committee only in certain details, which, however, experience has shown are important. For example, the size of the apparatus employed and the amount of zinc and acid needed are much smaller; the rate of evolution of the gas is less, and the arsenic is deposited over a smaller area of glass, which facilitates comparison with the standards.

The main advantages of this method are that it is sufficiently delicate, is rapid and easy of execution, and that the apparatus and materials needed are comparatively inexpensive.

The disadvantages attending it are:—

1. That zinc very frequently contains small amounts of arsenic, and hence must be carefully tested before use. It has been established that the arsenic when present is not uniformly distributed throughout the metal, and hence different portions of zinc from the same granulation may contain arsenic in very different amounts. It has been further shown that small quantities of admixed metals, and apparently iron in particular, tend to prevent the formation of arseniuretted hydrogen, and so prevent the detection of minute quantities of arsenic.

It is necessary therefore to ascertain not only that the zinc is free from arsenic, but that it will give rise to arseniuretted hydrogen when arsenic is actually brought in contact with it.

2. The character of the deposit of arsenic is influenced by the rate at which the hydrogen is evolved, and as this depends upon the "activity" of the zinc, which is not always under complete control, the deposits obtained by different operators, or with different specimens of zinc, are apt to show slight variations.

We desire to record our appreciation of the skill and care with which Messrs. Stubbs and Cheater, assistants in the Government Laboratory, have worked out the details of the several analytical processes described in this report.

We are also indebted to Dr. Dunn and Dr. H. S. Pattinson, of Newcastle-on-Tyne, for much valuable assistance, especially in connection with the zinc and acid method.

We have the honour to be, Gentlemen,

Your most obedient servants,

T. E. THORPE, Chairman.

WILLIAM A. TILDEN,

HAROLD B. DIXON,

GRAHAM ALDOUS,

JOHN PATTINSON.

March 11, 1903.

## APPENDIX.

(A.)—Ingredients of Beer which are liable, from their Origin or Mode of Preparation, to be Contaminated by Arsenic.

(1.) MALT:—

Malt may be contaminated by arsenic in the process of kiln drying if the products of the combustion of the coal or coke or the ash of the fuel are allowed to come in contact with the grain.

(2.) MALT SUBSTITUTES:—

(a) Solid and Liquid Glucose.—Solid glucose is composed mainly of dextrose, and liquid glucose mainly of maltose and dextrin; and both are manufactured from starch by treatment under pressure with hot dilute mineral acid, and subsequent evaporation after removal of the acid. The mineral acid unless specially purified is liable to contain arsenic, part of which may remain in the finished glucose.

(b) **Invert Sugar or Saccharum.**—Invert sugar is composed mainly of dextrose and levulose, and is manufactured from ordinary sugar or sucrose by treatment with acid in a manner similar to that in which glucose is prepared from starch.

(c) **Extract of Malt, Malt Extract, or Maltodextrin,** is composed mainly of maltose and dextrin, and is obtained by evaporating infusion of malt to the desired consistency.

(d) **Caramel and Colourings** are prepared by heating solid or liquid glucose or cane sugar. Priming and colouring solutions are often prepared from them.

Malt substitutes are sold under various proprietary and trade names indicative in most cases of their composition, origin, or action on polarised light.

#### (3.) HOPS :—

Arsenical contamination may occur during the process of kiln drying by contact of the hops with products of combustion of coal and coke, or may arise from "sulphuring" with impure sulphur, or from spraying with arsenical preparations.

Certain so-called "Hop Compos," or hop substitutes, may contain, in addition to other vegetable bitter or astringent principle, a certain proportion of hops. If the hops so used have been sprayed with arsenical preparations, or dried by means of arsenical fuel, or sulphured with impure sulphur, these substitutes may be contaminated by arsenic.

#### (4.) YEAST AND YEAST FOODS :—

Yeast is occasionally contaminated, probably from growth in worts containing arsenic.

Yeast, malt combings, spent grains, and phosphates are used in the preparations of yeast foods. These articles are known generally as maltopeptones; but they are advertised under a variety of trade names.

#### (5.) CHEMICALS :—

(a) **Sulphites.**—The sulphites and bisulphites of the alkalis and alkaline earths are used in beer as preservatives. Sometimes a little Extract of Quillaia is added to the sulphite and the mixture sold as a "frothing" agent. These substances are advertised as "antiseptic," "keeping," "preservative," "foaming," "frothing," and "heading" powders, but the majority pass under trade and proprietary names.

(b) **Carbonates.**—Alkaline carbonates are occasionally used to "correct" or neutralise the acidity of old or sour beer; preparations of this kind are sometimes known as neutralisers or regenerators.

(c) **Hardening salts.**—Carbonates, chlorides, and sulphates of the alkalis and alkaline earths are often added to waters naturally deficient in such salts.

(d) **Sulphur.**—Sulphur dioxide, obtained by burning sulphur in air, is sometimes used in the purification of foul casks.

#### (6.) FININGS.

Finings may occasionally become contaminated by minute traces of arsenic from the circumstance that isinglass or gelatine used in their preparation is "cut" or softened by old beer or sulphurous acid.

(B.)—Materials Used in the Preparation of the Ingredients of Beer which are Liable to Contain Arsenic.

(1.) **MINERAL ACIDS** (mainly hydrochloric and sulphuric acids):—

These are used in the preparation of solid and liquid glucose and invert sugar.

(2.) **SULPHUR.**

(3.) **FUEL.**

## APPENDIX 22.

## TESTS FOR ARSENIC IN FOODS, ETC.

REPORT BY DR. G. MCGOWAN AND MR. R. S. FINLOW ON THE METHODS EMPLOYED IN TESTING FOR ARSENIC THE VARIOUS SAMPLES OF FOODS AND OTHER SUBSTANCES (NOT INCLUDING FUELS) RECEIVED FROM THE COMMISSION.

## A.—PURIFICATION OF REAGENTS EMPLOYED.

## HYDROCHLORIC ACID.

So far as our experience goes, the hydrochloric acid which is sold as "arsenic-free" requires in nearly every instance to be further purified, this being no doubt largely due to the fact of its being stored in bottles, the glass of which contains arsenic as an ingredient. The preparation of a perfectly pure sample has often been a matter of difficulty, involving much loss of time, more especially in the earlier stages of our work. A useful suggestion made by Sir William Ramsay, that special bottles might be manufactured without any arsenic for storing such reagents, deserves recording in this connection.

We first tried the method recommended by the Con. joint Committee (Appendix No. 20), which consists shortly in treating the diluted acid with excess of bromine and then with excess of a solution of sulphurous acid. After this final mixture has stood for at least two hours, it is distilled; the first portions of the distillate containing all the sulphurous acid are discarded, while the residual acid should be arsenic-free. With some samples we were able to obtain perfectly pure acid\* by this method, but in many other instances we found it impossible to prepare either a residual acid or a distillate acid free from arsenic. For this reason we ultimately turned to the process recommended by Thomson ("British Food Journal," October, 1902), viz., the distillation of impure hydrochloric acid—preferably diluted with water down to a specific gravity of 1.1—with excess of potassic dichromate. Here, again, we did not meet with immediate success, but found by experience that, if the acid in process of distillation carries with it a constant stream of chlorine, the distillate is arsenic-free. Thus the continuous evolution of chlorine is evidently the crux of the method; should this fail, the non-volatile arsenic acid in the retort might be reduced to the arsenious state by traces of organic matter, and possibly even by the hydrochloric acid itself, with consequent contamination of the distillate. As Thomson has already explained, the free chlorine in the distillate can be readily got rid of by drawing air (preferably filtered air) through the liquid.

The flask (capacity about 900 c.c.) and condenser tube used in the distillation of the acid were of Jena glass, the flask having a glass stopper and the joints being ground. The receiver was a flask made of ordinary glass, of which the neck was ground to fit the lower end of the condenser tube; it had a side tube in the neck, which was attached to a bottle containing a few sticks of potash, any nuisance from escape of chlorine into the room being thus avoided.

The purified acid was kept in large flasks of Jena glass, with glass-bulb stoppers, paper being wrapped round these to prevent ingress of dust.

## SULPHURIC ACID.

On several occasions we were able to obtain this acid from the dealers free from arsenic, but, as a general rule, we found it necessary to purify it in the laboratory. The Joint Committee's method (i.e., distillation of ordinary pure sulphuric acid in a non-tubulated retort with a little sodium chloride, and rejection of the first portion of the distillate) was found to work easily, and we had no difficulty in obtaining the acid free from both arsenic and chlorine by means of it. The test of purity was the total absence of any mirror when 5 c.c. of the acid—diluted, of course—were "Marshed" in the ordinary way.

## NITRIC ACID.

This reagent was prepared by redistilling the ordinary pure acid with a little nitre and a few crystals of silver nitrate. It was tested for purity by evaporating 10 to 20 c.c. to dryness in a porcelain basin over a water bath, washing the residue into a Marsh apparatus with a little acidulated water, and "Marshing." Obtained in this way, it was invariably found to be arsenic-free.

## SULPHUROUS ACID.

An aqueous solution of this acid was prepared, when required, by gently warming a mixture of sodium sulphite and dilute sulphuric acid, the liberated gas being passed through water to saturation. Though it was not found necessary, it would be an additional safeguard to interpose between the generating and condensing vessels an intermediate flask or Wolff's bottle, containing a very little water, in case traces of hydrochloric acid should also be evolved. The aqueous sulphurous acid thus obtained was tested by oxidising 10 to 15 c.c. with nitric acid, evaporating to dryness in a small porcelain basin over the water-bath, and Marshing the solution of the residue.

## AMMONIA AND CARBONATE OF AMMONIA.

We found no difficulty in obtaining aqueous ammonia arsenic-free, and the same usually applied to ammonium carbonate also. Nevertheless, more than one sample of the latter was found to be arsenical, and such samples were of course rejected. These reagents were tested for purity by evaporating about 20 c.c. in a small basin on the water-bath, either to dryness or until the liquid no longer smelt of ammonia. The solution was then acidified with sulphuric acid, and Marshing either directly or after preliminary treatment with aqueous sulphurous acid.

## POTASSIC CHLORATE.

We have found no difficulty as regards this reagent. It must, of course, be tested for purity by decomposing a sufficient quantity—say 5 to 10 grammes—with a slight excess of arsenic-free hydrochloric acid (exactly as in a "Fresenius-Babo" estimation), evaporating down, reducing the residue with sulphurous acid solution, and Marshing.

## ZINC.

## Granulation of Zinc.

As a general rule, though not always, the "arsenic-free" zinc which we obtained from the dealers proved to be satisfactory, provided it was bought in block form (not granulated) and granulated in the laboratory as described below. For this latter purpose a small portion of a block was melted in a Berlin porcelain basin, the dross being skimmed off with a hard glass rod until the surface remained almost bright for a short time; the molten metal was then granulated by pouring it from a height of 4 ft. or 5 ft. into a clean vessel of glazed earthenware containing cold water. The fragments of granulated zinc to be used should be flaky and rather thin—not like buttons.

## Test for Arsenic in Zinc.

3 Grammes of the zinc thus obtained were then tested for traces of arsenic by Marshing with 5 c.c. of arsenic-free sulphuric acid in about 50 c.c. of water, the experiment being continued until the zinc was practically all dissolved.

\* The acid was regarded as pure if 20 c.c. of it gave no trace of a mirror when "Marshed."

### Test for "Sensitiveness" of Zinc.

If the above test proved satisfactory, the "sensitiveness" of the zinc was then ascertained by making a second similar experiment, but introducing into the generating flask, after all air was expelled, a very small quantity of a solution of arsenic (say equal to 0.0025 m. gram.  $As_2O_3$ ). When this small amount of added arsenic was recovered quantitatively in the mirror tube, the sample of zinc was regarded as being sufficiently sensitive to allow of its being used.

### ASBESTOS.

The fibres of asbestos, used for filtering precipitates containing sulphide of arsenic, should be soft and silky. The asbestos is prepared by repeated extraction with concentrated hydrochloric acid until the extract is no longer coloured by iron; it should be washed and squeezed between each two extractions. After the last washing it is preserved in a stoppered bottle under water. It must then, of course, be tested for arsenic, when making a blank with the other pure reagents, by the same procedure as in an actual determination by the Fresenius-Babo method (see below).

### WATER.

As the ordinary distilled water of the laboratory contained an appreciable quantity of copper, derived from the copper still and condensing tube, all the water employed in the following work was re-distilled from a glass retort.

## B.—METHOD OF ESTIMATION.

See Diagram, p. 226.

After having extracted the arsenic from any given sample (which did not admit of direct Marshing), the actual estimation of this arsenic in the final solution was invariably done by the Marsh-Berzelius method as modified by the Conjoint Committee of which Mr. Hehner was chairman (Appendix No. 20). We did, indeed, try some estimations by the Reinsch method in the earlier stages of this work, but the results obtained did not appear to be so satisfactory as those given by the modified Marsh process. At the same time we did not continue the use of the Reinsch method sufficiently long to allow of our venturing to offer any opinion upon the relative merits of the two.

### "MARSH" APPARATUS EMPLOYED.

The form of Marsh's apparatus used was a modification of that described by Scudder (Evidence, Vol. I., Q. 4270). It is shown in the lettered diagram I (not drawn exactly to scale) which accompanies this Report. As is well known, the main point of difference between this form of apparatus and the others more generally employed for the same purpose is that the greater part of the supply of hydrogen, other than that required for the formation of arseniuretted hydrogen, is derived from a source outside the "Marshing" flask proper, i.e., from a Kipp hydrogen apparatus filled with zinc and hydrochloric acid. For some time we used in this "Kipp" (A) reagents which were termed "arsenic-free" (but were not really so), but subsequently we found this to be a needless expense, for in any case it is essential that there shall be attached to the "Kipp" an arsenic-absorption apparatus such as that described below.

In order to ensure the Kipp hydrogen being really arsenic-free before it reaches the Marsh flask, it is passed successively through (1) a red-hot tube (B) of Jena glass, about 4 to 6 m.m. internal diameter, heated by a good Bunsen burner (this, of course, effects the deposition of much of the arsenic present); (2) a small narrow glass-stoppered wash-bottle (C), of about 30 c.c. capacity, containing some strong sulphuric acid, the object of this being to absorb any traces of heavy hydrocarbons;\* and (3) through two similar small wash-bottles (D) (D'), of about 40 c.c. capacity each, containing a solution of silver nitrate, the second having attached to it a small tower filled with fragments of glass also moistened with the nitrate of silver. These last absorb any traces of arsenic or of sulphuretted hydrogen which may have escaped the heated tube (B).

Between the last wash-bottle and the Marsh or generating flask, there is placed a short, rather wide, capillary glass tube (E) (an idea suggested by our colleague, Mr. R. B. Floris), preceded by a small piece of pressure rubber tubing, with screw clip attached (E), which allows the flow of hydrogen to be more easily regulated than can be done by the stopcock of the "Kipp" alone. By this means the latter may be turned full on, so that the pressure of the liquid in the "Kipp" has full play. The solution of nitrate of silver in the last two wash-bottles was at first used very dilute, but it was afterwards found better to employ a somewhat strong solution. Care must, however, be taken to renew this solution frequently (the frequency, of course, depending on the volume of gas passed through the apparatus), to prevent the contingency of nitrous fumes being carried over into the generating flask, with the possible result of evolution of arseniuretted hydrogen being hindered.

The remaining or essential portion of the apparatus, that in which the actual estimation of arsenic is carried out, is in principle the same as that used by most other chemists, since its introduction by the Conjoint Committee. It consists of a small generating flask (G), to which are attached short tubes (H H), containing respectively (1) paper moistened with acetate of lead solution and air-dried, and (2) small pieces of fused calcium chloride; the last is followed by the mirror tube (I). All joints between G, H, and I are made of short pieces of pressure rubber tubing.

A detailed description of this portion of the apparatus may, however, be of interest to some readers. The "Marsh," or generating flask (G) is blown from tubing of which the bore just fits a No. 6 rubber stopper; the bulb of the flask has a capacity of about 70 c.c., and the neck is, roughly, 9 c.m. long. The rubber stopper has three holes, through which pass (1) the tube which brings in the "Kipp" hydrogen (this tube is somewhat constricted at the lower end, which must dip under the liquid in G); (2) a long, narrow tap funnel, capable of holding 10 c.c. of liquid, which serves for the introduction into (G) of either the acid or of the liquid to be tested; and (3) an exit tube connected to the tube containing the lead acetate paper. This latter tube, which is about 3.5 to 5 c.m. long and 12 m.m. wide externally, contains a loose roll of filter paper, about 3.5 c.m. in length and 8 m.m. in thickness, which has been soaked in a solution of acetate of lead and then allowed to dry in the air. Its use—as everyone knows—is to absorb any traces of sulphuretted hydrogen which may have been formed in the generating flask. The calcium chloride tube—about the same length and width as the other—is plugged at either end with cotton or glass wool, to keep the small pieces of chloride in position; it serves to dry the gas before the latter passes into the mirror tube. The chloride of calcium in this tube should be renewed whenever the first pieces become visibly damp.

The mirror tube (Diagram II.) is made from rather thick-walled, milky Jena glass tubing of about 5 m.m. external diameter. At first we carefully cleansed this from all traces of dust, washed out with distilled water, and dried; but latterly this was dispensed with, unless the tube was obviously dusty. A piece of this tubing is thickened and drawn out over the blowpipe flame until the internal diameter of the drawn-out part is about 1 m.m., its length being about 9 to 10 c.m. It is, of course, important to keep the bore of this drawn-out portion, at the place where the arsenic mirror is deposited (A), as nearly uniform as possible. The fine end of the tube is turned up at right angles, its aperture being fused quite small, so as to prevent backward diffusion of air into the tube. The wide end (B), which is about 12 c.m. from the shoulder (C), is constricted a little, so that it may fit into the rubber pressure tubing connecting with the chloride of calcium tube, while at about the middle of this wide part (X) another slight constriction is made, to allow of the tube being fused up easily at the end of an estimation. Before use the tube is cleansed from traces of organic matter by heating to redness and drawing air through it.

\* In the earlier stages of our work this sulphuric acid bottle was not used.

† This stopper and the neck of the flask are drawn rather large in the diagram for the sake of clearness. It would, of course, be preferable if the stopper and all the joints of this apparatus from the generating flask to the mirror tube were of glass throughout. In the estimation of arsenic in fuels by Dr. McGowan and Mr. Floris (Appendix, No. 23), a very tiny ring of mirror (probably antimony) was sometimes found deposited close to the flame of the mirror tube; and in case this should have been caused by the spitting of the acid in the generating flask on to the red rubber stopper (the neck of this particular generating flask being very short), the bottom of the rubber stopper in the fuel estimations was latterly coated with paraffin.

## Appendix 22

In an actual experiment the mirror tube is supported at two points on an ordinary round iron tripod, small screens of tinned iron (which anyone can make for himself) being so arranged as to protect the Bunsen burner from draughts, and also to prevent the flame from being blown on to that part of the tube at which arsenic is deposited. The fine end of the tube (D) is also held by a wooden clamp, to prevent "buckling" while an estimation is in progress. The tube is heated to bright redness at E by means of a good, but small, Bunsen burner, the flame covering about 2 cm. of the wide part of the tube (including the shoulder).

## ADVANTAGES AND DISADVANTAGES OF THE ABOVE APPARATUS.

It may be well at this point to sum up shortly the main advantages and disadvantages of the above form of "Marsh" apparatus, as compared with other forms in general use.

*Advantages.*

1. A small generating flask can be used, because of the small quantities of reagents employed.
2. There is great economy in the use of these arsenic-free reagents, a consideration of moment when the frequent difficulty of preparing them pure is borne in mind.
3. The "washing-out" of the apparatus with hydrogen before and after an estimation can be done easily and rapidly.
4. The rate of flow of hydrogen can be very easily regulated and maintained constant throughout an estimation.

*Disadvantages.*

1. The slow bubbling of the "Kipp" hydrogen through the liquid in the generating flask causes the deposition of "double" mirrors; in other words, in the portion of the capillary tube where the arsenic is deposited there are two regions, one in front of the other. This of itself might be thought a fatal objection by many people, on the ground that it is less easy to read a double than a single mirror with accuracy; and there can be no doubt that a perfectly valid objection can be made on this score, for a single mirror is clearly better for quantitative reading than a double one. We have found, however, that with standards prepared in the same way as the mirrors in the actual estimations, the differences in a large number of readings made over a long period by both of us independently were almost invariably very slight.
2. The apparatus takes up much more room than most other forms. With a suitable arrangement of T tubes, however, this objection can be to a great extent overcome, one "Kipp" and one purifying apparatus being sufficient to serve several generating flasks.

## METHOD OF WORKING THE APPARATUS.

The portion of the apparatus dealing with the purification of the Kipp hydrogen having been fitted up and the hydrogen turned on, 5 grms. of zinc and about 30 c.c. of water are introduced into the generating flask. The complete apparatus—with the exception of the mirror tube—is now connected up, and the Kipp hydrogen allowed to flow through it for 10 minutes or so, at the rate of about four small bubbles per second. The mirror tube is then attached and the flow of hydrogen continued for another five minutes, after which the Bunsen burner under the mirror tube is lighted. If after a further period of 10 minutes the tube is still perfectly clean, the hydrogen is slowed down to the rate of about one small bubble per second, the diluted acid (10 c.c. of 1 in 4 sulphuric acid, or 10 c.c. of hydrochloric acid of 1.1 sp. gr., as the case may be) run into the generating flask, and another "blank" of 10 minutes performed. Should there still be no sign of any deposit in the mirror tube, the solution to be tested is run into the generating flask, and the experiment continued for at least an hour longer, by which time the whole of the arsenic present will have been deposited in the mirror tube. The rate of flow of the Kipp hydrogen is now slightly quickened for a few minutes, and the mirror tube fused off at X and then immediately at E (see Diagram II. above), labelled, and read against standards prepared in the same manner. The volume of liquid in the generating

flask is always kept as uniform as possible, i.e., at about 50 c.c.; and, if the flask should show any tendency to become warm, it is immersed in cold water.

## PREPARATION OF STANDARD MIRRORS.

For this purpose a standard solution of arsenious oxide in water was made by dissolving an accurately weighed quantity (about 0.3 gm.) of the pure dry powdered substance in 500 c.c. of water. After our first experiments the arsenious oxide was recrystallised beforehand from a hydrochloric acid solution, washed and dried; it left no residue on being vaporised. As is well known, a little time and patience is required to prepare an aqueous solution of even such a small quantity of arsenic as that given above. The solution thus obtained was made up to 500 c.c., and the amount of arsenic in it checked by titration with a standard solution of iodine. To instance one case:—0.3008 gm. arsenious oxide was dissolved in water, and the solution made up to 500 c.c. 1 c.c. therefore contained theoretically 0.000602 gm.  $\text{As}_2\text{O}_3$ . By titration with iodine the strength came out at 0.000577 gm.

From the above strong arsenical solution, dilute solutions were made as required; for, while the strong solution keeps its strength for a long time, perhaps indefinitely, a dilute solution has been found by some observers to weaken rather rapidly.

Standard tubes of the following "densities" were made (and renewed from time to time as required):—

0.0025 m.grm. $\text{As}_2\text{O}_3$
0.0035 " "
0.005 " "
0.010 " "
0.015 " "
0.020 " "
0.025 " "
0.030 " "
0.040 " "

Corresponding sets of tubes were prepared both with sulphuric and with hydrochloric acid (for comparison respectively with "Marsh" estimations done with the one or the other acid), but we found very little, if any, difference between the densities of the mirrors produced with equal amounts of arsenic by these two acids.

The mirror which we found it most convenient to read was that given by 0.01 m.grm. of arsenious oxide; we therefore endeavoured, as far as possible, to adjust the quantity of extract Marshes so as to yield a mirror approximating to this in value. But in many cases, of course, the mirror which had to be read was much smaller, while in a considerable number of instances it was, from one cause or another, denser.

## C—METHODS EMPLOYED FOR THE EXTRACTION OF ARSENIC FROM DIFFERENT SUBSTANCES BEFORE "MARSHING."

In this connection we should like to take the opportunity here of expressing our indebtedness more especially to Professor Wormley's excellent book on the "Micro-Chemistry of Poisons," from which we have derived much useful information and guidance.

Four different general methods, sometimes more or less modified according to the circumstances of the case, have been employed, viz.:—

- (1) Direct Marshing, without destruction of organic matter.
- (2) Marshing of the final extract after preliminary destruction of the organic matter by—
  - (a) The *Fresenius-Babo* method, with chlorate of potash and hydrochloric acid;
  - (b) *Gautier's* method, with nitric and sulphuric acids;
  - (c) The basic method of *Neulands* and *Ling*, with the use of lime and lime-water.

*Blanks.*—It should be added here that blank experiments with all the reagents and vessels used in the estimations were carried out, and, in doing these "blanks," the procedure and also the time occupied were as nearly as possible the same as in the actual

experiments themselves. This point is obviously of supreme importance when *post-mortem* cases are in question.

**DIRECT "MARSHING," WITHOUT PREVIOUS DESTRUCTION OF ORGANIC MATTER (IF PRESENT).**

Only a comparatively few samples, such as waters, sugars, the hydrochloric acid extracts of whole rice, and the constituents of effervescing drinks, were Marshled directly, as a rule, with hydrochloric acid, without previous destruction of the organic matter, if present. When it was necessary—as in the case of sugars—a larger generating flask than usual was employed (a flask of about 200 c.c. capacity), together with larger quantities of zinc and acid; but in the first instance it was ascertained by experiment that the use of this larger apparatus did not influence (at all events, appreciably) the "density" of the mirror produced by a given quantity of arsenic.

In the case of *sugars*, 10 grammes of the sample were taken, and the solution run gradually into the generating flask, so as to avoid any danger from frothing. The Marshing was continued for from 30 to 40 minutes after the addition of the sugar solution, more acid being added if required.

In the case of samples of *whole rice*, the method followed was that recommended for malt by the Joint Committee of the Society of Chemical Industry and of the Society of Public Analysts, viz., to digest 50 grammes of the substance with a mixture of 50 c.c. water and 50 c.c. hydrochloric acid of 1.1 sp. gr. at a temperature of about 50° C. for 15 minutes, and to Marsh a portion of the decanted extract. This treatment does not make the rice spongy, but rather granular, and, as it is not continued for a long period, the probabilities are against any appreciable absorption of arsenic from the acid solution by the grains of rice themselves. No water being subsequently added, 10 c.c. of the above extract correspond to 5 grammes of rice. In order to see whether any arsenic was kept back in the generating flask by the organic matter in solution or semi-solution in the hydrochloric acid extract, this organic matter was destroyed in a portion of one such extract, and the final inorganic solution Marshled; the results obtained showed that no arsenic had been kept back by Marshing the liquid directly.

*Malt Extracts* were also Marshled directly. Here again, in one case, practically identical results were obtained (a) by direct Marshing, and (b) by preliminary destruction of the organic matter with nitric and sulphuric acids.

We should, however, like to add here, in conclusion, that it must not be assumed without actual proof that direct Marshing is sufficient to extract the arsenic present in any substance, otherwise serious error may result (*cf.* samples of *Apple Green* and *Baking Powder* in Tables of Analysis, Appendix 25).

**DESTRUCTION OF ORGANIC MATTER PRELIMINARY TO "MARSHING."**

As already stated, one of three general methods was followed here, according to the nature of the substance under examination. It must, however, be borne in mind, when reading the details given below, that the methods were slightly modified in some instances. No hard and fast rule with regard to this can be laid down, much depending on the common sense of the operator.

**(a) The Fresenius-Babo method, i.e., destruction of organic matter by chlorate of potash and hydrochloric acid.**

This well-known and well-proved method is particularly applicable to those cases where a large weight of substance has to be treated, e.g., viscera, dried fish, etc., but it also answers equally well with smaller weights of such substances as hair. Gelatine and allied bodies, too, readily pass into a state of limpid solution when warmed with hydrochloric acid and a little chlorate of potash, and these latter solutions can, after reduction, either be Marshled directly or precipitated in the first instance by sulphuretted hydrogen, as described below. The chlorate method of destruction of organic matter is thus perhaps of more general application than any other. Its great disadvantage must always be the length of time which is required for carrying it out—not much less than five days; and, besides this, the number of points which require to be observed in its manipulation are consider-

able, so that some practice is necessary before accurate results can be achieved. In spite of these drawbacks, however, we—like others who have carefully examined this method—have found it invaluable where small quantities of arsenic have had to be extracted from large weights of material (test experiments under those conditions having shown that it can be made to yield good results).

The following are the details of the method:—

In the case of fresh viscera a convenient weight to take for examination is about 150 grammes; of dried fish not more than 30 to 40 grammes should be used; 12 grammes of hair (if obtainable) is a suitable quantity; while about 20 grammes of gelatine may be taken. In every case the substance in question is cut into as small pieces as possible and treated in a basin of Berlin porcelain with 20 to 70 c.c. hydrochloric acid of 1.1 spec. grav. (according to the weight taken), mixed with about three times its volume of water. After being well stirred, the whole is warmed over a low rose-burner flame almost, but not quite, to boiling. Small quantities of pure chlorate of potassium (about one-third of a gramme at a time) are now added at intervals of a few minutes, care being taken to keep the volume of the liquid constant by the addition of a little water from time to time. By this treatment the whole of the solid gradually goes into solution, and the liquid assumes a yellow colour. The addition of chlorate is continued until the yellow ceases to change to brown in about ten minutes, after which the liquid is further warmed till it just begins to darken in colour, an indication that all the chlorate has been decomposed. The liquid is now allowed to become quite cold, when a considerable quantity of solid matter separates out, after which the clear supernatant liquor is poured on to a filter of Swedish filter paper, and the residue in the basin washed two or three times by being warmed with water and a little hydrochloric acid, cooled and filtered. It is important that the liquid should be quite cold before filtration (ice being used for cooling, if necessary), otherwise the filtrate will deposit more solid matter and will require filtration a second time. The mixed filtrate and washings are now returned to the porcelain basin and evaporated slowly over a small rose-burner flame to a volume of about 200 c.c., one or two further crystals of chlorate being dropped in from time to time, should the liquid again tend to become dark coloured. After this evaporation it is allowed to cool somewhat, and 10 to 15 c.c. of a saturated aqueous solution of sulphurous acid are added, in order to reduce the arsenic to the arsenious condition. The liquid is now allowed to stand for some time and then the sulphurous acid is cautiously steamed\* off, care being, of course, taken that the hydrochloric acid present never becomes at all concentrated, otherwise arsenic will be lost as trichloride.

The residual liquid, whose volume—assuming that 70 c.c. of 20 per cent. hydrochloric acid were originally taken—should be rather less than 200 c.c. but not less than 150 c.c., is now cooled and filtered, if necessary, into a conical flask of about 200 c.c. capacity. A slow current of washed sulphuretted hydrogen is then passed through the liquid for an hour. The flask (which is nearly full) tightly corked† and put on the top of an incubator or some other moderately warm place until next day, when more sulphuretted hydrogen is passed into it, and the flask again corked. If after two days more the liquid still smells of sulphuretted hydrogen, it is filtered through purified asbestos in a Gooch crucible, the precipitate being washed with a little sulphuretted hydrogen water. It is important that the volume of this wash water should not be great, say, not more than 20 c.c., otherwise sulphide of arsenic, if present, is liable to assume the colloidal form and to pass through the filter.

The asbestos containing the washed precipitate is then transferred from the crucible to a small porcelain basin, the crucible being finally rinsed out with a little water. After warming the basin on a water-bath to disintegrate the asbestos, 2.5 c.c. of (1 in 5) aqueous ammonia are added, the warming continued for a short time, and the dark-coloured liquid poured from the asbestos on to a small (Swedish) filter; and this extraction with small quantities of ammonia and water is continued until both the asbestos and the filtrate are

\* The expression "steaming" is sometimes used in the course of this paper. It merely means evaporating quietly, not boiling.

† A softened cork, covered at bottom and sides with a piece of filter paper, makes a clean stopper.

## Appendix 22.

colourless. The whole of the arsenic is now in the filtrate. This is evaporated on a water bath to dryness, or, at least, until the whole of the ammonia is expelled; 2 c.c. of concentrated nitric acid are added to the residue, and digestion is continued on the water bath, with subsequent small additions of nitric acid, if necessary (not less than 1 c.c. at a time), until the liquid is pale yellow in colour. The free nitric acid is then evaporated off, or practically so, and the residue extracted about three times with a few c.c. of a warm aqueous solution of ammonium carbonate (1 in 4), in order to get rid of any sulphur which may have been deposited in the course of the treatment with nitric acid. After again filtering, the liquid is evaporated on the water bath until free from ammonia, and the residue again treated with nitric acid and evaporated to dryness. Then a very little concentrated sulphuric acid, say 8 to 10 drops, is added and the basin heated until the contents are thoroughly charred, when the excess of sulphuric acid is driven off with the precautions to be afterwards described under Gautier's method below. The subsequent treatment, i.e., extraction of the char with acidulated water, reduction of the extract with aqueous sulphurous acid, etc., are exactly the same as given under Gautier's procedure, to which the reader is therefore referred.

*Note.*—The remarks made under Gautier's method with regard to ignition of the final nitric acid residue with lime apply, of course, equally here also.

In conclusion, as has been already stated, some knowledge of the various points of this method—knowledge which can only be gained by practical experience—is essential before accurate results can be obtained by it. But, given that experience, we have every reason to rely confidently upon it.

As has been already stated, the mirrors obtained by the foregoing Fresenius-Babo method (which includes precipitation with sulphuretted hydrogen) were read against standard tubes prepared by the direct Marshing of an arsenic solution. The work on fuels done for the Commission (McGowan and Floris, Appendix X.) has shown that it is inadmissible to compare a mirror obtained from the precipitation of arsenic in an *inorganic* solution with a directly Marshled standard; sulphide of arsenic not being altogether insoluble, the results from such a comparison come out too low. The fuel mirrors were, therefore, read against standards obtained by precipitating known quantities of arsenic as sulphide, and working up the precipitate exactly as in the estimation itself.

Possibly the results given by the Fresenius-Babo method may tend for this reason to be a little low also, though the error cannot be very great here, because the precipitate of sulphide of arsenic always brings down with it very considerable quantities of organic matter, which no doubt have an absorptive and precipitating effect upon arsenic which would otherwise remain in solution. In an early test experiment, in which 0.05 m.grm. of arsenic was added to 100 grms. of moderately fat beef (finely cut up), the mixture being then chlorated, etc., practically the whole of this arsenic was recovered (a "blank" was done at the same time). To really test the point properly would have required estimations to be made with known amounts of arsenic mixed with a large variety of arsenic-free foods or other organic substances, similar in nature to those actually under examination.

(b) *Gautier's Method, i.e., the destruction of organic matter by nitric and sulphuric acids together.*

Briefly described, this method consists in first partially destroying the organic matter by oxidation with concentrated nitric acid, then charring the residue with concentrated sulphuric acid, driving off the excess of the latter, and extracting the thoroughly charred residue with acidulated water. The whole of the arsenic originally present should be obtained in the extract.

The method can, if necessary, be employed for the extraction of arsenic from large quantities of flesh, etc., but it is more suitable where smaller quantities—say, 5 to 10 grms.—of vegetable substances, such as flour, chicory, malt extract, etc., have to be dealt with. We have found it especially useful with the following classes of substances:—(a) Mixtures containing con-

siderable quantities of cellulose—a substance which is not attacked by chlorine, and which may possibly, therefore, be liable to act as an absorbent (or adsorbent) sponge if left undestroyed; (b) broken cereal grains, to which the other methods could not conveniently be applied; (c) organic and inorganic colouring matters.

*Process.*—The substance in question is first treated with about 5 c.c. of pure concentrated nitric acid in the cold, the basin being afterwards warmed very cautiously on a water bath. After the tendency to froth has ceased, this warming may be done more strongly, and further small quantities of nitric acid added from time to time until the whole of the substance has gone into solution. The heating of the basin is then continued over a low rose-burner flame or, preferably, a *dry*\* water bath, until the mass is semi-solid, when 1 c.c. of concentrated sulphuric acid is added, and the gentle heating renewed until the whole has become black, at which stage an ordinary Bunsen flame is substituted, in order to drive off all excess of sulphuric acid. This latter operation must be performed very cautiously, and great care must be taken to ensure that no part of the basin approaches a red heat. If the smell of sulphurous acid can be detected in the escaping fumes, the heating must be stopped and the contents of the basin again treated with nitric acid, as described above. When all the sulphuric acid has been driven off, the charred residue—which is dry, and easily pulverised—is extracted several times with small quantities of acidulated water (acidulated preferably with sulphuric acid) and filtered. To the filtrate, which must be clear, colourless, and without smell, a few drops of aqueous sulphurous acid solution are then added; after the excess of the latter has been gradually steamed off, the liquid is ready for Marshing.

That this method is accurate when properly worked, we have no doubt. In one test experiment—a severe one—0.05 m.grm. of arsenious oxide was added to 100 grammes of fat beef, which was then treated as described above. Although the large bulk of the material made it difficult to handle properly, 0.043 m.grm., or nearly 90 per cent. of the arsenic was recovered in the final extract. ("Blanks" were, of course, also done, to ensure the purity, etc., of the reagents employed).

The point at which there is danger of losing arsenic is in the expulsion of the excess of sulphuric acid. If part of the latter were reduced to sulphurous acid, that in its turn would reduce arsenic to arsenious acid, which would be volatilised at the comparatively high temperature employed. The only way to avoid this is to get rid of the sulphuric acid as rapidly as possible without overheating the basin. Should overheating occur, the arsenic acid present may be decomposed and the arsenic volatilised; this, however, is not likely to take place if the basin is kept well below a red heat. The point is one in which experience is the best guide.

Care must also be taken to get rid of the *whole* of the sulphuric acid before extracting the residue. If this be not done, the extract will be turbid and coloured, and a large quantity of sulphuretted hydrogen will afterwards be liberated in the Marsh apparatus. This point, i.e., the necessity of having a solution to "Marsh" which is quite free from organic matter, has also been emphasised by Bertrand (*Bull. Soc. Chem.*, Series 3, Vol. XXVII., No. 16).

*Suggested Simplification of Gautier's Method.*

In conclusion, we would suggest that this method of Gautier might be modified by conjoining it with the Basic Method in the following manner. After the organic matter has been disintegrated by treatment with nitric acid, as already described, the residue—instead of being charred by sulphuric acid—might be thoroughly mixed with an excess of lime and lime water, and, after drying, be incinerated. The lime residue could then be brought into solution and (in the absence of any appreciable quantity of iron†) be Marshled directly. We have tried this method with two samples, but have not had time to test it with known quantities of added arsenic. We have no doubt, however, from a considerable experience of the basic method in other directions, that it would be found to yield satisfactory results, as the combustion is a very easy one; it would also effect a considerable saving of time.

\* For this purpose a small enamelled basin fitted with copper rings is employed.

† McGowan and Floris.—Report on the Methods employed in the Examination of Fuel Samples for the Commission (Appendix, No. 23, below).

(c) *The Basic Method (Newlands and Ling: Chapman).*

This method, of which two modifications for the estimation of arsenic in fuel were recently introduced independently by Newlands and Ling<sup>1</sup> and by Chapman<sup>2</sup>, is now well known. We have employed the method of Newlands and Ling, modified sometimes by the use of lime water in addition to lime, as recommended by the Committee appointed by the Commissioners of Inland Revenue<sup>3</sup>, and have found it useful in the following cases:—(a) Starchy substances, such as broken cereal grains, flour, meal and malt; (b) organic colouring materials like "apple green," "carmine," etc.; (c) inorganic colouring matters, such as Bole Armenia, which consists mainly of oxide of iron (in such a case the arsenic must be precipitated with sulphuretted hydrogen from the lime extract, to get rid of this iron before Marshing); (d) substances like cigarette papers, which consist mainly of cellulose. Many of these would be difficult to treat in a satisfactory manner by other methods. Thus, cellulose is not attacked by chlorine, and nitric acid might form an explosive derivative with it; again, resistant inorganic colouring matters would be hard to treat in any other way than by ignition with a base.

The method usually followed with organic mixtures was to first moisten the substance thoroughly with lime water, and, after evaporating off the water on a water-bath, to mix with powdered lime and then ignite at a red heat in a platinum basin. When the residue became white, it was extracted (dissolved, if possible) with dilute hydrochloric acid, and, if the resulting solution did not contain any appreciable

quantity of iron, it was Marshled directly, after steaming, to get rid of carbonic acid. If, on the other hand, iron was present, the extract (filtered, if necessary) was poured into a conical flask of 150 c.c. capacity, and 5 to 10 c.c. of a saturated solution of sulphurous acid were added. The neck of the flask being then covered with filter paper to keep out the dust, it was placed on the top of a hot bath oven overnight. By next morning the sulphurous acid had either been absorbed or had evaporated, when the liquid was saturated with sulphuretted hydrogen. The sulphide precipitate was ultimately worked up as has been described under the chlorate method, the only difference being that, owing to absence of organic matter here, there was no need to carry the process further than evaporation with nitric acid of the residue from the ammoniacal extract of the precipitate. This final residue, after reduction with sulphurous acid, was then Marshled.

Strictly speaking, the mirrors obtained from substances treated by the basic method, conjoined with subsequent precipitation by sulphuretted hydrogen, should have been compared with special standards obtained in exactly the same way (i.e., not with the ordinary standards got by the direct Marshing of definite quantities of arsenic solution). But since only a very few samples would come into question here—probably only Nos. 45 (Bole Armenia), 47 (Coffee Colour), and 48 ("Sæster")—the results are not materially affected.

## APPENDIX 23.

Appendix 23.

## TESTS FOR ARSENIC IN FUEL.

REPORT BY DR. G. MCGOWAN AND MR. R. B. FLORIS ON EXPERIMENTAL WORK DONE IN CONNECTION WITH THE ESTIMATION OF ARSENIC IN FUEL, AND METHODS EMPLOYED IN THE EXAMINATION OF FUEL SAMPLES FOR THE COMMISSION.

In the course of making analyses of fuel for the Royal Commission on Arsenical Poisoning by the method of Newlands and Ling, it became apparent that the whole of the arsenic could not always be estimated by the Marsh-Berzelius method, when the residue after ignition with or without lime was dissolved in aqueous hydrochloric acid and "Marshes" directly. For it was found that, when using this method, the "non-volatile arsenic" was estimated in several cases as considerably in excess of the "total arsenic," and it was further notable that this contradictory result was obtained most markedly with a residue rich in iron, the latter thus appearing to be the disturbing factor in the analysis.

Attempts, shortly summarised below, were therefore made to obtain the true arsenic values, without having recourse to the rather lengthy process of separating the arsenic from the iron before estimating the former by the Marsh method.

It was found repeatedly that when a minute quantity of arsenious oxide was mixed with a large excess of arsenic-free lime, and the whole ignited in a platinum basin over a hot Bunsen flame for 2 to 3 hours (i.e., for as long a time as would be required to burn off all carbonaceous matter in an actual estimation of arsenic in a coal), the whole of the arsenic was recovered from the residue by dissolving the latter in hydrochloric acid and Marshing the solution. It was thus evident that even when arsenious oxide was heated with lime for the above length of time to bright redness, no arsenic was lost in the process, and, further, that the presence of calcium chloride and even of the traces of iron invariably occurring in lime prepared with limestone or marble did not prevent the production of a mirror of theoretical density.

A number of comparative estimations were then made with the addition of different quantities of ferrous and

ferric chloride respectively, in order to ascertain to what extent their presence vitiated the results.

The iron salt was purified from arsenic as completely as possible by zinc and hydrochloric acid, oxidised to the ferric state with nitric acid, the solution evaporated and the residue ignited; the latter was then dissolved, practically in its entirety, in aqueous hydrochloric acid (the solution now contained zinc as well as iron).

The above solution of iron salt, so purified, gave no trace of a mirror when a quantity of it containing 0.5 gramme of ferric chloride in about 50 c.c. of liquid was Marshes; but, as subsequent experiments showed that ferric chloride can hold back arsenic in the Marsh apparatus, this did not constitute sufficient evidence that the purified salt might not still contain traces of arsenic. The proportion of arsenic—if present—however, was almost certainly less than the equivalent of what may be termed the "Marsh saturation point" of the iron salt as regards arsenic. This last may safely be inferred, because, were the iron saturated with arsenic as regards the Marsh test, or, in other words, were the maximum amount of arsenic which the iron present could hold back in the Marsh test already there, the quantitative recovery of (subsequently added) arsenic would not be hindered by this iron. It will be seen, however, from the experiments quoted below, that the iron did actually exert a very marked effect.

To the purified ferric chloride, known quantities of arsenious or arsenic oxide were added, and it was found in twelve experiments, with but one exception, that the amount of arsenic recovered by the Marsh method was considerably less than that taken, as is shown by the results given in the appended Table A. The "Marsh" was in every case done with hydrochloric acid (not sulphuric), and in several instances lime was added, in order to approximate the conditions to those obtaining in an actual estimation of arsenic in fuel.

TABLE A.

Arsenic taken, expressed as arsenious oxide.	Form in which the arsenic was taken, i.e., whether as arsenious or arsenic oxide.	Lime added.	Ferric chloride added.	Reduced or not by aqueous sulphurous acid after the addition of ferric chloride.	Arsenious oxide recovered by the Marsh test.	Per cent. of arsenious oxide not recovered, i.e., loss.

Appendix 23. The foregoing results rather negative the "saturation" theory, and seem to indicate the precipitation by the iron of varying amounts of arsenic in an insoluble form. It is difficult to see how a solution of an iron salt, which contains considerable traces of arsenic, can be purified beyond its saturation point by zinc and hydrochloric acid, and can subsequently absorb a further quantity of arsenic while these same reagents are acting upon it.

An attempt was now made to separate the iron, by precipitation, from a solution containing arsenious oxide, ferric chloride and calcium chloride, of such strength as would be obtained by dissolving in hydrochloric acid the ignited lime residue from an estimation of "total arsenic" in coal. For this purpose an excess of alkali was employed, in one case lime in the solid state being used, and in another a solution of caustic potash.\* After the precipitated hydroxide of iron had been filtered off, the filtrate was "Marshed," and in both cases was found to be free from arsenic, the whole of

the latter having been carried down in the iron precipitate. On dissolving in hydrochloric acid the above precipitate obtained with lime, 80 per cent. of the added arsenic was recovered in the Marsh apparatus.

It was found that after igniting 0.00012 gramme of arsenious oxide with lime and extracting the residue with sulphuric acid, the whole of the arsenic was recovered from the filtered solution upon Marshing. It seemed worth while, therefore, to try the effect of adding to the solution containing iron a salt of some other metal with which the iron present would form a couple rather than with the arsenic, and so enable direct Marshing to be carried out with sulphuric acid. Copper sulphate, the use of which has been recommended by various experimenters, was therefore taken; but, as will be seen by a reference to the results given in Table B, it was not found to work satisfactorily under conditions approximating to those in the actual estimation of arsenic in a coal.

TABLE B.

Arsenic taken expressed as arsenious oxide.	Form in which the arsenic was taken, i.e., whether as arsenious or arsenic oxide.	Heated with lime or not.	Ferric sulphate added.	Copper sulphate added.	Reduced or not by aqueous sulphurous acid before addition of the copper.	Arsenic, expressed as arsenious oxide, recovered by Marsh.	Percentage not recovered, i.e., loss.

† Ignited 0.00006 gram arsenious oxide with 3 grams of lime, extracted with sulphuric acid and took one-fifth of filtrate for each of these four estimations.

The foregoing table shows that the arsenic was duly recovered (i.e., the results were quantitative) when the solution taken contained arsenious oxide, ferric sulphate and a little copper sulphate; but with arsenic oxide (whether or not the arsenic and iron had first been reduced by sulphurous acid before the addition of copper salt), some arsenic was kept back, i.e., the results were low. Further, where, in addition to the sulphates of iron and copper, calcium sulphate was present in solution—a condition which is unavoidable in such an extract of lime in dilute sulphuric acid—no more than 30 per cent. to 35 per cent. of the arsenic taken was (after reduction with sulphurous acid) recovered in the Marsh apparatus. We are at a loss to explain this last result.

The above investigation having occupied rather too large a proportion of the time fixed for the completion of the analyses, it appeared better to discontinue the research (although many points still remained obscure), and to proceed at once with the method of separation of arsenic by a preliminary precipitation as sulphide from the solution obtained by dissolving in hydrochloric acid the residues from ignition of the coal, alone and after admixture with lime.

The following is the method which we have therefore followed in dealing with the samples of fuel collected by the Commission.

The entire sample is roughly broken with a hammer, mixed and halved; one-half of this is again broken,

mixed and halved, and the process is repeated a third time. Of this last sample one-half or one-quarter is broken up with the hammer between sheets of glazed brown paper on a wooden block, until no pieces are left of larger diameter than about  $\frac{1}{4}$  inch; it is then carefully and successively mixed and halved until only about 50 grammes remain. From this final sample the amount required for the analysis is ground in two or three stages in Wedgewood mortars to an almost impalpable powder. The inside of the bottles in which the final sample is kept should be examined carefully, in order to ensure that there are no loosely adherent flakes of glass.

## TOTAL ARSENIC.

For the determination of "total arsenic" a weighed quantity of the finely powdered coal—from 1 to 10 grammes—is mixed with 3 grammes of arsenic-free lime and ignited in a platinum basin at a bright red heat over a strong Bunsen flame, until the ash shows only the red-brown colour of oxide of iron, and there are no obvious black specks left in it; this usually takes about three hours, more or less. After cooling, the residue is cautiously slaked with water and treated with about 5 c.c. of dilute arsenic-free nitric acid (1 in 10), dried on the water bath, and re-ignited for a short time to decompose any nitrate that has been formed. The entire mass is now dissolved in excess of arsenic-free hydrochloric acid (the excess amounting to about

\* This potash contained a minute trace of arsenic.

10 c.c. of 20 per cent. acid) the solution diluted with water, and gently warmed for some time. It is then filtered through Swedish filter paper, the iron and arsenic in the filtrate reduced with excess of aqueous sulphurous acid, and the excess of the latter steamed\* or boiled off very gently. After this sulphuretted hydrogen is passed to saturation through the cold liquid, which has a volume of about 70 c.c., and is contained in a small conical flask of Jena glass of 100 c.c. capacity; the flask is then tightly corked, allowed to stand until the precipitate has settled, and, if not still smelling strongly of sulphuretted hydrogen, it is re-saturated from time to time.

The precipitate is then filtered through asbestos in a small Gooch crucible, and washed first with sulphuretted hydrogen water until free from chlorides, and then in succession with alcohol, carbon bisulphide and alcohol again. The entire contents of the "Gooch" are now transferred to a small porcelain basin and extracted three times with about 5 c.c. of dilute aqueous ammonia (1 in 4), the extract being, of course, filtered from the insoluble matter each time.

The entire filtrate and washings are then evaporated to dryness on the water-bath, and the residue so obtained treated three times with a very little concentrated arsenic-free nitric acid (about 1 c.c. at a time), the contents of the basin being brought down to dryness after each addition of acid. The last-mentioned residue is finally extracted three times with a few c.c.'s of dilute aqueous ammonium carbonate (1 in 10), the extract being if necessary filtered; the ammonia is then got rid of on the water-bath and the arsenic in the liquid reduced with excess of aqueous sulphurous acid, the excess of the latter being steamed off as before. This final solution is then made up to a given volume, and a suitable portion—usually one-half—is Marshened with 3 grammes of zinc and 2.5 c.c. of sulphuric acid (previously diluted), the total volume of liquid in the "Marshing" flask not exceeding, as a rule, 40 to 50 c.c.

#### NON-VOLATILE OR "FIXED" ARSENIC.

For the estimation of "non-volatile arsenic" an exactly similar procedure is adopted, excepting that the ignition is done without lime.

\* The foregoing method for the estimation of arsenic in coal has also been carefully tested by us, as previously by Messrs. Newlands and Ling, upon an artificial mixture of pure coal with a little arsenical pyrites, the amount of arsenic in this pyrites being determined

by its conversion into magnesium-ammonium arseniate. Duplicate estimations (from the same solution of decomposed pyrites) gave (a) 27.98 per cent., and (b) 27.95 per cent. of metallic arsenic, the mean of these being equivalent to 36.91 per cent. arsenious oxide.

0.45 Gramme of the above pyrites was ignited with 3 grammes of lime and 2 grammes of a fairly pure coal, containing the equivalent of 0.0002 per cent. of arsenious oxide, the total addition of arsenious oxide from the coal being thus only 0.000004 gramme. The ash resulting from the ignition was dissolved in excess of hydrochloric acid, the solution made up to 150 c.c., and two separate portions of 1.5 and 3 c.c. of this were precipitated with sulphuretted hydrogen, the respective precipitates being treated exactly as described above in the method for "total arsenic" estimation. From the smaller quantity precipitated, an amount of final solution calculated as equal to 0.00001 gramme of arsenious oxide was Marshened and it gave a mirror equivalent to 0.0000095 gramme. From the final solution of the second precipitate a quantity calculated as equal to 0.00002 gramme of arsenious oxide was taken for Marshing, a mirror being obtained which was read as equivalent to 0.000021 gramme. These results go to show that the method is quantitative within the limits of error of reading the mirrors.

#### STANDARD MIRRORS.

The standard mirrors were prepared:—

(a) By precipitating with sulphuretted hydrogen in a dilute hydrochloric acid solution double the quantity of arsenious oxide that it was intended to "Marsh." Thus, to prepare a mirror equal to, say, 0.000015 gramme arsenious oxide, 0.00003 gramme would be precipitated in 70 c.c. of liquid, *i.e.*, in about the same volume of liquid as is used for the precipitation in an actual estimation of arsenic in fuel. The precipitate of arsenic trisulphide was then treated exactly as has been already described.

(b) By precipitating the arsenic with sulphuretted hydrogen in a solution containing not merely water and hydrochloric acid, but also an amount of calcium chloride equivalent to 3 grammes of lime.

It was found that those two sets of standards agree closely with one another.

GEORGE MCGOWAN.

R. B. FLORIS.

Ealing, January, 1903.

\* The expression "to steam" means in this instance to evaporate without boiling.

## APPENDIX 24.

## MR. HAMMOND SMITH'S REPORT ON FOODS, ETC.

REPORT BY MR. H. HAMMOND SMITH, M.R.C.S., TO THE ROYAL COMMISSION ON ARSENICAL POISONING ON INQUIRIES MADE BY HIM FOR THE COMMISSION AS TO THE LIABILITY OF ARTICLES OF FOOD AND DRINK (OTHER THAN BEER) TO BE CONTAMINATED BY ARSENIC.

Since my appointment by the Royal Commission last year my inquiries have been directed to the following points:—

(1) The use in the preparation of sundry articles of food and drink of substances liable to contain arsenic, or liable to introduce arsenic into the finished product.

(2) The precautions which have been and are now being taken by manufacturers and vendors of foods or drinks to avoid risk of arsenical contamination.

(3) I have further sought to obtain where possible an estimate of the degree of contamination of various foods or drinks by arsenic which might arise on the assumption that all precaution was neglected; and to collect any information available as to the quantities of arsenic which have been actually found to be present in samples of particular foods or drinks.

The selection of articles of food or drink for inquiry has been determined partly by suggestions made by witnesses to the Commission; partly also by the information which a large number of public analysts kindly put at the disposal of the Commission in response to the circular issued last autumn, and by information which has come to my knowledge in various other ways.

I wish to express my thanks to the large number of merchants and manufacturers whom I visited for the assistance which they gave me as a representative of the Commission. I received valuable help from Mr. Shirley Murphy, Medical Officer of Health of the London

County Council, Dr. Wright Mason, Medical Officer of Health of Hull, Dr. Davies, Medical Officer of Health of Bristol, and many other officials in the Public Health service. I am also indebted to several public analysts and to chemical advisers to various works for information readily supplied at my request.

The Commission having arranged that special samples needing examination should be tested for arsenic by Dr. G. McGowan, I have on several occasions obtained his assistance, and in this report I record results of analyses which he has made of samples received from me.

It is convenient to deal with the subjects of inquiry under sections, as follows:—

[In this report the term "food" is for brevity employed to cover articles of drink as well as of food. The term "arsenic" is used to denote arsenious oxide, not arsenium.]

SECTION I.—Preliminary notes as to certain ingredients of foods, or substances used in the preparation of foods, which are liable to contain arsenic, and as to the quantities of arsenic which they may contain.

SECTION II.—Certain foods in which opportunities of arsenical contamination may arise by reason of the use in their preparation of the above ingredients or substances.

SECTION III.—Foods prepared by direct exposure to products of combustion of fuel liable to contain arsenic.

SECTION IV.—Miscellaneous: Flesh of fowls receiving arsenic; arsenical insecticides; arsenic in enamel of cooking utensils, etc.

SECTION V.—Summary.

## SECTION I.

PRELIMINARY NOTES AS TO CERTAIN INGREDIENTS OF FOODS, OR SUBSTANCES USED IN THE PREPARATION OF FOODS, WHICH ARE LIABLE TO CONTAIN ARSENIC, AND AS TO THE QUANTITIES OF ARSENIC WHICH THEY MAY CONTAIN.

## SULPHURIC ACID.

*Acid prepared from pyrites.*—The acid supplied by Messrs. Nicholson may be regarded as showing the highest proportion of arsenic at all likely to be met with in commercial oil of vitriol obtained from pyrites, and not de-arsenicated. Subjoined are maximum amounts of arsenious oxide in Nicholson's acid which have been reported to the Commission:—Professor Dixon's analyses, 1.45 arsenious oxide per cent., apart from precipitate; Professor Campbell Brown, 2.6 arsenious oxide per cent., or 1.9 per cent., apart from precipitate.

The quantities of arsenic in commercial sulphuric acid which has not been de-arsenicated, and has not come from Nicholson's, have, in some instances, been mentioned to the Commission. Mr. Morris, for example, (Qs. 4724 to 4729) reported from 0.1 per cent. to 1.6 per cent. of arsenious oxide in such acid. Evidence has been given that where pyrites acid is de-arsenicated arsenic can be, and is, eliminated to such an extent as to be negligible as a possible contamination of food substances directly or indirectly prepared by its means. It has been pointed out, however, by certain witnesses that there is risk through lack of uniformity in the process of de-arsenication applied during the

manufacture of this acid, which goes on continuously day and night. Mr. G. E. Davis has especially insisted on this point (Q. 6381). I understand that no maximum limit of permissible arsenic in de-arsenicated pyrites acid has been adopted as a standard by sulphuric acid manufacturers. I have only visited one sulphuric acid manufacturer, Messrs. W. Berk and Co., of Stratford. At these works I was informed by the firm's chemist that de-arsenicated acid is tested by a Marsh test before being sent out, and is required to contain no more arsenic than 0.0001 of a grain (i.e. 0.0064 milligramme) in 12½ cc. of the acid as sold.\*

I may note that the tests for arsenic which are required by the British Pharmacopoeia to be applied to B.P. sulphuric acid are not defined in such a way as to fix any proportion of arsenic which may be permitted to be present; the official requirement being that "no arsenium" should be detected by certain qualitative tests.

*Acid prepared from spent oxide.*—The Commission has had evidence regarding the freedom from arsenic or otherwise of sulphuric acid prepared from spent oxide. Witnesses who have detected arsenic in acid thus pre-

NOTE.—*Price of Sulphuric Acid.*—The price paid by the consumer to the acid maker for sulphuric acid "commercially free" from arsenic appears to be the same by whichever process the acid has been manufactured. For example I am informed that at present the average price paid for any such "arsenic free," concentrated oil of vitriol of S.G. 1.840 is £4 a ton.

\* Mr. G. E. Davis, in 1903, kindly sent to the Commission two samples of oil of vitriol which in his view were, in a commercial sense, fairly representative (a) of acid before dearsenication, (b) of acid after thorough dearsenication. These were submitted to Dr. McGowan, who found (a) to contain 0.152 arsenic per cent., and (b) to be free from arsenic by the delicate test he employed.—H. H. S., July 1903.

pared in each instance have referred to its being present in "small quantities," or in "traces," no quantitative estimate being given (Morris 4812-14) (Davis 6381).

*Acid prepared from recovered sulphur, in its relation to arsenic, has been referred to by Professor Dixon (3475), Mr. Davis (6483, 6507-8), as liable to possible slight contamination by arsenic, no quantitative estimate however being given.*

The exclusive use of sulphuric acid prepared from Sicilian brimstone, in the preparation of articles of food has been advocated to the Commission by several witnesses. At Messrs. Berk's a plant for the manufacture of acid from Sicilian brimstone, at the date of my visit, had been recently set up in consequence of demands made by sugar manufacturers and others as a result of the "beer scare." Minute proportions of arsenic are occasionally met with in acid thus prepared, but no difficulty is experienced in producing, without the use of a de-arsenicating process, Sicilian brimstone acid which complies with the same limits that are adopted for de-arsenicated pyrites acid, viz., below .0001 of a grain in 12½ cc. of acid as sold. Having ascertained from sugar manufacturers the danger which may arise from the accidental mixture of arsenical with non-arsenical acids, I may note that at Messrs. Berk's the plant for the manufacture of the two kinds of acid is kept distinct, and that the carboys containing pyrites acid are carefully kept apart from those containing brimstone acid. At these works, at the time of the "beer scare," several consignments of de-arsenicated pyrites acid were returned to the firm on account of the arsenic which they contained, but this has not since occurred. The brimstone acid is sold under guarantee of being "commercially free," and the firm exhibits the Marsh mirrors obtained therefrom to customers.

*Acid prepared by the synthetic process.*—In the manufacture of sulphuric acid in this way, it appears to be essential for the success of the process to take the greatest care to eliminate arsenic. I understand that the synthetic acid is being increasingly used in this country. I have not, however, met with any instance in which it was being employed by any manufacturer of foods or food ingredients.

#### *Use of Sulphuric Acid for Food Purposes.*

This acid is, of course, largely used in the manufacture of glucose and invert sugar. It also enters into the manufacture of hydrochloric acid, tartaric acid, and citric acid, and many other chemical substances used in the preparation of food.

With regard to the direct addition of sulphuric acid to foods or drinks, it appears to be certain that at one time sulphuric acid was by no means uncommon as an adulterant of gin and other cheap spirits. I have myself been informed by a retired publican from the East of London that some years ago this practice was general among publicans in the East End, and was adopted by himself. He said, indeed, that a certain class of customers would not purchase spirits unless they had been sophisticated with acid. A recent writer in the *Daily Express* (October 11th, 1900) on adulteration of spirits referred to the addition of acid as being practised at the present day, and gave recipes in which oil of vitriol is directed to be added to gin and rum, and nitric acid to whiskey.

Besides this newspaper article and statements made to me on second-hand information which I have been unable to investigate further, I have received no suggestion that sulphuric acid is commonly used to adulterate spirits at the present time. I can find no record of any recent prosecutions under the Sale of Food and Drugs Acts for this form of sophistication of spirits. In view, however, of the statement of the retired publican to whom I have alluded, it would seem possible that acid adulterated spirit would be sold only to particular customers, and it is probable that specimens of such spirits would not be easily obtainable by inspectors under the Sale of Food and Drugs Acts. The Public Health Department of the London County Council has lately had this point under consideration, in view of the possibility that alcoholic neuritis in spirit drinkers may be related to arsenic introduced into spirits by means of added acid, and the Council has suggested to certain of the London borough councils that it is desirable to obtain specimens of cheap spirits for analysis. This action was quite recently taken, and I have not yet learned what results have been obtained.\*

I have heard of one instance in which a mineral water maker's chemist found free sulphuric acid in a sample of aerated water made by another firm, but I have met with no evidence that acidulation of aerated water by means of sulphuric acid is at all a general practice, and perhaps the presence of sulphuric acid in this particular sample may be referred to the plant for making carbonic acid gas, and not to intentional addition of acid.

The addition of free sulphuric acid to vinegar, according to the information given me by several vinegar makers, although formerly the rule, is now seldom, if ever, practised. A small quantity of free sulphuric acid (1 ounce to 10 gallons) appears to be occasionally added to pickles (Report of Departmental Committee on Food Preservatives. Evidence of Mr. Boseley, 1056).

Sulphuric acid may also be used to give the brown colouring to ordinary brown sugar.

#### HYDROCHLORIC ACID.

The liability of hydrochloric acid to contain notable quantities of arsenic in consequence of its preparation from sulphuric acid is, of course, well known. The largest quantity of arsenic in hydrochloric acid that has been mentioned to the Commission was 1.12 grammes per litre, in a sample recently examined by Mr. G. E. Davis (6466). The amount of arsenic in hydrochloric acid can, however, be reduced to very small limits by suitable processes of manufacture. It is evidently desirable that where hydrochloric acid is used in the manufacture of articles of food precautions should be taken to ensure the acid being satisfactory as regards arsenic.

As in the case of sulphuric acid, no maximum quantity of permissible arsenic in acid used for food purposes appears to be adopted by food manufacturers as a standard. As regards the hydrochloric acid of the British Pharmacopoeia, the official tests for arsenic do not fix any maximum proportion which may be permitted to be present.

#### *Use of Hydrochloric Acid for Food Purposes.*

This acid is stated to be largely used in the manufacture of glucose in America, but I have not met with its use for the purpose in this country. It is, however, largely employed at sugar refineries for cleansing the charcoal of the filters. Similarly, it is employed for cleansing vessels of various kinds which are used for food purposes—bakers' tins and the like. Hydrochloric acid enters into the preparation of certain forms of meat extracts, and is used in the preparation of gelatine. It is also employed in the manufacture of a certain patent preparation of rice used by brewers, and occasionally as a substitute for tartaric acid in making puff pastry.

#### PHOSPHORIC ACID.

The liability of phosphoric acid to contain arsenic appears to be generally recognised (cf. Thorpe's Dictionary of Chemistry, Vol. III., page 200). It will be remembered that Mr. G. E. Davis stated to the Commission that as long ago as 1876 he found a sample of phosphoric acid to contain as much as 2.6 grammes per litre (18.2 grains of arsenic per lb.).

