are heated *nearly* to their *point of decomposition*, and *alcohol* is gradually and cautiously dropped on them, the ethers of those acids are readily formed. In this way many of the acids which are wholly or partly volatile—as the *oxalic*, *benzoic*, and *succinic acids*—yield large quantities of ether. (Gaultier de Claubry.) This method is applicable to most of the *organic acids* that do not suffer decomposition at a low temperature, but in other cases the product would be vitiated and uncertain. Thus, *citric acid* under this treatment might yield *citric*, *itaconic*, *citraconic*, or *aconitic ether*, or a mixture of two or more of them, and this is in a way entirely beyond the power of the operator to influence. *Another method*, highly recommended, and very suitable to the preparation of the ethers of the fatty acids, is—to *dissolve* the *organic acid* in *alcohol*, and to *pass a current of dry hydrochloric acid gas* through the solution. A *still simpler plan*, and one which appears likely to supersede most others, at least in the majority of cases, is to place a mixture of equal parts of *alcohol* and the *organic acid*, with $\frac{1}{8}$th to $\frac{1}{4}$th of *oil of vitriol*, in a *flask* or *digester*, fitted with a cork, through which passes an *upright thin glass tube*, 5 or 6 feet long, and after luting the the joint quite securely, and making the proper arrangements for its safety, to keep the liquid in a state of *gentle ebullition* in a sand-bath, or over a spirit lamp for several hours. In this way the spirituous and ethereal vapours are condensed in the cooler portions of the tube, and fall back again into the matrass, by which means no loss of either can possibly occur. A Liebig's refrigerator *reversed* may also be used for this purpose. In this way several of the organic ethers may be formed that can scarcely be obtained pure by the usual plan. Thus *mucic ether* may be obtained by this process, which will become perfectly white by crystallization, while by other methods, the first product is quite black, and is purified with difficulty. One or other of the above plans may be adopted for the *preparation* of *all those ethers* for which *formulæ* are *not inserted in this volume.*

ETHEREAL OIL. See *Oils.*

ETHEREO-SULPHURIC ACID. See *Sulphovinic Acid.*

ETHEREUM. See *Ethyle.*

ETHERIFICATION. The act or operation of etherifying or making ether. See *Ether.*

ETHERINE. Syn. *Camphor of Oil of Wine.* A volatile, white, crystalline substance, deposited by *light oil of wine* when left in a cold situation for some time. It is isomeric with *etherole*, and received its name from the assumption of its being the base of the ethereal compounds. According to this hypothesis, ether is a *hydrate of etherine. Etherine* forms brilliant prisms and plates; is tasteless; soluble in alcohol and ether; fuses at 230° Fahr.; and boils at 500° Fahr.; and is a little lighter than water. The crystals are purified by pressure between the folds of *bibulous paper*, solution in *ether*, and evaporation. The word *etherine* has also been loosely employed by some as a *new* name for *olefiant gas.*

ETHEROLE. The yellowish, oily liquid, forming the residual portion of *light oil of wine*, after it has deposited its *etherine.* It is lighter than water; is freely soluble in both alcohol and ether; and has a rather high boiling point. *Light oil of wine* is also called *etherole.* It is probable that the two are identical. See *Etherine* and *Oils.*

ETHEROXAMIDE. See *Oxamethane.*

ETHIONIC ACID. *Prep.* An *alcoholic solution* of the *crystals* of *sulphate of carbyle*, is diluted with *water*, the whole neutralized with *carbonate of baryta*, the filtered liquid evaporated by a very gentle heat to a small bulk, and a large quantity of *alcohol* added; the precipitate (*ethionate of baryta*) is treated (cautiously) with *dilute sulphuric acid* (avoiding excess), by which the baryta is withdrawn, and *hydrated ethionic acid* left in solution.

Prop., &c. Ethionic acid closely resembles sulphovinic acid. It is decomposed by heat. Its salts (*ethionates*), however, differ completely from the sulphovinates. They are all soluble in water, and are said to be anhydrous. The *ethionates of ammonia*, *potassa*, and *soda*, crystallize readily; those of *lead*, *baryta*, *lime*, and the other earths, are uncrystallizable. According to Brande it is also formed by the action of the vapour of *anhydrous sulphuric* on *alcohol.* See *Isethionic Acid.*

ETHIOPS. Syn. *Æthiops*,—Lat. A name given by the older chemists to several black powders, on account of their colour, and recently re-introduced into medicine by certain eccentric practitioners.

ETHIOPS (Absorbent). Syn. *Æthiops Absorbens*,—Lat. The *quicksilver with chalk* of modern pharmacy.

ETHIOPS (Animal). Syn. *Æthiops Animalis*,—Lat. The calcined bodies of various animals, as the *bat*, *hedgehog*, *mole*, *sparrow*, &c., reduced to powder.

ETHIOPS (Antimonial). Syn. *Æthiops Antimonialis*,—Lat. This has been already noticed at page 73. The following are additional formulæ:—

Prep. 1. (James's Dispensatory, 1764.) *Black antimony* and *sea salt*, equal parts, fused together, and the product triturated with an *equal weight of quicksilver*, until the globules are perfectly extinguished.

2. (Ph. Bor.) From the *black sulphurets of antimony* and *mercury*, equal parts, triturated together.

3. (Ph. Lusitan.) *Oxysulphuret of antimony*, 3 parts; *quicksilver*, 2 parts.

4. (Dr. Plummer's.) *Golden sulphuret of antimony* and *calomel*, equal parts. This preparation appears to have been unjustly neglected in modern practice. See *Antimony* (Ethiops of).

ETHIOPS (Golden). Syn. *Æthiops Auripigmentalis*,—Lat. From *red sulphurets of arsenic* and *mercury*, triturated together. *Very poisonous.*

ETHIOPS (Graphitic). Syn. *Ethiops of Plumbago; Æthiops Graphiticus*,—Lat. From *plumbago*, 2 parts; *quicksilver*, 1 part; triturated together until the globules disappear. *Dose.* 5 to 10 gr.; in herpes, and some other obstinate skin diseases.

ETHIOPS (Martial). Syn. *Æthiops Martialis, Æ. Chalybeatus*,—Lat. *Black oxide of iron*, prepared by keeping iron filings under *water*, and occasionally shaking them. It is washed with *water*, dried as quickly as possible, and preserved from the air, to prevent further oxidation. Formerly much esteemed as a tonic.

ETHIOPS (Mineral). Syn. *Ethiops Mineral; Æthiops Mineralis*,—Lat. Black sulphuret of mercury.

Prep. 1. (Ph. L. 1721.) From *quicksilver* and *sulphur*, equal parts; triturated together until the globules are extinguished.

2. (Mr. Tyson's.) *Oxide of mercury* (prepared by decomposing *calomel* with an equivalent proportion of *liquor of potassa* to which a little liquor of ammonia has been added) and *flowers of sulphur*, equal parts, triturated together. Mr. Tyson recommends this as an efficient substitute for the old and uncertain preparation commonly sold under the name of *Ethiop's mineral.* It is, however, of more than *double* the usual strength, and should therefore be taken in proportionate doses. See *Mercury* (Sulphurets.)

ETHIOPS (of Mercury) Syn. *Æthiops per se, Æ. Mercurialis*,—Lat. Protoxide of mercury obtained by assiduously shaking a *little of the metal* in a large bottle.

ETHIOPS (Plummer's). Syn. *Plummer's Alterative Powder; Æthiops Plummeri, Pulvis Plummeri, P. P. Alterativus*,—Lat. *Prep.* See *Antimonial Ethiops* (No. 4.)

ETHIOPS (Saccharated). Syn. *Æthiops Saccharatus*,—Lat. *Prep.* (Ph. Madrit.) *Quicksilver*, 1 part; *white sugar*, 2 parts; as the last. A mild mercurial.

ETHIOPS (Vegetable). Syn. *Æthiops Vegetabilis, Pulvis Quercûs Marinæ*,—Lat. *Bladder wrack* (fucus vesiculosus), burned in a close vessel till it becomes black and friable. *Used* in bronchocele, scrofula, &c. Like *burnt sponge*, it probably owes its virtues to the presence of a very minute quantity of iodine. *Dose.* 20 gr. to 1 dr., or more, made into an electuary with *honey* or *sugar.*

ETHYLE. Syn. *Ethule, Ethereum.* The radical of the ether-compounds, or the so-called *ethyl-series*, according to the ingenious theory of Liebig. Until recently its existence was hypothetical, but Dr. Frankland has succeeded in obtaining it in an isolated form, by the action of *zinc*, at a high temperature, upon *iodide* of *ethyle* (hydriodic ether). The process is similar to that by which *amyle* is obtained from its *iodide.*

Ethyle is a colourless and inflammable gas, incondensable to the liquid state at zero; under a pressure of 2¼ atmospheres, at 37·5° Fahr., it assumes the form of a colourless, transparent, ethereal liquid. Sp. gr., in the gaseous state, 2·0039. ('Journ. Chem. Soc.,' vol. ii.) It is a *salt-basyle.* Its *oxide* is *ether;* its *hydrated oxide* is *alcohol.* Its compounds (*salts*) with the *halogen bodies* (bromine, chlorine, iodine, cyanogen, &c.), and those of its *oxide* with the *acids*, are the COMPOUND ETHERS already noticed. See *Zinc-ethyle* and *above.*

ETHYLAMINE. Syn. *Ethyl-ammonia.* One of the new bases furnished by the ethyl-series.

Prep. 1. *Iodide* or *bromide of ethyle*, (hydriodic or bromic ether) is digested with an *alcoholic solution of ammonia*, until the alkaline action disappears; the liquid is evaporated to dryness by a gentle heat, and the white crystalline residuum (*bromide of ethylammonium*), mixed with *powdered quicklime*, and distilled in a glass retort connected with a well-cooled receiver.

2. (M. Wurtz.) From a *mixture* of *cyanate of ethyl* (cyanic ether) and *hydrate of potassa*, distilled together.

Prop., &c. An ethereal liquid, boiling at 64½° Fahr.; it smells strongly of ammonia, and has an alkaline reaction. With the

acids it forms neutral, crystallizable salts, analogous to the corresponding compounds of ammonia. Treated with chlorine, it furnishes *chloride of ethylamine* and a yellow liquid (*bichlorethylamine*), the fumes of which rapidly excite tears. The *bichloride of platinum and ethylamine* forms orange-yellow, leaf-like crystals. *Ethylamine* is distinguished from *ammonia* by the inflammability of its vapour and producing a salt, crystallizing in *golden scales* which are rather soluble in water.

A mixture of solution of *ethylamine* and *bromic ether*, heated for several hours in a sealed glass-tube, solifies to a crystalline mass (*bromide of biethylamine*), which when distilled with *potassa* yields a colourless liquid, termed *Biethylamine*, or *biethyl-ammonia*. This compound is alkaline, boils at 133° Fahr., and forms beautiful crystallizable salts with the acids. The *bichloride of platinum and biethylamine* forms beautiful orange-red grains.

By heating a mixture of *solution of biethylamine* and *bromic ether* in a glass-tube, as before, a fibrous mass of *bromide of triethylamine* is obtained, which by distillation with *potassa* yields a new base, termed *triethylamine* or *triethyl-ammonia*. This compound is a colourless, highly alkaline liquid, which boils at 196° Fahr., and forms crystallizable salts. That of its chloride with bichloride of platinum (*bichloride of platinum and triethylamine*) is very soluble, and crystallizes in magnificent large orange-red rhombs.

Oxide of Tetrethyl-ammonium, another compound of this series, is formed by mixing *anhydrous triethylamine* with *anhydrous iodide of ethyle* (hydriodic ether), when a violent reaction ensues, and a white crystalline mass (*iodide of tetrethyl-ammonium*) forms, which is dissolved in *water*, and its *iodine* removed by agitation with *freshly precipitated oxide of silver;* the filtered solution, evaporated *in vacuo*, yields a semi-solid mass of *hydrated oxide of tetrethyl-ammonium*. The aqueous solution of this compound is bitter, alkaline, and caustic, and, as well as that of the iodide (see above), may be boiled without suffering decomposition, even when in contact with caustic potassa. In the dry state, however, it is rapidly decomposed by heat, pure *triethylamine* and *olefiant gas* being formed. It corrodes the skin, saponifies the fats, with the formation of true soaps, and exhibits the same reactions with the salts of the metals as hydrate of potassa. Its salts are neutral; several possess great beauty. The double chloride with platinum (*platino-chloride of oxide of tetrethyl-ammonium*) forms orange-yellow octahedrons, of little solubility.

Oxide of tetrethyl-ammonium is one of the most remarkable and interesting substances known, on account of its unusual stability, its resemblance to potassa, which is a metallic oxide, and its constitution being precisely the same as that of the hypothetical *oxide of ammonium* of Berzelius, if, indeed, it is not actually the same substance.

ETHYLAMYLANILINE. An aromatic ethereal oil, formed by treating *ethylaniline* with *iodide of amyle*, and distilling the resulting *iodide of ethyl-amyl-aniline* with *caustic potassa*. It boils at 503° Fahr.

ETHYLANILINE. Syn. *Ethylophenylamine*. A liquid resembling aniline, boiling at 400° Fahr., obtained by treating aniline with *bromide* or *iodide of ethyle*, in the way described under *ethylamine*. Another like compound is *biethylaniline* (biethylophenylamine). There are other members of the series, analogous to those of the *ethylamine-bases* just noticed, but the names which have been foolishly given them, are too long and complicated, and the compounds themselves are of too little practical interest to be included in this work. See *Nomenclature*.

ETHYLENE. See *Olefiant Gas*.

ETHYLOPHENYLAMINE. See *Ethylaniline*.

ETHYLOTOLUIDINE and *Biethylotoluidine*. Artificial mixed bases, obtained by treating *toluidine* with *bromide* or *iodide of ethyle*. See *Ethylamine*.

ETHYLO XAMIDE. A peculiar substance, obtained as a white precipitate, by adding *ethylamine* to *oxalic ether*.

EUCALYPTINE. A substance resembling a mixture of pectine and tannic acid, existing in Botany Bay kino.

EUCHLORINE. Protoxide of chlorine, on account of its vivid green-colour. The *euchlorine*, of Davy, prepared by gently heating *chlorate of potassa* with *hydrochloric acid*, is said to be a mixture of chlorous acid and free chlorine.

EUCHRONE. A deep blue, insoluble substance, formed when *euchronic acid* is placed in contact with *metallic zinc* or other *deoxidizing agents*.

EUCHRONIC ACID. An acid obtained along with *paramide*, when *neutral mellitate of ammonia* is submitted to distillation. It forms colourless crystals, which are sparingly soluble in water, whilst paramide is insoluble in cold water; properties which afford the means of their separation. See *Euchrone*.

EUGENIC ACID. Syn. *Heavy Oil of*

Cloves, Clove Acid, Caryophyllic Acid. Its salts are termed *Eugenates*, or *caryophyllates*, and those with potassa, soda, and ammonia, are also sometimes called *clove-acid alkalies.* See *Oils* (Volatile).

EUGENINE. Syn. *Stéaroptène of Oil of Cloves, Clove Camphor.* Thin, white, pearly scales, found by Bonastre in oil of cloves. It smells and tastes of cloves, is soluble in alcohol and ether, and is reddened by nitric acid. This name is applied by Brodie to *caryophyllin*, before noticed. This latter substance is also, sometimes, incorrectly, called *clove camphor.*

EUPHORBIUM. Syn. *Gum Euphorbium; Euphorbium*,—Ph. L. E. & D. The concrete resinous juice of the *euphorbia canariensis* (Linn.) or *Canary euphorbium tree.* It is a powerful acrid, purgative, rubefacient, sternutatory, and vesicant, and the violence of its action has led to its disuse. It is excluded from the recent edition of the pharmacopœia.

EUPION. An ethereal liquid forming the chief portion of the *light oil of wood-tar*, and which also exists in the *tar* obtained during the destructive distillation of *animal* and *vegetable substances*, particularly in the fluid product thus obtained from *rape oil.* It is separated from these substances by agitating them with *oil of vitriol*, or a *mixture* of *oil of vitriol* and *nitre*, and subsequent cautious distillation. *Pure eupion* is tasteless, exceedingly thin, limpid, and aromatic; boils at 116½° Fahr.; and is the lightest fluid known; sp. gr. 0.655. It is very inflammable, burns with a very bright flame, and gives a transient greasy stain to paper. It is isomeric with *hydruret of amyle*, and frequently consists chiefly of that substance, when its specific gravity and boiling point rises in proportion. Other volatile oils of like origin are often confounded with eupion by chemical writers. Thus, Brande and others, state its sp. gr. to be 0·74, and that it boils at 340° Fahr.

EUPYRION. Contrivances for obtaining instantaneous light; as *lucifer matches, &c.*

EUXANTHIC ACID. See *Purreic Acid.*

EUXANTHONE. See *Purrenone.*

EVACUANTS. Syn. *Evacuantia*,—Lat. Medicines which augment the secretions or excretions. *Cathartics, cholagogues, diaphoretics, diuretics, emetics, errhines, expectorants, and sialogues*, belong to this class.

EVAPORATION. The conversion of a fluid into vapour by means of heat, diminished atmospheric pressure, or exposure to a dry atmosphere. Evaporation is had recourse to—1. For the *vapour* as a *source of heat* or power, as in the case of *steam boilers, &c.;*—2. To *separate volatile fluids* from *impurities* or other bodies, which are either fixed or less volatile;—3. To *recover solid bodies from their solutions*, as in the preparation of *extracts, chemical salts, &c.*;—4. To *concentrate* or *strengthen* a *solution* by the expulsion of some of the fluid matter that forms the menstruum; — 5. To *purify liquids* by the *dissipation* of the *volatile matters* which may contaminate them.

It is found that, under ordinary circumstances, evaporation is confined to the surface of the heated liquid, and is therefore slower or quicker, in proportion to the extension of that surface. Hence has arisen the adoption of *wide shallow vessels* for containing fluids during their exposure to heat for this purpose. Evaporation proceeds most rapidly when a current of air (especially hot and dry air) is made to pass over the surface of the fluid; as, in this case, the vapour is prevented resting upon the surface, and impeding the process by its pressure. For a similar reason, liquids evaporate more rapidly in vessels *partially covered*, than in *open ones.* In the *former* case the cool incumbent air condenses and throws back a portion of the vapour, which thereupon, besides its cooling action, offers mechanical resistance to the diffusion of the vaporous particles as they arrive at the surface of the liquid. In the *latter* case these obstacles are avoided, and the impetus of the vapour pouring forth from a contracted orifice (or pipe), not only readily overcomes the pressure of the atmosphere, but offers less surface for its cooling action, until it has passed much beyond the points at which it can exert any influence on the fluid from which it has escaped. In this way the chemical action of the atmosphere on the liquid operated on, is also considerably lessened. On the *small scale*, shallow capsules of glass, Wedgwood-ware, porcelain, or metal, are commonly employed as evaporating vessels, and these are exposed to heat by placing them over a lamp, or naked fire, or in a water-bath, or sand-bath, according to the temperature at which it is proper to conduct the process. On the *large scale*, high-pressure steam is usually employed as the source of heat. The term "*spontaneous evaporation*" is applied to the dissipation of a fluid by mere exposure in open vessels, at the common temperature of the atmosphere, and without the application of artificial heat. The celerity of this species of evaporation wholly depends on the degree

of humidity of the surrounding air, and differs from the former, in which the rate of evaporation is proportionate to the degree of heat at which the process is conducted, and the amount of pressure upon the surface of the liquid. *Evaporation "in vacuo"* (as it is called) is conducted under the receiver of an air-pump, or in an attenuated atmosphere, produced by filling a vessel with steam, by which means the air is expelled, when all communication with the external atmosphere is cut off, and the vapour condensed by the application of cold. *Fluids* are also evaporated in air-tight receivers over *sulphuric acid*, by which they are continually exposed to the action of a very dry atmosphere. When such a receiver is connected with an air-pump in action, evaporation proceeds with increased rapidity, and intense cold is produced. It appears, from the experiments of Dr. Ure, that "if the bottom of a pan, and the portion of the sides immersed in a hot fluid medium, (solution of chloride of calcium for example,) be corrugated, so as to contain a *double expanse of metallic surface*, that pan will evaporate exactly *double the quantity of water*, in a given time, which a like pan, with smooth bottom and sides, will do, immersed equally deep in the same bath. If the corrugation contain *three times the quantity of metallic surface*, the evaporation will be *three-fold* in the above circumstances. But if the pan, with the same corrugated bottom and sides, be set over a fire, or in an oblong flue, so that the current of flame may sweep along the corrugations, it will evaporate no more water from its interior than a smooth pan of like shape and dimensions placed alongside it in the same flue, or over the same fire."

Mr. Williams, the inventor of the original "argand," or "smoke-consuming furnace," many years ago demonstrated the superior evaporative power of a boiler, with *small plugs* or *rods of metal* projecting from both the exterior and inner surfaces, when heated by an open fire. This principle is, we believe, included in one of his patents, now expired.

In the *laboratory*, steam heat is now almost exclusively employed. Copper, or tinned, glazed, or silvered copper pans, boilers, and stills, are surrounded by a "jacket" of cast-iron, and high-pressure steam admitted between the two. By due management of the supply-cock, a range of temperature may be thus obtained, extending from about 90° to 325° Fahr.

It is found that, under ordinary circumstances, 10 square feet of *heated surface*, will evaporate *fully* 1 *lb.* of water per minute; and that a thin copper tube exposing 10 feet surface, will *condense* about 3 *lb.* of steam per minute, with a difference of temperature of about 90° Fahr. This is equal to 30° Fahr. per *lb.*; and, consequently, the heat of the steam employed to produce the evaporation should be 212° + 30° = 242° Fahr. See *Steam*.

An attention to the facts and principles thus briefly explained above, will be found of great value in the laboratory.

EVERNIC ACID. From the *evernia prunastri*, or ragged hoary *evernia*; a parasitic lichen growing on the trunks of trees. It is obtained by digesting *the lichen* in *milk of lime*. It is feebly soluble even in boiling water, and is turned yellow by chloride of lime.

EVERNINIC ACID. A crystallizable substance obtained by boiling *evernic acid* with *alkalies*. It differs from evernic acid in its free solubility in boiling water.

EXCIPIENT. See *Prescription*.

EXCITANTS. See *Stimulants*.

EXCORIATIONS. Syn. *Sprays*, *Chafings*, —Vulg. Superficial injuries or affections of the skin, consisting of the removal of the scarf-skin or cuticle, accompanied with more or less irritation and slight inflammations. When arising from rough friction or attrition, they are more commonly called ABRASIONS. *Young children* are very apt to be chafed under the arms, behind the ears, between the thighs, and in the wrinkles and folds of the skin generally, unless great attention is paid to cleanliness, and wiping the skin *perfectly dry* after washing them. Whenever there is a tendency to excoriations of this kind, either in adults or children, a little *finely powdered starch*, or *violet powder*, applied by means of a *puff*, or a small bag of muslin, once or twice a day, will generally remove them, and prevent their occurrence in future. Mild unguents, as *cold cream*, or *spermaceti cerate* or *ointment*, may also be used with advantage. The preference should, however, be given to the remedies first named, from their not soiling the linen. Excoriations arising from the removal of the skin by friction or external violence, have been noticed under the head *Abrasion*.

EXERCISE is essential to the healthy performance of the functions of both body and mind. *Without* it, the stomach acts feebly, the bowels become inactive, and the circulation of the blood languid and imperfect; the chest contracts, the respiration becomes impeded, the brain is insufficiently supplied with pure arterial blood, the mind grows lethargic, the complexion assumes a

sickly and effeminate hue, and the whole features lack the energy and expression which they possess in perfect health. *With it*, the bodily functions are performed with vigour and regularity, by which the constitution is strengthened, and the attacks of disease repelled. By exercise the mind too is excited to healthy action, its gloomy reveries are dispelled, and the fair face of creation is presented to the mind's eye in its proper hues. It robs undue mental exertion of half its injurious effects upon the body, whilst it stimulates and directs it in its proper course. It improves the temper, and humanizes the character. The disposition is refined, the passions restrained, violent emotions checked, the habits improved, and the personal charms promoted under the stimulus of judicious exercise.

To *females*, exercise is even more necessary than to males. The disposition and education of females are such as to tend to produce habits of sloth and indolence to a greater degree than in the other sex. Hence to them exercise is doubly important,—it is inseparable from health. The more retiring dispositions of females leads them almost unconsciously into habits of inactivity, which, above all, they should endeavour to shake off and avoid. By so doing,—by replacing habits of indolence and inactivity, by liveliness and moderate exercise, the development of the body will be promoted, additional grace and elegance imparted to its natural movements, and the enjoyments arising from both mental and bodily health increased, whilst disease and deformity will be prevented by the removal of their cause.

The *necessity of exercise* exists equally in every grade of society and age of life. Those who are engaged in *sedentary employments* or *in-door occupations*, should particularly seek refreshing *out-door* exercise, during the periods of relaxation from their diurnal duties. To the studious and delicate of both sexes, this is absolutely necessary to preserve the health and vigour of the body.

In *infancy*, exercise of a *suitable kind* should be almost the constant occupation of the little beings that claim our protection and care. It should, however, be always borne in mind, that the muscular exercise of very young children must be of the *gentlest class*. Prejudice and ignorance frequently induce nurses and parents to "*teach their children to walk*," as they falsely call it, and thus their feeble limbs are urged to make premature efforts to totter along, before the bones and muscles have acquired sufficient strength to support the body in an erect position. From this course the legs and joints frequently become bent and misshapened, and severe injuries are often inflicted on the head and body by blows and falls. It should never be forgotten, that *crawling* and *rolling* are their first modes of progression, and require the least exertion. Next comes the sitting posture; from this the child gradually advances to the erect one; then to walk by *slight assistance;* and lastly, to walk safely *alone*. All this should come naturally, and never be promoted, further than by laying the infant on the carpet or floor, for the full exercise of its little strength. As soon as a healthy child is *able* to walk instead of crawl, its own disposition induces it to do so. The faculty of imitation, the spirit of enterprise, and the pride of "doing what others do," present even in infancy, is rather apt to lead the infant to over-exertion, than the contrary. The practice of constantly "dolling" children in the arms, is most prejudicial to the early development of their feeble powers.

In *childhood* the exercise should be regulated according to the constitution and age of the parties; avoiding inactivity on the one hand, and excessive exercise on the other. The out-door plays and pastimes of *boys*, will generally be found sufficient, and in some cases will even require to be curbed, to prevent fatigue and the overtasking of the young frame. With *girls*, it is frequently difficult to find sufficient exercise without trespassing on the prejudices of the ignorant, or the routine of their daily education. With them, walking, and some healthy amusement, as *skipping*, *hooping*, or *the like*, should be indulged in for some hours daily. When this is impossible or inconvenient, they may be habituated to the practice of the more simple and cleanly portion of the domestic duties. In the performance of the latter, the health will be promoted, whilst the care and attention which is always due by a female to herself and others, at all periods of her life, will become an easy acquisition, and assist the cultivation of the best feelings of her nature.

In *youth* exercise matures and promotes the development of the frame; and in *manhood*, it is equally necessary, as already noticed, to keep it in healthy action. In *age*, it will be found to assist the vital functions, and put off decay. In fact, to ALL,—*young*, *old*, *rich*, and *poor*, EXERCISE is *essential* to the *permanent enjoyment of health*.

In a medical point of view, "*exercise*,

employed *moderately*, has a tonic and stimulating influence on the system, and is calculated to prove beneficial in a great variety of complaints. Used *immoderately*, it exhausts both the mental and bodily powers, and produces great debility." (Pereira.) Well-directed exercise favours the preservation of the general health, by calling into direct action the majority of the organs of the body; and it also acts powerfully on the skin, by stimulating its functions, increasing its temperature, awakening its tone, and subjecting it to a current of atmosphere favorable to its respiratory offices. But to be beneficial in the highest degree, exercise must be accompanied by feelings of present interest and enjoyment. The mind must direct and go with it,—to insure its full benefits the "soul must be present." "What is it that makes the difference between the exercise of youth and that of the felon on the tread-wheel; between the pedestrian in the Isle of Wight or Switzerland, and the pedestrian from Chelsea to the Bank; between the light and quick footstep wending to Greenwich Park, and the dull tread of the nursery-maid at home? Is it not mind? Is it not the young and buoyant joy of the school-boy that inspirits his laugh and his leap? while, silent and morose, humiliated, not convinced, the felon suffers his monotonous existence, moving, it is true, but not in exercise. It is not the novelty or the beauty of the scene, the pleasant weather, or the immunity from customary labour, that gives spirit to the pedestrian's tour, as compared with the dull, desultory repetition of the same sights, same persons, same things, and same path to and from business? It is not the prospect of enjoyment, of gaiety, or pleasure, that makes the difference between the elastic step of the maiden enfranchised from present duties, and the same person in the pursuit of her necessity-impelled and ordinary offices? We need not ask which is most calculated to be beneficial to health; which to arouse the dormant functions of the skin; to promote the removal of irritating elements from the blood; to increase the vigour of the frame, purify the complexion, and enrich the beaming tints of beauty. In MIND lies the great secret of *beneficial exercise*, and without it, exercise is a misnomer, and a fraud upon the constitution." (Erasmus Wilson.)

"During *convalescence*, properly regulated exertion is highly serviceable; but it should never be carried so far as to produce exhaustion, and should be pursued for some time in doors, before it be attempted in the open air; the latter, at first, should always take place in a carriage, that can be opened or closed at will; the patient may then attempt short walks in the open air; but, in all cases, it is of importance that he is not *unduly fatigued*, as otherwise, injury instead of benefit will be the result. One of the most serious errors, committed with regard to exertion, is that of permitting a convaleseent to sit up too frequently, or for too long a time, under the mistaken notion of giving him strength. A patient should *never be allowed* to sit up *longer* than is *agreeable to his feelings*, and *never so long* as to produce a *sense of fatigue*." (Dr. R. E. Griffith.)

EXPANSION. The increased bulk which bodies acquire when heated. All substances, solid as well as liquid, when chemical change does not take place, expand by heat, and contract by cold. In some of them, this property occurs in a greater degree than in others, but is constant for the same substance under the same circumstances. The *chemist* avails himself of this property in the construction of his thermometer; the *wheelwright* in fixing on the tire of his wheels; the *engineer*, in restoring to the perpendicular the leaning walls of buildings; &c.

EXPECTORANTS. Syn. *Expectorantia*, —Lat. Medicines that promote the secretion of the tracheal and bronchial mucus. According to Dr. Good, true expectorants are "those medicines which rather promote the separation of the viscid phlegm with which the bronchiæ are loaded, than simply inviscate and dilute it; though these are also treated as expectorants by many writers." *Ammoniacum*, *antimonials*, *assafœtida*, the *balsams of Peru* and *tolu*, *benzoic acid*, *benzoin*; the *fumes of vinegar*, *tar*, and *several* of the *volatile oils*; *garlic*, *ipecacuanha*, the *oleo-resins*, *squills*, *tartarized antimony*, and the *smoke* of *tobacco* and *stramonium*, are among the principal substances commonly called expectorants. *Tartarized antimony*, *squills*, *chlorine*, and *ammoniacal gases*, have also been used (diluted) to provoke the coughing and favour the expulsion of foreign bodies from the aërian tube; and also to favour the expectoration of mucus, pus, and membranous concretions when the local irritation is not sufficiently great. (Schwilgue.) *Expectorants* are *commonly employed* in pulmonary complaints and affections of the air-tubes, attended by a vitiated state of the mucus, or an imperfect performance of the natural functions of the

secretory vessels. "Of all classes of the materia medica, none are more uncertain in their action than expectorants." (Pereira.) The act of ejecting matter from the chest is called *expectoration.*

EXPERIMENTS are acts or operations, intended to develop some unknown fact, principle, or effect; or to establish or demonstrate it, when discovered. Similar operations performed merely for amusement, are also often, though incorrectly, called by this name. In rational experiments these two objects are combined. To experimental research is due the present high state of advancement and usefulness of the various sciences most intimately connected with our happiness and well-being. The danger of taking things for granted has been thus pleasantly and instructively pointed out by Archbishop Whateley:—"It was objected to the system of Copernicus when first brought forward, that if the earth turned on its axis, as he represented, a *stone dropped from the summit of a tower* would *not fall* at the *foot* of it, but at a *great distance to the west;* in the same manner as a *stone dropped from the masthead of a ship in full sail* does *not fall at the foot of the mast,* but towards the stern. To this it was answered that a stone, being a part of the earth, obeys the same laws, and moves with it; whereas it is no part of the ship, of which consequently its motion is independent. The solution was admitted by some, but opposed by others; and the controversy went on with spirit; nor was it till one hundred years after the death of Copernicus that, the *experiment being tried,* it was ascertained that the *stone,* thus *dropped from the head of the mast,* DOES fall at the *foot of it.*"

EXPLOSIVE COMPOUNDS. See *Gunpowder, Fulminating Compounds, Perchloric Ether, &c.*

EXPRESSION. The mechanical operation by which a fluid contained in the pores or cells of a solid is pressed out or expelled. Many of the fluid substances employed in pharmacy and chemistry are obtained by expression. Thus, the *unctuous vegetable oils,* as those of *almonds, linseed, &c.,* are procured by submitting these substances to powerful pressure between iron plates, which are either made warm, or the bruised seeds are previously exposed in bags to the steam of boiling water. The *juices of fresh vegetables* are also obtained by expression. The substances are first bruised in a marble mortar, or, on the *large scale,* in a mill, and immediately submitted to the press, to prevent them passing into a state of fermentation, which would injure the quality of the product. *Fruits* which contain *highly-flavoured* or *fragrant seeds,* or which have *rinds* containing *essential oil,* are generally deprived of them before being sent to the press. The *subacid fruits* are also allowed to lay together for some days before pressing them, as the quantity and quality of the product is thereby increased. The *fluid matter* absorbed by the ingredients employed in the preparation of *tinctures, infusions, decoctions, extracts, &c.,* is generally obtained by powerful pressure. *Expression* is also frequently had recourse to for the purpose of obtaining *solids* in a *state of purity,* as in the *expulsion* of *oleine* from *stearine, water* from *bicarbonate of soda, &c.* On the *small scale,* the common *screw-press,* or one of like construction, is usually employed; but the power thus obtained is insufficient to expel the *whole* of a fluid diffused through the pores of a solid. Hence has arisen the use of the *hydraulic press,* which is now almost alone employed on the *large scale.* In all these cases, the substances are placed in bags made of *hair-cloth,* or *coarse canvass,* previously to their being submitted to pressure. For *tinctures* and *like pharmaceuticals,* a small screw-press (*tincture press*) made of zinc or tinned-iron, and varying in capacity from 1 quart to several gallons, is employed.

EXSICCATION. See *Desiccation.*

EXTIRPATION (of Vermin). See *Beetles, Rats, &c.*

EXTRACT. Syn. *Extractum,* — Lat. Among *chemists* this term is understood to apply to the residuum of the evaporation of aqueous decoctions or infusions of vegetable matter. In *medicine* and *pharmacy* it has a less definite signification, being applied to various preparations obtained by evaporating the expressed juices, or the decoctions, infusions, or tinctures of vegetable substances, until a mass, of a solid or semi-solid consistence, is formed. Extracts vary in their nature and composition with the substances from which they are prepared, and the fluids employed as solvents. When *water* is employed as the menstruum, the products (*aqueous extracts, watery do.; extracta aquosa, ext. simpliciora;*) usually consist of gum, starch, sugar, albumen, extractive, and saline and other matter, along with the pecular principles on which the medicinal virtue of the vegetable depends. When *spirit* is employed as the solvent, the products (*alcoholic extracts; extracta alcoholica;*) contain most of the substances

above enumerated, except the gum and starch, together with several other substances which are *soluble* in *spirit*, but which are either wholly or nearly *insoluble* in *water;* as *resins*, *essential oils*, and the *proximate principles of vegetables*. These preparations, with scarcely an exception, are considerably more powerful than the *aqueous extracts* of the same vegetables. In some cases *proof spirit* or *under-proof spirit* is employed, when the extracts (*spirituous extracts; extracta spirituosa;*) generally possess properties between those of the above. In other cases, *dilute acetic acid* or *acidulated water* is employed as the menstruum when the products (*acetic extracts; extracta acetica;*) possess much greater activity than when prepared with water; and would in many cases prove fatal, if exhibited in doses as large as those of the aqueous extracts. Still more active extracts are obtained by a *combination* of the *last two menstrua*. According to Ferrari, plants treated with *rectified spirit of wine*, mixed with $\frac{1}{35}$th part of *acetic acid*, yield extracts of remarkable activity. (Prov. Med. Jour. 1843.) On the Continent, *ether* is sometimes used as the menstruum for the active principles of certain substances, as *cantharides*, *cubebs*, *worm-seed*, &c., when the products are called "*ethereal extracts*" (*extracta etherea*). To this may be added, that the term "*simple extract*" is applied to an extract prepared from a *single* plant or vegetable substance, and the term "*compound extract*" to one prepared from *two* or *more* of such substances. The *fluid extracts* (*extracta fluida*) of modern pharmacy, are those which are only evaporated to the consistence of a *thin syrup*, and then mixed with 1-10th to 1-8th of their volume of rectified spirit.

Prep. The preparation of medicinal extracts may be conveniently considered under two divisions, viz.—*the production of a solution of the soluble portion of the substances operated on, and—the reduction of this solution by evaporation to the consistence of an extract.*

The *preliminary operations* in the manufacture of extracts are similar to those employed in the preparation of *decoctions*, *infusions*, and *tinctures*. The proper quantity of the ingredients being taken, the whole is *well bruised* or *reduced* to *coarse powder*, or otherwise divided by *slicing with a knife*, that every portion may be fully exposed to the solvent action of the fluid. In some few cases (as with *gentian*, &c.,) the "slicing," or reduction to fragments, is often conveniently deferred, until the action of the menstruum shall have so far softened the ingredients as to render them of easy division by the knife. Those substances (as *sarsaparilla*, *chamomiles*, &c.,) whose medicinal principles reside in the *cortical portion*, or which are of *easy solubility*, are commonly subjected to the action of the menstruum without being subjected to any particular preparation.

In the *preparation* of *aqueous extracts*, the ingredients are treated with *water* until *all* the soluble matter that it is desired to obtain is dissolved out. There are several methods of effecting this object, depending upon the nature of the substances acted on. In some cases, *maceration* in *cold water* is resorted to; in others, *percolation* with that fluid in a displacement apparatus. More generally, however, *boiling water* is poured on the substance, and is digested on it for some time, as in the preparation of *infusions;* or the substance is exhausted by *boiling* it in *water*, as in the preparation of *decoctions*. After the ebullition or infusion has continued a sufficient time, the heat is removed, and the liquid portion drawn off. The ingredients are then *pressed* to extract the remaining liquid; or they are *washed* or *sparged* with *hot water*, which expels it by displacement. According to the usual practice in the *majority of cases*, a *second quantity of water* is poured on after the first has been thoroughly drained off, and the *infusion* or *coction* is repeated a *second* and even a *third* time, or until the ingredients are *perfectly exhausted* of their soluble portion. The liquor or liquors thus obtained being allowed to repose for 15 or 20 minutes, for the purpose of depositing the sand or other gritty and heavy matter that is mechanically mixed with them, are carefully decanted from the sediment, and, after being run through a fine hair-sieve, or flannel bag, are ready for concentration. In some instances, however, this method proves insufficient to render the liquid *clear*. In such cases, the solutions may generally be rendered transparent by *clarification* with a *little white of egg*, removing the scum as it rises, and straining the liquid through flannel, as before; or the liquid may be filtered through a bag made of fine *Welsh flannel*, or of *tweeled cotton cloth* (Canton flannel), both of which should be soaked in clean water for at least an hour before use. In the small way, filters of linen or paper are sometimes employed; but as all media sufficiently fine to render vegetable solutions transparent soon choke up, this filtration is objectionable, from the length of time it occupies. In *some houses*, the

aqueous infusion or decoction is allowed to repose for 24 hours, and then decanted and evaporated; but such a plan is objectionable, as however smooth and glossy extracts so prepared may appear, their medicinal virtues are lessened by the lengthened exposure to the atmosphere.

When about *one-half* of an *aqueous solution* has evaporated, it is often advantageous to repass it through a *flannel* or *horse-hair strainer*, to remove the flocculi that generally form by the action of the heat and air. This is especially necessary with *vegetable solutions* prepared *without boiling*, and should be adopted whenever a smooth and sightly extract is desired.

The *reduction of the solution* to the *proper consistence* is effected by evaporation. The mode in which this is performed varies for different extracts. The London College directs that "unless otherwise ordered, the evaporation should be conducted as quickly as possible, in a *broad shallow pan*, placed in a *water-bath*, until a proper consistence is acquired for forming pills; stirring assiduously with a spatula towards the end of the operation." The Dublin College orders that "all *simple* (aqueous) *extracts* (extracta simpliciora), unless otherwise ordered, are to be prepared by *boiling* the *vegetable matter* in 8 *times its weight of water*, till the *liquid is reduced to one half;* the liquor is then to be *expressed*, and after a short time allowed for *defecation*, to be *decanted*, *filtered*, and *evaporated in a* (steam or) *water bath*, until it begins to thicken, and then finally inspissated by a reduced heat, with continual stirring until a consistence for forming pills be attained." The instructions of the Edinburgh College are similar, with the one important exception, however, of ordering the evaporation to be conducted in a *water-bath*, saturated with *chloride of sodium*.

Though the water-bath has the sanction of the *London college*, it is ill adapted for the purpose to which it is here ordered to be applied, as, from its low evaporative power, the advantages which are derived from its equable temperature, are vastly overbalanced by the lengthened exposure of the solution in a heated state to the action of the atmosphere. It has been shown that a vegetable extract so prepared is *inferior* in quality to a similar one formed by rapid evaporation in a shallow pan over a naked fire, or placed in a sand-bath, provided proper care is taken, and assiduous stirring is adopted during the *whole time* of the exposure to heat. *In practice*, however, the use of a naked fire is perfectly *inadmissible*, as the least neglect on the part of the operator would probably lead to the incineration of the whole. These objections are obviated by the addition of $\frac{1}{5}$th part of *salt* to the water of the bath, which raises its boiling point to 218¾° Fahr., when the temperature of the contained extract is fully 212°; the remaining 6° being lost by the interposition of the substance of the evaporating vessel.