At a large firm of sugar manufacturers, I was informed that arsenic was ordinarily detected in every sample of phosphoric acid examined. Commercial phosphoric acid containing no more arsenic than one part per million (1-140th of a grain per lb.) can, however, be obtained without much difficulty. In the spring of 1901 this firm rejected samples of phosphoric acid which contained more than three parts of arsenic per million (over 1.46th of a grain per lb.). Messrs. May and Baker, chemical manufacturers, informed me that phosphoric acid sent over from France and Germany as being free from arsenic, when tested by the Gutzeit method used at their works, has not infrequently been rejected as containing too much arsenic to be sold for food or drug purposes.

#### *Use of Phosphoric Acid for Food Purposes.*

The principal uses of phosphoric acid for food purposes are in the refining of sugar, and also as an ingredient of certain mineral waters. The phosphoric acid used at sugar makers, such as Messrs. Lyle's, was of the kind known as "commercial," the price of which is about 3d. a lb., and has to be distinguished from "chemical" acid, the price of which is from 1s. to 1s. 3d. a lb. The commercial acid is made from sul-

\* Now see Appendix, No. 28.—H. H. G., July 1903.

Appendix 24. phuric acid and bone ash or natural phosphate, the proportion of acid used to the total phosphoric acid produced being (Mr. Voss) about 70 lbs. sulphuric acid to 100 lbs. phosphoric acid.

With regard to "chemical" acid, which may be presumed to be the acid habitually used by druggists, I was informed by Mr. Voss and Mr. Tyrer that no risk of introduction of arsenic arose in the process of its preparation from phosphorus. Moreover, in order to remove any lead, the dilute acid before concentration is subjected to prolonged treatment by a stream of sulphuretted hydrogen which would remove arsenic if it were there. Messrs. May and Baker, who buy chemical phosphoric acid, inform me, however, that the foreign samples referred to above as being occasionally arsenical, are supplied to them as "chemical acid."

#### "Phospho-Citric" and "Liquid Tartaric" Acids.

A commercial substance called phospho-citric acid is largely used in the preparation of temperance drinks as a substitute for citric or tartaric acid. I am informed by chemical manufacturers that it consists of a mixture of commercial phosphoric acid, about 85 per cent., and citric acid, about 15 per cent. Commercial phosphoric acid is also sold to temperance drink manufacturers under the name of "liquid tartaric acid." Dr. Niven in his evidence before the Commission (535) stated as regards a particular firm which manufactures phosphoric acid for mineral water makers that he knew the origin of the acid and the bone ash from which the phosphoric acid is prepared, and that he did not think there would be any arsenic present.

#### PHOSPHATES.

The liability of phosphates of various bases to contain arsenic is also generally recognised.

I understand from Mr. Tyrer that certain chemical manufacturers prepare phosphates (for example, phosphate of soda) with phosphoric acid obtained by the combustion of phosphorus, and that in this instance the phosphate would be practically free from arsenic.

On the other hand, cheaper varieties of phosphates are not so prepared; the acid phosphates used in baking powder and the like are more usually obtained from bone ash or natural phosphate during the process of making superphosphate of lime, and, in consequence, are liable to contain arsenic. Mr. Tyrer stated that before the 1900 epidemic no particular care, as far as he was aware, was taken in the selection of the sulphuric acid employed to manufacture acid phosphates for making baking powders or for other food purposes. One large firm of wholesale chemists whom I visited had, at the time of the Manchester epidemic, tested a large stock of phosphate of soda, and returned it to the agents who supplied it in consequence of the arsenic it contained; in ordinary circumstances, this phosphate of soda would have been supplied to druggists or to food manufacturers. Another firm, who manufacture for druggists, informed me that they not infrequently reject samples of phosphate of soda for the same reason.

Large quantities of arsenic were reported early in 1900 in certain samples of phosphate of soda; some of these are given by analysts who have made returns to the Commission as follows:—

Professor Campbell Brown:

One sample rock phosphate, a trace of arsenic.

Mr. W. W. Fisher:

Phosphate of soda containing arsenic equal to .0724 per cent., or 5 grains to 1 lb.

Mr. W. F. Lowe:

Four samples of phosphate of soda, containing respectively 4.06, 1.96, 1.96, and 0.7 grains of arsenic per lb.

Mr. L. Reed:

Two samples of phosphate of soda containing .02 per cent. of arsenium.

Mr. F. W. Stoddart:

Three samples effervescing phosphate of soda containing respectively a trace of arsenic, 8½ grs. per lb., and 3½ grs. per lb.

Mr. T. H. Walker:

Three samples of phosphate of soda containing 1 part of arsenic in 200,000 to 1 part in 100,000.

I gather that the more grossly contaminated of these samples examined in 1900 probably came from one source, where the presence of arsenic was due to the accidental admixture of sodium arsenate with sodium phosphate. Attention having been directed, however, by this occurrence to arsenical contamination of phosphates in general, it was found that a large proportion of phosphates on the market also contained arsenic in varying degrees. I have no knowledge of the origin of the several arsenical samples referred to in the above list, but it is probable that the smaller proportions referred to were in samples not connected with the accident mentioned. Mr. Lowe informs me that the sample of sodium phosphate in which he found 0.7 of a grain per lb. was of this nature. It is right to add that Mr. Stevenson, who purchases phosphates on a large scale, informed me that recently phosphates have been much more satisfactory as regards arsenic than formerly.

The principal use of phosphates for food purposes, as has been indicated, is in the manufacture of baking powders, self-raising flour, and the like.

#### TARTARIC ACID.

That this acid is likely to be contaminated with arsenic has been stated to the Commission by Mr. Davis and Mr. Lawrence Brient. A similar statement has been made by Dr. Campbell Brown in his Analysts Return. In the British Pharmacopœia the liability of tartaric acid to arsenical contamination is also mentioned. In the British Pharmacopœia it is laid down that tartaric acid should yield no reaction with the pharmacopœial qualitative tests for arsenium. To what extent a minute quantity of arsenic in a gramme of substance might escape notice by these qualitative tests, I am unable to say. I have not any reference to the quantity of arsenic found in tartaric acid, except in the evidence given before the Commission by Mr. Lawrence Brient, who found 1.30th and 1.50th of a grain of arsenic per lb.

An important manufacturer of tartaric and citric acids informed me that notable quantities of arsenic have been found in foreign makes of tartaric acid; he, however, did not state any specific proportion of arsenic which had been determined.

As to the source of arsenic, the following information obtained from Messrs. Bennet, Lawes and Co., may be noted. In the manufacture of this substance from wine lees, hydrochloric acid is used in the first part of the process, which consists in decomposing the acid potassium tartrate in the lees, and recovering the tartaric acid as calcium tartrate. The latter is treated with sulphuric acid, forming sulphate of lime and tartaric acid. The solution of tartaric acid is purified by sulphuretted hydrogen, the principal object of which is to precipitate lead derived from the pans. The tartaric acid obtained after sulphuretted hydrogen treatment may be dried and powdered; or, if a pure crystallised article is needed it is redissolved and recrystallised, being subjected to additional sulphuretted hydrogen treatment.

A great difficulty in making tartaric acid is to insure its freedom from lead. At Messrs. Bennet, Lawes' works, the test employed to ensure sufficient removal of lead is to pass through a sample of the liquor from which the tartaric acid is to be crystallised, sulphuretted hydrogen five times as strong as that employed in the process. Such a test, it is claimed, would equally exclude any arsenic, which at these works would be detected if as much as .0002 per cent. were present. The test is applied by the chemist at the works. The sulphuric acid used at these works is guaranteed to be made from Sicilian brimstone or from spent oxide, and, together with the hydrochloric acid, is tested by sulphuretted hydrogen before use. At these works it is the custom to preserve for reference a number of small samples of the finished article from day to day. The presence of arsenic in considerable amount in tartaric acid, if this in fact occurs, would seem readily accounted for by neglect of such precautions as those just indicated. And that the quantity of arsenic that could be introduced under these circumstances might be considerable may be judged from the fact that, as Mr. Bennet informed me, the quantity of sulphuric acid used to produce 1 cwt. of tartaric acid at his works, is 190 lbs., and that, in the opinion of his chemist, the mere process of crystallisation, without sulphuretted hydrogen treatment, could not be depended on to remove arsenic introduced by contaminated acid.

*Use of Tartaric Acid in Food.*

This acid is largely used as an ingredient of various temperance drinks, lemonade powders, effervescing powders, sherbet, and the like. It is also employed to invert sugar in the manufacture of sweets, and it is an important ingredient of baking powders.

**CITRIC ACID.**

The liability of citric acid to contamination by arsenic has been frequently referred to by witnesses; like tartaric acid, it arises from the use in its manufacture of sulphuric acid. I have not, however, met with any statements as to the quantity of arsenic determined in particular samples. In the British Pharmacopœia, arsenic is not mentioned as being a contamination which should be looked for in citric acid. At Messrs. Bennet, Lawes and Co., citric acid is made by the action of sulphuric acid on citrate of lime in much the same way as tartaric acid from calcium tartrate, the same precautions as to selection of acid and treatment by sulphuretted hydrogen being followed. The sulphuretted hydrogen in this case is passed through the solution out of which the citric acid is to be crystallised two or more times before crystallisation, till the solution gives no "reaction for lead." The test employed is the same as in the case of tartaric acid, and similarly it is claimed that it ensures freedom from more than .0002 per cent. of arsenic.

In estimating the liability of citric acid to contain arsenic, in the absence of suitable precautions, it may be useful to note that at Messrs. Bennet and Lawes' works about 135 lbs. of sulphuric acid are used to produce 100 lbs. of citric acid.

*Use of Citric Acid in Food.*

Citric acid is an ingredient of various temperance drinks, flavouring syrups, artificial lemonade, lemon crystals, etc.

**SULPHUROUS ACID; SULPHITES AND BISULPHITES;  
ACETIC ACID.**

The liability of these substances to contain arsenic has been mentioned to the Commission (sulphites, Briant, 7232; acetic acid, Davis, 6453), but no instances in which notable quantities of arsenic have been detected in them have been mentioned either by witnesses or by public analysts in their returns.

It is perhaps hardly necessary here to deal with them in detail, as the degree of such liability appears slight, and as the proportions of these chemical substances which enter into foods is relatively small. As regards *sulphurous acid and sulphites*, I ascertained from one firm manufacturing it that the sulphur dioxide is passed through washing bottles. The firm claimed that this would prevent arsenic, if any, which might accidentally come over, from contaminating the finished product. Mr. Briant in his evidence (7233) informed the Commission that washing the gas is universally practised, and affords a sufficient safeguard against arsenic.

Sulphurous acid is used at sugar refineries; sulphites and bisulphites are largely used as preservatives in "British wines," beer, and temperance drinks, lemon juice, etc.

As regards *acetic acid*, it may be possible that in its preparation by the action of sulphuric acid on acetate of soda or lime, some arsenic, if present in the sulphuric acid, would come over with the distillate, although the temperature of distillation is below the volatilising point of arsenious oxide. But I understand it is usual to conduct the distillation in silver coils. The chemist of Messrs. Beaufays (who manufacture acetic acid on a large scale) stated that it is essential to the process to take strict precautions as regards the purity of the sulphuric acid employed, and that such precautions include securing freedom of the acid from arsenic, which if present would lead to corrosion of the silver.

Acetic acid is used in the preparation of certain cheap vinegars, especially foreign, and also in the manufacture of pickles.

**BORAX AND BORIC ACID.**

From evidence given before the Commission, it appears that borax and boric acid have frequently been found contaminated with arsenic. Dr. Stevenson in his

evidence (Q. 2358) stated that no sample of boric acid or borax examined by him was free from arsenic; the largest amount he found in borax was 0.35 of a grain per lb. (.005 per cent.). In his return to the Commission as Public Analyst, he has also stated that he examined 19 samples of borax, containing from .0003 to .003 per cent., equivalent to from 1.50th to 1.5th of a grain per lb. Mr. Dyer, Public Analyst for Leicestershire, states that in seven samples of borax he found from 1.100th to 1.6th of a grain per lb.

The liability of borax to contain arsenic is recognised in the British Pharmacopœia, a qualitative test being prescribed for the pharmacopœial article. The British Pharmacopœia does not mention arsenic as a contamination to be looked for in the case of boric acid.

As regards the probable source of the arsenic, Mr. Locke, Secretary and Managing Director of the Borax Consolidated Company, informs me that in his experience arsenic in small amounts is almost always present in borax. He attributed its presence to the fact that the borate of lime, from which borax is chiefly made, occurs in volcanic regions, and said that he thought the frequent presence of sulphur in natural borates, which no doubt is due to the washings of volcanic debris, gave a clue to the probable origin of the arsenic. Mr. Locke said that it was possible to eliminate arsenic from borax by repeated recrystallisation, but that it was a very costly procedure, and, as a matter of fact, the borax in general use, for food and other purposes, is not so treated. Much of the borax which is termed "commercially pure" contained, he thought, on an average, from 1 part of arsenic in 30,000 to 1 part in 50,000 (about  $\frac{1}{4}$  to 1.7th of a grain of arsenic per lb. of borax). Chemically pure borax, which would be demanded for drug purposes, costs about £3 a ton more than the commercially pure article.\*

Borax is now usually made by boiling the natural borate of lime with carbonate of soda. Boric acid is made from the same crude borate of lime by the action of sulphuric acid, the boric acid being left in solution, and then crystallised. The amount of sulphuric acid used in the process varies according to the amount of lime in the crude article. As a rule, about 1 ton of sulphuric acid is required to produce 1 ton of boric acid, but occasionally more is needed, as much as 2,700 lbs. per ton being sometimes employed. In the event of insufficient care being taken in the selection of the sulphuric acid, there would seem to be liability of considerable additional contamination from arsenic arising in this way. The sulphuric acid used at the various works of this company is, I was assured, carefully tested for arsenic before use. Like borax, boric acid can be freed from arsenic by repeated crystallisation. This would increase the price by from £5 to £9 a ton, constituting "chemically pure" boric acid, which would be demanded for druggists' purposes. The boric acid in general use for food purposes, however, is not the "chemically pure" acid. Mr. Locke informed me that the commercial acid contains on the average somewhere about 1 in 75,000 to 1 in 100,000 (1.11th to 1.14th of a grain of arsenic per lb.).

*Use of Borax and Boric Acid in Food.*—Borax and boric acid are largely used in preserving meat (especially hams and bacon) and other food products, particularly milk and butter.

**GLYCERINE.**

The liability of glycerine to contain arsenic appears to be generally recognised, and is referred to by several public analysts who have made returns to the Commission. Arsenious oxide is stated to be readily soluble in glycerine, forming a compound  $C_3H_5AsO_3$ , tritenyl arsenite (Allen's Commercial Organic Analysis, Vol. II., Part I., page 305). In the case of glycerine prepared from soapmakers' lyes, the principal source of the arsenic is the hydrochloric acid used to treat the crude glycerine first obtained. In the case of glycerine prepared by hydrolysis, the use of sulphuric acid appears to give an opportunity of arsenical contamination.

From data kindly supplied by Mr. Moore, of Liverpool, who has considerable experience of analysing glycerine, this substance when prepared by hydrolysis is seldom found to contain notable amounts of arsenic, whereas the commercial glycerine from soapmakers' lyes habitually contains arsenic.† The latter, however, for food and domestic purposes undergoes a

\* The price of borax and boric acid fluctuates: the following are said to be current prices of the commercially pure articles per ton:—Borax (crystals), £13; (powder), £14. Boric acid (crystals), £22; (powder), £24.

† The temperature of distillation of glycerine is high (200° C.) and arsenic is volatilised when glycerine is distilled.

Appendix 24. process of de-arsenication which, if thoroughly applied, can produce an article as free from arsenical contamination as hydrolytic glycerine. De-arsenicated glycerine costs about £10 a ton more than glycerine not so treated.\* Mr. Moore stated, however, that the degree of de-arsenication effected varied greatly at the works of various glycerine distillers.

The Gutzeit test of the British Pharmacopœia, 1898, constitutes the only official limit of arsenic in glycerine for domestic or drug purposes, and it is considered by no means stringent. Mr. Marshall, Public Analyst of Rochdale, has recently met with samples of glycerine containing 1-50th grain arsenious oxide per lb., which gave no indication by this Pharmacopœial test; Dr. Campbell Brown gives an instance of a recent sample estimated to contain between 9 and 11 parts arsenious oxide per million (up to about 1-13th grain per lb.), which passed the Pharmacopœial test; moreover, he has added to glycerine amounts of arsenic up to 1-60th grain per lb., without obtaining any reaction by the test. Mr. Moore has occasionally met with larger amounts of arsenic than the above in glycerine sold for food or domestic purposes, the highest quantity recently found being 1-7th grain per lb.

Some few years ago a considerable number of instances were recorded where the amounts of arsenic found in glycerine were conspicuously high. I have appended to this report a letter on this subject which Dr. Campbell Brown has kindly written, and which gives a number of useful references. Among quantities therein mentioned I note samples, referred to in "Pharmaceutical Journal," 1889, p. 205, in which the amounts of arsenic determined were from 1 in 6,000 (about 1 and 1-6th grain per lb.) to 1 in 2,500 (about 3 grains per lb.). In 1899 also, samples both English and foreign, intended for pharmaceutical purposes, were tested by Siebold. The majority contained from 1 part in 4,000 to 1 part in 6,000. Dr. Brown also gives references to several other instances in which large quantities of arsenic have been found by other observers. Mr. Fairley, of Leeds, examined in 1894 samples of glycerine taken in Leeds, with the following results: one contained 4 grains of arsenic per lb., another 2 grains, two others contained 1-75 grains, while seven contained traces.

I understand from Mr. Moore that, although the number of soapmakers in this country is large, they do not as a rule manufacture glycerine for sale, but sell crude glycerine to glycerine distillers, of whom there are about a dozen in this country. In his belief it is now rare for any of these firms to issue an article for food or domestic use which transgresses the Gutzeit test of the British Pharmacopœia, and the majority have far less arsenic in such glycerine than the above test would allow. He pointed out, however, that glycerine for domestic use is frequently imported. Some varieties of foreign glycerine are manufactured by well-known firms, but others come on the market merely as "glycerine," with no label or other indication of their origin. In certain of the latter he had found arsenic, but could not recall the proportion.

#### Use of Glycerine for Food Purposes.

The principal use of glycerine for food purposes which I have met with is as an ingredient of cakes and in the manufacture of certain forms of sweets. It is used in certain temperance drinks and in making meat extracts, also as an addition to wines.† It is, of course, given as a drug, the maximum pharmacopœial dose being 2 drachms. It is not infrequently taken, however, in larger doses than this.

#### MINERAL SUBSTANCES USED FOR COLOURING.

The liability of oxide of iron to contain arsenic has been mentioned to the Commission by Mr. Hehner (7931-7953), who pointed out that this oxide used as a colouring matter for food might contain 1-10th grain or more of arsenic per lb. I gather from his evidence that the pigment to which he referred was derived from the residue obtained in the manufacture of fuming oil of vitriol by the distillation of sulphate of iron. He has also stated that arsenic may be found in pigments composed of oxide of manganese (10210).

A sample of a mineral pigment, "Bole Armenia" (which in the belief of the manager was a natural earth), ob-

tained last year at one of the London "Stores," was found by Dr. McGowan to contain over 4-5th grain of arsenic per lb. I have no reason to believe that the amount of arsenic in this sample is exceptional, and it is possible that at times it may be exceeded. Bole Armenia, I learn from a colour maker, consists of oxide of iron mixed with whitening.

Bole Armenia, oxide of iron, and other mineral pigments, are extensively used in colouring sausages, anchovy sauce, etc.

#### "COAL TAR" COLOURING MATTERS.

The liability of certain pigments known generally as "aniline dyes" to contain arsenic, has occasionally been mentioned to me in the course of my inquiries. I gather, however, that so far as such liability arises from the use of arsenious acid in the actual preparation of the dye, at the present day it is practically confined to magenta pigments, and that much magenta is made without the use of arsenic. According to Mr. Allen (Vol. III., Part 1, p. 283) and others, arsenic has been found present in commercial magenta in considerable proportions, and at one time as much as 6½ per cent. was met with.

It is possible that the use of large quantities of sulphuric acid in the manufacture of coal tar colours or other processes by which they are prepared may occasion risk of introducing arsenic, and, in point of fact, I understand from Mr. Hehner and from Mr. Goodfellow (consulting chemist to the Confectioners' Union) that arsenic is frequently found in many.‡ As to the origin of the arsenic, however, I have made few inquiries, in view of the minute amounts of these pigments necessary to give the required colour to a large amount of the finished product. There are two references in the Report of the Departmental Committee on Food Preservatives, etc., to arsenic having been looked for and detected in colouring matters used in food, namely, in a colouring varnish used for smearing hams in Gothenburg (Report, p. 273), and in a chemical preparation for food called Kolichayam, used in Ceylon (Report, p. 278).

#### GLUCOSE.

Having regard to the considerable evidence which has been given to the Commission respecting the manufacture of glucose, and its liability to become contaminated by arsenic in the absence of suitable precautions, it will suffice if I here summarise certain points which have already been before the Commission, and add a few further notes.

*Quantity of Sulphuric Acid used in the preparation of Glucose in this country.*—At Messrs. Bostock's (Tattersall), 6 per cent.; at the Manbré Co.'s (Q. 7355), less than 2 per cent.; at Garton Hill and Co.'s (Q. 6059), 4½ to 8 per cent., average 5 per cent. In general (Salamon, Q. 1456), 6 per cent. In general (Delépine, Q. 5239), 4 to 6 per cent.

The above are "solid" glucoses manufactured in this country almost solely for brewing purposes.

The quantity of sulphuric acid used in preparing German solid glucose for brewing purposes is stated by Mr. Wahl to be "considerably less than 2 per cent." (Q. 7432). This smaller percentage, he informed the Commission, was attributable to the purity of the potato starch employed, and to the consistency of the liquid treated.

With regard to the manufacture of American solid glucose used for brewing purposes, little evidence has been received by the Commission. From information given me by Mr. Heron, and in a letter from Mr. Mahana of the Glucose Sugar Refining Co., Chicago, which Mr. Heron has forwarded, it is claimed that sulphuric acid is now seldom employed, hydrochloric acid having been substituted for several years in American glucose factories. If this is so, it might be expected that such glucose would show on analysis a higher proportion of chloride than the glucose prepared by sulphuric acid. I have no information, however, to show whether or not this is the case, nor have I been able to obtain information as to the proportions of the hydrochloric acid employed for the purpose.

\* The price of unpurified glycerine varies, and is, of course, related to its specific gravity. I am informed that £50 a ton is a usual figure.

† The addition of glycerine to wines is prohibited in France and Denmark.

‡ Compare Appendix No. 27 and Dr. McGowan's Appendix No. 25, which give results of analyses of colouring matters made since this report was written.—H. H. S., July 1903

*Amounts of arsenic found in solid glucose.*—The following data reported to the Commission may here be noted:—

*In Bostock's Glucose:—*

	As <sub>2</sub> O <sub>3</sub>	
	Per cent.	Grains per lb.
Government Laboratory	·013 to ·047	0·89 to 3·28
Mr. Gordon Salamon	·04 to ·07	2·8 to 4·9
Professor Delépine	·015 to ·095	1·05 to 6·6
Mr. E. W. T. Jones	·023	1·6
Professor Campbell Brown	·008 to ·131	0·56 to 9·17

*In Glucose other than Bostock's:—*

	As <sub>2</sub> O <sub>3</sub>	
	Per cent.	Grs. per lb.
Government Laboratory: Sample from Paisley Sugar Co., November 1901.	·0013	·69
Professor Campbell Brown: 1 Sample not from Bostock's	·004	·28
2 Samples not from Bostock's	·0025	·175
Mr. Estcourt: 1 Sample of German Glucose	·0014	·1
Professor Delépine: 1 Sample not from Bostock's	·00007	·005
1 Sample not from Bostock's	·0001	·007

Traces of arsenic in glucose other than Bostock's (quantities not specified) have been reported to the Commission by Mr. Miller (5341), Mr. Stein (5178), and by Dr. Stevenson (2480) in the case of old glucose of foreign origin.

Observations by Clouet and Ritter as to arsenic in glucose in 1876 or earlier have also been reported to the Commission. Prof. Delépine (table 12) quoted Ritter as finding from ·0013 per cent., or ·09 of a grain per lb. of arsenic to ·014 per cent., or about 1 grain per lb., in German glucose.

*Precautions against arsenic at glucose factories.*

The precautions (as regards the quality of acid used, and the testing of the finished product for arsenic) which were taken at British and German glucose factories before the epidemic of 1900, and those which have since been taken, have been stated by many witnesses to the Commission. References: Salamon (1435—1457), Francis (7347—7352), Garton (6122) (6126—33), Wahl (7470) (7473) (7476), Stein (5186).

As regards American glucose, Mr. Mahana states without specifying details that stringent precautions against arsenic in the hydrochloric acid used are taken in the factories controlled by the Glucose Sugar Refining Co.

*Arsenic in liquid glucose.*—The solid glucose referred to is seldom used for food purposes other than brewing. For these other purposes the glucose used is in the

form of syrup, termed "liquid glucose." The syrup is not manufactured in this country, but comes almost entirely from America, and what is not American comes from Germany. The liability of liquid glucose to contain arsenic, however, and the precautions taken and necessary to guard against that risk are substantially the same as with the solid product used for brewing.

Mr. J. Heron lately found arsenic in samples of American liquid glucose. In June, 1902, he found as much as 1·25th grain of arsenic per lb. in one sample, and condemned its use. He attributes the presence of the arsenic to the use of soda ash in neutralising. On his suggestion, the ash used at the American works was analysed, and was found arsenical.

Mr. Ling, in his evidence (Q. 10,576) stated he had found quite recently, in 1902, 1·12th grain per lb. in a foreign glucose, either American or German, he could not say which.

*Use of Glucose in Food Materials other than Beer.*

Liquid glucose is used, in greater or less proportion, in the preparation of the following, among other, articles of food:—

Sweetmeats, jams, marmalade, table syrup, liquorice, fruit syrups, temperance drinks, some clarets and British wines, biscuits, gingerbread, vinegar.

*Guarantees.*

It will be convenient here to note the nature of the demands which I ascertained were being made by certain English firms manufacturing some of the above substances. The larger number, in consequence of the "beer scare," took steps to ascertain by analysis (about the end of 1900) that the glucose which they were then using was free from arsenic. Since then they have been content to require from the glucose merchant or middlemen a guarantee in general terms that glucose supplied is, or will be, free from contamination. This may be done in various ways: for example, it may be stipulated in a contract, or by a written assurance, or (most commonly) the food manufacturer accepts an invoice with a statement (printed or stamped on it) that the glucose is free from arsenic.

In my previous evidence (Q. 8794), I referred to the somewhat loose manner in which such guarantees are given by merchants and middlemen. The chief glucose merchant I visited informed me he does not have the glucose analysed, but sells on a guarantee from manufacturers. He finds the buyers do not require a guarantee with each parcel or consignment of glucose, but are content with a general guarantee.

One firm of confectioners whom I visited, however, now require a specific guarantee relating to each consignment delivered. Certain other firms (since the "beer scare") have from time to time caused samples to be analysed, and in three instances I found that such analyses were being made frequently and systematically. I have heard of no instance in which any glucose was tested for arsenic by a food manufacturer before the epidemic of 1900.

I may here record my impression, derived from recent discussion with various users of glucose, that their present tendency is rather in the direction of relaxing than of strengthening the checks on the guarantees of the glucose vendors, which can be secured by analysis made by their own chemists. At one large confectionery works I was informed by the secretary that since he had been there, namely, for six months, glucose had not been analysed, and that he had no knowledge of its being analysed before he went there. At these works the glucose is bought under a guarantee, but only of quality, not of freedom from arsenic.

Appendix 24. The following summary of precautions taken to ensure freedom from arsenic since the Manchester epidemic at certain large firms visited, other than brewers using glucose, may be useful :—

Firm visited.	Glucose bought under Guarantee of Freedom from Arsenic by Vendor.	Tests applied for Arsenic since 1900 by Firms purchasing Glucose.
A. Confectioners, London	Yes	Every consignment tested by their own chemist, and occasionally tested by an independent chemist.
B. Confectioners, Bristol	Yes, but rely on analysis	Every consignment tested by their own chemist.
C. Confectioners, London	At date of first visit, no. At subsequent visits, yes.	At first occasional tests by outside chemists. Now the firm have engaged an analyst at their own works.
D. Mineral Water Makers	Yes	Tested by their own chemist.
E. Chocolate Makers, Bristol	Yes, subject to analysis	Occasionally tested by public analyst.
F. Confectioners, London	Yes	Once tested by Dr. Dupré.
G. Provision Manufacturers	Yes	Once tested.
H. Cake and Biscuit Makers, Reading	Yes	Occasionally by the public analyst.
I. Cake and Biscuit Makers, Bristol	Yes	Once tested.
J. Vinegar Maker, Bristol	Yes	Never tested.
K. British Wine Manufacturer, London	Yes	Never tested.
L. Jelly Makers, Maidstone	Yes	Never tested.
M. Confectioners and Makers of Golden Syrup, London.	No	None.

With regard to three wholesale merchants selling Glucose, the following may also be noted—

Firm.	Guarantee of freedom from Arsenic.	Tests applied.
N., London	Gives to purchaser a guarantee with each consignment, or a general guarantee, as may be demanded.	Has had glucose tested, but does not test each consignment sold, or even a sample of each consignment bought.
O., London	ditto	Do not test. Rely upon a guarantee given by the foreign manufacturer.
P., London	ditto	Do not test.

#### INVERT SUGAR.

The invert sugar, about which the Commission have received evidence on many occasions, is an important ingredient of beer. I have not learnt, however, that invert sugar, as such, is sold to manufacturers of articles of food and drink other than beer, with the exception of cider and certain fermented temperance drinks. The liability of the brewers' invert sugar to be contaminated by the use of arsenical sulphuric acid has been fully before the Commission. The quantity of arsenic reported in Bostock invert sugar (in the preparation of which about 3 per cent. of sulphuric acid was employed) varied as follows :—

	As <sub>2</sub> O <sub>3</sub>	
	Per cent.	Grains per lb.
Professor Delépine	·02	1·4
Professor Campbell Brown	·062	4·3
Government Laboratory	·024 to ·046	1·67 to 3·21

As will be seen below, certain golden syrups and articles of confectionery mainly consist of cane or beet sugar, inverted by mineral acids or otherwise. But in their manufacture invert sugar is not bought as such, but is produced in the process of the manufacture of the finished product.

#### CARAMEL.

The liability of caramel to contain arsenic has been illustrated by the evidence which the Commission have received (Miller, Q. 3325 to 3336), Briant (Q. 7268 to 7287). Mr. Miller informed the Commission that a sample of caramel not coming from Bostock's had been found to contain "about as much arsenic as Bostock's invert sugar." Mr. Briant had not found more than 1·100th of a grain per lb. The arsenical caramel in both cases was stated to have been of foreign manufacture. 1·40th grain of arsenic per lb. in a sample of caramel intended to be used for colouring black beer is referred to in the Government Laboratory Report for the year ending March, 1902.

The Commission have had evidence from Mr. Briant (Q. 7268, Q. 7286) as to the manufacture of caramel, and it would seem that many caramels are made from glucose either by heat alone or with the addition of alkali. Other caramels are prepared from cane or beet sugar.

Mr. Heron informed me that both caustic soda and caustic potash are used in the preparation of caramel, and that the danger of arsenical contamination mainly arises from the use of these substances.

#### Use of Caramel for Food Purposes.

Caramel is largely used as a colouring matter in many kinds of food, for example, vinegar, temperance drinks, cider, confectionery, and in cooking. Certain manufacturers make a practice of requiring an assurance that all caramel applied to them should be made from cane sugar.

Since the Manchester epidemic demand has been made by some manufacturers for a guarantee that the caramel supplied to them should be free from arsenic, and in a few instances this has been checked by analysis. Such guarantee, however, is often neither asked for nor offered by the vendors.

I think that, as a rule, manufacturers are less aware of the liability of caramel to contain arsenic than in the case of glucose.

#### RAW (UNREFINED) SUGAR.

The fact that raw sugar may contain small quantities of arsenic has been mentioned to me by sugar refiners; the same fact has been referred to by Mr. Hehner (Q. 10,209) in his evidence to the Commission on June 13th, 1902, when he stated that he had met with 1-100th of a grain of arsenic per lb. of beet sugar.

On visiting one firm of sugar refiners in July, 1902, I found that this subject had engaged the attention of their chemists for many months. Raw sugars, cane or beet, coming from various countries, had been frequently tested; sometimes 20 grammes of sugar (the quantity recommended by the Arsenic Committee of the Societies of Public Analysts and Chemical Industry) being employed in the Marsh-Berzelius test, sometimes considerably larger quantities. The result, broadly speaking, had been that traces of arsenic were found in many raw sugars of different kinds, and from different countries, the largest amount detected being about 1-140th of a grain of arsenic per lb. of raw sugar.

The presence of arsenic in raw (cane or beet) sugar appears capable of being accounted for by the use of lime in its preparation. In the first treatment of beet or cane juice to remove impurities, etc., lime is added to

the juice. The lime is then precipitated by passing carbonic acid gas through the liquor. Both lime and carbonic acid are usually derived from a special kind of lime kiln, in which the carbonate of lime is burnt with coke. There is thus opportunity of arsenic volatilised from the coke reaching the sugar liquor, as well as opportunity of arsenic from the coke reaching the lime used in the process.

Moreover, if, after the bulk of the sugar has been extracted, the residual molasses are treated to obtain a further quantity of sugar, the processes usually employed (lime, baryta, or strontium processes) consist in adding a much larger proportion of lime or other base than was used in the case of the beet juice, with the object of making a basic "sucrate," which afterwards is generally decomposed by carbonic acid gas. In these processes, therefore, the opportunities of contamination by arsenic derived from the base or from the carbonic acid gas would seem to be increased.

I inquired as to two processes of recovering sugar from molasses which are mentioned in Thorpe's "Dictionary of Chemistry": the alum process, and "Marguerittes process," in which sulphuric acid is added to the molasses to convert all bases present into sulphates. Neither of these processes now appears to be in practical use.

#### MALT.

Having regard to the amount of evidence given before the Commission as to the liability of malt to be contaminated with arsenic, in relation to beer, it is only necessary for me to refer here to malt, for the value of completeness, as in addition to its use in beer it is used as an ingredient in malt extracts and sundry malt foods.

Appendix 24.

AS TO CERTAIN SPECIAL FOOD SUBSTANCES, WHICH BY REASON OF THEIR MANUFACTURE WITH THE ABOVE INGREDIENTS APPEAR SUBJECT TO RISK OF ARSENICAL CONTAMINATION.

TREACLE, GOLDEN SYRUP, AND TABLE SYRUPS.

Syrups of this class may roughly be divided into—

- (a) Those in which the principal constituent is cane or beet sugar inverted in greater or less degree in order to prevent crystallisation.
- (b) Those in which the principal constituent is liquid glucose.

With regard to (a), I subjoin a few notes of a visit to Messrs. Lyle, who manufacture golden syrup on a very large scale. A syrup is made at the works from raw cane or beet sugar. From this syrup, in the process of sugar refining, a single crop of sugar crystals is obtained; the remainder of the syrup is utilised to make golden syrup. It was the firm's custom at one time to completely invert, by means of sulphuric acid, one-half of the bulk of this cane sugar syrup, and to add to that the other half which had not been so treated, but this process has now been discontinued, the plan at present adopted being to "partially invert" the whole bulk of the syrup employed. This is done by sulphuric acid, of which from  $\frac{1}{2}$  to 2 per cent. is used. The acid is neutralised by carbonate of lime, and the syrup is filtered through animal charcoal, and subsequently concentrated in vacuum pans to the density required.

At Messrs. Fowler and Co., who manufacture treacle on a large scale, the raw material used is imported molasses. These molasses are also subjected to a "partial inversion," by means of sulphuric acid, followed by neutralisation and filtration through charcoal. Two per cent. of anhydrous sulphuric acid is used. At these works no phosphoric acid is employed. Neither Messrs. Lyle nor Messrs. Fowler add glucose to their product. It should be noted that hydrochloric acid is employed at these works, and at sugar refineries generally, to cleanse the charcoal filters; also that a small amount of phosphoric acid may be added to the preparation of syrups of this kind.

The degree of risk from arsenic which syrups of this class would entail in the absence of efficient precaution, is evidently of the same high order as that presented by brewers' invert sugar (Section I.), and it deserves to be remembered in this connection that these are food substances which people consume in considerable quantities.

Below are notes regarding the precautions against arsenic in sulphuric, phosphoric, and hydrochloric acids taken at the dates of my visits at the works of the two firms above mentioned.

*Purchase under guarantee.*—At both these works it is stipulated that the sulphuric acid purchased should be made from Sicilian brimstone.

This is at both works a precaution taken in consequence of the Manchester epidemic, and in addition to those furnished by the system of testing for arsenic to which I am about to refer.

Phosphoric acid used at Messrs. Lyle's was "commercial acid," and was being guaranteed free from arsenic.

*Tests for arsenic.*—At Messrs. Fowler's, samples of sulphuric acid are collected from every carboy of a consignment. An aggregate sample is made up from every four samples thus taken; these are tested by a Marsh-Berzelius method, which is said to detect one part arsenic per million, the analysis being made by the works chemist. If arsenic is found in an aggregate sample, each of the four constituent carboys is separately analysed. Records of all analyses are kept.

This plan of systematically testing sulphuric acid for arsenic has been easy to adopt as a similar method of sampling has been practised for many years as a check on the strength of the acid. Before the 1900 epidemic, however, it had been the custom at these works to occasionally test the sulphuric acid for arsenic. Last

year one consignment of sulphuric acid was rejected as the result of the system of testing now employed.

At Messrs. Lyle's, a bulk sample representing every carboy is tested by the works chemist; if any arsenic is found each carboy is separately tested. The test employed is a Marsh-Berzelius. Records are kept of all analyses; these records are kept under the following heads, both positive and negative results being recorded: "Date of purchase; No. of carboys; Sp. gr.; Temp.; Arsenic." This practice, including the systematic examination for arsenic, has been followed by this firm for many years.

Hydrochloric acid and phosphoric acid are similarly tested, and the results similarly recorded.

I was informed that the phosphoric acid used commonly contained minute traces of arsenic, although it has lately been supplied much purer than was formerly the case. Occasionally consignments of phosphoric acid have been rejected as containing more arsenic than is considered admissible.

*Storage of acids.*—At one works I found that all acids when brought into the works are placed in a pen, the gate of which is locked, and the key given to the chemist; after he has tested the acid for arsenic, and found it pure, he affixes a label to each carboy to show it has passed his test, and gives the key to the foreman, who can then use the acid; but if in carrying the carboy from the pen to the inverting room the label becomes detached or torn off, the carboy is returned unused to be analysed and labelled again; the foreman in the inverting room not being allowed to use any carboy without the chemist's label being attached.

The two manufactories above mentioned are the only ones which I have visited at which syrups of this kind are prepared, and I am unable to say whether precautions against arsenic similar to those which I have detailed are in general use by other manufacturers in this country. Mr. Lyle informs me that the total number of such manufactories in this country is small—he knew of only five altogether. All are large firms.

Treacle, and golden syrup manufactured abroad, are also imported into this country from America. I have not obtained any particulars as to the mode of preparations of such imported syrups, or as to the precautions taken to prevent contamination by arsenic.

It is noteworthy that it is the custom of confectionery and other firms to purchase golden syrup wholesale, and to retail it, with or without the addition of flavouring essences, either in the condition in which it is bought, or after dilution with glucose.

At one large firm where this was practised, no steps had been taken at any time by the firm to ascertain whether precautions against arsenic were being adopted by manufacturers of the golden syrup, or whether the syrup supplied was free from arsenic. This firm manufactures a "syrup," in which 15 per cent. of glucose is added to the golden syrup purchased—the product being sold as "golden syrup containing 15 per cent. of glucose." The glucose used was American liquid glucose, and similarly no precautions had been taken to ascertain its freedom from arsenic.

As regards syrups of class (b), in which the principal constituent is liquid glucose, it is probable that the addition of glucose to a substance sold as "golden syrup" or "treacle," would be held to be an offence under the Sale of Food and Drugs Acts, on the ground that the substance demanded by the purchaser under these names is solely a cane sugar product. No such understanding, however, is implied if the article is sold under the name of "table syrup," "amber syrup," or some similar designation.

I have not met with any manufactories at which a mainly glucose table syrup is prepared, and hence I am unable to indicate what precautions against arsenic are taken in purchasing the glucose used. Table syrups consisting mainly of glucose are principally made by firms who purchase golden syrups (chiefly or entirely a cane sugar product), to which they add variable but large amounts of liquid glucose.

The quantities of glucose which occasionally are employed are illustrated by certain recent prosecutions, in which a mainly glucose syrup was sold as golden syrup or as treacle. For example, on December 19th, 1901 ("Food Journal," January, 1902, p. 18), a grocer was summoned at Southwark for selling as golden syrup a substance containing 15 per cent. cane sugar and 85 per cent. of starch glucose, and was fined 5s. and costs. At Fenton, on April 30th 1902 ("Food Journal" May, 1902, p. 117), a retailer was summoned for selling as treacle a substance which contained 70 per cent. of glucose, and was fined 20s.

#### *Presence of Arsenic in Golden Syrup.*

From the analysts' returns sent into the Commission I find that Dr. Parkes, of Chelsea, and Mr. Embrey, of Gloucester, have both found traces of arsenic in golden syrup, but no quantitative results are reported.

#### SUGAR.

I have referred in Section I. to the liability of raw (unrefined) sugar to contain small quantities of arsenic. Such arsenic may, however, be removed almost entirely in the process of refining. Mr. Lyle, who has given considerable attention to this matter, informed me that his firm was satisfied as the result of numerous experiments, that in the refining process as adopted at his works nearly all the arsenic in raw sugar is removed, and that this applied equally to other sugar factories in this country. The sugar, after crystallisation and recrystallisation, even when obtained from raw sugar containing such appreciable quantities of arsenic as 1-140th grain per lb., failed to show more arsenic than 1 part in 20,000,000 (about one 2800th grain per lb.). It had been found that the bulk of the arsenic in such cases remained in the residual molasses, which, at these works, is disposed of to distillers.

Although Mr. Lyle had no reason to believe that arsenic would come over in distillation, he had taken the precaution of ascertaining that the distillers to whom he sold molasses of this character did not propose to utilise them for making spirit for drinking purposes.

He added that the experience of the firm's laboratory was to the effect that any arsenic which had escaped removal in the process of crystallisation would probably be reduced by the subsequent filtration through charcoal.

An instance has come to my knowledge in which the chemical adviser of a large firm of English sugar refiners analysed a number of samples, selected as representing refined sugar of different origin, English and foreign, for arsenic. The results, so far as regards loaf sugar or brown sugar from English refineries, accorded with the statement made to me by Mr. Lyle: the largest amount of arsenic in any instance being estimated as no more than 1-1000th grain to the pound. In the case of brown sugar coming from various parts of the West Indies, however, the amount of arsenic determined was, in some instances, larger than had been anticipated. Many samples appeared to be completely free from arsenic when a Marsh Berzelius test was used, which was capable of detecting 1-1000th grain to the pound. A few, however, contained amounts such as 1-300th grain of arsenic to the pound, while five samples of different origin contained from about 1-70th to 1-50th grain of arsenic to the pound.

These tests have only recently been made, and I have not yet obtained any certain information as to the manner in which particular West Indian brown sugars may receive the larger proportions of arsenic referred to. The results that I have seen suggest that the liability arises only in the case of certain factories, and does not necessarily accompany the process of manufacture as generally carried out in the West Indies.

I have mentioned the use of sulphuric acid as a colouring matter of West Indian sugars. Another colouring matter, the use of which in these sugars was considered by the Departmental Committee on Food Preservatives, is chloride of tin, and it is possible that this salt, as obtained commercially, may contain arsenic.

I am informed also that in the process of manufacturing West Indian brown sugar, large quantities of phosphoric acid may be used to precipitate lime salts. This practice would occasion risk of arsenical contamination in the absence of suitable precautions.

#### GELATINE.

#### Appendix 24.

No information has come to my knowledge, from the Public Analysts' returns or otherwise, that arsenic has been looked for or detected in gelatine; but, having regard to the extensive use of mineral acids in its preparation, I have made a few inquiries concerning its manufacture, and for this purpose visited the works of two important gelatine manufacturers—A and B.

At the places visited, gelatine is made in three ways:—

(a) Without the use of mineral acid—by the action of lime and then of caustic soda on hides which are subsequently washed and boiled. In this process the hides are soaked in lime for 10 days, then cleaned and washed; they are then cut up into small pieces and soaked in caustic soda, again well washed, heated with water in steam jacketed vats, the resulting liquor being eventually evaporated in vacuum pans to the proper consistency and poured on to glass slabs to cool.

(b) By the action, first of lime, and then of hydrochloric acid, on hides, which are afterwards washed and boiled. In this process the hides are soaked for 14 weeks in a solution of lime; they are then washed and treated with hydrochloric acid and water, 120lbs. of acid to 3 tons of hides. The hides remain in the acid water 43 hours; they are then washed with water (but not with alkali) to remove the acid, boiled, the liquor evaporated, and cooled in pans.

(c) By the action of hydrochloric acid on bones. In this process the bones are put into large vats, and a solution of hydrochloric acid (proportion not given) poured on to them. They are left to soak till all the lime salts are dissolved out of the bones; the resulting "osseine" is then washed and treated with caustic soda in the same way as the hides in the second part of the process (a).

Assuming that a highly arsenical acid were used in the preparation of gelatine by the process b and c above, it would seem probable that the risks of arsenic reaching the finished product is largely diminished by the treatment employed after the acid has been added.

At neither of these works had the question of contamination of gelatine by arsenic contained in the acid arisen. At manufacturer A's the acid was bought as "chemically pure," but it had never been tested. At manufacturer B's the acid was neither guaranteed nor tested.

I understand that the bulk of gelatine used by confectioners in this country is imported from abroad.

The pure white colour of the German gelatine, so much used and asked for by makers of confectionery and table jellies in this country, is produced by the direct addition of sulphurous acid to the finished product.

A sample of gelatine taken at the works of manufacturer B, and also a sample of German make which I obtained, have been sent to Dr. McGowan, who has also had samples of gelatine, prepared for making into table jellies, from Messrs. A. Dr. McGowan's report on the samples is not yet to hand.\*

#### JAMS AND MARMALADE.

Various witnesses before the Commission have stated that they examined jams for arsenic after the 1900 epidemic with negative results, and similar statements appear in the returns made by several public analysts to the Commission. Nevertheless, it appeared desirable to make some enquiries as to the precautions taken at jam factories with regard to the purity and the quantity of the glucose employed. For this purpose I visited five London factories and one in Bristol.

Jams may be divided into—

(a) Those made exclusively with cane or beet sugar.

(b) Those made with cane sugar with the addition of varying amounts of glucose.

In the latter class the proportion of glucose used appears to be determined by various conditions such as the nature of the fruit and its degree of ripeness. Such amounts as from 5 to 10 per cent. are common. The principal object of the glucose is said to be for clarifying purposes, to prevent the jam from crystallising.

It is said that satisfactory jam cannot be made if glucose preponderates over the sugar, and that if more than 20 or 25 per cent. of glucose be added, the jam would require so much boiling that the fruit would

\* Since the above was written Dr. McGowan has reported on these samples (Appendix 25). It will be seen that gelatine from Messrs. B., who took no precautions with regard to their acid, contained most arsenic—5-110th gr. per lb.—H. H. S., July 1903.

Appendix 24. blacken. The fluctuations in price of glucose doubtless influence its employment in jam.

It is evident that the presence in glucose of such amounts of arsenic as have been occasionally determined in glucose other than Bostock's (for example: 0.9 grain per lb.), would cause an objectionable quantity of arsenic to be introduced into jam or marmalade containing these larger proportions of glucose.

**Precautions with regard to glucose.**—I have not learnt that glucose was tested for arsenic by any jam manufacturer before the 1900 epidemic. Since then the firms visited as a rule have purchased their glucose with a guarantee of its freedom from arsenic, given in the more or less exact way mentioned in Section I. under the heading Glucose, but in two cases this precaution had been omitted. Similarly the precaution of having the glucose analysed had been adopted more or less systematically by some firms, and had been omitted by others.

The glucose used at all the works visited was liquid glucose of American manufacture.

#### CONFECTIONERY.

Various witnesses to the Commission stated that after the 1900 epidemic they examined several samples of sweets with negative results; several analysts who have made returns to the Commission make a similar statement. The detection of arsenic in sweets has been reported in one or two instances; for example, in returns made to the Commission by the Public Analysts, Mr. Brierley reports "a trace" in highly coloured sweets, and Mr. Angell "a trace," or '0105gr. per lb. in another sample of sweets.

I visited eight large firms manufacturing sweetmeats, with reference to the use of ingredients liable to contain arsenic, and precautions taken.

Glucose is used in sweets partly for sweetening purposes, but mainly to prevent crystallisation of cane sugar; the quantity used of course varies with the class of sweet; some such as chocolate and other "creams" consist largely of glucose. The average quantity in sweets of all kinds taken together may be judged to some extent from the calculations on which claims for rebate of duty on exported goods are based. At three firms which gave me information on this point the proportions of glucose were estimated respectively as 20 per cent., 15 per cent., and 33 per cent. Another firm estimated its "heavy confectionery" as containing 15 per cent., and its "light confectionery" 40 per cent. It is evident, therefore, that if glucose used in confectionery were to contain even such amounts of arsenic as have been occasionally determined in samples other than Bostock's, objectionable quantities of arsenic might in this way be introduced.

At the firms visited the glucose principally employed was liquid glucose of American origin. Solid glucose of German manufacture is preferred on account of its greater density in certain kinds of sweets. At one firm they have lately left off using American glucose, and now only use German.

Particulars of the precautions now being taken by confectioners visited to guard against arsenic in glucose have already been indicated in Section I., under the heading "Glucose."

**Invert sugar** used in sweet-making, unlike brewers' invert sugar, is not purchased as such, the inversion being carried out by the sweet manufacturer on his premises. I met with no instance in which sugar for sweet-making is inverted by the addition of a mineral acid. Cream of tartar and citric acid are commonly employed; or reliance is placed on prolonged boiling as sufficient to bring about the required inversion.

**Citric and tartaric acids** are likewise used as flavouring for acid sweets; but the proportion is small. These acids were in all cases stated to be bought with a guarantee or with an assurance of their purity. Such guarantees sometimes state specifically that the substances are free from lead, and at one of the firms lead was occasionally looked for by the works chemist. None of the guarantees made specific mention of arsenic, and I did not learn of any instance in which arsenic had been looked for in citric or tartaric acid at the instance of any sweetmeat manufacturer. As above indicated, however, there is little reason to suppose that material quantities of arsenic could be introduced into sweets by these acids.

**Glycerine** is used in making certain forms of jujubes, and occasionally for other purposes, such as the treat-

ment of vanilla. The quantity of glycerine in jujubes at one works was stated to be 10 per cent. If arsenical glycerine, such as referred to in Section I. above, were employed, it is evident that objectionable quantities of arsenic might be introduced in this way. To take an extreme instance, glycerine containing 4 grains of arsenic to the lb., such as was found by Mr. Fairley in 1894, would introduce 2.5ths of a grain of arsenic to the lb. of the sweets in question.

On the other hand, quantities of arsenic such as those found by Dr. Campbell Brown in recent samples of glycerine the highest of which is about one 15th of a grain to the lb., would not introduce more than one 150th of a grain of arsenic to the lb. of such sweets.

Beyond stipulating in general terms for "pure" glycerine, the manufacturers I visited had taken no precautions to secure its freedom from arsenic, and indeed the liability of glycerine to arsenical contamination did not appear to be known to them.

**Gelatine.**—Certain kinds of soft sweets, called in the trade "Jellies," consist almost wholly of gelatine; the gelatine used at the works visited was imported gelatine. No question of testing this gelatine for arsenic had arisen in any instance.

**Colouring Matters.**—I have dealt below with the possibility of arsenic being introduced by means of colouring matters used in food, and with precautions taken with regard to them. I may here note, however, that oxide of iron (which is liable to be contaminated by arsenic to a high degree) is employed to give a brown colour to cheap chocolate and certain other kinds of sweets.\* In one instance (report of Departmental Committee on Preservatives and Colouring Matters) 35 grains of oxide of iron were used to the lb. of burnt almonds.

**Dextrine.**—At the works visited it was stated that no gummy substances which have been prepared from the action of mineral acid upon starch are used. The gummy ingredient of pastilles and the like is said to be gum acacia of natural origin.

#### Substitute for Cocoa-butter.

Cocoa-butter is used largely in the manufacture of chocolate, and for other confectionery purposes. It is also sometimes used in making certain kinds of pastry, and is added in the process of sugar refining in order to prevent frothing of the sugar solution.

Information was recently given me that a wool oil, known in the trade as "brown wool-grease," and prepared from sheep's wool, had in one instance been sold to a large firm of sugar refiners under the name of "cocoa-butter." The refiner said that he recognised that this wool-grease was not true cocoa-butter, but considered that it was suitable for his purpose. Subsequent to its use being discontinued for commercial reasons, it was found that this wool-grease or so-called cocoa-butter contained about 14 grain of arsenic per lb.

I understand that it is not generally recognised by manufacturers or users of cocoa-butter that a wool-grease is or may be sold as being cocoa-butter; and, in point of fact, the above is the only instance in which I have heard of its use.

I visited a manufacturer of brown wool-grease and lanoline, and by him was informed that in his view no opportunity of arsenical contamination was afforded by the processes used to obtain these substances from the wool. He was not aware of the fact that such grease might contain arsenic, but was of opinion that its presence could be accounted for by the use of arsenical sheep dip; the arsenic in the wool not having been sufficiently removed by the process of washing.

He also informed me that "lanoline," which is used chiefly for pharmaceutical and toilet purposes, receives considerably more washing than brown wool-grease. The firm of sugar refiners above referred to had caused a sample of lanoline, which they had for a time used for the same purpose as the cocoa-butter, to be tested for arsenic. It contained '0035 grain of arsenic per lb. I have not heard of any other samples of lanoline that have been tested for arsenic.

If wool-grease more or less purified is liable to be used by confectioners or other food producers, or in future comes to be used by them as a substitute for true cocoa-butter, it is clearly important that attention should be paid to the question of arsenic, the more so if the origin of arsenic is, as suggested, sheep dip, for it is evident that under particular circumstances the quantity of arsenic thus introduced into the wool might be considerable.

\* Now see report by Mr. Otto Hehner (Appendix 27), which refers to the estimation of arsenic in coloured sweets. — H.H.S., July 1903.

### Liquorice.

Mr. W. Thomson stated in his return to the Commission that he had found arsenic in a sample of liquorice jujubes. He has since written that the quantity was approximately 1-35th grain to the lb. Such jujubes would probably be prepared with a considerable proportion of glucose. That the origin of the arsenic may however have been the liquorice itself is shown by the fact that Mr. Thomson found 1-70gr. of arsenic per lb. in a sample of a stick ("Spanish juice"), into the preparation of which probably no glucose had entered. A sample of raw liquorice which I took haphazard at a confectioner's was found by Dr. McGowan to contain one 245th of a grain of arsenic per lb.

Two main classes of liquorice juice are imported into this country: the first is Italian juice, which contains a considerable quantity of sugar, and can be eaten without treatment. This is considered the best, and is simply the evaporated extract of the root without any added sugar or glucose. The other juice is imported chiefly from Russia, and some cases glycerine to make soft liquorice. I was informed that sulphuric acid was also sometimes added to give a bright appearance to the liquorice.

I have been further informed by Dr. Hillaby, Medical Officer of Health for Pontefract, that glucose can be used in "liquorice goods" to the extent of about 35 per cent., and that glycerine is used by some makers, but that "good glycerine" is too expensive for general use. The points just referred to, however, although they show several ways in which arsenic might be introduced into manufactured liquorice, do not suffice to explain the small quantities of arsenic found by Mr. Thomson and by Dr. McGowan in the crude liquorice—unless it was due to sulphuric acid.

### CIDER.

I have not heard of any instance in which arsenic has been detected in cider. None of the public analysts who have made returns to the Commission mention that they have examined cider for arsenic. In view of statements that invert sugar is used in the manufacture of cider, however, I have made a few inquiries of cider manufacturers. Mr. Symons, the proprietor of Messrs. Symons and Co., informed me that he used invert sugar only at certain seasons of the year, and under certain conditions, and that such sugar was inverted at his works by means of tartaric acid; he did not employ hydrochloric or sulphuric acid for the purpose.

At Bristol, the representative of Messrs. Woolway and Coleridge informed me that no invert sugar was used in their business, but that caramel was used for colouring cider. On the other hand, it is a fact that brewing sugar manufacturers supply brewers' invert sugar to cider manufacturers. The precautions against arsenic which are now adopted in manufacturing these brewing ingredients would presumably afford security to the cider manufacturer who procures invert sugar in this way.

I have not heard of other ingredients of cider which are likely to render it liable to arsenical contamination, and, therefore, I have not made detailed inquiry into the process of its manufacture.

I understand that no brewers' or distillers' yeast is used in cider making. The addition of glycerine to American ciders was referred to by Dr. Voelcker in his evidence to the Departmental Committee on Food Preservatives; he was not able, however, to state the quantity of glycerine present in the samples examined. It is stated that glucose is of no value as an ingredient in the manufacture of cider.

Mr. Radcliffe Cooke in his evidence before the same Committee (Q. 6582), states that "Walter Gregory's Powder," a mixture of oxide of iron and salicylic acid, is sometimes added to cider.

### HERB BEER.

In order to ascertain whether glucose or brewers' invert sugar is used in the preparation of this sort of fermented beverage I made some inquiry of Messrs. Youngs at the Botanic Brewery, Bermondsey, who

informed me that in view of the necessity of keeping the quantity of alcohol in these beverages below the limits permitted by excise regulations, there is no advantage in the employment of either of these substances. The herb beer manufactured at these works was prepared by fermenting a weak solution of cane sugar, to which saccharine and herbs are added.

### TEMPERANCE DRINKS.

No information has been received by the Commission that arsenic has been detected in mineral waters or other temperance drinks, and it would appear from the Public Analyst's return to the Commission that drinks of this class were rather extensively examined for arsenic after the Manchester epidemic. The possibility of arsenical contamination of these drinks, however was referred to by certain witnesses (including Dr. Niven and Mr. Salamon) in their evidence to the Commission. With reference to this I visited three firms in London, two in Manchester, and one in Bristol.

It will be useful to deal with temperance drinks by adopting the classification used in the trade—namely:—

- (a) Mineral or aerated waters.
- (b) Aerated sweet waters.
- (c) Brewed beverages.
- (d) "Fruit syrups," sold as such for adding to soda water or to plain water, either hot or cold.
- (e) "Crystals," or other powders, sold as such for making various "summer beverages."

(a) *Mineral Waters*, such as soda, seltzer, or lithia waters, are simply water charged with carbonic acid gas, to which certain salts are added—e.g., carbonate of soda or lithia. Phosphates are sometimes used in the preparation of seltzer water. The amount would be small, from  $\frac{1}{2}$ gr. to 2grs. to the pint (Kirkby). The carbonic dioxide is usually produced from sulphuric acid and carbonate of lime or soda. The gas is then twice washed, and goes either into a gas-holder, or it is forced direct into the bottle containing the water to be aerated. It is claimed that by this washing any arsenic that might be present would be removed. In some works the carbonic acid was bought compressed in bottles obtained from the Carbonic Acid Gas Company at Lea Bridge.

On one occasion Dr. Teed (analyst to Messrs. White and Co.), when testing mineral water manufactured by another firm, found free sulphuric acid, which might have been added for the purpose of acidifying the water, but he did not think the addition of free acid was a common practice. He had not tested the sample in question for arsenic. Messrs. Cazenove and Nicolle ("Analyst," 1892, p. 118) state that "aerated waters may contain free sulphuric acid mechanically carried over from the generator," and this, perhaps, explains the origin of the sulphuric acid in this case.

(b) *Aerated Sweet Waters*, such as lemonade, gingerade, kaola, champagne cider, etc., are waters aerated with carbonic acid gas, sweetened with syrups, and flavoured with coloured essences. In all these cases the syrups are said to be made from pure cane or beet sugar; in some cases they contain saccharin. It was stated at the places visited that no glucose was contained in these syrups.

Mr. Kirkby (of Messrs. Jewsbury and Brown) informed me that glucose would not make so good a syrup, as it is liable to ferment, and would require preservatives.

In order to give a sharpness to the taste of sweet waters it is the custom at some works to add phosphoric acid, or the substance known as "phospho citric acid" (Section I.). The proportion added is probably small, but, though I have been told of its employment, I have not visited any firm where I could obtain particulars as to its use.

In the case of lemonade, citric acid may be added.

I was informed at Messrs. White's that glycerine was at one time used to sweeten aerated waters, but that its use was now discontinued. And I did not hear of its use at any of the works visited, except that a very small amount was used in Kops ale. I have been given a sample of a French preparation called Porcherine, which appears to consist mainly of glycerine, and is being recommended for sweetening aerated waters; but

\* In connection with this process, Mr. Marshall, of Rochdale, informed me that early during the Manchester epidemic he was consulted by a mineral water maker, who was using a clear Nicholson's sulphuric acid to generate his carbonic acid. Mr. Marshall examined this sulphuric acid, which was highly arsenical. He then examined the mineral waters which he found quite free from arsenic. This acid was subsequently withdrawn by Messrs. Nicholson.

Appendix 24. I did not find that it was being used at any of the works I visited.

(c) *Brewed Beverages*, such as "hop ale," "non-intoxicating stout," "ginger beer," etc., are all made by a fermentation process. As a rule, the substance fermented is cane or beet sugar, to which may be added ginger, hops, or hop essence, etc., or malt in some form, according to the character of the beverage. Saccharine may also be added, and liquorice in the case of "non-intoxicating stout."

At one works glucose was used in brewing stone ginger beer, and invert sugar in brewing other non-intoxicating beers. Mr. Kirkby, at Messrs. Jewsbury and Brown's, informed me that the amount of glucose used was very small, in order to keep down the alcohol, in the case of "stone" ginger beer being less than  $\frac{1}{2}$  lb. per gallon. At most of the works I visited, "stone" ginger beer was brewed, without glucose, from cane or beet sugar and ginger, and was acidulated with tartaric acid.

In one instance, a "non-intoxicating beer," the beverage consisted of a brew of invert sugar flavoured with essence of hops and coloured with caramel. This invert sugar was described to me as a "malt substitute." It was, however, ordinary brewers' invert sugar, and was bought from a large firm of sugar makers. A "non-intoxicating stout" was also made at the same works, the only difference being the addition of more caramel.

(d) *Fruit Syrups*.—These are used for mixing either with water or soda water as a summer drink, but more extensively to manufacture "hot winter drinks," such as are sold by small shop-keepers and itinerant street vendors. They usually consist of cane sugar syrup, or a mixture of cane sugar syrup with glucose, flavoured with "fruit flavouring" and coloured.

Syrups of this class, sold under such names as "lemon squash" or "lime juice cordial," are manufactured at most of the works I have visited. The fruit juice utilised appeared in all cases to be lime juice purchased either directly or through an agent from the Montserrat Lime Juice Company. This juice, when imported, contains bisulphite of lime as a preservative, and other preservatives are added by the manufacturers of the syrup in this country. I was informed that neither citric acid, tartaric acid, nor mineral acid are added to these "lemon" or "lime juice" syrups.

(e) *Crystals or Other Powders Sold for Making Drinks*.—I include under this head various powdered and crystalline materials sold as "fruit or lemon crystals," "lemonade powders," "sherbet," "seidlitz powders," etc. Fruit crystals are a mixture of cane sugar with a small proportion of citric acid crystals, flavoured with fruit essences, which are either made from fruit or obtained synthetically. The proportion of citric acid in the drink prepared from these fruit crystals is said to be very small. Lemonade powders of the kind now extensively sold and advertised are essentially a dry mixture of cane or beet sugar with citric and tartaric acids, and flavoured with oil of lemon. Citric or tartaric acid may form about half the bulk of such powders. About 2oz. of the powder is commonly used to the pint of water to make a syrup, and two tablespoonfuls of this syrup make half a pint of the drink; in other words, the drink lemonade will contain about 4.5th oz. of the lemonade powder per gallon, a large portion of which would consist of citric and tartaric acids. Sherbet contains powdered sugar, together with citric or tartaric acid, or both, and carbonate of soda. It is flavoured, as a rule, with essence of lemon. From 10 per cent. to 20 per cent. of tartaric acid appears to be an ordinary quantity in sherbet. A pint of sherbet would be made from about  $\frac{1}{2}$  oz. of the powder, and may contain, therefore, from 48 to 24 grains of tartaric acid. The quantity of tartaric or citric acid used in a drink made from a Seidlitz powder may be taken as from 30 to 40 grains.

#### PRECAUTIONS WITH REGARD TO ARSENIC TAKEN IN THE MANUFACTURE OF THE VARIOUS DRINK SUBSTANCES ABOVE MENTIONED.

*Sulphuric acid* being used solely to manufacture carbonic dioxide gas, the risk of arsenical contamination of aerated waters by this means is small, even if a strongly arsenical acid were used. I found, however, that since the Manchester epidemic certain firms of

mineral water makers had caused occasional samples of their sulphuric acid to be tested for arsenic.

At Messrs. Jewsbury and Brown's, who manufacture other articles beside aerated water, it has been the custom for over twenty years to test for arsenic all carboys of sulphuric acid purchased, and to record the result of the test.

*Glucose*.—It is evident that the quantity of glucose used occasionally in brewed temperance beverages would be sufficient to cause objectionable contamination by arsenic, if the glucose used was seriously contaminated. A quarter of a lb. of Bostock's glucose, containing 4 grains of arsenic per lb., might introduce about 1 grain of arsenic to the gallon of ginger beer brewed with it. If the glucose contained arsenic to the amount which has occasionally been found in non-Bostock samples—for example, 1-10th grain per lb., the ginger beer might be contaminated to the extent of 1-40th grain per gallon. Similar considerations apply to the use of brewers' invert sugar in brewed temperance beverages.

The degree of possible contamination of aerated sweet waters and other beverages made from syrup containing glucose is obviously much less than in the last case, as the amount of syrup which enters into the composition of the actual drink is relatively small.

*Phosphoric Acid* used in mineral-water making appears to be "commercial" acid, which, as mentioned in Section I, is liable to contain arsenic. The quantity of phosphoric acid used is so small that there is little risk of the introduction of material quantities of arsenic into temperance drinks in this way. Whether any manufacturers make a practice of checking the purity of the phosphoric acid as regards arsenic I am unable to say.

I did not ascertain at any of the works visited that either citric or tartaric acids have been examined specifically for arsenic, or that any demand has been made in purchasing these substances that they should be free from arsenic. As has been said above, guarantees of freedom from lead are given by the manufacturers if required by the purchaser. At those works where I made inquiries on the point, I was informed that the manufacturer had not considered it necessary to check the correctness of this guarantee by analysis. For citric or tartaric acids to introduce a noteworthy quantity of arsenic into temperance beverages, such as those mentioned above, it would be necessary that the contamination of the acid by arsenic should be of a very high order. For example, assuming that the liquid "sherbet" contained 1-100th grain of arsenic in a pint (or 2-25th grain of arsenic per gallon), as a result of contaminated tartaric acid present in the sherbet powder, the tartaric acid must have contained as much as 1.6 grains to the lb. I have no evidence that tartaric acid has in fact been found contaminated to this extent.

I would here note that I had every assistance from the various temperance drink manufacturers, except from Messrs. Batey and Co., who, with the exception of stating that they used no glucose, would give me no information whatever.

#### BRITISH WINES.

Four firms which I visited manufactured British wines, and by one of these glucose is used at certain periods of the year, but in small quantity. The firm in question obtained American liquid glucose, once guaranteed free from arsenic, but not tested by themselves. It will be remembered that Mr. Watson (Q. 7443) stated that glucose is "largely used" in France to improve the quality of inferior vintages of clarets, and manufacturers of British wines have told me the same thing.

#### BREAD, CAKES, AND BISCUITS.

Although no evidence has been received by the Commission that any noteworthy amount of arsenic has been found in bread, yet the presence of minute quantities in bread has been referred to by Professor Delépine (Q. 5270 and 5280), and the matter seemed to call for some inquiry. I have visited several manufacturers of bread, cake, and biscuits in London and elsewhere on this point, and I have also received information from Mr. Goodfellow, who is chemical adviser to the Confectioners' Union.

The liability of bread, cake, and biscuits to contain arsenic seems to arise from the use of the following substances: Yeast, glycerine, glucose, "malt extracts," baking powders, dextrine.

**Yeast.**—Many witnesses have given evidence to the Commission as to the affinity of yeast for arsenic. In five samples of bakers' yeast, not from breweries, and having no relation with Bostock's sugar, the quantity of arsenic estimated by Professor Delépine was from about 1.60th to about 1.20th grain per lb. From the returns obtained from public analysts, it appears that Mr. White, of Derbyshire, and Professor Campbell Brown between them examined 53 samples of yeast (whether derived from breweries is not stated), of which 44 were arsenical. The largest quantity of arsenic, about 3.40ths grain per lb., was determined by Professor Campbell Brown. I understand that in consequence of the shorter hours of labour in bakeries very little brewers' yeast is now used in baking. Of the firms I visited, only one used brewers' yeast, and in that case it was sometimes mixed with distillers' yeast. The yeast now employed is generally pressed yeast, obtained through merchants, and comes either from distilleries in the United Kingdom or from the Continent. I have no evidence that distillers' yeast is less liable to arsenical contamination than brewers' yeast; indeed, having regard to the precautions against arsenic now generally adopted by brewers, it is not unlikely that brewers' yeast at the present time is the better of the two in this respect. Early in 1902 Mr. Heron found so much arsenic in a sample of distillers' yeast that he thought it necessary to warn the merchant who brought it to him that it should not be sold. He did not, however, tell me the actual quantity of arsenic in this particular sample. Apart from this instance, I have not heard of any cases where distillers or yeast merchants have taken steps to ascertain the condition of their yeast as regards arsenic. My information on this point comes from several large firms.

The quantity of yeast which is added to bread is, of course, small; 1lb. of yeast to 230lbs. of flour and 5 gallons of water is the usual proportion.

**Glycerine.**—This is largely used in the manufacture of cakes, chiefly of the cheaper sorts, and is put into them for the purpose of keeping them moist. The amount varies. Thus one firm used 1½lbs. glycerine to 100lbs. of mixing; at another they used 2lbs. to 3lbs. of glycerine to 100lbs. of mixing; in the latter case the completed cake would contain 2lbs. of glycerine in every 50lbs. of cake. In certain "gluten biscuits," for diabetic patients, about the same quantity (2½lbs. glycerine to 100lbs. of mixing) is used.

I am informed by Mr. Goodfellow that glycerine may be used in bread baking, but he is not aware of its use in any instance at the present time.

**Glucose.**—Glucose does not appear to be used in the manufacture of cakes. It is, however, a frequent ingredient in the manufacture of what is termed "hard dough" for making a certain class of biscuits. One of the objects of the glucose is to impart a fresh-looking appearance to the biscuit. The proportion of glucose was given me as 6lbs. of glucose to 1 sack of flour producing 360lbs. of biscuit. One firm which I visited informed me that they had given up the use of glucose in biscuits since the Manchester epidemic. As regards bread, the use of glucose is mainly as a "yeast food"—i.e., a food material on which yeast will act with greater facility than in the case of starch. These yeast foods are sometimes sold to bakers under the name of "malt extracts." True malt extract is also largely used in the baking trade as a yeast food, while several so-called malt extracts consist partly of glucose and partly of true malt extract. Some, however, contain no true malt extract at all. One such, I am informed, consists of glucose, pea flour, cane sugar, and phosphates. Another, sold as "super-malt," and very largely used, is said similarly to contain no true malt extract. Malt extracts or yeast foods are ordinarily employed in bread-making to the extent of about 1lb. of extract to 230lbs. of flour.

**Golden Syrup** is used in the manufacture of certain biscuits, such as gingerbread nuts. At one manufactory two kinds of syrup were used for this purpose, Lyle's golden syrup for the better class of nuts, and another syrup (purchased through a merchant), the origin of which was unknown to the manufacturer, for cheaper kinds of nuts.

**Baking Powders.**—In biscuit and cake making these powders are made according to a variety of recipes. The ingredients are generally cream of tartar and tartaric acid, along with carbonate of soda or carbonate of ammonia, or frequently the two former substances are replaced wholly or partly by acid phosphates, which are much cheaper. It is occasionally the custom to sub-

stitute hydrochloric acid for tartaric acid in making puff paste and other articles for which rapid evolution of gas is required.

Frequently the necessary powders are added direct to the flour, without having first been made up into a baking powder. Baking powders containing acid phosphates, and sold under various names, such as "cream substitute," etc., appear to be not infrequently arsenical. A powder of this kind in use at a cake-maker's, collected by me and analysed by Dr. McGowan, showed 1.39th grain of arsenic per lb. Mr. Ballantyne, chemist of the Fisons Flour Company, informed me that he recently reported against a sample of phosphate supplied to him for making baking powder, which showed immediate evidence of arsenic with the Reinsch test. A large wholesale chemical manufacturer informed me that he had refused to quote for a cheap phosphatic baking powder on account of the considerable quantities of arsenic which in his view it was necessarily liable to contain.

**Egg Powders, Self-raising Flours, Cake Flours, Mustard Powder, etc.,** usually consist of baking powder of one or another kind, mixed with flour, and coloured commonly with saffron yellow.

Mr. Gatehouse, of Bath, informs the Commission, in his analyst's return, that some four years ago he found arsenic in a specimen of egg-powder. He suspected, however, that the origin of the arsenic might have been a pink aniline dye contained in the powder.

**Dextrin.**—I met with a particular biscuit made from flour to which is added 1 per cent. of a liquid solution of dextrin, made from German farina by the addition of hydrochloric acid.

#### Summary.

It is evident from the foregoing that in general the degree to which cakes, biscuits, and bread are liable to arsenical contamination may be regarded as small. Taking, for example, yeast containing as much as one-third of a grain arsenic per lb., it would be unlikely that 1lb. of bread made from it would contain in consequence more than 1.1000th grain of arsenic.

Assuming chemical substances (for example, phosphates or hydrochloric acid) used in baking to contain 1 grain of arsenic to the lb., cake or biscuits made with it would not be contaminated with more than about 1.100th grain of arsenic per lb. of finished product. Taking the proportion given above, where glucose was used in biscuit-making to the extent of 1lb. in 60lbs., and assuming that the glucose was contaminated to the extent of 1.10th grain of arsenic per lb., the quantity of arsenic which would reach the biscuits in this way would be 1.600th grain of arsenic per lb. of biscuits. A Bostock glucose containing 4 grains of arsenic to the lb. would in this case introduce no more than 1.15th grain of arsenic per lb. of biscuits. At the same time it is not unlikely that considerably larger quantities of glucose may be used than was stated to be the case at the works I visited.

If the glycerine used in cakes was as arsenical as some of the examples referred to in Section I., the degree of contamination would be more serious. In the extreme instance of glycerine containing 4 grains of arsenic to the lb. (such as found by Mr. Fairley in 1894), then, taking the proportions used at one of the works which I visited, 1.6th grain of arsenic might be introduced by this means into 1lb. of cake. On the other hand, quantities of arsenic such as those found by Dr. Campbell Brown in recent samples of glycerine (up to 1.13th grain per lb.), would not introduce more than 1.325th grain of arsenic to the lb. of cake.

It may be said in general that precautions against the introduction of arsenic in the ways above indicated are seldom taken by the manufacturers. In two instances I found that biscuit bakers using glucose at the time of the Manchester epidemic had caused their glucose to be analysed. With one exception, I heard of no instances in which baking powders, malt foods, or yeast had been examined for arsenic at the instance of the manufacturer, or were specifically required to be free from arsenic; but I understand certain firms in purchasing the ingredients for baking powders make a general stipulation that they should be "chemically pure."

Glycerine at one cake manufacturers was purchased direct from the makers as "confectioner's glycerine," and was guaranteed by the maker to conform to all the tests of the British Pharmacopoeia. I have not, however, met with any manufacturer who has suspected that any risk of arsenical contamination of his product arose from the use of glycerine. The information given by Mr. Moore, that glycerine is frequently sold without its origin being known to the purchaser, is important

## Appendix 24.

in this connection, and it would seem very desirable that the cake manufacturer should invariably take effective precautions to secure the absence of arsenic from all the glycerine which he uses.

## MEAT EXTRACTS.

For the purposes of this report, meat extracts may be classed under three heads, namely:—

- (a) Those prepared without the use of mineral acid.
- (b) Those in the preparation of which mineral acid is used, and
- (c) Extracts of foreign manufacture, the process of preparation of which does not appear to be known to the agents of the manufacturers in this country.

The large majority of meat extracts, such as the Bovril and Liebig Companies' products, Brand's Essence of Beef, Hippi, Mutton Essence, etc., come in the first category. Their manufacture in the first instance is commenced either in America or New Zealand. The extract is obtained by a process of treating fresh meat and water with gentle heat, e.g., 135° F., and evaporating. On arrival in this country the "extractum carnis," as it is called, is manipulated and converted into different finished products by varying treatment in the matter of concentration, dilution, addition of salt, and the like. None of these additions, so far as I have been able to ascertain, involve risk of introduction of arsenic, with the exception of glycerine, which is added to certain preparations, in one instance to the extent of 22.5 per cent. I learn that this is the view taken by Mr. Helmer, who is chemical adviser to various meat extract firms, and who has tested certain samples of meat extracts for arsenic, always with negative results.

Mineral acids are used in the preparation of certain meat extracts, particularly those which are called "peptones." These are made by treating meat extract with calf's pancreas and hydrochloric acid. The percentage of the latter is very small. At Messrs. Brand's I was informed that only 1 drachm is utilised for 40 gallons of the finished product. Messrs. Savory and Moore informed me that hydrochloric acid is used in some of their preparations, but the firm's representative objected to give me information as to the quantities employed, or as to the precautions taken with regard to the acid. He stated, however, that pharmacopoeial acid was used.

Mr. Beech (secretary of the Carnrick Company) informed me that a food called "Carnrick Liquid Peptonoids," made in America, consists of the albumen of meat, the albumen of wheat, and the digested caseine of milk. He further stated that the caseine was digested with hydrochloric acid, but he did not know in what proportions it was used, or what precautions were taken with regard to the acid.

Mr. Lewis (secretary to Messrs. Armour and Co.), informed me that no acid was used in the preparation of their extractum carnis, but was used in the preparation of "lactated pepsin," to the amount of about 1 per cent. He did not, however, know what precautions were taken with regard to the acid. Lactated pepsin, however, is more of a drug than a food.

Reference is made in "Allen's Commercial Organic Analysis," Vol. IV., p. 301, to a patent by Etienne and Delhay, 1890, of a process by which the residue, after the liquid meat extract has been removed, is pressed and treated in the water bath with an equal weight of concentrated hydrochloric acid, in order to disintegrate the fibro-muscular tissue. The liquid is filtered, neutralised with sodium carbonate, and mixed with the extract first obtained. It is evident that if an arsenical acid were used in this process the finished product might contain notable amounts of arsenic. Mr. Helmer informs me, however, that hydrochloric acid is not used in this way to prepare meat extracts in this country.

As regards certain other forms of meat extract, I found that the process of manufacture was unknown to the English representatives on whom I called. These substances included "carnigen" and "somatose," and Valentine's meat juice.

It would seem, therefore, that meat extracts, concerning which I was able to get information, may be considered practically free from liability to arsenical contamination. In the few instances where I met with the use of hydrochloric acid, the quantity was so small that the employment of even highly arsenical acid would introduce only an infinitesimal quantity of

arsenic to the finished product, and as a matter of fact at the two English firms I visited I was informed that the acid used was British Pharmacopoeia acid. I did not hear of its being tested at Messrs. Savory and Moore's, but at Messrs. Brand's I was informed that the acid was guaranteed chemically pure, and subsequently to my visit a sample was analysed and reported to be free from arsenic.

As regards glycerine, however, it is evident that when such large quantities at 22½ per cent. are used, a serious degree of contamination by arsenic might arise if a highly arsenical glycerine were employed. As a matter of fact, at the Bovril Company, where this amount of glycerine is used in "Caffyn's Liquor Carnis," the glycerine is guaranteed to conform to Pharmacopoeial test. The validity of this guarantee is not, however, checked by analysis.

## CARNOS.

This is a food that has lately been advertised as a substitute for beef tea and for making soups.

I visited the factory (November 9th, 1901), at Grimsby, where I was informed by Mr. Overbeck, the manager and inventor of the process, that Carnos is made from six parts of yeast and one of malt culms. These substances are mixed with water and mashed, so as to enable the diastase in the malt culms to act upon the yeast. The resulting liquor is roughly filtered, boiled in a copper for three hours, filtered through filter presses, concentrated in vacuo, and then finally filtered. No mineral acid or other chemicals, except glycerine, are used in its preparation.

At the date of my visit I had obtained from Dr. McGowan the result of his analysis of a sample of Carnos, which I had purchased through a druggist in July, 1901. This sample contained 1.25th grain of arsenic per lb. There seemed little doubt that the arsenic was derived either from malt or yeast, or both.

Mr. Overbeck stated that the yeast employed is obtained from a neighbouring brewery, and the malt culms either from the maltings of that brewery or from elsewhere. At the time when the liability of malt to contain arsenic became known, the brewery in question was using malt obtained from Mr. Soames, of Grimsby, and dried over gas coke. Malt sold by this firm shortly after the 1900 epidemic has been described by Mr. R. G. Tomson, of Threlfall's Brewery, Manchester, as producing beer which had to be destroyed on account of arsenic (3094-3099). It came to Mr. Overbeck's knowledge that carnos contained an appreciable amount of arsenic, and he informed me that he took prompt measures to call in as much as he could of the carnos he had on sale at the time, and to guard against contamination in its further manufacture. After experimenting, he adopted the plan of adding to the boiling copper a solution, as I gather, of sulphuretted hydrogen in glycerine, the efficiency of this process being tested by placing two large squares of copper in the boiling vat. Mr. Overbeck claimed that if any arsenic remained unprecipitated, these strips would show a coating of arsenic. The brewery is said now to use malt dried over anthracite, and the malt culms purchased are also obtained from anthracite-dried malt.

I did not see this process in operation, as no carnos was actually being made at the time of my visit. Mr. Overbeck gave me, however, a sample of carnos (November 9th, 1901), in the preparation of which the above treatment had been applied. In this sample Dr. McGowan has found almost exactly the same amount of arsenic as was present in the sample purchased in July, 1901, which, according to Mr. Overbeck would not have been so treated. A further sample of carnos obtained from a druggist on May 14th, 1902, has been found by Dr. McGowan to contain a little over 1.6th grain of arsenic per lb.

In view of these results, I wrote on July 10th, 1902, to Mr. Overbeck, asking whether he had made any modification since my visit in 1901 in his method of treating the liquor to free it from arsenic. I also asked for a sample of the glycerine solution added for the purpose. In reply, Mr. Overbeck wrote on July 12th that he hoped I would not press him for further information, as the method he employed was a "trade secret."

If a liberal quantity of carnos was used to make soup or beef tea, say, 1oz. to the pint, and the carnos contained 1.6th grain arsenic per lb., the beef tea would be contaminated to the extent of 1.12th grain of arsenic per gallon. I have not heard of any foods or extracts

on the market, other than carnos, which consist largely of yeast. But I understand that the utilisation of yeast as a basis for prepared food has lately been receiving considerable attention.

#### CEREAL FOODS.

I have made some inquiries as to cereal foods, with a view to ascertain how far mineral acid or other substances liable to contain arsenic are used in their preparation. I did not hear of such ingredients being used in the majority. Ordinary flour, Hovis flour, Quaker Oats, Ridge's Food, for example, are essentially milled flours. Some are also torrefied by dry heat, and some are treated by super-heated steam.

In the preparation of cornflour by one manufacturer, I was informed that soda lyes are added to get rid of the gluten, which is thus caused to float on the surface of the liquor from which it is skimmed off, the process being much the same as in the preparation of washing starch. To correct this alkalinity of the liquor, either sulphuric or hydrochloric acid is added, but the quantity employed was said to be in any case very small, although varying according to the alkalinity of the solution, generally about one or two teaspoonfuls to the vat being used. The acid in this instance was not guaranteed, nor had it been tested as regards arsenic.

The chemical substances which may be added to "self-raising" flour have been above alluded to.

I have been unable to obtain information as to the method of manufacture of a number of prepared cereal foods, such as shredded wheat, cream of wheat, etc., which are imported principally from America. Mr. Heron, who has made special study of starch foods, informs me that he has no reason to believe that substances liable to contain arsenic are used in their preparation.

#### FOODS IN WHICH MALT IS AN INGREDIENT.

##### MALTINE AND MALT EXTRACTS.

There are several varieties of maltine and malt extracts on the market.

- (a) French or German Extracts.
- (b) American Extracts.
- (c) British-made Extracts.

(a) I could obtain very little information as to French and German maltine, except that it was chiefly used by bakers as a yeast food, but I could learn nothing as to its manufacture.

(b) A large portion of the "maltines" or "malt extracts" which are sold by druggists in this country is of American manufacture. They are imported chiefly by the Maltine Manufacturing Company. I could obtain no information at the London offices of this company as to the process of manufacture of the malt, or as to the method of kilning or fuel used.

(c) *British-made Malt Extracts.*—I went over the works of three of the largest manufacturers of malt extract in this country. At the first they make all their own malt over specially small, hand-picked anthracite. At the second the malt is bought, but in each instance is now analysed before being used. At the third malt is specially malted for them, and it is stipulated that any malt purchased should be made over anthracite. At the time of my visit at one of the works the test used was Reinsch, which the chemist claimed would detect the presence of 1-100th grain per lb. in the malt. At another works I found samples of both the malt and the finished product had been sent to a public analyst since the Manchester epidemic, and had always been returned as free from arsenic. At the third place I was told they used a Reinsch test, but the degree of delicacy was not stated.

##### *Presence of Arsenic in Malt Extract.*

From the returns of public analysts to the Commission, I find only three had examined maltine or malt extracts at the date of their return, but none of them report any arsenic. Mr. Goodfellow informed me that out of 13 samples of malt extract for bakers' purposes examined by him, two contained arsenic, but he has not furnished me with particulars of quantities. The presence of a small amount of arsenic in maltine had been recognised in a sample tested by the chemist of Messrs. Allen and Hanbury's, early in 1900, but here again the quantity is not available.

The proportions of malt which may be used in making malt extract differed at the various firms. In one instance it was calculated that approximately 2lbs. of malt entered into 1lb. of extract, so that supposing the malt were contaminated with arsenic to the extent of 1-100th grain per lb. of malt, about 1-50th grain of arsenic per lb. of extract might be introduced.

Mr. Free (Messrs. Edmé) suggested that if arsenic were present in the malt it might be removed from the finished article by the process of repeated filtration adopted at his works. At Messrs. Burroughs and Wellcome I was also informed that some observations had been made which suggested that, weight for weight, malt extract may contain less arsenic than the malt it is made from. Mr. Dodd, of Allen and Hanbury's, had made a similar observation in one instance. I do not think, however, that this could safely be accepted without more extended experiment.

Malt extract being made from malt wort, I have no knowledge of any other source of arsenic but the malt: the only extraneous substance used being a small amount of dextrin.

Although Maltine and malt Extracts are known rather as a drug than as a food, they are consumed in considerable quantity over long periods by many invalids.

##### OTHER MALT FOODS.

The proportion of malt used in foods such as "Allen and Hanbury's Food," "Hovis Malted Food," "Horlick's Malted Milk," "Grape Nuts," etc., is smaller than in the case of maltine, but it must be remembered that some of the foods in question are habitually consumed in large quantities as an ordinary article of diet, especially by children and invalids.

Messrs. Allen and Hanbury make a "Malt Food" by the addition of malt extract to flour; The Hovis Flour Co. make a malted food which is essentially a dried and ground wort obtained from malt and raw grain. At both places I found that precautions were being taken to obtain malt free from arsenic. At the Hovis Company a sample of each consignment of malt purchased is now analysed by the firm's chemist, and the finished product is also tested for arsenic. I visited Messrs. Savory and Moore, who also manufacture a malt food, but I was informed by Mr. Eykin that his firm preferred to withhold all information on the ground that their processes are "secret."

Mellin's Food also comes in the category of foods which are essentially dried worts. Rather more than half the ingredients of the wort consist of malt. The malt here is bought from a maltster, who furnishes a guarantee that it is free from arsenic. It had not, however, been analysed for the firm.

In the manufacture of an American product called "Grape Nuts," a dough is made from malt and wheat flour, and then specially cooked and ground.

In another American product, "Horlick's Malted Milk," 25 per cent. of malt is mixed with a similar amount of wheat flour, and added to 50 per cent. of the solid constituents of milk.

There are, no doubt, other foods on the market in which malt is an important ingredient. The use of malt as a food appears to be on the increase, particularly in America.

I have not been able to ascertain the nature of the precautions against arsenic, if any, taken at American maltings supplying malt for this purpose, except that my informants doubted if anthracite was used on account of the price.

In a communication from the Postum Cereal Co., however, I have had a copy of a letter from the American Maltine Co., Chicago, in which it is stated that "malt is dried with best anthracite coal absolutely free from smoke," the fumes being drawn through the malt with a fan. The letter further states "We have never heard of any case of arsenical poisoning in this country caused by malt."

From a letter from Mr. Ling, I gather that malt in America is made in the older malt-houses on floors through which the products of combustion pass on to the malt, and in some of the newer kilns in pneumatic drums; also that the fuel is anthracite, "pea coal," or "coke," and special care is taken to add fuel in small quantities at a time in order to reduce the smoke production to a minimum. In many parts of the States the price of anthracite would be prohibitive.

## Appendix 24.

## FOODS PREPARED FROM MILK.

In foods of this nature an acid is added to precipitate caseine which forms the bulk of the food.

In some foods consisting wholly or partly of milk caseine (e.g., plasmon), the precipitant of the caseine is acetic acid, and it appears unlikely that arsenic would be liable to be introduced in the process of manufacture.

The Plasmon Co. informed me that both the acetic acid and the bicarbonate of soda used by them are guaranteed to be free from arsenic, and are tested at their works in Germany, where the bulk of their products are made. Lately I hear they are opening a works at Cork.

"Casumen," like plasmon, consists mainly of milk caseine. It has lately become extensively used as an invalid diet, and as an infant food. It is also made up with cocoa, chocolate, and biscuits, and is recommended for mixing with flour for baking. The precipitant employed is sulphuric acid, 1 pint of concentrated acid being employed to precipitate the caseine of 100 gallons of separated milk. It is reckoned that from 550 gallons of milk about 340 lbs. of caseine are obtained in this way. Before being dried and made into the finished product, this caseine is washed to free it from all trace of acid, dissolved in a solution of carbonate of soda, and re-precipitated by acetic acid. It is probable that these after-processes would remove a considerable portion of arsenic if any were introduced by means of the sulphuric acid.

The management are aware of the danger of the acid being contaminated with arsenic, and take the following precautions:—The sulphuric acid is bought from two firms, both of which guarantee the acid free from arsenic, and one guarantees that it is made from brimstone. The guarantees bore date March and May, 1901. The sulphuric acids have also been analysed by an independent chemist, and are pronounced by him to be free from arsenic.

## VINEGAR.

Vinegar is to be regarded as liable to contamination by arsenic. Professor Campbell Brown and two other public analysts mention this liability in their returns to the Commission; Mr. Low, Public Analyst of Chester, mentions a sample of vinegar in which he found 1·25th grain of arsenic per gallon. I have also been informed by vinegar manufacturers that arsenic in quantities not stated has been found by several chemists in different samples of vinegar. The occurrence of arsenic in vinegar is referred to in Allen's Commercial Organic Analysis, Vol. I., p. 475.

Mention has been made to the Commission of arsenical poisoning, attributable to vinegar among the Artillery at Hillsea three or four years ago. This, however, is believed to have been due to the intentional addition of arsenic, which was present in enormous quantity in the vinegar (Hooper, Q. 7899).

It is possible that arsenic may gain access to vinegar in several ways—from the use of arsenical malt or sour beer; of arsenical sulphuric acid, used to "convert" raw grain for vinegar making; possibly also from use of arsenical glucose or caramel; of arsenical acetic acid; or from the direct addition of arsenical sulphuric acid. Taking these seriatim:—

**Malt.**—The proportion of malt to total materials used in making "malt vinegar" varies. I saw two manufacturers of "malt vinegar," for instance, who used practically all malt, while another used no more than 1·5th malt.

As regards the total amount of materials relative to the vinegar produced, I was informed by Messrs. Pott and Norbury, who are large vinegar makers, that a usual quantity would be 336 lbs. of material to produce eight barrels (288 gallons) of best vinegar. After eight barrels of wort have been drawn off to be fermented into best vinegar, the residue in the mash tun is used along with fresh material for a further mash, producing, when fermented, a vinegar of less strength.

I found that since the Manchester epidemic, in four instances, the malt was being purchased with a guarantee from the maltster of its freedom from arsenic. By three of these manufacturers samples of malt were occasionally sent to be tested for arsenic, or were tested by the firms' chemist. At Messrs. Beaufoy's samples of malt are systematically tested both before and after purchase: malts here having been rejected which, by the Marsh test, showed more than about 1·50th gr. of arsenic per lb.

On the other hand, four other manufacturers of malt vinegar at the date of my inquiry were not requiring guarantees as regards malt, or causing it to be tested for arsenic. One of these stated that so little malt is used in his malt vinegar that such a precaution is unnecessary.

Three of the vinegar brewers whom I visited made their own malt; the first dried his malt with anthracite, and did not test for arsenic; the second used a special process for making malt suitable for vinegar, which does not appear to occasion risk from arsenic; the third used a mixture of anthracite and gas coke, and did not test his malt for arsenic.

**Sour Beer.**—I have met with only one vinegar brewery in which sour beer is employed, although I understand it is frequently used. At the brewery in question about 1·10th of the total output of vinegar is derived from sour beer. Here the beer was being tested both in sample and during delivery, and I gathered that sour beer showing more than 1·50th of a grain of arsenic per gallon would be reported against by the works chemist, but that none had been found to contain this quantity.

**Raw Grain "Converted" by Mineral Acid.**—Various other grains besides malt are used in vinegar-making, such as barley, oats, maize and rice in proportion varying, for example, from 1·5th malt to 4·5th of other grain, to 2·5th malt to 3·5th other grain.

These grains are usually mashed without preliminary treatment. At certain works, however, it is the custom to convert the grain (rice or maize grits) into glucose by means of sulphuric acid and steam pressure in converters, and subsequent neutralisation with lime and filtration. It is stated that the process of conversion is not carried so far as is the case in brewers' glucose.

According to data supplied to me by two firms, A and B, who use converted grain, sulphuric acid may be employed in the conversion process to the extent of 3 per cent. of the grain used. One lb. of converted raw grain would go to the gallon of finished vinegar, 0·03 lb. of sulphuric acid being employed in the production of each gallon of vinegar.

An arsenical acid such as Nicholson's, containing 1·5 per cent. of arsenic, in this case might introduce 3·15 grains of arsenic to the gallon of vinegar.

At the works of firm A, since the Manchester epidemic, sulphuric acid has been purchased with a guarantee of freedom from arsenic, and each consignment has been tested by the firm's chemist, who uses a Gutzeit test. At Messrs. B's the acid used is purchased as "Best Brimstone Acid," and is now regularly tested by their own chemist at their works, who uses a preliminary Marsh test, and subsequently applies a more delicate Marsh-Berzelius test to specimens which have passed the preliminary test. He informed me that he had always found the amounts demonstrated by the Marsh-Berzelius test sufficiently small to be neglected.

**Molasses, Glucose, and Caramel.**—Glucose appears to be seldom used in the manufacture of vinegar. I heard of its use at one works only, and there it had been abandoned for some time. Caramel is largely used in colouring certain classes of vinegar, but in quite small quantities. It was usually understood by the manufacturer to be made from pure cane sugar; three vinegar brewers whom I visited had caused samples to be analysed for arsenic after the epidemic of 1900, but with negative results.

Molasses may be used to make vinegar, and I note in this connection that one firm of vinegar makers informed me that recently they had found arsenic in their vinegar (quantity not stated), which had been traced back to the molasses used.

**Acetic Acid.**—A certain class of vinegar consists of dilute acetic acid coloured with caramel, and flavoured with essences, and sold as "vinegar" or "wood vinegar." Much imported vinegar is of this nature. Acetic acid is sometimes added to ordinary vinegar to fortify it. As indicated in Section I., however, the liability of acetic acid to contain arsenic appears small.

**Direct addition of Sulphuric Acid to Vinegar** is, or was, considered a permissible practice. In "Allen's Commercial Organic Analysis" (3rd Ed., Vol. I., page 472), it is stated that the amount of one gallon of acid to 1,000 gallons of vinegar (or 1·85 per cent. by weight of sulphuric acid) "was permitted by an excise regulation."

I have not met with any vinegar brewery at which free sulphuric acid was added, and I was everywhere informed that the practice is not now at all common.

An arsenical acid such as Nicholson's, containing 1·5

per cent. of arsenic, if added in the proportions above given, as considered "permissible," would contribute 1.9 grain of arsenic to the gallon of vinegar.

**Distilled Vinegar.**—A certain class of vinegar is distilled before sale in steam jacketed stills. If arsenic were present in the original vinegar it is claimed that none would come over at the temperature of distillation.

**Tests applied to Finished Vinegar by the Manufacturer.**—As above indicated, certain of the manufacturers visited have adopted since the Manchester epidemic a more or less thorough system of testing their malt and sulphuric acid (if used) for arsenic, and as a rule these manufacturers also from time to time look for arsenic in their finished product. Several other manufacturers, however, at the dates of my visit, had taken no precaution as regards either ingredients or finished product. At the latter manufactories the vinegar was in each instance made from malt, and a proportion of other ingredients, but no sulphuric acid was employed. One large firm of vinegar brewers inform me that since my visit they have undertaken systematic examination of ingredients and product for arsenic.

#### FOODS IN WHICH COLOURING MATTERS ARE USED.

I have made inquiries as to a few food substances in which colouring matters, mineral or other, such as those referred to in Section I., are employed, with the object of ascertaining what degree of contamination of these foods by arsenic might arise, assuming an exceptionally arsenical pigment were used; and, further, to ascertain what, if any, precautions against arsenic were taken by manufacturers using these pigments or by the manufacturers of the pigments themselves.

Upon the whole it would seem that the quantity of colouring matter which would enter into a pound of a given substance is relatively small, so that a large amount of arsenic in the pigment would involve the introduction of a comparatively minute quantity of arsenic into the finished product.\*

For example, as regards materials in which *mineral colouring matters*, such as oxide of iron or Armenian bole, are used. From a report of the Departmental Committee on Preservatives and Colouring Matters in Food, it appears that these substances are used, *inter alia*, in the preparation of anchovy sauce, paste and essence; bloater and shrimp paste; cocoa; certain sweets, particularly burnt almonds; sausages and potted meats.

Assuming for convenience 1 grain of arsenic per lb. in the mineral pigment\* (approximately the amount found by Dr. McGowan in a sample of Armenian bole obtained at a London store), the following calculations may be made:—

**Anchovy Sauce.**—Proportion of Armenian bole (London stores), 10 per cent.; (provision manufacturer), about 5½ per cent. Taking the larger quantity, this would mean 1.10th grain of arsenic per lb. of sauce.

**Sweets.**—Proportion of ferruginous earth, 56 grains to the lb. (Cassal, Departmental Committee, 3847): this would mean 1.125th grain of arsenic per lb. of sweets. Proportion of oxide of iron 35 grains per lb. of burnt almonds (Fisher, Departmental Committee, Q. 4780). This would mean 1.200 grain of arsenic per lb. of sweets.

**Sausages and Potted Meats.**—The quantity of Armenian bole or other pigments used in these substances is determined by personal preference. The large number of recipes for sausages and potted meats in "Douglas Encyclopedia on Hog Products" seldom mention the quantities of colouring matters recommended, and there can be no doubt that they are often used in an entirely haphazard way.

Taking the largest proportion of any colouring matter which is mentioned in the above encyclopedia, namely, 2½ ozs. to 15 lbs. of "sausage meat," this would mean 1.96th grain of arsenic per lb. of sausage, on the basis of 1 grain of arsenic per lb. of mineral colour.

At the same time I may note that it is possible that a larger quantity of bole Armenia may at times be added; that it is possible that the pigment in question may occasionally contain more arsenic than the sample casually obtained from the stores, and that the distribution of the colour in the sausage may not be uniform.

As regards materials in which the innumerable varieties of "coal tar colours" are used, such as jam, sweets, table jellies, egg and cake powders, coloured

syrups and temperance drinks made from them, sausages, potted meats and hams, it is well perhaps to make special references to those food substances in which the colouring matter may be a magenta dye, in view of the large amount of arsenic which has been found in certain magentas (Section I.). Assuming one of the highest quantities reported in magenta, 6 per cent., then the following amounts might be contributed to:—

**Jam.**—Mr. Boseley (Departmental Committee, Q. 1063) states that at Messrs. Keiller's magenta in red jam would not exceed 1 part in 75,000; this would mean .0057 grain (approximately 1.180th grain) of arsenic per lb. of jam.

**Sweets.**—According to the same witness the largest proportion of colouring matter in sweets is (in certain lozenges) 1 part in 2,500. This would mean .18 grain (nearly 1.5th) arsenic to a lb. of such sweets.

**Sausages and Hams.**—Magenta colours appear to be used in these substances, but I have not been able to ascertain the proportions. They are said to be mainly used to colour the outside skins, but they are also used to colour the sausage meat.†

I am unable to make corresponding calculations with regard to "coal tar" colour other than magenta, as I have no knowledge of the exact quantities of arsenic which may be found in them; it may, I think, be safely assumed that none are likely to approach the exceptional amount above taken in the case of magenta. Evidence as to the extremely minute quantities of coal tar colours used in foods was given by witnesses to the Departmental Committee. (See, e.g., Appendix VIII. of that Committee's report in Tables P, Q, and R.)

**PRECAUTIONS AGAINST ARSENIC BY MANUFACTURERS COLOURING FOOD SUBSTANCES.**—Manufacturers of food using colouring matters in some instances take precautions with the object of ensuring purity of their colours. These precautions, as taken at jam and confectionery firms which I visited, consist in obtaining a guarantee from the colour manufacturer that his colours are "harmless and suitable for confectionery purposes"; such guarantees are sometimes given on the authority of well-known analysts. I gathered from Mr. Hehner, who acts as consulting chemist to many colour manufacturers, and from Mr. Goodfellow, who is chemist to the Confectioners' Association, that in regard to arsenic the estimate of harmlessness and suitability for food purposes is made with due regard to the small proportions in which these colours are used in foods. Mr. Goodfellow, for example, assured me that I should be surprised to learn how much arsenic he permitted in dry colour submitted to him, adding that he was satisfied that by the time that the dry colours had been diluted for use by the sweet manufacturer, and by the time that this diluted colour had been added to a large bulk of confectionery, the arsenic would not be detectable by the most delicate tests when applied to quantities usually employed for analysis. Mr. Goodfellow promised to send me precise data on this point, but they have not as yet come to hand.

After the Manchester epidemic certain large firms of confectioners required that "freedom from arsenic" of the colours supplied to them should be specifically guaranteed. I gather, however, that the colour manufacturer, for reasons above indicated, prefers that the form of guarantee should be restricted to "harmlessness for confectionery purposes."

One or two firms that I visited took the additional precaution of checking these guarantees by the occasional taking of samples; several, however, including some very large manufacturers, were content with the guarantee alone.

At three large manufactories where Armenian bole is used to colour anchovy preparations, no guarantee of the purity of the colour was required, and the manufacturers had no knowledge of the liability of the substance to contain arsenic.

Similarly with regard to the use of Armenian bole, and, indeed, colouring matters of all kinds, in meat preparations, I have been informed alike by a colour maker, a colour seller, and a colour user, that it is never the practice of the meat trade to require any guarantee of purity of the colours used, or to have the colours analysed. These colours are frequently procured at shops where sundry butchers' requisites are sold. At these shops the colour is obtained from middlemen without guarantee of purity.

\* As to later information given to the Commission on arsenic in mineral and coal tar colours, see McGowan (Appendix 25) and Hehner (Appendix 27).—H.H.S., July 1903.

† Magenta is used in preparation of catsup and chili sauce.—"Food Journal," July 1902, page 153.

## Appendix 24.

I visited an important firm of colour makers, whose practice is to take considerable care to secure that colours for food purposes are, in their chemist's view, practically free from arsenic; those which are reported arsenical being put aside for textile purposes. They stated, however, that in selling colours to middlemen they had often no knowledge of the purposes for which these pigments are required, and naturally they would accept no responsibility if ultimately such colours were rejected as unfit for food purposes. To their knowledge middlemen also obtain colours from other firms than themselves without asking for or receiving a guarantee of purity. This was confirmed by a firm of colour sellers; the colour is ordered from them without specific mention of the use to which it is going to be applied; no guarantee is asked for either by consumer or by the merchant from the maker.

I have referred in Section I. to evidence that *caramel* may occasionally be considerably contaminated by arsenic, and to the fact that its liability to be arsenical does not appear to be so generally recognised as that of glucose. The quantity of caramel used in any given article of food is so small that the amount of arsenic which might in this way be introduced per lb. of a given product would be extremely minute; nevertheless it is worth remembering that this colouring matter is used in a very great number of food substances, and is employed for many purposes in domestic cooking.

## FOODS IN WHICH PRESERVATIVES ARE USED.

The chief preservatives in regard of which question of arsenic arises are borax and boric acid, the liability of which to contain arsenic has been dealt with in Section I.

The report of the Departmental Committee on Preservatives and colouring matters in food shows that borax and boric acid, or mixtures of these two substances, are added to milk, cream, butter, sausages, and potted meats; they are also used for dusting over or making pickle for bacon, ham, fish, jam, etc. Solutions may also be injected into the substance of the bacon or ham.

I note from the same report a few instances in which boric acid preservatives have been used in considerable proportions.

*Milk*.—"Boric acid equivalent to 80 grains of borax per pint." Dr. Wynter Blyth (Q. 3439).

*Milk*.—"126 grains boric acid per gallon. Dr. B. Hill (Q. 2534).

*Cream*.—"56 grains boric acid preservative per lb. Otto Hehner (Q. 5584).

*Butter*.—"91 to 93 grains boric acid to the lb. Mr. Jones (Q. 1322).

*Butter*.—"17.4 to 47.6 grains of borax per lb. Dr. Still (Q. 6814).

*Butter*.—"3 per cent. or 210 grains boric acid per lb. Trengrouse (Q. 678).

*Sausages (German)*.—"Nearly  $\frac{1}{2}$  per cent. (35 grains per lb.) reckoned as boric acid. Fisher (Q. 4717).

*Sausages, Polony, etc.*—Up to 58.8 grains per lb. of a powder containing 93 per cent. boric preservative, estimated as boric acid recommended by the trader (Government Laboratory Table H, page 60).

It is unnecessary to give instances of the quantity of these preservatives for dusting or pickling, as the amount remaining in the food is necessarily uncertain.

It should be noted that the Committee recommended that the use of preservative in milk should be constituted an offence under the Sale of Food and Drugs Acts, and that as regards cream, butter, and margarine, boron preservatives should be restricted respectively to .25 per cent. and .5 per cent. in terms of boric acid. How far these recommendations have led to diminution in the use of boron preservatives in these substances I am unable to indicate; reports of their detection in considerable quantities in milk and butter continue to be reported from time to time.\* The Committee did not recommend restrictions in the amount of boron preservatives added to sausages, potted meats, etc. Considerable quantities of such preservatives are from time to time reported, e.g., in July, 1902, a case was reported of potted shrimps containing 41 grains of boric acid to the lb.

Taking a few instances of food containing exceptional amounts of boron preservatives, and assuming in each instance  $\frac{1}{4}$  grain of arsenic to the lb. of preservative (an amount which appears not infrequently to be present in commercial borax), then:—

Milk receiving 80 grains of borax per pint would contain about 1.44th grain of arsenic per gallon; that receiving 126 grains preservative per gallon would contain about 1.222d grain of arsenic per gallon.

One lb. of cream receiving 56 grains of preservative would contain 1.500th grain of arsenic.

One lb. of butter receiving 210 grains of the preservative would contain 1.133rd grain of arsenic.

One lb. of potted shrimps receiving 95 grains of borates per lb. (see "Times" report, November 10th, 1901), would contain about 1.300th grain of arsenic per lb.

Professor Delepine (Appendix to Evidence, Table XI), informed the Commission that he found 1.100th grain of arsenic per lb. in potted German shrimps.

It will be noted that in the above calculations, even when instances are taken in which these preservatives are used in exceptionally large quantity, the amounts of arsenic are small. But it must be remembered that they are based upon an amount of arsenic stated to be commonly found in commercial borax, not upon exceptionally arsenical samples.

Preservatives are usually obtained by milkmen, butchers, and sausage-makers, without any guarantee as to their purity.

Bi-sulphite of lime is added as a preservative to beer, cider, lime juice, etc., and is used as a meat preservative. The evidence, however, that bi-sulphite may contain material quantities of arsenic is meagre, and the quantity of this preservative which enters into the finished article is relatively small.

\* On July 3rd, 1902, Ernest White, at Bournemouth, was convicted of selling milk with 112 grains boric preservative per gallon ("Food Journal," July, 1902, page 161), and at Woolwich, on September 17th, 1902, a milk seller was fined in respect of 120 grains boracic acid per gallon of milk (September 18th, 1902).

## SECTION III.

Appendix 24.

## FOOD SUBSTANCES DRIED BY EXPOSURE TO THE PRODUCTS OF COMBUSTION IN THEIR RELATION TO ARSENIC.

In inquiring under this head, I visited several firms in London, Bristol, Hull, and other parts of Yorkshire. My object was to ascertain what foods, if any, are dried, like malt, by exposure to the fumes of fuel liable to contain arsenic, and to inquire what in each instance was the nature and duration of such exposure.

## SMOKED FISH AND MEAT FOODS.

The trade term "smoked," applied to articles such as bacon, ham, red and kippered herrings, Finnan haddocks, smoked salmon, smoked sausages, appears to be almost wholly restricted to those which are exposed for longer or shorter periods to the fumes of wood fires.

In all places visited I found that such smoking was being carried out over a smouldering fire of wood shavings, or more commonly sawdust (chiefly oak-dust), in almost closed chambers of varying size.

## DRIED FISH AND MEAT FOODS.

Bacon, ham, bloaters, etc., may also be what is termed in the trade "dried," and not smoked. In some instances (e.g., some kinds of ham), the food after drying received no further treatment from the curer; in others (e.g., some kinds of red herring), drying is a preliminary to smoking by wood.

As regards these drying processes:—

Ham and bacon may be dried without artificial heat, being merely hung up in the air; or the more modern method may be followed, of hanging them in well-ventilated rooms or chambers, specially constructed for the purpose, and warmed by hot water pipes, or by stoves, the fumes of which do not pass through the chamber.

Drying may also be effected by exposure to fumes of gas coke fires. Some firms visited had abandoned this method of drying, and adopted the hot air chamber; others used coke only exceptionally, when it was necessary to dry as many articles as possible in a short time. Some of the larger firms visited, however, dried exclusively over coke. Where this is done the hams may be hung in large chambers—as at one firm visited, where the chamber is a low building about 15 ft. square, in which the hams hang about 8 ft. above a large open brazier for about 48 hours. Sometimes, as at Bradford, a smaller chamber, like an ordinary smoke-hole, is similarly used. At a large drier's in Yorkshire the hams are hung in tiers in a separated portion of an old barn. The coke was placed in a brazier under the hams, the nearest tier being about 6 ft. from the fire. The duration of the drying varied according to the weather

from two to four days. Hams thus treated are usually mild-cured American hams, to which the coke is said to impart a suitable flavour. Some of these hams were afterwards smoked over wood. English York hams, at one Yorkshire firm visited, were always dried over coke, and were not subsequently smoked.

Herrings, red herrings, and kippers appear to be smoked over sawdust fires; it is said that coke is of no use for this purpose.

Bloaters in London and Yarmouth are usually dried over hard wood fires. According to information kindly supplied to me by the Public Health Department of the London County Council, at 46 out of 60 small fish shops in London, where bloaters were made for sale on the premises, wood was chiefly used, and at the large wholesale establishments in London which I visited this was also the case. A few small London shops dry bloaters over gas coke, especially in the winter, and gas coke drying is in general use throughout Yorkshire.

I visited several smoking and drying establishments in Hull and Bradford. The size of the drying chambers and the duration of the drying varied considerably. As a rule, the bloaters hang in tiers, the lowest tier being about 8 ft. from the fire. The ventilation of the chamber is regulated by Venetian shutters near the roof. From 6 to 18 hours are the ordinary limits of exposure to gas coke fumes. Occasionally, however, the time is considerably greater. A fish-curer at Bristol informed me that bloaters might be left a week in the curing-room pending their sale, and that if unsold at the end of the week they would be smoked over sawdust and sold as red herrings.

As regards the extent of arsenical contamination to which ham or bloaters thus dried over coke may be considered liable, it is impossible to make any positive statement in the absence of a sufficient number of experiments in which drying has taken place under varying conditions of temperature, length of exposure to the fumes, and the amount of ventilation, in instances where the fuel used is gas coke, known to contain considerable proportions of volatilisable arsenic. *Prima facie*, it would seem unlikely that the degree of contamination possible in the case of these dried foods would approach that to which malt is liable, for the reason that in proportion to bulk the surface exposed to the products of combustion is much less than in the case of malt. Moreover, the arsenic would be deposited on the skin of the ham or bloater, and is therefore not likely to be eaten.

Number of Sample.	Date of Collection.	Nature of Sample.	Origin.	How Smoked or Dried.	How long Smoked or Dried.	Nature of Sample Examined by Dr. McGowan.	Quantity of Arsenic in Grains per lb.	REMARKS.			
I.	14th June 1901.	Ham - - -	Messrs. Maconochie Bros.	Coke and sawdust.	Coke, 48 hours. Sawdust, 12 hours.	Liquor in which the ham was boiled. Ham skin -	No appreciable amount. '0025 grain per lb.	Examined 7th Nov. 1901.			
II. (a)	7th April 1902.	Bloaters from top tier of coke room.	Mr. H. Moody, Hull.	Coke	5 hours	Skin - -	'0016 grain per lb.		Examined when mouldy.		
(b)	7th April 1902.	Bloaters from lowest tier of coke room.				Skin - -	'002 grain per lb.	Examined when mouldy and decomposing.			
III. (a)	7th April 1902.	Bloaters from top tier of coke room.	Messrs. Tether & Son, Hull.	Coke	10 hours	Skin - -	'0047 grain per lb.	Examined when considerably mouldy.			
(b)	7th April 1902.	Bloaters from lowest tier of coke room.				Skin - -	'0015 grain per lb.				
IV. (a)	7th April 1902.	Bloaters from top tier of coke room.	Mr. Hodman, of Hull.	Gas coke	15 hours	Flesh - -	'0019 grain per lb.	Examined fresh.			
(b)	7th April 1902.	Bloaters from lowest tier of coke room.				Skin - -	'0009 grain per lb.				
						Flesh - -	'0006 grain per lb.				
						Skin - -	'0023 grain per lb.				
V. (a)	8th April 1902.	Bloaters from top tier of coke room.	Messrs. Fletcher, Bradford.	Coke	18 hours	Skin - -	'005 grain per lb.	Putrifying; not much mould.			
VI. (a)	8th April 1902.	Bloaters from top tier of coke room.	Messrs. Hibbert, Bradford.	Coke	18 hours	Skin - -	'007 grain per lb.	Putrifying; not much mould.			

Appendix 21. The above tables show the results of analysis of a few samples of ham and bloaters which were being dried over coke at the time of my visit, or had just been so dried. It will be observed that the quantities of arsenic in the skins is in no case large, the highest (Sample VI. (a)) being 1-140th grain per lb. In the case of the bloaters the small amount of arsenic in the skins appears to bear some relation to the number of hours the fish were exposed to the fumes of the coke.

In the case of the bloaters in which the flesh was examined, the highest quantity of arsenic determined was 1-350th grain per lb. I should add, however, that I have no knowledge of the amount of volatile arsenic in the gas coke used in drying these samples.

It would seem from the evidence which the Commission has received from Mr. Ling and others, that the possibility of arsenical contamination of dried foods would be largely diminished if it were made a practice to add milk of lime to the coke used in drying.

#### GRILLED FOODS.

The possibility that meats or other food grilled over an open fire, and particularly over coke, may become contaminated with arsenic, has been mentioned to the Commission; but, looking to the short time that the meat is exposed to the fumes, and to the free access of air during the cooking, it seems hardly conceivable that material contamination can take place. The ordinary grill of a restaurant where coke is used is so constructed that the smoke and fumes are drawn directly backwards into the chimney and so avoid the meat. I have been in communication with Mr. Fairley respecting the possibility of coal gas introducing arsenic into food cooked in gas stoves. Mr. Fairley is making some experiments to ascertain the fate of any arsenic which does not remain behind in the coke in the manufacture of the coal gas, and has kindly undertaken to inform the Commission of the results obtained.\*

#### CHICORY.

Chicory is grown and dried principally in Belgium and the North of France. According to a publication on Chicory† lent me by Messrs. Taylor and Churchill, chicory importers, the process consists in first washing the roots, which are then cut up into pieces, about 1½ in. long and 1 square inch in section, and dried in special kilns. These kilns appear sometimes to have more than one drying floor, and the products of combustion pass through the cut-up roots, being admitted through apertures in each floor.

The fuel (in more modern plans of drying) is said to be coke, although in some works, where old systems of drying are in vogue, "tourbe" (? peat) is used.

The drying process appears usually to take about 24 hours for ordinary chicory. I have no knowledge as to whether the coke used is gas coke or oven coke. I may quote, however, the following passage from M. Storme's book as showing that the noxious character of the coke fumes in the kiln is well recognised by those engaged in the trade:—

"Il faudrait avant tout pouvoir supprimer les ouvriers qui retournent les cossettes nuit et jour. On comprend que dans une atmosphère saturée de vapeur à une température moyenne de 60° C., et remplie des gaz suffoquants qui proviennent de la combustion de coke, le travail ne soit ni agréable ni hygiénique. Aussi se paie-t-il 3 fr. par jour ce qui est beaucoup dans les provinces où se cultive la chicorée."

According to the same author, it requires 60 kg. of coke to dry from 4,000 to 5,000 kg. of roots, and again it requires 350 to 425 kg. of green roots to produce 100 kg. of dried roots.

In addition to the drying described above, the chicory for the English market receives a further and special drying in kilns in consequence of the duty, namely, 13s. 3d. per cwt., which is payable on the weight, the object of the special kilning being to dry as much as possible short of burning.

In England the chicory thus dried is roasted (either before or after being ground) in drums, or else in open

pans over coke fires, the fumes from which do not reach the chicory.

Mr. W. Thomson, of Manchester, has found arsenic in two casual samples of chicory, about 1-100th grain of arsenic per lb. in each sample. No other of the public analysts have mentioned in their returns to the Commission any analyses for arsenic of chicory or coffee and chicory mixtures. The liability of chicory to contain arsenic has been mentioned by Mr. Thomson only.

It would seem that the method of drying chicory over coke involves a risk of arsenical contamination comparable to that in the case of malt, and by analogy it appears that the maximum extent of contamination by arsenic which may occur could be determined only by examination of a large number of samples representing various methods of kilning in which different fuels were used. The few samples which I obtained, without knowledge of their origin, are quite insufficient to determine this question. Dr. McGowan has tested six samples, with results as follows:—

No. 5: Chicory root as dried and imported ready for roasting, none by Reinsch test.

No. 20a: Raw chicory as bought from Holland ready for roasting, 1-730th grain of arsenic per lb.

No. 21a: Chicory dried and ground ready for roasting, 1-730th grain of arsenic per lb.

No. 22c: Chicory after roasting in open pans, 1-730th grain of arsenic per lb.

No. 22b: Chicory ground after roasting in cylinders, 1-200th grain of arsenic per lb.

No. 5 came from a London chicory importer; Nos. 22 to 23, all from another importer at Bristol.

The last four samples were not selected as coming from the same kiln, and therefore no inference can be drawn as to the effect of the roasting at the works upon the arsenic they contained.

"Chicory and coffee mixtures" are often sold which contain over 50 per cent. of chicory. If 1 lb. of such mixture were used to a gallon of coffee, then for the coffee to contain 1-100th grain of arsenic derived from the chicory it would be necessary for the chicory to contain 1-50th grain of arsenic to the lb.

#### COFFEE.

Quite recently the practice of roasting coffee in a drum outside the products of combustion has been superseded at several factories by a more rapid method of roasting in which the beans are exposed to the fumes of gas or gas coke.

Where gas is used, a large Bunsen flame is directed into the middle of the drum in which the beans are kept in rapid motion by the revolutions of the drum; the roasting is completed in from 10 to 20 minutes. Where gas coke is used, the coffee is placed in a drum of open wire mesh rapidly revolving over a glowing coke fire. The drum is just clear of the fire. Exposure to the coke fumes lasts from 10 to 20 minutes, according to the quality of the coffee required.

A sample taken immediately after roasting in this way over coke was taken by me on September 13th, 1902, and has been sent to Dr. McGowan for analysis. This sample contained 1-730th grain of arsenic per lb.

#### DRIED LEMON PEEL.

The peel of lemons and oranges may be dried over coke. I visited one manufacturer whose entire business consists of drying lemon peel in this way. This peel, however, is never used for candied peel. Its principal use is to make medicinal tinctures. The peel, cut into thin strips, is hung upon strings in a small room for three days to dry in the air; then a brazier of gas coke is brought in, the doors and windows tightly closed, and the peel exposed to the coke fumes for three hours.

I may note here that the manager of Messrs. Burroughs and Wellcome, manufacturing druggists, who test a large number of products systematically for arsenic, informed me that occasionally traces of arsenic had been found in certain spirituous extracts, the origin of which had not been discovered at the date of my visit. It is possible that the use of coke in drying materials for medicinal purposes may be found to afford an explanation.

\* Now see Addendum B to this report, below.—H.H.S., July 1903.

## SECTION IV.

Appendix 24.

MISCELLANEOUS; FLESH OF FOWLS RECEIVING ARSENIC; ARSENICAL INSECTICIDES;  
ARSENIC IN ENAMEL OF COOKING UTENSILS, ETC.ARSENICAL INSECTICIDES IN RELATION TO THE POSSIBLE  
CONTAMINATION OF FRUIT.

The principal arsenical insecticides are Paris Green, Scheele's Green, London Purple, and Arsenate of Lead. They are used to destroy the larvæ of the "Winter Moth," the "Great Winter Moth," the "Canker Worm," the "Lackey Moth," the "Brown Tail Moth," the "Gooseberry Saw Fly," the "Magpie Moth," the "Codlin Moth," the "Asparagus Beetle," the "Cherry Saw Fly," etc. The following are fruit trees and plants liable to be treated with these insecticides: Apples, pears, cherries, gooseberries, cabbages, and asparagus. The use of arsenical substances as paints to the bark of trees need not here be considered. In the case of fruit, these insecticides are used in the form of spray of varying strength, in the case of Paris green up to 1lb. to 100 gallons of water, in the case of arsenate of lead, 15lbs. to 100 gallons. They are applied at different periods of the growth of the fruit, from the time of the bursting of the fruit bud onwards. In the case of the cabbage, it is recommended in the "Farmers' Bulletin" of the United States Department of Agriculture, No. 127, that a powder consisting of 1oz. of Paris green to 6lbs. of flour should be dusted on the cabbages. I have not heard, however, of this practice in England.

In the case of asparagus, a solution of Paris green may be used to apply to the asparagus plant to destroy the asparagus beetle. It is recommended, however, that this should not be used until all the crop has been cut. (Board of Agriculture leaflet, No. 47.) It is similarly stated in other leaflets prepared by the Board of Agriculture that it may be dangerous to use arsenical preparations shortly before the fruit is to be picked, and I should imagine that most fruit-growers would not allow their use in these circumstances. From my knowledge of the indiscriminate way in which uneducated gardeners may use insecticides, however, I should not be surprised if through lack of supervision arsenical insecticides are occasionally applied at too late a date. As an instance of what might happen in such a case, the following experiment may be of interest. On July 16th, 1901, I watered a gooseberry tree, the fruit of which was then half-grown, with a mixture of Paris green and soft soap, the strength being  $1\frac{1}{2}$  drachms of Paris green to 1 gallon of soap and water. This strength was recommended to me some years ago by a friend of great experience in gardening as suitable for destroying the larvæ of the magpie moth. Rain fell heavily on the 22nd and 23rd, and was falling when the first sample (half-ripe gooseberries) was picked on the 24th. These berries showed, according to Dr. McGowan, 1-20th grain of arsenic per lb. On July 27th and 28th very heavy rain fell, on the 30th slight rain, on August 10th slight rain, on the 12th slight rain, on the 13th the remainder of the berries were sent to Dr. McGowan. They showed 1-60th grain of arsenic per lb., showing that one month after spraying and after heavy rain, a considerable proportion of arsenic still remained on the fruit. With reference to these experiments I should note that the object of the watering is to destroy the magpie moth larvæ on the leaves, but it is, as I found, practically impossible to prevent the solution from reaching the fruit. It is probable, however, that ordinarily the larvæ would make their appearance before the fruit had attained the size which it had at the time when I watered this bush with the Paris green, as usually in my experience these larvæ appear towards the middle or the end of June. If a gardener had occasion to apply Paris green when the fruit was nearly ready to pick, it may be assumed that he would pick the fruit before applying the insecticide.

Paris green is also stated to be syringed over gooseberry bushes to destroy the gooseberry saw fly. This fly appears (Board of Agriculture leaflet No. 12) early or late in April, according to the nature of the season, when the fruit is only beginning to set.

In his evidence to the Commission, Dr. Stevenson (Q. 2341) alluded to the possibility of dried apples containing small quantities of arsenic, which he attributed to the use of arsenical sprays during the growth of the apple, the arsenic adhering to the skins. The "Farmers' Bulletin" of the United States Department of the Board of Agriculture above referred to, deals with the use of arsenical insecticides, particularly for apples, and states on p. 13 that the poison disappears from the fruit completely within 20 to 25 days, and that if the plants were eaten immediately, an impossible quantity would have to be consumed before a poisonous dose could be taken.

## USE OF ARSENIC FOR FATTENING POULTRY.

It has been stated that arsenic is administered to poultry for the purpose of fattening them. A writer in the "Daily Mail" of March 4th, 1901, stated that it was the practice in forced feeding of poultry to administer arsenic shortly before the birds were killed, so as to enable them to assimilate more food and put on extra fat. The secretary of the Commission was put into communication with the writer of the article by the editor of the "Daily Mail." This gentleman was not a poultry breeder, but he said that the statements in his article were the result of information obtained at some poultry farms in one of the home counties. The use of arsenic had been mentioned to him casually by a man who claimed to know what was done at a particular farm; the writer of the article knew no details regarding this practice.

Mr. Tegetmeier, of the "Field," who is an authority on poultry, was positive that arsenic was not used for this purpose, and told me that in his opinion arsenic would cause loss of appetite and irritation of the fowl's crop.

From my inquiries among a few poultry fatteners and purveyors of poultry foods, I am led to infer that something more than meal and fat is used for feeding purposes, but naturally it is extremely difficult to find out what each man uses, as directly arsenic was hinted at all information ceased.

The experiments of Professor Delépine on rats indicate that so long as a growing rat is receiving abundance of food, arsenic will tend to quicken its normal increase of weight, and the well known use of arsenic to improve horses and cattle suggests that it is not improbable that a poultry fatterer would find a distinct advantage in its use.

In order to ascertain whether poultry are as intolerant of arsenic as Mr. Tegetmeier asserted, I made a few experiments with my own fowls. Not caring to use a forcing apparatus, I administered the arsenic with the soft food given daily in the morning, and no other food was given to these birds until the whole of the arsenical food had been consumed. I fed four chickens this way, and two others I fed on a similar diet but without arsenic; each bird had a separate run in the same field.

Six chickens taken in the middle of July; all of one brood, ordinary cross-bred birds. These weighed:—

Nos. 1 and 2—14 ozs.

Nos. 3 and 4—16 ozs.

Nos. 5 and 6—17 ozs.

Birds put in their separate runs and kept under exactly similar conditions until they were fit for fattening on August 12th.

From August 12th onwards food in each instance given daily as follows:—

First feed: Small quantity of mixed grain early in the morning.

Second feed: Measured and identical quantity of soft food, sharps, and house scraps at 10 a.m.

Third feed: Corn in the afternoon.

Birds 1 and 2 throughout had no arsenic.

## Appendix 24.

Birds 3, 4, 5, and 6 received with their soft food measured quantities of solution of arsenic of known strength prepared from B.P. Liquor Arsenicalis, the strength of which was checked by Dr. McGowan and found to be correct. This solution of arsenic was intimately mixed with the soft food.

Birds 3 and 4 received daily doses equal to 2 minims of Fowler's solution (1-55th grain of arsenious oxide) per day, from August 12th to December 2nd, a period of 16 weeks; total arsenic in each instance 2 and one-third grains.

Birds 5 and 6 received daily doses equal to 2 minims of Fowler's solution (1-55th grain of arsenious oxide) from August 12th to August 25th (12 days); the dose on August 25th being increased to 4 minims of Fowler's solution (2-55th grain of arsenious oxide) per day.

Bird No. 5 continued this double dose till October 28th, when it was killed. Total arsenic administered 2 and three-fifth grains.

Bird No. 6 continued this double dose till November 25th, when it was killed. Total arsenic administered 3 and three-fifth grains.

During the above periods practically all the soft food given was consumed by the birds each day, and nearly all the arsenic administered must have been taken.

*Appearance and Condition of Birds.*—All six birds grew and kept healthy; those taking arsenic showed an unusual gloss and brilliancy of plumage which was not shown in the control birds. This shows that birds may thrive, notwithstanding the administration of arsenic in considerable doses, for a long period. On 2nd December, Birds 3 and 4, however, had their dose of arsenic increased to 4 minims, on the 3rd to 5, and on the 6th to 6. The result of these larger doses was that both the birds refused their food.

*Gain in Weight.*—I append a table showing the results of weekly weighings. In each instance it is impossible to draw any very definite inference as to the effect of arsenic on the rate of increase, particularly as the two control birds turned out to be pullets, while of the four birds receiving arsenic three were cockerels and one was a pullet. Upon the whole, however, there are some indications that the arsenic produced at first a temporary gain in weight as compared with the controls, but that after the administration had been continued for eight or nine weeks the same rate of increase was not maintained. The weight of Bird No. 4, for example, having steadily increased up to October 14th, remained almost stationary during the following 10 weeks.

*Arsenic in Flesh and Liver of Birds Nos. 5 and 6.*—Bird 5 killed October 28th. Dr. McGowan found in flesh (white and dark), 1-600th grain of arsenic per lb.; in liver and heart together, 1-2,000th grain (1-200th grain per lb.); in gizzard, about 1-2,000th grain.

Bird 6 killed December 2nd: Liver, 1-2,000th grain arsenic in the whole (= 1-200th grain per lb.); flesh not examined. The coarse feathers of this bird were separated and analysed, with results as follows: Coarse feathers, 1-25th grain in weight taken, equivalent to 2-5th grain arsenic per lb.; medium and fine feathers, 1-60th grain in weight taken, equivalent to 1-5th grain arsenic per lb.

The above results suggest that the administration of a relatively considerable quantity of arsenic to the fowl under such conditions as I have described does not entail a contamination of flesh, liver, or gizzard to any appreciable extent. On the other hand, the illustration which they afford of the elimination of arsenic by the feathers is instructive as showing the affinity of the keratine tissue for arsenic.

#### POSSIBLE CONTAMINATION OF FOOD BY MEANS OF ENAMELLED COOKING UTENSILS.

In view of a statement made to me by Mr. Cochrane, a retired ironmonger, that he had had personal experience of illness caused by the use of new enamelled hardware pans, and the use of arsenic as a constituent in white enamel hardware goods being well known, I have procured samples of different makers of such goods for investigation.