On the *large scale*, the evaporation of infusions or decoctions for extracts is usually conducted in very wide, shallow, *copper* or *tinned-copper pans*, having steam-tight jackets of cast-iron, and heated by steam "playing" between the two. See *Evaporation*.

The *rapid deterioration* which *vegetable juices* and *solutions* undergo by *exposure to the air*, especially at high temperatures, has led to the introduction of apparatus, by which they may be concentrated without contact with the atmosphere, and at a less degree of heat than is required for that purpose in open vessels. Such is the method, commonly called *Barry's process*, in which the air is removed from certain air-tight refrigerators by the introduction of steam, which is then condensed by the application of cold, by which means a partial vacuum is obtained. *Another process* for attenuating the atmosphere over the surface of fluids during evaporation is by the action of an air-pump. This plan was introduced by Howard, and is commonly applied to the concentration of syrups in the sugar refineries. Extracts obtained by either of these methods are said to be prepared "*in vacuo*," and are found in practice to be immensely superior to the common extracts of the shops, and consequently require to be exhibited in proportionably small doses.

When *water*, *acidulated with acetic acid* is employed in the preparation of extracts, the vegetable substances are usually *macerated* in it, in the *cold*, or the *dilute acid* is sprinkled over the *bruised plant* in the *fresh* or *recent state*, and the whole is then submitted to strong pressure, to expel the juice, which is strained and evaporated in the usual way, but preferably in a well-tinned or plated-copper pan.

Alcoholic and *spirituous extracts* are prepared by evaporating a filtered concentrated tincture of the ingredients in any suitable vessel, by which the volatilized spirit may be saved. In general, *rectified spirit* is used as the menstruum; but in some cases *proof spirit* is employed; and

in others, the substances are *first* digested in proof spirit, and *afterwards* in water, and the *mixed tincture* and *infusion* evaporated in the usual manner.

Ethereal extracts are obtained in a similar manner to alcoholic ones; but being merely prepared in small quantities at a time, the process may be conveniently performed in glass vessels. When it is required to boil either of the above fluids (*alcoholic* or *ethereal*) or any other volatile liquid on the ingredients, a vessel fitted with a long tube, or a Liebig's refrigerator *reversed*, as noticed under ether, may be used to prevent any loss of the menstruum.

The *inspissated vegetable juices* are classed with extracts by the *London College*, and are ordered to be prepared by evaporating the *expressed juice*, without filtration, in a water-bath. The directions of the *Edinburgh College* for preparing their inspissated juices (*succi spissati*) are—"Beat the *fresh substance*, and press it strongly through a canvas bag, in order to obtain the juice; which, being put into a wide, shallow vessel, and heated by means of boiling water saturated with sea-salt, is to be reduced to the consistence of honey. The mass, when cold, is to be put into glazed earthen vessels, and moistened with strong alcohol." By operating in this way a considerable portion of the activity of narcotic vegetables is lost. Some of their juices, as that of *aconite*, are impaired in so short a time as scarcely to compensate for the trouble of preparing them. This deterioration does not, however, take place in any remarkable degree, if the expressed juice from the recent vegetable be evaporated by exposing it in a *thin stratum to a current of very dry air*, as adopted by Mr. Squire. This may be managed by putting the juice into small flat trays or dishes, placed on shelves in a suitably arranged apparatus, alternated with similar vessels of *concentrated sulphuric acid;* or by causing a current of *very dry air*, at the common temperature of the atmosphere, to pass over them. It has been shown that 10 gr. of extract, thus prepared, were more than equal to 20 gr. prepared *in vacuo;* and to more than 60 gr., and, in some cases, 90 gr. of those prepared by the common process of boiling down the juice to an extract.

The concluding portion of the process of extract-making, technically termed "*finishing off*," requires the most scrupulous attention. As the evaporation advances, the *heat should be lessened*, and as soon as the extract acquires the consistence of thick treacle, it should be *removed altogether*, and the remainder of fluid matter evaporated by the heat retained by the copper pan, the escape of vapour being promoted by assiduous and laborious stirring with a suitably-shaped wooden spatula. This part of the process should be continued until a proper consistence is attained and the extract is *nearly cold*. When *high pressure steam* or a *chloride of calcium bath* is employed, care must be taken to *withdraw the heat before stirring* the semi-liquid mass; as, if an extract having a temperature of about the boiling point of water, or even a few degrees below it, is agitated, it *becomes full of bubbles*, and appears *rough* and *puffy*, and this appearance cannot be removed by subsequent stirring, or by any method but re-dissolving it in water and re-evaporation. This is especially the case with the *extracts of sarsaparilla* (simple and compound), *gentian*, *liquorice*, and most others of a similar class. A good laboratory man knows from experience the proper time for the removal of the heat, but unpractised persons often fail in this particular. In such cases, should the heat retained by the evaporating pan, and by the extract, prove insufficient to complete the process, a little more may be *cautiously* applied. Without assiduous and laborious stirring in the way described, a very *smooth* and *glossy* extract *cannot* be produced. To promote this *artificial* appearance, some persons add 3% or 4% each of *olive oil* and *gum arabic*, dissolved in water, with about 1% or 2% of *spirit of wine*.

The *consistence* of the *ordinary extracts* of the shops, is the same as that of electuaries and confections, and is described in the Ph. E. as equal to that "of *thick honey*." The instructions of the Ph. L. and D., to evaporate the mass "until it acquires a consistence proper for making pills," except in 2 or 3 cases (as *Ext. Colocynth. Comp.*, *&c.*), is not adopted, and indeed would be found inconvenient in practice. Extracts evaporated to such a consistence are commonly termed "*pilular extracts;*" and when evaporated so that they are quite dry, and brittle when cold, they are called "hard extracts" (*extracta dura*).

Pres. Extracts should be put into pots as soon as taken from the pan, and, after being carefully and securely tied over with *bladder*, should be "stored" in a *dry* situation. *The London College* orders "a small quantity of rectified spirit to be sprinkled upon all the softer extracts, to prevent them becoming mouldy." A better way is to employ a *little spirit*, holding in solution a

few drops of *oil of cloves*, or a still *less* quantity of *creasote*. This should be added to them the last thing before removing them from the evaporating pan, and when they are nearly cold. The same object is effected by *moistening* the *inside of the bladder* (used to tie them over) with a few drops of *oil of cloves* or *creasote*. Hard extracts should be kept in bladders or gut skins, placed in stone pots, and well covered over. With care, extracts prepared from recent vegetable substances may be preserved twelve months, or from season to season; and those from dry ingredients, or such as are less inclined to spoil, for perhaps double that time; but beyond these periods their virtues cannot be relied on, and they should consequently be discarded, if remaining unused or unsold.

Pur., &c. The quality of an extract cannot be ascertained by mere inspection, nor is it readily discovered by chemical tests. A knowledge of these facts has induced the mercenary and fraudulent manufacturer to employ damaged and inferior drugs in their preparation, alike regardless of the welfare of the patient, and the credit of the practitioner. A common practice with some manufacturers is, not only to pick out the *least expensive variety of every drug* for the preparation of their extracts, but the *most inferior*, and often *damaged* and *worthless portion* of this already inferior article. The production of a *smooth*, *bright*, and *glossy* extract is *all* that is usually attempted by these individuals, and *all* that is sought after by the mass of purchasers, who mistake the simulation of the mere external signs of good quality for its actual existence. It is a fact, which we can verify from extensive experience in the laboratory, and from years of practical observation on this point, that extracts faithfully prepared from good materials, do not possess the sightly and pleasing appearance of those commonly vended by the wholesale druggists. On comparing the extracts prepared by different metropolitan houses, we have found that those which have exhibited a remarkably *bright* and *glossy* appearance, have been *uniformly inferior*, and sometimes *nearly inert;* whilst others, with a less prepossessing appearance, have been generally of *good quality*. These facts are well established by reference to the extracts of those houses and institutions that are remarkable for the superior quality of their preparations, and by comparing them with the common extracts of the shops, supplied by the wholesale trade.

A *good extract* should be—1. Free from grit, and *wholly soluble* in 20 parts of the *menstruum employed in its preparation*, forming a *nearly clear solution;*—2. It should have a *uniform texture* and *colour*, and be of a *proper consistence;*—3. If a narcotic or active extract, it may be exhibited in proper doses, and its effects watched. Its activity may also be tested on any small animal.—4. An assay for the *proximate vegetable principle* (*alkaloid*, *&c.*) contained in the plant from which it has been prepared may be made. The extracts prepared from the expressed juices of plants, without straining off the coagulated albumen, are of course exceptions to the *first* test. Unfortunately, these tests are not always easily performed, and the last two are inapplicable to those extracts that exercise no very marked physiological action, unless when taken in repeated doses, long continued. This want of a ready means of accurately testing the qualities of extracts has enabled the fraudulent manufacturer to sell inferior articles with impunity, and often without the least fear or danger of detection.

In general, an extract more than six months old contains only *half* the activity of a similar one *newly* made. When more than twelve months old they should be rejected as *worthless*, and the stock renewed.

Uses, &c The extracts of the shops are generally acknowledged to be the most varying, imperfect, and uncertain class of medicines belonging to modern pharmacy. They are mostly used in the same cases as the plants from which they are prepared, but in smaller doses.

Concluding Remarks. In the *preparation* of extracts the great desiderata to be aimed at are—to *suit* the *menstrua* and the *methods of manipulating* to the *peculiar characteristics* of the *active constituents* of the *vegetable substances* operated on. The pharmaceutist should always bear in mind that a *perfect* extract should be *a concentrated, solid mass, representing, as near as possible, in medicinal efficacy, the materials from which it has been prepared, and capable of being re-dissolved, so as to form a solution closely resembling that from which it has been derived.* An extract possessing *equal* strength to the *whole* mass of the ingredients from which it has been prepared, is almost next to an impossibility, however desirable such a degree of perfection may be. The medicinal properties of *all* solutions of vegetable matter are injured by being reduced to the solid state; and this deterioration, more or less, takes place,

whether the solvent be *water*, *acetic acid*, *proof spirit*, or *alcohol*. The volatile portions, (the *essential oils*, the *aroma*, &c.,) are nearly or wholly dissipated, and though these do not always form the principal or active ingredients of the vegetables from which extracts are prepared, yet they generally exercise a modifying and controlling influence over the other ingredients, which considerably alters their therapeutical action. The loss of aroma may often be a trifling deficiency, but in the *extracts* of *aconite*, *henbane*, *hemlock*, *belladonna*, and other narcotic plants, this is not the case. In these cases it is well known that the inert preparations are wholly deficient of the odour of the recent plant, and that in *proportion* as the *odour is developed*, so *is their activity preserved*. The powerful smell of the *recently expressed juice of hemlock* with the scarcely perceptible odour of the extractum conii, of the Ph. L., offers an excellent example of this fact. The *dose* of the *one* often reaches 20 or 30 gr.; whilst that of the *other*, seldom exceeds 5 or 10 drops, or a portion equivalent in dry ingredients to considerably less than ½ gr.

When extracts are ordered in prescriptions, those of the London Pharmacopœia should be alone employed by the dispenser, as the substitution of others for them, would not only be violating faith with the prescriber, but might also produce consequences alike injurious to the dispenser and the patient. Many medical gentlemen prefer extracts prepared by particular processes or persons, but such intention is always indicated in their prescriptions. A serious accident of this sort occurred lately in this very metropolis. A druggist had prepared a number of prescriptions from an extract which he had purchased of a wholesale drug house, and which was labelled *Ph. L.*, but was in reality almost inert, and in consequence of the presumed insensibility of the patient to its narcotic action, the medical practitioner had gradually increased the quantity to an enormous extent. In the mean time, the druggist's small stock of extract was exhausted, and another pot purchased of the same parties, which was of an average quality. The prescription was brought to be dispensed as usual; but this time it was prepared from the new extract. The consequences were *loss of speech*, *coma*, *delirium*, and *death*.

EXTRACT (Aconite). Syn. *Extract of Wolfsbane*, *E. of Monkshood*, *Inspissated Juice of Aconite*; *Extractum Aconiti*,—Ph. L. E. & U. S. *Ext. A. cum Fœculâ*,—P. Cod. *Succus Spissatus Aconiti*,—Ph. D. 1826. *Prep.* 1. (Ph. L.) Take of *fresh leaves of aconite*, 1 lb; bruise them in a stone mortar, express the juice, and evaporate it, *unstrained*, to a proper consistence. The *formulæ* of the Ph. D. & U. S. are similar.

2. (Ph. E.) Beat the *fresh leaves of aconite* to a pulp, and express the juice, then subject the residuum to percolation with *rectified spirit* until the latter passes through without being materially coloured; unite the *expressed juice* and the *percolated tincture*, filter, distil off the spirit, and evaporate in a vapour or a water bath to a proper consistence. Stronger than the preceding.

Obs. A variable and uncertain preparation. Numbness and tingling follow its application to the lips or tongue when it is of good quality. *Product.* 1 cwt. of fresh leaves yield between 5 *lb.* and 6 *lb.* of extract. *Prop.* Anodyne, sudorific and narcotic; *very poisonous*. *Dose.* ½ gr. to 2 gr., made into a pill with *liquorice powder*; once or twice a day in neuralgic pains, chronic rheumatism, glandular swellings, &c., gradually and cautiously increased to 5 or 6 gr.

EXTRACT (Aconite,—Alcoholic). Syn. *Extractum Aconiti Alcoholicum*,—Lat. *Prep.* 1. (P. Cod.) *Aconite* (in coarse powder), 1 lb; *proof spirit*, 3½ lb. (say 2½ pints;) proceed by the method of displacement, and when all the spirit has penetrated the powdered mass, keep this covered with distilled water, until the liquid begins to cause a precipitate in falling into that which has previously passed through; next distil the spirit from the tincture and evaporate the residuum to the proper consistence.

2. (Ph. U. S.) *Aconite*, 1 lb; *spirit*, sp. gr. 0·935 (= 13 u. p.), 1 quart, or q. s.; as last.

3. (Ph. Baden.) From the tincture prepared with *rectified spirit*, and by either maceration or displacement. Stronger than the last two.

4. (Ph. Bor.) The *juice* is expressed from the *fresh herb*, which is then sprinkled with about ⅓rd of its weight of *water*, and again pressed; the mixed and strained liquid is evaporated in a vapour bath at 122° to 140° Fahr., to about one-half; to this, as soon as cold, an equal weight of *spirit* (sp. gr. 0·900), is added, and after frequent agitation for 24 hours, the whole is filtered, with pressure; the *marc* is treated with *fresh spirit* (equal to about 1-4th that first used) and again pressed; the mixed liquors are next filtered, and are, lastly, evaporated, as before, to the proper consistence.

Obs. Resembles the simple extract, but s much more powerful. It has been exhibited internally in the form of pills, and used externally combined with ointment or spread on simple plaster. *Dose.* $\frac{1}{12}$ to $\frac{1}{6}$ gr. every three hours.

EXTRACT (Aconite,—Ammoniated). Syn. *Extractum Aconiti Ammoniatum*,—Lat. *Prep.* (Dr. Turnbull,) *Extract of aconite*, 1 dr.; *liquor of ammonia* (strongest), 10 or 12 drops; mix.

EXTRACT (Aconite,—Dried). Syn. *Extractum Aconiti Siccum, E. A. Durum, E. A. cum Fæculâ*,—Lat. *Prep.* (P. Cod.) The *expressed juice*, strained through a sieve or coarse linen, is at once, without depuration, exposed in earthen dishes, in layers of about 2 lines deep, in a stove or current of dry air, to a temperature ranging between 95° and 104° Fahr., until reduced to dryness. The dried extract is to be packed in bottles.

EXTRACT (Aconite,—Saccharated). Syn. *Extractum Aconiti Saccharatum, E. A. Siccum, E. A. Pulveratum*,—Lat. *Prep.* From *extract of aconite* (Ph. Bor.), 4 oz.; *sugar of milk* (in powder), 1 oz.; mix, and dry the mass in a warm place, adding *sugar of milk*, q. s., to make the whole equal in weight that of the extract used (4 oz.) An excellent preparation which keeps well. The other *narcotic extracts*, as those of *belladonna*, *hemlock*, *henbane*, &c., are to be treated in a similar manner.

EXTRACT (Aconite-root,—Alcoholic). Syn. *Extractum Aconiti Radicis Alcoholicum*,—Lat. *Prep.* (Dr. Fleming; Dr. Turnbull.) From a *tincture of the root* made with *rectified spirit*. It is said to be 12 times as strong as the extract of the leaves.

EXTRACT (Agaric). Syn. *Extractum Agarici*,—Lat. *Prep.* (P. Cod.) From the *infusion of white agaric*, prepared with *cold water*. Purgative. *Dose.* 1 to 4 gr.

EXTRACT (Agrimony). Syn. *Extractum Agrimonii*,—Lat. *Prep.* From a *decoction of the herb*. Vermifuge. *Dose.* 5 to 15 gr.

EXTRACT (Alcornoque). Syn. *Extractum Alcornocæ, E. Alchorneæ*,—Lat. *Prep.* From a *decoction* of *alcornoco bark* (South American). Astringent and tonic. *Dose.* 5 to 20 gr.; in phthisis, &c.

EXTRACT (Aloes). Syn. *Purified aloes, Washed do.; Extractum Aloës*,—Ph. L. *E. A. Purificatum*,—Ph. L. 1836. *E. A. Aquosum*,—Ph. D. *E. A. Hepaticæ*,—Ph. D. 1826. *Aloës Depurata, A. Lota, Gummi Aloes*,—Obs. *Prep.* 1. (Ph. L.) *Socotrine aloes*, 15 oz.; *boiling distilled water*, 1 gall.; digest with a gentle heat for 3 days, and strain; after repose, decant the clear portion, and evaporate it to the consistence of an extract.

2. (Ph. D.) *Aloes* (hepatic), 4 *oz.*; *water*, 1 quart; boil till dissolved; when cold, decant the clear liquid, and evaporate as before.

3. (Ph. Bor. 1847.) By macerating *powdered aloes* in *cold water* for 48 hours, with frequent agitation, and then evaporating in a water bath at a temperature not exceeding 150° to 165° Fahr., until a pilular consistence is attained.

Obs. The second is the form adopted in the laboratory. When made with the juice of borage, burgloss, &c., it forms the old *Aloes Insuccata*. *Dose.* 5 to 15 gr.

EXTRACT (Barbadoes Aloes). Syn. *Extractum Aloës Barbadensis*,—Ph. L. *Prep.* As the last.

EXTRACT (Anemone). See *Extract of Pasque Flower*.

EXTRACT (Angelica). Syn. *Extractum Angelicæ*,—Lat. *Prep.* 1. (Ph. Baden.) From a *tincture of the root*, prepared with *spirit* sp. gr. 0·944 (=21½ u. p.)

2. (Ph. Bor.) *Angelica root* and *rectified spirit*, of each, 2 parts; *water*, 9 parts; digest, strain, and evaporate. Inferior to the preceding.

3. (Dr. Moir.) *Angelica root*, 2 *lb.*; *rectified spirit*, 1 gall.; make a tincture; to the *marc* add *proof spirit*, 1 gall., and repeat the digestion; filter the two tinctures *separately*, mix, distil off the spirit, and evaporate. Balsamic, stomachic, and tonic. *Dose.* 10 to 20 gr. The last is the most balsamic and agreeable.

EXTRACT (Angola Seed). Syn. *Extractum Abrii, E. A. Precatorii*,—Lat. *Prep.* From the decoction.

EXTRACT (Apples,—Chalybeated). Syn. *Extractum Ferri Pomatum, Ext. Martis P.* sive *Cydoniatum*,—Lat. *Prep.* (Ph. Bor.) *Crab-apples* (unripe), 6 lb; peel them and reduce them to a pulp; add *iron wire* (in small coils), 1 lb; digest in a vapour bath for about a week, express, strain, decant, and evaporate in a porcelain vessel, with constant stirring, to the consistence of a soft extract; dissolve the residuum in *water*, 4 parts, strain and evaporate as before. *Dose.* 5 to 10 gr.; as a chalybeate tonic. The formula of the Ph. Baden is nearly similar.

EXTRACT (Arnica). Syn. *Extract of Arnica Flowers; Extractum Arnicæ Florum*,—Lat. *Prep.* 1. (P. Cod.) From the *dried flowers*, as *alcoholic extract* of *aconite*, P. Cod.

2. (Ph. Græca, 1837.) From a *tincture of the flowers*, prepared with *rectified spirit*,

3 parts; and *water*, 5 parts. *Dose.* 2 to 6 gr.; as a stimulant in various diseases accompanied with debility, deficient nervous sensibility, paralysis, dropsies, diarrhœa, amenorrhœa, dysentery, &c.

EXTRACT (Arnica). Syn. *Extract of Arnica Root, Extractum Arnicæ Radicis,— Prep.* 1. (Ph. Baden.) As *extract of angelica*, Ph. Baden.

2. (Ph. Græca.) As No. 2, (above.) The form of the Hamburg Codex is nearly similar. *Dose, &c.* As the last.

EXTRACT (Artichoke). Syn. *Extractum Cynaræ*,—Lat. From the *fresh leaves of the artichoke*, as *extract of aconite*, Ph. L. *Dose.* 3 to 6 gr., twice or thrice daily; in rheumatism, &c.

EXTRACT (Asparagus). Syn. *Extractum Asparagi*,—Lat. *Prep.* (Soubeiran.) From the *expressed juice of the shoots*, clarified and evaporated by a gentle heat.

EXTRACT (Asparagus-roots). Syn. *Extractum Asparagi Radicis*, — Lat. *Prep.* From the *roots*, as the last. Both the above are diuretic. *Dose.* 15 gr. to ½ dr. or more.

EXTRACT (Balsam Apple). Syn. *Extractum Balsaminæ*, — Lat. *Prep.* From the *fruit* or *fresh leaves* of the *balsam apple* (momordica balsamina,—Linn.) as *extract of aconite.* Balsamic, diuretic, restorative, and vulnerary. *Dose.* 5 to 20 gr.; in dropsies, &c.

EXTRACT (Bardana). See *Extract of Burdock.*

EXTRACT (Bark). See *Extract of Cinchona.*

EXTRACT (Bear's Whortleberry). See *Extract of Uva Ursi.*

EXTRACT (Belladonna). Syn. *Extract of Deadly Nightshade; Inspissated Juice* of *Belladonna; Extractum Belladonnæ*,— Ph. L. E. & D. *Succus Spissatus Belladonnæ*,—Ph. D. 1826. *Prep.* 1. (Ph. L.) As *Extract of aconite*, Ph. L.

2. (Ph. E.) Express the juice from the bruised *fresh plant*, sprinkle the *marc* with *water*, and again apply pressure; mix the expressed liquids, *filter* them, and evaporate the filtered liquid in a vapour bath to the consistence of an extract.

3. (Ph. D.) From the *leaves*, collected when the plant begins to flower. The expressed juice is allowed to stand for 24 hours, and the clear portion is decanted; the sediment is placed on a calico filter, washed with an equal bulk of *cold water*, and the filtrate mixed with the expressed juice. The mixed liquid is next heated in a water-bath, to coagulate its albumen, and after being skimmed, and filtered through flannel whilst hot, the *washed sediment* is added, and the whole evaporated, as before.

4. (Ph. U. S.) The *expressed juice* is heated to the boiling point, filtered and evaporated.

Obs. The P. Cod. directs this extract to be made by two different formulæ. The product of the one resembles that of the Ph. L.; that of the other, the *ext. belladonna*, Ph. E. That of the Ph. L., from retaining the fecula, is the weakest preparation. *Dose.* ½ gr. to 1 gr., gradually increased to 3 or 4 gr.; as an anodyne in neuralgia, tic-douloureux, &c.; as an antispasmodic to relieve rigidity and spasms, in various affections of the uterus, rectum, urethra, bladder, &c., and in hooping-cough; in various maladies of the eyes; and as a resolvent and discutient in several glandular diseases. It has been highly recommended as a preservative against scarlet fever. It is most frequently employed externally, under the form of a plaster, ointment, or lotion. It is *poisonous.* The treatment resembles that noticed under *aconite.* Fresh belladonna yields about 5% of extract. (Brande; 1-9th,—Gray.)

EXTRACT (Belladonna,— Alcoholic). Syn. *Extractum Belladonnæ Alcoholicum*, —Lat. *Prep.* 1. (P. Cod.) As *alcoholic extract of aconite*, P. Cod.

2. (Ph. U. S.) As the last (nearly), using spirit of 0·935 (= about 13 u.p.)

3. (Moir.) The *expressed juice* is coagulated by heat, cautiously applied, and filtered; the filtrate is reduced to the consistence of a syrup, and mixed with an equal volume of nearly *anhydrous alcohol* (say of 90%); the clear portion is lastly evaporated, as before.

Obs. The above is much more powerful than the common extract, and is chiefly used in external applications.

EXTRACT (Belladonna Berries). Syn. *Extractum Baccarum Belladonnæ*, — Lat. *Prep.* (P. Cod.) From the *expressed juice of the berries*, evaporated to the consistence of thick honey. *Dose.* 1 to 5 gr.

EXTRACT (Bistort). Syn. *Extractum Bistortæ*,—Lat. *Prep.* 1. (P. Cod.) From the *dried root of bistort* or *snake-weed*, by percolation with temperate *distilled water.*

2. From the *infusion* made with *boiling water*, or from the *decoction.* Astringent and tonic. *Dose.* 10 gr. to ½ dr.

EXTRACT (Bitter-sweet). Syn. *Extract of Woody Nightshade; Extractum Dulcamaræ*,—Lat. *Prep.* 1. From the *decoction of the stalks.*

2. (Ph. U. S.) From the *dried stalks*, by percolation with *temperate water*. Diaphoretic, diuretic, and narcotic. *Dose.* 5 to 10 gr.; in chronic asthma, rheumatism, and chest diseases; and particularly in chronic skin diseases.

EXTRACT (Black). Syn. *Extractum Nigrum*,—Lat. Extract of cocculus indicus. It is used by fraudulent brewers to impart an intoxicating property to ale.

EXTRACT (Black Pepper). See *Extract of Pepper.*

EXTRACT (Borage). Syn. *Extractum Boraginis*,—Lat. *Prep.* 1. (P. Cod.) From the *dried herb.*

2. (Ph. Lusit.) From the *clarified juice of the fresh plant.* Exhilarating, restorative, and pectoral. *Dose.* 10 to 30 gr., or more.

EXTRACT (Box). Syn. *Extractum Buxi, E. Corticis B.*, — Lat. *Prep.* (P. Cod.) From the *tincture of the root bark*, prepared (with *proof spirit*) by displacement, as *extract of aconite*, P. Cod.

EXTRACT (Broom). Syn. *Extract of Broom Tops; Extractum Scoparii; E. Cacuminum Genistæ*,—Ph. L. 1788. *E. Spartii Scoparii*,—Ph. D. 1826. From *decoction of broom tops.* Diuretic and cathartic; and, occasionally, emetic. *Dose.* 20 gr. to 1 dr.; in dropsy, &c. It is now seldom used.

EXTRACT (Bryony). Syn. *Extractum Bryoniæ, E. B. Albæ, E. Radicis B. A.*,—Lat. *Prep.* From the *infusion* or *decoction of the root of white bryony.* Purgative, diuretic, and emmenagogue. *Dose.* 10 gr. to ½ dr. It was once a favorite remedy in asthma, dropsy, epilepsy, &c.

EXTRACT (Buchu). Syn. *Extractum Buchu, E. Diosmæ*,—Lat. *Prep.* From *buchu leaves*, as the last.

EXTRACT (Buchu,—Ethereo-alcoholic). Syn. *Extractum Buchu Ethero-alcoholicum*, —Lat. *Prep.* (W. Procter.) *Buchu* (in coarse powder), 1 lb; *ether*, 4 fl. oz.; *alcohol* (rectified spirit), 12 fl. oz.; percolate without digestion, adding *dilute alcohol* until a pint of *ethereo-alcoholic tincture* is obtained, and suffer this to evaporate spontaneously; treat the residue in the displacer with *dilute alcohol*, till 2 pints are obtained; evaporate to a syrup, add the product of the *first tincture*, mix, and complete the evaporation. *Dose.* 5 to 10 gr.; in diseases of the urinary organs, &c. See *Diosma.*

EXTRACT (Buchu,—Fluid). Syn. *Extractum Buchu Fluidum*,—Lat. *Prep.* (W. Procter.) *Buchu leaves*, 8 oz.; *rectified spirit*, 16 fl. oz.; for a tincture by displacement, adding *water*, until 12 fl. oz. have passed through; allow this to evaporate spontaneously until reduced to *one half*; next digest the mass in the percolator with *cold water*, 1 pint, for 12 hours, express a pint, and evaporate this to 10 *fl. oz.*; lastly, add the 6 *fl. oz.* of residual tincture, agitate together, and in a few days filter, or decant the clear portion. *Dose.* 1 to 2 teaspoonfuls. (See *above.*)

EXTRACT (Buckbean). Syn. *Extractum Menyanthis*,— Lat. *Prep.* 1. (P. Cod.) From the *expressed juice of the fresh plant.*

2. (Ph. Bor.) From the *infusion* made with *boiling water.* Bitter, tonic, and astringent. *Dose.* 5 to 10 gr. In larger doses it is purgative, cathartic, and even emetic.

EXTRACT (Buckthorn). Syn. *Extractum Rhamni, E. Baccarum R.*,— Lat. *Prep.* From the filtered *expressed juice of buckthorn berries.* Some persons allow it first to run into a state of fermentation; but the quantity of the product is thereby greatly lessened. Hydragogue and purgative. *Dose.* 15 gr. to 1 dr., or more.

EXTRACT (Burdock). Syn. *Extractum Bardanæ*,—Lat. *Prep.* 1. From the *decoction of burdock root.*

2. (P. Cod.) As *extract of bistort*, P. Cod. In gout, rheumatism, skin diseases, &c. *Dose.* 10 gr. to 1 dr. Sir Robert Walpole praised burdock-root as a gout medicine; and others have considered it an excellent substitute for sarsaparilla. (Lindley.)

EXTRACT (Butter-nut). Syn. *Extractum Juglandis, E. J. Cinereæ*,—Lat. *Prep.* (Ph. U. S.) From the *inner bark of the root* of the *butter-nut* or *white walnut*, as *extract of bitter sweet*, Ph. U. S. A mild, yet efficacious aperient and vermifuge. *Dose.* As a laxative, 5 to 10 gr.; as a purgative, 15 to 30 gr.

EXTRACT (Cabbage-tree Bark). Syn. *Extractum Geoffroyæ, E. G. Inermis*,—Lat. *Prep.* (Ph. Belg.) From the *decoction.* Vermifuge. *Dose.* 2 to 4 gr.

EXTRACT (Cahinca). Syn. *Extractum Caincæ*,—Lat. *Prep.* From *cahinca root* (chiococca densifolia) as *extract of box*, P. Cod. Diuretic and cathartic. *Dose.* 6 to 20 gr.; in dropsy, &c.

EXTRACT (Calamus). See *Extract of Sweet Flag.*

EXTRACT (Calumba). Syn. *Extractum Calumbæ, E. Radicis C.*,—Lat. *Prep.* 1. From the *infusion of the root* made with *hot water.* *Dose.* 10 to 20 gr.

2. (*Spirituous*,—P. Cod.) As *extract of*

box. The Ph. Baden. orders spirit of 0·944 to be used. *Dose*. 5 to 15 gr.

3. (*Alcoholic*,—Ph. Bor.) As the last (nearly), but using *stronger spirit*; the evaporation is to be conducted at a heat not above 167° Fahr., until it acquires the consistence of a pill-mass, which, after being rendered quite dry by a very gentle heat, is to be reduced to fine powder. It should have a brownish-yellow colour, and give a turbid solution with water. *Dose*. 4 to 12 gr. They are all tonic and stomachic.

EXTRACT (Cantharides). Syn. *Extract of Spanish Flies; Extractum Cantharidis, E. Lyttæ*,—Lat. *Prep*. 1. (P. Cod.) As *extract of box*.

2. (Soubeiran.) From a *tincture* prepared with *spirit* of the sp. gr. 0·923 (about 2 u.p.) See *below*.

EXTRACT (Cantharides,—Acetic). Syn. *Extractum Cantharidis Aceticum*, — Lat. *Prep*. From a *tincture* prepared with *acetic acid*, sp. gr. 1·048.

EXTRACT (Cantharides,— Ethereal). Syn. *Extractum Cantharidis Ethereum*,—Lat. *Prep*. From the *ethereal tincture*. The ether, acid, and spirit distilled from the above, must be either thrown away, or used to make fresh extract, as it is highly poisonous. They are all for external use only, and should have the consistence of soft butter.

EXTRACT (Cardamoms, — Ethereal). Syn. *Extractum Cardamomi Æthereum*, —Lat. *Prep*. (W. Procter.) By spontaneous evaporation of the *ethereal tincture*. It consists of the volatile and fixed oils of the seeds, and is used to aromatize pills, powders, &c.

EXTRACT (Carob Beans). Syn. *Extractum Ceratoniæ*,—Lat. *Prep*. From the *decoction* of the *pods* (carob *or* algaroba beans) *of the ceratonia siliqua*, or *St. John's bread tree*. See *Algaroba*.

EXTRACT (Carolina Pink). See *Extract of Pink-root*.

EXTRACT (Carrot Root). Syn. *Extractum Carotæ, E. Radicis C.*—Lat. *Prep*. (Swediaur.) From the *clarified expressed juice*, evaporated to the consistence of honey. Recommended as an application to ulcerated cancers.

EXTRACT (Cascarilla). Syn. *Extractum Cascarillæ, E. Corticis C.*,—Lat. *Prep*. 1. (Guibourt.) From the *alcoholic* (rectified spirit) *tincture*.

2. (Ph. Baden.) As the last, but using *spirit* of the sp. gr. 0·944.

3. (Ph. L. 1788.) As *extract of jalap*, Ph. L.

Obs. This extract is tonic, aromatic, and stomachic. *Dose*. 5 to 15 gr., or more, 2 or 3 times a day. 28 *lb*. of bark yield about 5¼ *lb*. of extract.

EXTRACT (Cassia.) Syn. *Extractum Cassiæ*,—Lat. See *Cassia Pulp*.

EXTRACT (Catechu). Syn. *Extractum Catechu*,—Lat. *Prep*. 1. From *decoction of catechu*.

2. (P. Cod.) From the *infusion in boiling water*. Astringent and tonic. *Dose*. 5 to 25 gr. See *Catechu*.

EXTRACT (Cathartic). Syn. *Extractum Catharticum*,—Lat. Compound extract of colocynth, Ph. L. 1836.

EXTRACT (Celandine). Syn. *Extractum Chelidonii*,—Lat. *Prep*. 1. (Ph. Bor.) From the *herb*, as *alcoholic extract of aconite*, Ph. Bor. *Dose*. 3 to 10 gr.

2. (Van Mons.) From the *expressed juice*, coagulated by heat, filtered, and evaporated; towards the end adding the coagulum. *Dose*. 5 to 15 gr. or more. *Used* as a drastic hydragogue in dropsies; and in scrofula, &c.

EXTRACT (Centaury). Syn. *Extractum Centaurii*,—Lat. Extracts under this name are prepared from *American centaury* (chironia angularis,—*Linn*.), *lesser centaury* (gentiana centaurium,—*Linn*.), and *great centaury* (centaurea centaurium,— *Linn*.), either by evaporating the *decoction*, or the infusion made with *hot water*. The *dose* and properties resemble those of extract of gentian.

EXTRACT (Centaury,—Alcoholic). Syn. *Extractum Centaurii Alcoholicum*,— Lat. *Prep*. As *extract of box*. (See *above*.)

EXTRACT (Cevadilla,—Alcoholic). Syn. *Alcoholic Extract of Sabadilla; Extractum Sabadillæ*,—Lat. *Prep*. (Dr. Turnbull.) From *tincture of cevadilla seeds*, made with *rectified spirit*. Employed by Dr. Turnbull as a remedy in painful rheumatic and neuralgic affections, and, generally, as a substitute for veratria. *Dose*. $\frac{1}{10}$ to $\frac{1}{6}$ gr. It is *extremely poisonous*.

EXTRACT (Chamomile). Syn. *Extractum Anthemidis*,—Ph. E. *Ext. Florum Chamæmeli*,—Ph. D. 1826. *Ext. A. Nobilis, E. Florum A.*,— Lat. var. *Prep*. From *decoction of the flowers*.

Obs. This extract contains only the bitter portion of the chamomile, the aromatic volatile oil being dissipated during the evaporation. It is usually prepared from old flowers that have lost their smell and colour, and are thus rendered unsaleable. The extract of chamomile that *smells strongly of the flowers*, frequently vended by the druggists, is prepared by adding 1 dr. of the *essential oil of chamomile* to *every pound of extract*, when nearly cold,

and just before removing it from the evaporating pan. This addition, unlike many which are made in the laboratory, vastly increases the medicinal virtues of this article. The mass of extract of chamomile met with in the shops is nothing but extract of gentian scented with a little oil of chamomile. 1 cwt. of chamomiles yields about 48 *lb.* of extract.

Extract of chamomile is bitter, tonic, and stomachic. *Dose.* 10 to 20 gr., made into a pill, either alone, or combined with a little rhubarb and ginger. See *Pills, &c.*

EXTRACT (Chenopodium). Syn. *Extract of Stinking Goose-foot; Extractum Chenopodii,* — Lat. *Prep.* 1. From the *stinking orache* or *goose-foot* (chenopodium olidum), as *extract of aconite*, Ph. L.

2. (Mr. Houlton.) From the *expressed juice* by spontaneous evaporation. A better plan is to expose it to heated air. Antihysteric, emmenagogue, and vermifuge. *Dose.* 5 to 20 gr.

EXTRACT (Cinchona). Syn. *Extract of Bark, E. of Yellow do., E. of Heart-leaved Cinchona Bark; Extractum Cinchonæ Flavæ, Ext. Cinchonæ,*—Ph. L. & Ph. L. 1824. *Ext. Cinchonæ Cordifoliæ,*—Ph. L. 1836. *Prep.* 1. (Ph. L.) *Yellow cinchona* (coarsely bruised), 3 lb; *distilled water* (temperate), 4 pints; macerate for 24 hours (constantly stirring), and strain through linen; what remains, again macerate in *water*, 1 quart, for 24 hours, and strain; evaporate the mixed liquids to a proper consistence.

2. (Ph. L. 1836.) From the decoction.

Obs. The aqueous extracts of cinchona bark possess little medicinal virtue, owing to the insolubility of the alkaloids (*quinine, cinchonine, &c.*), in water, and also from the rapid oxidation of their extractive matter, when exposed in solution to the joint action of heat and atmospheric oxygen. *Dose.* 5 gr. to ½ dr., in mixtures, faintly acidulated with sulphuric acid. Cinchona bark yields from 24$\frac{0}{0}$ to 30$\frac{0}{0}$ of aqueous extract.

EXTRACT (Pale Cinchona). Syn. *Extract of Pale Bark, E. of Lance-leaved do.; Extractum Cinchonæ Pallidæ,* — Ph. L. *Ext. C. Lancifoliæ,*—Ph. L. 1836. *Ext. Cinchonæ,*—Ph. D. 1826. *Ext. Corticis Peruviani,*—Ph. L. 1745 & 1788. *Prep.* 1. (Ph. L.) From *pale bark*, as *extract of cinchona*, Ph. L.

2. (Ph. L. 1836, & Ph. D. 1826.) From the *decoction*. This forms the *extract of bark* of the shops. The *red* and *yellow cinchona barks* are scarcely ever used for making extracts. Their richness in *quinine* leads to their almost exclusive employment for the manufacture of that alkaloid, by which their value is greatly enhanced. As far as our knowledge extends, no other *extract of bark*, than this, is either employed or asked for.

EXTRACT (Red Cinchona). Syn. *Extract of Red Bark, E. Oblong-leaved do.; Extractum Cinchonæ Rubræ,*—Ph. L. *Ext. Cinchonæ Oblongifoliæ,* — Ph. L. 1836. *Prep.* 1. (Ph. L.) From *red bark*, as *extract of cinchona*, Ph. L.

2. (Ph. L. 1836.) From the *decoction.*

Obs. These extracts are ordered to be kept in two states, the one (*soft extract of cinchona; extractum cinchonæ molle;*) for making pills, &c.; the other (*hard extract of cinchona; extractum cinchonæ durum;*) for powdering. The *dose*, &c., of all the above are the same.

EXTRACT (Cinchona,—Dry.) Syn. *Essential Salt of Bark, Lagaraye's do.; Extractum Cinchonæ Siccum, Ext. C. per Aquam Frigidam,*—Lat. *Prep.* 1. (P. Cod.) From an *aqueous infusion of pale bark* (prepared by displacement with water at a temperature not above 77° Fahr.), evaporated to the consistence of a thick syrup, and then spread thinly and uniformly on earthenware dishes, or sheets of glass, and dried in a stove, by a very gentle heat. It is separated from the plates with a knife, and preserved in well-closed phials. Prior to spreading it out on the plates, about 4$\frac{0}{0}$ or 5$\frac{0}{0}$ of *thick mucilage* is commonly added.

2. (Ph. Bor.) As the above (nearly).

3. (Ph. Hann. 1831.) Similar to the above; but the liquid when it acquires the consistence of treacle is diluted with *water* and again evaporated to a like consistence; and this dilution and evaporation is repeated until, on the addition of water, it forms a clear solution. *Dose.* 5 to 25 gr. The product of the last formula is nearly inert, and that of the others possesses little activity.