The question I wished to investigate was whether arsenic is still used in making the enamel that lines cooking utensils, and I asked Mr. Cochrane to collect for me a number of samples from different makers, which have been sent to Dr. McGowan for examination, the result of which is not yet to hand. That some makers know the risk of using arsenic in the manufacture of their enamel goods is shown by many of them advertising on their price lists that their goods contain "No arsenic."

Mr. Cochrane stated that when in business he supplied a hotel in London with enamel stewpans, in an emergency, instead of copper pans, and everyone who partook of food cooked in these pans became ill. He also quoted two other cases of illness in his own family which he attributed to the use of new enamel stewpans, his theory being that when a new pan is used the act of washing with carbonate of soda and subsequent cooking dissolves the arsenic in the enamel, if present. Upon this point I have asked Dr. McGowan to make some experiments when examining the enamels in question.\*

TABLE SHOWING INFLUENCE OF ARSENIC ON WEIGHTS OF EXPERIMENTAL FOWLS.

Number of Bird.	Daily Dose of Arsenic during Period of Weekly Weighings.	Total Arsenic taken during Period of Weekly Weighings.	Weight when Bought in Middle of July 1901. \* As to chemical examination of enamelled hardware from various sources, see Dr. McGowan's Report in separate Appendix. No. 29.

## SECTION V.

Appendix 24.

## SUMMARY.

I may briefly summarise certain of the principal points dealt with in this report as follows:—

(1) *Glucose* is an important ingredient of numerous articles of food, particularly of table syrups, jams, marmalade, confectionery, and biscuits; also of sundry beverages, particularly brewed ginger beer and certain kinds of wine.

In most of these foods and drinks the proportion of glucose used may be considerable. Arsenical contamination of the glucose on the Bostock scale would involve serious contamination of the finished products. Use in these substances of glucose containing as much arsenic as has in exceptional instances been found in samples on the market in 1901-2, and not coming from Bostock's (e.g., 1-25th to 1-10th grain of arsenic per lb.) would also in most instances involve a material degree of contamination of the finished product by arsenic.

Nearly all the glucose used in these substances is of foreign, usually American, origin.

Food manufacturers using glucose differ very much in their method of taking precautions to secure that it is satisfactory as regards arsenic. At works visited by me analytical control of greater or less stringency had been adopted since 1900 by certain firms; others, the majority, were content with guarantees given by glucose manufacturer, middleman or agent; others again had required no guarantee and had not tested their glucose for arsenic.

(2) In instances where I heard of the use of *invert sugar* by cider makers or by manufacturers of brewed "temperance beverages," it was either obtained from brewing sugar manufacturers taking precautions to exclude arsenic from their invert sugar, or it was prepared by the cider maker without the use of sulphuric or hydrochloric acid.

(3) The use of sulphuric acid in the preparation of "golden syrup" and *treacle* involves risk of serious contamination by arsenic if the precautions taken to secure a satisfactory acid are insufficient. I visited the works of two large sugar refiners who make syrups of this class. Each had adopted a stringent system of analysis and control in this respect.

(4) The use of sulphuric acid to convert raw grain in *vinegar making* involves risk of serious contamination of the vinegar by arsenic in the absence of sufficient precautions. Care in this respect was taken by the two firms visited which manufactured vinegar in this way.

(5) Besides the foods above mentioned are a few others, in the preparation of which sulphuric or hydrochloric acid may be used. In the case of certain *meat extracts*, "peptones," the amount of hydrochloric acid employed is relatively minute. Direct addition of sulphuric acid to *vinegar* and *pickles* appears to be seldom practised. If a strongly arsenical acid were employed these substances might become contaminated by arsenic to a material degree. The information thus far obtained does not suggest that sophistication of *spirits* by mineral acids, if still practised, is common.

(6) Commercial *phosphoric acid* and commercial *phosphates*, such as are used in sugar refining and in baking powders, are liable to contain arsenic, but the quantity of arsenic which could be introduced in this way into finished products is in most instances small.

(7) *Tartaric and citric acids*, largely used for food purposes, particularly as ingredients of lemonade powders and the like, are liable to contain arsenic. The steps habitually taken by manufacturers of these acids in this country to secure freedom from lead also tend to make serious contamination by arsenic unlikely, and it is the custom of food manufacturers to demand that these acids should be satisfactory in regard of lead.

(8) The use of exceptionally large quantities of *boron preservatives* in articles such as milk, cream, and butter may involve the introduction of material quantities of arsenic into these substances.

(9) *Glycerine* has occasionally been found to contain large amounts of arsenic (e.g., 2 to 4 grains per lb.); quantities of arsenic less than 1-15th grain arsenic per lb., if present, might not be detected by the tests prescribed for glycerine in the British Pharmacopœia. Glycerine may be used in cakes to the amount of 4 per cent., and also an important ingredient of certain sweets and meat extracts.

Certain food manufacturers visited employed glycerine stated to conform to pharmacopœial tests; they had not, however, caused the glycerine supplied to be analysed for arsenic, and they did not recognise that arsenical glycerine might cause objectionable contamination of their products.

(10) Arsenic may be present in sundry "coal tar" *colouring matters* used in food. In the case of confectionery, it appears usual for the confectioner to obtain colours with a guarantee from a responsible analyst that they are harmless for confectionery purposes, such guarantee being given with due regard to the quantity of the colour likely to enter into the finished product. Samples of Bole Armenia and other *mineral pigments* have been found to contain over 0.8 grain of arsenic to the lb.; these pigments are used in sausages, anchovy preparations, and the like, without any steps being taken to secure their wholesomeness.

(11) In one instance *sheep wool grease* sold as "cocoa butter," and employed in sugar refining, contained about 1-6th grain arsenic per lb., probably derived from arsenical sheep dip.

(12) Samples of brown "*Demerara*" sugar coming from the West Indies in certain instances have been found to contain small amounts of arsenic, 1-300th to 1-50th grain per lb.

(13) The British manufacturers of *malline and malt preparations* visited were in each instance taking precautions to secure that the malt used was satisfactory as regards arsenic. Foods manufactured in America which consist largely of malt are coming into extensive use in this country. In the absence of more exact information as to American systems of maltings, and of analyses on a comprehensive scale, I am unable to indicate whether these foods are subject to any material risk of arsenical contamination.

(14) A food preparation consisting mainly of brewers' yeast, "*Carnos*," has been found to contain 1-6th grain of arsenic per lb., notwithstanding the precautions against arsenic adopted in its manufacture.

(15) *Chicory* may be dried by exposure of the roots to fumes of coke for several days. None of the few samples examined for arsenic has shown more than 1-100th grain of arsenic per lb. of chicory, but examination of a sufficient number of representative samples would be necessary before a satisfactory estimate of the degree of liability of chicory to contain arsenic can be obtained.

(16) *Hams, bloaters, coffee, lemon peel, etc.*, may be dried by exposure to the fumes of coke, but the degree to which these substances are likely to become contaminated by arsenic in this way is slight.

(17) Considerable daily doses of arsenic may be administered to *foals* for several weeks or months without causing their flesh or livers to contain more than extremely minute quantities of arsenic.

It will be seen that the food and drink substances referred to in this report vary within wide limits in respect of their liability to contain arsenic. Of foods which are subject to risk of serious contamination the principal are those in which glucose is used, or which, like glucose, are prepared by the use of a relatively large quantity of sulphuric or hydrochloric acid. There can be no question of the necessity that stringent precautions as regards arsenic should be taken by manufacturers of foods of this class, and by persons using them in the preparation of other foods. In the case of certain other foods dealt with, the liability to contamination

Appendix 24. by arsenic is not so great, but it seems nevertheless important that precautions against arsenic should be taken by those manufacturing them; for example, foods made with glycerine; foods consisting largely of yeast; chicory; or West India sugars. In a third class of foods dealt with in the report, it may be urged that the liability to arsenical contamination, in the absence of all precaution, is so slight that there is no occasion at all for the question of arsenic to be considered by the manufacturer; or again, in the case of particular substances (Anchovy sauce, for example), it may be claimed that precaution is unnecessary on account of the small quantities in which they are taken by the individual. But in the majority of cases it would seem a matter of little difficulty for the manufacturer of the substances here in question to secure that none of his ingredients, even if used in small amount, contains any noteworthy proportion of arsenic. A sugar refiner, or mineral water maker, for example, might use phosphoric acid or phosphates containing relatively large amounts of arsenic without contaminating his finished product to a degree which could be considered objectionable. But as he can obtain these substances practically free from arsenic with little additional trouble or cost, it would seem more satisfactory that he

should do so, and thus secure that his finished product was free from arsenic, in the sense that no arsenic would be detectable, by Marsh-Berzelius test, in quantities of his product such as are usually taken for arsenic analysis. And if the small proportion of a given ingredient renders its content of arsenic of less moment to the consumer, it also renders insignificant the extra cost of arsenic-free material.

In connection with these questions it is right that I should record the fact that several manufacturers asked me to represent to the Commission their desire that the quantities of arsenic to be considered inadmissible in particular ingredients of foods should be authoritatively laid down—to adopt the usual phrase, “in order to give them something to go upon.” Representations in this sense were specially made by food manufacturers using mineral acids and by chemical manufacturers. Maltsters appear particularly desirous of a “standard” as regards arsenic in malt, capable of adoption not only in transactions with brewers, but also with manufacturers of malt foods and malt extracts.

H. HAMMOND SMITH.

October 1902.

## ADDENDA TO REPORT OF MR. H. HAMMOND SMITH.

Appendix 24

## A—ARSENIC IN GLYCERINE: EXTRACTS FROM LETTERS RECEIVED FROM PROF. CAMPBELL BROWN.

(December, 1901, and subsequently.)

It is quite true that several years ago glycerine had objectionable quantities of arsenic in it. We have occasionally tested glycerine, and found it pass the Pharmacopœia test, but we also found that by more prolonged experiments even the mercuric chloride paper showed a reaction. We never had enough glycerine to determine the arsenic by the "drastic method."

Marsh's test is discarded by us, and by a good analyst who regularly analyses commercial glycerine; he uses Reinsch's method. I cannot tell you the degree of delicacy. We are all agreed that the Pharmacopœia method is most unsatisfactory.

I shall be glad to send you what information I can gather. Meanwhile I append such references as I have.

J. Soc. Chem. Ind. 1889, 639 (Chem. Zeit. Rep. XII. 293). Qualitative only—2 c.c. Sample, 3 c.c. HCl Zn & Ag NO<sub>3</sub> paper.

J. Soc. Chem. Ind. 1889, 726 (Pharm. J. 1889, 205). As<sub>2</sub>O<sub>3</sub> found in most samples, 1 part in 2,500—6,000, HgCl<sub>2</sub> test.

J. Soc. Chem. Ind. 1899, 404 (J. Amer. Chem. Soc. XXIX, 135). Quantitative—no figures given.

J. C. S. 1896, II., 519 (J. Amer. Chem. Soc. XVII. 683). Quantitative—no figures given.

J. C. S. 1899, II., 490. Quantitative—no figures given.

Pharm. J. 1899, 359 (Chem. Centr. bl. LX. II. 58).

Pharm. J., 1899, p. 968. English as well as German commercial glycerine contains arsenic "in notable quantity."

Pharm. J. 1899, p. 277. Siebold. Analysed many samples, both English and foreign; all were intended for pharmaceutical or toilet purposes, and were colourless and odourless. The majority contained 1 part As<sub>2</sub>O<sub>3</sub> in 4,000 to 1 part in 6,000. A few contained larger quantities, and 10 per cent. of the samples contained smaller quantities. Those free from arsenic were all traced to the steam distillation process.

Method was to pass the gas from Marsh's apparatus into AgNO<sub>3</sub> solution, and weigh the precipitate.

For qualitative work Siebold recommends Gutzeit's test—5 c.c. HCl (4 per cent.) solution, 15-20 drops glycerine, 1 gramme Zn-1 drop saturated HgCl<sub>2</sub> solution dried on filter paper. 1-100th milligramme arsenic in 1 gramme sample shows a stain in a quarter of an hour. The contamination is probably due to the H<sub>2</sub>SO<sub>4</sub> used in the manufacture. The amount of arsenic found would correspond to about 2 drops of Fowler's solution, which is serious (p. 682). The arsenic is not due to the glass bottles, nor to the solder of the drums. Gutzeit's test can be used quantitatively to estimate one part As<sub>2</sub>O<sub>3</sub> in 50,000. (I do not think this is really so).

Pharm. J. 1890, p. 241. Siebold. Redistillation does not remove the arsenic from glycerine. It can be completely removed by diluting, adding freshly precipitated Fe(OH)<sub>3</sub>, allowing to stand, and filtering.

Pharm. J. 1894, p. 588. Fairley, Public Analyst, Leeds, finds that five samples out of eight contained "appreciable quantities of arsenic."

p. 685, Paul and Cowley. Of seven samples, three were free from arsenic, two contained .01 milligram per c.c., and two contained .001 milligram per c.c. Used Gutzeit test, operating on 2 c.c. sample. Commercial glycerine contained much more arsenic than the above samples.

Pharm. J. 1895, p. 802. Lewkowitsch says the arsenic is present as As<sub>2</sub>O<sub>3</sub>(C<sub>2</sub>H<sub>5</sub>)<sub>2</sub>, which would distil over with the glycerine at 250°, and, therefore, the latter cannot be purified by distillation.

Pharm. J. 1895, p. 802. Tegarden. Seven samples contained "comparatively large amounts of

arsenic," two contained minute traces, four were absolutely free. He used Gutzeit's test.

Commercial glycerine was taken, proved free from arsenic by Gutzeit's test for two hours, also by Seudder's form of Marsh's apparatus, and by Reinsch's method. To this were added different proportions of arsenious oxide. The following three failed to give indications by B.P. tests, but showed a yellow stain after a longer time, namely:—

.001 milligram arsenious oxide in 2 c.c. Glycerine showed slight stain in 1 hour.

.002 milligram arsenious oxide in 2 c.c. Glycerine showed faint stain in  $\frac{1}{2}$  hour.

.004 milligram arsenious oxide in 2 c.c. Glycerine showed faint stain in 20 minutes.

These are the proportions of .65 parts per 100,000:—

$\frac{1}{2}$  " " "

The following proportions were detected by the B.P. test:—

.006 milligram in 2 c.c. Glycerine gave faint yellow stain in 15 minutes.

.008 milligram in 2 c.c. Glycerine gave stain just visible in 10 minutes.

.01 milligram in 2 c.c. Glycerine gave faint stain in 10 minutes.

.02 milligram in 2 c.c. Glycerine gave stain just beginning in 5 minutes; quite distinct in 6 minutes.

According to notes by a good consulting chemist, Mr. Charles C. Moore, who was examining glycerine before the beer scare, he had an initial difficulty in the absence of a recognised method of testing. The B.P. test gave no indication with samples containing very appreciable amounts of arsenic, and, although results were recorded, they were quite useless. He also tried, as a qualitative test, the Gutzeit test, using strong silver nitrate on filter paper, with a plug of cotton-wool inside the test tube. Ten c.c. of glycerine, 10 c.c. water, and 3 c.c. HCl, was used for each test. For pure glycerine this test is largely used by manufacturers. Mr. Moore says "if sufficient time is given, say half an hour, it is fairly delicate. Using the quantities just given, a glycerine containing  $\frac{1}{4}$  part by weight of As<sub>2</sub>O<sub>3</sub> per million parts by weight of glycerine, will give a distinct indication of arsenic. It is necessary to have the zinc in small pieces to ensure a current of gas. A rough idea of the amount of arsenic in a sample may be obtained by this test by adding a known amount of arsenic to perfectly pure glycerine (not more than 1-200th or 1-100th mgm. arsenious acid), and finding out the smallest quantity of the contaminated sample required to produce a corresponding stain. If larger amounts of arsenic are used it is useless trying to compare the stains produced. These results are of course only approximate, and probably too low, but they enable one to distinguish between several samples with ease.

Attempts to estimate the arsenic by precipitation with sulphuretted hydrogen, after diluting the sample with water and adding HCl were not successful, as it was impossible to obtain the slightest trace of any precipitate with samples containing as much as five or six parts per million of arsenious acid, even after long standing. As this is a larger amount of arsenious acid, by a long way, than is usually found in pure glycerine, it is obvious that results obtained by this method would be quite unreliable. Another way was tried to get results by using H<sub>2</sub>S in the following manner:—

About 100 to 150 grammes of glycerine was evaporated to a small bulk (about 5 c.c.), a little caustic soda being added before evaporation, with the object of retaining the arsenic. The results when using glycerine to which known quantities of arsenic had been added were fairly good, although the method is certainly rather tedious.

On the following page are tabulated the results of the examination of a number of samples of glycerine, which I know to be of home manufacture.

## Appendix 24.

## TESTS OF PURE GLYCERINE FOR ARSENIC.

No. of Sample.	Qualitative test according to the British Pharmacopœia.	Gutzeit test with silver nitrate as described. Parts $As_2O_3$ per million glycerine.	Quantitative by evaporation as described. Parts $As_2O_3$ per million glycerine.
1	None.	0.15	—
2	"	0.45	—
3	"	3.5	1.1
4	"	0.75	—
5	"	0.5	—
6	"	1.5	1.9
7	"	0.1	—
8	"	0.1	—
9	"	0.2	—
10	"	5.0	—
11	Trace.	5.5	5.2
12	"	7.5	9.2
13	None.	4.5	5.1
14	"	3.5	—
15	Trace.	8.0	9.4
16	None.	0.2	—
17	"	9.0	11.0
18	"	1.0	1.3

With reference to the above figures, I should consider the samples containing 0.25 part  $As_2O_3$  per million (or less), as being free from arsenic, while those containing about 1.0 part  $As_2O_3$  per million, may be considered as fairly good glycerines. Above that amount I would advise anyone to reject the glycerine as containing too much arsenic. Nearly all the bad samples in the above list were supposed to come from the same manufacturer, while each of the good samples represents a different manufacturer. As there are only about a dozen makers of pure glycerine in the country, it generally soon gets known in the trade if any brand falls below its standard.

Glycerine is now used in large quantities in the manufacture of cakes, I have been informed, which suggests an additional reason why its purity from arsenic should receive close attention. The whole of the samples mentioned above would, if judged by the standard of the British Pharmacopœia, have to be

pronounced pure, although they show wide variations in the amount of arsenic. It appears that anyone selling glycerine containing an objectionable amount of arsenic might justify his action by contending that the requirements of the British Pharmacopœia were complied with. I can see no reason why such a contention should be considered unreasonable while there is no recognised standard of purity, as at present. There is no doubt, as I pointed out before, that nearly all the glycerine sold by home manufacturers is of far higher purity as regards arsenic than is required by the B.P. So that it seems reasonable to assume that the makers would welcome some higher and more definite standard than the present very lax one."

May, 1902.

I send you some results of comparative tests, made in the County laboratory, of the amount of arsenic in glycerine by different methods

Series I.	Gutzeit, 2 c.c.		Reinsch, 25 c.c.	Marsh, 2 c.c.

Appendix 24.

N.B.—In the case of the samples bracketed, the second sample was a further quantity of the same glycerine obtained for the purpose of determining the quantity by an exact method.

The Reinsch method gives more nearly the correct figure than the Marsh method, and the true figure is always slightly greater than either.

#### B.—ARSENIC IN GAS COALS, GAS PRODUCTS, AND COAL GAS.

##### COPY OF LETTER AND ENCLOSURES RECEIVED FROM MR. T. FAIRLEY, CITY AND COUNTY ANALYST, OF LEEDS.

17, East Parade,  
Leeds,  
22nd June, 1905.

Dear Dr. Buchanan,—I enclose tabulated numbers relating to analyses of coals and their gas products for arsenic.

In no case have we been able to find arsenic in coal gas—though the tests applied would have detected 0·00002 or 1/50,000 grain per cubic foot.

Should you require the full analyses of these gas coals they are at your disposal. Yours faithfully,  
T. FAIRLEY.

### REPORT BY DR. G. MCGOWAN ON EXAMINATION FOR ARSENIC OF VARIOUS SUBSTANCES SENT TO HIM IN CONNECTION WITH MR. H. HAMMOND SMITH'S INQUIRY.

The results of the examination for arsenic of the various food and other substances submitted to me in connection with Mr. Hammond Smith's inquiry are set out in the accompanying Tables I. to III. The substances in question were of widely different nature and a variety of methods of treatment, preliminary to estimation of arsenic by the Marsh Berzelius test, had to be adopted accordingly. The tables indicate in the case of each substance the procedure adopted, and also show the basis on which the quantity of arsenic in the substance was calculated from the mirror or mirrors read. A full account of the various methods employed appears in the paper by Mr. R. S. Finlow, B.Sc., and myself, which is separately printed as Appendix 22 above. Here I would only add that the analytical

work in connection with the substances recorded in these tables, as also in connection with the foods and other specimens submitted to me by the Commission in connection with the beri-beri inquiry (Appendix 31, Tables IV. to VI.) and the enamelled cooking utensils inquiry (Appendix 29), was carried out in my laboratory almost entirely by Mr. Finlow, to whom I would express my great indebtedness, both for the care and thoroughness with which he has carried this through and for introducing modifications and improvements in the methods as the investigations progressed.

GEORGE MCGOWAN.

Ealing, August, 1903.

#### TABLE III.—Miscellaneous Substances other than Foods.

## APPENDIX, No. 25

TABLE I.

SHOWING RESULTS OF EXAMINATION FOR ARSENIC OF MISCELLANEOUS FOOD SUBSTANCES RECEIVED FROM THE COMMISSION.

1. Number of Sample.	2. Description of Sample.	3. Date when Analysed.	4. Quantity taken for Analysis.	5. Method of Analysis.	6. Arsenic mirror read, (Milligrammes.)	7. Arsenic (As <sub>2</sub> O <sub>3</sub> ) in grains per lb. Approximate fractions.	8. Parts per Million.	9. Notes as to Analysis.
	PREPARATIONS OF MALT, OR FOODS CONTAINING MALT:							
1	Maltine . . . . .	17 Jan. 1903 .	5.0 grms.	Direct Marshing .	Merest trace .	Arsenic-free .	—	25.0 grms. were made up with water to 100 c.c., and 20 c.c. of this were taken.
2	Kepler's Malt Extract . . . . .	22 Dec. 1902 .	4.07 grms.	. ditto . . . . .	Merest trace .	Arsenic-free .	—	40.7 grms. were made up to 200 c.c. with water and 20 c.c. of this were used. 1 c.c. amyl alcohol was added in the Marsh flask, to prevent frothing.
3	"Grape Nuts" . . . . .	4 Nov. 1902 .	5.0 grms.	Nitric and sulphuric acids .	Merest trace .	Arsenic-free .	—	The whole of the extract was Marshd.
4	Horlick's Malted Milk . . . . .	31 Oct. 1902 .	5.0 grms.	. ditto . . . . .	None . . . . .	Arsenic free . .	—	. ditto . ditto.
5a	"Carnos" I. . . . . Purchased July 1901.	(a) 29 July 1901	2.5 grms.	Direct Marshing (preliminary estimation).	.01 to .015	$\frac{1}{25}$ approximately .	5.7 approximately	This was an early estimation, and is merely to be taken as qualitative.
5b	"Carnos" I. . . . . Purchased July 1901.	(b) 27 Feb. 1902	5.7 grms.	Nitric and sulphuric acids .	.0135	$\frac{1}{24}$	6.0	The mirror read represented two- fifths of the whole extract, i.e., 2.28 grms. of Carnos.
6	"Carnos" II. . . . . Obtained at factory, 9th November 1901.	6 Mar. 1902 .	5.7 grms.	. ditto . . . . .	.0145	$\frac{1}{22}$	6.4	The mirror read again repre- sented two-fifths of the whole extract.
	"Carnos" III. . . . . Purchased 14th May 1902.	26 June 1902 .	6.7 grms.	. ditto . . . . .	.017	$\frac{1}{6}$	25	The mirror represents one-tenth of the whole extract.
7	"Carnos" III. . . . . Purchased 14th May 1902 .	26 June 1902 .	5.01 grms.	. ditto . . . . .	.0173	$\frac{1}{6}$	24	The mirror represents one-seventh of the extract.

## APPENDIX, No. 25—continued.

TABLE I.—Showing Results of Examination for Arsenic of Miscellaneous Food Substances Received from the Commission—continued.

1. Number of Sample.	2. Description of Sample.	3. Date when Analysed.	4. Quantity taken for Analysis.	5. Method of Analysis.	6. Arsenic mirror read. (Milligrammes).	7. Arsenic (As, O <sub>3</sub> ) in grains per lb. Approximate fractions.	8. Parts per Million.	9. Notes as to Analysis.
DEMERA SUGARS—continued.								
18	Demerara . . . . (London retailer B.) Received 11th October 1902.	31 Oct. 1902	10.0 grms.	Direct Marshing with hydro- chloric acid.	None	Arsenic-free	—	The whole extract was Marshed.
19	Raw Brown Demerara (Retailer C.) Received 11th October 1902.	29 Oct. 1902	10.0 grms.	ditto . ditto .	0.0015	$\frac{1}{1000}$	0.15	ditto . ditto.
20	Best Demerara . . . . (Retailer C.) Received 11th October 1902.	30 Oct. 1902	10.0 grms.	ditto . ditto .	Trace	Trace	—	ditto . ditto.
21	Demerara . . . . (Retailer D.) Received 11th October 1902.	27 Oct. 1902	10.0 grms.	ditto . ditto .	None	Arsenic-free	—	ditto . ditto.
22	Demerara . . . . (Retailer E.) Received 11th October 1902.	25 Oct. 1902	10.0 grms.	ditto . ditto .	0.0019	$\frac{1}{750}$	0.19	ditto . ditto.
23	Demerara . . . . (Retailer F.) Received 11th October 1902.	27 Oct. 1902	10.0 grms.	ditto . ditto .	0.0035	$\frac{1}{400}$	0.35	ditto . ditto.
24	Large white crystal sugar. Sample submitted on account of unusual acid taste.	About 25 Mar. 1903.	5.0 grms.	! ditto . ditto .	None	Arsenic-free	—	This sample was very acid to the taste, and was found to contain acid equivalent to 0.45 per cent. of tartaric acid. It con- tained no mineral matter, no heavy metals, and no sulphuric, hydrochloric, or oxalic acid. The acid present appeared to resemble tartaric more than citric. Without having gone very minutely into the matter, one may surmise that the sample contained about 1 per cent. of tartaric acid.
24*	PREPARED TABLE SALT: "Cerebos" Salt . . . .	8 Aug. 1903	2.5 grms.	ditto . ditto .	Merest trace	Arsenic-free	—	

TABLE SYRUP:									
25	* Bostock's Table Syrup I., made with invert sugar. Received 15th June 1901.	(a) 19 June 1901. (b) 29 October 1902.	10.0 grms. 28.8 grms. in 200 c.c. water.	Direct Marshaling with sulphuric acid. Direct Marshaling with hydrochloric acid.	Dense black mirror. 0.04	— 1.0	— 140.0	(b) 2.0 c.c. of the solution (= 0.288 gm.) were Marshaled. This mirror was too dense to read with great accuracy, but must be nearly right.  The whole was Marshaled.	
26	Bostock's Table Syrup II., made without invert sugar. Received 15th June 1901.	20 June 1901	10.0 grms.	Direct Marshaling with sulphuric acid.	None, or at any rate, merest trace.	Arsenic-free	—		
27	PRESERVATIVE: * Frigiline - 24th April 1901.	16 Jan. 1903	5.0 grms.	Direct Marshaling of the hydrochloric acid solution of the powdered substance.	0.035	$\frac{1}{21}$	7.0	The whole extract Marshaled. Note.-- This substance evidently contained boric acid and the whole did not go into solution with hydrochloric acid.	
28	BAKING POWDERS: Baking Powder - (From a baker's.)	(a) 3 Dec. 1901 (b) 15 Mar. 1902	1.0 gm. 3.0 grms.	(a) Direct Marshaling of hydrochloric acid solution (not all soluble.) (b) Basic method, followed by Marshaling of the hydrochloric acid extract.	None 0.0045	— $\frac{1}{60}$	— 2.6	(a) Whole solution Marshaled.  (b) Three-fifths of extract Marshaled. This was a white powder of strongly acid reaction, insoluble in water, partly soluble in hydrochloric acid. It contained organic matter, and also some phosphate or phosphoric acid.	
29	* Acid Phosphate of Lime, used in baking powder. Received 11th October 1902.	24 Oct. 1902	10.0 grms.	Basic method, followed by Marshaling of the hydrochloric acid solution ultimately obtained.	0.012	$\frac{4}{5}$	120.0	One-hundredth part of extract Marshaled. (The first mirror from one-tenth part was much too dense to read.) The whole of the lime residue did not dissolve in hydrochloric acid; the solution contained a little iron.	
30	POWDERS FOR BEVERAGES, CONTAINING CITRIC OR TARTARIC ACID: * Fruit Crystals	20 June 1902	5.0 grms.	Direct Marshaling of the hydrochloric acid solution.	None	Arsenic-free	—	Whole extract Marshaled.	
31	* "Eiffel Tower Lemonade"	19 June 1902	(a) 2.0 grms. (b) 5.0 grms.	ditto ditto	None None	Arsenic-free Arsenic-free	— —	(a) Whole extract Marshaled. (b) Whole extract Marshaled.	
32	Sherbet	25 June 1902	5.0 grms.	Direct Marshaling with hydrochloric acid.	None	Arsenic-free	—	Whole extract Marshaled. The carbonic acid was boiled off before the hydrochloric acid was added.	

## APPENDIX, No. 25—continued.

TABLE I.—Showing Results of Examination for Arsenic of Miscellaneous Food Substances received from the Commission—continued.

1. Number of Sample.	2. Description of Sample.	3. Date when Analysed.	4. Quantity taken for Analysis.	5. Method of Analysis.	6. Arsenic mirror read. (Milligrammes.)	7. Arsenic ( $As_2O_3$ ) in grains per lb. Approximate fractions.	8. Parts per Million.	9. Notes as to Analysis.
	POWDERS FOR BEVERAGES, CONTAINING CITRIC OR TARTRIC ACID—continued.							
	Seidlitz Powder:							
33a	(a) Acid powder	12 June 1902	3.0 grms.	Direct Marshaling of the hydrochloric acid solution.	None	Arsenic-free	—	Two-thirds of extract Marshaled.
		(12 June 1902	(a) 5.0 grms.	Direct Marshaling of the reduced sulphuric acid solution.	Trace, say, 0.001.	$\frac{1}{800}$ (?)	—	(a) Whole extract Marshaled; a little sulphide was generated in the Marshaling.
33b	(b) Alkaline powder	(14 June 1902	(b) 6.17 grms.	Direct Marshaling of the unreduced sulphuric acid solution.	None	Arsenic-free	—	(b) Whole extract Marshaled. Note.—Estimation (b) is probably the more reliable of the two.
	GELATINES:							
34	*Granulated Jelly (vanilla flavour) packet (Manufacturer A).	1 April 1903	30.0 grms.	Dissolved in hydrochloric acid, 1½ grms. of chlorate added, the chlorine boiled off, and the solution Marshaled directly.	None	Arsenic-free	—	One-fifth of the ultimate extract was Marshaled.
35	Cox's Gelatine, packet	1 April 1903	12.8 grms.	Done in same way as preceding sample, but only 0.75 gm. chlorate was used.	Trace, say, 0.00075.	about $\frac{1}{1000}$	0.15	Two-fifths of extract Marshaled.
36	*Gelatine (German) from a sweetmeat maker.	28 Mar. 1903	15.3 grms.	Done as above, with only a small amount of chlorate,—say, half a gramme.	None	Arsenic-free	—	Two-sevenths of extract Marshaled.
37	*Gelatine from Manufacturer B.	28 Mar. 1903	12.0 grms.	Done as above, using 1.0 gm. of chlorate.	0.0037	$\frac{1}{140}$	1.1	Two-sevenths of extract Marshaled.

## APPENDIX, No. 25—continued

TABLE I.—Showing Results of Examination for Arsenic of Miscellaneous Food Substances received from the Commission—continued.

1. Number of Sample.	2. Description of Sample.	3. Date when Analysed.	4. Quantity taken for Analysis.	5. Method of Analysis.	6. Arsenic mirror read. (Milligrammes).	7. Arsenic (As, O <sub>3</sub> ) in grains per lb. Approximate fractions.	8. Parts per Million.	9. Notes as to Analysis.
COLOURING MATTERS:								
44	"Bale Armenia" (From one of the "Stores.")	(a) 21 May 1902 (b) 22 May 1902 (c) 24 May 1902	5.0 grms. 1.01 grms. 1.05 grms.	Basic method, followed by direct Marshing. - ditto - ditto - - ditto - ditto -	Too dense to read. 0.0012 0.00135	- $\frac{4}{5}$ $\frac{9}{10}$	- 115.9 129.0	(a) Whole extract Marshled. (b) One-tenth of extract Marshled. (c) One-tenth of extract Marshled. Not very much iron went into solution, but the results should be regarded as approximate. (c.f. Appendix 25.) Half of the extract was Marshled. This sample was mainly composed of inorganic material.
45	"Bale Armenia" (Smithfield.)	4 March 1903	5.0 grms.	Basic method, followed by pre- cipitation as sulphide.	0.031	$\frac{1}{11}$	12.4	
46	"Apple Green" (From sweet maker.)	5 Aug. 1902	(a) 0.5 grm. (b) 1.67 grms.	Direct Marshing Nitric and sulphuric acids	(a) No mirror. (b) 0.016	- $\frac{1}{12}$	- 11.5	Five-sixths of extract Marshled. This was a very small sample.
47	Coffee Colour (From sweet maker.)	4 March 1903	1.375 grms.	Basic method, followed by pre- cipitation as sulphide.	0.026	$\frac{1}{4}$	38.0	Half of extract Marshled.
48	"Santor" (brown colouring matter from sausage makers).	3 March 1903	5.0 grms.	- ditto - ditto -	0.0075	$\frac{1}{50}$	3.0	Half the extract was Marshled. This sample was mainly of in- organic material.
49	Commercial Chloride of Tin (Obtained from the Society of Apothecaries in view of use of this substance to colour Deme- nara sugar).	31 Oct. 1902	2.5 grms.	Precipitation as sulphide and ex- traction of this precipitate with ammonium carbonate (both operations repeated twice). The second extract was worked up in the usual way for sulphide precipitates.	0.0015	$\frac{1}{14}$	10.0	$\frac{5}{14}$ ths of extract Marshled. Note.—This result is to be taken as approximate only. The mirror read was very small and the multiplication error was no doubt proportionately large. According to Bettendorf's test, this sample contained only a trace of arsenic (8th November 1902).

50	Dragon's Blood - (from sweet maker, 11th June 1902.)	14 Mar. 1903	3.0 grms.	Basic method followed by direct Marshing.	0.003	$\frac{1}{40}$	3.5	Two-sevenths of extract Marshel. This sample was almost wholly organic. It was a powder.
51	Caroline Colouring Matter - (from sweet maker, 11th June 1902.)	14 Mar. 1903	3.0 grms.	- ditto - ditto -	0.002	$\frac{1}{130}$	1.1	Three-fifths of extract Marshel. This sample was largely, if not wholly, organic. It was a powder.
52	Carnation Colour - (from sweet maker, 11th June 1902.)	14 Mar. 1903	0.55 grms. (of the paste).	- ditto - ditto -	0.031	$\frac{7}{10}$	103.0	20 c.c. out of a total of 37 c.c. were Marshel. This was a sticky paste, not a dry powder.
SMOKED OR DRIED FOODS:								
Chicory. (Fuel used for drying not known.) (From chicory roaster and importer.)								
53	*Sample A. ("Raw chicory as received from Holland.")	6 Aug. 1902	5.0 grms.	Nitric and sulphuric acids	0.001	$\frac{1}{730}$	0.2	Whole extract Marshel.
54	*Sample B. (Chicory dried and ground, ready for roasting in open pans.)	4 Sept. 1902	5.0 grms.	- ditto - ditto -	0.001	$\frac{1}{730}$	0.2	- ditto - ditto.
55	*Sample C. (Chicory, same as B., after roasting in open pans.)	4 Sept. 1902	5.0 grms.	- ditto - ditto -	0.001	$\frac{1}{730}$	0.2	- ditto - ditto.
56	*Sample D. (Chicory, ground, after roasting in cylinders; not from same bulk as A., B., and C.)	5 Sept. 1902	5.0 grms.	- ditto - ditto -	0.0038	$\frac{1}{200}$	0.75	- ditto - ditto.
57	*Coffee, roasted over gas coke fire. (18th July 1902.)	25 Mar. 1903	50.0 grms.	Extraction for 15 minutes at 50° C. with dilute hydrochloric acid, and subsequent direct Marshing.	0.001	$\frac{1}{730}$	0.2	The equivalent of 5 grms. coffee was Marshel.
58	*Lemon peel, dried over gas coke. (17th June 1901.)	28 Mar. 1903	33.0 grms.	Chlorate method	0.01	$\frac{1}{470}$	0.3	Whole extract Marshel.

Appendix 25.

## APPENDIX, No. 25—continued.

TABLE I.—Shewing Results of Examination for Arsenic of Miscellaneous Food Substances received from the Commission—continued.

1. Number of Sample.	2. Description of Sample.	3. Date when Analysed.	4. Quantity taken for Analysis.	5. Method of Analysis.	6. Arsenic mirror read. (Milligrammes.)	7. Arsenic (As, O <sub>3</sub> ) in grains per lb. Approximate fractions.	8. Parts per Million.	9. Notes as to Analysis.
594	SHOKED OR DRIED FOODS— <i>continued.</i>							
	Ham (dried over London gas coke). Received 12th July 1901. This ham weighed 12½ lbs. ;							
	Knuckle end (6½ lbs.) : (1) Steep water	Began 14 July 1901. July- Oct. 1901.	Whole of steep water.	(1) Knuckle-end steeped for 12½ hours on 14-15th July; the steep water concentrated 15-16th July, finally with addition of hydrochloric acid, and then the filtered solution precipitated as sulphide.	0.065	Trace (calculated on the 6½ lbs. of knuckle).	0.02	Whole extract Marshal.
	(2) Boil water	Began 17 July 1901. July- Oct. 1901.	½ of the whole boil water.	(2) The above knuckle-end, after steeping was boiled with water in an enamelled saucepan for 3½ hours, a portion of the liquid was evaporated down, finally with addition of hydro- chloric acid, and the filtered solution was precipitated as sulphide.	0.02	Trace (calculated on the 6½ lbs. of knuckle).	0.063	ditto ditto. 1. Though not probable, it is possible that the two results (1) and (2) may have been transposed. 2. There is no guarantee that the small quantity of arsenic found did not come from the enamelled pot. 3. It is, perhaps, hardly correct to calculate the arsenic found on the 6½ lbs. of ham; it might be better to do it on the liquid extract, as such an extract may be used as stock for soup. But even in that case the quantity of arsenic comes out very small.

## APPENDIX, No. 25—continued.

TABLE I.—Showing Results of Examination for Arsenic of Miscellaneous Food Substances received from the Commission—continued.

1. Number of Sample.	2. Description of Sample.	3. Date when Analysed.	4. Quantity taken for Analysis.	5. Method of Analysis.	6. Arsenic mirror read. (Milligrammes.)	7. Arsenic (As <sub>2</sub> O <sub>3</sub> ) in grains per lb. Approximate fractions.	8. Parts per Million.	9. Notes as to Analysis.
66	SMOKED OR DRIED FOODS— <i>continued.</i> Bloaters from Messrs. Hibbert, Bradford. Received 10th April 1902. (IV. a) From bottom layer of coke-room (i.e., nearest to coke fire). Skin.	21 May 1902	46.1 grms.	Chlorate method	0.031	$\frac{1}{140}$	1.9	Not examined until putrefying; not much mould. Two-thirds of extract Marshled.
67	Bloaters from Mr. Fletcher, Bradford. Received 10th April 1902. (V. a) From top layer of coke-room.	21 May 1902	50.0 grms.	ditto	0.024	$\frac{1}{200}$	0.7	Not examined until putrefying; not much mould. Two-thirds of extract Marshled.
68	Bloaters. Exuded liquor from eight bloaters (from Fletcher, Bradford, and Hibbert, Brad- ford). Bloaters received 9th April 1902.	21 May 1902	The whole of the liquid (not weighed).	ditto	0.0018	Arsenic-free	—	Two-thirds of the ultimate extract was Marshled.
68a	Smoked Herrings. Received July 1902. (a.) Skin of herring.	2 July 1902	Whole skin of one herring.	Extraction with ammonium carbonate and subsequent direct Marshing of the solution.	Negligible trace.	—	—	(a.) Whole extract Marshled. It would not do to depend on this estimation for a quan- titative result.
69b	(b.) Skin of large herring.	2 July 1902	Whole skin	Digestion with hydrochloric acid and "Reinschling" of the ex- tract.	Trace, if any	Arsenic-free	—	—
69c	(c.) Skin of medium herring weighing 104 grms.	3 July 1902	Whole skin (= 36.0 grms).	Distilled with hydrochloric acid alone, filtered the distillate and precipitated with sul- phuretted hydrogen.	0.01 (very ap- proximate).	$\frac{1}{350}$	0.4	Whole extract Marshled.

NOTE.—Samples marked \* in column 2 of this table were given to Mr. Hammond Smith by manufacturers or wholesale dealers. Other samples were purchased from retailers.

TABLE II.

SHOWING RESULTS OF EXAMINATION FOR ARSENIC OF SPECIAL SAMPLES RECEIVED IN CONNECTION WITH MR. H. SMITH'S EXPERIMENTS ON GOOSEBERRIES AND FOWLS.

1. Description of Sample.	2. Date when Analysed.	3. Quantity taken for Analysis.	4. Method of Analysis.	5. Arsenic Mirror read. (Milligrammes.)	6. Arsenic (As, O <sub>3</sub> ). Grains per lb. Approximate fractions.	7. Parts per Million.	8. Notes as to Analysis.
GOOSEBERRIES WATERED WITH PARIS GREEN:							
Gooseberries, No. 1.—Gathered eight days after watering.	24 July 1901	127.5 grms.	(a) Digestion for three hours with dilute ammonium carbonate, and subsequent "Reinschling" of the filtered solution. (b) Digestion with very dilute hydrochloric acid for about three hours, and fractional precipitation of the filtered liquid by sulphuretted hydrogen. Part of this bulky precipitate was subsequently worked up with chlorate.	A large number of well-defined octahedra.	—	—	—
Gooseberries, No. 1.—Gathered eight days after watering.	24 July 1901	127.5 grms.		0.035 { Different volumes of two extracts used. } 0.035 {	$\frac{1}{20}$	6.8	—
Gooseberries, No. 2.—Gathered 28 days after watering.	13 Aug. 1901	25.5 grms. (This was the whole of the sample.)	Digestion with dilute ammonium carbonate for 1½ hours, and subsequent treatment of the evaporated syrup with nitric and sulphuric acids.	0.06 approx.	$\frac{1}{60}$	2.4	Unfortunately the whole extract was Marshel, the resulting mirror being too dense to read with accuracy.
FOWLS TO WHICH ARSENIC WAS ADMINISTERED:							
Fowler's Solution used in experiment.	2 June 1903	5 c.c.	Direct Marshing, after steaming off the volatile oil present.	0.009	—	9000.0 (Theoretically this should give 10,000 parts per million.)	Mean of the original 5 c.c. were Marshel, i.e., $\frac{1}{1000}$ c.c.
Fowl, No. 5:—							
Liver and heart	30 Oct. 1901	55 grms. (i.e., whole sample.)	Chlorate method	0.025	$\frac{1}{200}$	0.7	Three-fourths of solution Marshel after preliminary trial with one-fourth.
Gizzard	30 Oct. 1901	41 grms. (i.e., whole sample.)	ditto	0.008	$\frac{1}{600}$	0.2	Three-fourths Marshel after preliminary trial with one-fourth.
Flesh (half of the breast and the flesh of one leg).	31 Oct. 1901	267.3 grms.	ditto	0.017	$\frac{1}{550}$	0.3	One-fourth of extract Marshel.
Fowl, No. 6:—							
Liver	28 Nov. 1901	47.3 grms. (i.e., whole sample.)	ditto	0.025	$\frac{1}{200}$	0.7	Three-fourths Marshel, after trying one-fourth.
Coarse feathers	28 Nov. 1901	8.0 grms.	ditto	0.023	$\frac{2}{5}$	28.0	One-twentieth of extract Marshel, after four trials with larger quantities.
Medium and fine feathers (about equal weights of each).	28 Nov. 1901	8.5 grms.	ditto	0.019	$\frac{1}{5}$	28.0	Four-fiftieths Marshel, after two preliminary trials.

## APPENDIX No. 25—continued.

TABLE III.

SHOWING RESULTS OF EXAMINATION OF CERTAIN MISCELLANEOUS SUBSTANCES (OTHER THAN FOOD) FOR ARSENIC.

1. Description of Sample.	2. Date when Analysed.	3. Quantity taken for Analysis.	4. Method of Analysis.	5. Arsenic mirror read. (Milligrammes).	6. Arsenic (As <sub>2</sub> O <sub>3</sub> ) Grains per lb. Approximate fractions.	7. Parts per Million.	8. Notes as to Analysis.
CIGARETTE PAPERS WITH METALLED TIPS: A. Bronze, made and sold by a firm in the East of London (labelled "Com- monest," 662.) Lengths (cms.) . . 1.25 5.7 Weights (grms.) . . 0.0134* 0.0334 * i.e., Metal, 0.0061; Paper, 0.0073.	(a) Paper	3.0 grms.	Basic method (lime water + lime), and Marsh- ing with hydrochloric acid.	0.0015	1 250	0.7	Seven-tenths of extract Marshel.
	(b) Tips (in- cluding the paper under the metal).	0.5 gm.	Chlorate method	0.0135	9 10	135.0	One-fifth of the extract was Marshel.
B. Loose packet—Bronze-tipped, sent by Dr. Buchanan, Liverpool. Uncovered Paper. Lengths (cms.) . . 1.25 5.75 Weights (grms.) . . 0.0119* 0.0333 * i.e., Metal, 0.0047; Paper, 0.0072.	(a) Paper	3.0 grms.	Basic method (as above)	0.001	1 250	0.7	Half the extract was Marshel.
	(b) Tips (in- cluding the paper under the metal).	0.5 gm.	Chlorate method	0.029	4	370.0	One-tenth of the extract was Marshel.
C. Aluminium-tipped, made and sold by a firm in the East of London. Uncovered Paper. Lengths (cms.) . . 0.9 6.3 Weights (grms.) . . 0.0057* 0.0312 * i.e., Metal, 0.0042; Paper, 0.0045.	(a) Paper	3.0 grms.	Basic method	None.	Arsenic-free	—	Half of extract Marshel.
	(b) Tips (in- cluding the paper under the metal).	1.0 gm.	Chlorate method (followed, as usual, by precipita- tion with sulphuretted hydrogen).	None.	Arsenic-free	—	Half of extract Marshel.

D. Imitation gold-tipped, made and sold by a firm in the East of London.	(a) Paper	21 May 1903	3.0 grms.	Basic method	None, or negligible trace.	Mere trace, or arsenic-free.	say 0.1	Seven-tenths of Marshal.	extract
Uncovered Paper. Lengths (cms.) - 1.3 Weights (grms.) - 0.0144* i.e., Metal, 0.0057; Paper, 0.0087.	(b) Tips (including the paper under the metal).	21 May 1903	0.5 grm.	Chlorate method	0.015	1 2	75.0	Two-fifths of extract Marshal.	
E. Loose packet, gold-tipped, sent by Dr. Buchanan, Liverpool, 23rd May 1901. Marked 306, a.	(a) Paper	22 May 1903	3.0 grms.	Basic method	0.0015	1 200	0.7	Seven-tenths of extract Marshal.	
Uncovered Paper. Lengths (cms.) - 1.6 Weights (grms.) - 0.0171* * i.e., Metal, 0.0056; Paper, 0.0115.	(b) Tips (including the paper under the metal).	21 May 1903	0.5 grm.	Chlorate method	0.009	3 5	90.0	One-fifth of extract Marshal.	
PARCHMENT PAPER, manufactured with sulphuric acid, used for wrapping foods.	—	3 Dec. 1901	3.5 grms.	Reinach's method	—	Arsenic-free.	—	Copper was only just stained after three hours, and in a blank with pure acid there was a similar stain after two and a-half hours.	
SULPHURIC ACID from vitriol works, reported as good average makes, 1903: A. Not de-arsenicated. As being sold from stock (sp. gr. 1.71). B. As running from dearsenicating apparatus (sp. gr. 1.54).		28 July 1903	0.005 c.c. (= 0.0085 grms.) 3 c.c. (= 7.70 grms.)	Direct Marshaling ditto	0.013 None	104 Arsenic-free.	159.0 —	— —	
WATER-SOFTENING POWDER, recommended for softening domestic and drinking water		7 August 1903	2.5 grms.	ditto	0.0009	1 40	3.6	—	

*Notes.*—The ungilded portions of a single cigarette paper of series A., B., and E., in each instance contained about one three-millionth of a grain of arsenic.

The metal of the gilded portion of a single cigarette paper contained:—Series A.,  $\frac{1}{1000000}$  grain of arsenic; Series B.,  $\frac{1}{1000000}$  grain of arsenic; Series E.,  $\frac{1}{1000000}$  grain of arsenic.

In all the above cases the gilt was loosely adherent to the paper, and became partly detached with only gentle rubbing, and would thus be liable to come off on the lips.

GEORGE MCGOWAN.

## Appendix 26.

## APPENDIX 26.

COPIES OF LETTERS FROM MR. J. N. BEACH, SECRETARY TO THE MALTINE COMPANY  
(See Q. 11,496).

S, Delahay Street,  
Westminster, S.W.,  
6th November, 1902.

Dear Sir,

I am directed by Lord Kelvin to inform you that this Commission wish to obtain information as to the liability of malt made in America and used for maltine and similar foods to contain arsenic, and as to the precautions against arsenic which may be taken by manufacturers of these foods in America.

Mr. Hammond Smith informs the Commission that he brought this matter to your notice last year, and that no doubt you would now be in a position to give the Commission the information they desire.

Accordingly I am directed to request that you will be so good as to attend at their next meeting on Friday, 21st instant, at 11.45 a.m. for the purpose of giving them brief evidence on the matter.

I should add that the Commission do not propose in connection with this branch of their inquiry to admit Press reporters.

I am, dear Sir,

Yours faithfully,

(Signed) G. S. BUCHANAN,  
Secretary to Commission.

J. N. Beach, Esq.

24 and 25, Hart Street,  
Bloomsbury, W.C.,  
10th November, 1902.

Dear Sir,

I have duly received your letter of the 6th instant. I remember Mr. Hammond Smith calling upon me, and he asked me to obtain from our friends in America, who manufacture a preparation called "Liquid Peptonoids," a statement as to the acid they use in their manufacturing process. Our friends wrote us, under date February 13th, 1902, as follows:—

"Inasmuch as we use only chemically pure hydrochloric acid, in the preparation of the peptonoids, the presence of arsenic is out of the question."

With reference to maltine, and the precautions adopted against contamination by arsenic, in the preparation of maltine in America, my recollection is that we only discussed this generally, and I stated that I did not see how it was possible for this preparation to contain arsenic. I did not write to the Chemist of the Maltine Company on the matter. I have, however, by last mail mentioned your letter, and requested full particulars on the subject, and I think it would be well to postpone my call, until I have received an answer from our works. If you have any special points on which you want information, perhaps you will be good enough to communicate these, and I will then submit them to the other side.

Yours very truly,

J. N. BEACH.

The Secretary,  
The Royal Commission on Arsenical Poisoning.

8, Delahay Street, S.W.  
12th November, 1902.

Dear Sir,

With reference to your letter, November 10<sup>th</sup>, I will inform the Commission at their forthcoming meeting that you are not at the moment prepared with information likely to be of service to their inquiry. As, however, they have decided that some evidence concerning maltine manufacture in America is desirable, they would

be obliged if, as you suggest, you would obtain information as to liability of malt made in America and used for maltine to contain arsenic; and also as to the precautions regarding arsenic which are taken by maltine manufacturers.

I may add that with regard to the hydrochloric acid used in "Liquid Peptonoids," &c., the Commission has received a considerable amount of evidence which shows that hydrochloric acid sold as pure may nevertheless contain notable amounts of arsenic, and I think it would be valuable to the Commission if you enabled Mr. Hammond Smith to state in somewhat greater detail in his report whether it is the custom of the manufacturers of these peptonoids to systematically test the acid for arsenic themselves, or what other steps are taken to secure its purity as regards arsenic.

I am,

Yours faithfully,

G. S. BUCHANAN,

Secretary to the Commission.

J. N. Beach, Esq.

24 and 25, Hart Street,  
Bloomsbury, W.C.,  
19th November, 1902.

Dear Sir,

I duly received your favour of the 12th instant, and I have written to our friends in America for the information you desire, and will submit this to you when it comes to hand.

Yours truly,

J. N. BEACH.

The Secretary,  
The Royal Commission on Arsenical Poisoning.

24 and 25 Hart Street,  
Bloomsbury, W.C.,  
24th December, 1902.

Dear Sir,

Referring to our letter of November 19th, our friends in Brooklyn write with reference to malt under date December 9th as follows:—

"The liability of malt to arsenic contamination is very, very remote. Neither our maltsters nor our chemist can conceive how such contamination could occur. The extreme care and cleanliness which are observed both in the malting process and in that of the manufacture of maltine preclude contamination of any kind."

With reference to the Liquid Peptonoids, the Arlington Chemical Company write us under date 2nd instant:

"Replying to yours of the 14th ultimo, in regard to the possibility of the presence of arsenic in the hydrochloric acid used in connection with Liquid Peptonoids, we will say that from every lot of this acid purchased by us we take a sample and submit same to tests for arsenic or other impurities, and if there is any question as to the presence of this substance we discard the lot. It is, therefore, quite impossible that there should be any contamination of Liquid Peptonoids with arsenic."

You might communicate this information to the Commission; I could not add anything to these statements if I appeared personally.

I am,

Yours respectfully,

J. N. BEACH.

The Secretary,  
The Royal Commission on Arsenical Poisoning.

## APPENDIX 27.

Appendix 27.

## LETTER FROM MR. OTTO HEHNER ON ARSENICAL CONTAMINATION OF CERTAIN FOODS THROUGH THE USE OF COLOURING MATTERS (MINERAL AND OTHER).

The Laboratory, 11, Billiter  
Square, E.C., London.  
June 26th, 1903.

DEAR SIR,

When I had the honour, some time ago, to give evidence before the Royal Commission on Arsenical Poisoning, I drew attention to the fact that oxide of iron was frequently used as a colouring substance of articles of food, and that commercial oxide was almost invariably strongly arsenical. I had, however, at that time not been able to trace any arsenic in any articles of food thus coloured, partly owing to the comparatively small quantity of oxide used in most cases, and partly to the then difficulty of dealing with articles of food analytically, the huge relative amounts of organic matter rendering direct testing almost impossible. The process of destroying the organic matter by means of nitric and sulphuric acids and extracting the carbon with water, recommended by the Joint Committee of the Societies of Chemical Industry and Public Analysts, is so easy to carry out, and gives within a very short time trustworthy results, that I have now examined a number of food samples in which I had found added iron oxide. The results of my tests—that is to say, the tubes containing the arsenic-mirrors—I now beg to submit, through you, to the Members of the Royal Commission. They show clearly that whenever oxide of iron is used as a colour, arsenic can be traced in the food thus contaminated.

Card I. holds four mirrors consecutively obtained from the solution yielded (after acid treatment) by 10 grammes of certain sweets, of which I also enclose a sample. The arsenic is contained only in the chocolate-coloured portion of the sweets, the colour being mainly iron oxide, while the pink portion is quite free from arsenic, as shown by the tubes on card No. II. I may say that these sweets were submitted to me in my capacity as Public Analyst for the Isle of Wight, and that I have declared them to be arsenical. Whether proceedings against the vendors are being taken I cannot at the time of writing state. I estimate the sweets to contain approximately '028 grain of arsenic per lb.

Card III. holds tubes obtained from chocolate powder lately largely sold in London at a very cheap price. The

firm selling the same immediately withdrew it from the market on being informed by me of the impurity. I estimate the chocolate powder to contain approximately between '04 and '05 grain of arsenic per lb. They submitted to me samples of the iron oxide, which were immensely arsenical.

Cards IV., V., and VI. hold tubes showing the arsenic in some brands of bloater-paste and anchovy-paste, purchased by me in the open market. The arsenic in these samples is obviously to be easily detected by the method employed.

Although arsenic is no longer used in the manufacture of aniline colours, yet some aniline colours largely used in the manufacture of sweets and jams are strongly arsenical, probably from the use of arsenical sulphuric acid. Such colours, when tested without destruction of the organic matter, give no arsenic reaction, but readily do so after heating with nitric and sulphuric acids. Evidently the arsenic is present in organic combination, not as "ionic" arsenic. Cards VII. and VIII. show the arsenic contents of stated quantities of colour.

Lastly, Card IX. shows the arsenic from different samples of paper shavings, used to pack cakes and other similar goods.

Although it is probable that arsenic when combined with iron oxide will exert less action, if any, upon the organism than the arsenious acid, it appears to me to be a matter of grave public danger, imperilling possibly the freedom or lives of innocent persons, to permit even what may be assumed to be physiologically inert arsenic to be present in food-materials. The evidence I am submitting herewith shows clearly that through even the small proportion of colouring matter used very heavy traces of arsenic can be conveyed into food.

I have the honour to remain,  
Yours very faithfully,  
OTTO HEHNER.

Dr. G. S. Buchanan,  
8, Delahay Street, Westminster, S.W.

P.S.—If the Royal Commission desire to see me on the matter, I am, of course, at their entire disposal.

## APPENDIX 28.

## POSSIBLE ADDITION OF MINERAL ACID TO WHISKY AND GIN.

## I. DR. MCGOWAN'S REPORT ON EXAMINATION OF SAMPLES OF WHISKY AND GIN OBTAINED FROM TWELVE PUBLIC-HOUSES IN THE EAST END OF LONDON.

At the end of November, 1902, Mr. Swinson, Inspector of the London County Council, obtained samples of cheap whisky and gin from twelve public-houses in poor neighbourhoods in Poplar, Wapping, Shadwell,

and St. George's in the East. In each instance he sent a labouring man into the public-house to purchase the sample. Dr. McGowan's report on these samples is as follows:—

## RESULTS OF EXAMINATION OF SPIRITS FOR MINERAL ACID.

These were received from Dr. Buchanan on February 5th, 1903.

Date of Collection.	Description of Sample.	Chloride.	Sulphate.	Acidity calculated as Acetic acid.	
				(1) Grains per gall.	(2) Per cent.
No. 1. Nov. 21st, 1902	Whisky from "The Old Star," Watts Street, Old Gravel Lane, Wapping.	Faint trace	None.	—	—
No. 2. "	Whisky from "The Red Lion," Old Gravel Lane, Wapping.	Faint trace	Faint trace.	—	—
No. 3. "	Gin from "The Bunch of Grapes," St. George Street, Wapping.	None	None	3.75	0.054

Note.—The above estimations were done by Mr. Eric H. Richards, B.Sc.

George McGowan.

Ealing, March 9th, 1903.

## METHODS.

*Qualitative Tests for Sulphuric and Hydrochloric Acids.*—The samples were first tested qualitatively for sulphuric acid and hydrochloric acid, either combined or free. In testing for sulphate, 5 cc. (approx.) of the spirit were diluted to about 25 cc. with water and 1 cc. of a 10 per cent. barium chloride solution was added. The liquid was boiled and any precipitate or turbidity noted. In no case was there more than a distinct turbidity, this indicating that if any sulphate was present, it was in very small amount only.

In testing for chloride with silver nitrate solution, the organic matter present in the samples of gin was found to reduce the silver salt and thus to interfere with the test. In order, therefore, to make sure that no free hydrochloric acid was present in these samples,

they were all examined by the quantitative method described below. The above qualitative tests do not, of course, distinguish between free and combined acid, but the results showed that the former, if present at all, must be so in only minute and inappreciable amount. All the samples were acid in reaction when tested with phenol-phthalein, and this indicator was used in determining their acidity by titration with standard soda solution.

*Detection and Quantitative Estimation of Free Mineral Acid.*—The method employed to detect and estimate free mineral acid quantitatively was that described by O. Hehner ("Analyst," I. 105) for the estimation of mineral acids in vinegar. A measured volume of the spirit, usually 100 cc. was titrated with decinormal soda solution,\* using phenol-phthalein as indicator.

\* This solution was prepared by dissolving sodium hydroxide in absolute alcohol, in order to remove sodium carbonate, which remained undissolved.

The neutralised spirit was then evaporated to dryness on a water bath, preferably in a platinum basin. When dry, the residue was gently ignited, so as to convert any alkaline acetates, tartrates, etc., into carbonate. The ignited residue, after digesting with a little water, was then re-titrated with standard sulphuric acid. If no free mineral acid was present originally in the spirit, the amount of standard acid now required should be exactly equivalent to the alkali originally added. If, on the other hand, less acid than this was required, it followed that some of the acid neutralised by the soda

must have been mineral acid, the sodium salt of which was consequently not converted into carbonate on ignition. It was not thought worth while to make this quantitative estimation with Nos. 1, 2, 7 and 9, seeing that they showed qualitatively either no chloride or sulphate, or only mere traces of these. No mineral acid was found in any of the samples tested by the above ignition process.

GEORGE MCGOWAN.

Ealing, March 9th, 1903.

## II. INFORMATION SUPPLIED TO THE COMMISSION BY THE LONDON COUNTY COUNCIL.

County Hall, Spring Gardens, S.W.  
6th March, 1903.

Sir,—I am directed to forward, for the information of the Royal Commission on Arsenical Poisoning, the enclosed statement showing the effect of the replies received from Metropolitan Borough Councils to the letter which I addressed to them by direction of the Council, suggesting that samples of whisky and gin should be analysed with a view to the detection of arsenic. It will be observed

that the replies show that only negative results have been obtained.

I am Sir,

Your obedient Servant,  
G. L. GOMME,  
Clerk of the Council.

The Secretary,  
Royal Commission on Arsenical Poisoning,  
8, Delahay Street,  
Westminster, S.W.

[See Table on the following page:—

## Appendix 28.

## EXAMINATION OF SAMPLES OF SPIRITS FOR TRACES OF ARSENIC.

Metropolitan Borough.	Number of Samples Analysed.	Results of Analyses.
Battersea - - - - -	—	Only negative results.
Bermondsey - - - - -	—	Negative results.
Bethnal Green - - - - -	24	Free from any trace of arsenic.
Camberwell - - - - -	—	No adulterated samples found.
Finsbury - - - - -	35	No arsenic found.
Fulham - - - - -	—	No result shown by the analysis.
Greenwich - - - - -	—	No arsenic found.
Hackney - - - - -	—	No arsenic detected.
Hammersmith - - - - -	27	No evidence of sulphuric acid having been used in their preparation.
Hampstead - - - - -	6	Found pure.
Holborn - - - - -	—	No evidence of the presence of sulphuric acid.
Islington - - - - -	16	Negative results.
Kensington - - - - -	—	Negative results invariably obtained.
Lewisham - - - - -	15	No arsenic detected.
Paddington - - - - -	—	Not the slightest trace of arsenic.
Poplar - - - - -	5	No arsenic found.
St. Marylebone - - - - -	—	Negative results.
St. Pancras - - - - -	—	No traces of arsenic.
Shoreditch - - - - -	18	All found to be free from arsenic.
Stoke Newington - - - - -	—	Entirely negative results.
Wandsworth - - - - -	—	Free from injurious ingredients.
Westminster - - - - -	135 (Spirits and Beer).	No arsenic detected.
Woolwich - - - - -	6	All free from arsenic.

No replies have yet been received from the Chelsea, Lambeth\*, Southwark and Stepney Borough Councils, and the Deptford Borough Council did not see their way to take action in the matter.

\* In May 1903 the Clerk to the London County Council forwarded a letter from Dr. T. Priestly on the results of examination of 31 samples of whisky taken in the borough of Lambeth. None of these contained arsenic or free sulphuric acid.

## APPENDIX 29.

Appendix 29.

## REPORTS ON EXAMINATION OF ENAMELLED COOKING UTENSILS FOR ARSENIC.

## SECTION I.—GENERAL ACCOUNT AND SUMMARY OF RESULTS.

The question of the use of arsenic as an ingredient of the white enamel of saucepans, dishes, and other "hollow ware" was referred to by Mr. Hammond Smith in Section IV. of his report to the Commission (Appendix No. 24, Section IV.). In his evidence (Q. 11,008-11,023) he stated that inquiries as to the manufacture of hollow ware in this country indicated that the use of arsenic in their enamelling had been altogether discontinued in recent years. He drew attention, however, to a recent instance reported by Mr. Albert Smith, analytical chemist, of Highbury, and communicated to the "Ironmonger" of August 2, 1902 (p. 185), where up to 2.03 per cent. of arsenic was found in the enamel of certain cooking utensils. Mr. Albert Smith had also stated that he had found that solutions of common salt or soda readily took up arsenic when boiled for a few minutes in these utensils.

The Commission considered it advisable that some samples of enamelled cooking utensils should be collected and tested by Dr. McGowan in order to ascertain whether arsenical specimens such as those met with by Mr. Albert Smith were common.

*Collection of Samples.*

At the date of his evidence Mr. Hammond Smith had already obtained, through Mr. Cochrane, a retired ironmonger, a collection of enamelled stewpans, frying pans, and pie-dishes from nine different sources, as follows:—

## Manufacturer.

- Series I. Duntz and Co., Homberger Co.  
 „ H. Hupfeld and Co., London.  
 „ H. Fearncombe and Co., Wolverhampton.  
 „ IV. Wm. Robinson and Co., Wolverhampton.  
 „ V. Orme, Evans and Co., Wolverhampton.  
 „ VI. Charles J. Price and Sons, London.  
 „ VII. Hermann Wappermann, Holstein.  
 „ VIII. W. A. Bayliss, Cardiff.  
 „ IX. Anglo-American Co.

Mr. Cochrane stated that he considered that the above list comprised nearly all the principal manufacturers of enamelled cooking utensils which are sold in this country. Unfortunately, Mr. Albert Smith was unable to give any information which allowed the samples in which arsenic was present to be identified with any firm of manufacturers. He had purchased them in a street in Shoreditch from an itinerant vendor, and they had no distinctive marks. He had been informed that probably they were of Belgian make, but this was only surmise.

It seemed advisable, therefore, to add to the above series samples of cheap enamelled hollow-ware, of foreign origin, taken from small shops or street barrows. Mr. Shirley Murphy, Medical Officer of Health of the London County Council, kindly gave his assistance in the matter, and Mr. Swinson, one of the Council's inspectors, purchased such samples for the Commission. Mr. Swinson, in addition, made careful inquiries, and ascertained in several instances the place of manufacture of the specimens purchased. At the beginning

of December, 1902, he had supplied the Commission with specimens as follows:—

Series.	Date of Purchase, 1902.	Vendor.	Origin of Ware if traced.
X.	18 Nov.	M. B., Commercial Road.	German Enamel Ware Company.
XI.	21 Nov.	Bought in Wentworth Street.	Said to be "German ware," but origin unknown.
XII.	20 Nov.	R. W., Soho	German ware (taken from crate).
XIII.	20 Nov.	Ditto	Belgian ware, from St. Servair (taken from crate).
XIV.	27 Nov.	S. S., Earl's Court.	Birmingham ware.
XV.	29 Nov.	L. M., Shoreditch.	Belgian ware.
XVI.	4 Dec.	G. C., Spitalfields.	Said to be German, but origin unknown.
XVII.	4 Dec.	H. K., White-chapel.	Ditto.
XVIII.	4 Dec.	?	? Belgian ware
XIX.	4 Dec.	?	? German ware.

In transmitting these samples, Mr. Swinson sent the following note:—

"31, Whitehall Gardens,  
 "Gunnersbury, W.  
 "12th January, 1903.

"Dear Sir,

"In connection with the samples of enamel ware obtained by me, the following particulars may be of interest to you.

"The cheapest ware sold in London is apparently that of German origin, and it is ware of this make which forms the principal stock-in-trade of street-hawkers, the majority of whom are found in East London.

"These hawkers also have a quantity of Belgian ware of the quality known as 'Thirds,' as well as ware which, owing to being damaged, is unsaleable in better class neighbourhoods.

"The larger portion of the ware sold in good class shops is of Belgian make, of the quality known as 'Firsts' and 'Seconds.' Most shops of this description also stock ware of English manufacture.

"The difference in the quality of 'Firsts,' 'Seconds,' and 'Thirds' is due to the number of coats of enamel placed upon the utensils. 'Thirds' are 40 per cent. to 50 per cent. cheaper than 'Firsts.'

"Ware of English manufacture is approximately 12½ to 20 per cent. dearer than Belgian ware of the quality known as 'Firsts.'

"It would appear to be impossible to distinguish between ware of Belgian and German manufacture, on which point the opinion of dealers, both wholesale and retail, is unanimous.

"This difficulty does not arise in connection with ware of English manufacture, as owing to its superior finish the latter is easily recognisable.

"The above-mentioned information was derived from various wholesale and retail hardware dealers, and I believe it can be relied on.

"Yours obediently,  
 (Signed) "E. THOMAS SWINSON."

H. Hammond Smith, Esq.

Appendix 29. Mr. Swinson usually took more than one article in each series, and the total collection comprised a large number of saucepans, frying-pans, pie-dishes, jugs and kettles. Series XIV. consisted of only one sample—an enamelled double saucepan used for sterilising milk for infants.

The whole of the utensils of Series I. to XIX. were sent to Dr. McGowan, it being arranged that examination for arsenic would in the first instance be restricted to one or two specimens, preferably saucepans, in each series; if solutions boiled in any one saucepan showed notable amounts of arsenic then the other specimens of that series were to be tested.

#### *Solubility of Arsenic when an Ingredient of Enamel.*

Before proceeding on this work, however, Dr. McGowan considered it desirable to ascertain whether a saucepan with arsenic in its enamel will yield a material quantity of arsenic when boiled with plain water, or whether for the purpose required it would be more satisfactory to use a boiling solution of common salt, or a boiling solution made alkaline by carbonate of soda. For this purpose Mr. Hammond Smith communicated with a firm in the Midlands, who, after study of the analyses made by Mr. Albert Smith, kindly undertook to prepare experimental saucepans of the kind required. They made four saucepans, A<sup>1</sup>, A<sup>2</sup>, B<sub>1</sub>, and B<sub>2</sub>, as follows:—

In A<sup>1</sup> and A<sup>2</sup> the enamel consisted of a ground glass to which lead carbonate and arsenic were added in the mill as follows:—

Anhydrous plumbic carbonate, 5 lbs.  
Arsenious anhydride, 6 ozs.  
To a 25 lb. charge of the glass.

In B<sub>1</sub> and B<sub>2</sub> the enamel consisted of a similar glass, to which were added in the mill:—

Anhydrous plumbic carbonate, 5 lbs.  
Arsenious anhydride, 8 ozs.  
Magnesium carbonate, 4 ozs.  
To a 25 lb. charge of the glass.

Each saucepan had two coats of arsenical enamel laid on a first coat which contained no arsenic. Each was a six pint saucepan, and the weight of the arsenical enamel used was roughly estimated at 6 ozs. in each case.

The results of testing solutions boiled in these saucepans are reported in Section II. below. It was found that a considerable quantity of arsenic was extracted from the enamel by boiling with London tap water, and still more by boiling with soft, glass-distilled, water. After such boiling the quantity of additional arsenic which was extracted by a further boiling with a saline or slightly alkaline solution was relatively small. Taking the highest result, the amount of arsenic extracted from saucepan A<sup>1</sup>, namely, 1.14th grain, was obtained by a single boiling with distilled water. It seemed sufficient, therefore, in the first instance to boil glass distilled water in each of the purchased specimens which were to be examined. If arsenic was detected in noteworthy amount in any particular instance, further experiments could be made with saline and alkaline solutions.

#### *Examination of Series of Enamelled Cooking Pots I. to XIX.*

The results of examination in this way of specimens of hollow ware from Series I. to XIX. are given by Dr. McGowan in Section III. Prolonged boiling with glass-distilled water did not in any instance extract more

than a trace of arsenic so small as to be almost incapable of estimation. In no instance would the proportion of arsenic extracted represent more than .005 per million, calculated approximately on the original volume of liquid taken. It was safe to conclude from these results that arsenic had not been purposely added as an ingredient of the enamel in any of the specimens examined. There was nothing to suggest that examination of all the specimens in any one series was specially called for, and accordingly the surplus samples obtained have not been tested.

G. S. B.

June, 1903.

#### SECTION II.—REPORT BY DR. G. MCGOWAN ON THE EXAMINATION OF SOLUTIONS BOILED IN SPECIALLY MADE SAUCEPANS, THE ENAMEL OF WHICH CONTAINED ARSENIC AS AN INGREDIENT.

The four saucepans in question were received in December, 1902. Their origin and composition have been described in Section I. Their capacity in each instance was about six pints or 3½ litres. As filled up with water to be boiled, they contained something like five pints, or 2½ litres.

The method followed was to fill the pot nearly full with either glass-distilled water or other liquid, and to boil vigorously at first, and then more gently as the volume of liquid became smaller. The boiling down usually required from four to five hours. When the volume had been reduced to about 300 c.c. or so, the liquid was transferred to a basin of Berlin porcelain, evaporated down to a small bulk and made up to 100 c.c. A suitable portion was then Marshaled with hydrochloric acid (hydrochloric acid standards being used).

The residual solutions were always more or less turbid, especially, of course, when tap water was used. In every case there was a small quantity of sediment which could not be washed out of the saucepans, and which it was not considered advisable to rub off, for fear of detaching other matter at the same time.

The saucepans were cleaned between two operations by running some water into them and rubbing with an ordinary saucepan brush.

It will be seen that the above conditions of experiment were not actually the same as those which obtain in cooking (the saucepans having no lids). Less surface was exposed to the water in the experiment, because the volume of the liquid gradually diminished; but, on the other hand, the long time during which boiling proceeded would tend to equalise this.

The results obtained are shown in Table I. below.

#### SECTION III.—REPORT BY DR. MCGOWAN ON EXAMINATION FOR ARSENIC OF ENAMELLED COOKING UTENSILS (SERIES I. TO XIX.) OBTAINED FROM VARIOUS SOURCES.

The method of examination here again consisted in each instance in boiling down glass-distilled water from one hour to four hours, according to the size and shape of the vessel, and Marshing as described in the last section.

The results obtained are shown in Table II. below.

June, 1903.

G. MCGOWAN.

## APPENDIX No. 29—continued.

TABLE II.

## ENAMELLED COOKING POTS OF SERIES I. TO XIX.

Vessel Employed.	Origin of Sample, Series	Approximate Total Capacity and Shape.	Date of Experiment, 1903.	Solution Boiled.	Time required for Boiling down.	Mirror read—Milligrams $As_2O_3$ .	Other Mirror besides the Arsenical Mirror.	Total quantity of Arsenic extracted in the boiling.	NOTES.
Small Saucepan	I.	700 c.c.	21 February	Glass-distilled water.	The time required for boiling down varied from about one hour in the case of the smallest vessels to between four and five hours in the case of the largest.	None	None	None	Whole extract Marshled.
Small Saucepan	II.	500 "	21 February	ditto		Trace	None	Trace	Whole extract Marshled.
Small Saucepan	III.	750 "	23 February	ditto		None	Fairly heavy mirror on both sides of flame.	None	Whole extract Marshled. This extract, like all others which gave non-arsenical mirrors, was distinctly turbid.
Small Saucepan	IV.	500 "	18 February	ditto		Mere trace	None	Mere trace	Whole extract Marshled.
Small Saucepan	V.	350 "	16 February	ditto		Mere trace	None	Mere trace	Whole extract Marshled.
Frying-pan	V.	500 "	20 March	ditto		0.0018	None	Mere trace	Whole extract Marshled.
Small Saucepan	VI.	750 "	23 February	ditto		None	Small	None	Whole extract Marshled.
Pie-dish	VII.	1,250 "	27 May	ditto		None	None	None	Whole extract Marshled.
Small Saucepan	VIII.	500 "	18 February	ditto		Probably a small amount which could not be estimated.	Large	(?)	Whole extract Marshled. This enamel had a bluish mottled appearance. The extract looked turbid like those from A <sub>1</sub> , B <sub>1</sub> , A <sub>2</sub> and B <sub>2</sub> .
Small Saucepan	IX.	350 "	16 February	ditto		0.0013	None	Mere trace	Whole extract Marshled.
Coffee-pot	X.	1,000 "	14 February	ditto		None	Slight	None	2 lbs of extract Marshled.
Jug	X.	1,000 "	20 February	ditto		0.002	None	Mere trace	Whole extract Marshled.
Mug	X.	500 "	27 February	ditto		None	None	None	Whole extract Marshled. Enamelling faulty.
Bowl	X.	500 "	27 February	ditto		Mere trace	None	None	Whole extract Marshled. Enamelling faulty.

Stewpan	X.	Depth . 1.750 c.c. Diameter 6.5 inches.	25 February	ditto	0.002	None	Merest trace	Whole extract Marshled
Stewpan	X.	Depth . 2.500 c.c. Diameter 7 inches.	26 February	ditto	0.001	None	Merest trace	Whole extract Marshled.
Saucepan	XI.	Depth . 2.750 c.c. Diameter 6.4 inches.	14 February	ditto	0.002	None	Trace (0.0001 grain).	1/3 of extract Marshled.
Pie-dish	XII.	Depth . 1.250 c.c.	27 May	ditto	Merest trace	None	None	Whole extract Marshled.
Pie-dish	XIII.	1.250 "	27 May	ditto	0.001	Distinct	None	Whole extract Marshled.
Milk Sterilizer :	XIV.							
(a.) Inside portion	-		16 February	ditto	Trace	None	None	Whole extract Marshled.
(b.) Outside portion	-		16 February	ditto	Merest trace	None	None	Whole extract Marshled.
Small Saucepan	XV.	Depth . 1.000 c.c. Diameter 5.5 inches.	26 February	ditto	0.001	None	Merest trace	Whole extract Marshled.
Stewpan	XV.	Depth . 3.000 c.c. Diameter 8 inches.	17 March	ditto	Very little, but could not be read with any accuracy in either of two estimations.	Large	(?)	Whole extract Marshled in both cases.
Porridge pot :	XVI.	Depth . 2.000 c.c. Diameter 5.75 inches.	24 February	ditto	None, so far as could be judged.	Mirror on wrong side.	(?)	Whole extract Marshled.
(a.) Inside vessel	-	Depth . 3.500 c.c. Diameter 6.75 inches.	17 March	ditto	Trace	None	Trace	Whole extract Marshled. Enamel not perfect. Small patches of metal exposed.
(b.) Outside vessel	-	1.000 c.c.	27 May	ditto	0.001	None	Merest trace	Whole extract Marshled.
Teapot	XVII.	1.500 "	25 February	ditto	Merest trace	None	Merest trace	Whole extract Marshled. Enamel not quite perfect around the bottom.
Stewpan	XVIII.		14 February	ditto	Merest trace	None	Merest trace	1/3 of extract Marshled.
Stewpan	XIX.	Depth . 1.000 c.c. Diameter 4.75 inches.						

## NOTES.

1. NOTE TO STEWPAN OF SERIES XV.—A third quantity of glass-distilled water was evaporated in Stewpan No. XV.n, the residual liquid digested in a porcelain basin with hydrochloric acid and chloride of potassium, reduced with sulphurous acid in the usual way and Marshled. The mirror obtained was almost identical with those in the first two estimations (which were Marshled directly). This proves that the mirror was not due to organic matter.

2. In certain instances I have worked out the approximate quantity of arsenic in parts per million of the solution, calculated approximately on the original volume of liquid taken for boiling. The highest proportion thus calculated is no more than 0.004 part of arsenic per million (S. STEWPAN OF SERIES IX.).

George McGowan.

## APPENDIX 30.

## REPORTS ON MALTING ANTHRACITE.

## REPORTS ON INVESTIGATIONS MADE FOR THE COMMISSION ON MALTING ANTHRACITE, AND "IMPURITIES" IN ANTHRACITE SEAMS, IN THEIR RELATION TO ARSENIC.

The Reports on this subject are arranged in parts as follows:—

## I. Account of Inquiry and Summary of Results.

II. Notes by Mr. H. Hammond Smith on inquiries as to anthracite used at certain maltings visited by him in August, 1901.

III. Notes by Mr. A. Strahan, F.R.S., District Geologist of H.M. Geological Survey, on visits made by him to certain anthracite collieries in South Wales which supply maltsters, and recommendations as to samples which should be collected for analysis.

IV. Report by Mr. S. Warren Price, Lecturer on Mining Engineering at University College, Cardiff, on

his collection of specimens for the Commission at these anthracite collieries in South Wales, together with notes on observations made by him in course of sampling in the mines.

V. Report by Dr. G. McGowan on the results of examination for arsenic of the specimens obtained by Mr. Price at anthracite collieries in South Wales, and also on a few other samples of malting fuel.

*N.B.*—A memorandum by Dr. McGowan and Mr. R. B. Floris on the methods adopted in estimating arsenic in fuel samples appears in a separate Appendix No. 23.

## VI. Account of two experiments at Newark maltings.

## PART I.—ACCOUNT OF INQUIRY AND SUMMARY OF RESULTS.

## ACCOUNT OF INQUIRY.

At the outset of the inquiry it was desired to obtain information as to the collieries which supplied some representative maltsters, and as to the custom of maltsters in selecting and ordering their fuel.

## MR. HAMMOND SMITH'S NOTES.

In these notes (*No. II., below*) Mr. Hammond Smith reports on visits made in August, 1901, to four large malting firms at Newark, Burton, Sawbridgeworth and Smethwick respectively. All these firms had used anthracite exclusively since attention was directed to the liability of malt to contain arsenic; two had formerly used coke. Their anthracite was obtained directly or through agents from nine collieries altogether, eight of which were identified by Mr. Smith. He gives notes of the considerations (heating power, "flavouring" properties, etc.) which appeared to influence the maltsters in the selection of particular collieries. All anthracite supplied was understood to be hand-picked at the colliery in order to remove impurities, but impure coal and pyrites were sometimes met with in the fuel delivered. Two maltsters had caused some analyses of anthracite for arsenic to be made, but there had been no question at any of the maltings of purchasing anthracite under guarantee as to arsenic. No weight was attached by the maltsters to copies of analyses which they received from colliery companies showing that anthracite samples had been found free from arsenic.

## MR. STRAHAN'S NOTES.

Following on communications between the Commission and the Geological Survey, Mr. A. Strahan, District Geologist of the Survey, arranged to make inquiries in

the directions desired by the Commission at a series of anthracite collieries in South Wales.

The collieries which Mr. Strahan selected for inquiry were the eight which Mr. Hammond Smith had ascertained to supply the malting firms visited, and three others which Mr. Strahan afterwards ascertained to supply malting anthracite. In one case the manager of the colliery, who had heard that inquiries were in progress, requested that his colliery should be visited. In other instances the secretary or manager of each colliery was advised of Mr. Strahan's proposed visit, and in every case facilities for the inquiry were readily afforded.

The great bulk of the anthracite used by English maltsters is derived from a limited portion of the South Wales coalfield, a strip of country some 25 miles by 4, which Mr. Strahan describes. Ten of the collieries which he visited are situated in various parts of this area, and they may be regarded as fairly representative of the whole of this anthracite field. A single colliery which is outside the main coalfield was also visited. The facts as to this colliery are separately dealt with in these notes.

After visiting these collieries Mr. Strahan drew up a Memorandum for the Commission (*No. III., below*), in which he set out the results of inquiries made at each colliery on the following points:—

What seams of anthracite were worked.

Whether malting anthracite was obtained solely from a particular seam or seams; if from more than one, whether it was the custom to consign mixed fuel to maltsters.

Whether visible pyrites (either as "brasses" or as "black pyrites") occurred in the malting seams; if so, whether it was present in lumps or in bands, whether it was restricted to the upper or lower parts of the seams, and how far it was separable from the coal either by the miners underground, or by hand picking if it came to the surface.

Whether impurities distinguishable by eye from pure anthracite, other than pyrites, occurred in the malting seams, and if so, to what extent such impurities were also capable of exclusion at the colliery.

What was the actual practice at the colliery in removing pyrites or other visible impurities from anthracite consigned to maltsters; and whether there had been any recent alteration in this respect in consequence of demands by maltsters for arsenic-free fuel.

Besides obtaining information on these points, Mr. Strahan obtained particulars regarding the depth of the several seams or "veins" of coal at each colliery. These, along with other data, enabled him to trace particular seams of anthracite through the various collieries, and to indicate which seams appear to correspond geologically in different mines.

At certain collieries only a single seam or vein of anthracite is worked for malting; at others several seams are so worked. The greater part of the coal used for malting is obtained from one seam, viz., "that which is known in various collieries as the Stanlydd, Big, or the Nine-foot Vein." Other seams lying above or below the Stanlydd there are five seams in the anthracite region from which malting coal may be derived. In Table IV. of this Appendix Mr. Strahan sets out a plan showing in order of sequence all the seams met with at the collieries visited and the names under which they appear at each colliery. The various seams "crop out and are worked near the surface as well as at great depths below it, the term "deep" which is applied to some of them in the trade having thus no significance."

Particulars corresponding to those obtained in the case of "malting" seams were also ascertained regarding other seams which were worked but which were said not to be used to supply maltsters. This made it more easy to see how far the characteristic impurities of a seam or vein in a given mine might be regarded as local, or how far, on the other hand, they appeared to accompany the seam from colliery to colliery.

On completion of his inquiries Mr. Strahan advised as to the samples which should be taken.

#### MR. PRICE'S REPORT.

The services of Mr. S. Warren Price, Lecturer on Mining Engineering at University College, Cardiff, were engaged by the Commission to procure the specimens. It was obviously of the first importance that the samples obtained should be properly representative and should be collected on a uniform system, and accordingly at the outset a scheme for their collection was drawn up in some detail in consultation with Mr. Strahan. At various dates between December, 1901, and August, 1902, Mr. Price visited the collieries in question. In each instance notice of the visit was given to the management of the colliery, together with a general statement of the nature of the samples which it was desired to collect.

The samples thus obtained by Mr. Price may be divided as follows:—

*A.*—An average sample (representing a considerable bulk) of the coal being supplied for malting purposes at each colliery, taken at the colliery from railway waggons consigned to maltsters, or from coal in course of being loaded or ready to be loaded.

*B.*—A sample or samples taken in the mine from each seam from which anthracite is obtained for malting purposes; every such sample adequately representing the whole thickness of the seam, and excluding bands of shale, pyrites, or other impurities (if present) which can be, and customarily are, picked out either in the mine or at the surface.

*C.*—Special samples, consisting (a) of the above impurities which can be, and customarily are, rejected, and (b) where desired, of seams not used for malting, analysis of which was desirable for purposes of comparison.

The samples (which in the case of each of the coal specimens were usually about 20 lbs. in weight) were labelled and packed in wooden boxes.

After completion of his visits to the collieries Mr. Price prepared a report (*No. IV. below*) detailing his proceedings in collecting the samples, and also giving some notes of his own observations at the collieries.

#### DR. MCGOWAN'S REPORT.

#### Appendix 30.

Dr. McGowan found that it was necessary to undertake a considerable amount of experimental work in his laboratory before deciding upon a satisfactory method of estimating the proportions of "total," "fixed," and "volatile" arsenic in these various fuel specimens, one of the principal difficulties which had to be met being the necessity of eliminating salts of iron from solutions added to the Marsh apparatus. In a separate Appendix, No. 23, he has set out (conjointly with Mr. Floris) the methods which were finally adopted, and which were applied to all the fuel samples submitted to him.

#### Supplementary samples, 1903.

In March, 1903, the results of the examination of the malting coals and samples of anthracite from the mines were nearly all available. On comparison it seemed desirable that a few further samples should be obtained. This was done by Mr. Price in April, 1903.

In 1903 also a few samples of coke were obtained. Four of these were Yorkshire gas coke carefully sampled from bulk at three gas-works in the neighbourhood of Halifax, each of which formerly supplied maltsters. There was some difficulty in getting to know of oven coke manufacturers who supply maltsters, as sale of this coke to maltsters is usually effected through agents. The four samples of oven coke examined came from different places of manufacture, and were carefully sampled from bulk at a Midland ironworks.

The results of analyses of these different samples have been included in the Table submitted by Dr. McGowan in his report. (*No. V. below*.)

#### SUMMARY OF RESULTS OBTAINED.

Much care has been taken by the writers of the several reports to set out the results of their inquiries in such a way that the facts regarding the nature and origin of each particular sample can be readily ascertained. It may however be convenient to summarise the main facts which have been brought out with regard to arsenic in anthracite obtained from South Wales.

With this object the following notes have been prepared by the Secretary of the Commission, in consultation with the writers of the reports.

#### A.—TABULAR STATEMENTS OF RESULTS.

Table I.

Table I. is restricted to the samples of anthracite ready for maltsters, taken at the colliery; the bulk from which the sample was derived having been in each instance indicated by the management of the colliery.

Table II.

Table II. relates to samples taken in the mine from the seams which are used to supply maltsters. It sets out the results of analysis of the sample or samples representing the thickness of the seam; the nature of impurities, if any, which are present in the seam and are capable of exclusion at the colliery, and the amount of arsenic determined in specimens of such impurities.

Table III.

Table III. relates to all the seams from which anthracite is obtained at the various collieries, including several not used for malting. It consists of two parts, *A* and *B*, both arranged in the same way. *A* is Mr. Strahan's table, showing, in descending order, the seams met with at each colliery, and their apparent geological correspondence.

in the several mines. *B* shows on the same arrangement the proportions of "total arsenic" determined in the samples taken from these seams.

*B*—PRESENCE OF "IMPURITIES" IN ANTHRACITE SEAMS AND THEIR REMOVAL AT THE COLLIERIES.

In a given colliery a particular seam of anthracite usually has certain definite characteristics as regards the presence or absence of impurities, and the nature of the impurities present. As a rule these characteristics are fairly constant throughout the seam at any particular colliery; they not infrequently extend over a considerable area and thus are met with in the same seam in several collieries.

Some seams are "solid"; in section they show anthracite of uniform appearance without "partings," or bands, and no pyritous or other lumps are met with. From such seams (save for fragments of roof or floor which may be sent to the surface along with the coal) there are practically no impurities to be removed.

Other seams contain visible impurities of one or another kind, *e.g.*

- Definite lumps or nodules of various sizes, some consisting of yellow pyrites; others (also termed "pyrites" at the collieries) consisting of hard black masses showing no yellow pyrites.
- Granular black bands (sometimes streaked with yellow pyrites) either of definite thickness and traversing the seam at some particular level or appearing intermittently.
- Bands of impure coal often consisting largely of shale—found chiefly near the top or bottom of the seam.
- In some cases there is a parting near the top or base separating off a thickness of the vein in which the anthracite, for one or another reason, is considered "inferior," and is accordingly separated from the remaining coal in the vein.

At all the collieries where inquiry was made steps appear to be taken to remove impurities such as those just mentioned, with the object of supplying maltsters with what may be termed "clean" anthracite. The removal is effected either in the mine or by hand picking at screens on the surface, it being usual to supply the maltster with anthracite in large lumps. Removal of large masses or nodules of pyrites can easily be effected at the colliery, but in the case of granular bands closely adherent to the coal the matter is more troublesome. (See Mr. Price's Report as to Colliery H.)

Probably the greatest difficulty of all arises where the pyrites is distributed in many small black bands about the seam. Mr. Price draws attention in his report to the advantage to be derived from treating these and other coals by suitable appliances (already provided at a few collieries) which afford greater facilities for the removal of impurities.

*C*.—"CLEAN" ANTHRACITE IN REGARD OF ARSENIC.

*Anthracite from seams used for malting.*

Twenty-two samples of this class were examined, each representing the whole thickness of a seam used for malting, exclusive of visible impurities, if any, which were capable of removal. They were found to contain amounts of "total" arsenic as follows:—

0-10 parts per million	(0-5 parts 5-10 " )	- 7 )	19
10-20 " " "	" " "	" " "	- 3
20-30 " " "	" " "	" " "	- 0
30-40 " " "	" " "	" " "	- 0
Over 40 " " "	" " "	" " "	- 0
			22

*Anthracite from seams not used for malting.*

Seven samples of this class were similarly taken. Of these, six contained less than ten parts of ("total")

arsenic per million, and one contained eleven parts per million.

*Anthracite as consigned to maltsters.*

Twelve samples of this class were taken at the ten collieries in question. Each of these samples represented a large bulk, which was indicated by the management of the colliery as satisfactory malting anthracite. They were found to contain amounts of ("total") arsenic as follows:—

0-10 parts per million	(0-5 parts 5-10 " )	- 6 )	12
10-20 " " "	" " "	" " "	- 0
20-30 " " "	" " "	" " "	- 0
30-40 " " "	" " "	" " "	- 0
Over 40 " " "	" " "	" " "	- 0
			12

It is interesting to compare these results with the only other series of reports of analysis of anthracite samples which the Commission have received, namely that given by Mr. Ling in his evidence to the Commission in June, 1902. In making this comparison it should, however, be remembered that Mr. Ling had not at that date fully dealt with the difficulty as regards iron which Dr. McGowan found so important in analyses of fuels (Q. 10488), and that Mr. Ling's samples were supplied by maltsters, and in many cases represented a small casual collection of pieces of anthracite rather than the result of systematic sampling such as was undertaken by Mr. Price.

The amounts of "total" arsenic in Mr. Ling's samples (neglecting his four "bad" anthracites, which were either stony or pyritous, and in the sense of these reports would constitute "impurities") were as follows:—

0-10 parts per million	(0-5 parts 5-10 " )	- 8 )	17
10-20 " " "	" " "	" " "	- 3
20-30 " " "	" " "	" " "	- 1
30-40 " " "	" " "	" " "	- 0
Over 40 " " "	" " "	" " "	- 0
			21

These may be contrasted with the amounts of total arsenic found by Mr. Ling in samples of coke supplied to maltsters:—

		Gas coke.	Oven coke.
0-10 parts per million	(0-5 parts 5-10 " )	5	0 5
10-20 " " "	" " "	3	1 2
20-30 " " "	" " "	4	4 0
30-40 " " "	" " "	0	0 0
Over 40 " " "	" " "	4	0 4
		16	5 11

Dr. McGowan, in 1903, analysed four samples of coke taken from a certain Yorkshire gas-works which formerly supplied maltsters, and other four samples of oven coke, taken from bulk at a Midland iron-works, with the following results as regards ("total") arsenic:—

					Gas	Oven	
					coke.	coke.	
0-10 parts per million { 0- 5 parts 0 } 2					0	2	
10-20	"	"	"	-	1	0	1
20-30	"	"	"	-	1	0	1
30-40	"	"	"	-	1	1	0
Over 40	"	"	"	-	3	3	0
					8	4	4

Taking into consideration the number and diverse origins of the various samples of "clean" anthracite examined for the Commission and the care taken to see that they were representative, it may be concluded that the results above summarised give a fair indication of the ordinary limits within which the small amounts of arsenic found

in "clean" anthracite from South Wales collieries may vary. Some samples contain much more arsenic than others, but the variations are within much narrower limits than is the case with gas cokes or oven cokes of the kind which are, or have been, used habitually by maltsters. It is evident that some oven cokes may contain quite small proportions of arsenic, and it is likely that many gas cokes would show much less arsenic than the Yorkshire samples above referred to. But it may be concluded the clean South Wales anthracites, as a class, are much purer as regards arsenic than either of these kinds of coke.

Reference must, however, be made in this connection to the examination of samples from Colliery Q. This colliery, with a few others of small size, is situated in an anthracitic region outside the main coalfields altogether. Two thin veins of anthracite (1) and (2) are worked. Both veins are "solid"; in each the anthracite appears uniform, and is comparatively soft. They may, however, have been modified in structure by some geological disturbance to which the strata of this field have been subjected.

In 1902 Mr. Price took a sample representing the whole thickness of Seam (1) at a particular spot underground, and also a similar sample from Seam (2). Neither showed exceptional amounts of "total" arsenic, the figures being 2.57 and 7.2 parts per million respectively; but in a third sample, taken from a considerable bulk of anthracite which had been in stock at the colliery, and was said to have been derived from both seams, the surprising amount of 90 parts of "total" arsenic per million was detected. In view of this result a second sample was taken by Mr. Price in April, 1903, from a "stock pile" of anthracite at this colliery. This sample also showed a very high arsenic content—50 parts per million.

The time available for these inquiries did not admit of the extensive series of field observations and chemical analyses which would have been necessary to establish the origin of the arsenic in these samples from Colliery Q. The results differ so greatly from all the other "clean" anthracite samples that it may be assumed that they are quite exceptional. Their chief importance lies in the fact that they show that caution is needed in judging anthracite solely from its appearance. It must not be assumed that a solid anthracite, which is free from the visible impurities referred to in this Report, contains invariably such small proportions of arsenic as those found in the numerous samples taken in the main anthracitic region of South Wales.

#### D.—IMPURITIES OF ANTHRACITE SEAMS IN REGARD OF ARSENIC.

(a) *Definite hard masses or nodules.*—As might have been expected, nodules consisting wholly or in part of yellow pyrites ("brass") contain large amounts of "total" arsenic.

Sample 24, Colliery D, 1,300 parts of "total" arsenic per million.

"	16,	"	B,	180	"	"
"	23,	"	D,	93	"	"

[It may be here noted that Mr. Ling's estimates of "total" arsenic in samples of "brasses" taken from anthracite at maltings were as follows (Evidence, June, 1902):

I.—1,000 parts of "total" arsenic per million.

II.—1,571 " " "

III.—107 " " "]

Hard black nodules locally termed "pyrites," but showing no yellow pyrites, met with at various collieries and always in the same (Big or Stanlyd) vein, showed comparatively small quantities of arsenic.

Sample 28, Colliery E, 10.0 parts of "total" arsenic per million.

"	32	"	F,	12.0	"	"
"	37,	"	G,	2.5	"	"
"	62,	"	K,	3.3	"	"

(b) *Granular black bands* ("black pyrites" mixed with variable amounts of coal) appearing intermittently or

constantly at particular levels in the seams showed notable amounts of arsenic. Appendix 30.

Sample 61, Colliery K, 200.0 parts of "total" arsenic per million.

"	51,	"	J,	18.4	"	"
"	44,	"	H,	15.3	"	"

Some of these bands are reported as liable to contain streaks of yellow pyrites. Practically speaking, however, there was no yellow pyrites to be seen in any of the above three samples.

(c) *Bands of impure coal, consisting largely of shale* in two instances out of three were highly arsenical.

Sample 15, Colliery B, 280.0 parts of "total" arsenic per million.

"	46,	"	H	83.0	"	"
			(shaly band at base of vein)			
"	45,		Colliery H,	6.4	"	"
			(thin shaly parting in middle of vein).			

In sample 15 a thin layer of yellow pyrites could be detected in a few portions; neither of the other samples showed any yellow pyrites.

[It may be here noted that Mr. Ling drew attention to the large amount of arsenic found by him in three "slaty" samples of anthracite. In the single specimen of shale which he examined he found 250 parts of arsenic per million.]

(d) *"Inferior coal" separated by partings from the rest of the thickness of the vein* showed in most instances more arsenic than the "better" coal of the rest of the vein.

"Inferior coal" at top of Big or Stanlyd Vein.

Sample 25, Colliery D, 9.25 parts of "total" arsenic per million.

"	31,	"	F,	19.0	"	"
"	39,	"	G,	23.0	"	"
"	52,	"	J,	4.0	"	"

"Inferior coal" at base of Big or Stanlyd Vein.

Sample 38, Colliery G, 19.5 parts of "total" arsenic per million.

"Inferior coal" at base of Pump Quart Vein.

Sample 7, Colliery A, 8.67 parts of "total" arsenic per million.

"	19,	"	C,	9.5	"	"
---	-----	---	----	-----	---	---

#### E.—ANTHRACITE AND IMPURITIES OF ANTHRACITE SEAMS IN REGARD OF "VOLATILE" ARSENIC.

Besides estimating the total arsenic in each sample, Dr. McGowan has in each instance reckoned the proportion of arsenic which was volatile when the anthracite was burnt under the conditions of his tests described in Appendix 23.

As regards "clean" anthracite, the proportion of "volatile" arsenic to total arsenic varied greatly in the different samples examined. Nothing like a constant ratio between the two is to be traced; samples showing much the same proportions of "total" arsenic varied greatly as regards the corresponding "volatile" arsenic, and vice versa. The results may be summed up as follows:—

21 Specimens of Anthracite from Malting Seams.

0-2.5 parts of "volatile" arsenic per million.	14:—"Volatile" arsenic per cent. of "total" arsenic; average, 23.7; range, from 5.6 to 57 per cent.
2.5-5 " "	6:—"Volatile" arsenic per cent. of "total" arsenic; average, 41.8; range, from 27 to 62 per cent.
5-10 " "	0.
10-20 " "	1:—"Volatile" arsenic 58 per cent. of the "total" arsenic

## Appendix 30. 12 Specimens of Anthracite Consigned to Maltsters.

0.2-5 parts of "volatile" arsenic per million	10:—"Volatile" arsenic per cent. of "total" arsenic; average, 28.6; range, from 10.4 to 48.7 per cent.
2.5-5 " " "	2—"Volatile" arsenic respectively 50 and 48.6 per cent. of "total" arsenic.

As regards impurities in the anthracite seams, in the "inferior coals," and also in the hard black nodules from the Stanlyd vein in various collieries, the proportions of arsenic which were "volatile" varied within a considerable range. In the case of the lumps of yellow pyrites, and also of the pyritous bands and shales met with in some collieries, Dr. McGowan draws attention to the fact that the proportion of "volatile" to "total" arsenic was generally high. Thus:—

	"Volatile" arsenic parts per million.	"Volatile" arsenic per cent. of "total" arsenic.
Three samples of yellow pyrites, occurring in lumps.	966	74.4
	110	61.1
	68	72.6
Three samples of impure coal consisting largely of shale.	211.4	75.5
	46.6	56.0
	2.1	32.9
Three samples of black pyritous band traversing a seam.	6.6	43.4
	13.2	71.7
	196.0	70.0

## SIGNIFICANCE OF "VOLATILE" ARSENIC.

The "volatile" arsenic in each of these examinations represents the difference between the estimated total arsenic in a given sample and the amount of ("fixed") arsenic which remains in the ash (as an arseniate) when the finely powdered fuel is completely burned in an open platinum basin at a red heat. The results are valuable as being comparable *inter se*, but how far they can be taken as a satisfactory index of the amount of volatilisation which may take place under other conditions of combustion is, of course, a different matter. On the kiln fire, for example, the temperature to which the anthracite is exposed varies greatly—often it reaches a white heat. The fuel is burnt in bulk, and the anthracite is in lumps, often of considerable size. These lumps may be suddenly thrust into a hot fire where they slowly burn away from the outside. Thus part of the anthracite which is being heated or burnt in the kiln (for example, the interior of the lumps or the centre of the fire) will be exposed not to an oxidising, but in the first instance to a reducing atmosphere. Moreover, the period of combustion is much more prolonged in the kiln than in the laboratory, and the character of the combustion as regards supply of oxygen and temperature in the case of the kiln must vary greatly with the structure of the furnace and with the method of firing adopted. The influence of these and other factors in determining the proportion of arsenic which will become "fixed" in process of combustion and the amount which will be volatilised has seemingly yet to be ascertained. The only way to arrive at this would be to carry on a large series of duplicate combustions in a kiln and in the laboratory over a considerable period of time. (*cf.* the two Newark Experiments, Part VI., p. 322.)

## BEARING OF RESULTS ON THE SELECTION OF MALTING ANTHRACITE BY COLLIERY OWNERS AND BY MALTSTERS.

The results above summarised show the extreme importance of careful exclusion, in the mine or on the surface, of all impurities which may be present in the veins worked for malting, and the need for constant supervision and watchfulness on the part of the colliery owner to ensure that his men carry this out properly and thoroughly, so that only "clean" anthracite is supplied to maltsters. It is essential to remove not only nodules of pyrites, lumps in which pyrites and coal are mingled, and bands of slate or shale attached to, or passing through, lumps of coal, but also any obvious granular "black" pyrites. In a seam where such granular black pyrites is present as a definite layer traversing the vein at a particular level, it can be more readily eliminated than where the pyritous portions are distributed irregularly throughout the vein. In the former case a system can be adopted as at Colliery H (see Mr. Price's Report), by which all pieces of anthracite in which the band is represented are rejected.

It is equally essential that maltsters should systematically keep a strict watch on the anthracite supplied to them with the view of detecting and discarding impurities of the kinds above mentioned.

It is important that "clean" anthracite, as supplied to maltsters, should from time to time be sampled for the colliery owner, and that the quantity of arsenic contained in it should be estimated and compared with all available data. For this purpose a thorough and accurate method of obtaining a fair sample is essential. This point cannot be too strongly emphasized. The analyses desired are for the information and guidance of the colliery, and not for the purpose of obtaining a favourable report on specially selected samples, for exhibition to maltsters.

Where more than one seam of anthracite is worked at a colliery, advantage may be gained by analysis of the seams separately, together with associated impurities. For example, at Colliery B, four seams are worked for malting coal, the "Big," "Green," "Gras Uchaf," and "Pump Quart" veins respectively. The samples from the last two, which are "solid" and have practically no impurities to be removed, and also the sample from the Big Vein, in which the impurities consist of large and easily-removed lumps of yellow pyrites, contained in each instance less arsenic than samples of "clean" anthracite taken from the "Green" Vein. This Green Vein also was found to have a band of impure top coal which showed 280 parts of arsenic per million. So far as arsenic is concerned, therefore, it would seem better not to work such a vein as the last named for the supply of malting fuel.

A similar contrast is afforded between the "Big" and "Brass" Veins in Colliery K.

When colliery owners run short of malting anthracite, they occasionally fulfil their orders by arrangements with owners of other collieries, and this of course is the regular practice of agents and middlemen in similar circumstances. Where this is done it would seem important that the person or firm who has undertaken to supply the maltster should inform him that the source of supply has been changed, and should ascertain that the new supply is satisfactory as regards removal of impurities.

The exceptional result obtained in the case of anthracite from Colliery Q shows that it is desirable that the maltster, besides taking steps to obtain a supply of anthracite that is "clean" and apparently free from visible impurities, should also take the precaution of occasionally submitting samples (thoroughly and fairly taken) to the analyst. This seems especially important when the supply is obtained from a new colliery, or when the maltster receives anthracite of a different character from that to which he has been accustomed.

G. S. B.

August, 1903.

## APPENDIX No. 30.

## REPORTS ON MALTING ANTHRACITE:—PART II

## PART II.—NOTES BY MR. H. HAMMOND SMITH ON INQUIRIES AS TO ANTHRACITE USED BY CERTAIN MALTSTERS

The object of these inquiries was to ascertain the practice of certain maltsters in the selection and purchase of malting anthracite, and the mines from which their anthracite is obtained.

The maltings of four large firms were visited. These are situated respectively at Smethwick (taken as representing Western Counties Maltings); Burton-on-Trent (Midland Counties and other Maltings); Newark-on-Trent (Eastern Counties Maltings); and Sawbridgeworth (Southern Counties Maltings).

Information was kindly given me by the representatives of the firms concerned, including their analysts. I also took the opportunity of speaking to the men who handled the anthracite, and had the charge of the malting fires both in closed and open furnaces.

*Exclusive use of anthracite.*

All the maltsters I saw agreed in stating that since the discovery that malt might be arsenical, they have used only anthracite for malting purposes.

Brewers now usually stipulate that the malt they buy should all have been kilned by means of anthracite, and not by the use of coke. Two of the maltsters whom I saw said that they had previously used nothing but anthracite, but at other two, coke, said to be oven coke, was formerly used—principally in conjunction with anthracite to "finish" the malt.

*Selection of Anthracite by the Maltster.*

At two of the maltings visited the anthracite is ordered direct from the colliery or collieries, at the other two it is obtained through agents. But in either case the coal comes direct from the colliery to the malting.

At each of the maltings visited I was told that the anthracite is hand-picked over at the colliery, and any lumps of pyrites, or pieces of coal showing pyrites, are rejected. This is believed to be invariably done at the colliery, but no special stipulation as to the picking over was made by the maltsters. To a certain degree there is additional hand-picking at the malting by the furnace-men, who usually throw on one side pieces that show what they term "glitter" (pyrites), or that look dull. The latter are rejected because of the smoke they produce. Surprisingly large lumps of pyrites and other impurities are sometimes found in the anthracite as delivered to the maltsters.

Anthracite is generally bought and stored in the summer time, but some is also bought in the winter. The custom seems to be that once a particular colliery has been found to give a satisfactory anthracite, orders are renewed year by year to that colliery, without obtaining fresh samples. The anthracite has in the past been selected by the maltster as that which, in actual practice, he finds to burn best, and to produce the best flavoured malt. Thus in one instance, some years ago trials were made of samples from various collieries. As a result of these trials, one colliery was selected, and has been exclusively used ever since.

In two cases the maltster obtained his anthracite from one or two or more collieries, and occasionally a mixture of fuels is used on the kiln. In other cases the maltster ordered all his anthracite from a single colliery.

*Collieries from which the fuel is obtained.*

In the list of mines given in the report of H.M. Inspectors of Mines, 1900, there are 28 anthracite collieries in Brecon, Glamorgan, and Carmarthen mentioned which employ over 100 men. Out of these 28 I found that the four large maltsters visited get their supply of anthracite from only eight collieries, in addition to one which I was unable to identify; some of the maltsters visited were supplied from the same colliery or collieries.

*Designation of Anthracite.*

The coal used is said to come from the "deep seams," and "deep-seam anthracite," whatever may be its significance, is always asked for when ordering.

All the maltsters visited promised to let the Commission have samples of their fuel if required.

*Analysis and guarantees of Anthracite by Colliery Owners.*

Up to the present time anthracite has not been bought or selected on chemical analysis at any of the maltings visited, although analyses of the fuel as regards carbon, ash, &c., are frequently made by colliery owners and sent to maltsters.

By one maltster I was shown several analyses of recent date (1901) which he had received from colliery owners advertising their coals as "free from arsenic." By another maltster I was shown an analysis received from the colliery in which the analyst, after giving the amount of carbon, ash, &c., in 100 parts, said he could not detect more than 0.00000026 per cent. of arsenic!

I found the maltsters visited attach no importance to analyses sent them from the collieries, and for this reason they do not ask for guarantees from the colliery owners that their coal is arsenic-free, nor do they require an analysis to accompany each fresh consignment of coal.

*Selection and Analysis of Anthracite by Maltsters.*

The coal up to now has been selected entirely for its burning and flavouring properties, and not on account of its freedom from arsenic. I found that at two of the maltings visited the maltsters had not had their anthracite analysed on their own account; the other two had done so.

At one malting I was told their own chemist had been analysing anthracite for arsenic, and other fuels also, and has had his analysis supplemented by an independent chemist. I was shown the analysis of samples of six South Wales anthracites. Out of these five showed from 1/70th to 1/50th of a grain of arsenic per lb. (2 to 3 parts per million), and one was "nearly free." These anthracites were samples taken from coals as delivered in the ordinary course and had been selected by the Chemist of the Works. By the same maltster's chemist I was shown analyses which he had made of samples of gas coals and oven coals as follows:—

<i>Gas Coke.</i>		<i>Per Million.</i>
1. Yorkshire sample	1/14th grain per lb.	10.2
2. Nottingham sample	1/18th " "	7.9
3. Lincolnshire sample	1/30th " "	4.8
<i>Oven Coals.</i>		
4 (a). Derbyshire sample	1/30th grain per lb.	4.8
4 (b). Derbyshire sample	1/7th " "	20.4
5. Babbington (washed)	1/35th " "	4.1
6. Durham (washed)	1/30th " "	4.8
7. Derbyshire (washed)	1/14th " "	10.2

At one malting I was shown an analysis of the coal used from one colliery, made by Mr. Moritz. A sample was taken of 20 lumps from the different heaps in the yard, and the analyst reported that "a minute trace" (of arsenic) "has been found in it, which is quite negligible."

H. HAMMOND SMITH.

August, 1901.

## REPORTS ON MALTING ANTHRACITE:—PART III.

Appendix

## PART III.—NOTES BY MR. A. STRAHAN, F.R.S. (DISTRICT GEOLOGIST), OF H.M. GEOLOGICAL SURVEY, ON VISITS MADE BY HIM TO CERTAIN SOUTH WALES COLLIERIES SUPPLYING MALTING ANTHRACITE.

*Arrangement of Notes.*

1. On the seams of anthracite worked in South Wales for malting purposes.

2. On the occurrence of pyrites and other impurities in the seams.

3. On the method in use of freeing the fuel from the impurities.

## 1.—ON THE SEAMS OF ANTHRACITE WORKED IN SOUTH WALES FOR MALTING PURPOSES.

§ The working of anthracite in South Wales is limited to the north-western part of the main coalfield, and also to the Pembrokeshire coalfield, in which there are a few collieries. The region which contains nearly all the collieries where anthracite is worked lies part in Carmarthenshire, part in Glamorganshire, and part in Brecknockshire. It extends from Carmarthen Bay on the west to the head of the Neath Valley, some 25 miles to the east, with a breadth from north to south of between two and four miles. To the north it is limited by the outcrop of the Coal Measures; to the south, where the seams descend to a great depth, their limits

have not been ascertained, but there is reason to believe that they gradually lose their anthracitic character.

The ten collieries visited are representative of different parts of this region. For the purposes of these notes they are designated by letters, A to K, and are arranged in order from west to east; Colliery A is that nearest the western limit, and Colliery K is that nearest to the eastern limit of the region referred to. At each of these ten collieries the supply of malting anthracite constitutes an important part of the business of the Colliery Company. There are, of course, other collieries in their neighbourhood from which coal is supplied for malting purposes.

At each of the collieries visited information was kindly supplied to me by representatives of the Colliery Company, in most instances by the Manager, in other cases by the Secretary or Agent.

Five seams are worked for malting, but the greater part of the coal is got from one seam—namely, that which is known in various collieries as the *Standlyd*, the *Big*, or the *Nine feet Vein*. This seam is generally stated to be superior to the others in calorific power and purity. The seams all occur in the lower part of the productive measures of the South Wales Coalfield. They crop out and are worked near the surface and at great depths below it, the term "deep," which is applied to some of them in the trade, having therefore no significance. Their sequence and approximate correlation are illustrated in the following Tables IV. and V.:—

a dix 39.

## 2.—ON THE OCCURRENCE OF PYRITES AND OTHER IMPURITIES IN THE SEAMS.

The facts ascertained are summarised in tabular form in Table II.

No visible iron pyrites occurs in the following seams :—

Pump Quart Seam	- - -	Colliery A.
Green Vein	- - -	} Colliery B.
Stanlyd Vein	- - -	
Gras uchaf Vein	- - -	
Pump Quart Vein	- - -	Colliery C.
Deep Stanlyd Seam	- - -	Colliery E.

In all the other seams named in the table, pyrites is visible in greater or less abundance. It occurs in lumps or thin impersistent bands, and takes one of two forms, namely, that of yellow pyrites, presenting the characteristic appearance of the mineral, or that of black material consisting largely of coal, but containing sulphide of iron in a form not distinguishable by eye. These will be referred to as yellow and black pyrites respectively.

Visible pyrites occurs in the following coals supplied for malting :—

In the Big Vein of B. Colliery (not the Stanlyd vein of other collieries). It takes the form of lumps, chiefly of yellow pyrites, lying about 12 or 15 inches above the bottom of the vein.

In the Stanlyd of D. It takes the form of balls, dark outside but usually yellow inside, lying about two feet above the bottom of the vein, but often irregularly distributed.

In the Big Vein of F. It takes the form of black kidney-shaped lumps which occur intermittently in the upper and lower parts of the seams. In the Big Vein of G it takes the form of black lumps of irregular size and shape. The lumps sometimes occur in one plane, but at others are irregularly distributed through the vein.

In the Brass Vein of H. It takes the form of a thin band of bright granular coal traversed by threads of yellow pyrites, and about one to three inches thick. This band usually lies about nine inches below the top of the vein, but disappears when the vein is thin. Small lumps of yellow pyrites also occur, but very rarely.

In the Big Vein of J it takes the form of dull black layers about 1½ to 2 ft. above the bottom of the bottom coal.

In the Big or Nine Feet Vein of K it takes the form of an irregular layer about two feet above the bottom of the vein; the layer consists partly of a bright granular coal, which is used as a fuel in the houses of the neighbourhood, and partly of black pyrites.

In the Brass Vein of K. It takes the form of an impersistent black layer lying nearer the top than the bottom of the vein. It generally shows thin seams or granules of yellow pyrites. The layer is sometimes absent for several hundred yards.

### Impurities other than Pyrites.

Seams of anthracite are usually "solid," that is, consist of coal from top to bottom without any partings of clay or stone. All the coals referred to in the table are solid with the following exceptions :—

The Green Vein of B has at its top two inches of impure coal, which is rejected.

The Pump Quart Vein of C has at its bottom a band of impure coal about three or four inches thick, which is rejected.

The Big Vein of G has at its base one to three inches of impure coal, which is rejected.

The Big Vein of J shows the following partings :—

	Ft. in.
Top coal interbedded with layers of black stone and not worked with the rest of the vein*	2 0
Parting of dirt, about	0 0½
Middle coal	3 6
Bottom coal	3 6

In the case of all seams fragments of shale from the roof or floor are accidentally sent up in the trams. Fragments of the roof especially not infrequently adhere to the lumps of coal.

## 3.—ON THE METHOD IN USE OF FREEING THE COAL FROM THE IMPURITIES.

The same method is in use at all the collieries, with slight differences in detail. The miner is supposed to pick out all visible pyrites, fragments of shale, etc.; but from the conditions under which he works is unable to do so completely.

The coal on reaching the top of the pit is tipped into an iron shoot, down which it passes with a rapidity which can generally be regulated. One or more men are stationed by the side of the shoot whose business it is to pick out pyrites or impure coal.

The coal then passes over two or more screens, in the last of which the bars are placed at distances apart varying from two to eight inches at different collieries. The small coal falls through, and large lumps only pass on to the truck for the maltster.

In this truck two or more men are stationed whose business it is to arrange the coal and throw out any impurities that have passed the men on the screens.

At all collieries it is stated that a special screen is kept for the malting coal, and that all screening is done in daylight.

As a rule no alteration has been made in the system in consequence of the demand for arsenic-free fuel, but in one or two cases the picking is done more carefully than it used to be.

Large lumps of coal in which no pyrites is visible are not broken, it being considered that pyrites, if it existed in them, would always show itself on their surface. Lumps in which pyrites shows itself are broken, and the coal generally put back upon the screen.

All the impurities picked out are thrown on the rubbish heap, except a certain form of bright coal associated with pyrites, which is used locally as a house coal.

At A the bars of the screen are 2½ inches apart. Coal in which pyrites is visible is thrown out and used for other purposes.

At B the bars of the screen are five inches apart. Three men are stationed by the screen for the purpose of picking. The coal then passes down a long shoot, when it is further picked over by a man and a boy. Lastly there are two men in the truck who also pick out any impurity. The long shoot was introduced in consequence of the demand for arsenic-free fuel.

At E the bars of the screen are five inches apart, or if requested, 3 inches apart. The impure coal, three or four inches thick at the bottom of the seam, is picked out on the screen and used for lime burning. It breaks readily and cleanly off the good coal.

\* According to Mr. Price's notes on observations made in the mine, this top coal is also represented in the Big Vein of Collieries F and G, where also it is not worked for malting coal. Mr. Price also noted the occasional presence of a black band containing no visible pyrites in the Stanlyd Vein of Colliery E.

## Appendix 30.

At D the bars are  $3\frac{1}{2}$  inches apart. The pyrites is thrown on the waste heap or burnt in the cottages of the neighbourhood. Previously to January, 1901, the Pump Quart was supplied to maltsters mixed with Stanlyd, but this caused complaints.

At E the bars are  $4\frac{1}{2}$  inches apart. Soft coal—even if in large lumps—is picked out, and nothing but hard coal in large lumps is sent to the maltster.

At F the bars are eight inches apart. Before the demand for arsenic-free fuel a conveyor arrangement had been introduced, by which the coal is conveyed from the screen to the truck. It is thus brought thoroughly into view, and can be freed from all visible impurities.

At G the bars are  $3\frac{1}{2}$  inches apart. The impurities are picked out by the miner, by the men on the screens, and by the men in the trucks. They consist of pyrites and of a band of impure coal, one to three inches thick at the bottom of the seam. It is believed that they are all removed.

At H the bars are  $2\frac{1}{2}$  or 3 inches apart. The coal is picked on the screens and in the trucks. Since the demand for arsenic-free fuel greater care has been exercised in picking out lumps containing the black band previously mentioned. But the band is closely blended with the coal, and does not break cleanly off it. If it is not more than about an inch thick it is not picked out.

At J the bars are two inches apart. The picking is done by two men on the screen and one in the truck. Lumps showing pyrites are wholly rejected. Fragments

of shale from the roof of the seam are attached to many of the lumps of coal. They break cleanly off the coal and are thrown out.

At K the bars are three inches apart. Two men are employed on the screen and three in the truck. Large lumps showing pyrites are thrown out on to a special stage, broken up, and the coal thrown back on the screen. The two seams (Big and Brass Veins) are mixed.

*Colliery Q.* I visited one anthracite colliery which is outside the anthracite region above described. There were here two seams of solid coal, containing no visible pyrites or other impurity, respectively 1 foot 8 inches and 1 foot 4 inches in thickness, and separated by 70 yards of measures.

It may be noted that the measures of the coalfield in which Colliery Q is situated have been subject to great pressure and disturbance by earth movements in past geological ages. It is not improbable, therefore, that the seams have been crushed out and re-consolidated. Any partings or impurities which they originally contained may thus have become so incorporated with the coal as to be indistinguishable to the eye.

*Analysis of anthracite made for the above collieries.* The following table gives in each instance the analyses of the fuel as prepared for the maltster, and as furnished by the colliery proprietor. They have been made by different analysts at different dates and probably by different methods. It is not possible to say, therefore, how far they are comparable or reliable (pp. 306-7).]

## SAMPLES.

It is recommended that samples of the following should be examined for the occurrence of arsenic:—

## A. Colliery:—

The Big Vein.  
The Lower Pump Quart Vein.  
The Green Vein.

## B. Colliery:

The Big Vein.  
The Green Vein.  
The Stanlyd Vein.  
The Gras uchaf Vein.  
Pyrites from the Big Vein.  
A two-inch band of impure coal on top of the Green Vein.

## C. Colliery:

The Pump Quart Vein.  
A three-inch band of impure coal at bottom of the vein.

## D. Colliery:—

The Stanlyd Vein.  
The Pump Quart Vein.  
Pyrites in the Stanlyd Vein.

## E. Colliery:—

The Deep Stanlyd Vein.  
Pyrites in the Gras uchaf Vein.

## F. Colliery:—

The Big Vein.  
Pyrites of the Big Vein.

## G. Colliery:—

The Big Vein.  
Pyrites in the Big Vein.  
A three-inch band of impure coal at the bottom of the vein.

## H. Colliery :—

The Brass Vein where no pyrites occurs.  
 The Brass Vein where pyrites does occur.  
 The band of supposed black pyrites which lies  
 nine inches below the top of the vein.

## K. Colliery :—

The Brass Vein where no pyrites is visible.  
 The Brass Vein where pyrites is visible.  
 Pyrites in the Brass Vein.  
 The Big Vein.  
 Pyrites in the Big Vein.  
 The roof of the Big Vein.

## J. Colliery :—

The Big Vein.  
 Pyrites in the Big Vein.  
 Top coal of the Big Vein.

In every case it would be advisable to examine a fair  
 sample of the fuel as prepared for the maltster.

AUBREY STRAHAN.

December, 1901.

## REPORTS ON MALTING ANTHRACITE.—PART IV.

## PART IV.—REPORT ON COLLECTION OF SAMPLES FROM ANTHRACITE COLLIERIES IN SOUTH WALES, BY MR. S. WARREN PRICE, ASSOC. R.S.M., F.G.S., MINST. MIN. ENG., LECTURER ON MINING IN THE UNIVERSITY COLLEGE, CARDIFF.

The samples were collected from the several collieries noted by Mr. Strahan at various dates between December 5th, 1901, and August 21st, 1902.

In collecting the samples I followed the general lines which had been agreed upon before I began my visits to the collieries.

## SAMPLES TAKEN UNDERGROUND.

The samples of seams were taken in the mine by cutting out pieces with a sharply-pointed pick; the pieces being taken closely together throughout the vertical section of the seam, and being as nearly as possible of equal size; or (where it was possible to remove such pieces) they consisted of thin flakes extending downward over a considerable vertical extent, but of small sectional area, in the plane of the seam.

The object in view in all such cases was to secure a fair representation in the sample of each portion of the seam, such as would be realised by cutting grooves of uniform cross section throughout the whole depth of the coal from roof to floor. In the case of anthracite coal, cutting such grooves is particularly troublesome, and in practice the same result was attained by the separation of pieces in the way described at points so chosen that the whole of the vertical section of the seam was properly represented in the sample. The samples taken in the mine were in all cases obtained from freshly worked faces of coal, or from faces being worked.

In all cases where the seam contained bands of dirt, stone, pyrites, or inferior coal, and where such impurities were removed by the miners or at the surface, these impurities were carefully excluded from the average sample of the seam; and when portions of any of these impurities were taken for special samples, great care was observed in packing to prevent any portion of the special sample from mingling with the sample of the seam.

It has in every case been stated by the colliery officials that visible pyrites, shale and other impurities are picked out either by the miner underground, or by the men employed at the surface for that purpose, where coal is being prepared for malting.

The samples of coal taken in the mine do not, therefore, include any obvious lumps or bands of pyrites or any other impurity that was capable of being removed in either of the above ways, with the exception of two special samples from Colliery H noted below.

Where thin films or small particles of pyrites or of a white mineral (? calcite) are found in joint planes, etc., in the coal, they are, of course, not rejected.

In some of the seams, as noted by Mr. Strahan, practically speaking no pyrites is visible. In others pyrites sometimes occurs in thin layers, black in colour and inconspicuous, and blending with the coal to which it firmly adheres. Sometimes these bands are the lateral extensions of small or thin lenticular nodules of pyrites; sometimes they are isolated and of small extent.

Evidence of the presence of impersistent thin streaks of pyrites was observed in portions of the Stanlyd seam at Colliery G and at Colliery F; also in the "Big Vein" at Collieries A and B.

With regard to obvious pyrites, which can be separated in the mine or on the surface, it is important to note that the thoroughness with which such impurities can be

removed depends upon the method adopted and also upon the degree of visibility and the firmness of adherence, or otherwise, of the impurity to the coal.

For example, at Colliery D, the pyrites in the Stanlyd seam occurs chiefly in large rounded lumps which easily separate from the coal and are picked out underground by the miners. In this case the miner can hardly fail to make the separation.

On the other hand, some of the seams, particularly in the collieries to the east of the anthracite coalfield, Colliery H (Brass Vein), Colliery K (Brass Vein and Big Vein), and Colliery J (Big Vein), show pyrites in the form of a more or less continuous layer, of varying thickness, often 2 to 3 in., which blends with the coal, and cannot be removed cleanly either in the mine or at the surface. In such cases exclusion of pyrites by the miner or picker needs much more care and attention. The way in which it is effected is by the picker who examines the coal on the surface removing all lumps in which the band of pyrites appears. If the lumps are large they are broken with a pick. The impure coal thus separated is used for boiler fires, or for local consumption as house coal.

In this connection I should note as regards the Brass Vein at Colliery H, that at the date of Mr. Strahan's visit, the custom was to choose malting coal from places where the pyritic layer is comparatively thin, and to allow pieces of coal in which the layer was not more than about an inch thick to be included in malting fuel. When I visited this colliery, however, I was informed that the method of picking the coal for malting had been altered within the last few months. At present the coal, after passing over a long inclined fixed screen, is received upon a plate from which it can be sent to either side into railway waggons for ordinary sales. When malting coal is being loaded the men have to drag or lift the lumps from the plate at the bottom of the inclined screen on to a narrow platform, and then pass the coal down a separate shoot into the railway waggons placed to receive it on a line of rails parallel to the former. It is claimed as an advantage that as the men must lift or move every lump of coal that goes into the malting coal wagon they have a good opportunity to satisfy themselves that there is no streak or band of pyrites in it, and are more likely to let such pieces pass into the waggons for ordinary classes of coal than to trouble to lift them into the malting coal wagon. The objection to this proceeding, of course, is the labour and time involved.

A somewhat similar system was followed at Collieries J and K. In each case the streak of pyrites is continuous, distinct, and in one plane, so that, although the band of pyrites cannot be removed by itself from the lumps without taking coal with it or leaving pyrites behind, yet it is not difficult to secure the removal of lumps of coal containing the band.

As regards collection of samples in these cases. At the Brass Vein of Colliery H, in view of the former custom noted by Mr. Strahan, I took two samples in the seams at points where the band of pyritic coal was fairly thick (1 to 2 in.) and included the bands in the sample—notes being given to the analyst of the proportions in which the coal and the band should be combined in order to make a representative sample of the seam. I also took a sample representing the whole thickness of the seam at a point where the band of pyrites was absent.

† When more than one sample was enclosed in a box the smaller ones were separately wrapped closely in several thicknesses of strong paper and tied securely. Large samples were usually enclosed in separate boxes, but when this could not be done, the box was divided into two parts by a closely fitted division or partition, fixed in place by the carpenter at the mine.

In the case of the Big Vein at Collieries J and K and of the Brass Vein at the latter, I excluded the layer of pyritic coal from the samples, but, as in the case of pyrites elsewhere, I took a special sample of the layer.

In all cases the whole operation of collecting the sample, labelling it and packing it up was carried out (except the final packing for those packed at Cardiff) by myself in the presence of the manager or some other official of the colliery, and the latter was in all cases invited to assure himself that the samples were correctly labelled and kept distinct.

Samples were collected in sample bags and labelled, and were transferred to the wooden boxes afterwards—usually at the colliery office. Owing to the fact that the sample required was of considerable weight, 20 lbs., it was seldom considered necessary to take a larger sample and reduce by "quartering." Ordinarily it was found to be possible to secure a completely representative sample without taking more than was required to be sent to the analyst. In some cases however, a first large sample was halved by breaking each piece and rejecting half of it.

I have made a point in collecting the samples of ascertaining whether the colliery manager or his representative considered the seam in the place chosen for sampling to be of a fair average character. I wished them to feel that the samples were fairly taken.

In nearly all cases I have details of the positions in the mine workings where the samples were taken, and can thus, if desired, show the positions on a map or plan. I have prepared sections in certain cases where the seam was not "solid," but contained partings or definite layers of impurity.

#### SAMPLES OF MALTING COAL.

In sampling the method followed was to make a heap, derived from as large a bulk as possible of the coal which had already been prepared for sale to the maltster. The anthracite usually being in large lumps, some of these were either broken down or pieces were broken off from a number of the lumps.

The bulk sample was then carefully reduced to the size (about 20 lbs.) required by Dr. McGowan.

In writing to make appointments I always stated that samples would be required. In a few cases, noted below, however, there was some difficulty, as I was informed that there were no trucks of malting coal at hand.

The following is a list of the samples of malting coal collected with comments upon each:—

*Colliery A.*—Sample taken from two waggons in presence of the Agent.

*Colliery B.*—No malting coal was being loaded at the time of my visit, and the screens had been temporarily altered for supplying other classes of coal.

I obtained a good average sample from about five waggons in a long train of them which were standing on the sidings at Llanelly. A clerk accompanied me to point out the waggons which contained malting coal.

*Colliery C.*—An average sample was obtained from three waggons in presence of the Manager.

*Colliery D.*—An average sample of the malting coal was obtained from three railway waggons in presence of the Sales Agent.

*Colliery E.*—An average sample of the malting coal was obtained from four railway waggons in presence of the son of the Underground Manager.

*Colliery F.*—An average sample of malting coal was taken from two railway waggons, in presence of the Foreman of the Surface Works.