EXTRACT (Cinchona,—Fluid). Syn. *Extractum Cinchonæ Fluidum,*—Lat. *Prep.* 1. See *Liquor of Cinchona.*

2. (Dr. Neligan.) From *yellow bark*, as *fluid extract of buchu.*

EXTRACT (Cinchona,—Resinous). Syn. *Alcoholic Extract of Bark; Extractum Cinchonæ Alcoholicum; Ext. Cinchonæ,*—Ph. E. *Ext. C. Resinosum,*—Ph. L. 1809. *E. C. cum Resinâ,* — Ph. L. 1788. *Prep.* (Ph. E.) From *any variety of cinchona bark* (in powder), 4 oz.; *proof spirit*, 24 fl. oz.; prepare a tincture by displacement, distil off most of the spirit, and evaporate

the residuum to the consistence of an extract.

2. (Ph. L. 1809.) From the *tincture* made with *rectified spirit*.

3. (Ph. L. 1788.) As *extract of jalap*, Ph. L.

4. (Ph. U. S.) *Peruvian bark*, 1 lb; *rectified spirit*, 4 pints; make 4 pints of tincture by displacement; add *water* to the mass in the percolator, digest, and obtain 6 pints of infusion; distil off the spirit from the tincture, and evaporate the infusion to the consistence of syrup, then mix the two, and complete the evaporation. More active than the aqueous extract. *Dose.* 5 to 20 gr.

5. (Ellis.) *Yellow bark*, 2 lb; *hydrochloric acid*, 4 fl. dr.; *water*, 1 gall.; boil, strain, and repeat the decoction with *fresh water* and *acid*; mix the decoctions, filter, and agitate it with *fresh-slaked lime*, 2½ oz.; filter or decant; dry the residuum and exhaust it with *hot alcohol*, q. s.; lastly evaporate the alcoholic tincture to a pilular consistence. *Dose.* 1 to 5 gr. Some persons have proposed to call this "*essential salt of bark.*"

EXTRACT (Cinchona,—Vinous). Syn. *Extractum Cinchonæ Vinosum*,—Lat. *Prep.* (Ph. Hesse.) *Peruvian bark* (in powder), 1 part; *white wine* (sherry), 8 parts; digest 3 days, express, filter, and evaporate.

EXTRACT (Cocculus). Syn. *Extract of Cocculus Indicus, Black Extract, Extract* (Brewer's), *Beer Strengthener, Hard Multum; Extractum Cocculi, E. C. Indici*,—Lat. *Prep.* From *cocculus indicus*, by decoction. It is kept in two states,—*one*, that of thick treacle; the *other*, that of a pilular extract. The *first* is "put up" in bladders; the *last* is made into ½ *lb.* rolls, like lead plaster or roll-chocolate. It is narcotic and poisonous, and is employed by fraudulent brewers and publicans to give a false strength to their liquors. There is scarcely a drop of *porter* retailed in London that is not *poisoned* with it. See *Black Extract, Beer, &c.*

EXTRACT (Colchicum). Syn. *Extract of Meadow Saffron, Ext. of the Corms of Colchicum; Extractum Colchici*,—Ph. L. *Ext. C. Cormi*,—Ph. L. 1836. *Prep.* 1. (Ph. L.) From the *fresh corms* or *bulbs* of *meadow saffron* (having removed the outer coat), as *extract of aconite*, Ph. L.

2. (Wholesale.) From the *decoction* of the *dried corms*. *Prod.* 50% to 55%.

Obs. This extract is given in the usual cases in which colchicum is employed. *Dose.* 1 to 4 gr., every third or fourth hour. (Thomson.) "A favorite remedy of Dr. Hue, of St. Bartholomew's Hospital, in the early stages of acute rheumatism. The dose is 1 gr. every four hours." (Pereira.)

EXTRACT (Colchicum,—Acetic). Syn. *Acetic Extract of Meadow Saffron; Extractum Colchici Aceticum*,—Ph. L. & E. *Ext. Cormi C. A.*,—Lat. *Prep.* 1. (Ph. L.) *Fresh corms* or *bulbs*, 1 lb; remove the outer coating, bruise them, and sprinkle on them, gradually, *acetic acid*, 3 fl. oz.; then express the juice, and, *unstrained*, evaporate it to a proper consistence, in wedgewood ware or earthen vessels.

2. (Wholesale.) *Dried corms*, 14 *lb.*; *acetic acid* (pyroligneous), 6 pints; *distilled water*, 5¼ gall.; digest for 14 days, express, filter, and evaporate. *Product*, 2½ to 3 *lb.*

Obs. The above extracts are generally prepared from the dried corms, and hence the very uncertain and inferior quality of those commonly met with. They also possess less activity than the Pharmacopœial preparations. They rapidly get dry and crumbly, and, unless a *little spirit* and *oil of cloves* are added, will scarcely keep a week in warm weather without becoming mouldy. *Dose.* 1 to 3 gr., two or three times a day. It is much stronger than the common extract, and contains the *acetate of colchicina*. Sir C. Scudamore prefers the acetic extract prepared by the 2d formula (see *above*).

EXTRACT (Colchicum, — Alcoholic). Syn. *Extractum Colchici Alcoholicum*,—Lat. *Prep.* (P. Cod.) As *extract of box*. More active than even the acetic extract. All the preparations of colchicum are *poisonous* in large doses.

EXTRACT (Colocynth). Syn. *Extract of Bitter Apple; Extractum Colocynthidis*,—Ph. L. & E. *Ext. C. Simplex*,—Ph. D. 1826. *Ext. C. Molle*,—Lat. *Prep.* 1. (Ph. L.) From *colocynth pulp* (cut in pieces and the seeds removed), by simple maceration in *cold water*, for 36 hours, frequently pressing it with the hands, and afterwards strongly pressing out the liquor, which must be strained before evaporating it.

2. (Ph. E.; Ph. L. 1836, & D. 1826.) From the *decoction*. This is the plan adopted at Apothecaries' Hall, and in the laboratory generally. Many houses do not even remove the seeds.

Obs. This extract rapidly gets hard, crumbly, and mouldy, by keeping. For the remedy see *above*. *Dose.* 5 gr. to 20 gr.; as a cathartic. Colocynth pulp yields about 6% of extract.

EXTRACT (Colocynth, — Alcoholic). Syn. *Extractum Colocynthidis Alcoholicum*,

—Lat. *Prep.* 1. (Ph. Baden.) As *extract of angelica*, Ph. Bad.

2. (P. Cod.) From a *tincture prepared* with *proof spirit.* Much more active than the simple extract. *Dose.* 2 to 7 gr.

EXTRACT (Colocynth, — Dry). Syn. *Extractum Colocynthidis Siccum*, — Lat. *Prep.* (Ph. Bor.) As the last, but using *spirit* of the sp. gr. 0·900 (*about* 16 o. p.), digesting at a tepid heat, evaporating to dryness, and powdering. *Dose.* 1 to 6 gr.

EXTRACT (Colocynth, — Compound). Syn. *Compound Extract of Bitter Apple, Cathartic Extract; Extractum Catharticum*,—Ph. L. 1746. *Ext. Colocynthidis Compositum*,—Ph. L. 1836, & Ph. D. 1826. *Prep.* 1. (Ph. L. 1836.) *Colocynth pulp* (sliced, without the seeds), 6 oz.; *proof spirit*, 1 gall.; digest with a gentle heat for 4 days, express, strain, and add of *extract of aloes* (Ph. L. 1836), 12 oz.; *powdered scammony*, 4 oz.; *Castile soap* (cut small), 3 oz.; and evaporate (distil) to a proper consistence; adding, towards the last, *powdered cardamoms*, 1 oz.

2. (Ph. D. 1826.) As the last, but using *hepatic aloes* in lieu of the aqueous extract.

3. (Wholesale.) The formulæ adopted by the wholesale druggists are mere modifications of that of the Ph. L. 1809; *water* being used instead of *spirit* as the menstruum, with actual benefit, as we honestly believe, to the quality of the preparation. The following are extensively employed by those who do most in this article, and we can speak highly of the quality of the products obtained by their use:

a. Turkey colocynth, 18 *lb.*, is boiled in about 20 times its weight of *water* for five or six hours; to the *strained decoction* is added *hepatic aloes*, 40 *lb.*, which are boiled until dissolved, when the solution is decanted. In the mean time the *colocynth* is *exhausted* with a *second quantity of water*, (less than the first,) and the strained liquor is added to the *undissolved residuum of the aloes*, and boiled for a few minutes; after which it is drawn off and mixed with the first *decoction of aloes;* the mixed liquors are then allowed to stand until *quite cold* (commonly until the next day) to deposit the resinous portion. The liquor is next decanted or drawn off, and set evaporating as quickly as possible; as soon as the consistence of treacle is arrived at, the whole is allowed to *cool considerably*, and *moist sugar* (clean), 4 *lb.*, and *Castile soap*, 10 *lb.* (previously melted with a *little* water), are added; *powdered scammony*, 6 *lb.*, is next gradually sifted in, the extract all the time being assiduously stirred by a second person. Lastly, the heat is further moderated, and the stirring continued until a *rather harder* consistence is acquired than is proper for the extract, when the steam is *wholly* "shut off," or the vessel removed from the heat, and as soon as the whole has become *sufficiently cool* to prevent any considerable *evaporation of the spirit, essence of cardamoms*, 2 *lb.* (say, 1 quart), is expertly stirred in; and the extract *at once* (whilst still warm) put into stone jars or pots, and tied or covered over, for store or use. The product is usually labelled *Ext. Colocynth. Comp. Opt.* It looks well, and smells very aromatic, and is really an excellent preparation.

b. Turkey colocynth, 2¼ *lb.; hepatic aloes*, 5½ *lb.; powdered scammony*, 1½ *lb.; powdered cardamoms*, 6 *oz.* (or *essence*, ½ pint); *Castile soap* (genuine), 1 *lb.* 2 *oz.; pale moist sugar*, ½ *lb.;* proceed as last. This produces a beautiful article, and of unquestionable quality, equally effective, and milder in its action than the college preparation. It is labelled and sent out as *Ext. Colocynth. Comp. Ph. L.* (1836.)

c. (Ph. L. 1809.) *Colocynth*, 6 dr., (6 parts;) *aloes*, 1½ oz., (12 parts;) *scammony*, ½ oz., (4 parts;) *hard soap*, 3 dr., (3 parts;) *cardamoms*, 1 dr., (1 part;) as No. 3, *a*, (nearly).

Qual., &c. Compound extract of colocynth is often adulterated with acrid cathartics to make up for the deficiency or inferiority of its proper ingredients, and foreign matter often becomes mixed with it by the use of impure scammony. The presence of CAPE ALOES may usually be detected by the *nauseous odour;* CHALK (an article frequently present in bad scammony), by placing a little ball of the extract in a glass tube, and pouring over it some *dilute hydrochloric* or *acetic acid*, when an effervescence will ensue, if that substance be present; JALAP, SCAMMONY *adulterated with fecula*, and other STARCHY SUBSTANCES, by the filtered decoction of the extract turning blue on the addition of *tincture of iodine;* GAMBOGE, by the decoction becoming deep red on the addition of *liquor of potassa*, and by a filtered alcoholic solution of the extract, forming a yellow emulsion with *water*, which becomes transparent and assumes a deep red colour on the addition of *caustic potassa;* and further, by this solution (if the alkali is not in excess) giving a yellow precipitate with *acids* and with *acetate of lead*, a brown precipitate with *sulphate of copper*, and a very dark brown one with the *salts of iron;* also by the *ethereal solution of the extract* dropped

on *water*, yielding an opaque yellow film, soluble in *caustic potassa*, if it contains *gamboge*.

Dose. 3 gr. to 15 gr. It is a safe and mild, yet certain purgative. It may be mixed with calomel without the latter being decomposed. 2½ or 3 gr. mixed with an equal weight of *blue pill* and taken overnight, forms an excellent aperient in dyspepsia, liver complaints, &c. See *Abernethy Medicines.*

Obs. There are few formulæ which have undergone so many alterations in the hands of the College as that for *compound extract of colocynth.* Before 1809, *proof spirit* was ordered to be employed as the menstruum, and, omitting the soap, the preparation resembled that of the Ph. L. 1836. In 1809, the College directed *water* to be used instead of *spirit*, and *added* a certain quantity of *soap.* In the next edition of the Pharmacopœia, (1815,) the *soap* was *again omitted;* but in the edition of 1824, the formula of 1809 was again adopted, substituting, however, *proof spirit* for the *water.* These directions were also continued in the edition of 1836. In the present Pharmacopœia (1851) the formula for this extract is omitted altogether, and in its place, a pill (*pilula colocynthidis composita*) is inserted. Can these repeated changes be explained with credit to the pharmaceutical talents of the Colleges?

The *compound extract of colocynth* and the *simple* and *compound extracts* of *sarsaparilla* are in greater demand in the wholesale trade, and are sold in larger quantities at a time, than *all* the other *medicinal* extracts put together. As a proof, if it were necessary, that "honesty is the best policy," it may be mentioned, that a certain metropolitan druggist, remarkable for the superiority of this preparation, has obtained no inconsiderable fortune by its sale alone; while the host of miserable vendors of the evaporated decoction of *musty* colocynth seed, *Cape* aloes, *worthless* scammony, and *scentless* cardamoms, sold under the name, attempt to ruin each other, by offering their rubbish at a price that precludes the possibility of a large profit, or even of the establishment of a *respectable* connexion.

EXTRACT (Contrayerva). Syn. *Extractum Contrayervæ*, Lat. *Prep.* (Palat. Cod.) From *contrayerva root*, as *extract of cinchona*, Ph. L. *Dose.* 10 gr. to ½ dr.; as a diaphoretic tonic, in low conditions of the system.

EXTRACT (Copaiba). Syn. *Resinous Extract of Copaiba; Extractum Copaibæ, E. C. Resinosum,*—Lat. *Prep.* (Mr. Thorn.) From *balsam of copaiba*, by distilling off the oil, until the residuum assumes the consistence of an extract. *Dose.* 10 to 20 gr., or more. One of the many useless preparations which encumber modern pharmacy. It may be taken in 3 dr. doses without any perceptible effect beyond a fit of indigestion.

EXTRACT (Copalche). Syn. *Extractum Copalchi, E. Corticis C.,* — Lat. *Prep.* From *copalchi bark* (croton pseudo-china), as *extract of cascarilla*, which it for the most part resembles. *Dose.* 1 to 3 gr.

EXTRACT (Couch Grass). Syn. *Extract of Dog's Grass; Extractum Graminis,* —Lat. *Prep.* 1. (P. Cod.) From the root of *couch grass* or *dog's grass* (triticum repens,—Linn.), as *extract of bistort*, P. Cod.

2. From the *fresh root*, as *extract of aconite*, Ph. L. (See *below.*)

EXTRACT (Couch Grass,—Fluid). Syn. *Mellago Graminis, Extractum Graminis Fluidum,*—Lat. *Prep.* (Ph. Hann. 1831.) From the *decoction* of the *fresh root* of *couch grass*, evaporated to the consistence of new honey. Pectoral. *Dose.* 15 gr. to ½ dr., or more.

EXTRACT (Cubebs). Syn. *Extractum Cubebæ,*—Lat. *Prep.* 1. From the *alcoholic tincture* evaporated by a very gentle heat. *Dose.* 5 gr. to 30 gr.

2. (Mr. Toller.) To the last add a little *powdered Castile soap*, when it begins to thicken, and evaporate to a pilular consistence. *Dose.* 10 gr. to 30 gr.

EXTRACT (Cubebs,—Fluid). Syn. *Liquor Cubebæ, Extractum C. Fluidum,*—Lat. *Prep.* 1. *Cubebs* (ground in a coffee-mill), 1¼ *lb.; rectified spirit*, 1 quart; prepare a tincture either by displacement, or by digestion for a week, and reduce it, by distillation at a *very gentle heat*, until the whole measures exactly 1 pint. Every *fl. oz.* represents 2 *oz.* of cubebs. *Dose.* 20 to 40 drops.

2. (M. Puche.) From *cubebs* and *proof spirit*, equal parts, by percolation; without subsequent evaporation. Represents its own weight in cubebs. *Dose.* ½ to 1 fl. dr.

3. (Ph. U. S. 1851.) *Cubebs*, 1 *lb.* (nearly); *ether*, q. s.; make 1 *quart of tincture;* then distil off 1½ pint of the ether by the heat of a water bath, and expose the residuum in a shallow vessel until the remainder of the ether has evaporated. See *Oleo-resinous Extract of Cubebs.*

EXTRACT (Cubebs, — Oleo-resinous). Syn. *Extractum Cubebæ, E. Cubebarum, E. C. Oleo-resinosum,* — Lat. *Prep.* 1. (M. Dublanc.) The *essential oil*, resulting from the careful distillation of any given

quantity of *cubebs*, is mixed with the *resinous extract* obtained by evaporating a *tincture* of the *dried residuum* made with *rectified spirit;* the whole being reduced to the consistence of a thick syrup. 1 *lb.* of cubebs yields about 6 *oz.* of this extract.

2. (Labelonge.) *Cubebs* are first exhausted with *ether*, and then with *proof spirit*, in a displacement apparatus; the *alcoholic tincture* is evaporated to an extract over a water bath, and when cold, the *ethereal tincture* is mixed with it, and the mixture abandoned to spontaneous evaporation until the ether is volatilized.

3. (W. Procter.) *An ethereal tincture* (by displacement) is poured into a large retort, and 5-6ths is drawn over by the heat of a water bath; the evaporation of the residuum, to the proper consistence, is carried on at a heat not exceeding 120° Fahr. The formula of the Ph. Baden is nearly similar. Said to represent 6 to 8 times its weight in cubebs. 1 *lb.* yields 2 *oz.* of this extract.

4. (Hamb. Cod. 1845.) This resembles No. 1, (*above.*)

Obs. This extract has a darkish-brown colour, and tastes and smells strongly of cubebs. It is only slightly soluble in water. *Dose.* 5 gr. to 20 gr.; made into an emulsion or pills, or enclosed in a capsule. See *Cubebs*, and *above.*

EXTRACT (Cucumber). See *Elaterium.*

EXTRACT (Cusparia). *Extract of Angostura Bark; Extractum Cuspariæ, E. Corticis C., E. Angosturæ,*—Lat. *Prep.* 1. From *angostura bark*, as *extract of cinchona*, Ph. L.

2. (Alcoholic.) As *extract of cinchona*, Ph. E. Stronger than the last. Both are aromatic, bitter, tonic, and stimulant. *Dose.* 10 gr. to ½ dr.; in dyspepsia, chronic diarrhœa, dysentery, &c.

EXTRACT (Daffodil). Syn. *Extractum Narcissi,*—Lat. *Prep.* 1. From the *fresh flowers of daffodil* or *yellow narcissus* (narcissus pseudo-narcissus,—*Linn.*), as *extract of aconite*, Ph. L.

2. (Alcoholic.) From the *dried flowers*, as *extract of box.* Both are pectoral and expectorant; and in large doses nauseant and emetic. *Dose.* ½ gr. to 2 gr.; in hooping-cough, &c.

EXTRACT (Dandelion). See *Extract of Taraxacum.*

EXTRACT (Digitalis). See *Extract of Foxglove.*

EXTRACT (Dog's Grass). See *Extract of Couch Grass.*

EXTRACT (Dogwood). Syn. *Extractum Cornûs, E. Corni,*—Lat. *Prep.* From *American* or *tree dogwood* (cornus florida,—Linn.), as *extract of cinchona bark.*

Obs. In its general effects American dogwood approaches the cinchonas, and is said to be not inferior to them in the cure of intermittents. (Bigelow.) It contains a peculiar bitter principle called *Cornine.* Several other varieties of the *genus* cornus, as *round-leaved dogwood* (cornus circinata), *swamp dogwood* (cornus sericea), &c., are used in America, but are less valuable.

EXTRACT (Dulcamara). See *Extract of Bitter Sweet.*

EXTRACT (Elaterium). Syn. *Inspissated Juice of the Squirting Cucumber; Succus Spissatus Momordicæ Elaterii.* For preparation and recent synonyms, see *Elaterium.*

EXTRACT (Elder Berries). Syn. *Elder Rob; Roob Sambuci, Extractum Sambuci, E. S. Nigræ, E. Baccarum S., Succus Sambuci Inspissatus,*—Lat. *Prep.* 1. (Ph. L. 1788.) The *expressed* and *depurated juice of elder berries*, evaporated to the consistence of honey.

2. (Ph. E. 1744.) To the above, when it begins to thicken, add 1-5th part of *sugar.*

3. (Ph. Bor.) As the last (nearly), but adding only 1 oz. of *white sugar* to each pound of the *extract* whilst still warm. *Dose.* 1 to 4 dr.; in rheumatism, gout, and various skin affections.

EXTRACT (Elecampane). Syn. *Extractum Inulæ, E. Radicum I. Campanæ, E. Helenii,*—Lat. *Prep.* 1. (Ph. L. 1746.) From a *decoction* of the *dried root.*

2. (P. Cod.) As *extract of bistort*, P. Cod.

3. (Ph. Suec. 1845.) From a *tincture* prepared with *proof spirit* and *water*, equal parts. *Dose.* 10 gr. to ½ dr.; as a diaphoretic, expectorant, and tonic; in asthma, hooping-cough, various skin diseases, &c.

EXTRACT (Elm). Syn. *Extractum Ulmi, E. Corticis U.,*—Lat. *Prep.* From the *decoction* of the bark of the *common elm* (ulmus campestris,—Linn.)

2. (Soubeiran.) As *extract of box.* Astringent and alterative. *Dose.* 20 gr. to 1 dr.; in secondary syphilis, chronic skin affections, &c.

EXTRACT (Ergot). Syn. *Aqueous Extract of Ergot, Hæmostatic Extract; Extractum Ergotæ, E. E. Aquosum, E. Secalis Cornuti, E. Hæmostaticum,*—Lat. *Prep.* See *Ergotine* (Bonjean's).

EXTRACT (Ergot,—Alcoholic). Syn. *Extractum Ergotæ Alcoholicum,* — Lat. *Prep.* See *Ergotine* (Wigger's).

EXTRACT (Ergot,— Ethereal). Syn. *Extractum Ergotæ Æthereum,*—Lat. *Prep.*

From the *ethereal tincture* by spontaneous evaporation.

EXTRACT (Fern). See *Extract of Male Fern.*

EXTRACT (Fleabane). Syn. *Extractum Erigeronis*,—Lat. *Prep.* From the *infusion* or *decoction* of the herb *Canadian fleabane*, (erigeron Canadense,—*Linn.*) Reputed to be diuretic, lithontriptic, and vulnerary, and useful in dropsies, diarrhœa, and the dysury of children. *Dose.* 5 to 10 gr. Less active extracts are prepared from *common fleabane* (erigeron acre,—*Linn.*), *Philadelphia fleabane* (erigeron Philadelphicum,—*Linn.*), and *American fleabane* (erigeron annuum,—*Pers.*); all of which are common in the United States of America.

EXTRACT (Flesh). Syn. *Extract of Meat; Extractum Carnis*,—Lat. See *Essence of Beef, Beef Tea, &c.*

EXTRACT (Foxglove). Syn. *Extractum Digitalis*,—Ph. L. and E. *Prep.* 1. (Ph. L. 1836.) From the leaves of *digitalis purpurea*, as *extract of aconite*, Ph. L.

2. (Ph. E.) From the filtered *expressed juice*, either evaporated *in vacuo*, with the aid of heat, or by exposure to a current of dry air.

3. (P. Cod.)—*a.* As *extract of bistort*, P. Cod.

b. As *extract of box*, P. Cod.

4. (Ph. Baden.) As *alcoholic extract of aconite*, Ph. Bad.

Obs. The juice of foxglove is very readily injured by exposure to air and heat. The evaporation should therefore be conducted as rapidly as possible, but at a low temperature. It is narcotic, sedative, and is powerfully *poisonous*. *Dose.* ½ gr. cautiously increased to 2 or 3 gr. It is principally given in fevers, dropsy, diseases of the heart, pulmonary consumption, epilepsy, scrofula, and asthma. This extract spoils by long keeping. The last two are stronger than the rest, and keep better. It is omitted in the present Ph. L.

EXTRACT (Fumitory). Syn. *Extractum Fumariæ*,—Lat. *Prep.* 1. From either the *infusion* or *decoction* of the *dried leaves* of *common fumitory* (fumaria officinalis,—*Linn.*)

2. (P. Cod.) From the *clarified juice* of the *fresh herb*. Slightly aperient, diaphoretic, and alterative. It has been given in obstructions of the liver and cutaneous affections of the leprous kind.

EXTRACT (Galls). Syn. *Extractum Gallæ, E. Gallarum*,—Lat. *Prep.* 1. From the infusion by maceration or displacement with *cold water*.

2. From the *hot infusion* or *decoction*. The first is to be preferred. Astringent. *Used* chiefly in ointments and injections for piles, foul ulcers, &c., and, *internally*, in hemorrhages, spitting of blood, &c.

EXTRACT (Gentian). Syn. *Extractum Gentianæ*,—Ph. L. E. & D. *Ext. G. Molle, Ext. Radicis G.; E. R. G. Luteæ*,—Ph. D. 1826. *Prep.* 1. (Ph. L.) *Gentian root* (sliced), 3 lb; *distilled water* (temperate), 4 pints; macerate for 12 hours, and gently express the liquor; repeat the maceration with *water*, 1 quart, for 6 hours; and evaporate the mixed liquors.

2. (Ph. L. 1836). From the ordinary *infusion of the root* made with 10 or 12 times its weight of *boiling water*, the maceration being continued for 24 hours.

3. (Ph. E.) From an *infusion* prepared by percolation with *cold water*. The formulæ of the Ph. Baden, Paris, and U. S. are similar.

4. (Ph. D.) *Gentian*, 1 *lb.*; *water* (cold), 1½ pint; macerate for 6 hours, and repeat the process a second time with a like quantity of *water*.

5. (Ph. D. 1826.) From the *decoction*.

Obs. On the large scale this extract is almost universally prepared by exhausting the root by coction with water, as in the last formula. When well prepared it is one of the smoothest and brightest extracts of the pharmacopœia. Good gentian root *yields* by *infusion in hot water* fully 50%, and by *decoction*, about 60% of extract. *Dose.* 10 gr. to 30 gr., two or three times daily, as a stomachic bitter, and tonic; either alone or combined with rhubarb, ginger, or aloes. It is, however, more especially used as a vehicle for chalybeates and other metallic preparations. The principal consumption of extract of gentian is by the brewers in lieu of hops.

EXTRACT (Gentian,—Hard). Syn. *Extractum Gentianæ Durum*,—Lat. The last dried by a gentle heat until brittle enough to powder.

EXTRACT (Ginger). See *Zingiberine.*

EXTRACT (Goulard's). See *Liquor of Diacetate of Lead.*

EXTRACT (Guaiacum Wood). Syn. *Extractum Guaiaci, Ext. Ligni G., E. L. G. Molle, E. L. Vitæ*,—Lat. *Prep.* 1. (Ph. L. 1746.) From *lignum vitæ shavings* or *sawdust*, exhausted by coction with *water*; as soon as the mass becomes thick, 1-8th of *rectified spirit* is to be added.

2. As the last, omitting the spirit. Diaphoretic, diuretic, and alterative; in dropsy, gout, rheumatism, skin diseases, &c.

EXTRACT (Guarana). Syn. *Extractum Guaranæ, E. Paullinieæ*,—Lat. *Prep.*

(Dr. Gavrelle). From *tincture of guarana* (seeds of *paullinia sorbilis*), prepared by coction with *proof spirit*. Tonic and alterative. *Dose.* 2 to 5 gr., twice or thrice daily.

EXTRACT (Hæmostatic). See *Extract of Ergot.*

EXTRACT (Hardhack). Syn. *Extractum Spirææ*,—Lat. *Prep.* From the *root* of *spiræa tomentosa*, as *extract of bistort.* The extract of the leaves and flowers is more active than that of the root. *Dose.* 5 to 15 gr.; as a tonic and astringent.

EXTRACT (Hedge Hyssop.) Syn. *Extractum Gratiolæ*,—Lat. *Prep.* (Ph. Bor.) From the *herb*, as *alcoholic extract of aconite*, Ph. Bor.

2. (Ph. Baden.) As *extract of aconite*, Ph. Baden.

3. (*Vinous.*) As *vinous extract of cinchona.* Purgative, diuretic, and vermifuge. *Dose.* 2 to 5 gr., gradually increased, watching its effects; in dropsy, jaundice, gout, &c. It has been said to be the basis of the celebrated "*Eau Médicinale d'Husson.*"

EXTRACT (Hellebore). Syn. *Extract of Black Hellebore; Extractum Hellebori; Ext. Hellebori Nigri*,—Ph. L. 1788. *Prep.* 1. From the *infusion* or *decoction* of *black hellebore.* *Dose.* 5 to 12 gr.

2. (*Alcoholic*,—P. Cod. & Ph. U. S.) As *extract of box* (nearly). That of the Ph. Bad. is similar. *Dose.* 3 to 8 gr.

3. (*Vino-alcoholic*,—Cottereau.) *Powdered black hellebore*, 2 lb; *salt of tartar*, ½ lb; *dilute alcohol* (sp. gr. ·935), 7 pints; digest 12 hours and express the tincture; add to the marc, *white wine*, 7 pints; digest for 24 hours, express, mix the tinctures, filter, and evaporate. *Dose.* 2 to 6 gr.

Obs. When prepared by coction with water till exhausted of soluble matter, black hellebore root yields about 40% of extract. In *small doses* it is alterative, purgative, and resolvent; in larger ones, it is a drastic, hydragogue cathartic, and emmenagogue, dangerous unless combined and its effects carefully watched.

EXTRACT (Hellebore,—Alkaline). Syn. *Extractum Hellebori Alkalinum, E. H. A. Bacheri*,—Lat. *Prep.* (P. Cod.) As *vino-alcoholic extract of hellebore.* See *above.*

EXTRACT (American Hellebore). Syn. *Extractum Veratri Viridis*,—Lat. *Prep.* (Osgood.) From the *fresh root of American hellebore* (veratrum viride), as *extract of aconite*, Ph. L. *Dose.* ⅙ gr. to ½ gr. *Used* in America in the same cases as white hellebore.

EXTRACT (White Hellebore). Syn. *Extractum Veratri, E. Hellebori Albi*,—Lat. As *extract of hellebore.* (See *above.*) *Dose.* 1/12 gr. to ¼ gr. Emetic, purgative, stimulant, and highly acrid. In gout, rheumatism, and nervous affections, mania, &c. See *Veratria.*

EXTRACT (Hemlock). Syn. *Inspissated Juice of Hemlock; Extractum Conii*,—Ph. L. E. & D. *Succus Spissatus Conii*,—Ph. D. 1826. *Succus Cicutæ Spissatus*,—Ph. L. 1788; and Ph. D. 1807. *Prep.* 1. (Ph. L.) From the *fresh plant*, as *extract of aconite*, Ph. L.

2. (Ph. E.) As *extract of foxglove*, Ph. E.

3. (Ph. D.) As *extract of belladonna*, Ph. D.

Obs. Of all the *inspissated juices*, (not even excepting that of aconite,) this is the one most readily injured by exposure to the air and heat, and which soonest loses its qualities by age. Its active principle is *conia.* Extract of hemlock has a greenish colour, and a strong odour of the fresh-bruised plant. It is "of *good quality* only when a very strong odour of conia (a *mouse-odour*) is disengaged by degrees, on its being carefully triturated with liquor of potassa." (Ph. E.) "The extracts of hemlock may become feeble, if not inert, in one of two ways,—either by the heat being continued after the concentration has been carried to a certain extent, or,—by long keeping. On the one hand, I have always observed, that from the point at which the extract attains the consistence of *thin syrup*, ammonia begins to be given off in abundance, together with a modified odour of conia; and, on the other hand, I have found extracts, which were unquestionably well prepared at first, *entirely destitute of conia* in a few years." (Christison.) The most active extract is that which is procured by *moderate pressure* from the *leaves* only." (Brande.) On the *large scale*, the whole of the green portion of the plant is pressed for juice. 1 cwt. of hemlock yields from 3 to 5 *lb.* of extract. *Dose.* 2 gr., gradually increased to 5 gr., or more, until some obvious effect is produced; as an anodyne, alterative, and resolvent in various obstinate disorders, as glandular and visceral enlargements, foul and painful ulcers, scrofula, cancer, neuralgia, rheumatism, troublesome coughs, &c.

EXTRACT (Hemlock,—Alcoholic). Syn. *Extractum Conii Alcoholicum*,—Lat. *Prep.* 1. (Ph. Baden.) As *alcoholic extract of aconite*, Ph. Baden.

2. (P. Cod.) As the last, but using *proof spirit*. *Dose.* ½ to 2 gr.

EXTRACT (Hemlock,—Dried). Syn. *Extractum Conii Siccum*,—Lat. *Prep.* As *dried extract of aconite*, P. Cod.

EXTRACT (Hemp). Syn. *Extract of American Hemp; Extractum Apocyni, Ext. A. Cannabini*,—Lat. *Prep.* From the *root of apocynum cannabinum* (Linn.), as *extract of gentian*. A hydragogue cathartic. *Dose.* 2 to 5 gr.; in dropsy, &c. The plant from which this extract is prepared, is called *Indian hemp* in the United States of America, a practice which should be avoided, as this name is now almost exclusively appropriated to *cannabis Indica*, a variety of the common hemp (*cannabis sativa*, var. *Indica;*) growing in India. We therefore proposed, some time since, to call apocynum cannabinum, *American hemp*, by which confusion would be avoided.

EXTRACT (Henbane). Syn. *Extract of Hyoscyamus; Extractum Hyoscyami*,—Ph. L. E. & D. *Succus Spissatus Hyoscyami*,—Ph. D. 1826. *S. S. H. Nigri, &c. Prep.* 1. (Ph. L.) From the *fresh leaves* and *leaf-stems* of *common henbane* (hyoscyamus niger), as *extract of aconite*, Ph. L.

2. (Ph. E.) As *extract of foxglove*, h. E.

3. (Ph. D.) As *extract of belladonna*, Ph. D.

4. (Ph. U. S.) From the *expressed juice* coagulated by heat and strained.

Obs. In the Paris Codex extracts are prepared from henbane both by the processes Nos. 1 and 4 above. *Product* (by the ordinary method);—1 *lb.* of the fresh leaves yielded fully 8 dr. of extract (Geiger); 1 cwt. yielded 4 to 5 *lb.* (Brande); 1 cwt. of the recent plant yielded, by an ordinary screw press, 59½ *lb.* of *juice*, and this, evaporated in a water-bath, gave 5 *lb.* 9 *oz.* of extract. (Squire.) 1¾ cwt. of the green herb yielded 11 *lb.* of extract. (Gray.) *Dose.* 2 to 10 gr. as an anodyne, hypnotic, antispasmodic, sedative, and narcotic; more especially in those cases in which the use of opium is objectionable. *Externally*, as a topical application to sore or inflamed parts, either made into an ointment or spread on plaster.

EXTRACT (Henbane,—Alcoholic). Syn. *Extractum Hyoscyami Alcoholicum*,—Lat. *Prep.* The formulæ of the Ph. Bad. Par. & U. S. are similar to those for *alcoholic extract of aconite*.

EXTRACT (Henbane Seeds). Syn. *Extractum Seminum Hyoscyami*,—Lat. *Prep.* (P. Cod.) An *extract of the seeds* made with *spirit*, sp. gr. 0.900 (= about 16 o. p.) is dissolved in 4 parts of *cold water*, and the solution filtered, and evaporated. Stronger than the simple extract. *Dose*, ¼ gr. to 3 gr.

EXTRACT (Holy Thistle). Syn. *Extractum Cardui Benedicti*,—Lat. *Prep.* 1. (Ph. Baden.) From *holy* or *blessed thistle* (cnicus benedictus,—*Linn.*) by displacement with *cold water*.

2. (Ph. Bor.) As *extract of gentian*, Ph. L. (nearly). Tonic, diaphoretic, febrifuge, often diuretic, and occasionally, emetic. *Dose.* 5 to 15 gr., as a tonic or stomachic, chiefly.

EXTRACT (Hops). Syn. *Extractum Lupuli*,— Ph. L. & E. *Ext. Humuli*,—Ph. D.; & Ph. L. 1824. *Prep.* 1. (Ph. L.) From the *strobiles* or *catkins* of *humulus lupulus* (commercial hops), 2½ ℔; *boiling distilled water*, 2 gall; macerate for 24 hours, boil to a gallon, strain whilst hot, and evaporate to a proper consistence. The form of the Ph. E. is nearly similar.

2. (Ph. D.) As *extract of aloes*, Ph. D. Tonic and stomachic, and slightly anodyne and hypnotic. *Dose.* 5 gr. to 30 gr.; in dyspepsia, and cases that do not permit of the use of opium. 1 cwt. of ordinary hops yield about 40 *lb.* of extract. (Brande.) The druggists usually employ hops 2 or more years old, called by the dealers "*yearlings*," "*olds*," or "*old olds*," because these may be purchased at ⅔ to ½ the price of those of the last season's growth. The first of the above are estimated to have only ⅔ the strength of new hops; the second about ½; and the last little or none, at least in a medical point of view.

EXTRACT (Hops,—Alcoholic). Syn. *Extractum Lupuli Alcoholicum*,—Lat. *Prep.* (Cottereau.) By displacement with *proof spirit*. Stronger than the last.

EXTRACT (Horehound). Syn. *Extractum Marrubii*,—Lat. *Prep.* 1. From the *fresh herb* as *extract of aconite*.

2. From the *infusion* or *decoction*. Antispasmodic, pectoral, tonic, and emmenagogue. *Dose.* 10 gr. to 1 dr.

3. (Ph. Baden.) By displacement with *cold water*.

EXTRACT (Horehound, — Alcoholic). Syn. *Extractum Marrubii Alcoholicum*,—Lat. *Prep.* From a *tincture* made with *proof spirit*. Said by M. Thoriel to possess considerable power as a febrifuge. *Dose.* 5 gr. to 20 gr.

2. (Ph. Lusit.) From a *tincture* made with a mixture of *rectified spirit*, 1 part; and *water*, 7 parts. Inferior to the last.

EXTRACT (Indian Hemp.) Syn. *Cannabine, Hemp Resin, Alcoholic Extract of*

Indian Hemp; Extractum Cannabis Indicæ, Ext. C. I. Alcoholicum, E. C. Resinosum, Cannabinum, Resina Cannabis,—Lat. *Prep.* (O'Shaughnessy.) The dried *resinous tops* of Indian hemp (*gunjah*) are boiled in *rectified spirit* until all the resin is taken up, when most of the spirit is distilled off, and the evaporation completed by the heat of a water bath. 1 cwt. yields about 7 *lb.*

2. (Mr. Robertson.) By slowly acting on the *gunjah* with the *vapour of alcohol*, by a species of percolation; the spirit of the resulting *tincture* is partly removed by distillation, and the rest by slow evaporation at a temperature not above 150° Fahr. 1 cwt. yields about 8 *lb.* *Dose* of the last two, 1 to 3 gr., gradually increased.

3. (Messrs. Smith.) The *bruised gunjah* is exhausted with *tepid water*, then with a *solution of carbonate of soda* (1 of *carbonate* to 2 of *gunjah*), and next with *pure water;* it is then pressed, dried, and exhausted by displacement with *rectified spirit;* the tincture is agitated with a *milk of lime* (containing 1 oz. of *lime* for every lb of *gunjah*), and after filtration or decantation, any retained lime is precipitated by a little *sulphuric acid* in slight excess; the tincture is next agitated with *animal charcoal*, and again filtered; most of the *spirit* is now removed by distillation, and 3 or 4 times its bulk of *water* being added, the *remaining spirit* is removed by a gentle heat; lastly, the remaining water is poured off, and the resin washed with *fresh water*, and dried. Product 6%. Commencing *dose*, ¼ gr.

Obs. Cannabine has been stated by different parties to be anæsthetic, anodyne, hypnotic, stimulant, phrenic, and aphrodisiac, and, in over doses, to produce catalepsy. (O'Shaughnessy, and others.) It has been recommended in hysteria, hydrophobia, cholera, rheumatism, chorea, convulsions, and various other painful spasmodic and nervous affections of a serious character. According to the above authority, 1 *gr.* produced catalepsy in a rheumatic patient. The extract prepared with the plant grown in our botanic gardens has quite a different effect to that of the Indian plant; and it also appears that the inhabitants of this country are less susceptible to its action than those of India, and consequently bear the drug in larger doses. This hemp is known in India as the "*increaser of pleasure*," the "*exciter of desire*," the "*cementer of friendship*," the "*causer of a reeling gait*," the "*laughter-mover*," &c. See *Extract of Hemp, Cannabine, &c.*

EXTRACT (Indian Hemp, — Purified). Syn. *Extractum Cannabis Indicæ Purificatum*, — Ph. D. *Prep.* (Ph. D.) *Extract of Indian hemp* (commercial), 1 *oz.; rectified spirit*, 4 *fl. oz.;* dissolve, and after defecation, decant, and evaporate.

EXTRACT (Ipecacuanha). Syn. *Extractum Ipecacuanhæ,*—Lat. *Prep.* 1. (P. Cod.) From *ipecacuanha*, as *extract of box*, P. Cod.

2. (Ph. Bor.) As *extract of henbane seeds*, Ph. Bor. Expectorant and emetic. *Dose.* 1½ to 8 gr.

EXTRACT (Iron). Syn. *Extractum Ferri, Ext. Martis,*—Lat. From *tincture of tartarized iron.* *Dose.* 2 to 10 gr. as a chalybeate tonic.

EXTRACT (Iron, — Compound). See *Extract of Apple* (Chalybeated).