*Colliery G.*—An average sample of the malting coal was taken from two railway waggons in the presence of the General Manager. There were a number of waggons of other coal, but the Manager stated that not more than the two waggons contained malting coal.

*Colliery H.*—The colliery was not working on the day when I visited it owing to deficiency of railway waggons, and there were no railway waggons loaded with malting coal at the colliery. In order to obtain a sample representing the malting coal I got the Manager to explain the system in use for selecting coal for malting (see above)

and the official who had accompanied me underground then placed a number (about 12) of large pieces of coal on the platform in the same way as would be done when selecting coal for malting, and I took a sample from them. The quantity of coal in the inclined screen and on the plate at the bottom from which the lumps were taken would amount to several tons.

*Colliery J.*—In this case no malting coal whatever was being loaded on the day when I visited the colliery, and there were no waggons loaded either there or at any place near the colliery.

The sample which I obtained I cannot, therefore, regard as quite satisfactory, and it was merely taken provisionally. One railway waggon was said to contain coal from the Big Vein from which malting coal is obtained, but it was said that this coal had not been cleaned as carefully as when sold for malting. Two others (out of a number) were said to contain coal from both Big and Brass Veins—the latter not used for malting.

The sample was taken from these three waggons, pieces being chipped from Big Vein coal only. It was taken in presence of the Colliery Surveyor. A second sample of malting coal was taken from railway waggons in April, 1903, in the presence of the Manager, which should prove a reliable sample.

*Colliery K.*—A sample of malting coal was taken from two or three railway waggons loaded with malting coal that were standing at the colliery.

*Colliery Q.*—There were no railway waggons loaded here with malting coal, but a large stock pile almost 15 feet high was carefully sampled. In April, 1903, I obtained a second sample of anthracite from this colliery, again from a large stock pile, which was carefully sampled all over its surface.

I should add that in April, 1903, I also re-visited Collieries A, B, and K, to obtain certain supplementary samples desired. These were taken in the same way as before. In the Green Vein of Colliery B, each sample represented an aggregate of samples of the whole thickness of the seam (except its top coal, which is rejected), taken from different points. In the new samples of the Brass Vein at Collieries J and K, and of the Big Vein at the latter, the layer of pyritic coal which traverses the seam was, as before, not included in the sample.

#### REMARKS ON THE PICKING AND SCREENING OF ANTHRACITE.

Anthracite is prepared in carefully graded sizes for various uses other than malting. These remarks refer solely to the preparation of the large clean lumps of anthracite supplied to the maltster.

In the older method, the trams of coal from the mine are tipped on to an arrangement consisting of a long inclined shoot combined with inclined screens formed of fixed iron bars.

The bar screens permit the coal below a certain size to fall through, while the larger lumps slide downwards over the bars and finally drop into the railway waggons. There is a moveable door or gate at the bottom of the screen to regulate the descent of the coal. As the coal slides downwards, and while it remains for a short time stationary on the screens, it is examined by men standing at the sides of the shoot who pick out and throw aside any pieces of pyrites, shale, dirty coal, etc., that they see. Pieces adhering to lumps of coal are broken off with a light pick—in most cases this is easily done, but there are some cases where the impurity is too closely united to the coal for this to be done effectively, as I have pointed out above.

The chief disadvantage of the inclined shoot lies in the fact that the coal when tipped on to it from the tram rushes down quickly until it is checked by the moveable door or by the coal which may have been retained in the lower part. During its descent, it at first moves too rapidly to be examined properly, and finally, when checked and held in the bottom of the shoot by the moveable door, it is usually too closely packed together to allow of the whole of the lumps being examined.

In some cases the screen is placed at a more moderate inclination so that the coal has to be pushed slightly to

Appendix 39 make it slide downwards. This gives the pickers a slightly better opportunity to examine the coal. Where these inclined shoots are in use it is usual to have one or two pickers in the railway waggons also.

A much more effective arrangement is that in which the coal first passes over screens—either of the "fixed bar" or of the moving or "jigging" type—whereby the small coal is removed. The large coal from the screens then slides on to a travelling picking belt or table. This picking band or table consists of an endless chain running over rollers and covered with narrow steel plates, and presents a horizontal surface about  $4\frac{1}{2}$  feet wide by 30 to 60 feet in length (varying according to circumstances). It moves constantly in one direction, and the coal (which slides on to it in such a way as to be spread over the whole width and evenly distributed along its length) can be thoroughly examined by the pickers who stand at the sides. The pickers have thus a better opportunity to

detect any impurities in the coal, and are better able to remove them than in the arrangement first described. These travelling picking belts are in use at a few anthracite collieries, and one was being installed at one of the collieries visited. They are in use at a very large number of steam coal collieries.

Supervision of the pickers and a good light to work in are, of course, essential to the satisfactory use of these methods.

In view of the increasing demand for good malting anthracite, colliery-owners will probably find advantage in considering how far their present methods of cleaning this class of coal can be improved. At the same time, the consumer should bear in mind that it is not possible on a commercial scale to turn out a product absolutely free from all impurities.

S. WARREN PRICE

June, 1903.

## [REPORTS ON MALTING ANTHRACITE.—PART V.]

Appendix 30.

## PART V.—REPORT ON THE EXAMINATION OF MALTING ANTHRACITES, AND OTHER SPECIMENS SUBMITTED IN COURSE OF THE COMMISSION'S INQUIRY AS TO ARSENIC IN MALTING FUELS, BY DR. G. MCGOWAN.

In submitting the accompanying tabular statement of results (Table VII., below) to the Commission, I may be allowed to call attention to a few points as follows :—

1. This work has been carried out in my laboratory by Mr. R. B. Floris, A.I.C. It has been arduous and prolonged, and I would here express my thanks to him for the great care which he has taken throughout. Any improvements in the methods followed, which have come in the course of working, have been mainly due to him.

2. The details of the analytical process followed in the case of fuels have already been sufficiently given in the joint paper by Mr. Floris and myself which has already been submitted to the Commission (Appendix 23). It is, therefore, unnecessary to say anything further on this subject, except that the method might probably be appreciably shortened (in the absence of any considerable quantity of copper) by re-igniting the precipitated sulphide of arsenic with lime, and "Marshing" the hydrochloric acid extract of the residue directly. This modification was first suggested by Mr. R. S. Finlow in connection with the examination of other substances for the Commission.

3. The necessity for very careful sampling from bulk, and of careful "sub-sampling" in the Laboratory (*cf.* Appendix 23), in the case of fuels, cannot be too strongly insisted upon.

4. All the samples of coal examined contained large quantities of iron relatively to the arsenic present, some of course much more than others; the "Big Vein"

samples, for instance, contained a great deal. With regard to the anthracites proper, speaking generally, one might say that the softer the coal the more iron there was present.

5. In the estimations of arsenic, as far as possible, mirrors approximating to the standard (*i.e.* the precipitated standard) of 0.02 mgrm.  $\text{As}_2\text{O}_3$  were read; but, of course, there were many exceptions to this.

6. In a few cases, where the results obtained in the first instance were for one or another reason unsatisfactory, several different mirrors were made from more than one precipitation (this is not shown in the tables).

7. Nos. 45 and 46 may be taken as an example of two impure coals presenting much the same appearance, but containing totally different quantities of arsenic.

8. It will be noted that in the samples which contained visible yellow pyrites, the volatile arsenic constituted a large percentage of the total arsenic present.

9. In some of the impurities, *e.g.* No. 37, No. 60 and No. 62, the results show the "volatile" arsenic as coming out very low, but it should be borne in mind that there was very little combustible matter altogether in these samples.

GEORGE MCGOWAN.

Ealing, London, W.,  
July 7th, 1903.]

Consecutive Number.	Sample Number.	Anthracite Colliery.	Nature of Sample.	Notes as to Collection and Appearance of Sample.
33	11	COLLIERY G	MALTING COAL	From railway waggons
34	12	ditto	Big Vein, taken in the mine 1,400 yards S.E. of New Pit.	—
35	14	ditto	Big Vein, taken in the mine 1,100 yards on the west side of New Pit.	—
36	29	ditto	Peacock Vein, taken underground.	—
37	15	ditto	"Pyrites" of Big Vein, part of a large nodule from same spot as No. 35.	Hard, heavy black mass, showing a few minute specks only of yellow pyrites.
38	13	ditto	Impure bottom coal from Big Vein taken at the same spot as No. 34.	—
39	16	ditto	Impure granular top coal from Big Vein, 1½ to 4 inches thick, taken at the same spot as Nos. 34 and 37.	—
40	45	COLLIERY H	MALTING COAL	—
41	46	ditto	Brass Vein, together with black granular band traversing the vein at the same spot; the whole sample representing a section of the vein.	The black band in these samples, 41 and 42, consisted of granular anthracite with a considerable black band running through it. No visible yellow pyrites in the band.
42	47	ditto	Similar sample from Brass Vein from another spot, also including band.	
43	56	ditto	Another sample from Brass Vein, taken where black band was absent. Sample represents a section of the vein.	—
44	48	ditto	Granular band in Brass Vein traversed by threads of yellow pyrites, sampled separately.	The notes given under No. 47 apply here also, excepting that the anthracite and the black band were more sharply separated in this sample.
45	57	ditto	Impure coal from the middle of the Brass Vein.	Half-inch parting, consisting largely of shale.
46	58	ditto	Impure coal from the bed of the Brass Vein.	Contained bands of shale and carbonate of lime. No visible yellow pyrites.

## PART VI.—ACCOUNT OF TWO EXPERIMENTS AT MALT KILNS AT NEWARK.

Soon after commencing his analyses of samples of anthracite, Dr. McGowan pointed out that the value of the work on which he was engaged would be enhanced by an experiment made at a malt kiln to determine under practical conditions the amounts of arsenic respectively in the anthracite consumed, in the residue after combustion, and in the malt produced. Mr. Earp's evidence to the Commission indicated that the question of arsenic in malt was being closely studied at the maltings of Messrs. Gilstrap, Earp and Co., and advantage was taken of an offer kindly made by Mr. Walter Hervey to conduct an experiment of the kind required at one of the malt kilns of this firm in Newark.

## FIRST EXPERIMENT, 1902.

On March 21st, 1902, a 30-quarter kiln was selected and its furnace was thoroughly swept out. A weighed quantity of anthracite was set aside. The anthracite used was part of a sample truck sent from a South Wales colliery, which had been considered unsatisfactory and liable to cause arsenical contamination of the malt to a degree which was well marked by the Reinsch test, the test habitually used at these maltings.

The experiment was conducted under Mr. Hervey's supervision. The anthracite was sampled before the kiln was loaded, and weighed; the fire was started with wood.

On March 25th the malt was taken off the floor and screened by hand. The malt and culms were put up in bags and weighed; the weight of the unused anthracite was taken and deducted from the weight of that which had originally been set aside. The residue from combustion was separated into three portions—(1) ash and fine cinders which had passed through a half-inch riddle; (2) cinders which were rejected by the riddle; and (3) a few slag-like portions termed "dross."

The weights were as follows:—

Anthracite burnt—1 ton, 3 cwt., 14 lbs. = 2,560 lbs.

Cinder, 23 stone, 9 lbs. = 331 lbs.

Ash, 39 stone, 11 lbs. = 557 lbs.

Dross, 13½ lbs.

Malt, 32 qrs., 6 bushels = 11,004 lbs.

Culms, 363 lbs.

These weights were taken carefully under Mr. Hervey's supervision on March 25th, and samples of the anthracite, cinder, ash, dross, malt, and culms were sent to Dr. McGowan.

Owing to various circumstances, examination of these samples in Dr. McGowan's laboratory was necessarily delayed, and the whole results were not available for comparison until the end of the year. They are shown in the first part of Table VIII.

Two points should be noted with regard to this experiment. The question arose, in view of the analytical results obtained, whether the sample of anthracite had been representative. Mr. Hervey reported that it had been sampled by selecting a bulk of pieces which looked typical of the whole and (after breaking and mixing) taking a portion of this bulk sample for analysis. In his view, however, it was quite likely that by this method a considerable amount of pyrites which may have existed—secreted as it were—in the anthracite was not represented in the analysed sample. It will be seen that the proportion of arsenic determined in the sample—7.6 parts per million—was not unusual by comparison with the malting anthracites collected at South Wales Collieries, whereas the arsenic in the malt produced was obviously very much greater than would be expected in the case of malt dried over an anthracite of ordinary composition.

With regard to the large amount of ash and cinder which was obtained from this experiment, Mr. Hervey noted

that the anthracite in question was very "soft," and that some of it was a good deal broken up, so that in practice much fell through the bars. Moreover, the anthracite was a bad burning coal and could not properly consume its own "small" and cinders. The kiln in which the experiment was conducted has longer bars to its furnace, and wider spaces between the bars than is usual at most of the kilns of these Newark maltings, and this again afforded a greater opportunity for small coal to escape proper combustion.

## SECOND EXPERIMENT, 1903.

The second experiment was carried out at Messrs. Gilstrap, Earp and Co.'s maltings at Newark on April 4th, 1903. It was evidently desirable that in repeating the experiment there should be no doubt as to the sample of anthracite being thoroughly representative, and arrangements were therefore made for Mr. Price, who had obtained considerable experience in sampling anthracite when collecting samples for the Commission at South Wales collieries, to visit Newark and to sample the anthracite used.

On April 4th Mr. Price weighed and sampled the fuel selected, and witnessed the commencement of the kilning on April 5th. Mr. R. B. Floris, who has been engaged with Dr. McGowan in the examination of anthracite samples for the Commission, went to Newark on April 8th, when the kilning was about to be completed, took samples of malt, culms, ash, etc., and saw to the weighing. Mr. R. M. Morris and Mr. Hervey, on behalf of the firm, took great trouble in supervising the operations throughout, and in making special arrangements for their being conducted by careful and trustworthy men.

The following are the principal details of this experiment.

*Kiln.*

The kiln selected was a 30-quarter kiln, built about nine years ago. It differed in certain respects from the kiln used in the first experiment, the main difference being due to alterations made last year in the construction of the furnace, in order to secure better regulation of the draught and economy of fuel.

The malting floor of this kiln is a German wire floor, 33 ft. 6 in. by 23 ft. 10 in., supported on girders. It stands 15 ft. 10 in. from the bottom of the kiln. Above the malting floor the four walls of the kiln rise vertically to 6 ft., and then converge to the air outlet, the throat of which is 15 ft. 9 in. above the malting floor. Below the malting floor is the hot-air chamber, which has brick walls. At the foot of the chamber is the brick tunnel containing the fire. This tunnel is 8 ft. long, and its height inside is 44 in. Its base is formed by the fire-bars, the fire being confined to the front 3 or 4 feet of the tunnel. The breadth of the tunnel at the base is 21 in.; its greatest breadth, just below the arch of the roof, is 34 in. On either side of the tunnel are inlets which can admit air direct to the hot-air chamber, without passing through the tunnel. These inlets are opened when required and regulated by the fireman. There is a large iron dispersing plate between the opening of the tunnel inside the hot-air chamber and the malting floor above.

This kiln had been in use throughout the malting season. The anthracite used during this period had been considered satisfactory, and the malt produced on this kiln had uniformly failed to show arsenical contamination by the Reinsch test used at these maltings.

*Sweeping of kiln before experiment.*—On April 4th the fire having been let out, a number of men were employed all day in sweeping down every part of the kiln and furnace, including the girders beneath the malt floor and all corners in which dust might lodge. After the sweepers had been

over it several times, and had removed several bags full of kiln dust, a final sweeping was given which resulted in the collection of an additional quantity—a few pounds—of dust. The walls of the hot-air chamber were then lightly sprinkled over with water, the malting floor was given a final polish, and the kiln was closed for the night. In the morning, before the kiln was loaded, the hot-air chamber and malting floor were carefully inspected, and it was found that scarcely any dust was perceptible.

#### *Anthracite used, and its Sampling.*

The anthracite taken for the experiment was part of a truck load which Messrs. Gilstrap and Earp had received this season from a South Wales colliery. The coal in question, when burnt on another kiln at these maltings, had been found to produce contamination of malt which was perceptible by the Reinsch test, and this truck load had consequently been set aside.

It consisted mainly of large masses such as are usually preferred for malting, together with some smaller pieces. Small patches or streaks of what appeared to be impure coal or black pyrites were to be observed here and there in the coal.

About 1½ tons was taken to the kiln and weighed. After the larger lumps had been broken the whole was spread out over the brick floor of an adjoining store.

In sampling, Mr. Price divided the bulk into three portions:—

- (1) Larger or smaller pieces of coal showing obvious streaks of impure coal or evidence of pyrites on the surface .. 152 lbs.

Remainder consisting of—

- (2) Larger lumps, over 4-inch cube .. 1,627 lbs.  
(3) Smaller pieces, under 4-inch cube .. 1,016 lbs.  
Add remnants from sampling .. 54 lbs.

Total weight set aside for burning in kiln .. 2,849 lbs.

In the case of (1) and (3), samples were obtained by systematically reducing the bulk and breaking up the coal. In the case of (2), numerous small pieces were broken off the large lumps, mixed together, and sampled. In all, three separate samples were obtained, each made up by combining representative samples of (1), (2) and (3) in proportion to the weights above given. This method of sampling was adopted in order to ensure (a) that a correct proportion of the visible pyrites in the coal should be obtained in the samples; and (b) that the coal left should be in a condition suitable for use in the kiln.

#### *Kilning.*

On April 5th the kiln fire was lighted at 7 a.m. The fire was started with wood, the twigs of three besoms being sufficient. The kiln was loaded at 9 a.m., the depth of the barley on the malting floor being then about 10 inches. The grain used was English barley, which had been kiln-dried before steeping. A sample was taken, which Dr. McGowan found to be free from arsenic. The whole kilning was then carried on in the ordinary manner. The firing was kept under careful supervision, to ensure that the larger and smaller pieces of the anthracite were used up in proper proportion, and to make certain that none of the ash should escape collection. The space below the firebars was raked out from time to time and the cinders and ashes riddled into a large iron skip through a riddle of about ¼-inch mesh. What did not pass through the riddle was returned to the fire. In this way the fuel was more completely burnt than would usually be the case, as ordinarily a half-inch riddle is employed. When the

malt was taken off the floor, at 3 p.m. on April 8th, 313 lbs. out of the 2,849 lbs. of anthracite had not been used. The temperature of the malt during the kilning was taken every two hours. Mr. Hervey stated that in view of the temperatures and also of his analysis of the malt, he considered that the heating had been effected in a regular and satisfactory manner.

#### *Weighing and Collection of Samples at end of Experiment.*

**Malt.**—The malting floor was unloaded by passing the malt through a hopper, and thence by means of shoots to an elevator, which discharged the malt into a revolving drum screen. This screen separated the bulk of the culms, which fell through its meshes and were collected below. The screened malt passed by other shoots and a second elevator to a floor in the malt house, where it was discharged over a flat screen, which separated a small quantity of culms and of husks that had been detached from the malt in the screening process. Before the malt left the kiln, the shoots, elevators and screens were thoroughly brushed down to remove dust or malt from previous kilnings.

Samples of the screened malt were taken from the foot of the flat screen. The discharge of malt over this sieve went on evenly for nearly 1½ hours, and every few minutes small samples were taken; these samples were mixed in a bushel measure and made a final sample of about 5 lbs.

When this was done the malt was put into sacks and weighed. Including a little additional malt taken out at the foot of the elevator, the total weight of malt was 10,390 lbs.

**Culms.**—The culms were swept from below the revolving screen; what had collected beneath the flat screen was added, and the bulk, weighing 390½ lbs., was sampled by successive quartering.

**Ash, etc., from kiln fire.**—When the malt was taken off, a large iron skip was nearly full of ashes, resulting from the riddling mentioned above. The fireman claimed that this residual ash had been kept to the smallest practicable limits by careful attention to firing. As soon as the malt had been taken off, the fire was let out, and all residue in the furnace was collected and riddled over the skip containing the ashes. What did not go through the riddle was either "cinder"—i.e., partly-burnt coal—or "dross," harder masses consisting of residue which had fused and resembled clinker in appearance.

The weights were as follows:—

Cinder	-	-	-	-	46 lbs.
Ash	-	-	-	-	65½ "
Dross	-	-	-	-	38½ "
Total residue	-	-	-	-	150 lbs.

In sampling, the cinder was broken down to pass through a ¼-inch riddle, and was sampled by successive quartering and crushing. The ash was also sampled by successive quartering, and a representative sample of mixed cinder and ash was taken in proportion to the above weights.

The dross was sampled separately; it was broken roughly, and half was taken and crushed till it all went through the riddle. This was then reduced by successive quartering.

**Kiln Dust.**—The sides and bottom of the hot air chamber (including the arch of the tunnel and the top of the iron disperser) were swept down. A small amount of dust remained on the top of the girders which was not removed. The weight of the dust collected, which consisted mainly of rootlets, was 164½ lbs. A sample of this was taken by quartering.

The chemical results obtained in this second experiment are shown in the second part of Table VIII.

Appendix 30.

## OBSERVATIONS.

It will be seen from the results (Table VIII.) that both experiments failed to indicate anything like an equation between the arsenic in the fuel used, and the arsenic in the materials obtained at the end of the kilning. And the failure was of an opposite kind in the two experiments. In the first, according to the calculations, the malt produced, and the ash which was left, each contained a greater weight of arsenic than that which had been estimated to be present in the fuel. In the second, according to the calculations, only a small proportion of the arsenic present in the fuel was recovered in the malt, culms, and ash.

Nevertheless, it has been thought worth while to place the results on record, as illustrating the complexity of the question, and the danger of generalising from isolated experiments on a malt kiln, however carefully conducted.

The following probably influenced the results obtained in Experiment I.:-

(a) The kiln had been in continuous use throughout the season, and, though the furnace was swept thoroughly, the deposit on the large hot air chamber beneath the malting floor was left undisturbed. Hence some of the arsenic in the malt may have been derived from volatilisation of arsenic deposited on the walls of the hot air chamber as a result of previous burnings during the season. (Compare Mr. Baker's observations, Q. 10653.)

(b) The anthracite used was known, as a result of previous kilnings, to be unsatisfactory as regards arsenic, although this was not shown by the sample analysed. It is quite likely that this sample was not representative. On the other hand, proper sampling in the case of the cinders, ash, "dross," and malt was a matter of much less difficulty, and probably the samples here were representative.

The following probably influenced the results obtained in Experiment II.:-

(a) The combustion was much more thorough than is ordinarily practised, the whole of the fuel being burnt to a relatively small amount of fine ash.

(b) The preliminary thorough sweeping of all the parts of the kiln (including the final sweeping of the walls

of the hot air chamber beneath the malting floor, which removed dust containing 180 parts of arsenic per million) must have materially influenced the results. In the first place, there was no opportunity of the malt becoming contaminated by arsenic derived from previous kilnings; in the second place, the sweeping involved the kiln fire being out for some twenty-four hours, and hence the walls of the kiln were cooler than usual and probably condensed more arsenic.

(c) The sample of kiln dust obtained on completion of the kilning was the result of a single superficial sweeping. The sweepings consisted principally of malt culms, and would not contain all the arsenic which had been deposited on the interior surface of the heating chamber, still less that which had been condensed in its porous walls.

(d) There was no doubt some loss of arsenic in the various shoots and elevators, which detached culms and portions of the husk. This was not the case in Experiment I., where the malt did not go through elevators and was screened by hand.

The influence of the above conditions, however, must remain a matter of mere surmise. But it should be noted that in the second experiment, whatever may have been the ultimate destination of the arsenic originally present in the fuel, there can be no question that the samples of fuel and of ash were as representative as it was possible to make them, or that the weighings were accurate in each case. The results of analysis of these samples are instructive, as they show that very little arsenic, comparatively speaking, remained behind in the ash. The extreme difficulty of accurate sampling in the case of a "bad" anthracite containing numerous streaks of black pyrites is also brought out by this experiment. The analyses of the three separate samples of the fuel used show a fairly close correspondence, both as regards "total" and "volatile" arsenic, but the correspondence is less exact than might perhaps have been anticipated in view of the great care which was taken in sampling. It should be added that the anthracite in question was of a kind which on inspection would at once be recognised as unsatisfactory by any one aware of the necessity of looking for granular black pyrites in anthracite specimens.

## APPENDIX 31.

## REPORTS ON BERI-BERI.

REPORTS ON INQUIRIES AND CHEMICAL EXAMINATIONS MADE FOR THE COMMISSION  
REGARDING THE RELATION OF BERI-BERI TO ARSENICAL POISONING.

## SECTION I.—GENERAL ACCOUNT OF INQUIRIES AND SUMMARY OF RESULTS.

In their evidence regarding the character of the illness met with during the beer poisoning epidemic of 1900, Dr. Reynolds, Dr. Kelynack, and others drew attention to a general similarity said to exist between this illness and the disease beri-beri. The resemblance in question was said to be most marked in cases of beer poisoning characterised by well-marked peripheral neuritis and affections of the heart. Comparison was made, not only with descriptions of beri-beri as met with in tropical countries, where it is frequently endemic or epidemic, but also with comparatively recent outbreaks of this disease in the Richmond Asylum, Dublin, in 1894, 1896, and 1897. An account of these outbreaks, by Dr. Conolly Norman,\* illustrated by photographs, showed a striking clinical resemblance between these cases and the bulk of those met with at the end of 1900 in the Poor Law Infirmary at Manchester and Liverpool, as a consequence of arsenical beer poisoning.

Major Ronald Ross, C.B., F.R.S., Lecturer in Tropical Medicine at University College, Liverpool, who had seen a number of the arsenical cases in 1900, wrote to the Commission that in his view the difficulty in distinguishing these cases from the "dry" forms of beri-beri was very great, and he gave other particulars regarding the uncertainty which prevails regarding the origin, nature and cause of this disease.

In his later evidence, on March 7th, 1902, Dr. Reynolds gave an account of some further inquiries which had led him and Major Ross to conclude that the existence of a causative relation between arsenic and tropical beri-beri was possible or probable. (Q. 8379-8401.)

In view of these considerations the Commission decided that it was desirable to obtain some further knowledge on this subject. The suggestion that arsenic might be concerned with beri-beri was, however, new; scarcely any chemical examinations had been made to test it, and it seemed to the Commission advisable, therefore, to institute some preliminary inquiries, along with chemical examinations, in order to determine how far, for their purpose, it was necessary to make further investigations.

Beri-beri is met with comparatively rarely in this country, but cases occasionally come to notice at British ports in vessels arriving from foreign. Such cases usually fall into two classes:—

(1) Indians, Chinese, Lascars, and others employed on steam ships trading with Eastern and tropical ports.

(2) Europeans on board sailing ships which arrive at the end of long voyages (usually many months) from almost any part of the world. Among sailing ships arriving at English ports, Scandinavian vessels appear exceptionally prone to be attacked by beri-beri. Many of these vessels bring cargoes from South America, and use Falmouth as a port of call, waiting there for orders.

The disease in cases of the second class is generally accepted as identical with the beri-beri which is common in the East; in most of these cases the clinical mani-

festations seem to be essentially those of "tropical" beri-beri. It should be noted, however, that there is often no evidence that beri-beri was prevalent at the port of departure of these sailing ships. The disease frequently does not appear until the vessel has been many weeks at sea.

Difficulty frequently arises in assigning a definite date or period to beri-beri, as its onset is often extremely gradual. A sailor, for example, may have been ailing for many weeks before he was sufficiently ill to be unable to work, but on giving an account of his illness he will probably date its commencement to the time when he was incapacitated from duty.

COLLECTION OF INFORMATION AND SAMPLES FROM SHIPS  
AT HOME PORTS.

In September, 1901, the Commission communicated with the Medical Officers of Health of the ports of London, Liverpool, Tyne, Hull, Cardiff, Bristol, Plymouth and Falmouth, with the object of obtaining information as to cases of beri-beri which came to notice on the arrival of ships. The Medical Officers in each instance readily undertook to assist the Commission. From September, 1901, to October, 1902, a total of 21 vessels on which beri-beri had occurred during the voyage were reported to the Commission. None of these arrived at Bristol, Tyne, or Plymouth, 8 arrived at London, 9 at Falmouth (some of which afterwards came to London), 2 at Liverpool, 1 at Hull, and 1 at Cardiff. Much trouble was taken by the Port Medical Officers of Health and their inspectors to supply the Commission with the information asked for, and to obtain samples of food.† The vessels so reported are shown in tables below. Table I. relates to 14 vessels from which samples of food stuffs were obtained and examined; the remaining vessels are noted in Table II. The following is a summary of the facts regarding beri-beri on the 14 ships noted in Table I. Twelve of these were Scandinavian sailing ships: two were steamships coming from India or Burma. The cases on the latter vessels were Lascar or African firemen; all those on the Scandinavian ships, with one exception, were Europeans.

"FRAY," Norwegian barque, 298 tons, arrived Falmouth, September 9th, 1901. Reported by Mr. Cecil Bullmore, Port Medical Officer of Health.

Left Laguna with cargo of logwood 52 days before arrival.

Crew of nine; one case of beri-beri.

Captain of vessel, Norwegian, aged 42. Illness two or three weeks' duration. Captain quartered aft by himself. No illness among rest of crew; no beri-beri on previous voyages.

Transactions of the Royal Academy of Medicine in Ireland, Vol. XVII.

† In a few cases the mere fact of the arrival of the vessel was reported, and for one and another reason no details were obtained. These have not been included in the figures given.

‡ On one or two occasions Mr. Hammond Smith, being in the neighbourhood in course of his general food inquiries, assisted in obtaining post-mortem specimens and samples of foods from the ships.

Diet of captain: salt beef and pork, tinned mutton and beef, fish balls\*, stock fish\*, dried potatoes\* and vegetables, lime juice, vinegar, red wine, no spirits, no rice.

"PEGU," ss., 2,511 tons, arrived Liverpool December 10th, 1901. Reported by Dr. Hope.

Left Rangoon with general cargo on November 7th, 35 days on voyage.

Crew of 74 hands, 24 of these being Lascars quartered aft. Four Lascars (all firemen) attacked by beri-beri. Ages from 22-27 years. They had signed on in July, 1901, and since then the ship had made one previous voyage to Liverpool. The four men were quartered with 20 other Lascars in crews' quarters aft; accommodation good and quarters well ventilated and clean. No illness among rest of crew, save a few cases of malaria, one of dysentery, and one of acute rheumatism. No beri-beri on previous voyages; vessel launched only 12 months previously.

First patient consulted surgeon on November 17th, previously four days ill. Other two patients fell ill on November 29th, and the fourth on December 1st. The latter had complained of illness for a fortnight before.

Diet of Lascar firemen attacked: Chief food, rice\* from Rangoon. Curries varying from time to time—at one time of mutton, another of fish (Bombay duck\*) with chillies, tamarind, coriander and other spices from bazaar, Rangoon. Also "samsu"—a native drink—and gin\*, tea, no lime juice. Tinned meats were never used by the men. Tinned ghee\* (native butter) from Rangoon was taken. Dahi (native peas), and fresh beans occasionally used. Drinking water from artesian well at Rangoon, stored in iron tanks. No diet known to have been taken by patients which differed from that of other Lascars on board.

On arrival in Liverpool four cases, considered by Major Ross and others undoubtedly beri-beri, all had considerable oedema. Ahmed, 27, died in hospital from heart failure, December 15th. Post-mortem, liver\*, hair\*, brain\*, and nails\*, obtained. Abid, aged 26, died in hospital from cardiac failure, December 13th. Hookan, 22, slight attack, recovering. Hasan Ali, 26, severe attack, now no oedema, recovering; specimen of hair taken\*.

"CIMBRIA," Norwegian barque, 1,000 tons, arrived London, January 15th, 1902. Reported by Dr. Herbert Williams, Medical Officer of Health of the Port of London.

Left Moulmein with cargo of teak, July 31st, 1901, 168 days before arrival. Touched at St. Helena, November 9th, 1901, and Falmouth, January 12th, 1902.

Crew of 12 on departure. Six cases of beri-beri on voyage. W. Lyons, A.B., aged 45, taken ill about August 14th, swollen feet, oedema gradually extended to all parts of body, including head; died November 3rd. L. Weins, a Dane, aged 26, taken ill about October 9th, landed St. Helena Hospital, November 9th, where beri-beri diagnosed. H. Langson, half-caste native of Bombay, aged 19, ill off and on throughout voyage, suffering from swollen legs. On arrival in London had slight oedema of legs, complains of pain in abdomen and back. Three other men who shared the same quarters in the house on deck were slightly ill with swollen legs, but not incapacitated from work on the vessel's arrival at St. Helena. Slight illness, accompanied by swelling of legs, in master, steward, and first officer, who lived in after-house.

Notes on Diet.—Rice\* from Rangoon four times a week. Lime juice issued daily after arrival at St. Helena, not before. A little red wine, otherwise no alcoholic liquor. Stock fish\* taken on board in Norway, issued and eaten once a week. Flour\* issued twice a week. Vinegar, drinking water taken at Moulmein, stored in iron tanks.

"COLLINGWOOD," Norwegian barque, 950 tons, arrived Cardiff, January 24th, 1902. Reported by Dr. Walford and Dr. Hughes.

Left Cape Town June 15th, 1901, arrived Rangoon July 27th, sailed September 11th, 135 days before arrival at Cardiff. Called at St. Helena October 16th.

Four men ill on arrival. H. W., aged 24, carpenter, taken ill about November 30th. H. L. B., aged 52, sail-maker, taken ill about December 24th. S. S., aged 19, and D. P., aged 24, both A.B.'s, taken ill about December 27th. On arrival the men had well-marked paralysis of lower limbs, slight dropsy, loss of patella reflex, and weak action of the heart, but all seemed to be recovering. The carpenter and sail-maker slept by themselves and apart from the rest of the crew; the other men were in the fore-castle. Captain states that there were no other cases of illness during voyage. No beri-beri on previous voyages.

Notes on Diet.—The Captain states that the men drank beer and spirits freely in Rangoon. The food on the voyage consisted mainly of tinned meat, dried fish\*, dried potatoes\*, peas, and flour\*. No rice on voyage, but rice taken at Rangoon. No alcohol during whole voyage except two bottles of whisky.

Some samples of hair from these cases were examined by Dr. Savage, of Cardiff, who found distinct evidence of arsenic. Samples of hair were also sent to the Commission, but they were not sufficiently large to enable a satisfactory determination of arsenic to be made. Dr. Savage also tested certain samples of food and water for arsenic, but without affirmative result.

"ARGO," Norwegian barque, arrived Goole, April 6th, 1902, reported by Dr. Mason, Medical Officer of Health of the Port of Hull.

Left Cape Haytien (Hayti) February 22nd, with cargo of logwood. Jon Jansen, 47, carpenter, living on board vessel for nine months, taken ill after leaving Hayti, but symptoms of illness believed to have begun about a fortnight before the ship's departure. Had suffered from "pins and needles" in palms and soles and oedema. On arrival could hardly walk, owing to loss of power in limbs; no knee jerks, slight oedema above ankles. Skin of soles of feet rough, no pigmentation, save in parts exposed to weather. Hair specimen taken. No illness among rest of crew, numbering 11.

His diet included dried codfish\*, tinned fish\*, tinned meat, dried vegetables\*, potatoes, rice\*, in small quantity. Sample of drinking water\* obtained.

"BEN MORE," Norwegian sailing ship, arrived Falmouth April 15th, 1902. Reported by Mr. Cecil Bullmore.

Left Nicaragua with cargo of cedar and mahogany 167 days before arrival.

Crew of 20, including three officers. One case of beri-beri: E. Liennigh, first mate, aged 46. Had joined ship in Liverpool three years ago. Was taken ill three weeks after leaving Nicaragua. On arrival, partial paralysis of both legs; knee jerks absent, oedema of both feet and legs, extending to abdomen and thorax; heart irregular, slight desquamation of soles of feet; no catarrhal symptoms, no pigmentation.

Notes as to Diet.—Monday: Salt meat in cold weather, rice\* porridge in hot weather. Tuesday: Tinned meat\* or soup, preserved potatoes and mixed preserved vegetables\*. Wednesday: Salt fish\* and potatoes. Thursday: As Tuesday. Friday: Salt meat and beans. Saturday: Salt fish, soup, sago, and preserved fruit. Sunday: As Tuesday, with pudding. Bread or biscuit, butter, tea, coffee, and condensed milk at other meals. Lime juice\* regularly. Water\* from cement tanks—washed 16 months ago in Newcastle.

"CHARLES RACINE," Norwegian sailing ship, about 2,000 tons, arrived London, March 16th, 1902. Reported by Dr. Herbert Williams.

\* Samples obtained and sent to Commission

## Appendix 31.

Left Fremantle, Australia, November 30th, 1901, 105 days before arrival. Touched at St. Helena January 21st.

Crew of 15 hands. Six cases of beri-beri: Cornelius Fortensen, 68, joined ship November 27th, working passage home. Taken ill January 17th, 1902; O. Stanisland, carpenter; G. Fagenstrom, sail-maker; J. Gabriel, A.B.; A. Valstrom, A.B.; J. Eliassen, A.B., all Norwegians, who joined ship in Norway. Taken ill at different dates between January 5th and 18th. All six cases landed at St. Helena. Cornelius Fortensen died there January 22nd. No other illness amongst crew.

*Notes on Diet.*—Rice\* about once a week, salt fish,\* tinned meat,\* lime juice\* when no fresh vegetables to hand, no alcoholic liquors, drinking water in iron tanks.

"PRINCE GEORGE," Norwegian barque, 474 tons, arrived London, April 18th, 1902. Reported by Dr. Herbert Williams.

Left Port Victoria (Seychelles) October 23rd, 1901, with cargo of guano.

Crew of 10. Three cases of beri-beri: G. Carlsen, Norwegian mate, 27; Carl Hansen, Swede, A.B., 23; Franz Biji, Norwegian, O.S., 22. All taken ill about January 14th, 1902. On arrival, G. Carlsen and Carl Hansen on duty, the first has oedema of right arm and leg, no pigmentation, gums spongy; the second has both legs swollen from knee to ankles. Franz Biji seriously ill, whole body much swollen. Died on April 17th. Post-mortem (Stratford Infirmary, April 21st). Brawny oedema of legs and chest, veins engorged, heart enlarged, and the walls thinned, valves healthy. Fluid in pleura and peritoneum, spleen engorged, kidneys appear healthy. Case seen by Dr. Ross, of London School of Tropical Medicine, considered to be undoubtedly beri-beri.

Carlsen was berthed in quarters with master and steward, the two other cases were berthed in the fore-castle with five others of the crew. No evidence of their diet having differed from that of their companions.

*Notes on Diet.*—Said to have been good supply of food throughout voyage. Salt pork and salt beef, potatoes, tinned mutton,\* no dried fish, as supply had given out before leaving Port Victoria, Norwegian tinned fish,\* rice\* bought on outward voyage at Port Louisa taken moderately, lime juice\* taken moderately, drinking water\* obtained at Port Victoria, stored in iron tanks.

"SOMALI" (ss.), 8,000 tons, arrived London May 15th, 1902. Reported by Dr. Herbert Williams.

Left Calcutta with general cargo, April 12th, 1902.

Crew of 171. Two cases of beri-beri among African firemen, A. and B.; quartered in fore-castle with 15 others. Date of A.'s attack not known; he died April 25th. B., aged 26, fell ill on April 10th. He had joined the ship in London for outward voyage. On arrival showed oedema, weakness, and loss of power in lower limbs; no knee jerks, slight dropping of toes. No beri-beri on previous voyages of "Somali."

*Notes on Diet.*—Mainly rice,\* curry,\* dahl, and fish.\* No alcoholic liquor.

"SORATA," Norwegian barque, arrived Falmouth June 3rd, 1902. Reported by Mr. Cecil Bullmore.

Left Punta Arenas (Chili) January 2nd, 1902, 152 days before arrival.

Crew of 12, including three officers. Five cases of beri-beri. Captain (Norwegian, aged 45): Illness began about four months after leaving Punta Arenas. On arrival showed oedema, well-marked paralysis of legs, weakness of arms, great muscular tenderness, dyspnoea; probably fluid in pericardium; had an attack of beri-beri six years ago. First mate (Norwegian, 33): Fell ill about four months after leaving Punta Arenas. On arrival oedema, slight paralysis, and great

weakness; marked tenderness of muscles of legs; no recent pigmentation; some "sea-boils." Second mate (Norwegian, 49) also taken ill about the same time as captain and first mate. On arrival slight oedema, no definite paralysis, muscular tenderness, no pigmentation. Steward (Norwegian, 31), slight oedema, loss of power in right leg, muscles tender, no pigmentation. Carpenter (Norwegian, 29): Date of onset of illness not stated; on arrival showed oedema of legs and abdomen, loss of power in legs, muscular tenderness; seemed very ill.

Others of crew complained of feeling ill, but no indications of beri-beri. Sanitary condition of vessel very bad; fore-castle dirty, closets filthy, ventilation of fore-castle and cabins bad; one not lighted.

*Notes on Diet.*—Provisions have been short. Usual diet, including officers:—Monday: Milk, soup, and fish. Tuesday: Pea soup and salt meat. Wednesday: As Monday. Thursday: Salt or meat and tinned vegetables (tomatoes,\* cabbage, etc.). Friday: Bean soup. Saturday: As Monday. Sunday: Preserved meat and dough; also oatmeal, sugar, lime juice,\* barley, flour, rice,\* drinking water dirty; iron tank needed cementing.

"MORGENGRY," Norwegian barque, arrived Falmouth June 3rd, 1902. Reported by Mr. Cecil Bullmore.

Left Santos March 11th, with a cargo of coffee, 84 days before arrival.

Crew of 11, including three officers. Two cases of beri-beri. Barbadoes negro, aged 19, fell ill two weeks after leaving Santos; died just before arrival; believed to have been beri-beri from symptoms reported by captain. Post-mortem, June 5th: Slight oedema of face and legs; veins engorged; small amount of fluid in pleura; blood very dark and fluid; heart enlarged, walls of ventricles thin; much fluid in pericardium; spleen and kidneys appeared normal; congestion of vessels at base of brain and of spinal cord noted; much fluid in membranes of cord. Jacob Neilson (Dane, aged 18) taken ill one month after leaving Santos. On arrival showed loss of power, symptoms of dilatation of heart, oedema of legs, abdomen, and chest. Both cases slept in fore-castle with three others. Fore-castle was clean; its ventilation not good.

*Notes on Diet.*—The following were usual:—Monday: Fish balls,\* preserved potatoes, soup. Tuesday: Pork or tinned meat or fish, boiled rice.\* Wednesday: Stock fish,\* and preserved potatoes. Thursday: Tinned meat or fish, vegetable soup, balls of dough. Friday: Salt pork or beef, no vegetables. Saturday: Pancakes, pork, porridge. Sunday: Tinned meat, sago and potato soup, dried fruit. Lime juice. Bread half the week, biscuits the other half.

"HANDEL JUST," Norwegian barque, arrived Falmouth May 31st, 1902. Reported by Mr. Cecil Bullmore.

Left Bahia (Brazil) March 29th, 1902, with cargo of iron ore, 63 days before arrival.

Crew of 14. Two cases of beri-beri, both able seamen. Friedrichsen (Dane, 19), joined ship in Denmark eight months before. Illness began a month before arrival. Closter (aged 60) joined the ship at Carliff. Illness began a fortnight before arrival.

Symptoms in both cases on arrival: Shortness of breath, no appetite, malaise, oedema of legs and feet, pains in calves of legs, no pigmentation. Friedrichsen had slight ankle drop. Closter attacked by beri-beri eight years ago. Both slept in fore-castle; ventilation very bad.

*Notes as to Diet.*—Food has run short; crew lived on bread and butter for last week. Previously diet was beans, potatoes, salt or tinned

\* Samples obtained and sent to Commission.

meat, dried fish, fishballs, rice, apples. No lime juice taken by anyone, though plenty on board.

"H. C. RICHARDS," Norwegian sailing ship, 766 tons, arrived London June 30th, 1902. Reported by Dr. Herbert Williams.

Left Port of Spain with cargo of pitch April 25th, 1902, 66 days before arrival.

Crew of 12. One case of beri-beri. Norwegian seaman, 26. Had joined ship at Barbadoes, March 22nd; fell ill June 16th, 1902. Both legs swollen from ankle to knee, vomiting, shortness of breath, unsteadiness in walking. Diagnosed beri-beri on arrival. Quartered in fore-castle with seven others. No illness in rest of crew, save one slight case of ague (?). On previous voyage of this ship, leaving Madagascar November 16th, 1901, three fatal cases of beri-beri occurred (the captain and two seamen).

*Diet* of beri-beri case the same as rest of crew. Included small quantity of rice,\* no alcoholic liquor, salt and tinned beef,\* tinned fish, fishballs.

"VICTOR," Norwegian barque, arrived London August 8th, 1902. Reported by Dr. Herbert Williams.

Left Moulmein with a cargo of teak, March 6th, 1902, 155 days before arrival; called at Ponta Delgada, Western Islands, July 17th-25th.

Crew of 10. Three cases of beri-beri. Campbell (Canadian A.B., 50) joined vessel at Moulmein; sick and off duty nearly all the passage; could not go aloft owing to weakness and swollen feet. J. Jonson (Swede, A.B.), taken ill about July 8th, swollen legs and feet; treated at shore hospital in Delgada on July 17th for beri-beri; able to rejoin July 24th. W. Hubner (O.S., 20), ill and suffering from swollen feet since July 25th. All three cases recovering on arrival in London. They were quartered in house on deck with three other men. No other cases of illness during voyage; no beri-beri on previous voyages.

*Notes as to Diet.*—Rice\* obtained at Moulmein served out three times a week to all members of crew. Flour\* obtained at Moulmein in March, 1902, made into bread daily. Dried fish\* obtained in Cape Town December, 1901, eaten twice weekly. No lime juice or acid drink or any alcoholic liquor used. Drinking water stored in iron tanks.

\* Samples obtained and sent to Commission.

## APPENDIX, No. 31—continued.

TABLE I.

VESSELS ON WHICH BERI-BERI WAS REPORTED AND FROM WHICH SAMPLES OF FOOD, &amp;c. WERE EXAMINED FOR ARSENIC.

Vessel.	Tonnage.	Port of Departure.	Port of Arrival.	Date of Departure.	Date of Arrival.	Number of Days on Voyage.	Cases of Beri-beri during Voyage.		Nationality of Beri-beri cases.	Cases of Beri-beri on or after Arrival.		Number of Days on Voyage before illness of first case occurred.*	Whether cases of Beri-beri on previous Voyage.
							Total Number.	Number of Fatal on Voyage.		Total Number.	Number Fatal.		
"Fray" (Norwegian barque).	Tons. 298	Laguna	Falmouth	19 July 1901	9 Sept. 1901	52	1	—	Norwegian	1	—	About 4 weeks	No.
"Pega" (Steamship)	2,511	Rangoon	Liverpool	7 Nov. 1901	10 Dec. 1901	33	4	—	Lascars	4	2	About 6 days	No.
"Cimbria" (Norwegian barque).	1,000	Moulmein	London	31 July 1901	15 Jan. 1902	168	6	1	1 British, 1 Dane, 1 native of Bombay; 3 not stated.	4 (3 slight)	—	About 14 days	Not known.

Trace in each column = below  $\frac{1}{1000}$  grain per lb.

# EXAMINATION FOR ARSENIC OF FOOD SAMPLES FROM THE ABOVE VESSELS.

Appendix 31.

In the above list of vessels on which beri-beri occurred, the articles of food which were obtained by the Port Medical Officers of Health and transmitted to the Commission have been indicated by an asterisk. It is, of course, evident that the foodstuffs remaining on board a vessel when it puts into port at the end of a long voyage are not necessarily representative of the diet actually taken by the crew during the voyage. In some instances the Port Medical Officer of Health, in transmitting the samples, has noted that usual foodstuffs, such as dried vegetables or tinned meats, had all been consumed, and no specimens were obtainable. This was the case in several of the Norwegian vessels. Mr. Cecil Bullmore notes, in a memorandum on beri-beri made in 1902 to the Falmouth Port Sanitary Authority (a copy of which he has sent to the Commission), that as regards Norwegian ships "the whole arrangements for a voyage seem to be cut down to the hour, and if they are a few weeks overdue owing to contrary winds this becomes most apparent."

Nevertheless, the samples obtained from the ships as a whole covered a considerable range of substances, such as preserved and dried foods, which are used to a greater extent on ship board than on shore. The majority of these have now been examined for arsenic in Dr. McGowan's laboratory, with the results shown in his reports in Section II. below, and also in the Table III. above. Two food materials, rice and fish, were always sent for examination when available, in view of various statements which have been made regarding possible causative relations—apart from arsenic—between use of these foods and beri-beri.

It is noteworthy that rice has not formed an important article of diet on some of the Norwegian vessels: in two instances no rice at all was taken. On the other hand, in the s.s. "Pegu" and "Somali," where the sufferers were Lascars or African firemen, rice was the main

article of food. No arsenical contamination—save to a minute extent—was, however, detected in the rice samples obtained from any of the vessels.

With regard to fish, it will be seen that neither of the two specimens of fish balls (fresh fish dried and powdered and mixed with flour), nor any of the three samples of tinned fish, contained more than the merest trace of arsenic. Dried fish, on the other hand, habitually contained arsenic, in varying amounts up to 1-80th grain per lb. In most instances the fish was dried cod, obtained in Norway. Large stores of this fish are usually carried in Norwegian sailing ships. According to information supplied by Professor Uchermann, of Christiania, this fish is cured by drying in the sun, and not by smoking over fuel. The origin of the arsenic is perhaps to be sought in the subsequent salting, possibly in preservatives used,\* but no authoritative information has been obtained by the Commission on this point.

Tinned meat and tinned vegetables were examined for arsenic in four instances, tinned milk in one case, lime-juice in five cases, drinking water (on account of its storage in iron tanks) in four instances, all with negative, or practically negative, results. 1-90th grain of arsenic per lb. was found in one sample of "dried potatoes"—i.e., potatoes which have gone through some process of drying or curing after being cut up in slices. Possibly here preservatives may again afford an explanation.

In view of the evidence that cheap cocoa containing oxide of iron may be contaminated by arsenic (Hehner, Appendix 27; H. Smith, Appendix 24) it is unfortunate that no samples of cocoa were obtained, particularly as cocoa is sometimes taken largely by sailors. The fact that notable amounts of arsenic may be found in cocoa of this kind was ascertained only after these inquiries had been completed.

## EXAMINATION FOR ARSENIC OF SPECIMENS FROM FATAL CASES OF BERI-BERI, AND OF HAIR OF BERI-BERI CASES.

In three instances the Commission was informed of deaths from beri-beri among the cases reported in Table I. above, and at post-mortem examinations some of the organs were obtained and sent to the Commission. In each of the three cases the liver was examined in Dr. McGowan's laboratory, and in two cases the brain also was tested for arsenic. The results are given in Table VI. below, together with the results of testing for arsenic in the hair and nails of these cases, and also in the hair of three non-fatal cases.

The estimated quantities of arsenic were as follows:—

*Ahmed*, fireman, s.s. "Pegu."

Arsenic in whole brain, .0012 grain.  
Arsenic in whole liver, taken as 60 oz., .006 grain.  
Arsenic in hair, .02 grain per lb.  
Arsenic in nails, .04 grain per lb.

*F. Biji*, seaman, barque "Prince George."

Arsenic in whole liver, taken as 60 oz., .0063 grain.  
Arsenic in hair, .014 grain per lb.

*Negro*, barque "Morgengry."

Arsenic in whole brain, .0018 grain.  
Arsenic in whole liver, taken as 60 oz., .0052 grain.  
Arsenic in hair, .007 grain per lb.

*Hasan*, fireman, s.s. "Pegu."

Arsenic in hair, .012 grain per lb.

*J. Jansen*, carpenter, barque "Argo."

Arsenic in hair, .04 grain per lb.

*J. Nielson*, barque "Morgengry."

Arsenic in hair, .0028 grain per lb.

Minute quantities of arsenic were thus detected in the organs examined post mortem, and in the hair, of all the six cases in question. In the case of liver and brain in the three fatal cases the total amount of arsenic estimated to be present is in each instance so very small that no significance can safely be attached to the results in the absence of comparable analytical data from "control" cases. As regards the hair, it will be seen that two cases showed less than 1-100th grain of arsenic per pound of hair, while the remainder showed 1-80th, 1-70th, 1-50th, and 1-25th grain respectively. In general, these are larger proportions of arsenic than were found in the specimens of hair from "control" cases—persons taking no arsenic medicinally—which were examined in course of the Commission's hair inquiries (Appendix 32, Table A). On the other hand, the arsenic in the hair of these beri-beri cases is generally less than that which was found in the recently grown hair of persons taking small medicinal doses of arsenic (3 to 4 minims of liquor arsenicalis daily, Appendix 32, Table E).

In three out of the four cases showing more than 1-100th grain of arsenic to the pound of hair there is evidence that the patients ate dried fish containing some arsenic (1-80th grain to the pound in the specimens examined), and it seems probable that the arsenic detected in the hair of these cases was derived from the fish eaten or from some other food containing small quantities of arsenic. Two of the cases were firemen, and their occupation may have led to the inhalation of dust or fumes containing arsenic.

\* The Commission's attention has been drawn by Professor Delepine and others to the presence of arsenic in potted shrimps due to the boric acid used. See also Mr. Hammond Smith's Report (Appendix 24). Two samples of fish were consequently examined (though not exhaustively) for boron by Dr. McGowan. In each case the result was negative.

## Appendix 31. CONCLUSIONS AS TO INQUIRIES REGARDING SHIP-BORNE BERI-BERI AND ARSENIC.

Looking to the general effect of the evidence which the Commission has received as to chronic arsenical poisoning, it may be concluded that the above inquiries and chemical examinations, so far as they go, do not afford grounds for assuming that the beri-beri met with on ships arriving at home ports is essentially due to arsenic.

This may be said notwithstanding that minute amounts of arsenic have in some instances been found in specimens from beri-beri cases and in certain foods taken from the ships. Thus it seems possible that on Scandinavian sailing vessels dried fish containing as much arsenic as 1-80th grain per pound may be taken by sailors almost daily for months or years, and it is likely enough that arsenic taken in this way over long periods may here and there produce peripheral neuritis or other symptoms of poisoning in an individual who is specially susceptible to arsenic, particularly if his susceptibility is enhanced by deficiency of food. But quan-

titles of arsenic of this order can hardly be related to the sudden appearance of the disease among several members of a crew at about the same time, in the manner which is illustrated by the history of a number of the vessels dealt with in these notes.

It should be added that several of these beri-beri cases are reported to have shown, in addition to affections of motor and sensory nerves, an amount of oedema, and an acuteness of cardiac symptoms, which have no parallel among the cases of arsenical beer poisoning in 1900. On the other hand it will be noted that the symptoms reported in one of the six cases from which specimens of tissue were obtained, Jon Jansen, barque "Argo," appear to have a closer resemblance to those of chronic arsenical poisoning than to those of "tropical" beri-beri. In this case the amount of arsenic found in the hair (1-25th grain per pound) suggests that the man must have recently taken a relatively considerable quantity of arsenic, either by way of the dried fish on the "Argo" or otherwise.

## INQUIRIES AS TO ARSENIC AND BERI-BERI IN THE MALAY STATES.

A considerable number of inquiries into the causation of beri-beri have been made in the Federated Malay States, where serious prevalence of the disease is common, and copies of certain recent reports on beri-beri in these States have been sent by the Colonial Office to the Commission. It is evident that as yet the etiology of the disease in the Malay States (particularly as to the relation of beri-beri to particular articles of food or to particular toxins) is not understood. One or two of the reports in question discuss the possibility of arsenic being concerned with beri-beri, but they do not record any investigations for the detection of this or other mineral poison. Dr. A. J. McClosky has sent to the Commission a memorandum of the results of treating 38 beri-beri cases with arsenic at the District Hospital, Kuala Lumpur, a comparable series of 45 cases being treated at the same time without arsenic. The facts given show that arsenic was not beneficial; relatively fewer cases recovered when treated with arsenic. But, on the other hand, in certain cases protracted administration of considerable doses of liquor arsenicalis did not appear to retard recovery.

It will be remembered that in connection with the occurrence of beri-beri among communities in the tropics whose diet consists largely of rice, Dr. E. S. Reynolds (Q. 8381) drew attention to the statement that it is a common custom to put arsenic on rice fields to poison rats and keep them off the rice, and he referred to a letter from Dr. W. C. Brown regarding this practice in Aceh. Similar statements have been made by others. According to information supplied by Dr. Hughes in connection with the "Collingwood" cases, arsenic is also said to be used in Indian granaries to kill insects.

In 1902 Dr. H. E. Durham, who is inquiring, on behalf of the Beri-beri Committee of the London School of Tropical Medicine, into the etiology of beri-beri, kindly sent some rice samples to the Commission. Two of these samples consisted, in each case, of the total siftings through a fine sieve of a large bulk of rice (about 200 lbs.) forming the main diet of prisoners at a gaol in Kuala Lumpur. One (B) weighing about 1-7th lb., was taken on September 24th, 1902, at a time when beri-beri was rife; the other (A), weighing about 1-10th lb., had been taken earlier, on July 28th, when the prevalence of the disease in the gaol had for a time diminished. Dr. Durham has since sent some further samples (C and D) of the siftings of a considerable bulk of rice (each representing a week's supply) consumed by sufferers from beri-beri in Pudu Gaol.

Dr. McGowan found (Table V. below) in rice siftings A 1-45th grain, in B 1-70th grain of arsenic per lb. of the dust. In C and D the proportions of arsenic per lb. of the siftings were 1-29th and 1-25th grain per lb. respectively. It is evident that the arsenic in these siftings could not have represented any appreciable quantity of arsenic in the large bulk of rice from which they were derived.

Dr. Durham also sent two pigtails from fatal cases of beri-beri, which have been examined for arsenic, with result shown in Table VI. It will be seen that a portion of one of the pigtails was specially extracted with ether and dilute hydrochloric acid in order to ascertain whether the arsenic present was due to extraneous matter. Nearly all the arsenic, however, was found to be contained in the substance of the clean hair.

July, 1903.

G. S. B.

SECTION II.—DR. MCGOWAN'S REPORTS ON EXAMINATION FOR ARSENIC OF VARIOUS  
SUBSTANCES IN CONNECTION WITH THE INQUIRY INTO BERI-BERI.

The results of these examinations are set out in the three following Tables, IV., V., and VI. Details of the methods summarised in Col. 6 of these tables appear in Appendix No. 22.

---

## APPENDIX, No. 31—continued.

TABLE IV.

SHOWING RESULTS OF EXAMINATION FOR ARSENIC OF FOODS TAKEN FROM SHIPS IN CONNECTION WITH BERTHBERG.

1. Number of Sample.	2. Ship.	3. Description of Sample.	4. Date when Analysed.	5. Quantity taken for Analysis.	6. Method of Analysis.	7. Arsenic Mirror read. (Milligrammes).	8. Arsenic (As <sub>2</sub> O <sub>3</sub> ) Grains per lb. (Approximate fractions).	9. Parts per Million.	10. Notes as to Analysis.
1	"Fray"	Lime juice	29 Sept. 1901	20 c.c.	Direct Marshing	Mere trace			The whole 20 c.c. was Marshel, sulphides having been previously tested for.
2	"Fray"	Fish balls	3 Oct. 1901	51·2 grms.	Nitric and sulphuric acids	None	Arsenic-free		Seven twentieths of extract Marshel, after boiling with dilute sulphuric acid. A considerable quantity of antipode came off in the Marsh, but some subsequently added arsenic was recovered quantitatively from the same solution.
3	"Fray"	Stood fish from River	19 Oct. 1901	50 grms.	Chlorate method	0·023	3/4	1·8	One-fourth of solution Marshel. N.B.—An estimation was made in the first instance by the nitric and sulphuric acids method, and this gave 1/16th grain of arsenic per lb. But, owing to the large quantity of glue present, this method could not be trusted to give accurate results.
4	"Fray"	Potatoes (dried)	7 Dec. 1901	30 grms.	Chlorate method	0·024	3/4	1·6	One-half of solution Marshel. A special test, made afterwards, showed that practically all the arsenic had been extracted from the potatoes.
5	"Collingwood"	Preserved potatoes	12 Mar. 1902	30·0 grms.	Nitric and sulphuric acids	Mere trace	Mere trace		Two fifths of extract Marshel. N.B.—An estimation was first made with 5·0 grms., which showed only a very faint indication of a mirror, and so it was thought well to make a second.

7	"Collingwood"	Flour	18 Mar. 1902	10.0 grms.	Basic method, followed by direct Marshing.	None	Arsenic-free	—	Two-fifths of solution Marshd.
	"Collingwood"	Dried fish	12 Dec. 1902	32.9 grms.	Chlorate method	0.015	3/10	0.5	Whole extract Marshd.
8	"Pegu"	Saman (an alcoholic liquid of acid reaction).	15 Jan. 1903	50 c.c.	Evaporated with lime, the residue neutralized with hydrochloric acid to get rid of carbon dioxide; then Marshd.	Trace	Trace	—	Whole extract Marshd.
9	"Pegu"	Gin made at Schiedam in Holland.	23 Dec. 1902	40 c.c.	Alcohol evaporated off; then Marshd.	Mere trace	Arsenic-free	—	Whole extract Marshd.
10	"Pegu"	Rice	25 Mar. 1903	50 grms.	Extracted with known volume of aqueous hydrochloric acid at 50° C. for 15 minutes, decanted, and Marshd the solution.	Say 0.001	1/10	0.2	10 c.c., i.e., the equivalent of 5 grms., were Marshd.
11	"Pegu"	Bombay duck	2 Jan. 1902	58.4 grms.	Chlorate method	0.022	3/10	1.9	One-fifth of extract Marshd.
12	"Cimbria"	Dried cod fish from Norway.	9 Dec. 1902	39.7 grms.	Chlorate method	0.016	1/10	0.8	Half of the extract Marshd.
13	"Argo"	Dried cod fish	29 Jan. 1903	20 grms.	Chlorate method	0.029	1/10	1.9	Half of the extract Marshd.
14a	"Argo"	(a) Tinned stock fish (balls in bouillon).	2 Feb. 1903	90 grms.	Chlorate method	0.0015	Mere trace, (arsenic-free).	0.02	Whole extract Marshd.
14b	"Argo"	(b) Juice from tinned stock fish.	7 Feb. 1903	88.6 grms.	Chlorate method	Mere trace	Arsenic-free	0.01	Whole extract Marshd.
15	"Argo"	Dried vegetables	19 Nov. 1902	10.0 grms.	Nitric and sulphuric acids	0.01	Trace	0.1	Whole extract Marshd.
16	"Argo"	Rice	16 Mar. 1903	50.0 grms.	Extracted with aqueous hydrochloric acid at 50° C. for 15 minutes, decanted, and— (a) Marshd 10 c.c. directly, (b) Treated 68 c.c. by chlorate method.	Mere trace	Arsenic-free	—	The equivalent of 5 grms. Marshd.
17	"Argo"	Drinking water	(a) 26 Apr. 1902 (b) 1 May 1902	200 c.c. 200 c.c.	(a) Evaporation, extraction of residue with hydrochloric acid, and Marshing of filtered solution. (b) As above, but Marshd the unfiltered extract.	None Faintest trace of greyish mirror.	(a) Arsenic-free (b) Arsenic-free	0.05 —	The equivalent of 34 grms. Marshd. Whole extract Marshd.

## APPENDIX, No. 31—continued.

TABLE IV.—Shewing Results of Examination for Arsenic of Foods taken from Ships in connection with Beri-beri—continued.

1. Number of Sample.	2. Ship.	3. Description of Sample.	4. Date when Analysed.	5. Quantity taken for Analysis.	6. Method of Analysis.	7. Arsenic Mirror read. (Milligrammes).	8. Arsenic (As <sub>2</sub> O <sub>3</sub> ) Grams per lb. (Approximate fractions).	9. Parts per Million.	10. Notes as to Analysis.
18	"Ben More"	Dried cod fish	17 Sept. 1902	30.0 grms.	Chlorate method	0.0165	$\frac{1}{40}$	0.6	Whole extract Marshel. Sample covered with small crystals.
19	"Ben More"	Tinned mutton	12 Dec. 1902	100 grms.	Chlorate method	0.0225	$\frac{1}{60}$	0.2	Whole extract Marshel.
20	"Ben More"	Lime juice	2 August 1902	10 c.c.	Direct Marshing	Faint dark ring	Trace.	—	—
21	"Ben More"	Rice	7 April 1903	50 grms.	Extracted with 100 c.c. of aqueous hydrochloric acid at 50° C. for 15 minutes; then Marshel 10 c.c.	None.	Arsenic-free.	—	The equivalent of 5 grms. Marshel.
22	"Charles Racine"	Dried fish	4 Dec. 1902	34.1 grms.	Chlorate method	0.011	$\frac{1}{45}$	0.3	Whole extract Marshel.
23	"Prince George"	Tinned fish from Norway.	7 Feb. 1903	100 grms.	Chlorate method	0.0025	Trace.	0.05	Half of extract Marshel.
24	"Prince George"	Juice from tinned fish sample.	7 Feb. 1903	91 grms.	Chlorate method (using very little chlorate).	0.015	$\frac{1}{65}$	0.17	Whole extract Marshel.
25	"Prince George"	Tinned Australian beef, packed in Queensland.	7 Feb. 1903	100 grms.	Chlorate method	0.0013	More trace, or arsenic-free.	—	Whole extract Marshel.
26	"Prince George"	Nestlé's milk	10 Feb. 1903	5.2 grms.	Nitric and sulphuric acids	None.	Arsenic-free.	—	Whole extract Marshel.
27	"Prince George"	Lime juice from the Seychelles.	20 Dec. 1902	20 c.c.	Direct Marshing (hydrochloric acid).	Merest trace.	Arsenic-free.	—	—
28	"Prince George"	Rice	18 Feb. 1903	5 grms.	Nitric and sulphuric acids	Trace.	Arsenic-free.	—	Whole extract Marshel. This sample was wrapped in a dirty newspaper. It was partly in the state of dust, and was weevilly.

## Appendix 31.

## APPENDIX, No. 31—continued.

TABLE IV.—Showing Results of Examination for Arsenic of Food taken from Ships in connection with Beri-beri—continued.