EXTRACT (Jalap). Syn. *Extractum Jalapæ,*—Ph. L. & D. *Ext. sive Resina Jalapæ,*—Ph. E. *Ext. Jalapii,*—Ph. L. 1788. *Ext. Jalapæ Resinosum, E. Radicis J., E. Jalapii Molle,*—Lat. var. *Prep.* 1. (Ph. L.) *Jalap* (powdered), 2½ lb; *rectified spirit*, 1 gall.; digest 4 days, and express the tincture; boil the *marc* in *water*, 2 gall., until reduced to ½ gall.; filter the tincture and decoction separately, and let the one *distil* and the *other* evaporate until each thickens; lastly, mix the two and complete the evaporation. The *formulæ* of the Ph. E. and U. S. are similar. *Product.* About 66%, = 16% of *alcoholic*, and 50% of *aqueous extract.* (Brande.) 18 *lb.* yield 12 *lb.* of extract. (Lab. Journ.) *Dose.* 6 to 15 gr.

2. (Ph. E.) From *tincture of jalap* prepared by displacement with *rectified spirit.* It consists of *impure resin of jalap.* It is more active than the last. *Prod.* 16%. *Dose.* 2 to 6 gr.

Obs. Extract of jalap is an active purgative. It should be well beaten up with a little *sulphate of potassa*, *sugar*, or some *aromatic powder*, to prevent it griping. The substance commonly sold as *extract of jalap* in the shops is prepared by *boiling jalap root* for 3 or 4 hours in water, when it is taken out, and well bruised or sliced, and again *boiled with water* until *exhausted of soluble matter.* The mixed decoctions are then allowed 12 or 14 hours for defecation, after which the supernatant portion is decanted and evaporated.

Extract of jalap "should be kept in the soft state, (*extractum jalapæ; e. j. molle;*) so as to form pills; and in the hard state, (*hard extract of jalap; extractum jalapæ durum;*) that it may be rubbed to powder." (Ph. L.)

EXTRACT (Jalap,—Alkaline). Syn. *Extractum Jalapæ Alkalinum,*—Lat. *Prep.*

(Ph. E. 1744.) By adding *subcarbonate of potassa*, 1 oz.; to the *water*, used to make the *extract of jalap* (Ph. L.). The object was to increase its solvent power. *Dose.* 5 to 15 or 20 gr.

EXTRACT (Juniper). Syn. *Extractum Juniperi, Ext. Baccarum, J.*,—Lat. *Prep.* (P. Cod.) Macerate *juniper berries* in *water* at 77° to 86° Fahr., for 24 hours, strain, repeat the process with a fresh quantity of water, mix the liquors, filter, and evaporate. *Dose.* 20 gr. to 1 dr.; as a stimulant diuretic, in dropsy, &c.; and also as a pill-basis.

EXTRACT (Kaladana). Syn. *Extractum Kaladanæ*,—Lat. *Prep.* (Bengal Disp.) From the *tincture* of the berries of *convolvulus nil* (Linn.) or *kaladana*. Purgative. Said to be equal to extract of jalap, and of double the strength.

EXTRACT (Koochla Nut). See *Extract of Nux Vomica.*

EXTRACT (Lettuce). Syn. *Inspissated Juice of Lettuce; Extractum Lactucæ*,—Ph. L. *Succus Spissatus Lactucæ Virosæ*,—Ph. E. *Prep.* 1. (Ph. L.) From the *fresh leaves of garden lettuce* (lactuca sativa, — *Linn.*) as *extract of aconite*, Ph. L. Anodyne, sedative, hypnotic, and antispasmodic. *Dose.* 3 to 10 gr. 1 *cwt.* of lettuce *yields* 4 *lb.* to 5 *lb.* of extract.

2. (Probait.) From the *external parts of the stalks* and the *old* and *yellow leaves*, after the plants have flowered, by *maceration* in *water* for 24 hours, and *decoction* for 2 hours; the expressed liquid is first evaporated by a gentle heat, and afterwards spread on shallow dishes and dried by exposure to a current of air. Stronger than the last. *Dose.* 1 to 5 gr. See *Lactucarium* and *Thridace.*

EXTRACT (Wild Lettuce). Syn. *Inspissated Juice of Wild Lettuce; Extractum Lactucæ Virosæ; Succus Spissatus Lactucæ Virosæ*,—Ph. E. *Prep.* 1. (Ph. E.) From the *leaves* of *strong-scented wild lettuce* (lactuca virosa,—*Linn.*) See *general instructions*, page 419.

2. (P. Cod.) As *alcoholic extract of aconite*, P. Cod.

3. (Ph. Baden.) As *extract of foxglove*, Ph. Baden. *Prod., dose, &c.* Same as *extract of lettuce.*

EXTRACT (Liquorice). Syn. *Extractum Glycyrrhizæ*,—Ph. L. E. & D. *Ext. G. Molle*,—Lat. *Prep.* 1. (Ph. L.) From *fresh liquorice root*, as *extract of hops*, Ph. L.

2. (Ph. E.) From the *fresh root*, cut into slices, dried, and powdered, as *extract of gentian*, Ph. E. The form of the Ph. Baden, is very similar.

3. (Ph. D.) As ordered for *simple extracts* (extracta simpliciora,—Ph. D.)

4. (U. S. Disp.) *Crude liquorice* (Spanish juice), q. s., is dissolved in *water*, and the solution filtered and evaporated. To produce a good article (*extractum glycyrrhizæ purificatum*) in this way, the solution should be allowed some hours for defecation, and should not be decanted and strained until *quite cold.*

Obs. Soft extract of liquorice is often employed as a pill basis, and the *hard* extract (*Spanish juice, &c.*) is used as a lozenge to allay tickling cough. The principal portion of the latter is, however, consumed by the *porter brewers* and *brewers' druggists.* The product of the last formula evaporated until it is quite solid when cold, and made into small pipes, sticks, or rolls, forms the *best refined liquorice* or *refined juice* of the shops.

EXTRACT (Liquorice,— Hard). Syn. *Spanish Juice, S. Liquorice, Italian do., Black Sugar; Extractum Glycyrrhizæ Simplex, E. G. Durum, Succus G., S. G. Spissatus*,—Lat. This is seldom prepared by the English druggists, being principally imported in the dry state, from Spain and Italy. That from *Solazzi* (*Solazzi juice*) is the most esteemed. A great deal of the foreign extract is mixed with fæcula, or the pulp of plums, hence its inferior quality. It also frequently contains copper, derived from the boilers in which it is prepared. The *extract* prepared from the *fresh root* is usually preferred to the *best* foreign, as the latter has a less sweet and agreeable taste. *Refined juice* is prepared by dissolving the *foreign juice* in water, filtering and evaporating. See *Liquorice* and *above.*

EXTRACT (Lobelia). Syn. *Acetic Extract of Indian Tobacco; Extractum Lobeliæ, E. L. Inflatæ*,—Lat. *Prep.* (W. Procter.) *Lobelia seeds* (bruised), 8 oz.; *dilute alcohol* (sp. gr. 0·935), 4 pints; *acetic acid*, 1 fl. oz.; by maceration for 24 hours, and subsequent displacement. Expectorant and diaphoretic, in *small doses;* emetic and narcotic, in *larger ones.* It is principally used in asthma and other chest diseases. *Dose.* ¼ gr. to 5 gr.

EXTRACT (Logwood). Syn. *Extractum Hæmatoxyli*,—Ph. L. *Ext. H. Campechiani*,—Ph. E. *Ext. Scobis H. C.*,—Ph. L. 1826. *Ext. Ligni Campechensis*,— Ph. L. 1788. *Prep.* 1. (Ph. L.) From *cut logwood* (logwood chips), as *extract of hops*, Ph. L.

2. (Ph. E.) As the last nearly.

3. (Ph. D. 1826; & *Wholesale.*) From the decoction.

Obs. The Ph. U. S. 1841, orders the wood

to be rasped. The Ph. Baden directs displacement with *cold water*. On the *large scale* it is prepared solely by decoction. 1 cwt. of wood yields about 20 *lb.* of extract, (Brande;) 80 *lb.* yield 14 *lb.* of extract. (Gray.) It is kept in two states, hard (*extractum hæmatoxyli durum*), and soft (*e. h. molle.*) The *Dose* of the *first* is 10 to 20 gr. dissolved in wine, or any cordial water; as an astringent, after each motion in diarrhœa; the *second* is often employed as a lozenge in the same disease, and is an inexpensive and agreeable remedy for simple relaxation of the bowels.

EXTRACT (Lovage). Syn. *Extractum Levistici*,—Lat. *Prep.* (Ph. Baden.) From *lovage* (levisticum officinale), as *extract of bistort*, P. Cod. Aromatic, stomachic, and diaphoretic. *Dose.* 5 to 15 gr.

EXTRACT (Lupuline). Syn. *Extractum Lupulinæ*,—Lat. *Prep.* 1. From *lupuline* by *infusion* in *cold water*, or by displacement.

2. (*Ext. Lupulinæ Coctione Paratum.*) From the *decoction*. Both similar to extract of hops, but stronger. The first is the most aromatic; the *last* the most bitter.

EXTRACT (Madder). Syn. *Extractum Rubiæ*,—Lat. *Prep.* (Ph. Hamb.) From the tincture of *dyer's madder* (rubia tinctorum), made with *rectified spirit*, 1 part; and *water*, 3 parts. *Dose.* 10 gr. to 30 gr.; as a diuretic, emmenagogue, and parturifacient; and in jaundice, &c.

EXTRACT (Mahogany). Syn. *Extractum Mahogonis.* From the *chips* and *saw dust* of *mahogany* (swietenia mahogoni, — *Linn.*) It is astringent, and is frequently sold for kino. It is also employed in tanning.

EXTRACT (Male Fern). Syn. *Alcoholic Extract of Male Fern; Extractum Filicis, Ext. F. Alcoholicum*,—Lat. *Prep.* (Dr. Ebers.) From the *tincture* of the *dried root* of male fern (*aspidium filixmas*), made with *rectified spirit.* In tape worm. *Dose.* 20 gr. to ½ dr., twice a day, made into an electuary with powdered sugar, and followed by a strong dose of *castor oil.*

EXTRACT (Male Fern,—Ethereal). See *Oils.*

EXTRACT (Malt). Syn. *Extractum Malti, Ext. Bynes*,—Lat. *Prep.* From the *infusion* made with *water* at a temperature ranging between 160° and 170° Fahr., drained off, without pressure, and evaporated to the consistence of honey. Nutritious and laxative. *Dose.* A tablespoonful, or more, ad libitum.

EXTRACT (Marygold). Syn. *Extractum Calendulæ*,—Lat. *Prep.* 1. (Guibourt.) By maceration of the *herb* and *flowers* of the *common marygold* (calendula officinalis, —*Linn.*) in *tepid water* for 24 hours, and subsequent coction for 15 or 20 minutes.

2. (Ph. Baden.) As *extract of angelica*, Ph. Baden. *Dose.* 2 to 10 gr.; cordial, diaphoretic, alterative, and emmenagogue; in dyspepsia, and schirrous and cancerous affections.

EXTRACT (May-apple). Syn. *Extractum Podophylli*,—Lat. *Prep.* (Ph. U. S. 1841.) From the *tincture* of the *root* (rhizomes) of *may-apple*, (podophyllum peltatum,— *Linn.*) *Dose.* 5 to 15 gr.; as a substitute for extract of jalap.

EXTRACT (May-lily). Syn. *Extractum Convallariæ*,—Lat. *Prep.* From the *flowers* or *roots* of the *lily of the valley* (convallaria majalis,—*Linn.*), as *extract of hops.* Aperient and stomachic. *Dose.* 15 gr. to ½ dr. Its action resembles that of aloes, but milder.

EXTRACT (Meadow Saffron). See *Extract of Colchicum.*

EXTRACT (Meat). Syn. *Extractum Carnis*,—Lat. *Prep.* (Liebig.) The *lean of recently killed meat* (chopped very small), 1 part; *cold water*, 8 parts; agitate it well together for 10 minutes, then heat it gradually to the boiling point, let it simmer gently for a few minutes, and strain through a hair sieve whilst still hot; lastly, evaporate to a soft mass. 1 *lb.* of meat yields barely 1 *oz.* See *Essence of Beef, Beef Tea, &c.*

EXTRACT (Mezereon,—Alcoholic.) Syn. *Mezereon Resin; Extractum Mezerei Alcoholicum, Resina Mezerei*,—Lat. *Prep.* 1. (Ph. Hamb.) By distilling off ⅝ths of the *tincture* made with *rectified spirit*, and filtering the residue, retaining what is left on the filter.

2. By the simple *distillation* of the *tincture.*

Obs. Green or brownish-green; insoluble in water. ½ oz. mezereon root-bark yielded 1 dr. of dry resin. (Squire.) 1 lb yielded 1½ oz. (Hamb. Disp.) It is chiefly used in preparing blistering ointments and plasters.

EXTRACT (Mezereon,—Ethereal). Syn. *Green Oil of Mezereon; Extractum Mezerei Æthereum*,—Lat. *Prep.* 1. (Guibourt.) From the *ethereal tincture.*

2. (Ph. Bor.) By digesting *alcoholic extract of mezereon* in *ether* for some days with agitation, reducing the tincture to 1-4th by careful distillation, and evaporating the residuum by a gentle heat to the consistence of an extract.

Obs. Both the alcoholic and ethereal extract of mezereon must be kept in stoppered bottles. *Used* as an external irritant. (See *above.*)

EXTRACT (Milk). Syn. *Essence of Milk; Extractum Lactis, Essentia L.*,—Lat. *Prep.* (Plenck's Ph. 1804.) From *cow's milk* (skimmed) evaporated to dryness over a very slow fire, constantly stirring until reduced to a proper consistence. A better plan is to employ a current of warm dry air.

EXTRACT (Millefoil). Syn. *Extractum Millefolii, Ext. Achilleæ* M.,—Lat. *Prep.* From the *herb milfoil* or *yarrow* (achillea millefolium,—*Linn.*), as *extract of hops*, Ph. L. Astringent, tonic, and alterative. *Dose.* 10 gr. to ½ dr.

EXTRACT (Mimosa Bark). Syn. *Extractum Corticis Mimosæ*,— Lat. *Prep.* From the *bark* of several Australian species of acacia or mimosa (*acacia mollissima, a. decurrens, a. melanoxylon.*) It is chiefly imported from Van Diemen's Land. Astringent. Said to be superior to oak bark for tanning.

EXTRACT (Monesia). Syn. *Extractum Monesiæ, E. M. Purificatum*,—Lat. *Prep.* From *buranheim bark* (bark of *crysophyllum buranheim*); or from *commercial monesia*, as *extract of catechu.* Astringent. *Dose.* 4 to 8 gr.

EXTRACT (Mugwort). Syn. *Extractum Artemisiæ*,—Lat. *Prep.* From the *tops* of *artemisia vulgaris* (Linn.; common mugwort;) as *extract of box*, P. Cod. An active emmenagogue.

EXTRACT (Myrrh,—Aqueous). Syn. *Extractum Myrrhæ, Ext. M. Aquosum*,—Lat. *Prep.* 1. From the *strained decoction.*

2. (Ph. Bor.) As *extract of aloes* (Ph. Bor.), afterwards reducing it to fine powder. The formula of the Ph. Baden is similar. *Dose.* 6 to 15 gr.; or more.

EXTRACT (Myrrh,—Alcoholic). Syn. *Resin of Myrrh; Extractum Myrrhæ Alcoholicum, E. M. Resinosum*,—Lat. *Prep.* From the *tincture.* Tonic and stimulant. *Dose.* 5 to 10 gr. or more.

EXTRACT (Myrrh,—Compound). Syn. *Extractum Myrrhæ Compositum*,— Lat. *Prep.* (Swediaur.) *Myrrh*, 2 oz.; *gum arabic* (in powder), 2 dr.; triturate, add *water*, q. s. to form a thick emulsion, and add *extract of couch grass*, 4 oz. Much recommended in phthisis and uterine ulcerations. *Dose.* 1 to 2 dr. in water, twice or thrice daily.

EXTRACT (Nettles). Syn. *Extractum Urticæ*,—Lat. *Prep.* (P. Cod.) From the *juice of nettles* (urtica dioica,—*Linn.*), as *extract of aconite*, Ph. L. Antiscorbutic, diuretic, and narcotic.

EXTRACT (Nosegay). Syn. *Essence of Nosegay; Extrait de Bouquet. Prep. Flowers of benzoin*, 1 dr.; *essence of ambergris*, 2 fl. oz.; *spirits of jasmine* and *extract* (esprit) *of violets*, of each, 1 pint; *spirits of cassia, roses, orange flowers* and *gilly-flowers*, of each, ½ pint; mix. A delightful perfume.

EXTRACT (Nux Vomica.) Syn. *Extract of Koochla Nuts; Extractum Nucis Vomicæ, Ext. N. V. Aquosum*,—Lat. *Prep.* (Ph. Bor.) From the *powdered nut*, as *extract of hops*, Ph. L. (nearly). *Dose.* 1 to 5 gr. (See *below.*)

EXTRACT (Nux Vomica,—Alcoholic). Syn. *Extractum Nucis Vomicæ*,—Ph. L. E. and D. *Ext. N. V. Alcoholicum, &c. Prep.* 1. (Ph. L.) *Koochla* or *poison nuts* (seed or fruit of *strychnos nux-vomica*,—Linn.), 8 oz.; *rectified spirit*, 3 pints; expose them to steam until softened, then bruise, slice, and dry them, and macerate them in 2-3rds of the spirit for 7 days; express the tincture, and repeat the maceration with the remaining 1-3rd of the spirit; again express the liquid; lastly, filter the mixed tinctures, distil off the greater part of the spirit, and complete the evaporation by a gentle heat. The formula of the P. Cod. is similar, but using *spirit*, sp. gr. 0·863 (= 41 o. p.)

2. (Ph. E.) The *sliced* and *dried nuts*, are to be ground in a coffee mill, and either exhausted by percolation with *rectified spirit*, or by boiling the powder in repeated portions of the menstruum. The formulæ of the Ph. Baden and U. S. are similar.

3. (Ph. D. 1826.) From a *tincture* of the *rasped nut* made with *proof spirit*, observing that the extract whilst thickening should be properly stirred.

Obs. This extract consists chiefly of impure *igasurate of strychnia*, and is exhibited in similar cases to that alkaloid. *Dose.* ½ gr. *gradually* and *cautiously* increased to 2 gr. It is very *poisonous.* On *the large scale*, the nuts are ground in a drug mill.

EXTRACT (Oak Bark). Syn. *Extractum Quercûs, E. Corticis Quercûs*,—Lat. *Prep.* (Ph. D. 1826.) From the *decoction.* Astringent. *Dose.* 10 gr. to ½ dr. Now seldom used.

EXTRACT (Opium.) Syn. *Aqueous Extract of Opium, Simple do. do.; Extractum Opii*,—Ph. L. and E. *Ext. Opii Aquosum*,—Ph. D. *Ext. O. Purificatum*,—Ph. L. 1836. *Opium Purificatum*,—Ph. L. 1788. *Ext. Thebaicum, Opium Colatum*,—Ph. L. 1721–1745. *Prep.* (Ph. L.) *Opium* (powdered), 1½ lb.; *distilled water* (cold), 2½ pint; mix gradually and macerate for 24 hours, frequently stirring with a spatula; (press), strain, and repeat the maceration for 24 hours with a fresh *quantity* (2½ pints) of

water; lastly, evaporate the (mixed) strained liquors to a proper consistence. The formulæ of the Ph. E. D. and Baden, and P. Cod., are essentially the same.

2. (Ph. D. 1826.) As the last, but using *boiling water*, and exposing the mixed liquors to the air for 2 days, before filtering and evaporating them. Inferior to the last.

3. (*Purified.*) The *extract* prepared with *cold water*, is evaporated to dryness, powdered, and re-dissolved in *cold water;* after 48 hours' exposure, and defecation, it is decanted from the dregs, filtered, and gently evaporated, as before. Superior to any other extract of opium made.

Obs. Good opium yields from 60 to 70% of its weight of extract, but much depends upon the variety used. *Dose.* ¼ gr. to 2 gr., as an anodyne, sedative, and hypnotic. It is less stimulant than ordinary opium. That prepared by the *third* formula, is indeed scarcely inferior in its action to the salts of morphia.

This extract is kept in both the *hard* and *soft* state, (*hard extract of opium, extractum opii durum; soft do. do., ext. o. molle.*) A solution of the *former*, in *distilled water*, with the addition of a *little spirit* to keep it, forms Battley's "*liquor opii sedativus*," as we clearly showed some 14 or 15 years ago. The *second formula* is that adopted by the wholesale druggists.

EXTRACT (Opium,—Acetic). Syn. *Extractum Opii Aceticum*, — Lat. *Prep.* (Soubeiran.) *Opium*, 1 oz.; *distilled vinegar*, 1 quart; digest 2 days (with heat), decant, filter, and evaporate.

EXTRACT (Opium,—Alcoholic). Syn. *Extractum Opii Alcoholicum*,—Lat. *Prep.* (Ph. Antwerp.) From the *tincture.*

EXTRACT (Opium,—Aqueous). See *above.*

EXTRACT (Opium,—Aqueo-Alcoholic). Syn. *Ext. Opii Aquo-alcoholicum*,—Lat. *Prep.* (Taddei.) The *opium*, exhausted by *spirit*, is digested in *warm water*, and the infusion and tincture separately filtered, are mixed and evaporated.

EXTRACT (Opium, — De-narcotized). Syn. *Extractam Opii absque Narcotina*,—Lat. *Prep.* 1. (P. Cod.) The *aqueous extract* is reduced with *hot water* to the consistence of a syrup, and when cold this is mixed with 8 times its volume of *ether*, and the whole is frequently shaken for a day or two; the ethereal solution is then decanted, and the process repeated with *fresh ether*, as long as it dissolves anything. The original form of Robiquet is similar. Said to consist entirely of *impure muriate of morphia, gum* and *extractive.*

2. (M. Lamousin-Lamothe.) *Aqueous extract*, 4 parts; *resin*, 1 part; beat well together, add *boiling water*, 16 parts; boil to one-half, add *cold water*, 8 parts, filter, and evaporate.

EXTRACT (Opium,—by Fermentation). Syn. *Extractum Opii per Fermentationem*, —Lat. *Prep.* 1. *Opium* and *sugar*, of each, 4 *oz.; water*, 1 quart; rub together, and keep the mixture, loosely covered, in a warm situation (about 70° Fahr.), for 10 days or more; then add of *cold water*, 1 quart, and the next day, filter, and evaporate.

2. (Deyeux.) From an unstrained mixture of *opium*, 1 part, with *water*, 8 parts; and a *little yeast;* left for a week at a temperature of 68° to 77° Fahr., and then diluted, filtered, and evaporated. Some parties have recommended *quince juice* as the menstruum.

EXTRACT (Opium, — Roasted). Syn. *Extractum Opii Torrefacti*, — Lat. *Prep.* (Guibourt.) *Powdered opium* is heated on a flat dish over a *moderate fire*, with constant stirring, as long as fumes are given off; it is then exhausted by treating it *twice* with 6 times its weight of water, and the mixed liquor, after filtration, is evaporated.

EXTRACT (Opium, — Vinous). Syn. *Extractum Opii Vino Paratum*, — Lat. *Prep.* (P. Cod.) From *wine of opium.* The above extracts of opium (excepting the *alcoholic*) are regarded as less exciting than the other preparations of the drug. The *dose* of each, is similar to that of the aqueous extract. (See *above.*)

EXTRACT (Orange-peel). Syn. *Extractum Corticis Aurantii*,—Lat. *Prep.* 1. From the *thin yellow peel*, as *extract of madder.*

2. See *Aurantiine.*

EXTRACT (Ox-gall). Syn. *Inspissated Ox-gall; Fel Bovinum Spissatum, Extractum Fellis Bovini*,—Lat. *Prep.* (P. Cod.) From *ox-gall*, strained, and evaporated in a water bath. *Dose.* 5 to 15 gr.; in pills.

2. (Hunter Lane.) As the last, but reducing the gall to dryness, and then powdering it. It must be preserved in well-corked bottles. *Dose.* 3 to 12 gr.

EXTRACT (Pareira). Syn. *Extractum Pareiræ*,—Ph. L. & E. *Prep.* 1. (Ph. L.) From the *root* of *velvet leaf* or *pareira brava* (cissampelos pareira,—*Linn.*), as *extract of hops*, Ph. L.

2. (Ph. E.) As *extract of liquorice*, Ph. E. The P. Cod. formula is similar. Alterative, tonic, and diuretic. *Dose.* 10 gr. to ½ dr.; chiefly in affections of the bladder.

EXTRACT (Parsley). Syn. *Extractum Petroselini*,—Lat. *Prep.* (P. Cod.) From the root, as *extract of bistort*, P. Cod.

2. (M. Peraibe.) From the *fresh leaves*, as *extract of aconite*. Febrifuge and tonic. *Dose.* 5 to 10 gr.

EXTRACT (Pasque Flower). Syn. *Extractum Anemonis*,—Lat. *Prep.* (P. Cod.) From the *recent* or *dried flower*, as either of the *extracts of aconite*,—P. Cod. *Dose.* 1 to 4 gr.

Obs. Several species of anemone have been used in medicine, especially *anemone pratensis* and *a. pulsatilla*, (Linn.) According to Baron Stoerck, the former is resolvent, and is an effectual remedy in various chronic diseases, particularly in amaurosis, cataract, opacity of the cornea, nocturnal pains, suppressions, &c. ½ to 1 gr., combined with sugar of milk, has been highly recommended in hooping-cough.

EXTRACT (Patientia). Syn. *Extractum Patientiæ*,—Lat. *Prep.* From the *root* of *rumex patientia* or *garden patience* (occasionally called *patience dock*), as *extract of hops*. Aperient and stomachic. *Used* in double doses in lieu of extract of rhubarb.

EXTRACT (Paullinia). See *Extract of Guarana.*

EXTRACT (Peach Blossoms). *Prep.* From *essence of lemons*, 1 *oz.*; *pure balsam of Peru*, 2 *dr.*; *essence* (oil) *of bitter almonds*, 1 *dr.*; *rectified spirit*, 3 pints; *spirit of orange flowers*, 1 pint; *spirit of jasmin*, ¼ pint; mix. A pleasant and powerful perfume.

EXTRACT (Pellitory, — Ethereo-alcoholic). Syn. *Extractum Pyrethri, Ext. P. Æthereo-alcoholicum*,—Lat. *Prep.* (W. Procter.) *Alcohol* (rectified spirit), 1 pint; *ether*, ½ pint; mix, and pour it gradually on *root of pelitory*, 1 lb, placed in a percolator; afterwards pour on *alcohol*, 1 pint, and subsequently, sufficient *dilute alcohol* (proof spirit) to displace 2½ pints of tincture, (*Essence of Pellitory, Tooth-ache essence;*) the latter is either suffered to evaporate spontaneously, or by a very gentle heat, until a soft extract is attained. *Used* to destroy the sensibility of the nerves of teeth, previous to plugging, and for tooth-ache.

EXTRACT (Pepper). Syn. *Extractum Piperis, E. P. Nigri*,—Lat. *Prep.* From *decoction of black pepper* (bruised). Stimulant; stronger tasted than the berries, but less aromatic. *Dose.* 10 gr. to 1 dr.; in agues.

EXTRACT (Pepper,—Fluid). Syn. *Extractum Piperis Fluidum*, — Lat. *Prep.* (Ph. U. S.) From *black pepper*, as *fluid extract of cubebs*, P. U. S., separating the piperine by expression through a cloth, and keeping the fluid portion for use. (See *above.*)

EXTRACT (Pimpinella). Syn. *Extractum Pimpinellæ*,—Lat. *Prep.* From the *root of burnet saxifrage* (pimpinella saxifraga,—*Linn.*), as *extract of hops*. Astringent. *Dose.* 10 to 20 gr.

EXTRACT (Pinkroot). Syn. *Extract of Worm Grass, Ext. of Wormseed Root; Extractum Spigeliæ, E. S. Marilandicæ*,—Lat. *Prep.* From *Carolina pinkroot*, as *extract of box*, P. Cod. *Dose.* 5 to 20 gr.

EXTRACT (Pinkroot, — Fluid). Syn. *Essence of Pink Root, Liquor of do; Extractum Spigeliæ Fluidum*,—Lat. *Prep.* 1. *Pink root*, 1 *lb.*; *proof spirit*, 3 pints; make a tincture, evaporate to 10 fl. oz., add *sugar*, ¾ *lb.*, and *rectified spirit*, q. s. to make the whole measure exactly a pint. *Dose.* For a child, beginning with ½ a tea-spoonful. (See *above.*)

EXTRACT (Pinkroot, — Compound). Syn. *Compound Liquor of Pinkroot; Extractum Spigeliæ Fluidum Co.*, — Lat. *Prep.* 1. (Estlack.) *Carolina pinkroot* or *spigelia* (bruised), 4 oz.; *senna*, 3 oz.; *savine*, 1 dr.; pour on *boiling water*, 1 quart; when cold, add *rectified spirit*, ½ pint; digest 24 hours, express (or percolate), filter, evaporate to 12 fl. oz., in which dissolve, *manna*, 1 oz.; *sugar*, 8 oz. Every fl. oz. is equal to 2 dr. of pinkroot, and 1½ dr. of senna. *Dose.* For a child, ½ to 1 tea-spoonful; for an adult, a table-spoonful.

2. (W. Procter.) *Pinkroot*, 16 oz.; *senna*, 8 oz.; (both in coarse powder;) *dilute alcohol* (sp. gr. 0·935), 2 pints; macerate for 2 days, then proceed by displacement, adding *fresh spirit*, until 4 pints have passed through; filter, evaporate to 20 fl. oz., and add *carbonate of potassa*, 1 oz.; next add *oils of caraway* and *aniseed*, of each, ½ dr.; (previously triturated with) *powdered sugar*, 24 oz.; lastly, apply a *gentle* heat to dissolve the sugar.

3. (*Extractum Spigeliæ et Sennæ Fluidum*, —Ph. U. S.) As the last (nearly). *Dose.* As above. All the above preparations of pinkroot, are regarded as powerful and certain anthelmintics; particularly the last two.

EXTRACT (Pipsissewa). See *Extract of Winter-green.*

EXTRACT (Poison Oak). Syn. *Extractum Rhois Toxicodendri*,—Lat. *Prep.* (P. Cod.) From the *expressed juice* of the *leaves* of *rhus toxicodendron*, (Linn.) Narcotic, stimulant, and alterative. *Dose.* ½ gr.

to 1 gr., gradually increased; in chronic rheumatism, obstinate skin diseases, &c.

EXTRACT (Pomegranate). Syn. *Extractum Granati, E. G. Corticis G.*,—Lat. *Prep.* (Soubeiran, & P. Cod.) From the *root-bark of pomegranate*, as *extract of box*. In tape-worm. *Dose.* 10 to 20 gr.; followed by a purgative.

EXTRACT (Pomegranate-rind). Syn. *Extractum Granati, E. G. Corticis Fructûs*, — Lat. *Prep.* From the *decoction*. As the last.

EXTRACT (Poppies). Syn. *Extractum Papaveris*,—Ph. L. & E. *Ext. P. Albi*,—Lat. *Prep.* 1. (Ph. L.) *Bruised poppy-heads* (without the seeds), 15 oz.; *boiling distilled water*, 1 gall.; macerate 24 hours, boil to one-half, strain, and complete the evaporation.

2. (Ph. E.) As the last (nearly).

Obs. The medicinal action of extract of poppies, for the most part, resembles that of opium; but it is considerably weaker, and is generally regarded as less prone to produce headache and delirium. *Dose.* 2 to 12 gr. It is usually prepared by the large manufacturers, by exhausting the capsules, by coction with water; hence the inferior quality of the extract of the shops, which contains a considerable quantity of inert matter.

The principal consumption of this extract is among the brewers, brewers' druggists, and wine-merchants. For this purpose it is evaporated until it becomes hard on cooling, when it is formed into half-pound rolls, and covered with paper, like lead plaster. One of these rolls added to a hogshead of ale, stout, or sherry, materially increases the "headiness" or apparent strength of these beverages.

EXTRACT (Potato). Syn. *Extractum Solani Tuberosi*, — Lat. *Prep.* (Dr. J. Latham.) From the *stem* and *leaves* of the *potato plant*, as *extract of aconite*, Ph. L. Narcotic. *Dose.* 2 to 10 gr.

EXTRACT (Purging Flax). Syn. *Extractum Lini Carthartici*, — Lat. *Prep.* (Dr. B. Lane.) From the *dried herb*, as *extract of hops*, Ph. L. Aperient and diuretic. *Dose.* 5 to 10 gr. 14 *lb.* yielded 2¼ *lb.* of extract.

EXTRACT (Pyrola). See *Extract of Winter-green*.

EXTRACT (Quassia). Syn. *Extractum Quassiæ*, — Ph. E. *Ext. Q. Ligni, &c. Prep.* 1. From the *decoction of quassia chips*. *Product.* 5% to 6%.

2. (Ph. E.) From the *rasped wood*, as *extract of bistort*, P. Cod. Bitter and stomachic. *Dose.* 5 to 10 gr., or more.

Obs. This extract is almost universally prepared by coction, and is principally consumed by the brewers, who employ it as a substitute for hops. The bark is frequently substituted for the wood, but is considerably less bitter. The Ph. Baden has an extract prepared with spirit of 0·944.

EXTRACT (Quince Seeds). Syn. *Extractum Cydoniæ, Ext. C. Seminum. Prep.* From the *decoction*. Sucked as a lozenge, in hoarseness, &c.

EXTRACT (Ragwort). Syn. *Extractum Jacobææ*,— Lat. *Prep.* From the *fresh plant* (senecio jacobæa,—*Linn.*), as *extract of aconite*. In cholic pains, gonorrhœa, &c. *Dose.* 10 to 12 gr.

EXTRACT (Rhatany). Syn. *Extractum Rhataniæ; Ext. Krameriæ*,—Ph. E. *Prep.* 1. (Ph. E. Baden. & U. S.) From *dried rhatany root* (krameria triandria), as *extract of bistort*, P. Cod.

2. (Ph. Bor.) By two successive macerations in *boiling water* of 24 hours each, and evaporating at a temperature not exceeding 165° Fahr.

Obs. Extract of rhatany is astringent and tonic. *Dose.* 10 to 20 gr. A large quantity of this extract, of very inferior quality, is imported from Brazil, and other parts of South America. It is kept in two states, *hard* and *soft*; the former resembles kino, and is often sold for it; the latter is chiefly consumed by the *manufacturers* and "*improvers*" of port wine.

EXTRACT (Rhubarb). Syn. *Extractum Rhei*,—Ph. L. E. & D. *Prep.* 1. (Ph. L.) *Rhubarb* (in powder), 15 oz.; *proof spirit*, 1 pint; *distilled water*, 7 pints; macerate 4 days, strain, and set it aside that the fæces may subside; next decant the clear portion, strain, and evaporate to a proper consistence.

2. (Ph. E.) As *extract of cinchona*, Ph. L. (nearly.) "The extract is obtained of finer quality by evaporation in a vacuum with a gentle heat." The Baden formula is similar.

Obs. This extract is usually prepared by decoction from inferior and damaged rhubarb, picked out from the chests on purpose; hence the inferior quality of the extract of the shops. When made of *good* Turkey, or even East India rhubarb, it is a very valuable preparation. *Dose.* As a stomachic, 5 to 10 gr.; as a purgative, 10 gr. to ½ dr. It is seldom exhibited alone. *Product.* 50%.

EXTRACT (Rhubarb, — Fluid). Syn. *Liquor of Rhubarb, Essence of do.; Liquor Rhei, Extractum Rhei Fluidum*, — Lat. *Prep.* (W. Procter.) *Rhubarb* (in coarse

powder), 8 oz.; mix it with an equal bulk of coarse sand, and moisten it with *dilute alcohol* (sp. gr. 0·935=13 u. p.) to form a pasty mass; in a short time introduce it into a percolator, shake it until uniformly settled, and cover it with cloth or paper; then pour on the rest of the spirit (the remainder of 2 pints) until the product has little odour or taste of the root; next gently evaporate the tincture to 5½ fl. oz., and add *sugar*, 5 oz.; when the whole should measure 8 fl. oz. *Dose.* 15 to 30 drops.

2. (Ph. U. S.) As the last, adding of *oils of fennel* and *anise*, of each, 4 drops, (dissolved in) *tincture of ginger*, 4 fl. dr.

EXTRACT (Rhubarb, — Compound). Syn. *Extractum Rhei Compositum*, *E. Panchymagogum*,—Lat. *Prep.* (Ph. Bor.) *Extract of rhubarb*, 3 dr.; *extract of aloes*, 1 dr., (softened with) *water*, 4 dr.; mix, and add of *soap of jalap*, 1 dr., (dissolved in) *proof spirit*, 4 dr.; lastly, evaporate to an extract, dry this in a warm place, and powder. Stomachic and purgative. *Dose.* 4 to 20 gr.

EXTRACT (Rue.) Syn. *Extractum Rutæ*, *E. Foliorum Rutæ*,—Ph. D. 1826. *Prep.* (Ph. D. & Ph. L. 1788.) From *rue leaves* (rutæ graveolens,—*Linn.*), as *extract of hops*, Ph. L.

2. (*Alcoholic*,—P. Cod.) As *alcoholic extract of aconite*, P. Cod. (nearly). The formula of the Ph. Wert. is similar.

Obs. This extract is stomachic, carminative, and emmenagogue. *Dose.* 10 to 20 gr., twice a day. It is usual to add a little of the essential oil to the extract, just before taking it out of the evaporating-pan, and when nearly cold. The first is the form adopted in trade in this country.

EXTRACT (Saffron). Syn. *Polychroite; Extractum Croci*,—Lat. *Prep.* 1. From *hay saffron*, as *extract of colocynth*, Ph. L.

2. (P. Cod.) From the *tincture*. Superior to the last.

Obs. The first is *used* chiefly as a colouring and flavouring substance by cooks, confectioners, wine and cordial brewers, &c. *Dose.* 5 to 15 gr.; as an excitant, antispasmodic and emmenagogue.

EXTRACT (Sarsaparilla). Syn. *Extractum Sarzæ*,—Ph. L. 1836 & E. *Ext. Sarsaparillæ*,—Ph. D. & Ph. L. 1824. *Extrait de Salsepareille*,—Fr. *Prep.* 1. (Ph. L. 1836.) From *sarsaparilla*, as *extract of hops*, Ph. L. The Ph. D. 1826, is similar. *Dose.* 10 gr. to 1 dr. *Product.* (From Jamaica sarsaparilla) 32⅜ to 36⅜.

2. (*Wholesale.*) See *Decoction of Sarsaparilla* (and *below*).

EXTRACT (Sarsaparilla,—Alcoholic). Syn. *Extractum Sarzæ Alcoholicum*,—Lat. *Prep.* 1. From a *tincture* of the *root-bark*, prepared with *proof spirit*, either by digestion or percolation.

2. (P. Cod., and Ph. U. S.) From *sarsaparilla root* (powdered), as *alcoholic extract of aconite*, P. Cod. Superior to the aqueous extract. *Dose.* 10 to 20 gr.

EXTRACT (Sarsaparilla,—Fluid). Syn. *Liquor of Sarsaparilla*, *Essence of do.*; *Liquor Sarzæ*, *Essentia Sarsaparillæ*; *Extractum Sarzæ Liquidum*,—Ph. L. *Ext. S. Fluidum*,—Ph. E. & D. *Ext. Sarsaparillæ F.*,—Ph. D. 1826. *Prep.* 1. (Ph. L.) *Sarsaparilla*, 3½ lb; *distilled water*, 3 gall.; boil to 12 pints, pour off the liquor, and strain whilst hot; again boil the sarsaparilla in *water*, 2 gall., to one-half, and strain; evaporate the mixed liquors to 18 *fl. oz.*, and when cold, add of *rectified spirit*, 2 *fl. oz.* Each *fl. oz.* represents 2⅛ oz. of the *root* (nearly).

2. (Ph. E.) *Sarsaparilla*, 1 lb; *boiling water*, 4 pints; digest 2 hours, then bruise the root, boil it for 2 hours, filter, and express the liquid; repeat the coction with *water*, 2 pints, as before; evaporate the mixed liquors to the consistence of a *thin syrup*, and, when cold enough, add of *rectified spirit*, q. s. to make up 16 *fl. oz.* Each *fl. oz.* represents 6 dr. of the *root*, and 6 *fl. oz.* of the decoction.

3. (Ph. D.) *Sarsaparilla*, 1 *lb.* (avoir.); proceed as before, and add of *rectified spirit*, q. s. to make the product up to 20 *fl. oz.* Strength, as the last (nearly). In the Ph. D. 1826, the decoction of *sarsaparilla*, 1 lb (troy), was ordered to be evaporated to 30 oz., which with the spirit (2 oz.) made the preparation only half the strength of the present one.

EXTRACT (Sarsaparilla,—Compound). Syn. *Extractum Sarzæ Compositum*, *Ext. Sarsaparillæ Comp.*,—Lat. *Prep.* There is no form for this preparation in the Pharmacopœias, but it is nevertheless in *immense demand*, from its great convenience in dispensing. The following formulæ are employed by one of the wholesale houses that does largest in this preparation:—

1. *Guaiacum shavings* (from which the small has been sifted), 30 *lb.*; *Italian juice*, 24 *lb.*; *mezereon root*, 6 *lb.*; are boiled with *water*, q. s., for 1 hour; the decoction is then drawn off, and the boiling repeated with *fresh water* a *second* and a *third* time; the mixed decoctions are allowed to deposit for 6 or 8 hours, or longer, and the clear portion decanted and strained through flannel; the liquid is now reduced

to the consistence of treacle, when *extract of sarsaparilla*, 9 *lb.* is added, and the evaporation conducted at a considerably lower temperature until near its completion, when the source of heat is removed, and the remaining evaporation conducted at the expense of that retained by the metal of the "pan;" when nearly cold, and just before removing the extract to the "pots" or "jars," *essential oil of sassafras*, 2 dr., dissolved in *rectified spirit*, 1 quart, is added, and quickly but completely stirred in. The *product* is a very showy article, if well managed, and weighs about 45 *lb.*, the precise quantity depending on the quality of the juice employed. It is labelled *Ext. Sarzæ Comp.*

2. As the *last*, but only using 15 *lb.* of juice, and that *Solazzi*. *Prod.* About 35 *lb.* It is labelled and sent out as "*Ext. Sarzæ Co. Opt.*"

3. By any of the forms given under *Compound decoction of Sarsaparilla*, either *common* or *concentrated*, by continuing the evaporation. *Dose.* Same as that of the simple extract.

EXTRACT (Sarsaparilla,—Fluid Compound). Syn. *Compound Liquor of Sarsaparilla*. *Prep.* 1. From any of the preceding formulæ by arresting the evaporation when the fluid has acquired the consistence of a *thin syrup*, and adding to each pint, when *cold*, *rectified spirit*, 4 fl. oz.

2. (*Alcoholic*,—W. Hodgson.) *Sarsaparilla* (bruised), 16 oz.; *liquorice root* (bruised), *guaiacum wood* (rasped), and *sassafras bark* (sliced), of each, 2 oz.; *mezereon* (sliced), 6 dr.; *spirit*, sp. gr. 0·935 (=13 u. p.), 7 pints; digest 14 days, express, filter, evaporate to 12 fl. oz., add of *sugar*, 8 oz., and as soon as this is dissolved, withdraw the heat. Stronger than the last. *Dose.* 1 fl. dr.

3. (*Ext. Sarsaparillæ Fluidum*,—Ph. U. S.) As the last (nearly).

EXTRACT (Sarsaparilla Root-bark). Syn. *Extractum Corticis Sarzæ*,—Lat. *Prep.* From the *decoction* or *tincture* of the *root-bark*. The cortical portion of sarsaparilla yields fully 50% of aqueous extract. "Five times as much as the meditullium." (Pope.)

Obs. Each of the above extracts of sarsaparilla (*simple*, *fluid*, and *compound*), when of good quality, dissolves in water, forming a deep reddish-brown solution, perfectly transparent, and depositing *little* sediment, even by standing some days. See *Sarsaparilla*.

EXTRACT (Savine). Syn. *Extractum Sabinæ*, *E. Foliorum S.*,—Lat. *Prep.* (Ph. L. 1788.) From the decoction of the *dried plant*. *Prep.* It is now seldom asked for. A little *essential oil of savine* is generally added in "finishing it off," to give it an odour of the recent herb. Some of the foreign Ph. have an *extract of savine* prepared like *extract of box*, P. Cod.

EXTRACT (Scammony,—Alcoholic). Syn. *Resin of Scammony; Resina Scammonii*, *Extractum Scammonii*, *E. S. Alcoholicum; E. sive Resina Scammonii*,—Ph. E. *Prep.* 1. From *powdered scammony*, exhausted with *proof spirit*, and the resulting tincture distilled until little but water passes over; the remaining water is then poured from the *resin*, which is next well-washed in *boiling water* and dried at a temperature below 240° Fahr. Brown; impure.

2. As the last, but using either *alcohol* of 90% or *ether*, and *animal* charcoal. White; pure.

Obs. Scammony resin is translucent, fusible, and combustible; and freely soluble in alcohol, ether, and oil of turpentine. It is frequently adulterated with *jalap-resin*, a fraud readily detected by its insolubility in the last two menstrua. *Dose.* 5 to 10 gr. "When pure or virgin scammony can be procured, it is an unnecessary preparation." (Pereira.)

EXTRACT (Scurvy-grass). Syn. *Extractum Cochleariæ*,—Lat. *Prep.* (P. Cod.) From the *clarified juice* of *fresh scurvy-grass*, by exposure to warm air. Antiscorbutic, stimulant, anti-rheumatic, and diaphoretic. *Dose.* 1 to 2 dr. The valuable principles of the juice are dissipated by much heat.

EXTRACT (Senega). Syn. *Extractum Senegæ*,—Lat. *Prep.* (P. Cod.) From *seneka* or *snake-root* (polygala senega,—*Linn.*), as *extract of box*, P. Cod.

EXTRACT (Senega,—Compound). Syn. *Extractum Senegæ Compositum*, *E. S. et Scillæ*,—Lat. *Prep.* (Ecky.) From equal parts of *squills* and *senega*, as the last, but by displacement. Both the above are stimulant, expectorant, sudorific, and diuretic. *Dose.* 1 to 12 gr.

EXTRACT (Senna). Syn. *Extractum Sennæ*, *Ext. S. Aquosum*,—Lat. *Prep.* 1. As *extract of colocynth*, Ph. L.

2. (P. Cod.) As *extract of bistort*, P. Cod.

3. (Ph. Bor.) From *senna leaves*, by maceration in *tepid water* (104° Fahr.) for 24 hours, and expression, and filtration; the operation is repeated with *fresh water*, and the strained liquors evaporated to a thick extract (at 149° to 157°Fahr.), which

is dissolved in *water*, 4 parts, the solution filtered, and again evaporated. *Dose.* 10 to 20 gr. It is principally used as a basis for purgative pills. When prepared by decoction it is nearly inert. A better extract is prepared from the common tincture made with proof spirit.

EXTRACT (Senna,—Alcoholic). Syn. *Extractum Sennæ Alcoholicum*,—Lat. *Prep.* (Guibourt). *Senna* (in powder), 1 part; *rectified spirit*, 5 parts; heat gradually to boiling, let it cool; in 24 hours, express, strain, and repeat the process with fresh spirit; lastly, distil and evaporate. Proof spirit answers for this purpose.

EXTRACT (Senna,—Fluid). Syn. *Extractum Sennæ Fluidum*, — Lat. *Prep.* (Ph. U. S.) *Senna* (in coarse powder), 2½ lb; *spirit* (at or near proof), 64 fl. oz.; macerate 24 hours, then act by displacement, subsequently adding *weak spirit* (1 of rectified spirit to 3 of water) until 10 pints of tincture are obtained; evaporate to 1 pint, filter, add *sugar*, 20 oz.; and *oil of fennel*, 1 fl. dr.; (dissolved in) *compound spirit of ether*, 2 fl. dr. Every *fl. oz.* represents 1 oz. of senna.

EXTRACT (Smoke). Syn. *Extractum Fuliginis*, — Lat. *Prep.* 1. (Aqueous.) *Wood-soot*, 2 oz.; *water*, 1 pint; boil to 16 fl. oz., filter, and evaporate.

2. (Acetic). *Wood-smoke*, 2 oz.; *distilled vinegar* and *water*, of each, ½ pint; as the last. Formerly reputed antispasmodic, alterative, &c. *Dose.* 3 to 6 gr., two or three times a day; in dyspepsia, hysteria, cancer, scrofula, and various syphilitical affections.

EXTRACT (Snake-root). See *Extract of Senega.*

EXTRACT (Soapwort). Syn. *Extractum Saponariæ*,—Lat. *Prep.* (P. Cod. & Ph. Bad.) From the *dried roots* of *soapwort* (saponaria officinalis,—*Linn.*), as *extract of bistort*, P. Cod. Aperient and alterative. *Dose.* 15 gr. to ½ dr.

EXTRACT (Spruce). See *Essence of Spruce.*

EXTRACT (Squills). Syn. *Extractum Scillæ, Ext. S. Aquosum*,—Lat. *Prep.* 1. (Ph. Baden.) From *squills*, as *extract of colocynth*, Ph. L. (nearly).

2. (Ph. Bor.) From *squills*, as *extract of senna*, Ph. Bor. (nearly), but using *boiling water*, avoiding ebullition during the evaporation, and powdering the residuum. *Dose.* 1 to 5 gr. (See *below.*)

EXTRACT (Squills,—Alcoholic). Syn. *Extractum Scillæ Alcoholicum*,—Lat. *Prep.* (P. Cod.) From the *tincture* prepared with *proof spirit*, by distillation and evaporation. *Dose.* ½ to 3 gr., as an expectorant and diuretic, twice or thrice a day. In larger doses it is nauseant and emetic.

EXTRACT (Storax). Syn. *Extract Styracis*,— Ph. E. See *Strained Storax.*

EXTRACT (Stramonium). Syn. *Extract of Thorn-apple, Extractum Stramonii*,—Ph. L. & D. *Prep.* 1. (Ph. L.) *Seeds of thorn-apple* (datura stramonium,—*Linn.*), 15 oz.; *boiling distilled water*, 1 gall.; macerate for 4 hours in a vessel lightly covered, near the fire; afterwards take out the seeds, bruise them in a stone mortar, and return them to the liquor; then boil down to 4 pints, strain whilst hot, and evaporate. The Ph. D. is similar. *Product*, (about) 12%. Anodyne and narcotic. *Dose.* ¼ gr. to ½ gr., gradually increased, twice or thrice a day; in neuralgia, rheumatism, tic douloureux, spasmodic asthma, epilepsy, worms, &c.

2. (P. Cod. & Ph. U. S.) From the *expressed juice* of the *fresh leaves*, heated to boiling and filtered. The P. Cod. also orders it to be prepared as *extract of aconite*, Ph. L. Anodyne and narcotic. *Dose.* ½ gr. to 1 gr.

Obs. On the large scale, this extract is prepared by expressing the juice of the *fresh* herb, and boiling the remainder in water; the juice and decoction are then mixed, filtered and evaporated. 1½ cwt. of stramonium yielded 37 *lb.* of juice, and this, with the decoction, gave 31 *lb.* of extract. (Gray.)

EXTRACT (Stramonium, — Alcoholic). Syn. *Extractum Stramonii*,—Ph. E. *Ext. S. Alcoholicum*,—Lat. *Prep.* 1. (Ph. E. & Ph. U. S.) From the *seeds* (ground in a coffee mill), by percolation with *proof spirit*. *Product*, (about) 14%; 1 *lb.* yielded 2¼ *oz.* (Recluz.)

2. (P. Cod.) From the *leaves*, as *extract of aconite*, P. Cod. *Dose.* ¼ gr., gradually increased. (See *above.*)

EXTRACT (Succory). Syn. *Extractum Chicorii*,—Lat. *Prep.* (Guibourt.) From the *fresh root*, as *extract of aconite*, Ph. L. Aperient, deobstruent, and tonic. *Dose.* 10 gr. to ½ dr.

EXTRACT (Sweet Flag.) Syn. *Extractum Acori, Ext. Calami Aromatici*,—Lat. *Prep.* From the *rhizomes*, as *extract of rhubarb*, Ph. L. See *Acorus Calamus.*

EXTRACT (Tansy). Syn. *Extractum Tanaceti*,—Lat. *Prep.* 1. From the *herb* (tanacetum vulgare,—*Linn.*), as *extract of hop*, Ph. L.

2. (Giordano.) As *extract of horehound*, Ph. Lusitan.

Obs. This extract is said to be tonic,

stomachic, anthelmintic, emmenagogue, and febrifuge. Dr. Clark says that in Scotland it was found to be serviceable in various cases of gout. The infusion is, however, preferable. *Dose.* 5 gr. to 20 gr.

EXTRACT. (Taraxacum). Syn. *Extract of Dandelion; Extractum Taraxaci*, Ph. L. &. E. *Ext. T. Herbæ et Radicis*, Ph. D. 1826. *Prep.* 1. (Ph. L.) From the *recent root of dandelion* (Leontodon taraxacum,—*Linn.*), as *extract of hop*, Ph. L. The formulæ of the Ph. E. &. U. S. are nearly similar.

2. (Ph. D.) From the *herb* and *root* as the other simple extracts (*extracta simpliciora*).

3. (P. Cod.) From the *expressed juice*, as *extract of stramonium*, P. Cod.

4. (Ph. Bor.) As *extract of senna*, Ph. Bor. (nearly).

5. (Ph. Baden.) By *displacement* with *cold water*.

6. (*Wholesale.*) From the *decoction*.

Obs. The extract of the shops is usually prepared by exhausting the root by coction with water. The products of the *first two* of the above formulæ, when recent, have a faint and agreeable odour, and a sweet, bitter taste; those of No. 3, 4, and 5, smell strongly of the recent root, have a pale and lively brownish yellow colour, and a bitter acidulous taste without any trace of sweetness; that of the last one is devoid of odour, and possesses a coffee-brown colour, and a sweetish, burnt taste, not much unlike a solution of burnt sugar. The medicinal virtue of this extract is greatest when the aroma and bitter taste of the recent root is well developed; and when sweet, its efficacy as a remedy is impaired. (Squire.)

Taraxacum root should be gathered during the winter months, when the quantity of the product is looked at; as then a given weight of the juice yields more extract; but in summer and autumn it possesses more bitterness and aroma. 4 *lb.* of juice from roots gathered in November and December yielded 1 *lb.* of extract, while it took from 6 to 9 *lb.* of juice from the root, gathered in spring or summer, to yield a like quantity. (Squire.) The *herb* yields by the evaporation of its expressed juice, about 5% of extract. According to Mr. Jacob Bell the average yield of 1 *cwt.* of root is about 7⅓ *lb.* (Pharm. Journ., x. 446.)

Good extract of taraxacum should be *wholly* soluble in water. *Dose.* 10 gr. to ½ dr.; as a resolvent, aperient and tonic in liver and stomach complaints, &c.

EXTRACT (Taraxacum,—Fluid). See *Liquor taraxaci.*

EXTRACT (Tea). Syn. *Extractum Theæ*,—Lat. *Prep.* 1. From an *infusion* of any of the *rougher kinds of black tea.* Astringent. Has been recommended in diarrhœa; formed into pills. *Dose.* 10 gr. to ½ dr. A hard black-looking substance, smelling and tasting faintly of tea, is imported under the same name from China.

2. (*Pidding's.*) The joint products of *distillation* and *infusion* combined. Proposed to be made in China, and exported as a condensed preparation of tea (*Essence of tea; Essentia theæ;*) to be used as a substitute for the leaves, in order to save the expense of freight, &c.

EXTRACT (Thorn-Apple). See *Extractum of Stramonium.*

EXTRACT (Tobacco). Syn. *Extractum Tabaci, Ext. Nicotianæ*, — Lat. *Prep.* (Chippendale.) From *decoction of tobacco.* Proposed as an external application in neuralgia, &c.

EXTRACT (Tobacco,—Alcoholic). Syn. *Extractum Tabaci Alcoholicum*, — Lat. *Prep.* (Ph. Bor.) *Tobacco leaves*, 1 ℔; *spirit* (sp. gr. 0·900), 2 ℔; digest in a warm place for some days, express strongly, and again digest in a mixture of *water* and *spirit* (0·900), of each, 1 ℔, for 24 hours; again press out the liquor, and evaporate the strained and mixed liquors in a vapour bath, at a temperature not exceeding 167° Fahr. (See *above.*)

EXTRACT (Tormentil). Syn. *Extractum Tormentillæ*, — Lat. *Prep.* (Ph. Amst.) From the *root* of *tormentilla erecta* (Linn.), as *extract of hops*, Ph. L. The Ph. Baden. directs its preparation by displacement with *cold water.* Astringent and febrifuge. *Dose.* 15 to 30 gr.; in diarrhœa. It was formerly regarded as a specific in syphilis. (Lindley.)

EXTRACT (Uva Ursi). See *Extract of Whortleberry.*

EXTRACT (Valerian). Syn. *Extractum Valerianæ*,—Lat. *Prep.* 1. From *valerian root*, as *extract of hop*, Ph. L.; but using a covered vessel.

2. (Ph. Bor. and Baden.) As *extract of cinchona*, Ph. L. (nearly), employing strong force in the expression of the liquor, and only evaporating to the consistence of syrup.

Obs. It is usual to add to this extract a *little* of the essential oil of valerian, dissolved in a small quantity of rectified spirit, just before removing it from the evaporating pan, and when nearly cold. Anti-spasmodic, and nervine. *Dose.* 10 gr. to ½ dr. In

hysteria and spasmodic diseases. Valerian yields about 4% of soft extract.

EXTRACT (Valerian,—Alcoholic). Syn. *Extractum Valerianæ Alcoholicum*,—Lat. *Prep.* (P. Cod.) As *extract of box*, P. Cod.

EXTRACT (Valerian, — Fluid). Syn. *Extractum Valerianæ Fluidum*,—Lat. *Prep.* (Ph. U. S.) *Rectified spirit*, 12 fl. oz.; *ether*, 4 fl. oz.; mix, add of *valerian* (in coarse powder), 8 oz.; digest, and percolate, adding subsequently, *spirit* (at or near proof) until 16 fl. oz. of tincture have passed through; let this evaporate spontaneously, in a shallow vessel, until reduced to 5 fl. oz.; in the mean time, add *fresh spirit* to the mass in the percolator, until 10 fl. oz. more of tincture are obtained, which add to the above residuum of the evaporation, observing to dissolve any *oleo-resinous deposit* in a little *rectified spirit*, and to add it to the rest; lastly, filter, and add of *rectified spirit*, q. s. to make the whole measure 16 fl. oz.

EXTRACT (Vanilla). See *Liquors*.

EXTRACT (Wall Pellitory). Syn. *Extractum Parietariæ*,—Lat. *Prep.* From *fresh pellitory of the wall* (parietaria officinalis,—*Linn.*), as *extract of aconite*, Ph. L. Aperient, diuretic, and pectoral. *Dose.* 10 gr. to ½ dr.

EXTRACT (Walnuts). Syn. *Extractum Juglandis Immaturæ, Roob Diacaryon sine Melle*,—Lat. *Prep.* 1. From *unripe walnuts* (juglans regia,— *Linn.*), as *extract of aconite*, Ph. L.

2. From the *decoction* of the *green shells*. Vermifuge. *Dose.* 20 to 30 gr. in cinnamon water.

EXTRACT (Walnut Leaves). Syn. *Extractum Juglandis Foliorum*,—Lat. *Prep.* 1. From the *decoction* of *dried walnut leaves*.

2. (Soubeiran.) By displacement with *tepid water*. Diaphoretic and alterative. *Dose.* 2 to 4 gr. twice or thrice a day, in scrofula, scirrhus, &c.

EXTRACT (Walnut-leaves,—Alcoholic). Syn. *Extractum Juglandis Foliorum Alcoholicum*,—Lat. *Prep.* (Ph. Bor.) From *walnut leaves* (cut), as *alcoholic extract of tobacco*, Ph. Bor. (nearly).

EXTRACT (Water-dock). Syn. *Extractum Rumicis Aquatici*, — Lat. *Prep.* From the *root*, as *extract of hops*, Ph. L. Astringent and antiscorbutic. *Dose.* 15 gr. to 1 dr.; in skin diseases, &c.

EXTRACT (Whortleberry). Syn. *Extract of Bear's Whortleberry, Ext. of Bearberry; Extractum Uvæ Ursi*,—Ph. L. *Prep.* From the *dried leaves*, as *extract of hops*, Ph. L. *Dose.* 5 to 15 gr., twice or thrice a day, in chronic diseases of the bladder and kidneys, attended with increased secretion of mucus, without inflammation.

EXTRACT (Winter Cherry). Syn. *Extractum Alkekengi*,—Lat. *Prep.* From the *berries* of *physalis alkekengi*, (Linn.), as *extract of elder*. (See *above*.) Aperient, detergent, and diuretic. *Dose.* 2 to 4 dr.

EXTRACT (Winter-green). Syn. *Extractum Chimaphilæ, E. Pyrola*, — Lat. *Prep.* From the herb *winter-green, pyrola*, or *pipsissewa*, as *extract of hops*, Ph. L. *Dose.* 10 gr. to ½ dr.; in dropsy, scrofula, and chronic affections of the urinary organs.

EXTRACT (Wood Sorrel). Syn. *Extractum Acetosellæ*.—Lat. *Prep.* (Pideret.) From the *expressed juice of the fresh herb*. Acid, bitter, and antiscorbutic. *Dose.* 15 gr. to ½ dr.

EXTRACT (Worm Grass). See *Extract of Pinkroot*.

EXTRACT (Worm Seed, — Ethereal). Syn. *Extractum Cinæ Æthereum, E. Seminum C. Æ.*,—Lat. *Prep.* (Hamb. Cod. 1845.) *Worm seed*, 1 oz.; *ether*, 4 oz.; digest 3 or 4 days, press, filter, distil off 4-5ths, and evaporate the residuum to a proper consistence. *Prod.* 25% to 30%. Vermifuge. *Dose.* 3 to 10 gr., night and morning for 2 or 3 successive days, followed by a brisk purge.

EXTRACT (Wormwood). Syn. *Extractum Absinthii; Extractum Artemisiæ Absinthii*,—Ph. D. 1826. *Ext. Cacuminum A., &c. Prep.* 1. (Ph. D. 1826.) From the *dried flowering tops* of *wormwood*, as the other *simple extracts* (extracta simpliciora,—Ph. D.)

2. (Ph. Bor.) As *extract of rhatany*, Ph. Bor.

3. (P. Cod. & Ph. Baden.) By displacement by cold water.

Obs. Bitter stomachic, tonic, and vermifuge. *Dose.* 10 gr. to 20 gr., 2 or 3 times daily; in dyspepsia, loss of appetite, gout, &c. It is usual to add a few drops of the oil of wormwood to the extract before taking it from the pan.

EXTRACT (Wormwood, — Alcoholic). Syn. *Extractum Absinthii Alcoholicum*,—Lat. *Prep.* (Guibourt.) From a *tincture* prepared from the *dried tops of wormwood* boiled in *proof spirit*. More active than the last.

EXTRACT (Yew). Syn. *Extractum Taxi*,—Lat. *Prep.* 1. (Loder.) From the *inspissated juice* of the *fresh leaves of the yew* (taxus baccata,—*Linn.*) Its action on the circulation greatly resembles that of digitalis, but is more manageable. *Dose.* 1 to 7 gr.; in epilepsy, &c.

2. (*Alcoholic*,—Ph. Baden.) From the *dried leaves*, as alcoholic extract of aconite, Ph. Baden.

EXTRACTIVE. Syn. *Extractive Principle.* This substance was discovered by Fourcroy, and presumed by him to be the common basis of *all* extracts. It has since been proved by Chevreul and other chemists, to be a heterogenous compound, varying in composition with the plant from which it is extracted. Extractive has a brown colour, or one becoming so in the air, it speedily putrefies, and becomes oxidized, and is rendered insoluble by long exposure to air, and by repeated solutions and evaporations. In its unalerted state it is soluble in water, and in alcohol, is nearly insoluble in ether, and is precipitated from its solutions by the acids and metallic oxides. With alumina it forms the basis of several brown dyes. See *Extracts.*

EXTRACTS (Dried). See *below.*

EXTRACTS (of Flowers). See *Extraits.*

EXTRACTS (Fluid). Syn. *Extracta Fluida, Extracta Liquida*,—Lat. This name has been applied in *modern pharmacy* to various preparations differing materially from each other in their degree of fluidity and concentration. Some of these have been already noticed, and others will be found under one or other of their synonyms. Much confusion would be avoided by confining the name "fluid extract" to those preparations only which differ from the ordinary officinal extracts in being in the liquid form; whilst others of a like character, but of less consistence or concentration, might be conveniently classed under the general denomination of *liquors* (liquores). The various condensed preparations of vegetable substances, now common in trade, professedly several times stronger than the common decoctions, infusions, and tinctures, might be simply and advantageously distinguished by the addition of "*concentrated*" to their names. Tinctures made with *rectified spirit*, and of (say) at least 8 times the usual strength, might be appropriately termed "*essences.*" See *Decoctions, Essences, Extracts, Infusions, Solutions, Tinctures, &c.*

EXTRACTS (Hard). See *Extract*, (p. 419), *&c.*

EXTRACTS (Medicinal). See *above.*

EXTRACTS (in Powder). Syn. *Dried Extracts, Desiccated do., Pulverulent do., Saccharated Extracts; Extracta Pulverata, Ext. Sicca, Ext. cum Saccharo*,—Lat. *Prep.* 1. Ordinary *soft extract of the drug*, 4 parts; *white sugar*, (in powder), 1 part; mix, and dry by exposure in a warm situation; lastly, reduce the mass to powder, and if it weighs less than 4 parts, triturate it with more *powdered sugar* until *its weight* is equal to the *original weight* of the *extract* used in its preparation. The strength of the extract thus continues unchanged.

2. (Ph. Bor.) As the last, but using powdered *sugar of milk* in lieu of cane sugar.

3. (Gauger.) *Alcoholic extract*, 3 parts; *rectified spirit*, 1 part; are triturated together in a porcelain mortar until thoroughly incorporated, when *white sugar* (in powder), 15 oz., is *gradually* added, and the two *carefully* and *completely* blended together; the mixture is dried as before, and *more sugar* added until the whole weighs *exactly* 18 oz. *Six grains* represent *one grain* of the unprepared extract.

Obs. The above are admirable preparations, intended chiefly to render the perishable extracts of the narcotic plants (*extractica narcotica*) less liable to suffer by age. See *Extract of Aconite* (Saccharated), *&c.*

EXTRACTS (Soft). See *Extract* (p. 419), and *above.*

EXTRAITS (*Fr.*) Extracts. Among *perfumers*, these are mostly spirituous solutions of the essential oils or odorous principles of plants and other fragrant substances. The French commonly apply the term to any concentrated spirit, either simple or compound. In the shops of the Parisian perfumers upwards of 60 preparations of the kind are distinguished by this name. The *extracts* of *jasmine, jonquille, may-lily, orange blossoms, violets*, and other *like flowers* of delicate perfume, are obtained by agitating and digesting the *huiles* and *pommades* of the flowers with the *purest rectified spirit*, in the manner described under *Scented Spirits* (esprits). This process is repeated with *fresh oil* or *pommade* until the spirit is rendered sufficiently fragrant. The other *extracts* (both *simple* and *compound*) are made by the common methods of infusion and distillation. See *Essences, Extracts, Spirits, &c.*, (and *above.*)

EYE-DROPS (Marshall's). *Prep.* 1. *Nitrate of silver*, 2 gr.; *dilute nitric acid*, 2 drops; *pure soft* or *distilled water*, 1 fl. oz.; dissolve, add *powdered gum*, 15 gr., agitate until dissolved, and the next day decant the clear portion.

2. (Original.) *Lunar caustic* (fused nitrate of silver), 3 gr.; *juice of snails* and *water*, equal parts. See *Eye Waters.*

EYE SALVE (Smellome's). Syn. *Smellome's Eye-Ointment. Prep.* From *prepared verdigris* and *salad oil*, of each, ½ dr.; triturate well together, then add of *resin*

cerate, 1 oz. See *Cerates* and *Ointments*.

EYE-WATERS (Dr. Wisdom's). *Prep.* From *bole*, 4 dr.; *white copperas* (sulphate of zinc), ½ dr.; *camphor*, 1 dr.; dissolved in *rectified spirit*, ½ fl. oz.; *water*, 1 quart; agitate for an hour, and the next day decant the clear, and filter. The above are quack nostrums. See *Waters*.

FACE AGUE. The common name for the intermittent form of facial neuralgia or tic douloureux. See *Neuralgia*.

FACE PAINTS. Syn. *Fards*,—Fr. See *Almond Bloom*, *Carmine*, *Pearl White*, *Rouge*, *&c.*

FAC SIMILE. See *Signatures*.

FACTITIOUS. Syn. *Factitius*,— Lat. Artificial; made by art, in distinction from that produced by nature. Numerous illustrations of the application of this word occur in the pages of the present work.

FÆCES. Excrement. In the *laboratory*, the "settling" or sediment deposited by a liquid. See *Defecation*.

FAINTING. Syn. *Swooning; Syncope*. A disease in which the respiration and circulation are apparently suspended for a time, or are extremely feeble. The *symptoms* are too well known to require description. The *causes* are supposed to be—diminished energy of the brain, and organic affections of the heart or neighbouring vessels. This has lead nosologists to divide *syncope* into two varieties:—

1. *Occasional*, (syncope occasionalis, s. accidentalis;) primitively induced by sudden and violent emotions of the mind, powerful odours, derangement of the stomach or bowels, constrained position of the body, tight-lacing, pressure, loss of blood, debility from disease, &c. This variety is frequently followed by vomiting, and, occasionally, by convulsions or epileptic fits. The *recovery* is accelerated by the horizontal position, *without* the head being the least elevated, by which the arterial blood is more vigorously thrown upon the brain, and thereby stimulates it to resume its usual functions. Pungent substances (*smelling-bottle*, *vinaigrette*, *&c.*) may be applied to the nostrils, and *cold water* sprinkled on the face and chest. In all cases the dress (*corset*, *waist-band*, *neck-cloth*, *&c.*) should be instantly loosened, and indeed this is the first assistance which should be given, either in syncope or apoplexy. As soon as the patient can swallow, a *little* brandy-and-water, or wine, or a few drops of *ether* or *spirit of sal volatile*, may be given.

2. *Cardiac*, (syncope cardiaca;) arising without any apparent cause, with violent palpitation during the intervals, and altogether of a more formidable character than the preceding. The *subsequent treatment* must here be directed to the cure or alleviation of the original disease.

FAINTS. The first and last runnings of the whiskey-still. The one is technically termed the *strong faints;* the other, the *weak faints*. They are both purified by rectification, &c. See *Distillation*.

FAITH. Dr. Pereira remarks, that "*faith* in the beneficial agency of remedies, and *confidence* in the skill of the medical attendant, are important adjuvants in the treatment of disease. To them both the physician and empiric owe part of their success."

FALLING SICKNESS. See *Epilepsy*.

FALLTRANCK. See *Swiss Vulnerary*.

FARCY. See *Glanders*.

FARDS. See *Face Paints*.

FARINA. See *Flour* and *Meal*.

FARINACEOUS FOOD. Several preparations of this character advertised in the papers or met with in the shops, are noticed under their respective heads. The following are others of the class:—

Baker's Alimentary Compound. *Fine flour* (pastrycook's), 2 parts; *finely ground rice*, 1 part.

Baster's Compound Farina. *Wheat flour*, 14 *oz.*; *white sugar*, 2 *oz.*

Braden's Farinaceous Food. Same as *Hard's*.

Bright's Nutritious Farina. *Rice flour* and *potato farina*, equal parts.

Bright's Breakfast Powder. *Chocolate*, 1 part; *nutritious farina* (Bright's) 2 parts.

Densham's Farinaceous Food. *Wheat flour*, 3 parts; *barley meal*, 1 part; the mixture is slightly baked, and again ground and sifted. Said to be slightly laxative.

Gardner's Alimentary Preparation. *Pure rice flour*.

Hard's Farinaceous Food. *Wheat flour*, slightly baked, and resifted.

Leath's Alimentary Farina. *Wheat flour* (baked), with some *sugar*, *Indian meal*, and *tapioca*. According to some it also contains *potato starch*.

Leath's Homœopathic Compound. As the last.

Maidman's Nutritious Farina. *Potato starch* tinged with *beet-root*.

Plumbe's Farinaceous Food. *South-sea arrow-root*, with about 1-3rd its weight of *pea flour*.

Prince of Wales's Food. Chiefly *potato-flour.*

Smith's Nursing Farina. Equal parts of *baked wheat flour* and *rice-flour.*

Obs. The same remarks apply to the above compounds as to arrow-root and jellies. Many of them being deficient in the nitrogenous elements of nutrition, and *all* of them nearly destitute of the mineral and saline matters which are absolutely necessary to the formation of the bones and tissues, and the support of the body in health, are consequently utterly unsuitable as an exclusive article of diet, especially for young children. Unfortunately, it has been too much the fashion of medical men of late years to recommend these compounds, and even to furnish testimonials as to their excellence (?), apparently relying *solely* on the representation of their proprietors or vendors. We deem it, however, to be a public duty to caution parents and nurses against their injudicious use. As mere adjuvants or auxiliaries, when the natural food supplied by the mother may be insufficient for the nutrition of the infant, some of them may doubtless be of value; but in all other cases, they should be largely combined with *pure cow's milk, beef tea, meat broths* or *gravies, eggs,* or other substances rich in the nitrogenous and saline elements of nutrition. Even with this reservation, those consisting chiefly of *potato* or *rice-flour,* and other like farinas, should be used with the greatest caution.

FARMING. See *Agriculture, Butter, Cheese, Manures, Soils, &c.*

FASTING. See *Abstinence.*

FAT. Syn. *Adeps,*—Lat. The *fat of animals* is a concrete oil contained in the cellular membrane of their bodies, more especially round the kidneys, in the folds of the omentum, at the base of the heart, upon the surface of the intestines, and among many of the muscles. Fat varies in consistence, colour, and odour, with the animal from which it is obtained. That of the *carnivora* is soft and rank-flavoured; that of the *ruminantia,* solid and nearly scentless. It is usually whitest and most copious in the well-fed young animal, and yellowish and more scanty in the old. That under the skin, and surrounding the kidneys (*suet*) is also more solid than that in the neighbourhood of the moveable viscera. In the *cetacea,* or *whale tribe,* the fatty secretion assumes the form of oil. These variations in consistency depend upon the relative quantity of *stearine* and *elaine* present in the fat.

TABLE *of the composition, and fusibility of certain fats, according to the researches of* Braconnot *and* others.*

Name.	*Composition.*		*Melting Point.*
	Elaine.	*Stearine.*	
Butter (Summer)	60	40†	Variable.
,, (Winter)	37	63	
Duck Fat . .	72	28	78° to 82° F.
Goose Fat . .	68	32	78° to 81° ,,
Hog's Lard . .	62	38	81° to 82° ,,
Mutton Suet .	26	74	98° to 105°
Ox Marrow-fat .	24	76	112° to 115°
Ox Suet . . .	25	75	97° to 104°

* In this table *margarine* is included under *stearine.*

† According to Dumas, butter contains *no* stearine (properly so called).

In *former times* the fats of many animals were employed in *pharmacy;* but, at present, those principally used are *lard* and *suet.* In *perfumery,* in addition to these, *beef-marrow* and *bear's grease,* are employed. For both these purposes the crude material is cut into small pieces, and freed as much as possible from all extraneous membranes; after which it is placed in a boiler with water, and heated until it is completely fused, when the whole is strained, and allowed to cool very slowly. By this means a cake of cleansed fat is obtained, which may be readily separated from any adhering water.

Fats and the *fat oils* are best PRESERVED by being run into glazed jars, and secluded from the action of the air. A little *benzoic acid* or *gum-benzoin,* dissolved in them by heat, will generally *prevent,* and in all cases, greatly *defer* the accession of *rancidity.* We introduced this method into the laboratory in our early days of manipulation, and ourselves, and others to whom we have made it known, have since employed it with undeviating advantage in the manufacture of *cerates, ointments,* and other preparations containing *fatty matter* or the *fixed oils.* It has recently been shown by Dr. Griesler, that *nitric ether,* and its *alcoholic solution,* act in the same manner. A few drops are not only sufficient to *prevent* rancidity, but, it is said, will even destroy the disagreeable odour of rancid fat. When heated to remove the alcohol, they immediately become bright, clear, and scentless. See *Fixed Oils, Stearine, tallow, &c.*

FAT (Curriers'). *Fat* or *tallow* boiled until it is very hard and blackish when cold. *Used* for leather.

FATTY ACIDS. The *fatty-acid series* embraces all those compounds evincing acid properties, which are derived from the various fats. See *Butyric*, *Oleic*, and *Stearic Acid*, *&c.*

FATTENING. Until comparatively a recent date, the plan used to *fatten domestic animals*, was to prevent their taking exercise, and to gorge them with food. The excessive fat produced by these means was, however, found to be far from wholesome, and was less delicate than that arising in the natural way. This system was therefore gradually abandoned in favour of the present one, which consists in supplying the animal with abundance of wholesome food, and with the means of taking exercise, as far as the disposition or feelings dictate. Hence the farmers "in the most enlightened districts, such as Berwickshire, East Lothian, &c., instead of tying up their *fattening cattle* in stables like horses, and placing their food before them, put two or three together in small yards with sheds attached, in which they can run about, eat when they choose, and take shelter from the rain, or cold, or the sun, at pleasure, under the open shed. *Swine* are treated in the same manner, and also *spring lambs* that are fattened for the market. *Poultry* are no longer kept in coops and crammed, or *rabbits* in hutches; but the *former* are allowed to take exercise in fields sown with various herbs, and the *latter* are kept in a species of artificial warren, where they can take exercise by burrowing." (Loudon.)

FAYNARD'S POWDER. *Beech-wood charcoal*, reduced to an almost impalpable powder. *Used* to suppress hemorrhage.

FEAR, in general, is a depressing and debilitating passion, and sometimes acts prejudicially, but, more frequently, as a curative or preventive of disease. It is a well-known fact, that females who are the most faint-hearted and desponding during the period of their sex's trial, generally experience a more rapid convalescence than those who are more confident and resolute. During the late visitation of cholera in this metropolis, many instances came under our notice of parties being suddenly attacked, even whilst the song of revelry or triumph was on their lips, and dying in a few hours, whilst those around them, though living in fear and trembling for weeks lest they should "catch" the malady, and even sleeping in the room with the unburied corpses of their less fortunate relatives or friends, passed through the ordeal of the pestilence *unhurt*. Besides, fear induces temperance, cleanliness, and the adoption of other precautions, which tend powerfully to prevent disease. If the assertions so loudly made by interested parties to the contrary were true, why did the heaviest rate of mortality occur among the young and thoughtless—among children who knew no fear? Boerhaave, according to Pereira, is said to have prevented the occurrence of epileptic attacks (brought on by the sight of a person falling down in a fit in the sight of the hospital patients), by directing a red-hot iron to be applied to the person who should next be affected.

FEATHERS. *Ostrich feathers* are those most esteemed as articles of personal decoration, and *goose feathers*, for beds; but the feathers of other birds are commonly used for both purposes.

Feathers are *prepared* for *ornamental purposes* by SCOURING them with *white soap-and-water* (1 *oz.* to the *pint*), used hot; they are next well-rinsed in several successive portions of *pure water*, and after being drained and shaken, are, lastly, passed through *water slightly blued with pure indigo*, and dried out of the dust. When dry, the ribs are generally rubbed with a piece of glass, having a curved notch in it, for the purpose of increasing their PLIANCY, and the filaments are CURLED by drawing them between the edge of a blunt knife and the ball of the thumb of the hand which holds it.

Feathers are *bleached* either by exposure for 2 or 3 weeks, to the sun and dew, planted upright on the grass; or by *sulphuring* them.

Feathers are *dyed*—

Black. By immersion for 2 or 3 days in a bath (at first hot) of *logwood*, 8 parts; and *copperas* or *acetate of iron*, (about) 1 part.

Blue. With the *indigo vat.*

Brown. By any of the *brown dyes* for silk or woollen.

Crimson. A mordant of *alum*, followed by a hot bath of *brazil wood*, and afterwards by a weak one of *cudbear*.

Pink or *Rose.* With *safflower* and *lemon juice.*

Plum. The *red dye*, followed by an alkaline bath.

Red. A mordant of *alum*, followed by a hot *brazil-wood bath.*

Yellow. From an *alum mordant*, followed by a bath of *turmeric* or *weld.* Other shades may be obtained by a mixture of the above dyes.

Goose feathers for *beds* are generally "purified" by simply exposing them to the sun, or in a stove until *perfectly dry*, and then beating them to remove loose dirt. When carelessly collected and dirty, they are sometimes *first* "cleansed" with *lime water*, or better still, with a *weak solution of carbonate of soda*, or *water to which a little solution of chloride of lime* has been added; after which they are rinsed in *clean water*, and dried or stoved as before. *Old feathers* are "cleansed" or "purified" in the same way.

FEBRIFUGES. Syn. *Febrifuga.*—Lat. Substances or agents which cure or alleviate fever. The term is more particularly applied to medicines used against the ague, as bark and arsenious acid, and their preparations. The extreme value of *cold water*, as a drink in ardent fever, has been known in all ages. In 1723 Dr. Hancocke published a work entitled—'*Febrifugum Magnum*, or *Common Water* the *best Cure for Fevers, and probably for the Plague*,' which in a short time ran through several large editions, but appears to have been overlooked by the hydropaths of the present day.

FEBRIFUGE OIL. Syn. *Oleum Febrifugum*,—Lat. A liquid obtained by subliming a *mixture* of *antimony* and *sal ammoniac*, and allowing the resulting flowers to deliquesce in the air.

FEBRIFUGE POWDER. Syn. *Pulvis Febrifugus*,—Lat. An old compound of *tartar emetic* with about 12 or 15 times its weight of *powdered crab's eyes* (oculi cancrorum). *Helvetius's styptic* was formerly so called in Germany.

FECULA. Syn. *Fœcula*,—Lat. The peculiar matter which subsides from *cold water* which has been rendered milky by washing in it certain bruised or rasped vegetable substances, more especially the seeds of the cereals and leguminosa, and the tuberous or bulbous roots. It is present in most plants, and in those which yield it most plentifully, consists of nearly *pure starch*. In some cases it is associated with the green colouring matter (*chlorophile*) and the narcotic principles of the vegetables which yield it. The *green fecula* obtained by straining the expressed juices of the leaves and herbaceous parts of plants is of this character.

The *fecula* of all the *amylaceous roots*, *rhizomes*, and *tubers*, may be easily obtained, on the *small scale*, by rasping them, pressing, and working the pulp in *cold water*, and after straining the resulting milky liquid through a hair sieve, allowing it to settle. The sediment may be again washed by diffusion through clean *cold water*, and must be, lastly, collected, and dried out of the dust, and without artificial heat.

The *fecula* of *narcotic plants* for medicinal purposes, is obtained by allowing the *expressed juice* to repose for 24 hours, and then decanting the clear portion, and drying the residue. Sometimes heat is employed. See *Arrow-root*, *Starch*, *&c.*, (and *below*.)

FECULA (Hemlock). Syn. *Fœcula Conii*,—Lat. *Prep.* (Van Mons.) The *expressed juice of hemlock* is gently heated, and the *coagulum* collected, washed, dried, and pulverized. *Dose.* 5 to 20 gr.