1	2	3	4	5	6	7	8	9	10
Number of Sample.	Ship.	Description of Sample.	Date when Analysed.	Quantity taken for Analysis.	Method of Analysis.	Arsenic Mirror read. (Milligrammes).	Arsenic ( $As_2O_3$ ). Grains per lb. (Approximate fractions.)	Parts per Million.	Notes as to Analysis.
40	"Handeljust"	Drinking water	15 Jan. 1903	500 c.c.	Evaporated to small bulk, warmed with a little hydrochloric acid, and Marshled.	Mere trace	Arsenic-free	—	—
41	"Handeljust"	Sugar (white crystals)	29 Jan. 1903	10 grms.	Direct Marshing (hydrochloric acid).	None.	Arsenic-free	—	—
42a	"H. C. Richards"	Fish balls	27 Feb. 1903	100 grms.	Chlorate method	0.0018	Mere trace	0.02	Whole extract Marshled.
42b	"H. C. Richards"	Juice from above fish balls.	27 Feb. 1903	45.6 grms., i.e. nearly all the juice.	Chlorate method	Trace.	Mere trace	—	Whole extract Marshled.
43	"H. C. Richards"	Rice	20 Mar. 1903	50 grms.	Extracted with 100 c.c. aqueous hydrochloric acid at 50° C., as before.	Mere trace	Arsenic-free	—	The equivalent of 5 grms. Marshled.
44	"Victor"	Dried fish	17 Sep. 1902	21.4 grms.	Chlorate method	0.018	1½	0.9	Whole extract Marshled.
45	"Victor"	Rice	7 Apr. 1903	50 grms.	Extracted with 100 c.c. aqueous hydrochloric acid at 50° C., as before.	None. A slight trace of a whitish mirror.	Arsenic-free	—	The equivalent of 5 grms. Marshled.

NOTE.—In column 8, the term "trace" in each instance denotes a proportion of arsenic below 1/100th grain per lb. The term "arsenic-free" denotes either that no arsenic was detected, or that if arsenic appeared to be present, it was in such small proportion, relative to the weight of the substance examined, as to hardly admit of the use of the term "trace."

## APPENDIX, No. 31—continued.

TABLE V.

SHOWING RESULTS OF EXAMINATION FOR ARSENIC OF THE SIFTINGS OF RICE (RICE DUST), CONSUMED BY SUFFERERS FROM BERIC-BERI IN GAOLS IN KUALA LAMPUR, SENT BY DR. H. E. DURHAM.

1. Number of Sample.	2. Description of Sample.	3. Date when Analysed.	4. Quantity taken for Analysis.	5. Method of Analysis.	6. Arsenic mirror read, (Milligrammes).	7. Arsenic (As <sub>2</sub> O <sub>5</sub> ). Grains per lb.	8. Parts per million in dust.	9. Notes as to Analysis.
46	A.—Rice Siftings: Dust sifted through iron wire gauze from rice in use at gaol during hull in beri- beri. Packet sent represented about 200 lbs. of rice. July 28, 1902.	4 Nov. 1902	5.0 grms.	Nitric and sulphuric acids	0.016	1/16	3.2	The whole extract Marshled. (Total dust = 46.9 grammes). Calculating this result on the 200 lbs. of rice, we get the nearest trace of arsenic.
47	B.—Rice Siftings: Similar to "A," but taken at the height of an outburst of beri-beri. September 24, 1902.	6 Nov. 1902	5.0 grms.	Nitric and sulphuric acids	0.010	1/16	2.0	The whole extract Marshled. (Total dust = 65.3 grammes). Here, again, this gives the nearest trace of arsenic in the bulk of the rice.
48	C.—Rice Siftings: Rice siftings from Pudooh Gaol. Sample of week's supply for week ending January 8, 1903.	May 1903	5.0 grms.	Nitric acid.—The nitric acid residue was extracted with ammonia, to get rid of dirty sand, the amount of which was considerable. The filtrate was then evaporated with lime water and the residue ignited. It was then dissolved in hydrochloric acid for Marsh- ing.	0.10	1/16	5.0	Two-fifths of extract Marshled. As stated, this contained at least 5% of dirty sand. Weight of rice corresponding to siftings sent not stated.
49	D.—Rice Siftings: Similar sample to "C," but representing the week's supply for week ending January 19, 1903.	8 May 1903	5.0 grms.	Nitric acid, etc.—As with sample "C."	0.012	1/16	5.8	Two-fifths of extract Marshled. This sample also contained much dirty sand. Weight of rice corresponding to siftings sent not stated.

Appendix 31.

Appendix 31.

## APPENDIX, No. 31—continued.

TABLE VI.

SHOWING RESULTS OF EXAMINATION FOR ARSENIC OF POST-MORTEM AND HAIR SPECIMENS FROM BERLBERI PATIENTS.

1. Number of Sample.	2. Description of Sample.	3. Date when Analysed.	4. Quantity taken for Analysis.	5. Method of Analysis.	6. Arsenic Mirror read. (Milligrammes).	7. Arsenic (As <sub>2</sub> O <sub>3</sub> ). Grains per lb.	8. Parts per Million.	9. Calculated quantity of arsenic in whole liver or brain.	10. Notes as to Analysis.
	A.—Specimens obtained post-mortem from fatal case. "Ahmed S.S. 'Pegu.' Received December 23rd, 1901, and kept in ice.								
51	Brain	28 Jan. 1902	149.2 grms., chiefly cerebellum and grey matter. (Whole brain = 108.2 grms.)	Chlorate method	0.0053 After deducting blank done in case of liver.	$\frac{1}{100}$	0.07	$\frac{1}{100}$	Half the extract Marshled.
52	Liver	13 Jan. 1902	162.2 grms. (This constituted about half the liver in Jar I.)	Chlorate method	0.0290 After deducting blank of 0.0010.	$\frac{1}{100}$	0.26	—	$\frac{1}{100}$ of extract Marshled. Note.—Another portion of the extract, 10 c.c., was Marshled also. This gave a mirror equal to 0.0145, after deducting 0.0005 for blank. The two Marsh's thus agree very closely.
53	Liquor from Jar.—(The jar contained liver, hair, nails, kidney, spleen, lung, heart, skin and muscle. The total liquor weighed 511 grms.)	7 Feb. 1902	162.5 grms.	Chlorate method	0.0165 After deducting two-thirds of liver blank.	—	0.32	$\frac{1}{100}$ in whole liquor.	Whole extract Marshled.
54	Hair.—This hair had got steeped in the liquor. It weighed 6.1 grms. wet. An experiment made with another portion of hair showed that it would have weighed about 2.06 grms. if dry.	13 Jan. 1902	6.1 grms. wet hair = 2.06 grms. dry hair.	Chlorate method	0.0057 After deducting blank of 0.0023. This blank was not so satisfactory as that of the liver.	$\frac{1}{100}$ On the dry hair.	2.8	—	Whole extract Marshled.
55	Nails.—These were wet and weighed 2.6 grms.	13 Jan. 1902	2.6 grms. wet nails	Chlorate method	0.0093 After deducting blank of 0.0007.	$\frac{1}{100}$ On the wet nails.	5.4	—	$\frac{1}{100}$ of extract Marshled.

56	B.—Specimens obtained post-mortem from Franz Bjh, Norwegian, aged 22, Barque "Prince George." Received April 22nd, 1902. Liver	2 May 1902	107.7 grms.	Chlorate method	0.017 Mean of four readings. No blank done; not considered necessary.	0.24	Two-thirds of extract Marshel.
57	Hair.—This weighed 4.2 grms.	27 Feb. 1903	4.2 grms.	Chlorate method	0.009	2.1	Whole extract Marshel. <i>Note.</i> —The first "Marsh" done was with 10 c.c., i.e., with one-third of the extract. This gave a mirror equal to 0.0095, which agrees well with the above.
58	Nails.—These weighed only 0.5 grm.  C.—Specimens obtained post-mortem from negro aged 19, Barque "Morgengry." Received June 6th, 1902.	6 May 1902	0.5 grm.	Nitric and sulphuric acids.	Only the faintest mirror	—	Whole extract Marshel. <i>Note.</i> —The proportion of arsenic in the nails may possibly have been appreciable, but the weight of the sample was much too small for an accurate estimation.
59	Liver	10 June 1902	113.1 grms.	Chlorate method	0.015	0.2	Two-thirds of extract Marshel.
60	Brain	10 June 1902	126.5 grms.	Chlorate method	0.009 Not a very good reading.	0.11	Two-thirds of extract Marshel.
61	Hair	17 Sept. 1902	12.5 grms.	Nitric and sulphuric acids.	0.014	1.1	Whole extract Marshel.
62	Nails	17 Sept. 1902	2.25 grms.	Nitric and sulphuric acids.	Mere trace	—	Whole extract Marshel. <i>Note.</i> —This was another very small sample. It may quite possibly have contained an appreciable proportionate quantity of arsenic.

## APPENDIX, No. 31—continued.

TABLE VI.—Showing Results of Examination for Arsenic of Post-mortem and Hair Specimens from Beri-beri patients—continued.

1. Number of Sample.	2. Description of Sample.	3. Date when Analysed.	4. Quantity taken for Analysis.	5. Method of Analysis.	6. Arsenic Mirror read. (Milligrammes).	7. Arsenic (As <sub>2</sub> O <sub>3</sub> ). Grains per lb.	8. Parts per Million.	9. Notes to Analysis.
	D.—Hair Specimens from non-fatal cases of Beri-beri:							
63	Hasan, S.S. "Pegu," aged 26.	2 March 1903	1.9 grms.	Chlorate method	0.0033	$\frac{1}{5}$	1.7	Whole extract Marshel.
64	Jon Jansen, Barque "Argo," aged 47.	17 March 1903	1.5 grms.	Chlorate method	0.0085	$\frac{1}{5}$	.7	Whole extract Marshel. <i>Note</i> .—Brown mirror on wrong side of flame, and also on the right side, but this latter too close to the flame to be read as arsenic.
65	Jacob Nielson, Barque "Morgenty," aged 48.	18 Feb. 1903	5.0 grms.	Nitric and sulphuric acids.	0.002	$\frac{1}{10}$	0.4	Whole extract Marshel.
	E.—Two pigtails sent by Dr. Durham:							
66(a)	No. 45A. Root portion, about 9 inches long.	7 March 1903	8.3 grms. <i>i.e.</i> whole portion.	Chlorate method	0.019 Not a very satisfactory reading.	$\frac{1}{5}$	9.2	One-quarter of extract Marshel. This pigtail was very dirty, and it had a strong acrid smell like butyric acid.
66(b)	No. 45B. Remainder, about 18 inches long.	7 March 1903	8.2 grms. <i>i.e.</i> whole portion.	Chlorate method	0.018 Not a very satisfactory reading.	$\frac{1}{5}$	8.8	One-quarter of extract Marshel.
67(a)	No. 44A. Root portion, 4 inches long.	2 March 1903	9.7 grms. <i>i.e.</i> whole portion.	Chlorate method	0.015	$\frac{1}{5}$	6.2	One-quarter of extract Marshel.
67(b)	No. 44A. Third portion, about 4 inches long. <i>Note</i> .—The second portion, about 18 inches long, was tested later.	2 March 1903	5.0 grms. <i>i.e.</i> whole portion.	Chlorate method	0.012	$\frac{1}{5}$	4.8	One-half of extract Marshel.
67(c)	No. 44A. Remainder ( <i>i.e.</i> loose end), about 14 inches long.	2 March 1903	10.1 grms. <i>i.e.</i> whole portion.	Chlorate method	0.025	$\frac{1}{5}$	5.0	One-half of extract Marshel.

\* In order to see how far the arsenic might be contained in dirty matter adhering to the hair, the second portion of pigtail No. 44a was thoroughly extracted, (1) by ether (five or six extractions in the cold), and (2) with excess of dilute hydrochloric acid (containing 1 per cent. HCl.) for half an hour at 50° C. The arsenic extracted by the ether represented  $\frac{1}{10}$ th grain per lb. of hair (1.74 parts per million); no farther arsenic was extracted by the hydrochloric acid; the remaining hair, which was clean and tough, contained  $\frac{1}{10}$ th grain of arsenic per lb. (6.12 parts per million). The second portion of No. 44a thus contained altogether  $\frac{1}{10}$ th grain per lb. (7.86 parts per million), 78 per cent. of the arsenic remaining in the hair after the above two extractions.

GEORGE MCGOWAN.

## APPENDIX 32.

Appendix 32.

## ARSENIC IN HAIR.

## REPORT ON INVESTIGATIONS MADE FOR THE COMMISSION AS TO THE ELIMINATION OF ARSENIC BY THE HAIR.

The reports on this subject are arranged as follows:—

I.—General account of inquiry and tables giving an analysis of the principal results obtained.

II.—Report by Mr. R. F. Wood Smith on the methods adopted by him in testing specimens of hair.

III.—Tabular statements showing the condition as to arsenic of the persons whose hair was examined, and the results of examination, namely:—

TABLE A.—Males who had taken no arsenic medicinally at the date of collection of the specimen of hair.

TABLE B.—Females who had taken no arsenic medicinally at the date of collection of the specimen of hair.

TABLE C.—Males who at the date of collection of the hair specimen had taken, or who had recently discontinued taking, arsenic in known quantities medicinally.

TABLE D.—Females who at the date of collection of the hair specimen had taken, or who had recently discontinued taking, arsenic in known quantities medicinally.

TABLE E.—Later series of male cases who at the date of collection of the hair specimen had lately been taking arsenic medicinally in very small doses.

TABLE F.—Cases of alcoholic neuritis from certain London hospitals and infirmaries.

## I.—GENERAL ACCOUNT OF THE INQUIRY AND TABLES GIVING AN ANALYSIS OF THE PRINCIPAL RESULTS.

Evidence given to the Commission by Dr. Dixon Mann (Q. 3741-8) as to finding arsenic in the hair of patients suffering from arsenical beer poisoning at Manchester, and also information supplied by Messrs. Dearden and Knecht of Manchester, who had reported ("Lancet," March 23rd, 1901) on the examination of hair of one or two other Manchester cases\* suggested that the fact of elimination of arsenic by the hair might prove important in instances (such as supposed alcoholic neuritis) where it was desirable to ascertain whether a given patient had lately been taking arsenic, either as a contamination of beer or food, or medicinally.

The Commission desired that some experimental evidence on this subject should be obtained with a view to throwing light on the following points:—

Whether persons known not to have taken arsenic medicinally, and not, so far as known, specially liable to receive arsenic in other ways, ordinarily show any noteworthy quantity of arsenic in their hair.

Whether persons whose hair is free from (or contains no more than a minute trace of) arsenic come to show noteworthy quantities of arsenic in their hair as a consequence of taking arsenic medicinally; how soon after arsenic has begun to be taken will evidence of arsenic appear in the recently grown hair; and whether arsenic can be detected in the hair of persons who have discontinued taking arsenic medicinally for a considerable number of weeks.

In the case of long female hair, whether any differences which may be observed between the quantity of arsenic near the roots and towards the tips re-

spectively, correspond to known facts as to arsenic taking.

The Commission engaged the services of Mr. R. F. Wood Smith to analyse hair samples for arsenic. In order to obtain specimens of hair for examination, advantage was taken in the first instance of an offer kindly made by Dr. A. E. Garrod, who at that time was Medical Registrar of St. Bartholomew's Hospital, and who is also one of the physicians at the Hospital for Sick Children, Great Ormond Street. At the latter hospital children are frequently admitted suffering from chorea, and there treated with arsenic, and these cases seemed likely to be suitable for the purpose required.

*Preliminary Specimens.*

Between April and June, 1902, Dr. Garrod obtained some fifteen samples, both before and after treatment, from children at Great Ormond Street who were taking arsenic medicinally, and these samples were tested in Mr. Wood Smith's laboratory. Considerable difficulty arose, however, in interpreting the results obtained. In some cases no arsenic was detected in the hair before treatment, and a notable quantity (e.g., 1-50th to 1-80th grain per lb.) was apparent after arsenic had been taken for three or four weeks. But in other cases amounts such as 1-55th and 1-30th grain of arsenic per lb. were found in the hair sample before arsenic had begun to be given at the hospital. It seemed possible that these latter cases had in fact been taking arsenic before they were admitted to hospital, particularly as

\* See also Gautier, *Comptes Rendus*, 1899 and 1900.

## Appendix 32.

this drug is often given in cases of chorea, but no definite information on the point could be obtained. There was also another reason why these Great Ormond Street cases proved to be less satisfactory than was anticipated, namely, the fact that the patients were seldom sufficiently long in the hospital, and consequently it was often impossible to obtain specimens of hair which had grown solely during the period of arsenic taking.

In these circumstances it was considered that future specimens had best be obtained from general hospitals in London, and from those cases only in which there was a probability that the patient would remain in hospital for a considerable number of weeks, and would be taking arsenic throughout his or her stay there.

*Control Specimens.*

The suggestion obtained from the Great Ormond Street cases that possibly hair of persons not known to have been taking arsenic might nevertheless show such amounts as 1-30th grain per lb., made it necessary however to examine a preliminary series of "control" samples before proceeding further. Twelve such hair samples were obtained, some from private sources and some from hospitals. It was arranged with Mr. Wood Smith that if any of these samples showed a noteworthy amount of arsenic, then experiments were to be tried with washing to see if the arsenic present was in the substance of the hair or was due to dust, etc., on the outside.

All the samples of this preliminary series yielded, however, a negative result, or else a proportion of arsenic below 1-250th grain per lb., with one exception (a man whose hair showed 1-150th grain per lb.).

A series of samples of male hair collected in August by a London hairdresser (13 in all) yielded similar results. Seven showed no arsenic, two contained less than 1-250th grain per lb., and four contained amounts between 1-250th and 1-150th.

These results did not suggest that any considerable amount of arsenic was likely to be contained in hair as the result of contamination by dust, and accordingly the question of washing was not pursued.\*

Subsequently additional "controls" have been examined in connection with hospital and infirmary cases. Altogether the total number of control samples, male and female (exclusive of the hairdresser's samples), examined for arsenic was 41. These are shown in Tables A and B. Of these, 17 showed "no arsenic" by Mr. Wood Smith's test (which allows an approximate assessment of quantity down to 1-400th grain per lb.), 16 showed a "trace" of arsenic (in each instance below 1-250th grain per lb.); of the remainder, one showed 1-250th, one 1-200th, three 1-150th, and one 1-100th grain of arsenic per lb. In one sample (Table C, No. 77), 1-50th grain arsenic per lb. was estimated, but there is some element of doubt in this case, as it was afterwards found that the patient, an epileptic, had been taking large doses of Easton's Syrup (phosphates of iron, quinine, and strychnine), three drachms daily, for two months before the control sample was taken. In one other (Table E, No. 93) the control sample showed 1-25th grain of arsenic per lb. The source of the arsenic in this case could not be ascertained. No hair dye or other application to the hair appeared to have been used.

*Specimens from Arsenic-takers.*

The next set of specimens from persons taking arsenic was obtained from London hospitals through the kindness of their medical registrars, especially Dr. Garrod at St. Bartholomew's and Dr. French at Guy's. Mr. Hammond Smith also obtained some samples from Middlesex Hospital, and Dr. Redfern, of Croydon, supplied some hair from private sources. It was found difficult, however, to obtain sufficient samples of the kind required; in-patients taking arsenic were sur-

prisingly few; there was often uncertainty as to medicine taken before admission; frequently the patient left the hospital without having taken arsenic sufficiently long for a satisfactory sample to be obtained. Moreover, although forms for particulars were drawn up for the convenience of the collectors, and the nature of the samples required was stated, there was necessarily an element of uncertainty due to the fact that the specimens might be collected in different ways by different observers.

These difficulties were ultimately met by resorting to certain of the London Poor Law infirmaries, where it is usual for patients to be under treatment in the institution for a considerable time. Mr. Hammond Smith undertook to visit the medical superintendents of the infirmaries selected, and to personally take, or supervise the collection of, the specimens required. Subjoined are notes which he has furnished on the result of these visits:—

"After visiting these infirmaries I found that there would be no difficulty in securing by the co-operation of the medical staff an abundance of samples of the kind desired. A considerable number of patients had been taking arsenic for some time at the date of my visit, and from these I obtained samples of hair. I endeavoured to obtain in each instance at least a 2-gramme weight of sample. In a few instances the hair was so scanty that less than 2 grammes was obtained.

"Other cases were considered by the medical superintendent to be likely to benefit by small doses of arsenic. At Paddington, Marylebone, Wandsworth and Clapham, Tooting, and St. George's Infirmaries, the medical superintendents were good enough to inform me of such cases, and to give me facilities for obtaining samples of hair before the arsenical treatment was commenced. In these cases I was able to obtain a considerable number of 'control' samples, and I selected those which had been in the infirmary for many weeks, and were known to have taken no arsenic medicinally during that period.

"In obtaining these 'control' samples, in the case of males, the hair of the back of the head was cut as near as possible to the roots with scissors, or preferably clippers. In the case of females, a lock was made up by cuttings from various parts of the head, and the root ends tied together. Owing to the objection which the women had to parting with their hair this was not always an easy task.

"I then procured samples from the same cases after the arsenic had been taken, in known doses, for various periods; wherever possible, after an interval as long as two months. In the case of men the hair was again cut at the spot where the control sample had been taken. The length of growth during the two months, of course, varied in different individuals; the usual length was about 1½ inches—exceptionally it was up to 2 inches. In the case of the women, the sample was taken exactly as in the control, and the instruction given to the analyst was to test only about 2 inches at the root end of the sample. It is evident that in the case of the women this 2 inches of sample would not represent so exactly hair which had grown during the period of arsenic taking, as in the case of the men. The 2 inches was merely guess work and might or might not have represented the length which had grown in two months. Moreover, in women the rate of growth of old hairs that are already long is probably much slower than that of young short hairs. A further uncertainty in the female cases was due to the fact that the analyst requires somewhere about 2 grammes, and, where the lock obtained was thin he could not get the weight desired in 2 inches taken at the root end.

"The samples obtained from women who at the date of my visit had already been taking arsenic for some weeks were obtained in a similar way. In these cases the instructions to the analyst usually depended on the time the arsenic had been taken, and also on the abundance of the hair. Sometimes, for instance, he was asked to examine the whole

\* Prolonged washing in a stream of water through a sieve with a fine mesh was tried in two instances. One hairdresser's sample (1-150th grain per lb.) still showed 1-150th grain per lb. after washing; in another sample the arsenic was reduced by the washing from 1-200th to 1-250th grain per lb.

† Such samples constitute the bulk of cases recorded in Tables C. and D.

length of the hair; sometimes to take so many inches at the root end, and test them separately from the remaining portion.\*

"From these infirmaries I obtained a considerably larger number of samples and controls than could be examined by the analyst. In selecting, in consultation with Dr. Buchanan, which samples should be analysed, regard was had (1) to the question whether the samples (control and sample after taking arsenic) were sufficiently abundant; (2) to the dose taken; and (3) to the form in which the arsenic had been administered. It was thought best to exclude all cases in which the arsenic had been given in pill or as 'Donovan's solution'; and to select only those taking liquor arsenicalis—or, in one or two cases, liquor sodii arsenatis, which contains the same quantity of arsenic as liquor arsenicalis. As the effect of small quantities of arsenic on the hair was particularly important for the inquiry, we did not select any cases that had taken more than 9 minims of liquor arsenicalis (about 1-12th grain—or 5-4 milligrams—arsenious oxide) per day. Many of the cases had taken just 9 minims a day, usually in 3 minim doses three times a day.

"I did not at first obtain any samples where the daily dose had been so very small as 1-30th

grain—or 2-16 milligram—per diem, but subsequently on March 1st, 1903, the medical superintendent of one infirmary was good enough to arrange to administer very small doses (1 minim three times a day, and 1½ minims three times a day before meals) to cases under his observation where arsenic would probably be beneficial, after giving me an opportunity of taking control samples. After an interval of about two months, the hair in some of these cases was collected for analysis.

"I may note that, as it happened, hardly any of the samples taken were of light coloured hair. Most of them were dark brown or black, and a few were white or grey."

The facts regarding the various specimens obtained from persons taking arsenic medicinally are shown in Tables C (males) and D (females), from which, for reasons given above, the children from Great Ormond Street have been excluded.

The degree of correspondence which was found to exist between the proportions of arsenic in the hair examined and the known conditions as regards the medicinal administration of arsenic will be gathered from the tables referred to, and also from the following summary tables:—

Appendix 32.

\* The instructions given are noted in each instance in the last column of Table D.

## APPENDIX, No. 32—continued.

\* Cases in which arsenic has been discontinued for no longer than 14 days before the sample was collected are included under this head.

† In order not to overcrowd this table with details, no classification as regards the dosage of arsenic is here made. The details as to dosage can be obtained from the General Table D.

June, 1903.

## Appendix 32.

In the above Summary Tables cases which at the date of collection of the hair specimen had been taking arsenic for less than five weeks are shown separately from the rest of the cases taking arsenic. In nearly all these cases no "control" samples were available, and, owing to the short time during which arsenic had been given, the extent to which the samples examined contained hair which had grown during the period of arsenic taking was necessarily uncertain.

Looked at as a whole, the facts summarised in the above tables are striking. They leave no room for doubt that the hair grown by persons, both male and female, whilst they are taking solutions of arsenious oxide nearly always contains arsenic in notable amount. The proportions of arsenic in such hair are usually of an order quite different from the small quantities occasionally met with in the hair of "controls" believed to be taking no arsenic.

The distinction is evident even when the dose of arsenic is small. Table E shows separately the results of examination of the hair in the special series of male cases referred to in Mr. Hammond Smith's notes, where minute doses of arsenic (1 or  $1\frac{1}{2}$  minims of liquor arsenicalis three times a day, or 1-33rd to 1-22nd grain of arsenic daily) were given for about two months. Excluding case 95 (the exceptional "control" alluded to above), there were "control" samples, taken before arsenic was given, from 11 cases as follows:—

Free from arsenic	-	-	-	-	6
Trace of arsenic below 1-250th grain per pound of hair	-	-	-	-	4
1-100th grain of arsenic per pound of hair	-	-	-	-	1

At the end of two months samples from the same 11 cases showed amounts of arsenic per pound of hair as follows:—

Trace, below 1-250th	-	-	-	-	1
1-100th	-	-	-	-	1
Above 1-100th and below 1-25th	-	-	-	-	5
1-25th and over	-	-	-	-	4

Here it may be added that in one or two instances in course of the inquiry an exceptional chemical result led to information being obtained as to means, previously unknown, by which the patient had been taking arsenic. For example, in case 103a (Table E.) the sample of hair taken in March 3rd, before liquor arsenicalis was given, was free from arsenic; the sample 103b, cut to the roots with clippers on May 6th, after  $4\frac{1}{2}$  minims of liquor arsenicalis had been taken daily for nine weeks, showed 1-50th grain per lb. On June 30th sample 103c was collected, in the belief that no liquor arsenicalis had been taken since May 6th. Notwithstanding that this man's hair had been cut in the ordinary course once between May 6th and June 30th, this sample (103c) showed 1-40th grain per lb. Further inquiry showed that on May 25th he had resumed taking liquor arsenicalis in the same doses as before, and had continued this medicine up to June 30th.

The difficulty which arises in obtaining satisfactory samples representing women's hair which has grown during the period of arsenic taking has already been mentioned. No doubt for this reason there was in the case of females less correspondence between the hair of patients under identical conditions as to dosage and period of arsenic taking than in the case of males.

Samples of hair were taken in a few instances where the patient had ceased to take arsenic for a considerable number of weeks. In most of these samples noteworthy amounts of arsenic were present. It seems possible that elimination of arsenic by the hair may continue for some while after arsenic has ceased to be taken, but the data available are not sufficient to allow any precise conclusion on this matter to be drawn.

*Hair of Brewers' Draymen.*

Mr. Wood Smith this year obtained samples of hair from three brewers' draymen who habitually take large quantities of beer supplied by a brewery at which much attention has been given to the exclusion of arsenic from beer. Two of these samples were free from arsenic; one showed a trace of arsenic, below 1-250th grain per pound of hair.

*Hair from Alcoholic Neuritis cases.*

In some instances, shown in Table F, specimens of hair were obtained from cases of alcoholic neuritis in London hospitals and infirmaries, together with particulars of the kind of alcoholic drink habitually taken. None of these cases showed pigmentation or other symptoms pointing to arsenic as the cause of the neuritis, and none had been taking arsenic as medicine.

Now that the results obtained in persons taking small doses of arsenic medicinally are available, it may be concluded that examination of hair is capable of affording a valuable indication in cases of "alcoholic neuritis," where it is important to know whether or not arsenic has been concerned in producing the illness. In the cases shown in Table F, however, the samples obtained were seldom of a kind which allowed a satisfactory positive or negative conclusion with regard to arsenic to be drawn from the results of examination of the hair. Two cases only were men, and at the date on which the hair specimen was taken each had been in hospital, and had left off alcohol for several weeks, and his hair had been cut once or oftener since admission. In some of the female cases the hair was collected and examined at an early stage of the inquiry before the importance of dividing the hair specimen into sections was fully realised; in several others the sample sent was so small that examination in sections was impracticable. It is evident that a result of, say, 1-100th grain of arsenic per lb. in a thin lock of hair 12in. long is not conclusive as a test of recent arsenic taking. Such a proportion in the whole lock may be consistent with the presence of an amount such as 1-30th grain per lb. in a particular one or two inches. The latter quantity, if detected, would afford a strong indication of the patient's past history as regards arsenic.

The time available for this inquiry did not enable a new and more satisfactory series of hair specimens from alcoholic neuritis cases to be collected and examined in the light of the experience gained when all the results from persons taking arsenic medicinally had been put together and studied. It may, however, be useful to note the following points which it seems important to regard in future examinations of hair from cases of peripheral neuritis. In order that the hair examined may correspond approximately with the period in which it is suspected that arsenic may have been taken, the hair specimen, in the case of men, should be obtained as early as possible. If it is not taken for several months after the onset of the illness it will probably be hair which has grown at a time when the condition of the patient as regards arsenic and alcohol have been quite different from those in which he contracted the disease. In the case of women, it is perhaps less important to take the specimen early, as their hair is long and can be examined in sections; for example, a lock can be divided into portions (a) 0-2in., (b) 2-4in., (c) 4-7in. from the scalp. But if this is done it is essential to get a lock sufficiently thick to allow each of these portions to be as much as 2 grammes in weight. A lock which at the scalp end is as thick as the little finger will ordinarily be sufficient for the purpose. It is best obtained by "thinning" the hair from different parts of the head.

July, 1903.

G. S. B.

## II.—REPORT BY MR. R. F. WOOD SMITH ON METHODS ADOPTED IN TESTING SPECIMENS OF HAIR FOR ARSENIC

*Bacteriological and Chemical Laboratory,  
89, Bartholomew Close.*

In general principle the method of procedure was in each case to destroy the organic matter in a weighed sample of hair in such a manner as to retain the arsenic in the inorganic residue, and then to examine this residue by means of the Marsh-Berzelius apparatus. In detail I give herewith accounts of the various operations necessary to attain that end.

### *Collection and Reception of Samples.*

In nearly all cases I received these from Dr. Buchanan in white envelopes of a strong texture and suitable size, and I feel satisfied that the samples sent in this manner always arrived in a dry and sound condition. In a few instances I personally collected the samples, which were then carefully wrapped up in stout white paper.

### *Weight of Samples Analysed.*

I found that the most suitable quantity for work was from 4 to 5 grammes, but as it was found impossible to rely upon obtaining such amounts for analysis, I fell back upon 2 grammes as being a reliable quantity to employ. When 2 grammes were taken I satisfied myself that, with my apparatus, good approximations can be assessed down to 1-100th grain of  $As_2O_3$  per lb. of sample, and a rough assessment even down to 1-400th grain per lb. Since, however, the samples were even smaller than the 2 grammes in some instances, I have, for the sake of uniformity, referred to all proportions under about 1-250th grain per lb. as "a trace." Instances where considerably less than 2 grammes were available, and where in consequence the delicacy of the estimation was diminished, have been noted in my reports.

### *Oxidisation of Samples.*

As nearly as possible 2 grammes of the hair to be tested were weighed out on a paper tray and transferred to a Jena glass flask of about 250 c.c. capacity. Upon the hair were then poured about 30 c.c. of strong arsenic-free nitric acid, and then 4 c.c. of strong arsenic-free sulphuric acid. The contents of the flask were then warmed on a sand bath under a funnel hood within the fume chamber until rapid oxidation set in, when, after the first violence of the action had subsided, the temperature was raised so as to thoroughly boil the liquor. After continued boiling the liquor darkens, when more nitric acid must be added, but a point was always finally arrived at when only clear colourless vitriol remained, and in which was dissolved all the arsenic which might have been in the sample taken.

This vitriol liquor was then treated with five or six times its bulk of water, and again boiled down to the same consistency, this operation being advisable to guard against the possibility of nitrogen compounds obtaining access to the Marsh apparatus. This re-boiled liquor was now ready for direct analysis.

### *Marsh Apparatus and Re-agents.*

A small flask having a detachable ground-in separator and side tube of about 100 c.c. capacity was employed, an absorption tube containing lead acetate paper and calcium chloride being attached to the side tube, which, as usual, formed the delivery tube to the depositing tube.

15-20 grammes of arsenic-free zinc were introduced into the flask, and the apparatus set in operation by the employment of 1 in 4 arsenic-free sulphuric acid.

I had very little difficulty in obtaining arsenic-free sulphuric and nitric acids, but only a very small proportion of the zinc sold is really free, and considerable quantities had to be tested before a reliable metal could

be found. Blank experiments on the re-agents were constantly being carried out during the series of analyses, and these blank analyses were performed by boiling down as much nitric acid and sulphuric acid as would be actually employed in the experiments proper and then testing the obtained vitriol in the Marsh apparatus.

Standard mirrors with known amounts of arsenic were frequently prepared, and compared with one another. In this way the "sensitiveness" of the zinc was frequently checked.

### *The Marsh Experiment.*

This was performed in the apparatus described in the ordinary manner; that is, after introducing the necessary amount of acid to fill the whole apparatus with hydrogen and maintain a steady flame of about 2 to 3 m.m. in length at the outlet jet, the diluted vitriol-liquor referred to (or, in the case of a standard preparation, the desired amount of arsenical solution) was introduced into the apparatus, and the action continued for 18 to 20 minutes, when a fresh deposit tube was fitted to the apparatus and the action continued for a further 10 minutes.

### *Comparison with Standards.*

In dealing with the vitriol liquors obtained from hair samples, unless I had reason to the contrary, I always measured half the liquor obtained after dilution for a first test, as very heavy mirrors were often obtained, and I was thus enabled in such cases to repeat the operation on a small quantity of the residue in order to arrive at a mirror adequate for comparison with the standards. I never have more than seven or eight of these standard tubes, and their range is only from 1-100,000th grain to 20-100,000th grain, as I prefer to be constantly renewing all of these, and to bring by dilution experimental quantities into this range.

For instance, I have often obtained from half the vitriol liquor a dark mirror, which I judged to be three or four times greater than my largest standard mirror. Then I have repeated the experiment, using a suitable fraction of the remaining portion. The obtaining of the large mirrors, however, was always a most useful qualitative test, and the finest crystals could be obtained by burning the deposit within the tubes; in other words, the proportions of arsenic then were always judged, not from heavy, but from medium-sized mirrors, but the corroboration by burning, on the other hand, was performed, where possible, on the largest deposits.

In carrying out all the experiments I took every precaution which I could think of as necessary to secure that the mirror obtained represented accurately and comparably the arsenic derived from the hair, and that no error should arise through any accidental contamination. For example, in diluting the vitriol liquors after oxidation, I carried out the measurements in a small cylinder, and took very small quantities by means of a graduated capillary pipette. More accurate amounts might have been taken by transferring the liquor to a graduated flask, and then measuring from a burette, but, on the other hand, the chances of contamination would have been much greater, and I should have felt less confident of the value of the results.

Estimating the quality of the mirror by comparison with standards necessarily introduces an element of uncertainty. I did not think it necessary or advisable to attempt minute differentiation—for example, as between 1-70th and 1-75th grain per lb.—but rather I sought to obtain a reliable approximate estimate by comparison with standard mirrors which presented substantial contrasts.

R. F. WOOD SMITH.

April, 1903.

## III.—DETAILED TABULAR STATEMENTS OF CASES AND RESULTS.

These will be found below in Tables A to F:—

17	Gay's	E. C.	43	Osteoarthritis	9 min. daily for 36 days	9 min., 2 months	1/80	1/126	—	—	Divided into (a) about 1 1/2 in. from scalp end, (b) rest.
27	Middlesex	M. G.	55	Pernicious anaemia	7 1/2 min. daily for 4 days, from 8 Nov. to 11 Nov. 15 min. daily for 3 days, from 12 Nov. to 14 Nov. 22 1/2 min. daily for 2 days, from 15 Nov. to 16 Nov. 30 min. daily for 17 days, from 17 Nov. to 3 Dec.	24 min., 1 month (average).	1/120	Trace.	—	—	Divided into (a) root portion, (b) rest of lock.
28	Middlesex	M. M.	22	Acute rheumatism	12 min. daily for 22 days, from 10 Nov. to 3 Dec.	12 min., 3 weeks	1	Trace.	—	—	ditto
29	Middlesex	A. L.	19	Sub-acute rheumatism.	12 min. daily for 25 days, from 5 Nov. to 7 Nov. and from 12 Nov. to 3 Dec.	12 min., 4 weeks	150	—	Free.	—	Whole lock was tested. Very little of sample could have grown during the 4 weeks.
31	Paddington	S. M.	43	Chorea	9 min. daily for 15 days, from 3 Nov. to 17 Nov. 24 min. daily for 20 days, from 18 Nov. to 9 Dec.	18 min., 5 weeks	—	—	Trace.	—	Whole lock tested. Compare 66 below for another sample from this case.
40	Marylebone	S. C.	43	Rheumatism	9 min. daily for 23 days, from 21 Mar. to 29 Nov. Discontinued 13 days, from 29 Nov. to 12 Dec.	9 min., 9 months; and discontinued, 2 weeks.	1/10	Free.	(Middle) 1/100	—	Divided into (a) 4 ins. at root end, (b) 4 to 8 ins. from root, (c) rest of lock.
46	Tooting	H. L.	66	Asthma	12 min. daily for 131 days, from 4 Feb. to 15 June Discontinued 37 days, from 16 June to 23 July. 12 min. daily for 19 days, from 24 July to 11 August. Discontinued 44 days, from 12 Aug. to 23 Sept. 12 min. daily for 87 days, from 24 Sept. to 19 Dec. Discontinued 11 days, from 20 Dec. to 30 Dec.	12 min., 8 months; and discontinued, 3 months.	—	—	1/10	—	Sample weighed .86 gm. only.
48	Fullham	E. H.	38	Epilepsy	10 min. daily for 140 days, from 16 Aug. 1902 to 3 Jan. 1903.	10 min., 20 weeks	1/40	Free.	—	—	Lock about 10 ins. long. Divided into (a) root half, (b) end.

Appendix 32.

## APPENDIX, No. 32—continued.

## D—continued.

TABLE D.—Female Cases over 15 Years of Age taking or having lately discontinued taking Liquor Arsenicalis—continued.

Reference No.	Hospital or Infirmary.	Initials.	Age.	Disease.	Daily Doses taken and Dates.	Approximate Summary of Daily Dose and Period of Arsenic-taking.	Results, As <sub>2</sub> O <sub>3</sub> in grains per lb. of hair.			Result of Examination of Control Sample, if any, obtained before Arsenic began to be taken.	Special points as to sample noted, Instructions given to Analyst, &c.
							Roots.	Tips.	Whole Length.		
49	Fulham	L. W.	15	Chorea	16 min. daily for 64 days, from 6 Nov. 1902 to 9 Jan. 1903.	16 min., 9 weeks	$\frac{1}{40}$	—	—	—	Long lock about 4 ins. from scalp end tested.
50	Fulham	J. D.	34	Epilepsy	6 min. daily for 54 days, from 16 June to 8 Aug. Discontinued for 5 days, from 8 Aug. 13 Aug. 10 min. daily for 153 days, from 13 Aug. 1902 to 8 Jan. 1903.	9 min., 30 weeks	$\frac{1}{40}$	Trace	—	—	Lock about 12 ins. long. Divided into (a) root half, (b) rest.
51	Fulham	S. R.	56	Lupus	12 min. daily for 146 days, from 16 Aug. 1902 to 8 Jan. 1903.	12 min., 5 months	$\frac{1}{10}$	—	—	—	Only 4 to 5 ins. at root end tested.
56	Islington	L. J.	34	Psoriasis	9 min. daily for 26 days, from 12 Dec. 1902 to 7 Jan. 1903. 15 min. daily for 8 days, from 8 Jan. to 15 Jan.	10 min., 5 weeks	$\frac{1}{8}$	$\frac{1}{100}$	—	—	Divided into (a) 3 ins. at root end, (b) rest.
58	Islington	M. J.	54	Myxodema	9 min. daily for 203 days, from 11 June to 29 Dec. Discontinued 15 days, from 30 Dec. to 13 Jan.	9 min., 29 weeks; and discontinued, 2 weeks.	—	—	$\frac{1}{8}$	—	Small sample, weighed 48 grammes.
60	Lambeth	E. C.	33	Phthisis	9 min. daily for 36 weeks, from 1 May 1902 to 9 Jan. 1903.	9 min., 36 weeks	—	—	$\frac{1}{5}$	—	About 7 ins. lock.
61	Lambeth	G. B.	19	ditto	9 min. daily for 1 month, from 9 Dec. 1902 to 19 Jan. 1903.	9 min., 1 month	Trace.	Trace.	—	—	Thick lock about 18 ins. long. Divided into (a) 2 ins. at root end, (b) rest.
63	Lambeth	M. W.	20	Anæmia	12 min. daily for 5 days, from 23 Oct. to 28 Oct. Discontinued 10 days from 28 Oct. to 7 Nov. 12 min. daily for 20 days from 8 Nov. to 28 Nov. Discontinued 49 days, from 29 Nov. to 16 Jan.	12 min., 3½ weeks; and discontinued, 7 weeks.	$\frac{1}{15}$	$\frac{1}{40}$	—	—	Large lock Divided into (a) 3 ins. at root end, (b) rest, 9 ins.
64	Lambeth	M. P.	40	Neurasthenia	9 min. daily for 32 days, from 31 Oct. 1 Dec. 15 min. daily for 15 days, from 2 Dec. to 16 Dec. Discontinued 3 weeks from 16 Dec. to 7 Jan.	11 min., 7 weeks	$\frac{1}{2}$	—	—	—	Small, thick lock, 4 ins. at root end tested only.

65	Lambeth	L. F.	46	Tubercular hip	9 min. daily for 1 month, from 9 Nov. to 9 Dec. Discontinued 1 month, from 9 Dec. to 9 Jan.	9 min., 1 month	$\frac{1}{50}$	Trace.	-	-	Long lock. Divided into (a) 3 ins. at root end, (b) next 2 ins
66	Paddington	S. M.	43	Chorea	9 min. daily for 16 days, from 3 Nov. to 18 Nov. 24 min. daily for 49 days, from 19 Nov. to 6 Jan. Discontinued 17 days, from 6 Jan. to 23 Jan. 9 min. daily for 9 days, from 23 Jan. to 1 Feb.	Varying amounts at intervals for 8 weeks since last collection (see sample 31).	-	-	$\frac{3}{10}$	-	Sample is of quite short hair.
69b	Paddington	E. H.	43	Eczema	9 min. daily for 55 days, from 9 Dec. 1902 to 2 Feb. 1903.	9 min., 2 months	-	-	$\frac{1}{8}$	Free	Hair taken from same spot as control; length 1½ ins.
71b	Paddington	A. P.	35	Psoriasis	9 min. daily for 55 days, from 9 Dec. to 2 Feb.	9 min., 2 months	Trace.	-	-	Trace	Length taken 21 ins. Tested only 2 ins. at root end.*
72b	Paddington	E. D.	41	Right hemiplegia	9 min. daily for 25 days, from 9 Dec. to 3 Jan. Discontinued 6 days, from 3 Jan. to 9 Jan.	9 min., 3½ weeks; and discontinued 1 week.	$\frac{1}{30}$	-	-	Trace	Tested not more than about 1 inch at root end.
84	Tooting	M. G.	27	Epilepsy	9 min. daily for 55 days, from 1 Jan. to 24 Feb.	9 min., 2 months	$\frac{1}{25}$	-	-	Trace	Tested only about two inches from r. of end.
85	Tooting	M. H.	21	Epilepsy	9 min. daily for 25 days, from 1 Jan. to 25 Jan. Discontinued 1 month, from 25 Jan. to 24 Feb.	9 min., 1 month	$\frac{1}{20}$	-	-	Trace	- ditto.
86	Tooting	A. M.	20	Epilepsy	9 min. daily for 55 days, from 1 Jan. to 24 Feb.	9 min., 2 months	$\frac{1}{15}$	-	-	Free	- ditto
87	Tooting	M. P.	35	Epilepsy	6 min. daily for 55 days, from 1 Jan. to 24 Feb.	6 min., 2 months	Trace.	-	-	Free	Thin lock, 81 grammes only examined.
88	Tooting	E. M.	28	Epilepsy	9 min. daily for 55 days, from 1 Jan. to 24 Feb.	9 min., 2 months	$\frac{1}{25}$	-	-	Free	Tested only about two inches from root end.

\* Another lock taken 3 months after liquor arsenicalis discontinued showed: 1½ inches at root, 1½th; next 1½ inches, 6th; next 2 inches, 6th grain; remainder free.

## Appendix, No. 32—continued.

TABLE SHOWING CASES OF CHILDREN UNDER 15 YEARS OF AGE TAKING OR HAVING LATELY DISCONTINUED TAKING LIQUOR ARSENICALIS.

Reference No.	Hospital or Infirmary.	Initials.	Age.	Disease.	Daily Dose taken and Dates.	Approximate Summary of Daily Dose and Period of Arsenic-taking.	Results, As <sub>2</sub> O <sub>3</sub> in grs. per lb. of hair.	Results of Examination of Control Sample, if any, obtained before Arsenic began to be taken.	Special points as to Sample noted, instructions to Analyst, &c.
6	Guy's	D. G.	12	Chorea	6 min. daily for 60 days	6 mns., 2 months	Scalp portion, Trace; ends, Trace.	—	Divided into two portions.
12	Guy's	E. D.	11	Chorea	7½ min. daily for 1 month, from 28th Oct. to 23rd Nov. 1901 Discontinued from 23rd Nov. to 12th May 1902 7½ min. daily for 3½ months from 12th May to Aug. 25.	7½ min., 4½ months, and discontinued 2½ weeks.	1 89	—	Hair not divided.
15	Guy's	M. W.	12	Chorea, rheumatism	7½ min. daily for 150 days 15 min. daily for 2 days. 30 min. daily for 3 days.	8 min., 5 months (average).	1 25	—	ditto.
18	Croydon	D. T.	11	Chorea	24 min. daily for 42 days. Discontinued for 35 days.	24 min., 6 weeks, and discontinued 5 weeks.	(a) Free (b) Free. (c) Scalp 150 tips a trace.	—	(a) Small specimen cut 2 ins. from head. (b) Small specimen about 3 in. hair cut close to head. (c) Large sample take 1½ in. near head separately. Sample (a) weighed .35 gramme only; (b) .15 gramme only; (c) scalp 1.62 grammes; tips 3.4 grammes.
19	St. Bartholomew's	A. M.	7	Chorea	15 min. daily for 3 days 18 min. daily for 1 day. 21 min. daily for 14 days.	20 min., 3 weeks (average).	1 20	—	—
23	St. Bartholomew's	C. E.	11	Chorea	9 min. daily for 3 weeks	9 min., 3 weeks	1 150	—	—
33	St. George's	E. D.	12	Impetigo	7½ min. daily for 36 weeks, from 2nd May 1902 to 7th Jan. 1903	7½ min., 36 weeks	1 2	—	—
54	Islington	F. W.	13	Chorea	9 min. daily for 5 days, from 5th July to 10th July. 15 min. daily for 6 days, from 10th July to 16th July. 21 min. daily for 181 days, from 16th July to 13th Jan. 1903.	20 mns., 6 months	1 2	—	Small specimen.
55	Islington	W. H. J.	8	Scabies	3 min. daily for 14 weeks, from 10th Oct. to 14th Jan. 1903	3 min., 3 months	1 100	—	—

## E

TABLE E.—ADDITIONAL SERIES OF SAMPLES FROM MALE CASES TAKING LIQUOR ARSENICALIS IN TOTAL DAILY DOSES OF 3 TO 4½ MINIMS (1 OR 1½ MINIMS THREE TIMES A DAY BEFORE MEALS).

Reference No.	Hospital or Infirmary.	Initials.	Age.	Disease.	Daily Doses taken and Dates.	Approximate Summary.	Results, As <sub>2</sub> O <sub>3</sub> in grs. per lb. of hair.	Result of Examination of Control Sample, if any, obtained before Arsenic began to be taken.	Special points as to Sample noted.
93	St. George's Infirmary.	R. H. C.	50	Epilepsy	4½ min. for 67 days, from 28th Feb. to 6th May 1903	4½ min., 9½ weeks	$\frac{1}{25}$	$\frac{1}{25}$ gr.	R. H. C. had been in infirmary (except for one week) since July 1902. No facts could be ascertained which threw light on the amount of arsenic in control sample.
94	St. George's Infirmary.	F. A.	42	Rheumatism	ditto ditto ditto	ditto ditto	Over $\frac{1}{50}$	Free.	—
95	St. George's Infirmary.	G. H.	49	Rheumatism	3 min. for 67 days, from 28th Feb. to 6th May 1903	3 min., 9½ weeks	$\frac{1}{10}$	Trace.	—
96	St. George's Infirmary.	A. H. J.	46	Phthisis, rheumatoid arthritis.	4½ min. for 67 days, from 28th Feb. to 6th May 1903	4½ min., 9½ weeks	$\frac{1}{8}$	Free	A. H. discontinued arsenic May 19th. His hair was cut in ordinary course at beginning of June. A later specimen cut to roots with clippers on June 30th showed a trace of arsenic.
97	St. George's Infirmary.	J. B.	41	Ulcerated leg	3 min. for 67 days, from 28th Feb. to 6th May 1903	3 min., 9½ weeks	$\frac{1}{25}$	$\frac{1}{100}$	—
100	St. George's Infirmary.	J. S.	36	Ulcerated leg	ditto ditto ditto	ditto ditto	$\frac{1}{80}$	Free.	—
101	St. George's Infirmary.	H. L.	51	Morbus cordis	3 min. for 64 days, from 2nd Mar. to 6th May 1903	3 min., 9 weeks	$\frac{1}{100}$	Trace.	—
102	St. George's Infirmary.	W. D.	47	Locomotor ataxy	3 min. for 67 days, from 28th Feb. to 6th May 1903	3 min., 9½ weeks	$\frac{1}{80}$	Free.	—
103	St. George's Infirmary.	J. S.	29	Epilepsy	4½ min. for 63 days, from 2nd Mar. to 6th May 1903	4½ min., 9 weeks	$\frac{1}{50}$	Free	Another sample tested later, see text of Report.
106	St. George's Infirmary.	F. H.	45	Synovitis	1½ min. for 67 days, from 28 Feb. to 6th May 1903	4½ min., 9½ weeks	$\frac{1}{40}$	Trace.	—
107	St. George's Infirmary.	J. O.	61	Morbus cordis	3 min. for 67 days, from 28th Feb. to 6th May 1903	3 min., 9½ weeks	Trace.	Trace.	—
108	St. George's Infirmary.	C. B.	36	Bronchitis	3 min. for 64 days, from 2nd Mar. to 6th May 1903	3 min., 9 weeks	$\frac{1}{25}$	Free.	—

## APPENDIX, No. 32—continued.

TABLE F.—ALCOHOLIC NEURITIS CASES RECENTLY ADMITTED TO CERTAIN LONDON HOSPITALS OR INFIRMARIES. (See p. 350.)

Reference No.	Hospital, &c.	Initials.	Age.	Sex.	Length of time in Hospital.	Duration of Illness at date of Collection of Specimen.	Form of Alcohol.	Arsenic found. Grains per lb. of hair.	Remarks.
9	London . . . . .	M. O.	50	F.	3 days . . . . .	Less than 1 month . . . . .	Probably chiefly spirits . . . . .	$\frac{1}{80}$	Whole length examined.
10	London . . . . .	E. S.	48	F.	2 days . . . . .	Less than 2 months . . . . .	Beer . . . . .	Trace.	" "
11	London . . . . .	L. M.	39	F.	15 days . . . . .	1 month . . . . .	Probably brandy and gin . . . . .	$\frac{1}{150}$	" "
20	St. Bartholomew . . . . .	L. B.	38	F.	?	?	Beer and gin, freely . . . . .	$\frac{1}{10}$	" "
89a	Paddington Infirmary . . . . .	A. D.	44	F.	20 days . . . . .	3 months . . . . .	Entirely beer . . . . .	$\frac{1}{100}$	2 ins. from roots.
89b	" . . . . .	"	"	"	" . . . . .	" . . . . .	" . . . . .	$\frac{1}{50}$	The next 2½ ins.
89c	" . . . . .	"	"	"	" . . . . .	" . . . . .	" . . . . .	Free.	Rest of the hair.
A.N. 1	Lambeth Infirmary . . . . .	J. P.	46	M.	57 days . . . . .	2 months . . . . .	Beer . . . . .	$\frac{1}{20}$ (Approximate result: antimony also present.)	About 2 ins. long, rather small sample. Mirror also of antimony.
A.N. 2	St. Pancras Infirmary . . . . .	L. R.	51	F.	3 months . . . . .	4 months . . . . .	Beer and rum . . . . .	(a and b) free.	White hair about 13 ins. long, (a) root 3 or 4 ins.; (b) rest.
A.N. 3	Fulham Infirmary . . . . .	M. S.	55	F.	15 days . . . . .	Less than 1 month . . . . .	Beer, two glasses daily . . . . .	(a) trace, (b) free.	Scanty lock about 12 ins. long, (a) root 4 ins. (b) rest.
A.N. 4	Fulham Infirmary . . . . .	J. F.	38	F.	24 days . . . . .	4 months . . . . .	Beer . . . . .	Trace.	Scanty lock about 12 ins. long, not sufficient to examine in sections.
A.N. 5	St. George's Infirmary . . . . .	F. L.	68	F.	Less than a month. 2 days . . . . .	21 months . . . . .	Spirits . . . . .	Free.	Short lock of greyish hair, about 8 ins.
A.N. 6	Fulham Workhouse . . . . .	H. B.	48	F.	2 days . . . . .	2 months . . . . .	Whisky chiefly, a little stout . . . . .	(a) trace, (b) trace.	(a) 4 or 5 ins. (b) rest.
A.N. 7	Lambeth Infirmary . . . . .	J. C.	46	M.	14 weeks . . . . .	5 months . . . . .	Whisky and beer . . . . .	Free.	Short hair.
A.N. 8	Lambeth Infirmary . . . . .	E. K.	51	F.	17 days . . . . .	3 months . . . . .	Beer . . . . .	Trace.	Scanty hair about 5 ins. long; whole examined.
A.N. 9	Bethnal Green Infirmary . . . . .	C. M.	27	F.	12 days . . . . .	ditto . . . . .	Beer and gin . . . . .	$\frac{1}{100}$	Short lock about 4 ins. long, cut to roots.

July, 1903.

INDEX TO  
MINUTES OF EVIDENCE, &c., IN THIS VOLUME,  
AND MEMORANDA.

---

INDEX TO  
MINUTES OF EVIDENCE & IN THIS VOLUME  
AND MEMORANDA

# INDEX TO MINUTES OF EVIDENCE IN THIS VOLUME.

## ACETIC ACID:

Liability of, to contain arsenic (Appendix 24), p. 233.

## ADDISON'S DISEASE:

Pigmentation in (Reynolds), 8318-20.

## ALCOHOL:

Toxic effect of alcohol when taken along with arsenic (Reynolds), 8338; (Delépine), 10388-424; (Appendix 16), pp. 183-195.

## ALCOHOLIC NEURITIS:

Alcoholic neuritis in relation to arsenic (Reynolds), 8322-38; none observed in beer drinkers since 1900 epidemic, 8332; exceptionally common among beer drinkers in Manchester before 1900, 8339-44; difference due to previous presence of arsenic in Manchester beer, 8402, which was largely attributable to malt, 8357-8, and to exclusion of arsenic from beer since epidemic, 8343.

Rarity of neuritis caused by alcohol without arsenic (Reynolds), 8338.

See also HALIFAX, NEURITIS.

## ALL-MALT BEER:

Arsenic in (Expert Committee), Appendix 19, p. 201; at "Cross Keys," Halifax (H. Smith), 8628, p. 20; 8653-64.

## ANALYSTS:

### PUBLIC ANALYSTS:

Total number in England and Wales (Lithiby), 11505.

Relation with local authorities (Allen), 11987, 12008; often not consulted or asked to advise, 12005; (Hehner), 10203.

Quarterly report to local authority (Lithiby), 11629; (Allen), 12009-11. Four quarterly reports sent annually to Local Government Board (Lithiby), 11630-1. Extracts from, in Board's annual reports (Lithiby), 11513; (Allen), 12008. Terms of report (Lithiby), 11506, 11632-3; do not show what adulterations or impurities looked for, 11634-40.

Terms of report in individual cases (Hehner), 10197, 205; (Allen), 11983-7. Significance of "genuine" (Lithiby), 11637-40; (Allen), 12007.

Work by, needs greater co-ordination (Allen), 12008, 12038-9.

### PUBLIC ANALYSTS, SOCIETY OF:

Opinions of members on report of Joint Committee on Arsenic (Chapman), 10228, 10260-1, 10293-8.

### WORK BY, FOR BREWERS AND OTHER MANUFACTURERS, in relation to arsenic:

Extent of analysis at Halifax breweries (H. Smith), 8628, 8706, 8784-8826; (Thompson), 8909-32, 8973-85, 9023-35; (Buckley), 9268-75, 9300-46, 9389-96.

Analysis of various brewers' samples (Thomson), 9654-9783; (Fairley), 9863-73; (Salamon), 9994-5; (Chapman), 10272-88, 10325-67. Extent of information, etc., received by analyst (Thomson), 9708-12; (Fairley), 9858, 9865-8.

Analysis of various substances used in food preparation; extent to which practised by different manufacturers (Appendix 24), pp. 230-254; (Lyle), 11028-59, 11077-11140, 11159-60; (Howell), 11181-4, 11215, 11259; (Overbeck), 11291-6; (Walker), 11327, 11341; (Pronk), 11378, 11387-8; (Palmer), 11465; (Appendix 27), p. 277.

## ANILINE DYES:

Arsenic in. See COLOURING MATTERS.

## ANTHRACITE. (See FUELS.)

## ARSENIC:

One-hundredth grain daily may be considered a harmless quantity (Reynolds), 8373, 8443-7; might be injurious in certain cases (Neech), 9100, (Delépine), 10400-16. Small medicinal dose producing paralysis (Neech), 9264-5.

## ARSENIC ACID AND ARSENATES:

"Marsh" estimations in the case of solutions containing arsenic as arsenic acid (Angell), 8507-13; (McGowan and Floris), Appendix 23, p. 227.

## ARSENIURETTED HYDROGEN:

Poisoning by (Legge), 11747-52, 11792-5, 11819-20.

## BARLEY:

Arsenic in kiln-dried barley, and also in barley not kiln dried (Expert Committee), Appendix 19, p. 202; latter attributed to use of superphosphates (Salamon), 9999-10006.

Negative evidence: no arsenic detected in barley and other cereals grown on soil manured under various experimental conditions. See VEGETABLES.

No arsenic in barley used for Newark experiment, Appendix 30, p. 322.

## BEER:

### MANUFACTURE OF:

Use of malt adjuncts in beer at Halifax (H. Smith), 8628, p. 18; action of Board of Inland Revenue as to arsenic in beer ingredients, preservatives, "regenerators," etc. (Primrose), 11844-967.

## BEER, ARSENIC IN:

Will apparently diminish on keeping if the organic matter of the beer is not destroyed before testing (Hehner), 19212-5; more arsenic in sediment of beer than in liquid (H. Smith), 8844-7. Suspended matter may influence results of analysis (Neech), 9104-6, 9257-60.

Presence of arsenic in various beers. See QUANTITIES. Improvement in beers since the 1900 epidemic (Reynolds), 8367-72; (Thomson), 9758; (Fairley), 9846-52; (Salamon), 9967. Less than one-hundredth grain of arsenic per gallon now easily attainable (Salamon), 9966; (Hehner), 10123, 10169-78; (Chapman), 10277-9; (Primrose), 11847; (Allen), 11973.

Possible combination of arsenic with organic matter of beer. See ORGANIC MATTER.

## BEER FREE FROM ARSENIC:

No arsenic found by delicate tests in some recent beers (Thomson), 9686-7; (Fairley), 9851-2; (Chapman), 10277; (Primrose), 11847. All arsenic should eventually be excluded from beer (Thomson), 9684-5. Absolute freedom from arsenic cannot be secured (Hehner), 10160.

## BERI-BERI:

Possible relation to arsenical poisoning (Reynolds), 8381; Liverpool case, inquired into with Major R. Ross, 8381-97; Cardiff cases, 8381; relation of tropical beri-beri and arsenic requires investigation (Reynolds), 8381-6, 8398-401.

**BERI-BERI—continued.****REPORTS ON BERI-BERI IN APPENDIX 31.**

Section I.—General account of inquiries made for the Commission; collection of information and samples from ships arriving at home ports with cases of beri-beri, account of ships, cases, samples, and analyses, pp. 326-333.

Conclusions as to inquiries relating to ship-borne beri-beri, p. 334; inquiries reported from Malay States, p. 334.

Section II.—Report by Dr. McGowan on examination for arsenic of various substances in connection with beri-beri inquiry, pp. 335-344.

**BIRTH RATE.****DIMINUTION FOLLOWING THE 1900 EPIDEMIC:**

APPENDIX 17.—Dr. Niven's observations on the apparent relation between the 1900 epidemic in Manchester and the drop in the birth rate in 1901, with statistics, annual and quarterly, for Manchester and other towns affected by or free from arsenical poisoning in 1900 (Appendix 17), pp. 196-8.

**"BOARD OF REFERENCE":**

Question of establishing an authority to prescribe "standards" for foods and food ingredients (Moulton), 9945; (Lithiby), 11516-7, 11542, 11650-3; (Allen), 12033, 12056-61. If established, should be advisory not executive (Lithiby), 11543-6.

**"BOLE ARMENIA":**

Arsenic in (Pronk), 11444; (Appendix 24), p. 234; (Appendix 25), p. 268; (Appendix 22), p. 225; no arsenic found in (Howell), 11250-5.

Use of, to add to sausages, etc. (Appendix 24), p. 247.

**BORAX AND BORIC ACID:**

Arsenic in, manufacture, and prices (Appendix 24), p. 233; foods liable to arsenical contamination by their use, p. 248; absence of guarantees or tests as regards preservatives obtained commercially, p. 248; purchased on guarantee and analysis (Howell), 11224; arsenic in "Frigiline" (Appendix 25), p. 265.

Boron preservatives still used in milk, notwithstanding report of Preservatives Committee (H. Smith), 10984; (Appendix 24), p. 248.

**BOSTOCK AND CO.:**

Disposal of Bostock's contaminated glucose, invert sugar, and table syrup (Secretary), 10982.

Action by, against Nicholson and Sons (Secretary), 10983.

**BOSTOCK'S TABLE SYRUPS:**

Manufacture commenced in 1900; scarcely any sale to public; 14 tons on Bostock's premises in May, 1901; Nicholson's acid used in their preparation; dangerously contaminated (H. Smith), 10971-82. Result of analyses (McGowan), Appendix 25, p. 265.

**BREWED BEVERAGES (OTHER THAN BEER):**

Use of glucose and invert sugar in preparation of (Appendix 24), p. 242.

**BREWERS:**

Precautions regarding arsenic taken by brewers since 1900 epidemic. See BEER, EXPERT COMMITTEE, HALIFAX, MALT.

Nature of precautions taken or desirable (H. Smith), 8628, 8671-8700; (Hehner), 10162-6; (Chapman), 10325-32; (Thomson), 9708-20; (Fairley), 9846-75; (Salamon), 10025-47; precautions will be relaxed unless some official control (Ling), 10576-82; 10596-7; (Thomson), 9782-3; (Allen), 12037.

No drawback claimed by brewers in consequence of destruction of arsenical beer since 1901 (Primrose), 11961.

**BREWING SUGARS (OTHER THAN BOSTOCK'S):**

Result of testing for arsenic (Thorpe), 8847; (Thomson), 9669; (Ling), 10574-7; (Primrose), 11847; (Appendix 19), p. 201.

See also GLUCOSE, INVERT SUGAR, CARAMEL.

**CACODYL:**

No evidence that compounds of cacodyl or its homologues are present in arsenical beer; experiments on this question; tests under (Delépine), 10381-3.

Experiments on action of yeasts and moulds on cacodylates (Delépine), 10384.

Toxicity of (Delépine), p. 190, note. Effect of cacodylate of soda on experimental rats (Appendix 16), pp. 186, 190.

**CARAMEL:**

Recent analyses of samples from breweries (Thorpe), 8847; (Thomson), 9669, 9689; (Primrose), 11847 (Table I.); arsenical samples, 11847 (Table II.); 11878. Arsenic in various samples: may be due to caustic soda (Appendix 24), p. 236; foods in which caramel is used (Appendix 24), pp. 246, 248. Should be tested for arsenic (Appendix 19), p. 204; (Appendix 21), p. 215.

**"CARNOS":**

Nature and mode of preparation from yeast and malt culms (Appendix 24), p. 244; (Overbeck), 11261-2. Arsenic in (Appendix 24), p. 244; (Appendix 25), p. 262; (Overbeck), 11270-4.

Samples called in by manufacturer on account of arsenic (Overbeck), 11271. Subsequent process to exclude arsenic, 11272, 11291-307; amount of arsenic not excluded by process, 11274-6. Company now in liquidation (Overbeck), 11274.

**CARPETS, CLOTH, Etc.:**

Examined for arsenic on account of prohibitions of Swedish and Norwegian Governments (Thomson), 9797-800.