FEET (The). To preserve the feet in a *proper condition*, they should be frequently soaked, and well washed in warm or tepid water. The *nails of the toes* should be pared to prevent their becoming inconveniently long, and from growing into the flesh. Many persons suffer severely from *tender feet*. This generally arises from the use of thin cotton or silk stockings, and boots or shoes, that are either too tight or stiff, or not sufficiently porous to permit of the escape of the perspiration. *Waterproof boots* and *shoes* which are also air-tight, (as those of *gutta percha* and *India rubber*,) are common causes of tender feet, and even of headaches, dyspepsia, and apoplexy. The best *treatment* of *tender feet* is the immediate adoption of *worsted* stockings or socks, and light easy shoes of buckskin, goatskin, or some other equally soft kind of leather. It is highly necessary for the preservation of health to preserve the *feet* DRY: persons who are, therefore, exposed to the wet, or who are frequently passengers through the public streets in bad weather, should regard sound and good boots and shoes as of the first importance. In fact, in a hygienic point of view, a *wet back* should be less shunned than *wet feet*. Many persons frequently experience *extreme coldness* and *numbness of the feet*. The best and most natural remedy for this is *active exercise* or friction, the former being always adopted when possible. In such cases the use of warm woollen stockings is absolutely necessary, and the *debilitated* and *aged* may advantageously keep them on throughout the night, or at all events until the feet acquire a comfortable degree of warmth. The *peculiar and disagreeable odour* which is evolved by the feet of some individuals in hot weather may be removed by the observance of *extreme cleanliness*, and by occasionally soaking the feet in warm

water, to which a *small quantity* of *chloride of lime* or *sal ammoniac* has been added.

Distortion of the feet is not uncommon in childhood, being sometimes congenital, but as frequently the result of weakness or bad nursing. "A child with its feet turned inwards is called *varus;* when they are turned outwards it is styled *valgus.* The proper use of bandages, early applied, will generally correct these deformities; but if they be neglected in infancy they become incurable." (Med. Lex.) *Club foot,* of which there are several varieties, may also be frequently relieved by a simple surgical operation.

FELLIC ACID and *Fellinic Acid.* Products obtained from bile. (Brande.)

FELTING. This is a process by which various species of fur, hair, and wool, are blended into a compact texture, in many respects resembling cloth. It depends on the peculiar anatomical construction of these substances enabling them to interlace and intertwine with each other, by which they become permanently matted together. Felt was formerly chiefly employed for hats. It is now commonly used for mill-bands, filters, &c.; and when *varnished* or *japanned,* or saturated with *asphalte* or *bitumen,* as a durable substitute for japanned leather, and for *roofing.*

FENNEL. Syn. *Fœniculum,*—Ph. L. "The fruit" (seed) "of *fœniculum dulce*" (Ph. L.) or *sweet fennel.* The "oil distilled from the fruit," (*oil of fennel; oleum fœniculi;*) as well as a distilled water, (*fennel water; aqua fœniculi;*) are officinal in the Pharmacopœias. They are stimulant and carminative; but are now seldom employed.

FENUGREEK. The seeds of *trigonella fœnum græcum* (Linn.) Resolvent and stomachic. The *seeds* dye yellow; formerly roasted for coffee; now chiefly employed in veterinary medicine.

FERCULUM SAXONIA. *Prep.* (Barret.) *Barley flour,* 21 *oz.; sugar,* 7 *oz., cinnamon,* 1 *dr.*; mix, and bake them in an oven, enveloped in a *paste of wheat flour,* and placed in an earthen vessel. When baked, remove the crust, and when the whole is cold, reduce it to powder. A little is boiled with broth, &c., as thickening. Occasionally it is used separately, and is medicated with sarsaparilla, bark, &c.

FERMENT. Syn. *Fermentum.* — Lat. A substance which induces fermentation. Ferments are compounds whose decomposition proceeds simultaneously with that of the body undergoing metamorphosis. They all contain albuminous or azotized principles which in a moist state putrefy and suffer spontaneous decomposition. Ferments are either naturally present in the fermentable substance, as in the *juice of grapes;* or are added to it, as in the fermentation of worts, where *yeast* constitutes the ferment. See *Fermentation* and *Yeast.*

FERMENTATION. Syn. *Fermentatio,* —Lat. The spontaneous decomposition of the proximate principles of organic substances, under the joint influence of *warmth, air,* and *moisture,* and the reunion of their elements forming new compounds. Fermentation, according to Liebig, is nothing else but the *putrefaction* of a substance containing *no nitrogen;* or a metamorphosis, by which the elements of a *complex molecule,* group themselves, so as to form more *intimate* and *stable compounds.* It is excited by the contact of all bodies, the elements of which are in a state of active decomposition or fermentation. "In nitrogenized substances of a very complex constitution, putrefaction or fermentation is spontaneously established when water is present, and the temperature sufficiently high, and it continues till the original compounds are wholly destroyed. Substances destitute of nitrogen, on the contrary, require, in order to their undergoing this metamorphosis, the presence of a nitrogenized substance, *already in a state of putrefaction* (fermentation)." (Liebig.) The substances which promote this change are termed *ferments;* and among these, the principal are *gliadine, gluten, vegetable albumen,* and *all nitrogenous substances* in a state of spontaneous decomposition or fermentation. "It is imagined that when these substances, in the act of undergoing change, are brought into contact with neutral ternary compounds of small stability, as sugar, the molecular disturbance of the body, already in a state of decomposition, may be, as it were, propagated to the other, and bring about the destruction of the equilibrium of forces to which it owes its being. The complex body, under these circumstances, breaks up into simpler products, which possess greater permanence." (Fownes.) *Yeast,* the ferment most commonly employed for inducing the vinous fermentation, is such a substance in an active state of putrefaction, and whose atoms are in continual motion. *Putrefying animal* substances are equally capable of exciting the same action. "If we add to a solution of pure sugar an albuminous substance, a caseous or fleshy matter, the development of yeast, becomes

manifest, and an additionel quantity of it is found at the end of the operation. Thus with nourishment, ferment engenders ferment. It is for this reason that a little *fermenting must*, added to a body of *fresh grape-juice*, excites fermentation in the whole mass. These effects are not confined to alcoholic (vinous) fermentation. The smallest portion of *sour milk*, of *sour dough*, or *sour juice of beet-root*, of *putrefied flesh* or *blood*, occasion like alterations in *fresh* milk, dough, juice of beet-root, flesh, and blood. But further, and which is a very curious circumstance, if we put into a liquid containing any fermenting substance, another in a sound state, the latter would suffer decomposition under the influence of the former. If we place *urea* in the presence of *beer-yeast* it experiences *no change;* while, if we add it to *sugar-water* in a fermenting state, the urea is converted into *carbonate of ammonia*. We thus possess two modes of decomposition; the one *direct*, the other *indirect*." (Ure.)

It is only in complex organic molecules of a higher order that fermentation or putrefaction takes place. The immediate cause of fermentation in such bodies as are not sufficiently complicated to undergo this change by the mere action of water and caloric, is most rationally presumed to arise from immediate contact with the atoms of those bodies, which are undergoing this change. Thus, the motion, or conflict of the elements of the body in a state of decomposition, as those of *yeast* when employed to excite the *vinous fermentation*, destroys the equilibrium of the atoms of the sugar, and these grouping themselves according to their special attractions, enter into new combinations, and form new compounds. The charcoal (carbon) of the sugar partly unites itself to the oxygen, forming *carbonic acid*, and partly to the hydrogen, forming *alcohol*. A similar kind of decomposition and interchange of elements take place in all organic substances during the state of fermentation; the proportions of the elements liberated, and the compounds formed by their reunion, varying, of course, according to the precise composition of such substances.

Fermentation or *putrefaction* differs from *eremacausis* or *decay*, in being limited to changes occurring in and beneath the surface of water, the effect being a mere transposition of elements, or a metamorphosis of the organic body. *Eremacausis*, on the other hand, refers to the decomposition of moist organic matter, when freely exposed to the air, by the oxygen of which it is gradually burned and destroyed, without any sensible elevation of temperature. Although the presence of oxygen is essential to the commencement of this change, whenever fermentation is freely established, it is no longer necessary, as it proceeds without the aid of any other substance external to the decomposing body, unless it be water or its elements. Every case of *putrefaction* or *fermentation* therefore commences with *decay;* and if the decay or its cause, namely, the absorption of oxygen, be prevented, no putrefaction occurs. The entire absence of the exciting causes,—*warmth*, *air*, and *moisture*,—leaves even those substances which under ordinary circumstances are most liable to change, in a state in which they may remain for an almost indefinite period without perceptible alteration. Thus, animal substances in a frozen or dry state, do not undergo decomposition, nor does a solution of sugar, or the juice of grapes (*must*), when perfectly excluded from the air; but on the mere exposure of these substances to warmth, moisture, or atmospheric air, putrefaction or fermentation immediately commences. Remove the cork from the bottle of capillaire on the parlour sideboard, or pierce the skin of one of the grapes on the dessert table with a needle, and these bodies, which would have otherwise suffered no change for weeks, or even months, will soon exhibit symptoms of spontaneous decomposition. The knowledge of this fact has been practically applied to the preservation of animal and vegetable substances for food. Even the most putrescible of these may be preserved for an unlimited period by enclosure in metallic cases, or glass bottles, from which the air has been *completely* removed and excluded.

The important duties which *fermentation* or *putrefaction* performs in the economy of our globe, and in several of the arts of life and civilization, have long rendered the development of its principles an object of the highest interest and importance both in a scientific and practical point of view. In its most extended sense, this subtile process of nature, though occasionally productive of injurious effects, may be regarded as one of the most necessary and beneficial with which we are acquainted. Like the labours of a scavenger, it speedily removes from the surface of our globe those matters which would otherwise remain for some time without undergoing decomposition. It

either dissipates in air, or reduces to more fixed and useful forms of matter, those organic substances, which, by their presence, would prove noxious, or, at all events, useless to the animal and vegetable kingdoms. It is the giant power that cleans the Augean stable of nature, at the same time that it provides some of the most esteemed articles of utility and luxury for the well-being and enjoyment of man.

Chemists have distinguished fermentation into different varieties, which, in general, are named after the more important products of its action. Of late years, the number of these varieties has been greatly increased by the extension of the term to several operations besides those formerly included under it. Most of those mentioned by previous writers are noticed in the present work. See *Acetification*, *Bread*, *Putrefaction*, *Brewing*, *Mucilaginous*, *Saccharine*, and *Vinous Fermentation*, *&c.*

FERN (Male). Syn. *Male Shield Fern*, *Blunt do. do.; Filix Mas*, *Radix Filicis*,—Lat. The *root* (rhizoma) of the *aspidium filix mas* (polypodium filix mas,—*Linn.*) or *male fern*. It is bitter, astringent, and vermifuge. *Dose.* 1 to 3 dr., in powder, or made into a decoction, repeated for 3 or 4 days, and followed by a purge. It is chiefly given in tape-worm. In Switzerland it is deemed almost infallible, but has proved less successful in these countries. See *Oils*.

FER REDUIT. See *Iron* (Quevenne's.)

FERRIC ACID. Syn. *Acidum Ferricum*,—Lat. A peculiar compound of iron and oxygen, discovered by Fremy, obtained in combination with potassa (*ferrate of potassa*, *perferrate of do.*), from which it has never been separated.

Prep. 1. (Fremy.)—*a.* From a mixture of the *peroxides of iron* and *potassium*, ignited together.

b. From a mixture of *potassa* and *oxide of iron*, as last.

c. By projecting *nitre* on *iron in fine powder*, and heated to redness in a crucible.

2. (J. D. Smith.) By exposing a mixture of *peroxide of iron*, 1 part; and *nitre* (dry), 4 parts; (both in fine powder;) to a full red heat.

3. (Trommsdorff.) From *iron filings*, 2 dr.; *nitre*, 4 dr.; (both in fine powder;) mixed together, and placed in an 8 or 10 *oz.* crucible, heated to a glowing red, and still standing on red hot coals; when combination takes place on one side, shown by the evolution of light and white fumes, it is removed from the fire, and as soon as the deflagration of the mixture has ceased, the mass is scraped out on a *cold* plate, by means of an iron spatula, and at once crushed to pieces and bottled.

Prop., &c. The product is a dark reddish-black mass, forming a superb cherry-red solution with water, which quickly undergoes decomposition, depositing sesquioxide of iron, and evolving pure oxygen. It is the substance employed by Dr. Payerne to keep up the vitality of the air in diving-bells, unconnected with the atmosphere. For this purpose, it is only necessary to drop a piece occasionally into a vessel of water. According to Dr. Ure, the preparation succeeds best when a large crucible, capable of holding about a pint, is heated so strongly that the bottom, and a couple of inches above it, appear faintly but distinctly red. The weight of the mixture (*Trommsdorff's*) should be about 300 gr., and should be "thrown at once upon the side of the crucible."

FERRIC-CITRATE and *Ferrocitrate*. See *Ammonio-citrate of Iron*.

FERRIDCYANIDES. Syn. *Ferric-cyanides*, *Ferri-cyanides; Ferridcyanates*, *Ferridcyanurets*, *&c.* Compounds of ferridcyanogen with the bases. The principal of these is the *ferridcyanide of potassium* or *red prussiate of potash*. The *ferridcyanides* of *ammonium*, and the *alkalies* and *alkaline earths* are soluble; those of the *non-alkaline metals*, insoluble. See *Hydroferridcyanic Acid*.

FERRIDCYANOGEN. Syn. *Ferri-cyanogen*, *Ferric-cyanogen*. The peculiar salt-radical which exists in "*red prussiate of potash*." It is isomeric with ferrocyanogen, from which it differs in capacity of saturation (being tribasic), and in the behaviour of its compounds with solutions of the metals. It is formed by treating *ferrocyanide of potassium* with *chlorine*, but has not been isolated. It unites with hydrogen, forming a tribasic acid, termed hydroferridcyanic acid. See *Ferridcyanide of Potassium* and *Hydroferridcyanic Acid*.

FERROCHYAZIC ACID. See *Hydroferrocyanic Acid*.

FERROCYANIC ACID. As the last.

FERROCYANIDE. Syn. *Ferrocyanate*, *Ferrocyanuret*, *Hydroferrocyanate*, *Prussiate; Ferrocyanidum*, *Ferrocyanuretum*, *&c.*,—Lat. A compound of ferrocyanogen with a metal. The principal substance of this kind is the *ferrocyanide of potassium* or *yellow prussiate of potash*. See the *respective bases* (and *below.*)

FERROCYANIDE OF AMMONIUM. Syn. *Ferrocyanate of Ammonia*, *Prussiate of do.; Ammoniæ Ferrocyanas*, *Ammonii*

Ferrocyanidum,—Lat. *Prep.* Digest *ferrocyanide of lead* in a solution of *sesquicarbonate of ammonia*, at a gentle heat, filter, evaporate, and crystallize.

FERROCYANIDE OF COPPER. Syn. *Prussiate of Copper; Cupri Ferrocyanidum*, —Lat. *Prep.* From a *solution of a cupreous salt* (as *blue vitriol*), precipitated with a *solution of yellow prussiate of potash;* the powder which falls being carefully collected, washed, and dried. It has a beautiful reddish brown-colour, and is sometimes used as a pigment.

FERROCYANOGEN. Syn. *Ferrocyanogenium*,—Lat. A bibasic salt radical, composed of cyanogen, or its elements, and iron. Its compounds are the *ferrocyanides*. See the *respective bases*, and *Hydroferrocyanic Acid*.

FERRO-SESQUICYANIC ACID. See *Hydroferrocyanic Acid*.

FERRO-TARTRATES. See *Iron*.

FERRUGO. Rust of iron. See *Hydrated Sesquioxide of Iron*.

FEVER. Syn. *Febris*, *Pyrexia*,—Lat. The name of an extensive and important class of diseases, one of the most general symptoms of which is an increased heat of the body. Fevers have been divided by nosologists into *intermittents* (intermittentes), *remittents* (remittentes), and *continued fevers* (continuæ). The first of these are generally known by the name of *agues;* the second differ from agues in there being one or more marked exacerbations and remissions of the symptoms, every 24 hours, but without any entire intermission; and the last have been divided into *inflammatory fever* (synocha), *putrid* or *low fever* (typhus), and the common *continued* or *mixed fever* (synochus), which commences with symptoms allied to those of ordinary inflammatory fever, but terminates with those of typhus. The terms *hectic*, *nervous*, *bilious*, *inflammatory*, *&c.*, have also been applied to particular varieties of *fever;* and names indicative of certain cutaneous appearances connected with them have been given to others; as *scarlet* fever, *yellow* fever, &c.

The usual *symptoms* of incipient fever (*febrile symptoms*) are—chilliness (varying from a simple shiver to a sensation of cold water running down the back), a quick pulse, hot and dry skin or flushing, languor, often evinced by yawning, depression of spirits, alternate fits of shivering and heat, hurried and uneasy respiration, flying pains in various parts of the body, as the head, back, and loins; loss of appetite, nausea or vomiting, dry mouth, furred tongue, costiveness, urine small in quantity, and usually of a deep colour, &c. When any of these symptoms appear, their progress may often be arrested by the timely exhibition of an emetic, followed by a saline purgative, and diaphoretics; at the same time promoting the action of these remedies by a low diet and drinking *copiously* of diluents, and carefully avoiding animal food, spirits, fermented liquors, or anything at all stimulant. Whenever symptoms of fever become established, medical advice should be sought and implicitly followed. In parts where it cannot be obtained the treatment recommended under *Ague*, *Inflammatory Fever*, *Remittent Fever*, and *Typhus* may be followed with advantage.

In *visiting* or *attending persons* labouring under fevers, it is advisable to avoid immediate contact with them or their clothing, or standing near them in such a position as to inhale their breath, or the effluvia evolved (in some cases) by their bodies; and when remaining for some time in the apartment, it is preferable to sit or stand near the fireplace, or between the window and door, as such parts of the room are generally better ventilated than the other portions. The greatest purifier of the atmosphere of a sick chamber is a *good fire*, because it occasions a continual current of the impure air up the chimney, and a corresponding influx of fresh air from without. *Chloride of lime*, or *chloride of zinc*, or their solutions, are also good purifiers. The *first*, however, should not be used in quantity, as the evolved chlorine, might in that case, impede the respiration of the patient. It is also advisable to avoid entering the room of a patient labouring under *contagious diseases* of any class, when the stomach is empty, or the spirits depressed; and it has been recommended to clear the mouth of the saliva immediately after quitting the chamber. See *Ablution*, *&c.*

FEVER POWDER. See *Antimony* and *Powders*.

FIBRE. Syn. *Fibra*,—Lat. The filamentous textures of animal and vegetable bodies. Many of them are used in the arts. See *Catgut*, *Lignine*, *&c.*

FIBRINE. A peculiar proteine substance, forming the coagulable portion of fresh-drawn blood, and the principal constituent of the muscular or fleshy parts of animals. It also occurs in vegetable juices, the gluten of wheat, and in the seeds of the cereals generally. It is eminently nutritious, and capable of yielding in the animal body, albumen, caseine, and the tissues derived from them. (Liebig.) It is a modification of proteine, and as such,

contains in itself the elements of all the softer portions of animals, and is hence capable of supporting life without the addition of any other aliment. This is what no other substances but albumen and caseine (also modifications of proteine) can do.

Fibrine is easily obtained in a nearly pure state, by agitating or beating *newly drawn blood* with a small bundle of twigs, when it attaches itself to the latter under the form of long reddish filaments, which become white when worked with the hands in a stream of *cold water*. It may also be procured by washing the *coagulum of blood*, tied up in a cloth, in *cold water*, until *all* the soluble portions are removed. A small quantity of fat, which it still contains, may be removed by digesting it in *ether*.

Pure fibrine occurs as long, white, elastic filaments, which are tasteless, inodorous, and insoluble in both hot and cold water. Wetted with acetic acid, it forms, after a time, a transparent jelly, which is slowly soluble in pure water. Very dilute solutions of the caustic alkalies dissolve it completely, and the new solution greatly resembles liquid albumen. Dried by a gentle heat it loses about 80/0 of water.

According to M. Mulder, dried fibrin, besides the elements common to most animal substances, *contains,—phosphorus*, 0·3%; *sulphur*, 1·2%; and its ash or incombustible portion, varying from 0·7% to 2·5%, consists chiefly of *phosphate of lime*.

FIG. Syn. *Ficus*,—Ph. L. E. & D. *Carica, Caricæ Fructus*,—Lat. Figs (*fici*) are the "dried fruit" of "*ficus carica*" (Linn.) or *common fig-tree*. They are demulcent, emollient, laxative, and pectoral. *Roasted* and *boiled figs* are occasionally employed as poultices to gum boils, and other affections of the mouth.

FILBERTS. Syn. *Filberds*. The fruit of the cultivated *hazel* or *nut-tree* (corylus avellana,—*Linn.*) Filberts are distinguished from common nuts by their lengthened figure and larger size. The best are imported from Spain.

FILES. The manufacture of these articles do not come within the limits of this work. It may, however, be useful to mention that *files*, *floats*, and *rasps*, which "cut dull" from age, dirt, or being much worn, are greatly improved by being kept wet, or immersed in water for some hours, or even for a day or two. The reason of this is evident.

FILICINE. Syn. *Filicina*, *Filicia*. An alkaloid found by Batso, associated with a peculiar acid (*filicic acid; acidum filiceum;*) in the rhizomes of male shield-fern (*aspidium filix mas*).

FILTER. Syn. *Filtrum*,—Lat. An instrument or apparatus for straining or filtering liquids. See *Filtration*.

FILTERING POWDERS. *Prep.* 1. *Fuller's earth* washed, dried without heat, and reduced to coarse powder.

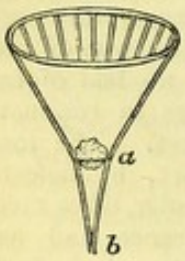
2. From *pipe clay* or *potter's clay*, as the last. Both the above are used to *filter* and *bleach oils*.

3. From *clay* or *fuller's earth*, 1 part; *fine silicious sand*, 2 parts; the two are separately washed, after which they are drained, and mixed together, and dried, as before. *Used* for *glutinous oils*.

4. *Granulated animal charcoal*, sifted and fanned from the dust. *Used* to filter and *bleach syrups* and *vegetable solutions*.

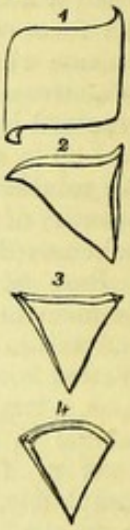
Obs. Filtering powders are prepared of several degrees of coarseness, and should be chosen with reference to the degree of fluidity of the liquid to be filtered through them. In no case should they be reduced to *fine powder*, as not only is the process of filtration thereby rendered unnecessarily tedious, but in some cases (as when charcoal dust is mixed with glutinous vegetable solutions and syrups), the filtrate carries off a portion of the powder, which can afterwards be separated from it only with considerable difficulty. See *Charcoal, Filtration, Oils, &c.*

FILTRATION. Syn. *Filtratio*,—Lat. The separation of liquids from substances mechanically suspended in them, by passing them through the pores of media sufficiently fine to retain or keep back the solid matter. *Filtration* is one of the most common and useful of the chemico-mechanical operations of the arts, and its successful performance in an *economical* and *expeditious manner*, is therefore a matter of the highest importance in the laboratory, and, indeed, in almost every branch of human skill and industry in which liquids are employed. Simple in principle, and *apparently* easily performed, it is, nevertheless, one of those operations which require no less of care, than of tact and experience to conduct it with certainty and success. The losses sustained in the laboratory, by defective manipulation in this particular, often exceed those arising from ignorance and accidents in every other department conducted in it.



Filtration is usually *resorted to* for the purpose of freeing liquids from feculence, dirt, and other foreign matter, and for obtaining them in a clear or transparent state; but, in some cases, it has for its

object the collection of the suspended substances, as precipitates, &c., and in others, both these intentions are combined. The word *filtration* is absolutely synonymous with *straining*, but, in the *language of the laboratory*, it is usually applied to the operation of rendering liquids transparent, or nearly so, by passing them through *fine* media, as *filtering paper*, *sand*, and the like; whilst the term *straining* is employed to designate the mere separation of the grosser portion, by means of *coarse* media, as *flannel*, *horse-hair cloth*, *&c.*, through which they flow with considerable rapidity. *Filtration* is distinguished from *clarification* by its mere mechanical action, whereas the *latter* operates by depuration, or the subsidence of the suspended substances or fæces, arising from their gravity being naturally greater than the fluid with which they are mixed, or being rendered so by the application of heat, or by the addition of some foreign substance.



The *apparatus*, *vessels*, or *media*, employed for filtration, are called FILTERS, and are technically distinguished from *strainers* by the superior fineness of their pores.

Both *strainers* and *filters* act on the same *principles* as the *common sieve* on *powders*; they all, in like manner, retain or hold back the *coarser matter*, and permit the *liquid*, or *smaller* and *more attenuated particles* to pass through. The term *medium* (plural *media*) is applied to the substance or substances through the pores of which the liquid percolates.

The *forms of filters*, and the *substances of which they are composed*, are various, and depend upon the nature of the liquids for which they are intended. On the SMALL SCALE, *funnels* of *tin*, *zinc*, *copper*, *Wedgwood ware*, *earthenware*, *glass*, or *porcelain*, are commonly employed as the containing vessels. (See *Engr.*) The *filtering medium* may be any substance of a sufficiently spongy or porous nature to allow of the free percolation of the liquid, and whose pores are, at the same time, sufficiently small to render it limpid or transparent. *Unsized paper*, *flannel*, *linen*, *calico*, *cotton wool*, *felt*, *sand*, *coarsely-powdered charcoal*, *porous stone*, or *earthenware*, and numerous other substances of a similar kind, are employed for this purpose.

For many liquids that *filter easily*, and in which the suspended matter is of a coarse and porous nature, it is often sufficient merely to place a little *cotton wool* or *tow*, or a *small piece of sponge*, in the neck of the funnel, as at (*a*) in the above engr.; but such an apparatus, from the small extent of the filtering surface, acts either slowly or imperfectly, and soon gets choked up. *Filters* of *unsized paper* are well suited for all liquids that are not of a *corrosive* or *viscid nature*, and are universally employed for filtering *small quantities of liquids* in the laboratory. A piece of the paper is taken of a size proportionate to the quantity of the liquid to be filtered, and is first doubled from corner to corner into a triangle (see *engr.*), which is again doubled into a smaller triangle, and the angular portion of the margin being rounded off with a pair of scissors, it constitutes a paper cone, which is placed on a funnel of proportionate capacity, and is then nearly filled with the liquid. A piece of paper so cut, when laid flat upon a table, should be nearly circular. Another method of forming a paper filter, preferred by some persons, is to double the paper once, as above (see fig. 2), and then to fold it in a similar way to a fan, observing so to open it and lay it on the funnel, that a sufficient interval be left between the two, to permit of the free passage of the filtered liquid on its descent towards the receiver. (See *Engr.*)

In reference to *funnels* it may be remarked, that to promote the object last referred to, they should be deeply ribbed on the *inside*, or *small rods* of *wood* or *glass*, or *pieces of straw*, or *quills*, should be placed between them and the paper. The neck or tubular part of the *funnel* should, in like manner, be deeply ribbed or fluted, on the outside, to permit of the free passage of the air, when it is placed in a narrow-mouthed bottle or receiver. When this is not the case, filtration proceeds but slowly, and the filtered liquid is apt to be driven up the outside of the neck of the funnel by the confined air, and to be continually hissing and flowing over the mouth of the vessel. The *breadth of a funnel*, to filter well, should be about *three fourths* of its *height*, reckoning from the throat (*a*). When *deeper*, the paper is liable to be continually

ruptured from the pressure of the superincumbent fluid; and, when *shallower*, filtration proceeds slowly, and an unnecessarily large surface of the liquid is exposed to the atmosphere, and is lost by evaporation. To *lessen this* as much as possible, the upper edge of the glass is frequently ground perfectly smooth, and a piece of smooth plate-glass is laid thereon. When *paper filters* are of *large dimensions*, or for *aqueous fluids* that rapidly soften the texture of the paper, or for collecting *heavy powders*, or *metallic precipitates*, it is usual to support them on *linen* or *calico*, to prevent their breaking. This is best done by folding the cloth up with the paper, and cutting the filter out of the two, in the same way as would be done with doubled paper, observing so to place it in the funnel that the paper and calico may remain close together, especially towards the bottom.

The *filtration* of *small quantities* of *liquid*, as in chemical experiments, may often be conveniently performed by merely placing the paper on the circular top of a recipient (see *engr.*); or on a ring of glass or earthenware laid on the top of any suitable vessel. A filter of this kind that will hold one fluid ounce, will filter many ounces of some liquids in an hour.

Good *filtering paper* should contain no soluble matter, and should not give more than $\frac{1}{250}$ to $\frac{1}{250}$ of its weight of ashes. The soluble matter may be removed by washing it, first, with *very dilute hydrochloric acid*, and secondly, with distilled water.

For *filtering* a *larger quantity of a liquid* than can be conveniently managed with a *funnel*, and also for substances that are either too *viscid* or too much *loaded with feculence* to allow them to pass freely through paper, conical bags made of *flannel*, *felt*, *tweeled cotton cloth* or *Canton flannel*, *linen* or *calico*, and suspended to iron hooks by rings or tapes, are commonly employed. The first two of the above substances are preferable for *saccharine*, *mucilaginous*, and *acidulous liquids;* the third for *oily ones;* and the remainder for *tinctures*, *weak alkaline lyes*, and *similar solutions*. These bags have the disadvantage of sucking up a considerable quantity of the fluid poured into them, and are therefore objectionable, except for large quantities, or when they are to be continued in actual use as filters for some time. On the *large scale*, a number of them are usually worked together, and are generally inclosed in cases to prevent evaporation, and to exclude dirt from the filtered liquor that trickles down their sides. These arrangements will be noticed further on.

A *simple mode* of *filtering aqueous fluids*, which are *not injured by exposure to the air*, is to draw them off from one vessel to another, by means of a number of threads of loosely twisted cotton or worsted, arranged in the form of a syphon. (See *Engr.*) The little cotton rope at once performs the operations of decantation and filtration. This method is often convenient for sucking off the water from a small quantity of a precipitate.

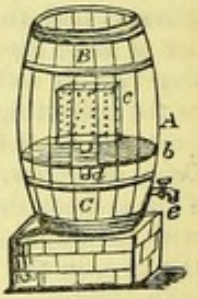
When *solid substances*, as *porous stone* or *earthenware*, are used as the media for filtration, vessels of *metal*, *wood*, or *stone-ware* are employed to contain them and the supernatant liquid. In these cases, the filtering medium is usually arranged as a shelf or diaphragm, and divides the vessel into two compartments; the upper one being intended to contain the dirty liquid, and the under one to receive the same when filtered. Such an apparatus is set in operation by merely filling the upper chamber, and may at any time be readily cleaned out by reversing it, and passing clean water through it in an opposite direction. Small arrangements of this kind, intended to be screwed on to the water supply-pipe by either end, and which answer the purpose intended in the most satisfactory manner, have been recently manufactured and vended under the name of "*reversible*" or "*self-cleaning filters.*" When pulverulent substances, as *sand*, *coarsely powdered charcoal*, *&c.*, are employed, a similar arrangement is followed; but in this case, the shelf or diaphragm must consist of any convenient substance pierced with numerous holes, over which must be placed, first a *stratum of coarse pebbles*, next some of a *finer description*, and on this a proper quantity of the *sand*, *charcoal*, or *other medium*. Over the whole should be placed another *layer of pebbles*, or a board or plate of *metal* or *earthenware*, pierced with a number of holes, to allow the liquid to be poured into the filter without disturbing its arrangement. Apparatus of this kind of a permanent description, and arranged for filtering large quantities of liquids, are

properly denominated "*filtering machines.*"

Among the liquids usually submitted to filtration, the following may be mentioned as the principal—*water, oils, syrups, tinctures, vegetable juices, infusions, and decoctions.*

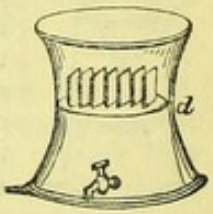
The *water of our wells* is presented by nature ready filtered to the hand of man, and often exhibits an admirable degree of transparency and purity. It acquires this state by percolating through the mineral strata of the earth, which deprive it of the organic matter it derives from the soil and subsoil, but, at the same time, it dissolves a portion of the saline and earthy media through which it passes, and hence acquires that peculiar "hardness" which is constantly found in spring water. On the large scale, this natural system of filtration has been imitated by some of the commercial companies that supply our cities and towns with water. Extensive beds of sand and gravel have been employed, with variable success, as the filtering media, and were it not that filters gradually lose their porosity by the accumulation of the retained matter in their pores, such a method would be excellent. But the great expense of such filters precludes the possibility of frequently cleaning or renewing them, by which means they can alone be kept in an efficient state.

A *filter* which possesses the advantages of being easily and cheaply cleaned when dirty, and which *purifies water* in an *almost perfect manner*, and with immense rapidity, may be formed by placing a *stratum of sponge* between *two perforated metallic plates*, united by a central screw, and arranged in such a manner as to permit of the sponge being *compressed* to any required degree. Water, under gentle pressure, flows with such rapidity through the pores of compressed sponge, that it is said, that a few square feet of this substance will *perfectly filter* several millions of gallons of water daily. This method of filtration has been made the subject of a patent, and has been favorably noticed by the legislature.



A *few barrels* or *hogsheads of water* may be *easily filtered daily*, by the arrangement represented in the engraving.

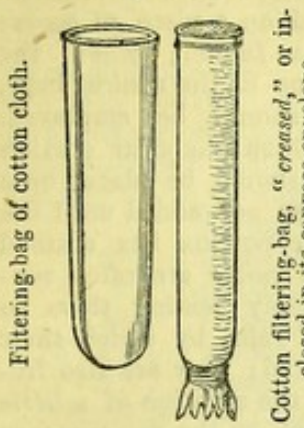
It is evident that when water is poured into the upper portion *B*, of a vessel so arranged, it will sink through the filter *c*, and pipe *d*, into the lower chamber *C*, and this filtration will go on as long as the supply continues, and water is drawn from the cock *e*. By uniting the cock *e* with a tank or casks, and by keeping the upper portion *B* always full by means of a ball-cock, a considerable quantity of water may be thus filtered. The advantage of this plan is, that the filter *c* can be always readily got at, and easily cleaned or renewed.



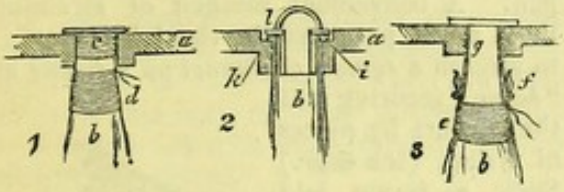
A, A common water-pipe or cask.

b, A false bottom, fitting in perfectly water-tight.

c, A perforated wooden or metallic vessel or box, covered with a bag of felt or other filtering substance, (not shown in the engraving.) *d*, A small tube, fitting water-tight into the false bottom, and uniting the *interior* of the filter with the lower portion of the cask.



For *filtering water* on the *small scale*, and for domestic use, *alcarazzas* or *porous earthenware*, *filtering-stone*, and *layers* of *sand* and *charcoal*, &c., already referred to, are commonly employed as filtering media. The filtering power of the first two may be greatly increased by adopting the arrangement represented in the margin, which consists in making the diaphragm of the shape of a disc (*d*), supporting plates of the same material, the whole forming but *one* piece. The *platylithic water-filters*, which are formed of porous stone cut on this plan, present 200 to 300 square inches of filtering surface, and may be purchased for a few shillings each. They are perhaps the best portable filters made; they impart great brilliancy to the water, and filter with extraordinary rapidity. The *portable artificial filters*, set up in *stone-ware*, that are commonly sold in the shops, contain a *stratum of sand*, or *coarsely-powdered charcoal;* before, however, having access to this, the water has to pass through a *sponge*, to remove the coarser portion of the impurities. An excellent *filter* of this class, and one less likely to get out of order, and more easily managed, perhaps, than any other, is that made by Mr. Lipscombe, of Temple Bar. As any person may satisfy himself, before purchasing one, it is capable of converting the filthy water of the Thames into a pellucid liquid, rivalling in brilliancy that of a crystal fountain.



Oils are *filtered*, on the *small scale*, through cotton-wool, or unsized paper, arranged in a funnel; and on the *large scale*, through long bags, made of tweeled cotton-cloth (*Canton flannel*). These bags

are usually made about 12 or 15 inches in diameter, and from 4 to 8 feet long, (see *engr.*,) and are inclosed in bottomless casings, or bags, of coarse canvass, about 5 to 6 or 8 inches in diameter, for the purpose of condensing a great extent of filtering surface into the smallest possible space. A number of these double bags (from 1 to 50 or 60) are connected with corresponding holes in the bottom of a *block-tin*, or *tinned-copper cistern*, into which the oil to be filtered is poured. The mode in which these bags are fastened to the cistern is of the utmost importance, as on the joint being close and secure depends the integrity of the apparatus. Three methods of doing this are figured in the engraving, which, with the references, will explain themselves, the same letters referring to the same parts of each.

Filtering-bag of cotton cloth.

Cotton filtering-bag, "*creased*," or inclosed in its canvass envelope, ready for fixing

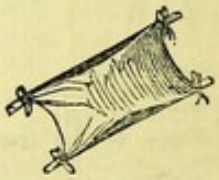
a, Bottom of cistern.
b, Filtering bag.
c, Screw of the conical nozzle fitting into the cistern.
d, Binding cord connecting the bag and nozzle.
e, Binding cord connecting bag and lower nozzle.
f, Bayonet-catch, connecting the lower portion of the nozzle fastened to the bag with the upper and fixed part, *g*.
i, The thick hem at the top of the bag, (purposely made large by inclosing a piece of thick cord therein,) resting on the shoulders, *k*.
l, A metallic cylinder, loosely fitting the hole in the cistern, and over which the top of the bag is drawn, before being put into its place; when fitted, as in the engraving, it retains the hem *i* securely in its place above the shoulder *k*.

The *second* of the above arrangements is the least expensive, and certainly the most convenient in practice; and when the cylinder *l* fits the hole closely, (allowing for the bag,) is as safe, or safer, than an ordinary screw.

The *bags* are surrounded by a wooden screen fitted up with doors for the purpose of keeping off the dust; and the bottom of the apartment is furnished with large steam-pipes, by which a proper temperature may be kept up in cold weather. The use of heat should, however, never be had recourse to, when it can be avoided, as although it vastly increases the rate of filtration, the oil so filtered is more apt to become opaque in cold weather, than when the process is conducted at the natural temperature of the atmosphere. This is particularly the case with *castor oil*, and *sperm oil*. In the United States of America, where the latter is consumed in enormous quantities for illumination, the best is always "*winter strained*," as it is popularly called. In practice, it is more convenient to have a number of small cisterns at work, (say 50 or 100 galls. each,) than one or two larger ones; as any accident that may occur is more easily remedied, and that without stopping the whole operation.

When *cotton-cloth bags* are employed without being *creased*, or inclosed in others of canvass, they should not be longer than about 3 or 4 feet, and not wider than about 5 or 6 inches when filled. When larger they are dangerous.

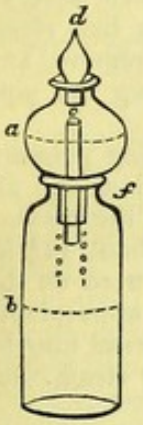
A convenient method of filtering a *single cask of oil*, is to insert the pipe of a *two-way patent filter* into the cork-hole, by which means the whole will be filtered as drawn off, without any trouble on the part of the operator. This filter consists of a *porous bag* stretched over a *perforated metallic vessel*, nearly the shape and size of the exterior casing, and its edge is tightly screwed between the sides and bottom of the latter, so as to be quite water-tight. The cock communicates with the *interior* of the perforated plate and filter, and the supply-pipe with the *exterior*. By this means the interior chamber, which occupies $\frac{5}{6}$ths of the vessel, rapidly fills with filtered oil, and continues full as long as any liquor remains in the cask. This arrangement is also well adapted to the *filtration* of *wines*, *beer*, *cordials*, *porter*, and *various other liquors*. It is unequalled in simplicity and usefulness. The same filter may be removed from cask to cask, with the facility of a common cock.



The filtration of syrups is now generally effected on the *large scale* by passing them through the "*creased bag filter*" just described. On the *small scale*, as employed by *confectioners* and *druggists*, they are usually passed through *conical*

flannel bags. (See page 457.) The filtration of *thick syrups* is, however, attended with some difficulty, and it is therefore a good plan to filter them in a somewhat dilute state, and afterwards to reduce them to a proper consistence by evaporation in clean vessels of tinned copper, by steam heat. Syrups, when filtered in a heated state, run well for a time, but the pores of the fabric rapidly get choked, from the thickening of the syrup and partial crystallization of the sugar, occasioned by the evaporation of the aqueous portion from the surface of the bag. This may be partially prevented by inclosing the bag in a metallic casing. On the whole, *clarification* is preferable for syrups to *filtration*, on the *small scale.* They need only be well beaten up while *cold* with a *little white of egg*, and then heated; a scum rises which must be removed as soon as it becomes consistent, and the skimming continued until the liquid becomes clear. Any floating portions of scum that may have escaped notice are easily removed by running the syrup through a *coarse* flannel strainer, whilst hot. The most extensive application of the process of filtration in the arts is in the refining of sugars.

Tinctures and *dilute spirits* are usually filtered, on the *small scale*, through *bibulous* or *unsized paper* placed on a funnel; and on the *large scale*, through *thin* and *fine-cotton* bags. In general, however, tinctures clarify themselves by the subsidence of the suspended matter, when allowed to repose for a few days. Hence it is the bottoms alone that require filtering; the supernatant clear portion need only be run through a small *hair sieve*, a *piece of tow* or *cotton* placed in the throat of a funnel, or some other *coarse medium*, to remove any floating substances, as pieces of straw, &c. *Spirits* which are *largely loaded with essential oil*, as those of aniseed, &c., run rapidly through paper or calico, but usually require the addition of a *spoonful* or *two* of *magnesia* before they will flow *quite* clear. When possible, *tinctures*, *spirits*, and all *similar volatile fluids*, are better and more economically cleared by subsidence or clarification, than by filtration, as, in the latter way, a portion is lost by evaporation, and the strength of the liquid is thereby altered.

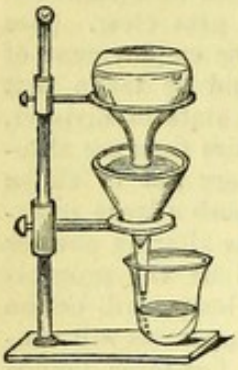


Vegetable juices should be allowed to deposit their feculous portion before filtration. The supernatant liquid will then be often found quite clear. It is only when this is not the case, that filtration should be had recourse. A *small* quantity may be filtered through *coarse* or *woollen filtering paper*, supported on a piece of *coarse calico* placed on a funnel; when the *quantity is large*, one of the conical bags, before described, should be employed. The *bottoms* from which the clear portion has been decanted, should be placed on a separate filter, or else not added until the whole of the other portion has drained through. *Vegetable juices* are often rendered clear, by simply heating them to about 180° or 200° Fahr, by which their albumen is coagulated; they are also frequently *clarified* by the addition of a *little white of egg* and *heat*, in the same way as syrups. Many of them (as those of *hemlock*, *henbane*, *aconite*, &c.) are greatly injured by heat, and must consequently be filtered, or only simply decanted after repose. In all cases they should be exposed to the air as little as possible, as they rapidly suffer decomposition.

Vegetable infusions and *decoctions* may be cleared by defecation followed by filtration. The conical bags of flannel before described are usually employed for this purpose. When the liquid is to be evaporated to an extract they are commonly suspended by a hook over the evaporating pan. A convenient method of straining these fluids practised in the laboratory, is to streteh a *square of flannel* on a *frame* or "*horse*," securing it at the corners by pieces of string, (see *engr.*) Such a frame laid across the mouth of a pan, is more easily fed with fresh liquid than a bag, whose mouth is 40 or 50 inches higher. The same purpose, for *small quantities* of liquid, is effected by laying the flannel across the mouth of a coarse hair sieve. The *concentrated infusions* and *decoctions*, being usually weak tinctures, may be filtered in the same way as the latter. (See *tinctures*, above.) Many *vegetable solutions*, that from the *viscidity* of the suspended matter can scarcely be filtered, may be readily *clarified with white of egg* in *the cold*, or pass the *filter rapidly*, if a *very small quantity* of *acetic*, *tartaric*, *sulphuric*, or *other strong acid*, is previously added. (See *Brewing*, p. 169.)

Corrosive liquids, as the *strong acids*, are filtered through *powdered glass*, or *siliceous sand*, supported on *pebbles* in the throat of a glass funnel, or through *asbestos* placed in the same manner. *Charcoal* has also been employed for the same purpose, but is

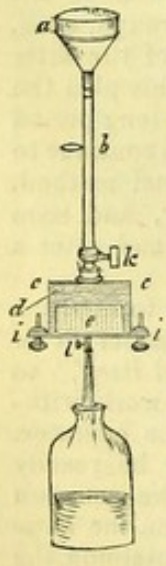
not fit for some acids. *Strong caustic alkaline lyes* are also filtered through *powdered glass* or *sand*. *Weak alkaline lyes* may be filtered through *fine calico*, stretched across the mouth of a funnel. Many corrosive liquids, as *liquor of potassa*, *&c.*, require to be excluded from the air during filtration. The simplest apparatus that can be employed for this purpose is that figured in the margin:—(*a*) is a globular bottle fitted with the ground stopper (*d*), and having a perforated neck (*f*) ground to the bottle (*b*); (*c*) is a small tube, wrapped round with as much *asbestos*, *linen*, or *calico* as is required to make it fit the under-neck of the bottle through which it passes. The tube (*c*) may also be fixed by placing *pebbles* and *powdered glass* or *sand* round it, as before mentioned. For use, the solution to be filtered is poured into the bottle (*a*) nearly as high as the top of the tube (*c*), and the stopper is replaced. The liquid then descends into (*b*), and a similar quantity of air passes up the tube into (*a*). The *liquor of potassa* (Ph. L.) may be always obtained fine by depuration in close vessels, when the sediment of lime only need be filtered, which may be effected with *calico* fixed across the mouth of a funnel.



When *precipitates*, or the *suspended matter* in a liquid, is the object of the filtration, the filter should be of such a nature that the powder may be easily separated from it, when dry, and that with the least loss possible. *Linen filters* are for this reason preferable for large quantities, and *smooth bibulous paper* for small ones. The powder should be washed down the sides of the filter, and collected, by means of a *small stream of water* in one spot at the bottom, assisting the operation with a camel-hair pencil; and, when the whole is dry, it should be swept off the paper or cloth with a similar pencil or brush, and not removed by a knife, as is commonly done, when it can be possibly avoided.

The "*first runnings*" of liquid from a filter are commonly foul, and are pumped back or returned until the fluid runs perfectly limpid and transparent, when it is "turned into" the "*filtered liquor cistern*" or proper receiver. In many cases the liquid does not readily become transparent by simply passing through the filter; hence has arisen the use of *filtering powders*, or substances which rapidly choke up the pores of the media in a sufficient degree to make the fluid pass clear. (See *Filtering Powder*.) In the employment of these powders, care should be taken that they are not in too fine a state of division, nor used in larger quantities than are absolutely necessary, as they are apt to choke up the filter, and to absorb a large quantity of the liquid. The *less* filtering powder used, the *more rapid* will be the progress of the filtration, and the longer will be the period during which the apparatus will continue in effective action. For some liquids these substances are employed for the double purpose of *decolouring* or *whitening*, as well as rendering them transparent. In such cases, it is preferable, first to pass the fluid through a layer of the substance in coarse powder, from which it will "run" but slightly contaminated into the filter; or, if the powder is mixed with the whole body of the liquid, as in bleaching *almond oil*, *&c.*, to pass the mixture through some coarser medium, to remove the cruder portion before allowing it to run into the filter. *Another plan* is, after long agitation and subsequent repose, to decant the clearer portion from the grosser sediment, and to employ separate filters for the two. *Granulated animal charcoal* is used, according to the *first* method, to *decolour syrups*, *oils*, *&c.*; and *filtering powder* by the *second* and *third*, to remove a portion of the *colour*, and to *clarify castor* and other *oils*. The common plan of mixing *large quantities* of filtering powder with *castor oil*, and throwing the whole into the filter, as adopted by the druggists, is injudicious. When *simple filtration* is required, it is better to use *little* or *no powder*, and to continue returning the oil that "runs" through, until, by the swelling of the fibres of the filter bags, it flows quite clear. By this plan the same filters may be used for a long period of time (for many years), and will continue to work well; whilst, by the usual method, they rapidly decline in power, and soon deliver their contents slowly, and after a short time, scarcely at all.

It is often of great advantage to render a filter "*self-acting*," or to construct it in such a way that it may "*feed itself*," so that it may continue full and at work, without the constant attention of the operator. On the *small scale*, this may be readily effected on the principle of the common fountain lamp (see *engr.*), and on the *large scale*, by placing the vessel containing the unfiltered liquid on a higher level than the



filter, and by having the end of the supply-pipe fitted with a ball-cock, to keep the liquid in the filter constantly at the same height.

The *rapidity of filtration* depends upon the—*porosity of the filtering medium* — the *extent of the filtering surface* — the *relative viscidity* or *mobility of the filtering liquid*,— the *pressure* or *force by which the liquid is impelled through the pores of the filter*, and—the *porosity and fineness of the substances it holds in suspension*. The most efficient filter is produced, when the first two or the first three are so graduated to the others, that the liquid filters rapidly, and is at the same time rendered perfectly transparent.

In the common method of filtration no *pressure* is exerted beyond that of the weight of the column of the liquid resting on the filtering medium, but in some cases additional pressure is employed. This is had recourse to for the purpose of producing a more rapid filtration, and more especially for filtering liquids that, from their viscidity, will scarcely pass through the pores of substances sufficiently fine to remove their impurities in the ordinary way.

One of the *easiest means* of employing *pressure in filtration* is to increase the height of the column of the filtering liquid. From the peculiar properties of fluids, by which they transmit pressure in an equal degree in all directions, this column need not be of equal diameter throughout, but may be conveniently contracted to the size of a small pipe, as in the accompanying engraving, which represents a small filter on this construction at work. (*a*) is the funnel or reservoir of foul liquid; (*b*) a small pipe conveying the liquid to the filter; (*c c*) a chamber, of which the upper portion (*d*) is filled with the descending liquid, and the lower portion (*e*) with the filtering media; (*i i*) are screws by which the bottom plate is fastened on; which plate is removed to clean out or renew the filter. For use, the cocks (*k*) and (*l*) are closed, and the liquid poured into the funnel (*a*); the cock (*k*) is next opened, and, in a few minutes after, the cock (*l*), when an uninterrupted flow of filtered liquor will be obtained as long as any fluid remains in the funnel (*a*), and the tube (*b*). The length of the tube determines the degree of pressure. Care must be taken first to pass the foul liquid through a hair sieve, or some other strainer, to remove any substance that might choke up the pipe (*b*).

Another method of employing *pressure in filtration*, is the withdrawal of the air from the receiving vessel, as in the *vacuum filter*, by which a pressure of about 14½ *lb.* to the square inch becomes exerted on the surface of the liquid by the atmosphere. The vacuum in the receiving vessel may be produced by the air-pump or by steam. See *Refrigeration*.

A *commoner method* of *applying pressure* than either of those already mentioned is to condense the air over the surface of the liquid by means of a *forcing-pump*, or by *steam*.

On the SMALL SCALE, pressure may be applied to filtration by means of a syphon, whose shorter leg has its mouth blown into the shape of a bell or funnel, over which *filtering paper* or *fine calico* may be stretched.

The *application of pressure to filtration* is not *always advantageous*, and beyond a certain limit, is generally attended with inconvenience, if not with absolute disadvantage. It is found in practice that fluids *under pressure* take a longer period to run clear than *without pressure*, and that ruptures of the media more frequently take place in the *former* case, or with pressure, than in the *latter*. Great pressure is in *no* case advantageous.

The filters already noticed are those that act by the fluid *descending* through the media; but in some cases, the reverse method is employed, and the liquid *filters upwards*, instead of downwards. These are called *ascending filters*, and are often preferable to those on the descending principle, because, the suspended matters that require removal by filtration usually sink, and thus a portion escapes being forced into the pores of the filter. They are also more convenient, when pressure is employed. Their construction depends upon the same principles as the common filter, and merely requires that the feeding vessel should be higher than the upper surface of the filtering media. *Oils* are conveniently filtered in this way, because of their little

specific gravity. By fixing a small filter on this principle into the head of a cask, and pouring in water through a funnel, whose neck reaches nearly to the bottom of the cask, the oil will float up and pass the filter, leaving the sediment behind. In cold weather, hot water may be employed.

a, Cask of oil. *b*, Stand. *c*, Funnel for water. *d*, Filter.

In some cases, the upward and downward systems of filtration are united in the same apparatus, and this plan is advantageous where the space for operating is limited. For this purpose, it is merely necessary to connect the *bottom* of an *ascending filter* with the *top* of a *descending one*, or the reverse; the proper pressure being in either case applied. See *Clarification*, *Defecation*, *Finings*, *&c.*

FINING. See *Clarification*, *Filtration*, *&c.*

FININGS. Substances used by publicans, brewers, wine-merchants, &c., to clarify their liquors.

Prep. 1. (Brewer's Finings; Cooper's do.) *Isinglass* (finely shredded), 1 *lb.*; and *sour beer* or *cider*, or *vinegar*, 3 or 4 pints; are macerated together, and more of the *sour liquor* added, as the isinglass swells, until about a gallon has been used, agitation with a *whisk* or a small bundle of twigs being occasionally had recourse to, for the purpose of promoting the solution. As soon as the whole of the isinglass is dissolved, the mixture is reduced to the consistence of *thin syrup*, with *weak*, *mild beer*, or *cider*, or *any other liquid* that the finings are intended for. The whole is next strained through a tammy cloth or a hair sieve, and at once reduced to a proper state of dilution, by the addition of more liquor. *Product.* 6½ to 7 gall. "A pound of *good isinglass* will make about 12 gall. of finings." (Ure.) *Used* to clarify fermented liquors, especially beer. 1 to 1½ pint is the usual dose for a *barrel* of *ale* or *porter*; and a quart for a *hogshead* of *cider* or *wine*.

2. (Spirit Finings.) — *a.* *Alum* (ord. cryst.), 1 *lb.*; powder, and divide it into 12 equal portions, which are to be separately wrapped in *blue paper*, and marked No. 1. Next take of *carbonate of soda* (sesquicarbonate of the shops), 6 *oz.*; divide this as the last, wrap it in *white paper*, and mark each parcel No. 2. Keeps dry anywhere.

b. From *alum*, 1 *lb.*; *salt of tartar* (dry), ¼ *lb.*; proceed as before. The *white papers* containing the salt of tartar, must be kept in a dry well-corked wide-mouthed bottle or jar. Both of the last two are *used* to clarify *gin* and *cordials*. The contents of one of the *blue papers* are dissolved in about a pint of *hot water*, and the resulting solution is well "rummaged up" with the liquor. A solution of the contents of one of the *white papers* in about ½ pint of *hot water*, is then added, and the agitation continued for some minutes longer; after which the cask is "bunged" close, and the whole allowed to repose until the next day. This is sufficient for a barrel (say 30 to 36 gall.), but many persons use double the quantity. The effect is not only to *clarify*, but also to "*blanch*" the liquor.

Obs. Good liquors, either *fermented* or *spirituous*, need no artificial "fining," as they always clarify themselves by repose. With those, however, which are "out of condition," or of inferior quality, it is often necessary, as without such a proceeding, they remain unsaleable. This is particularly the case with malt liquors. "Attempts to clarify it in the cask seldom fail to do harm. The only thing that can be used with advantage for fining *foul* or *muddy beer*, is *isinglass*." (Ure.) The disadvantages resulting from the *artificial clarification* of *fermented liquors* are—that they do not afterwards "stand well on draught," that much of the conservative astringent matter which they contain is precipitated with the "finings," that their piquancy and flavour is more or less diminished, and that they are more than usually liable to become flat and vapid, whether in cask or bottle. The larger the proportion of "finings" used, the more marked are their injurious effects, and the shorter the interval which elapses before the accession of the several symptoms referred to. We have seen the most disastrous consequences follow the injudicious use of "finings," more especially in respect to those liquors in which a certain amount of piquancy, astringency, and briskness, is an essential condition. In one instance which came under our notice, upwards of 30 barrels of "underground" (a very strong old ale) was thus reduced in value to less than 1-3rd its original cost; and in another, a large bottled stock of the "finest old Burton" was found to be utterly unsaleable. In both cases the "spoiled liquor" was got rid of by mixing it in, and selling it with 3*d.* and 4*d.* beer.

Liquors which "refuse" to "*fine*" or become clear, when treated with "finings"

in the usual manner, are called "*stubborn*" by coopers and cellarmen. See *Brewing* (p. 169), *Cordials*, *Gin*, *Malt Liquors*, *Wines*, *&c.*

FIRE. The calamities resulting from this destructive agent, are of such frequent occurrence, as to justly claim a notice of the subject here. The *causes* of fires are numerous, and of a varied character, and, in most instances, difficult to determine, because it is the interest of those concerned, to suppress all evidence connected with the matter. *Accident*, that convenient word given to the imaginary hack to which so many fires are referred, if truthfully interpreted, will, in general, be found to be equivalent to *carelessness*, *recklessness*, or *guilt*. We believe that there are few fires which have happened that might not have been prevented by the exercise of *common prudence*, and that a vast number have been caused by direct *negligence*, arising from sheer *laziness* and *indifference*, to use no harsher terms. As familiar instances, may be mentioned—*allowing sparks* to *fall on the ground* and remain there, *without extinguishing them;* carrying a *naked candle into rooms containing inflammable substances; smoking carelessly* and in *dangerous places*, as workshops, warehouses, on shipboard, &c.; *keeping instantaneous light matches* in *improper places*, and *neglecting* to *pick those up* that may *happen to fall on the ground*, *&c.*, *&c.* The list might easily be extended, but we believe every reflecting reader can do so for himself. The great increase in the number of fires since the introduction of *congreve matches*, and the almost general use of tobacco, cannot fail to have attracted the attention of every one.

Prev. This consists of the exercise of those ordinary precautions which the good sense of every careful and trustworthy man, be he taskmaster or servant, cannot fail to suggest. It would be useless to enumerate them.

Fires might often be readily extinguished when first discovered by the timely application of a few buckets of water. When an apartment is found to be on fire, the door, chimney, and windows should be immediately closed, if possible, and only opened for the purpose of projecting water on the flames. By this means, the supply of air will be cut off, and rapid combustion prevented. The same applies to the lower doors and windows of a house (especially the shop window), which are often injudiciously kept open or removed, under the pretence of rendering assistance. The neglect of this precaution has often caused a mere smouldering fire, that might have been easily put out, to burst into an inextinguishable mass of flame.

It has been proposed at various times to make certain additions to the *water* used for the purpose of extinguishing fires, in order to render its action *more certain* and *effective*. It is found that *sal ammoniac* (5 *oz.* to the *gall.*) exerts this property in a remarkable degree. The action of water so prepared has been known for ages, but has recently been ostentatiously put forth as "Dr. Clanny's *Solution.*" Several other articles, as *common salt*, *pearlash*, and *kitchen soda*, act in the same way, though less effectively. A few buckets of such water will speedily arrest the progress of a fire before it has much extended itself. Such a plan is easily applied, by adding the saline matter to the buckets of water, which are either used by hand, or to feed the engine for the first few minutes of its working. When, however, a fire has made much progress, the action of such substances becomes scarcely perceptible. See *Fire Annihilator*, *&c.*

Chimneys on *fire* are readily extinguished in several ways, without having recourse to throwing water down them from the top, by which much damage is frequently done to the furniture in the rooms. One of the *simplest methods* is, to cautiously scatter a handful of *flowers of sulphur* over the *dullest part* of the burning coals, the mephitic vapours arising from which being incapable of supporting combustion, rapidly extinguish the flames. *Another method* is, to *shut* the *doors* and *windows*, and to *stop up* the *bottom of the chimney* with a piece of *wet carpet* or *blanket*, throwing a *little water* or *flowers of sulphur*, or even *common salt*, on the fire immediately before doing so. By this means the draught is stopped, and the burning soot extinguished for want of air. In most of the first-class houses recently erected, "*fire-place shutters*" are provided, which when *partly* drawn down act as powerful bellows or "*blowers;*" and which when *wholly* drawn down, so as to touch the hearth-stone, entirely close up the fire-place, and instantly extinguish the combustion of the fuel in the grate, or that of the soot in the chimney. This simple arrangement, the advantages of which we pointed out in a former edition, renders fires in chimneys of little moment, as it is only necessary to draw down the shutter to put them out. If a chimney is stopped at top, instead of at the bottom, the whole of the smoke must, of necessity, be driven into the apartment.

Escape from apartments on fire may be best effected by creeping on the hands and knees. In this way the window or door may be reached. It is found that the atmosphere of a room so full of smoke as to produce suffocation to a person *standing upright*, may generally be *safely breathed*, on nearly a *level with the floor*. In the course of an inquest held a short time since, Mr. Wakley, the coroner, observed, that a *damp cloth*, or *handkerchief*, tied over the *mouth* and *nostrils*, or *still better* over the *whole face and head*, would enable a person to effect a passage through the densest smoke, and, in many cases, to *escape* from buildings on fire, when otherwise it would be *impracticable*. Should descent by the staircase be found impossible, then the window should be immediately sought, and a *ladder* or *fire-escape* waited for. In the absence of either, if the danger is imminent, a rope should be made by tying the sheets and blankets of the bed together, one end of which should be firmly secured to a chair or table, or preferably to one of the bedposts, and with this apparatus descent should be cautiously attempted. Jumping out of the window should be avoided, as persons who have not been brought up as clowns or harlequins, run just as much danger in performing such an exploit, as they do by remaining in the burning building. When it is impossible to escape from a burning building by the stairs or windows, retreat may be sometimes secured by a trap-door opening on to the roof, or by a sky-light; when, unless it be an isolated house, the roof of one of the adjoining buildings may probably be gained with safety.

Fire-escapes of various kinds have been employed of late years in the metropolis, and have proved of the greatest value in rescuing persons from burning buildings. At the late extensive fire on Thames Bank, we had the pleasure of being present when one of these machines, from the Horse-ferry Road Station, was applied by William Hudson, its gallant conductor, to a third-story window, under the most trying circumstances, and with perfect success. The danger and importance of such a service deserved a corresponding reward and acknowledgment, which, however, we are given to understand, was either forgotten or neglected. *Of domestic fire-escapes*, that invented by Capt. Manby is, perhaps, the best.

It is said that there is no instance on record of a person being burnt to death in a dwelling-house in *Edinburgh*, where the houses are usually high; yet in *London*, where fire-engines and fire-escapes are provided in greater numbers, deaths are *very frequent* from this cause. The reason of this difference is, that in the former city, the stairs are all made of *stone*, by which means a road of escape is secured.

The *clothes* of *females and children*, when on fire, may be most readily extinguished by rolling the sufferer in the carpet, hearth-rug, table-cover, a great-coat, cloak, or any other woollen article at hand. If this be expertly done, the flames may be rapidly put out. Should assistance not be at hand, the person whose clothes are on fire should throw herself on the ground, and roll the carpet round her, as before described; or if such a thing is not in the room, she should endeavour to extinguish the flames with her hands, and by rapidly rolling over and over on the floor. In this way the fire will be stifled, or at least the combustion will proceed so slowly that less personal injury will be experienced before assistance arrives. The advantage of assuming the horizontal position is manifest from the fact, that *nine* times out of *ten* it is the lower parts of the dresses of females that first catch fire. For the mode of rendering *muslin* and other inflammable articles of ladies' apparel *fire-proof*, see *Incombustible Fabrics, &c.*

The *extinction* of *fires on board ships* by means of *carbonic acid gas*, was some years since suggested to the Admiralty by Mr. J. R. Hancorn. He proposes that a simple and economical apparatus should be attached to every decked vessel, capable of supplying this gas, which is a well-known *non-supporter* of combustion, and will *extinguish fire at the very instant of coming in contact* with the burning matter. *Chalk* with *sulphuric acid* diluted with water, (vinegar, or any other acid will do,) yields $44\frac{0}{0}$ of the gas: hence, a *ton of chalk*, and a *fourth part of that quantity of sulphuric acid* will be found sufficient to extinguish any fire on board a ship. Mr. Hancorn also proposed this as a method of destroying vermin in ships, such as *rats* and *cockroaches*, for which purpose it is more easily applied and more effectual than that usually adopted. This plan was rejected by the Admiralty from a fear that the destructive action of the gas might extend to the crew as well as the fire. But "it surely is possible by mechanical means to expel the gas before again entering the ship's hold. At any rate, the grand point would be obtained of extinguishing the fire—though the crew might have only the *deck* to stand on." (Chemist, 1844.)

It is often *difficult* to *get horses* out of buildings on fire, but it is said that they will readily come out, if, after being blindfolded, the saddle and bridle, or the harness, &c., to which they are accustomed, are thrown over them as usual.

FIRE ANNIHILATOR (Phillips's). This is essentially a *gaseous fire engine*, and is likely, as soon as prejudice and rival interests will permit, to entirely supersede the common and ineffective water engines of the present day. Its effects are not merely surprising, but absolutely startling, and must be seen to be believed, and comprehended to be fully admired. "The fiercest flame, the most terrific conflagration, the most intense heat, are as easily subdued by the power of the *Annihilator*, as a farthing rushlight is capable of being put out by an extinguisher." "We have no hesitation in declaring that, no matter how open or exposed the situation may be, the *Annihilator* will certainly and safely extinguish the most extensive fire, if applied in reasonable time, and in quantity proportioned to the urgency and extent of the mischief going on." (Chem., 1, 1853.) The public exhibitions and trials of this instrument, fully justify these strong remarks in its favour, and we hope soon to see its general adoption in all public establishments and large buildings.

The *composition* with which the Fire Annihilator is *charged*, is a mixture of *dried ferrocyanide of potassium*, *sugar*, and *chlorate of potassa*. It is set in action by a blow on a glass vessel containing *oil of vitriol*, which, being fractured, permits the acid to flow over the "charge," when the *anti-combustion* gas is liberated, and rushes forth with great impetuosity.

Notwithstanding our confidence in the value of the above invention, we must record the fact of our having been, with others, forgetful of the presence of two of these instruments, on the occasion of the breaking out of a fire, some time since, in one of the most extensive works in the immediate neighbourhood of the City Road. No one on the premises recollected the fact of their presence in the Board room until after the fire had been subdued. This oversight, may, however, surely be pardoned, when we state, that we saw the works of the Fire Annihilator Co., at Battersea, burnt down some two years since, with loss of life, although, of course, there were plenty of Annihilators on the premises. None, however, were used on the occasion by those who had the charge of the building.

FIRE DAMP. See *Carburetted Hydrogen.*

FIRE EATING. The power of *resisting* the *action of fire* is imparted to the skin by frequently washing it with *diluted sulphuric acid*, until the part becomes sufficiently callous. It is said that the following mixture is very efficacious:—*dilute sulphuric acid*, 3 parts; *sal ammoniac*, 1 part; *juice of onions*, 2 parts; mix. The appearance of *smoke issuing from the mouth* is produced by skilfully retaining a quantity of *fine flour* or *calcined magnesia* in it, and puffing out a small quantity occasionally.

It is found that the unprepared finger may be dipped into a stream of *molten iron* or other metal, with absolute impunity. This depends on the same principle which occasions water to freeze in a white hot crucible, and will be explained further on.

FIRE ENGINE (Gaseous). See *Fire Annihilator.*

FIRE (Greek). This compound, so often mentioned in the history of the wars between the Christians and Saracens during the Middle Ages, is said to have had *naphtha* for its principal ingredient. (Dr. M'Culloch.) Other authorities assert that it consisted of a *mixture* of *asphaltum* or pitch, *nitre*, and *sulphur.*

FIRE-PROOFING. See *Incombustibility.*

FIRE (St. Anthony's). See *Erysipelas.*

FIRE-WORKS. See *Pyrotechny*, (and *below.*)

FIRES (Coloured). These may be termed, not inaptly, the chefs-d'œuvre of the pyrotechnist's art, since, on their excellence, the attractions of most other varieties of fire-works depend. The following forms, under judicious management, yield coloured fires of remarkable beauty:—

1. Blue Fire. *Prep.—a.* From *metallic antimony*, 1 part; *sulphur*, 2 parts; *nitre*, 5 parts.

b. From *realgar*, 2 parts; *charcoal*, 3 parts; *chlorate of potassa*, 5 parts; *sulphur*, 13 parts; *nitrate of baryta*, 77 parts.

c. (Mr. A. Bird.) *Charcoal* and *orpiment*, of each, 1 part; *black sulphuret of antimony*, 16 parts; *nitre*, 48 parts; *sulphur*, 64 parts.

d. (Fownes.) *Tersulphide of antimony*, 1 part; *sulphur*, 2 parts; *dry nitre*, 6 parts. This is the composition used for the *Bengal* or *blue signal light*, employed at sea.

e. (Prof. Marchand.) *Sulphur*, *sulphate of potassa*, and *ammonio-sulphate of copper*, of each, 15 parts; *nitre*, 27 parts; *chlorate of potassa*, 28 parts. For theatrical illuminations. This may be rendered either

lighter or darker coloured, by lessening or increasing the quantities of the sulphate of potassa and ammonio-sulphate of copper.

f. (*Light Blue*,—Marchand.) *Sulphur*, 16 parts; *calcined alum*, 23 parts; *chlorate of potassa*, 61 parts.

g. (*Dark Blue*,—Marchand.) *Calcined alum* and *carbonate of copper*, of each, 12 parts; *sulphur*, 16 parts; *chlorate of potassa*, 60 parts.

h. (Marsh.) *Sulphate of copper*, 7 parts; *sulphur*, 24 parts; *chlorate of potassa*, 69 parts.

i. (Ruggieri.) *Nitre*, 2 parts; *sulphur* and *zinc*, of each, 3 parts; *gunpowder*, 4 parts.

k. From *sulphur*, 1 part; *dried verdigris*, 2 parts; *chlorate of potassa*, 9 parts.

2. Crimson Fire. *Prep.*—*a.* (Marsh.) *Chlorate of potassa*, 4¼ parts; *charcoal* (alder *or* willow), 5¾ parts; *sulphur*, 22½ parts; *nitrate of strontia*, 67½ parts. For pots.

b. (Marsh.) *Charcoal*, 4¼ parts; *sulphuret of antimony*, 5½ parts; *chlorate of potassa*, 17¼ parts; *sulphur*, 18 parts; *nitrate of strontia*, 55 parts. For boxes and stars.

c. (Marchand.) *Sulphur*, 16 parts; *chalk* (dry), 23 parts; *chlorate of potassa*, 61 parts. Turns on the purple.

3. Green Fire. *Prep.*—*a.* From *charcoal* and *nitrate of baryta*, equal parts. *Used* in ghost scenes.

b. From *metallic arsenic*, 2 parts; *charcoal*, 3 parts; *chlorate of potassa*, 5 parts; *sulphur*, 13 parts; *nitrate of baryta*, 77 parts. Very beautiful, particularly when burnt before a reflector.

c. (Mr. A. Bird.) *Charcoal* and *black sulphuret of antimony*, of each, 2 parts; *chlorate of potassa*, 5 parts; *sulphur*, 6 parts; *nitrate of baryta*, 80 parts.

d. (Fownes.) *Lamp black*, 1 part; *chlorate of potassa*, 4 parts; *sulphur*, 6 parts; *dry nitrate of baryta*, 18 parts.

e. (Marchand.) *Boracic acid*, 10 parts; *sulphur*, 17 parts; *chlorate of potassa*, 73 parts. Very beautiful.

f. (Marchand.) *Chlorate of potassa*, 18 parts; *sulphur*, 22 parts; *nitrate of baryta*, 60 parts. For theatrical illuminations.

g. (*Light Green*,—Marchand.) *Sulphur*, 16 parts; *carbonate of baryta*, 24 parts; *chlorate of potassa*, 60 parts. Extremely delicate.

h. (Marsh.) *Charcoal* and *sulphuret of arsenic*, of each, 1¾ part; *sulphur*, 10½ parts; *chlorate of potassa*, 23¼ parts; *nitrate of baryta*, 62½ parts. For pots or stars.

4. Lilac Fire. *Prep.*—*a.* (Marsh.) *Black oxide of copper*, 6 parts; *dry chalk*, 20 parts; *sulphur*, 25 parts; *chlorate of potassa*, 49 parts. For pans.

b. (Marsh.) From *black oxide of copper*, 3 parts; *dried chalk*, 22 parts; *sulphur*, 25 parts; *chlorate of potassa*, 50 parts. For stars.

5. Orange Fire. See *Red Fire*.

6. Pink Fire. *Prep.* (Marchand). *Charcoal*, 1 part; *chalk* and *sulphur*, of each, 20 parts; *chlorate of potassa*, 27 parts; *nitre*, 32 parts. For theatrical illuminations. See *Rose-red Fire*.

7. Purple Fire. *Prep.* — *a.* From *lamp black*, *realgar*, and *nitre*, of each, 1 part; *sulphur*, 2 parts; *chlorate of potassa*, 5 parts; *fused nitrate of strontia*, 16 parts.

b. (Marsh.) *Sulphuret of antimony*, 2¾ parts; *black oxide of copper*, 10 parts; *sulphur* and *nitrate of potassa*, of each, 22¾ parts; *chlorate of potassa*, 42 parts. For pans.

c. (Marsh.) *Sulphate of copper*, 9¾ parts; *sulphur*, 13 parts; *chlorate of potassa*, 77¼ parts. For stars.

d. From *sulphur*, 1 part; *black oxide of copper*, 8 parts; *chlorate of potassa*, 16 parts.

8. Red Fire. *Prep.*—*a.* From *sulphur*, *sulphuret of antimony*, and *nitre*, of each, 1 part; *dried nitrate of strontia*, 5 parts.

b. (Mr. A. Bird.) *Charcoal*, 1 part; *black sulphuret of antimony*, 4 parts; *chlorate of potassa*, 5 parts; *sulphur*, 13 parts; *dried nitrate of strontia*, 40 parts.

c. (Fownes.) *Lamp black*, 2 parts; *chlorate of potassa*, 8 parts; *sulphur*, 9 parts; *dried nitrate of strontia*, 32 parts.

d. (Marchand.) *Sulphur*, 16 parts; *carbonate of strontia*, 23 parts; *chlorate of potassa*, 61 parts.

e. (Marchand.) *Chlorate of potassa*, 20 parts; *sulphur*, 24 parts; *nitrate of strontia*, 56 parts. For theatrical illuminations.

f. (Marsh.) *Coal dust*, 2 parts; *gunpowder*, 6 parts; *sulphur*, 20 parts; *dried nitrate of strontia*, 72 parts.

g. (Ruggieri.) *Sulphuret of antimony*, 4 parts; *chlorate of potassa*, 5 parts; *sulphur*, 13 parts; *fused nitrate of strontia*, 40 parts. A little *charcoal* or *lamp black* makes it burn quicker.

h. (*Orange Red*,—Marchand.) *Sulphur*, 14 parts; *chalk*, 34 parts; *chlorate of potassa*, 52 parts.

i. (*Purple Red*,—Marchand.) *Sulphur*, 16 parts; *chalk*, 23 parts; *chlorate of potassa*, 61 parts.

k. (*Rose-red,* — Marchand.) *Sulphur*, 16 parts; *dried chloride of calcium*, 23 parts; *chlorate of potassa*, 61 parts. See *Pink Fire.*

l. From *charcoal*, 2 parts; *chlorate of potassa*, 5 parts; *sulphur*, 13 parts; *dried nitrate of strontia*, 40 parts.

9. VIOLET FIRE. *Prep.—a.* From *charcoal*, 8 parts; *sulphur*, 10 parts; *metallic copper*, 15 parts; *chlorate of potassa*, 30 parts.

b. (*Dark Violet,*—Marchand.) *Alum* and *carbonate of potassa*, of each, 12 parts; *sulphur*, 16 parts; *chlorate of potassa*, 60 parts.

c. (*Pale Violet,*—Marchand.) *Sulphur*, 14 parts; *alum* and *carbonate of potassa*, 16 parts; *chlorate of potassa*, 54 parts.

10. WHITE FIRE. *Prep.—a.* From *nitre*, 60 parts; *sulphur*, 20 parts; *black antimony*, 10 parts; *meal powder*, 6 parts; *powdered camphor*, 4 parts. For either pans or stars.

b. (Mr. A. Bird.) *White arsenic*, 1 part; *charcoal*, 2 parts; *black antimony*, 16 parts; *nitre*, 48 parts; *sulphur*, 64 parts.

c. (Marchand.) *Charcoal*, 2 parts; *sulphur*, 22 parts; *nitre*, 76 parts. For theatrical illuminations.

d. (Marchand.) *Gunpowder*, 15 parts; *sulphur*, 21 parts; *nitre*, 64 parts. As the last.

e. (Marsh.) *Gunpowder*, 12½ parts; *zinc filings*, 18 parts; *sulphur*, 23 parts; *nitre*, 46½ parts. For pans.

f. (Marsh.) *Zinc dust* or *filings*, 15 parts; *sulphur*, 28 parts; *nitre*, 57 parts. For stars.

g. (Ruggieri.) *Sulphur*, 13¼ parts; *sulphuret of antimony*, 17¼ parts; *nitre*, 48 parts.

h. (Ruggieri.) From *realgar*, 2 parts; *sulphur*, 7 parts; *nitre*, 24 parts.

i. (Ruggieri.) *Charcoal*, 1 part; *sulphur*, 24 parts; *nitre*, 75 parts.

k. (Ruggieri.) *Iron* or *zinc borings*, 25 parts; *gunpowder*, 100 parts.

11. YELLOW FIRE. *Prep.—a.* From *sulphur*, 16 parts; dried *carbonate of soda*, 23 parts; *chlorate of potassa*, 61 parts.

b. (Marchand.) *Gunpowder*, 14 parts; *sulphur*, 16 parts; *dried soda*, 20 parts; *nitre*, 50 parts.

c. (Marchand.) *Charcoal*, 1½ part; *sulphur*, 17½ parts; *dried soda*, 20 parts; *nitre*, 61 parts.

d. (Marsh.) *Charcoal*, 6 parts; *sulphur*, 19½ parts; *nitrate of soda* (pure and dry), 74½ parts. For pans. Very beautiful.

Obs. The ingredients in the above compounds are to be separately reduced to powder, and sifted through lawn, after which they should be kept in well-corked wide-mouth bottles until the time of mixing them for use. The *chlorate of potassa*, more especially, must be *separately* treated, and *cautiously* handled, in order to prevent the possibility of explosion, from friction, whilst it is in contact with combustible matter. The requisite quantity of each of the ingredients being weighed out and placed on a clean sheet of white paper, the whole is to be thoroughly, but carefully mixed together, with a "light hand," by means of a bone or wooden knife. The compound is next "lightly" packed into *small cups* or *pans*, for ILLUMINATIONS; or into *small pill-boxes*, for STARS and TRAINS, a little *priming* and *quick-match* being lastly attached to each. To *ensure success* the several ingredients must be *dry* and *commercially pure*, and though reduced to the state of an uniform powder, care must be taken that they are not absolutely "dusty," or too finely pulverized. The *nitrate of strontia*, *alum*, *saltpetre*, *carbonate of soda*, &c., before being weighed, require to be gently heated in an iron pot or pan, until they fall to powder, and lose their hygrometric moisture, or water of crystallization. To ensure the perfect admixture of the ingredients, the whole, after they have been stirred together on paper, as before directed, may be passed through a *hair* or *perforated zinc* or *brass sieve.* Further, as "coloured fires" rapidly deteriorate by "keeping," and even sometimes inflame spontaneously, to *prevent disappointment* and *accidents*, they should not be prepared long before they will be required for use; and should be stored in some situation in which their spontaneous combustion would be productive of no after consequences.

Of the above formulæ, those bearing the name of the late lamented Mr. Marsh, of Woolwich, more especially deserve the attention of the pyrotechnist. These, by kind permission, we were enabled to give the reader in our last Edition. We have since been grieved to see these formulæ appropriated and republished by certain parties who live on the industry and brains of others, without the least acknowledgment by them of the source from which they had stolen them.

FISH. Syn. *Pisces*,—Lat. *Fishes* form the *fourth class* of vertebrate animals (*vertebrata*) in the Cuvierian arrangement of the animal kingdom, and in the variety of their genera and species, are second only to the *insecta;* whilst in prolificness and number,

they probably exceed all other animated beings that reach a size equal to that of even the smallest member of their prodigious race. Besides their value to man as food, they furnish him with *oil*, *whalebone*, *ambergris*, and various other articles of utility and luxury, and provide, either directly or indirectly, an inexhaustible supply of manure for the fertilization of his fields. As *food*, fish are undoubtedly wholesome and nutritious, although less so than the flesh of animals, or the grains of the cereals. Of all the various substances used as aliments by man, fish are, however, the most liable to run into a state of putrefaction, and should therefore be only eaten when perfectly fresh, or, if not recently taken, then only when they are in a state of good preservation by any of the ordinary methods employed for the purpose. Those that are the whitest and most flaky when cooked, as *cod*, *flounders*, *haddock*, *hake*, *soles*, *turbot*, *whiting*, *&c.*, are the most easily digested; and those abounding in oily matter, as *eels*, *herrings*, *mackerel*, *salmon*, *&c.*, are most nutritious, though the most likely to offend the stomach. *Salt-water fish* have been said to be more wholesome than *river fish*, but without sufficient reason. *Salted fish* are hard of digestion, unless when carefully cooked, and well masticated. The *frequent use of fish* as an *aliment* is said to promote the sexual feelings, but not the increase of population, unless a sufficiency of other food is taken at the same time. Skin diseases are also said to be more common among those who live continually on fish than among those who abstain from it; but this probably arises from their use being unaccompanied by a proper quantity of fresh vegetables or fruit, both of which are scarcer on the sea-coast than further inland. As one of the components of a mixed diet, the value of fish is indisputable. Acid sauces and pickles are the proper additions to fish, from their power of retarding the progress of putrefaction, and of correcting the relaxing tendency of large quantities of oil and butter.

Comp. Fish consist of about 80% of *water*, 14% of *albumen* and *fibrine*, and 6% of *gelatine;* making about 20% of *nutritive matter*. (Brande.)

Artif. Propag. Perhaps no animal multiplies so fast as fish. The *tench* produces 38,000 eggs; the *mackerel*, 546,000; the *cod-fish*, 1,357,000. The *herring* also produces vast numbers. If only 2000 of any one of these came to perfection, there would be, in the second year, 12,000,000; in the third, 2,000,000,000. To protect the spawn and the young animal until it becomes able to take care of itself, is, therefore, to ensure the production of millions of fishes; but how any of the less powerful and rapacious fish now happen to escape their enemies, natural and artificial, seems even more wonderful than their powers of production. The artificial propagation of fish consists chiefly in introducing the adult fish to the locality, at the proper season, and affording the protection alluded to. Sometimes the spawn is collected in tubs or cisterns, and artificially impregnated by gently pressing the male fish in the hand, so as to discharge the milt immediately over it. The vessels, after a short interval, are removed to the breeding pond.

Mr. Shaw appears to have been the first to show that the *parr* and *smelt* are only stages of the salmon; and to prove that, by the construction of side ponds, with a small stream running over them, with sufficient water to keep them covered (but not too deep), so as to favour the development of the spawn with as much rapidity as possible, the desired end can be accomplished. The small fish will thus be preserved from their larger enemies until they have an opportunity of shifting better for themselves; and vast supplies will be afforded to the sea, to return either to the same spot, or most certainly to the same river, in another year.