**CASKS:**

Shavings from casks which had held arsenical beer, showed no arsenic (Expert Committee), Appendix 19, p. 203.

**CHEMICAL SUBSTANCES:****USED IN FOOD PREPARATION.**

Sulphuric, hydrochloric, phosphoric, citric, tartaric, and acetic acids, sulphites, glycerine, etc., in relation to arsenic (Appendix 24), Sections I. and II., pp. 230-248. Food manufacturer sometimes ignorant of risk of arsenic from use of certain of these substances (H. Smith), 10923-8; recent demand for arsenic-free chemicals (Howell), 11166; purity ultimately depends on sulphuric acid, which should be obtained free from arsenic (Howell), 11229.

Chemical substances liable to be arsenical sold to food manufacturers under misleading names (Howell), 11201-2.

Demand by manufacturers for "standards" as to arsenic in (H. Smith), Appendix 24, page 254, 10939-49; (Howell), 11190; (Palmer), 11478. Pharmacopoeial standards of uncertain value (H. Smith), 10912-3; (Howell), 11190; (Appendix 24), pp. 255-6.

Chemical substances which may introduce arsenic into beer (Appendix 21), p. 215; (Primrose), 11847, 11869-73.

**USED IN TESTING FOR ARSENIC:**

See TESTS.

**CHLORIDE OF TIN:**

Used in manufacture of West India sugar; may be a source of arsenic in the sugar (Appendix 24), p. 239; (Appendix 25), p. 268; (Lyle), 11064-5.

**CHICORY:**

Chicory drying in relation to arsenic; exposure of chicory roots to fumes of coke; additional drying for English market; analyses of, for arsenic (Appendix 24), p. 250; (Appendix 25), p. 259; (Thomson), 9790-3; (H. Smith), 10995-6.

**CHRONIC ARSENICAL POISONING:**

Accelerating death from tuberculosis and other causes (Reynolds), 8412-31; (Neech), 9160-7; (Delépine), Appendix 16, p. 189.

Toxic effect of arsenic when taken with alcohol (Reynolds), 8338; experimental administration to rats, influence of food (Delépine), 10388-424; (Appendix 16), pp. 183-195. Effect of small quantities of arsenic in beer (Reynolds), 8373, 8443-7; (Neech), 9100; (Delépine), 10400-16. Pathological changes in human and rat (Appendix 16), p. 189.

In Halifax outbreak. See HALIFAX.

In industrial poisoning (Legge), 11738-843.

**CIDER:**

Use of invert sugar in manufacture (Appendix 24), p. 241.

**CIGARETTE PAPERS:**

Imitation gold and bronze tipped, analyses for arsenic (Appendix 25), p. 274.

**CITRIC ACID:**

May contain arsenic (Davis), 6423.

Preparation of, in relation to arsenic; selection of acid and treatment with sulphuretted hydrogen by Bennet, Lawes, and Co. (Appendix 24), p. 233. Purchase and sale of (Howell), 11212-8.

**COAL GAS:**

No arsenic detected in (Fairley), Appendix 24, p. 257.

**COKE, GAS AND OVEN (See FUELS, SMOKED FOODS.)****COLOURING MATTERS IN FOOD:****MINERAL COLOURS:**

Arsenic in oxide of iron and "Bole Armenia" may be in large amount (Hehner), 10210, and Appendix 27, p. 277; (Pronk), 11444; (Appendix 24), p. 234; (Appendix 25), p. 268; (Appendix 22), p. 225. In oxide of manganese (Hehner), 10211.

Arsenic introduced into foods by: chocolate powders, anchovy paste, etc. (Appendix 27), p. 277; sausages, etc. (Appendix 24), p. 247.

Should not be used for food purposes (Pronk), 11401-5. No knowledge of arsenic in (Howell), 11253-5.

**COAL TAR COLOURS:**

Arsenic in various coal tar colours (Appendix 24), p. 234; in samples used in food, apple green, carnation, coffee colour, dragon's blood, "Saster" (Appendix 25), pp. 268-9; (H. Smith), 10964-6, 10944.

Organic matter must be destroyed in testing (McGowan), Appendix 22, p. 223; (Hehner), Appendix 27, p. 277.

Origin of arsenic, use of arsenic acid now rare, probably due to impure sulphuric acid (Appendix 24), p. 234; (Pronk), 11367-71. Arsenical process should not be used (Pronk), 11382-3, 11435.

System of testing: arsenical specimens set aside for textile purposes (Pronk), 11378-81, 11386-94; usually knows purpose for which required (Pronk), 11424-33.

Foods coloured with (Appendix 24), p. 247; advantages of using (Pronk), 11412-23.

**CONFECTIONERY:**

Use of ingredients in confectionery which are liable to contain arsenic: glucose, glycerine, colouring matters, lanoline, liquorice, etc. (Appendix 24), p. 240. Precautions taken by confectioners in order.

4576.

**CONFECTIONERY—continued.**

ing glucose, etc., p. 236; (H. Smith), 10922-7; (Walker), 11368-61; (Palmer), 11456-96. Arsenic in "chocolate" sweets (Hehner), Appendix 27, p. 277.

**CORNWALL:**

Symptoms occurring in arsenic workers in (Legge), 11807-27.

**"COURT OF REFERENCE":**

See "BOARD OF REFERENCE."

**"CREAM OF TARTAR SUBSTITUTE":**

(Palmer), 11469-72, 11492-3; (Howell), 11201, 11244.

**CUMULATIVE EFFECT OF ARSENIC:**

Relatively greater when doses small (Delépine), 10423-4 (Appendix 16), p. 190.

**DEPARTMENTAL COMMITTEE ON TESTS FOR ARSENIC IN BREWING INGREDIENTS, ETC.:**

Appointment of, by Board of Inland Revenue (Primrose), 11896. Work by, on electrolytic and zinc and acid methods, conclusions, and recommendations (Thorpe), 11654-737; Report of (Appendix 21), pp. 208-219.

**DEXTRIN:**

Manufacture of, and use in certain biscuits (Appendix 24), p. 243.

**DUST:**

Arsenic in, on laboratory shelves and bookcases (Fairley), 9824; in dust generally (Lyle), 11104; (Howell), 11233-6.

**ELECTROLYTIC TESTS FOR ARSENIC:**

See TESTS.

**ELIMINATION OF ARSENIC FROM THE BODY:**

Ways in which arsenic is eliminated (Reynolds), 8292-8314, 8360-72, 8448-53; (Delépine), 10423-4 (Appendix 16), p. 190; (H. Smith), 8628, p. 16. Hair experiments (Appendix 32), pp. 345-362. Arsenic in feathers of fowls receiving arsenic with food (H. Smith), 10997-11007; (Appendix 24), p. 252.

**EMERALD GREEN, SCHEELE'S GREEN, and PARIS GREEN:**

Nature, manufacture, and use of (Legge), 11775-8, 11796-800. Use of, as insecticides (Appendix 24), p. 251. Use to colour green tapers (Legge), 11769-73.

**ENAMELLED COOKING UTENSILS:**

Arsenic as an ingredient of enamel; use by English manufacturers discontinued: much arsenic found by Mr. Albert Smith in cheap Belgian ware: illness said to have been caused by arsenical enamel (H. Smith), 11008-23; (Appendix 24), p. 252.

**REPORTS ON, IN APPENDIX 29:**

Section I.—General account of Commission's inquiry and summary of results; collection of British and foreign made samples from various sources; manufacture of experimental saucepans using arsenic in enamel, p. 281.

Section II.—Solubility of arsenic in enamel of experimental saucepans (McGowan), p. 282-3.

Section III.—Examination for arsenic of the collected samples; results uniformly negative (McGowan), p. 284-5.

**ENTRY:**

Power of entry on premises of manufacturers. See OFFICIAL CONTROL.

## EPIDEMIC DUE TO ARSENIC IN BEER, 1900:

Cases still under treatment in Manchester in 1902 (Reynolds), 8315. Total fatal cases in Crumpsall Infirmary (Reynolds), 8315-7, 8422-31. Pathological changes in fatal cases (Appendix 16), p. 189. Cases in Halifax in 1900 (Neech), 9128.

Class of persons attacked, influenced by feeding and other conditions (Delépine), 10389-416, (Appendix 16), p. 191.

Effect of, on birth rate in 1901 (Niven), (Appendix 17), p. 195.

Cessation of arsenical symptoms, "alcoholic neuritis," "alcoholic heart," etc., in Manchester since epidemic (Reynolds), 8287-8359, 8402.

## EXPERT COMMITTEE APPOINTED BY MANCHESTER BREWERS' ASSOCIATION:

Final report (Appendix 19), p. 201.

Its object, work, and conclusions (Moulton), 9924-63; (Salamon), 9964-10091. Adoption of recommendations by brewers (Moulton), 9935; (Thompson), 9060; (Buckley), 9379-85.

Reinsch test for arsenic first recommended by (Salamon), 9964. Later test more stringent, and should be better known (Salamon), 10026-35. Advantage of easily applied test for unskilled use (Moulton), 9939, 9957-63; (Salamon), 9968-73, 10036-47.

Use of test recommended by (Fairley), 9820-3, 9879-80; (Hehner), 10109-13; at Halifax (H. Smith), 8628, p. 17; (Neech), 9208-13; (Buckley), 9389.

## FININGS:

Appendix 21, p. 215.

## FISH:

Arsenic in samples of preserved fish used on board ship; practically no arsenic in fresh fish samples (Appendix 31), pp. 332-3.

Process of drying over coals introduces scarcely any arsenic into bloaters, etc. (H. Smith), 10988-94; (Appendix 24), p. 249.

## FOODS AND DRINKS (OTHER THAN BEER) IN RELATION TO ARSENIC:

## REPORTS ON, IN APPENDICES 24 TO 27.

Mr. Hammond Smith's inquiries and report:

Nature and methods of inquiry (Appendix 24), p. 250. Section I., Food Ingredients liable to contain arsenic, pp. 230-7. Section II., Certain food substances liable to contain arsenic by reason of their manufacture with these ingredients, pp. 238-248. Section III., Foods dried by exposure to products of combustion, pp. 249-50. Section IV., Miscellaneous: Flesh of fowls receiving arsenic, arsenical insecticides, etc., pp. 251-2. Addenda, Arsenic in glycerine and in gas products, pp. 255-9.

Summary of Mr. H. Smith's report, p. 253. Evidence on report (H. Smith), 10911-11026.

Analyses by Dr. McGowan of certain foods obtained during above inquiry (Appendix 25), pp. 261-275. Preparation of maltine (Appendix 26), p. 276.

Letter from Mr. Hehner on arsenical contamination of food by certain colouring matters (Appendix 27), p. 277.

Inquiries as to addition of mineral acids to whisky and gin (Appendix 28), pp. 278-80.

## FOOD AND DRUGS ACTS, SALE OF:

Authorities appointing public analysts, total number (Lithiby), 11505. Local authorities have specific duty of administering Acts since 1899 Act, 11501.

## PRESENT ADMINISTRATION AND USE OF:

Mainly directed to well-known forms of adulteration (H. Smith), 10929, 10931. Use to prevent deleterious substances limited (Lithiby), 11511; insufficient for this purpose (Allen), 12005.

Total samples under Acts increased since 1899 Act (Lithiby), 11500-4; increase largely milk and butter, 11586-8, due to pressure by Board of Agriculture, 11645; increase also due to arsenic question, 11596-9.

## FOOD AND DRUGS ACTS, SALE OF—continued.

Few samples of beer now received from local authorities (Hehner), 10206-7; none taken in Halifax or Huddersfield in 1901 (H. Smith), 8826-30; (Neech), 9193. Food samples seldom taken for arsenic analysis (H. Smith), 10930.

Penalties often inadequate: Home Office circular (Lithiby), 11506.

See also ANALYSIS, PUBLIC.

## LOCAL GOVERNMENT BOARD AND ADMINISTRATION OF:

Duties of Board under Acts very limited before 1899 Act (Lithiby), 11499; additional powers since, 11499. Extent to which these have been used, 11500, 11537-41. Issue of circular as to arsenic, 11513, 11541.

Extent of advice by Board to local authorities (Lithiby), 11513. No organised system, 11514. Board have no special expert staff to advise, etc., on food questions, 11519, 11537; or to recommend sampling of particular articles, 11642-4. Advice in this direction is needed (Allen), 12008, 12048-50, 12054.

## POWERS UNDER:

Action under Acts must be taken against retailer (Lithiby), 11507, 11616-7; person responsible often cannot be reached (Allen), 12013-4. No powers to take samples from places of manufacture of food (Neech), 9224-9, 9246-51; (H. Smith), 10958-9; (Lithiby), 11508; (Allen), 12012.

As to samples in transit (Lithiby), 11507; object, 11558-61. Samples cannot be taken outside the district, 11605-6. Samples taken and divided must be "separate articles" (Allen), 12034.

## WARRANTY:

Effect of (Lithiby), 11618-28; (Allen), 12013-9. Evasion of Acts by notices (Allen), 12021-31.

Advantage if warrantor could be reached on first hearing of the case (Allen), 12062.

## OFFICIAL "STANDARDS" FOR PURPOSES OF:

Need for such "standards," particularly as regards arsenic; nature of "standards" required, etc. (Thomson), 9765-9; (Moulton), 9942, 9954-6; (Hehner), 10154-9; (Lyle), 11074-6, 11154; (Allen), 11981-2, 12006, 12040. Illustrations of need for "standards" or definitions of foods (Allen), 12006-14, 12020, 12069. See also BOARD OF REFERENCE.

## FUELS:

## SELECTION OF FUEL BY MALTSTERS:

Use of gas-coke. In Halifax district in 1900-1 (H. Smith), 8628, 8647. Still used at certain maltsters, 8628, 8764-8, 8807; in some cases 85 per cent., 8741-2; (Thompson), 8933-5. Gas-coke discontinued at Halifax (H. Smith), 8724-8; (Thompson), 9055-61; (Buckley), 9293, 9369-84; (Worsick), 9431-2; use generally abandoned, should be prohibited (Salamon), 9976-9.

Anthracite preferred to oven coke (H. Smith), 8728-36; (Buckley), 9293-9300, 9368-84; (Salamon), 10050-3; (Appendix 19), p. 203. Recommended (Chapman), 10355; now almost exclusively used (Thomson), 9691-4.

## TESTS FOR ARSENIC IN FUELS:

See TESTS.

## ANALYSES OF FUELS FOR ARSENIC:

Fuels seldom analysed for maltsters (H. Smith), 8628, p. 21, 8807; (Thompson), 8935-7, 9044; (Appendix 30), p. 298.

Difficulties of sampling for analysis; importance of accurate samples; objections to relying on analysis for selection of fuel (Worsick), 9447; (Thomson), 9787-9 (Moulton), 9935, 9950-2; (Salamon), 9984, 10059-64; (Chapman), 10353; (Ling), 10490-525, 10533-5, 10661-79; (Appendix 30), pp. 290, 308-9.

Guarantees of freedom from arsenic given by collieries; such guarantees have little value (H. Smith), 8769-83; (Thompson), 8938-41; (Salamon), 10059-64; (Chapman), 10356-67; (Appendix 30), pp. 290, 304-7.

## FUELS—continued.

## "VOLATILE" AND "FIXED" ARSENIC IN FUEL:

Methods of determination and significance (Ling), 10451-683, 10697-708; (Thorpe), 11671-719; (Appendix 20), p. 207; (Appendix 21), pp. 210, 214; (Appendix 23), pp. 227-9; (Appendix 30), p. 311. Observations on results (Appendix 30), pp. 289-90.

## GAS COKE:

Amounts of arsenic in different samples (Ling), 10536; (Appendix 30), p. 288.

## OVEN COKE:

Amounts of arsenic in different samples (Ling), 10536; (Appendix 30), p. 320. Comparison with gas coke and anthracite (Ling), 10540-9; (Beaven), 10886-90; (Salamon), 10050-3; (Appendix 19), p. 203; (H. Smith), 8728-36; (Buckley), 9293-300, 9368-84; (Appendix 30), p. 288.

Manufacture of, and hand picking of coal (H. Smith), 8751-61. Suggestion of coking with base (Ling), 10621-6. Advantage of oven coke treated with lime (Ling), 10627-31. Sulphur in foundry coke (Fairley), 9899-9904.

## ANTHRACITE:

Amounts of anthracite in different samples and "impurities" of anthracite (Ling), 10536; in sample analysed for Commission (Appendix 30), pp. 286-321; colliery analyses (Appendix 30), p. 306. Unequal distribution of arsenic (Ling), 10490-525; recent samples have been better, 10526.

Presence of lumps of pyrites in anthracite supplied to maltsters (H. Smith), 8736-41; (Appendix 30), p. 298.

Necessity of careful picking over (H. Smith), 8757-61; (Salamon), 9981, 10054-5; (Chapman), 10356-67; (Ling), 10661-5; (Appendix 30), pp. 286-310.

## REPORTS ON MALTING ANTHRACITE IN APPENDIX 30:

Part I.—*Account of Commission's Inquiry, and Summary of Results.*—Presence of impurities (pyrites, shales, etc.) in anthracite seams, and their removal at collieries; arsenic in clean anthracite and in impurities; fixed and volatile arsenic, pp. 286-90.

Bearing of results on selection of malting anthracite by collieries and maltsters, p. 290.

Tabular summaries of results, pp. 291-7.

Part II.—*Mr. H. Smith's Notes* on inquiries as to anthracite used by certain maltsters, p. 298.

Part III.—*Mr. A. Strahan's Notes* on visits to S. Wales collieries supplying malting anthracite. Seams worked for malting, p. 299; occurrence of impurities, p. 303; methods of removing impurities, p. 303; samples recommended, p. 304.

Part IV.—*Mr. S. W. Price's Report* on collection of samples. Samples taken underground, p. 308; samples of malting coal, p. 309. Picking and screening of anthracite, p. 309.

Part V.—*Dr. McGowan's Report* on arsenic in malting anthracites and other specimens. Observations, p. 311. Tables, pp. 312-321.

Part VI.—*Account of two experiments at Newark maltings*, pp. 322-5.

## TREATMENT OF MALTING FUEL:

Addition of lime to "fix" the arsenic (Ling), 10458-60, 10467-8, 10477-8, 10536, 10555-69, 10588-92, 10627-31, 10660.

New adopted at Halifax (Buckley), 9316-7.

## BRIQUETTES:

Possible advantage of (Salamon), 10088-91, if made with a base (Ling), 10614-20.

## GAUTIER, M.

Statement that arsenic is normally present in the thyroid gland (Reynolds), 8307-12.

## GLASS:

Arsenic in glass bottles and flasks (Reynolds), 8364; (Thomson), 9741; (Fairley), 9824.

Jena glass flasks should be used for storing acids (Appendix 20), p. 206. Manufacture of special bottles without arsenic for storing re-agents (Appendix 22), p. 220.

## GLUCOSE:

Use of, in various articles of food: General memoranda as to manufacture of, and arsenic in; precautions now taken or neglected by food manufacturers in ordering; guarantees; tests (Appendix 24), pp. 234-6, 238-243.

Use of, by Messrs. Castell and Brown: guaranteed as regards arsenic, analysis unnecessary (Walker), 11308-61. Looseness of guarantee system (H. Smith), 8794; (Primrose), 11959-60.

Arsenic in certain recent samples (Appendix 24), p. 235; (Ling), 10576-8, 10632-6; (Primrose), 11847, Table II.; (Allen), 11988.

Numerous instances where brewers' glucose recently found practically free from arsenic (Thorpe), 8847; (Thomson), 9669; (Primrose), 11847, Table I.; 11874; degree of purity attainable (Chapman), 10285-8; (Primrose), 11934-8.

Treasury Order prohibiting use of arsenical glucose in breweries: samples obtained by Inland Revenue officers from British factories, and from brewers using imported glucose without guarantee (Primrose), 11844-7. Difficulty in accurate sampling small (Chapman), 10340-3; 10352.

## GLYCERINE:

Use of, in food: as addition to cakes, jujubes, meat extracts, etc. (Appendix 24), pp. 234, 240-4; (H. Smith), 10912; (Howell), 11173-4; (Palmer), 11473; (Allen), 11998-12004. Food manufacturers often ignorant that glycerine may be arsenical (H. Smith), 10923; (Palmer), 11463-4.

Manufacture of, in relation to arsenic (Appendix 24), p. 233. Amounts of arsenic in various specimens (C. Brown), Appendix 24, p. 255. Uncertainty of limit of arsenic as defined by Gutzeit test of B.P. (C. Brown), p. 256; (H. Smith), 10916-8.

## GOVERNMENT LABORATORY:

Various work done at, in reference to arsenic, since 1901 (Primrose), 11844-11967. Results of testing large numbers of brewing ingredients, etc. (Primrose), 11847. Analyses of various substances in connection with Halifax outbreak (Thorpe), 8847.

Work at, in reference to tests and inquiry of Inland Revenue Departmental Committee (Thorpe), 11654-737, (Appendix 21), pp. 208-219.

Extent of testing for arsenic at (Salamon), 9974-5, 10072-6. Control by, at brewery, might be exercised by testing wort (Salamon), 9991-3, 10077-80; (Chapman), 10317-48, 10349-51; (Primrose), 11948.

## GRILLED FOODS:

Arsenical contamination from fumes of open fire negligible (H. Smith), 10988-94, (Appendix 24), p. 250.

## GUARANTEES: AS REGARDS ARSENIC:

Advantages and limitations of (Moulton), 9936-8; trade customs regarding (H. Smith), 8794, 8781-2; (Howell), 11195-6; (Walker), 11341-3, 11349-59; objections to, if based on "blunt" tests (Hehner), 10147-53.

In respect of brewing ingredients: Recommendations of Expert Committee (Appendix 19), p. 203; (Moulton), 9936. Methods of testing, on which guarantees could be based (Departmental Committee), Appendix 21, p. 208; (Primrose), 11940-50, 11956-8. Guarantees in respect of imported glucose (Primrose), 11959-60. Guarantees obtained by Halifax brewers (H. Smith), 8777-82; (Buckley), 9398. Not usually given with malt (Worsick), 9442-3, 9484-7. Sampling in relation to, see MALT.

## GUARANTEES: As regards Arsenic—continued.

In respect of fuel used by maltster: Guarantees of "freedom from arsenic" in anthracite supplied and accepted (Thompson), 8938-40; (Buckley), 9404; (Appendix 30), pp. 298, 304, 306. May be of no value, owing to sampling and other considerations (H. Smith), 8769-76, 8783; (Thomson), 9787; (Salamon), 9984, 10060; (Chapman), 10353-67; (Ling), 10524, 10667-80; (Appendix 30), p. 290. Guarantees as to hand picking, or origin of anthracite (Salamon), 10060-3; (Chapman), 10367. Guarantee that no gas coke used (Expert Committee), Appendix 19, p. 204.

In respect of sulphuric acid, colouring matters, and chemical substances used in food: (Lyle), 11045-9; 11132-5; (Howell), 11195-9, 11247-9; (Walker), 11312-24, 11349-59; (Palmer), 11492-6; (Prunk), 11453; (Appendix 24), p. 235.

See also WARRANTY, OFFICIAL CONTROL.

## HAIR:

Arsenic in, in cases of arsenical poisoning (Reynolds), 8292-3, 8298-8306, 8350-2, 8448-9. In hair of rats receiving arsenic (Delépine), Appendix 16, p. 188. In cases of beri-beri (Reynolds), 8381, 8389-91; (Appendix 31), pp. 333-4, 344.

## REPORTS ON ARSENIC IN HAIR, IN APPENDIX 32:

Part I.: General account of Commission's inquiry and tables giving analysis of chief results: Preliminary specimens; specimens from arsenic takers; control specimens; specimens from brewers' draymen and alcoholic neuritis cases, pp. 345-350.

Part II.: Mr. Wood Smith's report on methods of testing hair samples, p. 351.

Part III.: Detailed tabular statements, pp. 352-62.

## HALIFAX, ARSENICAL POISONING AT, IN 1902:

## DR. E. S. REYNOLDS:

Arsenical poisoning from beer in 1902 at Halifax, 8403-8442.

## MR. H. HAMMOND SMITH:

Origin of his inquiry as Assistant Commissioner; cases reported in infirmary; inquest on McNulty, etc., 8628, p. 15.

Details and symptoms of Infirmary cases: Case in private practice. Review of cases; outbreak one of arsenical poisoning, p. 16. Other cases suspected both in and outside the Infirmary, 8628-34, 8719. Dr. Woodyatt's view of outbreak, 8635, 8710.

Beer implicated; local inquiry and action with regard to outbreak, 8628, p. 16. Analyst's results, p. 17. Attitude of brewers, 8628, 8800-4. The Halifax brewery implicated during 1900 epidemic had destroyed their beer, 8746-9.

Inquiry as to suspected beers; origin of ingredients used; source of arsenic, 8628, pp. 18-20, 8640.

Malt seldom tested for arsenic: Malts used in implicated brews prepared in 1900-1 season mainly by use of local gas coke. Greater care since taken in most instances, 8628, p. 21, 8665-6.

Evidence implicating gas coke dried malt as the cause of outbreak, 8628, p. 21; 8647-744. Mr. Firth's malt previously found to contain 1-30th grain arsenic per lb., 8647-8660. Inadequacy of brewers' precautions since Manchester scare subsided, 8669. Little or no testing by maltsters for sale, 8695.

Maltsters abandoning gas coke, 8724-7. Brewers demanding malt prepared with anthracite, 8728-9. Maltsters who continue to use gas coke, 8741, 8764.

Halifax Town Council and Medical Officer of Health's report, 8701. During 1901 no samples of beer submitted to public analyst, 8702; or at Huddersfield, 8829. Halifax public analyst used test first recommended by Brewers' Expert Committee, 8833-6. Brewers' records of analyses not kept systematically, 8706-9.

No action by local Excise officers as to arsenic before outbreak, 8837.

Representations made to Coroner on behalf of brewers, 8839-8843.

Dregs of casks containing much arsenic, 8844.

## HALIFAX, ARSENICAL POISONING AT, IN 1902—continued

PROFESSOR THORPE'S MEMORANDUM on Halifax beers and brewing materials tested for arsenic at the Government Laboratory. (Excise samples and special samples obtained by Mr. Hammond Smith.) Results. Arsenic in urine of Halifax patients, 8847.

## MR. G. S. THOMPSON:

Evidence in respect of Whitaker's brewery. Observations on Mr. Hammond Smith's report, 8849-63, 8900. Recent precautions against arsenic, 8901, 8938-41, 9044-54. Malting fuels used, oven coke substituted for gas coke, 8901-8, 9055-64. Gas coke, 85 per cent. used before outbreak, 8933-7.

Construction of Messrs. Whitaker's kilns claimed to safeguard against arsenic, 8864-8882, 8936-9023, 9065-81. No recent change in their construction, 8883. Arsenic in kiln dust, 8954-8, 9009-9016; cleansing girders, etc., 9017. Brushing of malt, 8888-90, 8942-9, 9082-9; found to remove arsenic, 8950-3.

Extent of analyses of beer and malt and results, 8909-32, 8973-85, 9023-35. Recommendations of Brewers' Expert Committee not adopted at this brewery, 9060-4. Formation of Brewers' Association in Halifax, 8858.

## DR. J. T. NEECH:

Evidence by Borough Medical Officer of Health. Observations on Mr. Hammond Smith's report, 9092-6. Notes of five additional cases, 9097. Cases were arsenical poisoning, 9096, 9111-2; due to malt, 9123.

Difference between malts of 1900-1 and 1901-2 seasons, 9114-9120. Implicated beer from 1900-1 malt, dried over gas coke, 9121-7.

McNulty's case: Dr. Woodyatt's evidence at inquest, 9146-55; Lee's case, Dr. Woodyatt's evidence, 9156-67; other infirmary cases, 9168-91. Whalan's case one of arsenical poisoning, 9174-82.

No samples of beer taken under Sale of Food and Drugs Acts between Manchester scare and present outbreak, 9193-9200. Action by Medical Officer of Health regarding outbreak: beer samples taken, reports by Mr. Ackroyd (public analyst), and by Mr. Richardson, 9202-12; difficulties owing to divergent results, 9107, 9257. M.O.H.'s inquiries outside Halifax, 9218-9; given facilities by Halifax brewers, 9220-3; samples taken at breweries, etc., 9230-1; no powers to take malt officially under Sale of Food and Drugs Acts, 9224-9, 9246-51. M.O.H.'s report to Town Council, 9214-6, 9238-40.

Arsenical poisoning in Halifax during 1900 epidemic, 9128.

## MR. F. BUCKLEY:

Evidence in respect of Webster's brewery. Extent of analyses made in 1901 for brewery, 9268-74; and since outbreak, 9275. Precautions taken against arsenic, 9281. Divergent results of analyses in a recent instance, 9300-3, 9318-46. Chemist of brewery is public analyst of Halifax, 9389.

Implicated beer made from gas-coke malt, 9276-7, 9348-9350. Kinds of fuel used, gas coke now abandoned, 9293-9, 9368-84. Brushing malt practised, but no experiments as to its effect on arsenic, 9282, 9351-6. Construction of his malt kilns, 9358-67. Contamination of malt by kiln dust, 9412-9.

Formation of Brewers' Association in Halifax, 9287-90.

## MR. A. WORSICK:

Evidence in respect of Worsick's maltings. Precautions adopted since 1900 epidemic; anthracite substituted for gas coke; malt brushed, etc., 9425-37; precautions have reduced arsenic, 9441; advantage of brushing, 9457, 9488-90. Construction of his kilns and their cleansing, 9478-83.

Some gas coke used in 1900-1 season, 9451; possible use of gas-coke malt in August, 1901, at Alderson's brewery, 9463-70.

## DR. J. F. WOODYATT:

Cases in Halifax Infirmary, 1902; arsenical poisoning diagnosed in certain cases but not in others, 9501-9641.

HALIFAX, ARSENICAL POISONING AT, IN 1902—*continued*.Dr. J. F. Woodyatt—*continued*.

Case of McNulty, 9508-10; inquest, 9545-60; Whalan, 9511-3; diagnosis of "pernicious anemia" in his case, 9572-92, 9652; and certificate of death given by witness to that effect, 9606; no post mortem, 9599; inquest in this case undesirable, 9619; Dr. Mantle consulted, 9593, 9508-14, 9624-8; after communication with brewers, 9594-5; evidence of arsenical poisoning in Whalan, 9598, 9615; Lee, 9563, 9571; statement to Coroner of cause of his death, 9564; Wilkinson, 9538; Shearing, 9541; Lowrie, 9543, 9639.

Cases not reported to M.O.H. of Halifax, 9633. Opinions regarding outbreak, 9552-3.

Mr. T. Fairley:

Arsenic in Halifax beer, 9923.

## HEART:

"Alcoholic heart," no longer observed in Manchester since 1900 epidemic (Reynolds), 8288, 8322-7.

## HOPS:

In relation to risk of contamination by arsenic (Thorpe), 8847; (Thomson), 9669; (Primrose), 11847; (Expert Committee), Appendix 19, pp. 202, 204. "Hop Compo" (Primrose), 11879-93.

## HYDROCHLORIC ACID:

Arsenic in (Fairley), 9824; (Appendix 24), p. 231; use of, for food purposes (Appendix 24), pp. 231, 243-4.

Purification of, for testing purposes (Thomson), 9741; (Hehner), 10116, 10129; (Appendix 20), p. 206; (Appendix 21), p. 212; (Appendix 22), p. 220.

## INDUSTRIAL POISONING BY ARSENIC:

Various forms of, occurrence, and symptoms; reports on to Home Office, etc. (Legge), 11738-11843.

## INLAND REVENUE, BOARD OF:

## RECENT ACTION BY, IN RELATION TO ARSENIC IN BEER:

Issue of Treasury Order under 1888 Act, prohibiting arsenical glucose and invert sugar, October, 1901; instructions to Revenue officers thereon; samples of various brewing ingredients, worts etc., obtained; results of analyses in Government Laboratory (Primrose), 11844-51.

Action taken in certain cases, on report of arsenic in malt, malto-peptones, "regenerators," beer softening material, glucose, colouring solutions, caramel, "hop compo." (Primrose), 11852-95. See also HALIFAX.

Appointment of Committee on Tests (Primrose), 11896-9; question of utilising their report for purpose of "standards" (Primrose), 11896-9, 11940-58. See also DEPARTMENTAL COMMITTEE.

Extent to which Inland Revenue control could be utilised for protection against arsenic (Primrose), 11900-23; (Moulton), 9939-46; (Salamon), 9989-93, 10072-82; should be limited to breweries and brewing trade (Primrose), 11903-4. Revenue officers no power of entry on maltster's premises, 11954. No increase of staff required in consequence of recent action, 11963-7.

Revenue officers now take samples from factories of brewers' glucose and "invert" (Primrose), 11847; (Lyle), 11060-2; visit his works, re rebate on essences (Howell), 11237-9; do not visit (Walker), 11360-1.

## INSECTICIDES:

Use of, in relation to contamination of fruit and vegetables by arsenic; experimental application of Paris green to gooseberry bush (Appendix 24), p. 251.

## INVERT SUGAR:

Use of, in brewed "temperance" drinks, cider, etc. (Appendix 24), pp. 236, 241. Confectioners' sugar not "inverted" by mineral acid, p. 240.

INVERT SUGAR—*continued*.

Recent analyses for arsenic of brewers' samples (Thorpe), 8847; (Thomson), 9669; (Primrose), 11847. Treasury order prohibiting use of arsenical invert in preparation of beer, and consequent sampling (Primrose), 11844-7; (Lyle), 11060-2. Analyses by Expert Committee (Appendix 19), p. 201.

## IRON:

Reduced iron of British Pharmacopoeia, arsenic in (Reynolds), 8456-8462.

Iron oxide in food, See COLOURING MATTERS.

Iron salts impairing estimation by Marsh Test, See TESTS.

## JOINT COMMITTEE OF SOCIETIES OF PUBLIC ANALYSTS AND CHEMICAL INDUSTRY.

Appointed to investigate tests for arsenic: work by, report, and recommendations (Hehner), 10092-10225; (Chapman), 10226-372. Report (Appendix 20), pp. 206-7; discussed at joint meeting of societies (Hehner), 10094; opinion of Society of Public Analysts also obtained by circular (Chapman), 10223; general favourable opinion of the Marsh-Berzelius method recommended (Hehner), 10109; objections mainly in respect of minor details of procedure (Chapman), 10228; Hehner, 10115-8. Use by chemists of methods recommended (Ling), 10469; (Allen), 11976-80; (Appendix 21), p. 212; (Appendix 22), p. 220; (Appendix 27), p. 277.

## KERATIN:

Affinity of, for arsenic (Appendix 24), p. 252.

## KERATOSIS:

None seen in Manchester patients since 1900 epidemic (Reynolds), 8287; arsenic in keratosis scales (Reynolds), 8296-7. In Halifax cases (H. Smith), 8628, p. 16.

## KILNS:

Structure, cleansing, etc., in relation to arsenic. See MALT.

## LANOLINE:

Use of as a substitute for cocoa-butter; found arsenical, due to sheep-dip (Appendix 24), p. 240.

## LEMONADE POWDERS, "FRUIT CRYSTALS," &amp;c.:

(Appendix 24), p. 242; (Appendix 25), p. 266.

## LIME:

Addition of, to coke or other fuel used in malt drying, in order to "fix" the arsenic (Ling), 10440-708; (Buckley), 9316.

Use of, in malt kilns, to absorb volatilised arsenic (Beaven), 10787, 10818-32; use of heated limestone blocks as absorbents (Appendix 18), p. 199.

Use of, in estimation of arsenic in organic substances. See TESTS.

## "LIQUID TARTARIC ACID":

Contains little or no tartaric acid (Howell), 11201.

## LIQUORICE:

Arsenic in certain samples (Thomson), 9794-6; its possible origin (H. Smith), 10912 (Appendix 24), p. 241; analysis of four samples (Appendix 25), p. 267.

## LIVER:

Arsenic found in, in fatal case at Halifax (H. Smith), 8628, p. 14; in liver of beri-beri cases (Appendix 31), pp. 333, 342.

## LOCAL GOVERNMENT BOARD:

Relation of, to administration of Sale of Food and Drugs Acts, etc. See ANALYSTS, FOOD AND DRUGS ACTS, OFFICIAL CONTROL.

**MAIZE:**

Flaked maize found free from arsenic (Thorpe), 8847; (Primrose), 11847; (Appendix 19), p. 202.

**MALT:****ARSENIC IN MALT:**

Responsible for contamination of beer sufficient to cause illness (Reynolds), 8357; medical evidence (Moulton), 9951. Responsible for Halifax outbreak, 1902. See HALIFAX.

Quantity of arsenic in malt (H. Smith), 8628, 8650-61; (Thorpe), 8847; (Thomson), 9669, 9691, 9758-64; (Fairley), 9820-9, 9853-7; (Salamon), 9982, 9994-5; (Chapman), 10282-4; (Ling), 10536, 10684; (Beaven), 10869-82; (Primrose), 11847-52; (Appendix 19), p. 203.

Recent improvement in malts (Reynolds), 8353; (Worsick), 9441-2; (Thomson), 9706-7; (Salamon), 9977, 9994-5; will not be maintained without official control regarding arsenic (Ling), 10596-7.

More arsenic in northern malts in 1900-1 (Moulton), 9948; at Halifax, more than in 1901-2 (H. Smith), 8628, 8665-9; (Neech), 9113-24; (Buckley), 9276.

Increase of arsenic in malt as season progresses (Ling), 10693-5.

Unequal distribution of arsenic in malt (Thomson), 9699-9700. Sampling malt (Salamon), 10065-7; (Chapman), 10337-40.

Analyses of malt for brewers and maltsters. Few or none at Halifax (H. Smith), 8628, 8668-95, 8805-25; (Thompson), 8909-16, 9031-41; (Buckley), 9267-74. Analyses for maltsters (Worsick), 9424-36. Frequent analyses for certain breweries (Thomson), 9675, 9719-21; (Fairley), 9824; (Salamon), 10067-8; (Chapman), 10282.

See also FUELS.

**PREPARATION OF MALT:**

Fumes of fire should not pass through malt (Thomson), 9697-8, 9701-2, 9771-8. This would involve great interference with trade (Salamon), 9980, 10048; (Ling), 10612; (Beaven), 10836-42. Products of combustion necessary for flavour (Salamon), 9980; (Beaven), 10735-71; may not be essential (Ling), 10605-13.

**MALT KILNS in relation to arsenic:**

Structure of Kilns (Beaven), 10709-910; kilns in which drying largely effected by hot air without fumes, 10733-4, 10897-10; furnace gases, 10713-34, 10771-5; use of screens for condensing arsenic, 10775-86; use of lime to intercept arsenic, 10787-832, 10844-8, and Appendix 18, p. 199. Construction of Messrs. Whitaker's kilns (Thompson), 8864-9081.

Cleansing of Kilns (H. Smith), 8754; (Thompson), 8894-8; (Buckley), 9304-7; (Worsick), 9480-3; (Fairley), 9861, 9920; (Salamon), 9987, 9996; (Ling), 10693-6.

**KILN DUST, arsenic in:**

(H. Smith), 8752-3; (Thompson), 8955; (Buckley), 9305; (Salamon), 9988. From various parts of kiln (Fairley), 9859-60, 9905. Present as arsenious oxide (Fairley), 9912-3. Risk to malt from dust carried mechanically is small (Ling), 10570-3. Volatilisation of arsenic (Thorpe), 11691-4.

**BRUSHING in relation to arsenic:**

(Thomson), 9780; (Fairley), 9863-4; (Salamon), 10018-24. Effect of moisture (Neech), 9130-45. Brushing in the case of Halifax malts (H. Smith), 8628, 8795-9, 8810; (Thompson), 8942-53, 9082-9; (Buckley), 9277-83, 9353-6; (Worsick), 9425, 9457-62, 9488-90.

**MALT CULMS:**

Arsenic in (Neech), 9138; (Salamon), 9987; (Overbeck), 11297; (Appendix 19), p. 203; (Appendix 19), p. 204.

**MALTED FOODS:**

Various foods of which malt is an ingredient (Appendix 24), p. 245, largely imported; no knowledge of precautions against arsenic in their manufacture (H. Smith), 10935; no information available in the case of maltine made in America, 11496, and Appendix 26, p. 276. Four samples free from arsenic (Appendix 25), p. 262. Arsenic in "Carnos," p. 262.

**MEDICAL OFFICER OF HEALTH:**

Powers of, with regard to condemnation of arsenical products (Neech), 9224-51; (Lithiby), 11497-512; 11548-9; 11580-3.

See also FOOD AND DRUGS ACTS, OFFICIAL CONTROL.

**MINERAL WATERS:**

(Appendix 24), p. 241.

**NASAL SEPTUM:**

Perforation of, through exposure to arsenical dust (Legge), 11779-82.

**NEURITIS:**

Seldom a symptom of industrial poisoning by arsenic (Legge), 11754.

Rarity of neuritis caused by alcohol without arsenic (Reynolds), 8338.

In rats receiving arsenic for considerable periods (Delépine), 10006 (Appendix 16), p. 191.

See also ALCOHOLIC NEURITIS, HALIFAX.

**OFFICIAL CONTROL:**

IN RESPECT OF DELETERIOUS SUBSTANCES, ETC., IN FOOD:

Precautions against arsenic will become lax unless official control exercised (Ling), 10576-82, 10596-7; (Thomson), 9782-3; (Allen), 12037.

POWERS OF ENTRY, SAMPLING, ETC., ON PREMISES OF FOOD MANUFACTURER:

In general, Medical Officers of Health and other local officers have no such powers (Lithiby), 11508-9, 11533, 11548-55, 11608. Facilities may be given to M.O.H. notwithstanding absence of powers (Neech), 9220-30, 9246-51 (Lithiby), 11580-3. No powers in respect of new preparations, or new methods of manufacture, of food (H. Smith), 10950; (Lithiby), 11568-76.

Exist in certain instances, Bread Act, 1836; Revenue Acts; Margarine Act; Horseflesh Act; local Acts (ice-cream, etc.) (Lithiby), 11510-1, 11533-4.

By Revenue officers where articles subject to duty (Lyle), 11060-2; (Howell) 11237-9; (Walker), 11360-1; (Primrose), 11844-923; no powers on maltsters' premises (Primrose), 11954.

POWERS OF SEIZURE AND CONDEMNATION of contaminated food or food ingredients:

Powers under Public Health Acts (Lithiby), 11510, 11562-4. In general, no power when article not on sale, 11512, 11547-9, 11610-2. Duties of Medical Officer of Health in relation to unsound food, 11514-5, 11547-9.

No power to lay an embargo on suspected food, etc., pending analysis (Lithiby), 11613-5.

CONTROL UNDER SALE OF FOOD AND DRUGS ACTS:  
See FOOD AND DRUGS ACTS.

RESPONSIBILITY OF VENDOR OF FOOD UNDER COMMON LAW:

(Lithiby), 11518-9, 11520-9.

SUGGESTED POWERS OF INSPECTION AT PLACE OF MANUFACTURE:

Question of providing official control respecting purity of food ingredients, etc., and methods of manufacture (H. Smith), 10298, 10932-3, 10950-63; (Lyle), 11060-3, 11141-7; (Howell), 11241-2; (Overbeck), 11286-7; (Walker), 11336-8; (Allen), 12012, 12046-7, 12071. Objections to (Lithiby), 11519, 11530-1; especially if powers given to

## OFFICIAL CONTROL—continued.

Suggested Powers of Inspection at Place of Manufacture—continued.

officers of local authorities, 11533-6, 11565-76, 11605. Less objection by manufacturers to officers of Government Departments (Lithiby), 11602-4; (Legge), 11838-43. Many manufacturers would not object to inspection (H. Smith), 10960-2.

Suggested schedule of dangerous foods or ingredients (H. Smith), 10332-8; (Lithiby), 11517, 11519, 11651. Prohibition of arsenical sulphuric acid and of use of gas coke in malting advocated (Salamon), 10009, 10086-7.

## SUGGESTED OFFICIAL "STANDARDS":

In respect of arsenic in various ingredients of food; relation of "standards" to prescribed methods of testing; principles on which official limits and tests should be prescribed; extent to which they might be "advisory" or penal (Thomson), 9770, 9309-15; (Moulton), 9935-45, 9950-63; (Salamon), 10007-8; (Chapman), 10290-1, 10318-51; (Ling), 10668-82; (H. Smith), 10928-49; (Thorpe), 11720-37; (Primrose), 11931-50, 11956-8; (Allen), 12061, 12069, 12072-7.

B.P. "standards" as to arsenic at present of little service to food manufacturer (H. Smith), 10912-8; (Appendix 24), pp. 240-3; (C. Brown), pp. 255-7.

"Standards" for purposes of Sale of Food and Drugs Acts. See FOOD AND DRUGS ACTS.

Authority by which standards might be prescribed. See BOARD OF REFERENCE, INLAND REVENUE.

## ORGANIC MATTER:

Considerations as to possible combination of arsenic with organic matter of beer (Delépine), 10380-4; in the case of stale beer (Hehner), 10219-25; as to organic combination in plant tissue (Angell), 8514-8; 8610-20; (Fairley), 9876; (Voelcker), 12118.

Advantage or necessity of destruction of organic matter in beer and various organic substances preliminary to "Marshing" (Angell), 8472-518; (Thomson), 9688-9, 9755-7; (Hehner), 10132-9, 10179-85; (Chapman), 10262-71; (Voelcker), 12139; (Appendix 20), p. 207; (Appendix 21), p. 213; (Appendix 22), p. 223; (Appendix 32), p. 351. Importance in case of coal tar colours (Appendix 22), p. 223; (Appendix 25), p. 268; (Appendix 27), p. 277.

Destruction unnecessary when beer and wort are tested electrolytically (Thorpe), 11658-9; (Appendix 21), p. 212.

## OXIDE OF IRON:

Arsenic in, and use of in various foods (Hehner), 10210, and Appendix 27, p. 277; (Pronk), 11444; (Appendix 24), pp. 234, 237.

## PARIS GREEN:

See EMERALD GREEN.

## PHARMACOPŒIA, BRITISH:

Official tests for arsenic (H. Smith), 10912-8; (Appendix 24), pp. 230-3; (C. Brown), pp. 255-7.

## "PHOSPHOCITRIC" ACID:

Contains very little citric acid (Howell), 11201; (Appendix 24), p. 232. Use in aerated waters (Appendix 24), p. 241.

## PHOSPHORIC ACID AND PHOSPHATES:

Arsenic in (Appendix 24), pp. 231-2; (Appendix 25), p. 265. Use of phosphates, under various names, in foods (Appendix 24), pp. 238-243; (Howell), 11167-9, 11201, 11256; (Palmer), 11470, 11492.

Purity attainable commercially, in case of phosphoric acid (Lyle), 11042-4, 11095.

Arsenic in phosphates used as manure. See VEGETABLES.

4576.

## PIGMENTATION:

As a symptom of poisoning by arsenic and observed during epidemic; less seen since epidemic; pigmentation attributed to vermin may have been arsenical (Reynolds), 8297-95, 8326-9. In Halifax cases (H. Smith), 8628, p. 16; (Woodyatt), 9506.

## PLANTS:

Grown on arsenical soil. See VEGETABLES.

## POST-MORTEM EXAMINATIONS:

In Manchester cases (Reynolds), 8429; (Delépine), Appendix 16, p. 189; in Halifax cases (H. Smith), 8528.

## POULTRY:

Use of arsenic in fattening (Smith), 10997-11005. Experimental administration of arsenic to fowls; analyses, little arsenic in flesh and liver, considerable amount in feathers. (Appendix 24), p. 252; (Appendix 25), p. 273.

## PRESERVATIVES:

In beer (Primrose), 11847; (Appendix 19), p. 202.

Boron preservatives in relation to arsenic (Appendix 24), pp. 233, 248; (H. Smith), 10934; (Howell), 11224; (Appendix 25), p. 265.

## PYRITES:

Formation of, in coal (Thorpe), 10708. Presence, appearance, and distribution in anthracite, and analyses (Appendix 30), pp. 288-321; (Ling), 10490-523. Proportion of volatile arsenic (Ling), 10547-59; (Appendix 30), p. 290.

## QUANTITIES OF ARSENIC DETERMINED:

## IN BEER:

In recent beer in Manchester (Reynolds), 8444; in Halifax beers, 1902 (H. Smith), 8628, pp. 14, 17; 8649; (Thorpe), 8847; (Buckley), 9318-46; (Fairley), 9925; in various samples of beer and brewing ingredients (Thomson), 9669, 9758; Fairley, 9834-52; (Chapman), 10277; (Primrose), 11847.

## IN MALT:

(H. Smith), 8623, 8650; (Thorpe), 8847; (Thomson), 9669, 9691, 9758-64; (Fairley), 9820-9, 9853-7; (Salamon), 9982, 9995; (Chapman), 10282-4; (Ling), 10536, 10684; (Beaven), 10869; (Primrose), 11847-52.

## IN OTHER FOODS AND INGREDIENTS:

See under several headings.

## RATS:

Action of arsenical beer and other solutions administered in small quantities to. Experiments by Prof. Delépine: alterations during life of experimental animals; estimation of arsenic in tissues after death; pathological appearances; general summary of results; note on development of paralysis in experimental animals; tabular statements. Delépine, Appendix 16, pp. 183-195; 10388-424; deductions as regards human subject (Delépine), 10389-93.

## REBATE OF DUTY:

None claimed since 1900 epidemic in respect of arsenical beer destroyed (Primrose), 11961.

## RICE:

Possibility of contamination of, by arsenic; use of arsenic on rice fields (Reynolds), 8581-6. Amounts of arsenic in rice taken by beri-beri cases in Kuala Lumpur, and on ships, very small, if any (Appendix 31), pp. 332, 334.

## ROOTS:

Grown on arsenical soil, arsenic in.

See VEGETABLES.

## SAMPLING FOR ANALYSIS:

## IMPORTANCE OF CAREFUL SAMPLING, AND DIFFICULTIES:

*In the case of Malt*:—(H. Smith), 8656-7; (Thomson), 9699; (Salamon), 10065; (Chapman), 10337-40; (Ling), 10681-2.

*In the case of Fuels*:—(Thomson), 9787-9; (Salamon), 10064; (Chapman), 10353; (Ling), 10490-679. System adopted in collecting samples for Commission (Appendix 30), p. 287, 290, 308-9.

## SCHEELE'S GREEN:

See EMERALD GREEN.

## SHALE:

Presence of, in anthracite seams, much arsenic in some specimens (Ling), 10494-7; (Appendix 30), pp. 289-295.

## SMOKED AND DRIED FOODS.

Process of drying over gas coke introduces scarcely any arsenic into bloaters, hams, etc. (H. Smith), 10990-4; nature of foods so dried (Appendix 24), pp. 249-50; analyses (Appendix 25), p. 269-72.

See also CHICORY.

## SOIL:

Arsenic in cultivated soil, and manuring with arsenical super-phosphates. See VEGETABLES.

## SPIRITS:

Analyses of whiskey and gin for mineral acids and for arsenic. Results negative (Appendix 28), pp. 278-80; (Allen), 12020.

## "STANDARDS":

As regards arsenic and other impurities and adulterations of food, for purposes of Sale of Food and Drugs Acts, and of manufacturers.

See FOOD AND DRUGS ACTS, OFFICIAL CONTROL.

## SUGAR:

Arsenic in certain samples of "Demerara" or West India sugar, possibly due to phosphoric acid or chloride of tin (Appendix 24), p. 239; (Lyle), 11064-6; uncommon, and avoidable (Lyle), 11067-8; analyses of ten samples (Appendix 25), p. 263.

In German beet sugar, attributed to lime or strontia process (Hehner), 10208-9.

## SULPHITES:

(Ling), 10635-6; (Appendix 20), p. 207; (Appendix 21), p. 215; (Appendix 24), pp. 235, 248.

## SULPHUR:

In fuel, in relation to arsenic (Fairley), 9896-9904. Arsenic in (Appendix 21), p. 215.

## SULPHURIC ACID:

Price of different kinds of (Salamon), 10009; (Appendix 24), p. 230.

No evidence of its addition to spirits (Appendix 28), p. 278; (Appendix 24), p. 231; (Allen), 12020.

Should be penal to use arsenical acid for food purposes (Salamon), 10009.

Use of, in preparation of various foods and ingredients (Appendix 24), pp. 230-248. Precautions by manufacturers of treacle and syrup in purchasing, p. 238; (Lyle), 11032-41, 11077-95.

Commercially attainable free from arsenic by delicate tests (Salamon), 10009; (Lyle), 11032-41; (Howell), 11229; (Appendix 20), p. 206; (Appendix 22), p. 220; (Appendix 25), p. 275; (Appendix 32), p. 351.

Purification of, for testing purposes (Thomson), 9747; (Appendix 20), p. 206; (Appendix 22), p. 220.

## SUPERPHOSPHATES:

Arsenical, effect upon plants.

See VEGETABLES.

## SUSCEPTIBILITY TO ARSENIC:

(Neech), 9264-5; (Reynolds), 8373-7; 8447; (Moulton), 9931; (Delépine), 10390-418.

## SWEETS:

See CONFECTIONERY.

## SYMPTOMS:

Of poisoning by arsenic in beer (Reynolds), 8287-8388.

See also HALIFAX.

Of industrial poisoning by arsenic (Legge), 11733-11843.

## SYRUP, GOLDEN AND TABLE, AND TREACLE:

Manufacture of golden syrup and treacle; precautions taken against arsenic (Appendix 24), p. 238; (Lyle), 11028-11160. Use of golden syrup in certain biscuits, etc. (Appendix 24), p. 245; (H. Smith), 10954.

"Table" and other syrups, consisting largely of glucose; precautions taken, or neglected, by manufacturers in obtaining glucose used (H. Smith), 10953-4; (Appendix 24), p. 238, 235-6; (Walker), 11308-61.

Fruit syrups (Appendix 24), p. 242.

## BOSTOCK'S TABLE SYRUP.

Manufacture, sale, and disposal of amount of arsenic in (H. Smith), 10971-82; (Appendix 25), p. 265.

## TARTARIC ACID:

Preparation of, in relation to arsenic; selection of acid and treatment with sulphuretted hydrogen by Bennet, Lawes and Co. (Appendix 24), p. 232. Retail sale of (Howell), 11172, 11212-8. Analyses (Thomson), 9659, 9758.

Use in confectionery, baking, and beverages (Appendix 24), pp. 240-3; no arsenic in various "fruit and lemon crystals," etc. (Appendix 24), p. 242; (Appendix 25), p. 266.

## TESTS FOR ARSENIC:

*Reports and Evidence as to Marsh-Berzelius method, as applied to various substances*:—

## MR. W. THOMSON'S DESCRIPTION OF METHODS:

Apparatus, and preliminary treatment of various substances (Thomson), 9688-9; diagram, p. 200. Delicacy of test after destruction of organic matter, 9686, 9755-7. Size of flask, 9735. All arsenic present recovered in mirror, 9736.

## REPORT OF "JOINT COMMITTEE" ON ARSENIC (IN APPENDIX 20):

Materials employed: Hydrochloric, sulphuric, nitric acids, zinc, lime, calcium chloride. Apparatus. Mode of testing. Preparation of standard mirrors. Destruction of organic matter (acid and basic methods). Fuel. Sulphites. Procedure without destruction of organic matter. Delicacy of method (Appendix 20), pp. 206-7; (Hehner), 10092-10225; (Chapman), 10225-10372; (Ling), 10469; (Allen), 11976-80.

## REPORT OF INLAND REVENUE DEPARTMENTAL COMMITTEE (IN APPENDIX 21):

Application of Marsh-Berzelius (zinc and acid) method to various substances used in brewing. Materials employed: Zinc, hydrochloric acid, fuming nitric acid, copper sulphate. Preparation for test of malt (basic and acid methods); malt substitutes; wort (basic and acid methods); hops; beer; yeast and yeast foods; chemicals; finings; fuel. Mode of working; preparation of standard mirrors (Appendix 21), pp. 212-219; (Thorpe), 11654-737.

## TESTS FOR ARSENIC—continued.

## DR. MCGOWAN AND MR. FINLOW'S DESCRIPTION OF METHODS (IN APPENDIX 22):

Methods of testing various foods and other samples received from Commission. Purification of reagents, hydrochloric, sulphuric, nitric, sulphurous acids, carbonate of ammonia, potassic chlorate, zinc, etc. Method of estimation, "Marsh" apparatus used, with hydrogen from outside generator. Method of working, preparation of standard mirrors. Methods employed for the extraction of arsenic before "Marshing." Destruction of organic matter by Fresenius-Babo method, Gautier's method, basic method. Suggested simplification of Gautier's method (Appendix 22), pp. 220-6. See also (Appendix 25), pp. 262-275, (Appendix 31), pp. 335-344.

## DR. MCGOWAN AND MR. FLORIS: METHODS IN TESTING FUEL (IN APPENDIX 23):

Preliminary experiments: Method of estimating "total" and "fixed" arsenic; preparation of standard mirrors, (Appendix 23), pp. 227-9.

## MR. WOOD SMITH: METHODS OF TESTING HAIR FOR ARSENIC:

Account of methods (Appendix 32), p. 351.

## OTHER REFERENCES TO USE OF MARSH-BERZELIUS TEST (Angell), 8472-518; (Fairley), 9852, 9882-83; (Salamon), 10007; (Lyle), 11051-4; (Allen), 11975-87.

Preferable to Reinsch test for skilled chemists (Salamon), 9968. Unskilled man can be trained to use (Hehner), 10167-8.

## MIRRORS:

Comparison of mirrors obtained when hydrochloric and sulphuric acids are used respectively (Angell), 8481-2; (Thomson), 9749-50; (Fairley), 9885-8; (Hehner), 10179-82.

Time allowed for deposition of mirror (Angell), 8512; (Thomson), 9736. "False mirror" (Angell), 8506; (Appendix 29), p. 285. Action of light on mirrors (Thorpe), 11706-10. All arsenic recovered in mirror (Thomson), 9736-7; probably so (Hehner), 10139.

Effect of volume of liquid, etc., on mirror formed (Hehner), 10141-4; (Ling), 10470-3. Margin of experimental error (Hehner), 10146; (Chapman), 10369-72; (Allen), 12040-1; (Appendix 22), p. 222.

Preparation of "standard" mirrors with arsenic-free samples of material tested (Appendix 21), p. 214; (Thorpe), 11687-90; (Appendix 22), pp. 222-5; (Appendix 23), p. 229.

## ZINC:

(Angell), 8475; (Thomson), 9750-4; (Fairley), 9882-8; (Hehner), 10096-7, 10105, 10119, 10129; (Chapman), 10236-49; (Thorpe), 11666-74; (Appendix 20), p. 207; (Appendix 21), p. 212; (Appendix 22), p. 221; (Appendix 32), p. 351.

## PRESENCE OF IRON AND OTHER METALS:

Effect on "Marsh" estimations (Thomson), 9689, 9752-4; (Hehner), 10102; (Chapman), 10236-51, 10299-304; (Ling), 10486-9, 10645; (Appendix 22), p. 225; (Appendix 23), p. 227.

## DESTRUCTION OF ORGANIC MATTER. See ORGANIC MATTER.

## DETERMINATION OF ARSENIC IN FUEL:

Basic method (Ling), 10451-89, 10646; (Appendix 23), pp. 227-9; (Appendix 30), p. 311.

Oxygen method (Appendix 22), pp. 210, 214; (Thorpe), 11691-719.

## Reports and Evidence as to Electrolytic Method:—

Possible advantages of electrolytic method (Hehner), 10098-10108; (Chapman), 10252-8. Advantages found by Departmental Committee, (Thorpe), 11656-85. Now preferred at Government Laboratory, 11682. Delicacy, 11675-81.

## REPORT OF INLAND REVENUE DEPARTMENTAL COMMITTEE (IN APPENDIX 21):

Description of apparatus. Application to malt, malt substitutes, wort, hops, beer, yeast and yeast foods, chemicals, fuel. Mode of working. Preparation of standard mirrors. Advantages of method (Appendix 21), pp. 208-212.

4576.

## TESTS FOR ARSENIC—continued.

## Reinsch Method:—

Use of, for beer and other samples. Quantities of arsenic detected by (Fairley), 9820-9, 9879-80; (Salamon), 9968-73, 10026, 10036-47; (Hehner), 10109-13; (Appendix 19), p. 204. Unsatisfactory for quantitative estimations (Thomson), 9738-9, 9806-7; (Hehner), 10127. See also EXPERT COMMITTEE.

Quantitative estimation by extracting arsenic by means of copper gauze (Allen), 11975.

Quantitative estimation by comparison of sublimes, (Delépine), 10375-80, 10425-39.

## Gutzwiller Method:—

Not reliable for quantitative estimations, (Thomson), 9740. Uncertain value of B.P. test for arsenic in glycerine (C. Brown), pp. 255-6.

## THYROID GLAND:

Gautier's statements as to presence of arsenic in require confirmation (Reynolds), 8307-12.

## TOLERANCE OF ARSENIC:

(Reynolds), 8375-7; (Delépine), 10411-13; (Legge), 11738-43.

## TREACLE:

See SYRUP.

## TUBERCULOSIS:

Chronic poisoning by arsenic increases susceptibility to; many fatal cases in 1900 epidemic died from (Reynolds), 8315-7; 8424-31.

## URINE:

Arsenic in (Reynolds), 8363-6, 8450-4; (H. Smith), 8628, p. 16; (Thorpe), 8847, p. 31; (Woodyatt), 9515.

## VEGETABLES:

Arsenic in various vegetables when grown on soil containing arsenic or manured with arsenical superphosphates.

Opinion that barley and roots may be contaminated in that way (Salamon), 9999-10006; 10013-17. Effect of ferruginous soil on absorption of arsenic, 10056-8.

## MESSRS. A. AND A. F. ANGELL'S EXPERIMENTS AND RESULTS (8463-8627).

Mode of applying the manure to experimental plants, 8470-1, 8485, 8526-35, 8603. Nature of experimental plants and results, 8524. Places of experiment, 8593-5. No arsenic in ripened fruit or grain, 8541, 8555; traces of arsenic found in some roots and young leaves, and in green pods, 8543-90. Form in which arsenic taken up by plant, 8566; such arsenic not necessarily assimilated, 8568.

Methods employed in testing, 8472-93, 8540; control and blank experiments, and their sufficiency, 8499-8521. Organic matter not entirely destroyed before testing, 8494; desirable to investigate effect of destroying organic matter, 8514-8, 8610-5; comparison with phosphorus, 8614.

Quantity of superphosphates usually applied to land, 8599; amount of arsenic in commercial superphosphates, 8575.

## MR. T. FAIRLEY'S EXPERIMENTS AND RESULTS (9824):

Amount of arsenic in certain specimens of soil; traces in stubble, possibly due to soil contamination; no arsenic detected in ears, grain, or roots of barley and wheat, 9824; possible retention of arsenic due to iron in soil, 9876.

References to literature on subject, p. 66, note.

## DR. J. A. VOELCKER'S EXPERIMENTS AT WOBURN, AND RESULTS, 12078-12163:

Experiments restricted to barley, mangels, and swedes, tabular statement of results, 12093. Mode of applying manure in different experi-

## VEGETABLES—continued.

ments; controls; quantity of arsenic in superphosphates used, 12089-97, 12120-2. Soils of fields used for experiment, 12086-8, 12123-9, 12141-5; two specimens of soil contained arsenic apart from recent manuring, 12160-3. No arsenic found in bulbs or grain in any case, 12089-90, 12120; small amounts in straw and leaves, partly due to adherent soil, 12120-2, 12153. Sampling, 12136-7.

Organic matter destroyed in each instance before testing; analyses made by Mr. Hehner, 12088, 12139.

Quantity of superphosphates usually applied to land, 12094; amount of arsenic in commercial superphosphates, 12094, 12135.

## VINEGAR:

Manufacture of, in relation to arsenic; use of malt, raw grain "converted" by mineral acid, sour beer, etc. (Appendix 24), p. 246.

## "VOLATILE" ARSENIC, IN FUEL:

Relation to "total" arsenic, and significance (Ling), 10671-80, 10697-708; (Thorpe), 11691-705; (Appendix 30), pp. 289-90, 325.

Tests for (Ling), 10451-75, 10479-89; (Appendix 20), p. 207; (Appendix 21), pp. 210, 214; (Appendix 23), pp. 227-9.

## VOLATILISATION OF ARSENIOS OXIDE:

(Thorpe), 11691-4.

## WALL PAPERS:

No guarantee as to arsenic demanded by purchaser of colours for (Pronk), 11424-32, 11449-53.

## WARRANTY:

Defence of, in prosecutions under Sale of Food and Drugs Acts (Lithiby), 11618-28; (Allen), 12013-9, 12062.

## WINES:

Use of glucose in certain wines, (Appendix 24), p. 242.

## WORT, BREWERS:

Advantage in obtaining control by analysis of (Salamon), 9993; (Chapman), 10318-324, 10324-35; (Thorpe), 11726; (Primrose), 11948.

## YEAST:

Affinity of, for arsenic (Neech), 9104, 9257-60; (Appendix 19), p. 202. Action of yeasts and moulds upon various arsenical solutions (Delépine), 10384-5. Bakers' yeast (Appendix 24), p. 243.

YEAST AS AN INGREDIENT OF CERTAIN FOODS: (Appendix 24), p. 244; (Overbeck), 11262.

"YEAST FOODS": Nature and use of; examination for arsenic; certain samples arsenical (Primrose), 11847, 11856-68; (Appendix 24), p. 343.

## ZINC:

Nature of zinc recommended for "Marsh" estimations. See TESTS.

"Sensitiveness" of (Thomson), 9750-4; (Hehner), 10096-10119, 10129; (Chapman), 10236-49, 10299-304; (Thorpe), 11666; (Appendix 20), p. 207; (Appendix 21), p. 212; (Appendix 22), p. 221; (Appendix 32), p. 351.

## MEMORANDA.

TABLE OF EQUIVALENTS OF PARTS PER MILLION AND GRAINS PER GALLON AND GRAINS PER POUND, RESPECTIVELY.

Parts per Million.	Equivalent to Grains per Gallon.	Equivalent to Grains per lb.
018	0033 = $\frac{1}{300}$	00033 = $\frac{1}{3000}$