The grisle, or young salmon, of from 2½ to 3 *lb.* weight, has been sent to market, the spawn from which they have come having only been deposited in the preceding October or November—three months of this to be allowed for hatching—and often a longer period. A grisle weighing 6 *lb.* in the month of February, after spawning, has, on its return from the sea in September, weighed 13 *lb.;* and it is said that a salmon fry of April will in June weigh fully 4 *lb.*, and in August fully 6 *lb.*

The artificial propagation of fish has been taken up with vigour by the French government. A committee of savans, with a proper staff under them, have been appointed for the purpose. *Salmon*, *perch*, *tench*, and even *lobsters*, are now domesticated,—so far, at least, as being bred and reared out of the reach of their numerous enemies. Rivers and lakes, in which there were formerly no fish, or none of the more esteemed species or varieties, now literally teem with them.

Choice, &c. "The flesh of any fish is always in the highest perfection, or in season, as it is called, during the period of the ripening of the milt and roe. After

the fish has deposited the spawn, the flesh becomes soft, and loses a great deal of its peculiar flavour. This is owing to the disappearance of the oil or fat from the flesh, it having been expended in the function of reproduction." (Fleming's Phil. of Zoology.) Fish should be dressed as soon after being caught as possible, as much of their peculiar delicacy and flavour is lost by keeping, even for a few hours. *Turbot* and *salmon* are said by the fishmongers to be improved in flavour when 2 or 3 days old, but this is surely a mistake, as the former, when dressed immediately after being caught, possesses a fine creamy taste which it afterwards loses; whilst the latter, by the loss of a *single tide*, loses a portion of the fine white curd which is previously found between the flakes, and by longer keeping, this curd, with the larger flakes, disappear altogether. In the eyes of some epicures the richness is, however, increased by this change. *Mackerel* and some other fish suffer so much from keeping only a few hours that they become quite unwholesome. *Herrings* offer a remarkable example of the advantage of dressing fish as fresh as possible. When cooked soon after being caught, they possess considerable delicacy and flavour, but after being kept for only a few hours, the oil separates from the flesh, and they become soft, greasy, and strong-flavoured.

In the *choice* of *every kind of fish*, stiffness, brightness of the eyes, and redness of the gills may be regarded as invariable signs of freshness. A peculiar elasticity will also be perceived in fish recently caught; little or no permanent impression being made by the ordinary pressure of the fingers, from the flesh immediately rising when the pressure is withdrawn. Fresh fish also lie in a partly *curled position*, and never *quite straight*, as is the case when they have been kept for some time. *Thickness* and *fleshiness* are deemed marks of the good condition of all fish.

Pres. See *Food* and *Putrefaction*.

On the proper *cleaning of fish* preparatory to dressing it, depends much of its delicacy and flavour. Ordinary cooks seldom do this *well*, from not slitting the fish sufficiently open to permit the inside to be *thoroughly* washed, and seldom using sufficient water. The superior flavour of fish cleaned by the fishmongers arises from their performing the operation more completely, and from the large quantity of water they employ about them. The *flavour* of all fish is improved by adding a *little salt* or *vinegar* to the last water in which they are washed. The *sound*, *milt*, and *roe* should be carefully cleaned and preserved.

Fish is preferably "*dressed*" by simply *boiling*, *broiling*, or *frying* it; in fact, the finer kinds of fish are often injured by the excessive interference of the cook. When *boiled*, "all large fish, with the skin whole, must be placed on the fire in *cold water;* if crimped, or cut into slices or pieces, in *boiling water;* if whole, it must not be covered with more than two or three inches of water, or the skin will crack, and not only spoil the appearance of the fish, but will diminish the gelatine and gluten it contains, and instead of eating firm and full of flavour, it will be soft and woolly, especially if over-boiled." (Soyer.) As soon as a scum rises from boiling, it should be removed by the skimmer. The addition of a *little salt* or *vinegar* to the water improves the flavour of most fish, and renders the flesh firmer. The proportions should be "two tea-spoonfuls of salt to every quart of water." "If the fish be whole, as soon as it begins to boil, remove the cover on one side, and let it simmer gently until done." (Soyer.) A fish is known to be sufficiently dressed by the flesh in the thicker parts separating easily from the bone. "If a large fish, I generally try it by gently pushing a wooden skewer through the thickest part; if it goes in easily, it is done." (Soyer.) When this is the case it should be removed from the kettle, as by soaking in the water fish loses its firmness, and becomes soddened. *Sole*, *skate*, and *mackerel* are usually put into boiling water, whether whole or sliced. *Fish* for *broiling*, should be well washed in *strong vinegar*, wiped dry with a towel, and floured before placing them on the grid-iron; and the bars of the latter should be *hot*, and well buttered. (Rundell.) *Fish* for *frying* should be prepared as for broiling, and the *butter*, *oil*, or *lard*, should be allowed to boil for a minute or two, before putting them into the frying pan. The latter should be perfectly smooth and bright, and the butter or oil in *abundance*, to prevent the fish sticking to it and burning. As the fish are cooked solely by the heat of the melted fat, to fry them in the highest perfection, there should be enough of it to cover them. Butter or oil is the best for the purpose. To avoid loss, the contents of the frying pan, after the fish is removed, should be poured into a clean jelly-jar or basin, and reserved for another occasion. The fish being removed from the pan, the superfluous fat should

be drained from them, preparatory to "serving them." When fish is divided into *fillets* or *cutlets* before being cooked, it is usual to take out the bones, and to dress it with *force-meat*, &c.

In *serving fish* of the finer kinds, *no other additions* are required, than *melted butter* and the *ordinary fish sauces* and *pickles*. The dishes are commonly *garnished* with *raw parsley*, for the sake of appearance, but *boiled parsley*, chopped small, should accompany it. All kinds of fish should be *served* on a napkin.

Caution. It sometimes happens that a fish-bone accidentally swallowed remains in the œsophagus, and occasions serious inconvenience; in fact, instances have been known where so much irritation has arisen that death has followed. In such cases it is advisable, as soon as possible, to take of *tartar emetic*, 4 gr., dissolved in *warm water*, ½ pint; and immediately afterwards, the *whites of six eggs*. The coagulated mass will not remain in the stomach more than two or three minutes, and the remedy has been known to "remove no less than 24 pins at once."

FISH GLUE. See *Glue* and *Isinglass*.

FISH PONDS. Formerly these were almost exclusively employed for the breeding and fattening of fresh-water fish only, except on the sea-coast, where the water could be conveniently renewed by the influx and efflux of the tides. At present the breeding of fish is extended to numerous varieties. (See *above*.) The successful management of fish in ponds, consists, chiefly, in as close an imitation as possible of the ordinary conditions connected with them in the natural state. *Carp* is the favorite fish of English breeders.

FISH SKIN. Syn. *Shark Skin*. The skin of the *spotted dog-fish* or *rough hound* (chien de mer,—Fr.), stretched, and dried. *Used* for polishing wood and ivory. Several other varieties of fish-skin are employed in the arts. The dressed skin (*galuchat*) of the *rousette* (raia sephen) is transparent, and is very beautiful. Cemented on green paper, and rubbed down and polished, it is used as veneer for fancy boxes. The skins of several varieties of *squalus* are also used for both the above purposes. See *Shagreen*.

FISH-SKIN DISEASE. Syn. *Ichthyosis*,—Lat. An affection of the skin which derives its name from the surface of the cuticle suggesting the idea of the scaly skin of a serpent or fish. It is distinguished from lepra and psoriasis, by the absence of deciduous exfoliations, distinct or partial patches, and the constitutional disorder which more or less accompany those diseases. It is generally confined to patches in the arm-pits, and on the breast or chest, but sometimes attacks the face. The *treatment* consists in the frequent use of the warm or vapour bath and friction, the due regulation of the diet, and attention to such other matters as tend to improve the general health. "The easiest mode of removing the scales, is to pick off carefully with the nails, whilst the part is immersed in hot water." (Dr. Willan.) In some cases this disease assumes another form (*ichthyosis cornea*), when it is accompanied with the production of excrescences of an indurated character somewhat like spikes or even horns. When it assumes the appearance of the first of these, it is popularly called the *porcupine disease*, from the supposed resemblance to porcupine's quills. Under the latter form, several very extraordinary examples have occurred in females of advanced age. "Instances of *porcupine men* and *porcupine boys* are not uncommon at country fairs." (Eras. Wilson.) The only treatment of the last is excision, and the *entire* eradication of the cyst or morbid secreting surface.

FISTULA. This name is given by surgeons to a deep, narrow, sinuous ulcer, having only a small external opening, and usually showing a great indisposition to heal. A sinus of this kind by the side of the rectum is called "*fistula in ano*;" when it occurs in the perinæum, it is called "*fistula in perinæo*." The last is generally the result of neglected or mistreated stricture. An ulcerated opening in the lachrymal sac is termed *fistula lachrymalis*. Their treatment is purely surgical.

FIVE GEMS. In ancient medicine and among the superstitious at less remote periods, various medicinal and magical virtues were attributed to gems and precious stones. The Persians believed that wine drank out of an amethystine cup would not intoxicate, and the *five gems* (cornelian, emerald, garnet, hyacinth, and sapphire) were, by others, reputed cordial.

FIVE HERBS. See *Species*.

FIXATURE. Syn. *Bandoline*, *Clysphitique*, *Eau Collante*, *Fixateur*. This consists of any of the simple vegetable mucilages, combined with a little spirit, to preserve it, and with a little perfume, to render it more agreeable.

Prep. 1. From *carrageen*, *Irish*, or *pearl moss*, soaked in *cold water* for an hour or two, and after being drained, and pressed dry in a clean napkin, dissolved by boil-

ing in *soft water*, q. s. The decoction is strained through cambric, and when nearly cold is mixed with about ⅓rd or ¼th of its volume of *eau de Cologne* or other *scented spirit*, with the further addition of a few drops (5 or 6) of *oil of cloves*. Sometimes a little brandy is added to the mucilage, and when it is intended for *present* use, as is common with home manufacturers, the spirit is frequently omitted altogether. ¼ *oz.* of the *prepared moss* is *fully* enough for ¾ pint of strained decoction, if rightly managed.

2. From *quince seed* boiled in *water*, as the last. ¼ *oz.* yields *nearly* ¾ pint of strained decoction.

3. Pale *gum arabic* (picked), 1½ *oz.*; *rose water*, 2 *fl. oz.*; *pure water*, 3 fl. oz.; dissolve.

4. *Gum arabic*, 3¼ *oz.*; *water*, ½ pint; dissolve, and drop in *eau de Cologne*, gradually, until the cloudiness at first occasioned, ceases to be removed by agitation; the next day decant the clear portion. All of the above are very superior, and keep well.

5. (Redwood.) *Gum tragacanth*, 1½ dr.; *water*, 7 oz.; *proof spirit*, 3 oz.; *otto of roses*, 10 drops; macerate 24 hours, and strain.

6. *Malt*, 7 *oz.*; *hot water* (that will barely permit the finger to be held in it without pain), ½ pint; infuse in a covered jug or basin, *gently* press out the liquid, and as soon as cold, add of *proof spirit* (or brandy or Cologne water), 2½ *fl. oz.*, and strain.

Obs. Bandoline is used by ladies, and by hairdressers for stiffening the hair, and to make it curl firmly and remain in place. It is applied either by moistening the fingers and passing the hair through them, or by means of a small sponge. *Mild beer* has a similar effect, and we remember, in our juvenile days, having seen the female members of our family apply it to this purpose. See *Pommades*.

FIXED AIR. See *Carbonic Acid*.

FIXED OILS. See *Fat* & *Oils*.

FLAKE WHITE. See *White Pigments*.

FLAME. See *Light* (Artificial).

FLAMES (Coloured). These are employed for in-door illuminations, or what are often erroneously called *artificial fireworks*. They are generally produced by the combustion of *alcohol* or *rectified spirit* holding certain salts in solution. In this way a *green colour* is communicated by boracic acid or chloride of copper; a *red one* by the nitrates of iron, lime, or strontia; a *violet*, by potassa and its salts; and a *yellow*, by nitrate of soda. See *Fires* (Coloured) and *Pyrotechny*.

FLANNEL. It has been shown by the experiments of Count Rumford that the conducting power of the different materials employed for clothing varies considerably. A thermometer surrounded with *cotton wool*, and heated by immersion in boiling water, took 1046 seconds to lose 135° Fahr., when plunged into a bath of melting ice; but, under the same circumstances, when *sheep's wool* was employed, 1118 seconds elapsed before a like sinking of the thermometer took place, (Phil. Trans. 1792;) thus showing the greater conducting powder of the former, and consequently the superiority of the latter substance for the manufacture of warm clothing. But the chief advantage of wool as an article of under-clothing, depends less upon its actual power of conducting heat than its peculiar texture. *Flannel* acts as a gentle stimulus on the skin, and exercises the most beneficial action, by keeping the pores clean, and in a state most favorable to perspiration. This action is a species of friction similar in character, although inferior in degree, to that of the common *flesh-brush*, or *horse-hair glove*, so long advantageously employed as a skin stimulant. Flannel has also the advantage of absorbing the perspiration as soon as emitted, and allowing its watery portion to pass off into the atmosphere almost as soon as formed, but this is not the case with cotton and linen fabrics. The different effects of flannel and linen are particularly perceptible during brisk exercise. When the body is covered with the former, though perspiration be necessarily increased, the perspired matter freely passes off through the flannel, and the skin remains dry and warm. If the same exercise be taken in linen shirts, perspiration, as in the former case, is indeed also increased, but the perspired matter, instead of being dispersed into the atmosphere, remains upon the linen, and not only clogs the pores of the skin, but gives a disagreeable sensation. From this property of flannel, persons who wear it next the skin seldom catch cold from changes of temperature, even though perspiring profusely; but in similar cases, when linen or calico shirts are worn, chilliness immediately comes on, following by "*sniffling*, *sneezing*, and *cough*," and all the other symptoms of *severe catarrh*.

The *common objections* raised against the use of flannel are founded on vulgar prejudices, ignorance, obstinacy, or bravado, and are undeserving of the notice of sensible

people. In a fickle and moist climate like that of England, *every* person should wear a robe of flannel next the skin, or at all events a waistcoat of flannel reaching below the loins; and this should not be discarded as soon as the cold weather has passed, but its use should be continued all the year round; for in reality, flannel is, if possible, even more required in summer than in winter, because persons perspire more freely in hot than in cold weather, and are consequently more susceptible of cold, while at that period of the year their clothing is less capable of protecting them from the effects of sudden changes of temperature and draughts of cold air, moisture, &c. Females, children, persons of delicate constitutions, and all others who from their habits of body or life, perspire freely, or are much exposed, should wear flannel.

In *washing flannels*, it is recommended that they should be only put into *warm water*, by which method their colour will be preserved, and they will be prevented from shrinking. See *Cold, Dress, Hygiène, &c.*

FLASH. *Prep.* From *burnt-sugar colouring*, 1 gall.; *fluid extract of capsicum* or *essence of Cayenne*, ¾ pint, or enough to give a strong fiery taste. *Used* to colour spirits, and to give them a false strength. It is made by the brewers' druggists, and labelled "*isinglass and burnt sugar.*"

FLASKS. The late lamented and ingenious Mr. Fownes, suggested the employment of *Florence oil-flasks* as cheap substitutes for retorts, receivers, digesters, and some other vessels used for chemical purposes. His plan was to cut the neck smoothly round with a hot iron, and softening it in the flame of a good argand gas-lamp, to turn over the edge so as to form a lip, or border. The neck will then bear a tight-fitting cork without splitting.

FLATNESS. See *Malt Liquors* and *Wines.*

FLATULENCE. Syn. *Flatulency; Wind.* A morbid collection of gas in the stomach and bowels. Its most common cause is indigestion. When the natural fluids of the stomach are secreted in a healthy state, they exercise an antiseptic and digestive action on the food, by which it is speedily reduced to a magma that is little liable to spontaneous change whilst in the body; but when the reverse is the case, fermentation soon commences, and the stomach and associated viscera become distended with gas, and all the well-known symptoms of flatulency are developed in rapid succession. The quantity of gas thus accumulated in the primæ viæ, is often enormous. An ordinary apple during fermentation yields about 600 times its bulk of gas, and many vegetables yield much more. (Dr. Hales.) It is, therefore, not at all surprising that so much inconvenience should be felt when the food, instead of being digested and assimilated, runs into the state of active fermentation.

The *treatment* of *flatulency* consists mainly in the selection of proper articles of food. *Oleraceous vegetables, peas, beans, under-dressed potatoes,* and *indigestible fruits* should be especially avoided, as well as the use of large quantities of *weak* or *warm* liquids. The diet should consist principally of *animal food*, carefully, but not over-cooked, with a sufficient quantity of good *mealy potatoes* (mashed, *not* whole), and good *wheaten meal-bread*, moderately seasoned with *common salt* and *spices.* The most suitable beverages are *toast-and-water*, and a *little good brandy* largely diluted with water. The healthy tone of the stomach may be re-established by the proper use of tonics, bitters, and mild aperients.

To relieve the *fit of flatulency*, carminatives and aromatics, as *mustard, peppermint, ginger, cinnamon, lavender,* and the *peppers*, may be had recourse to. A glass of *peppermint cordial*, or of *brandy* strongly flavoured with *peppermint* or *ginger*, is a popular and efficient remedy. A few drops (15 *to* 30) of *ether*, with a little *tincture of capsicum* or *spirit of sal volatile*, seldom fail to give relief. See *Indigestion.*

FLAVOURING SUBSTANCES. See *Essences, Oils* (Volatile), *Spices, Wines, &c.*

FLAX. See *Linseed* and *Oils.*

FLEA. This troublesome little animal is the *pulex irritans*, of Linnæus, and belongs to the *suctoria*, or fourth order of the *insecta.* Its food is the living blood of animals. Its favorite haunts are our warm under-clothing, and its most productive breeding-places are in the "flue" which careless servants allow to accumulate underneath our beds. Cold, light, perfumes, and ventilation, are inimical to its propagation. We are assured by a living entomologist that an effectual method of speedily getting rid of these insects is to wage a war of extermination against the small blackish-coloured ones, a few of which only, are to be found in every colony.

The *pulex irritans*, diminutive, troublesome, bloodthirsty, and proscribed though it be, is a marvel of activity, vigilance, and muscular power. Like the larger animals

it may be domesticated, and educated, and then exhibits a degree of docility and sagacity which is truly surprising. *Learned fleas* were formerly exhibited in London. A friend of the writer, who, perhaps, has more time on his hands than wit, is particularly successful in educating fleas. We have seen them, arrayed in their minute golden belts and helmets, disport on his hand at order, or yoked in harness drag carriages many times their own size and weight. He informs us that the first step in his system is to anoint the medial line of the back with a little thick mucilage or varnish. In some cases he at once puts on a belt of gold or silver foil.

FLESH. Syn. *Caro*,—Lat. The muscular substance of animals; the softer, solid portions of the body, as distinguished from the bones and fluids. See *Fibrine, Food, Proteine, &c.*

FLESH-BRUSH. The use of this simple instrument is extremely advantageous in exciting the cutaneous circulation, and may be adopted to any extent short of actual irritation. Those which have the bristles set on a leather back are esteemed the best. The *flesh-glove* or *hair flesh-rubber*, is a useful modification of the common flesh-brush. Those manufactured by Messrs. Savory & Moore, in imitation of the *Indian kheesah* or *mitten*, are superior to all others. In the absence of both flesh-brush and glove, a rough towel wound round the hand is no bad substitute. See *Friction.*

FLIES. The common house-fly (*musca domestica*,) causes considerable annoyance to the person in hot weather, as well as damage to handsome furniture, especially to picture frames, gilding, and the like. The best way to exterminate them, is said to be to expose on a plate one or other of the following mixtures:—

1. *Black pepper*, 1 tea-spoonful; *brown sugar*, 2 do.; *cream*, 4 do.

2. Strong *decoction of quassia*, thickened with *moist sugar.*

Obs. Flies (*blow-fly; musca vomitoria;*) and other insects, may be kept from attacking meat by dusting it over with *black pepper, powdered ginger*, or any other *spice*, or by skewering a piece of paper to it on which a drop or two of *creasote* has been poured. The spices may be readily washed off with water before dressing the meat.

It is a fact not generally known, that *flies will not pass through* a *netting* made of fine silk, thread, or wire, even though the meshes may be an inch apart, unless there is a window or light behind it. This affords us a ready means of excluding these insects from all our apartments which have windows only on one side of them, without keeping the latter closed. It is merely necessary to have an ornamental netting stretched across the opening, when although flies may abound on the outside, none will venture into the rooms so protected. If, however, there is a window on the other side of the room, they will fly through the netting immediately.

FLIP. See *Egg Flip.*

FLOUNDERS are a wholesale species of fish, found in both our seas and rivers; those from the latter are preferred. See *Bills of Fare* and *Fish.*

FLOUR. Syn. *Farina*,—Lat. The finely ground and "dressed" meal of bread corn, and of the seeds of some of the leguminosa. That known specifically as *flour* in this country is obtained from the winter and spring varieties of *triticum vulgare* (triticum hybernum and t. æstivum,—*Linn.*)

Var., &c. Of these there are several, depending chiefly on the amount of bran which they contain, and the relative fineness of the sieves through which they are passed:—

Fine Wheat Flour, Pastry Flour; Farina, F. Tritici, F. Seminis Tritici. The finest flour, obtained from the meal produced in the first grinding of wheat between sharp stones, by means of a sieve of 64 wires to the inch. *Used* for pastry.

Middlings. The remainder of the flour of the first grinding obtained by means of a slightly coarser sieve. *Used* for making household bread, but is mostly reground for the next variety.

Seconds. The finest part of the flour, obtained by regrinding "middlings" between blunt stones. *Used* by the bakers for their finest wheaten bread.

Pollard. The coarse flour, from which the seconds has been sifted. *Used* for making sea biscuits and gingerbread, and to fatten poultry and hogs.

Country Household Flour. This is usually ground only once, and sifted to $\frac{4}{5}$ths of the weight of the wheat.

Ammunition Flour is ground and sifted to $\frac{1960}{2280}$, or nearly $\frac{5}{6}$ths the weight of the wheat.

According to Mr. Accum, thirty-two pecks of wheat in the London mills yield of *flour*, 38½ parts; *pollard*, 8 parts; and *bran* (furfur tritici), 12 parts; the bulk of the wheat being doubled by grinding.

According to Mr. Hard, miller, of Dartford, quoted by Dr. Pereira, the wheat having been ground in the usual way, is

allowed to remain in the state of meal for some time before "dressing," which removes the heat caused by the process, and enables the miller to obtain more flour, and the baker a better quality, than if "dressed" immediately it is ground.

"The *process* of *dressing* is by a wire cylinder containing a certain number of sheets of different texture or fineness, which cylinder contains eight hair brushes attached to a spindle passing through the centre of the cylinder, and laid out so as to gently touch the wire. This cylinder is fed by a 'shoe' with the meal; then the 'flour' and 'offal,' after passing through the wire in this way, are divided by wooden partitions fixed close to the outside of the cylinder." "The produce of the wheat-meal dressed through the wire machine consists of—1, *Flour*;—2, *White Stuff*, or *Boxings*, or *Sharps*; — 3, *Fine Pollard*; — 4, *Coarse Pollard*, or *Horse Pollard*;—5, *Bran*. The 2d product (*i. e.* the *white stuff*) is then submitted to another 'dressing' through a fine cloth machine, and produces—1, *Fine Middlings*, for biscuits;—2, *Toppings*, or *Specks*;—3, *Dustings*; — 4, *Best Pollard*, *Turkey Middlings*, or *Coarse Middlings*."

TABLE *of the Produce of One Quarter of Wheat* (= 504 *lb.*) By Mr. HARD.

Flour	392 *lb.*
Biscuit or fine middlings	10 ,,
Toppings or specks . .	8 ,,
Best pollard, Turkey do., or twenty-penny . .	15 ,,
Fine pollard	18 ,,
Bran and coarse pollard	50 ,,
Loss by evaporation and waste	11 ,,
	504 ,,

Comp. According to Vauquelin, *French wheat flour* contains about 10% of *water*, 11% of *gluten*, 71% of *starch*, 5% of *sugar*, and 3% of *gum*; and the *water of the dough* amounts to about 50%. The quantity of the *bran* in wheat, ranges under 2%.

Pur. This article of food is very frequently adulterated both by the miller and the baker, as has been before alluded to in the article on *Bread*. The principal physical characteristics of wheat flour of good quality, are the following:—it has a dull white colour, somewhat inclining to yellow; —it exhibits no trace of bran, even when pressed smooth with the hand, or with a polished surface; —its cohesiveness is so great, that on being squeezed in the hand, the lump is some time before it loses its shape;—it has a homogeneous appearance, and does not lose more than from 6% to 12% by being carefully dried in a stove. The smaller the loss in this way, the finer is its quality, other matters being equal, and the more economical in use. (See *below*.)

Tests. 1. *Liquor of ammonia* turns *pure* wheat-flour *yellow*; but if *any other corn* has been ground with it, *pale brown*; or if PEAS or BEANS have been ground with it, a still *darker brown*.

2. *Liquor of potassa*, containing about 12% of caustic alkali, dissolves *pure* wheat-flour almost completely; but when it is adulterated with the flour of the *leguminous seeds* (BEANS, PEAS, &c.), the cellulose of these substances remains undissolved, and its hexagonal tissue is readily identified under the microscope. Mineral substances (CHALK, PLASTER OF PARIS, BONE DUST, &c.) are also insoluble in this test, and appear as a heavy white sediment.

3. *Boiling water* poured on the sample, causes the evolution of the peculiar odour of PEA OR BEAN FLOUR when these substances are present. Bread made with such flour, evolves a like odour on being toasted.

4. Pure *hydrochloric acid* poured on POTATO FLOUR, or on wheat flour adulterated with it, develops a smell of rushes; it also dissolves STARCH, but changes the colour of *pure* wheat flour to a *deep violet*.

5. *Nitric acid* turns *wheat flour* of an *orange-yellow colour*, but forms a stiff and tenacious jelly with POTATO FECULA, the colour of which it does not alter.

6. A portion of the suspected sample submitted to dry distillation in a stoneware retort, and the distillate collected in a receiver containing a little water, the latter is found to remain *perfectly neutral* if the wheat flour is *pure*, but acquires a distinctly *alkaline reaction* when BEANS, PULSE, or PEA MEAL is present. (Rodrigues.)

7. Triturate 300 *gr. of the sample* with an equal weight of *clean siliceous sand*, and after 5 minutes form a homogeneous paste with *water*; afterwards further adding *more water*, until about 2 *fl. oz.* have been used. The filtered liquid treated with an equal quantity of a strong and pure *aqueous solution of iodine*, develops a *pink colour* which gradually disappears, when the specimen examined consists of *pure* wheat flour; but assumes a *deep purple colour*, which disappears much more slowly, if the flour is adulterated with even 10% of FECULA or POTATO FLOUR. This test succeeds not only with flour and meal, but also with *macaroni, vermicelli, &c.* (M. Chevallier.)

8. The milky liquid holding the *starch* in suspension (see *Anal.*, below,) is poured into a small conical glass, and left at rest for some time; the clear liquid is then decanted, and any remaining water carefully sucked up with a pipette, and the whole left for some time, in order that the deposit may harden. The upper gray layer is next removed with a teaspoon, and the harder and stiffer second layer left undisturbed until it becomes quite solid by drying. When in this state, it may be upset in the form of a cone, upon a lump of dry plaster. The FECULA or POTATO STARCH (if any is present) being heavier than that of wheat, forms the apex of the cone, and its quantity may be estimated in the following manner:—The operator cuts from the apex of the little cone above mentioned, a slice, which he triturates only for a short time in an *agate mortar* (one of *glass*, or *porcelain*, or *wedgewood-ware*, will not do), and he tests that with *aqueous solution of iodine.* If it turns *blue*, it is FECULA. Another slice is treated in the same manner, until the operator comes to the wheat starch, which, in the present instance, is not affected by the aqueous solution of iodine. This difference of behaviour of the two species of starch with iodine, is due to the friction of the pestle and mortar, which is sufficient to divide or tear the envelopes of the particles of the potato starch, which then become blue, when treated by solution of iodine. The particles of wheat starch, on the contrary, are not disaggregated by that treatment, and being therefore protected by their envelope, are not acted upon by solution of iodine, or, at most, assume only a brown tinge. (M. Robine.)

9. Wheat flour adulterated with PLASTER OF PARIS, GROUND BONES, CHALK, and POTATO FLOUR, has a higher specific gravity than a sample of the pure flour. This may be readily ascertained by any person, by filling a small vessel with some pure flour, and then with the given sample. "A vessel which will contain 1 *lb.* of wheat flour will contain 1½ *lb.* of fecula" (*potato flour*), and hence "the proportion of this adulteration may be easily estimated." (Ure.)

10. If to a sample of wheat flour, is added a *solution of potassa*, containing about 1¾ % of the pure alkali, the granules of POTATO FARINA, or of BEAN MEAL, or PEA MEAL present (if any) will acquire 4 or 5 times their original volume, whilst those of the *pure* wheat starch will be scarcely affected by it. This change is very perceptible under a microscope of small power. 2 parts of *liquor of potassa* (Ph. L.) and 5 parts of *distilled water*, form a mixture that answers for the above purpose.

11. By means of the *microscope* the admixture of the CHEAPER FECULAS and MEALS with *wheat flour* is readily detected by the characteristic appearance of the starch-grains; and when the adulteration exceeds 9% or 10%, its extent may be readily estimated with considerable accuracy. As the range of adulteration is generally from 12% to 27%, this method is applicable in the greater number of cases.

12. See *Bread* (Adult. & Exam.), pp. 160-1.

Anal. The value of wheat flour as an aliment depends upon the quantity of *gluten*, *sugar*, *starch*, and *phosphate of lime*, which it contains; and its superiority over the flour of the grains of the other cereals, is referred to its containing a larger proportion of the first and last of these substances than they do. The *qualitative analysis of flour* is very simple, and may be easily made by persons unacquainted with chemistry, by attending to the instructions below:—

a. Make 1000 gr. of *the sample* into a dough with a *little water*, let it rest an hour, and then *gently* knead it in *successive waters*, until the starchy particles are perfectly removed. Collect the portion (GLUTEN) left in the hand, drain off the water, place it on a piece of filtering or blotting paper, several times doubled, and set it aside.

b. Mix the several waters employed in the preceding process, and set them aside in a tall vessel, to deposit the suspended portion (STARCH). After a sufficient time, pour off the clear liquid, and throw the *whole* of the sediment on a *weighed* paper filter, placed in a funnel, observing to remove the portion adhering to the bottom of the vessel by means of a little clean water, that none may be lost.

c. Evaporate the decanted liquid, as well as what runs from the filter, until it becomes *curdy*, then filter it through a piece of *weighed blotting paper*, and preserve the sediment (ALBUMEN); next evaporate the residuum to the consistence of a syrup, agitate it with 10 times its weight of *alcohol*, and filter, observing to wash the paper filter clean with a *little alcohol*, after the solution has passed through it. The substance on the paper is PHOSPHATE OF LIME and GUM, and must be set aside. By subsequent digestion in *water*, filtration, and evaporation, the two may be obtained separately.

d. Evaporate or distil off the spirit form the solution and washings as above; the residuum is SUGAR.

e. Dry the substances educed as above, by a *gentle* heat, and weigh them. The weight of the *albumen* may be taken with that of the *gluten*, as it possesses about the same nutritive value, and also because it has been asserted by some persons that the former substance is in reality gluten, and not albumen. By dividing the given weights by 10, the per centage value of the sample is obtained. The pieces of filtering paper employed should be carefully dried and weighed before using them, and the same degree of heat should be employed for this purpose as that to which they will be afterwards exposed in the drying of the substances resulting from the operations.

Obs. The above method of ascertaining the actual value of any sample of flour as an article of food, though not strictly accurate, approximates sufficiently to the truth for all practical purposes, and is well adapted to the wants of the baker and large purchaser. In many cases it will only be necessary to perform the first part of the process, (*a*,) which will give the *per centage* of the most important constituent of the flour; the rest being of minor consequence.

In addition to what has been already stated in the article on *Bread*, it may be useful to mention, that a pound of the *best flour*, from thoroughly dried wheat, will take 10 *fl. oz.* of *water* to form it into *ordinary dough*, or 9 *fl. oz.* to form it into *bread dough*. Under the *old parliamentary acts*, a sack of flour (280 *lb.*) was presumed to produce 80 loaves (*quartern* or *quarter-peck*), the weight of which, within 48 hours after being baked, was to be 4 *lb.* 5½ *oz.* each. At the *present time* fully 92 loaves, weighing 4 *lb.* each, are produced by the London bakers from one *sack of flour*, when honest weight is given; but as the latter is rarely the case, and the bread is frequently "slack" or "under-baked," and thus contains more water than good bread ought to do, a much larger product is commonly obtained. The *dough loses* about ⅛th of its weight in *baking*, if in batches; but fully ⅙th, if baked in small loaves and placed in the oven separately. The *best bread* contains about $\frac{11}{16}$ths of its weight of *added water;* and *common bread*, often *much more* than ¼th. The proportion of water in the *London bread* has greatly increased during the last few years, owing to the introduction of the fraudulent plan of making the dough with *rice jelly* or *moss jelly*. (See p. 162.) This is the reason why the bread of some bakers suffers such a loss of weight in a few hours after being taken from the oven. A 4 *lb.* loaf of bread purchased some short time since from a baker living within 100 miles of the Lower Marsh, Lambeth, after remaining on the sideboard of a sitting-room for 24 hours, was found to have lost no less than 6½ *oz.* by evaporation, and in two days longer, its interior cells were covered with green mould, and the whole was unfit for food. The bakers, aware of these facts, are particularly careful not to bake more bread than they can dispose of whilst "new," and are in the habit of refusing to weigh their bread before selling it, when it is more than 10 or 12 hours old, although they are liable to be "fined" for such a refusal.

FLOUR (Baked). Syn. *Farina tosta, F. tritici tosta. Prep.* From *wheat flour*, carefully baked in a "slack" oven, until it acquires a pale-buff hue. Astringent; used to make food for infants troubled with diarrhœa. See *Farinaceous Food.*

FLOUR (Barley,—Prepared). Syn. *Farina Hordei Preparata*,—Lat. *Prep.* (Ph. Bor.) From *barley flour*, compressed into a tin cylinder until the vessel is 2-3rds full, which is then suspended at the upper part of a still 2-3rds filled with *water*, and after the "head" is fitted on, the water is kept boiling for 30 hours (2 days of 15 hours each). Lastly, the upper layer being removed, the rest is reduced to powder, and kept in a dry place.

FLOUR (Boiled). Syn. *Triticina; Farina Preparata*,—Lat. *Prep.* From *fine flour*, tied up in a linen cloth as tight as possible, and after it has been frequently dipped into *cold water*, the outside of the cloth is dredged over with flour, until a crust is formed round it, to prevent the water soaking into it, whilst boiling; it is then boiled for a long time, and when cold, it is divided into small oblong pieces. For *use*, it is reduced to powder, either by grinding or grating it, and is then prepared like arrow-root. It forms a good diet for children, in diarrhœa, &c.; and as it may be easily prepared at home, it has the advantage of being free from adulteration.

FLOUR (Jones' Patent). *Prep.* From *kiln-dried flour*, 1 *cwt.*; *tartaric acid*, 10½ *oz.;* mix thoroughly; after 2 or 3 days, add of *bicarbonate of soda*, 12 *oz.; lump sugar*, ½ *lb.; common salt*, 1½ *lb.;* mix, and pass the compound through the "dressing machine." It is necessary that the whole of the ingredients should be *perfectly dry*, and separately reduced to fine powder before adding them to the flour. By simply mixing

it with *cold water*, and at once baking it, it produces light porous bread.

Obs. We have already had occasion, more than once, to pay a passing tribute to the excellence and usefulness of *Jones' Patent Flour.* (See pp. 164, 185, &c.) It is, indeed, invaluable in every household, as furnishing the means of producing, with great economy, and extemporaneously, not merely *cakes*, *puddings*, *pastry*, and *fancy-bread*, but the staff of life itself, *household bread*, of a purity, flavour, and lightness, seldom, if ever, met with in that purchased of the bakers. We have long employed this flour exclusively in our kitchen, and therefore speak from experience, and not from hearsay, of its value. The economy of its use is evident, as it can only be made of the *finest kiln-dried* flour. If made with ordinary flour it will not keep. This accounts for it taking *more water* to make it into dough than the best flour purchased at the bakers; whilst it acts both as a safeguard against adulteration, and a guarantee of superior quality to the purchaser. Unfortunately, prejudice and ignorance, and still more, apathetic indifference to hygiene on the part of the public, together with the opposition of rival interests, has prevented the "patent flour" coming into such general use, as its merits deserve. Englishmen appear to prefer "*alumed bread*" and "*narcotized porter*," with headaches, dyspepsia, and antibilious pills, to *pure beer* and *pure bread*, with a clear head and a vigorous digestion.

The Editor of the Lancet has justly declared "*Jones' Patent Flour*" to be "the greatest invention of the age." To this we may add, that its exclusive use in this country would save to the nation no less a quantity than 2 millions of quarters of corn per year, which are now dissipated in carbonic acid gas, or lost through defective manipulation by the common process of making bread.

FLOUR (Sewell's Patent).—*a.* (No. 1.) *Flour*, 1 sack (280 *lb.*); *hydrochloric acid* (sp. gr. 1·14), 45 *oz.*; mix, by adding the acid in a "spray."—*b.* (No. 2.) To the last, add (expertly) *bicarbonate of soda*, 39 *oz.*; mix thoroughly, and pass the whole through a sieve or "dressing machine."

Obs. This flour is used as the last, to which, however, it is inferior in quality. No. 1, will keep 5 weeks. No. 2, will keep a month. (*Jones' flour* will keep good in a *dry place* for years.) If No. 1 is alone employed for the dough, to each pound of the flour, 63 gr. of *bicarbonate of soda*, with *salt*, q. s., must be added. The patentee claims for his invention the merit of the *soda* and *acid* being converted into *culinary salt* in the process of mixing up the flour and baking the dough. See *Bread* (Unfermented).

FLOWERS. Syn. *Flores*,—Lat. These beautiful and fragrant ornaments of our gardens, and our dwellings, are too highly esteemed by all classes of the community to require anything in favour of their cultivation to be said here. Our remarks will, therefore, chiefly refer to their collection, improvement, and preservation.

"*Full*" or "*Double flowers*," or those in which the internal organs become petals, are so much more beautiful than the "*single flowers*" of the corresponding species and varieties, that their production, with tolerable ease and certainty, has long been a desideratum with both the professional and amateur florist. Various plans have been proposed having this object in view, among which are the following:—1. The use of the *best seed only*, but not before it is *at least* 3 or 4 *years old.*—2. The selection of the *outer row of seed* only, and its careful *preservation intact* for *at least* 2 *seasons before sowing it.* We are assured that this method is particularly successful with dahlias.—3. The *removal* of the plants to a *shady situation* as soon as the flower-buds begin to develope themselves, and stinting them with water and nourishment for a few weeks. In this method a few only of the buds are permitted to mature; the rest being snipped off with a pair of scissors as early as possible.—4. The use of *small pots* and a *scanty supply of water* until the flowers are partly developed, when *water* is supplied in abundance, with or without the addition of a little *liquid* manure.

To *hasten* the "*blooming*" *of flowers* it is a common practice with the gardeners to grow them in as *small pots* as is *consistent with their healthy existence*, and carefully to avoid transplanting them to larger pots, for several weeks before their usual time of blossoming. A plant on the point of flowering, if transferred to a larger pot and a richer soil, immediately commences making roots and leaves, whilst the embryo flowers either wholly decay, or their development is checked until the usual season of their production has passed over.

The *following liquid* has been used with great advantage to promote the *vigorous growth* and the *early flowering* of plants:—*Sulphate* or *nitrate of ammonia*, 4 *oz.*; *nitrate of potassa*, 2 *oz.*; *sugar*, 1 *oz.*; *hot water*, 1 pint; dissolve and keep it in a

well-corked bottle. *For use*, put 8 or 10 drops of this liquid into the water of a hyacinth glass or jar, for *bulbous-rooted plants*, changing the water every 10 or 12 days. For *flowering plants* in *pots*, a few drops must be added to the water employed for them. The preference should be given to *rain water* for this purpose. A similar fluid is sold by Mr. Potter, under the name of "*liquid guano*."

Flowers may be *preserved* in a *fresh state* for a considerable time, by keeping them in a *moist atmosphere*. When growing on the parent stem, the large amount of evaporation from the surface of their leaves, is compensated for by an equivalent proportion of moisture supplied by the roots; but when they are plucked, the evaporation from the surface continues, while the supply of moisture is cut off. To supply, in part, this loss of moisture by evaporation, has arisen the almost universal practice of placing flowers in water; but their mutilated stems possess a far inferior power of sucking up fluids to that of the roots, and thus their decay is only deferred for a time. To preserve them more effectually, or at least to render their existence less ephemeral, we may surround them with a moist atmosphere, by which the loss of water from the surface of their leaves will be reduced to the smallest possible amount. "It is now eighteen years ago since we first saw, in the drawing-room of a gentleman, in the hot dry weather of the dog-days, flowers preserved day after day in all their freshness by the following simple contrivance:—A *flat dish of porcelain* had *water* poured into it. In the water a *vase of flowers* was set; over the whole a *bell-glass* was placed, with its rim in the water. This was a '*Ward's case*' in principle, although different in its construction. The air that surrounded the flowers being confined beneath the bell-glass, was kept constantly moist with the water that rose into it in the form of vapour. As fast as the water was condensed it ran down the sides of the bell-glass back into the dish; and if means had been taken to inclose the water on the outside of the bell-glass, so as to prevent its evaporating into the air of the sitting-room, the atmosphere around the flowers would have remained continually damp. We recommend those who love to see plenty of fresh flowers in their sitting-rooms in dry weather to adopt this method. The experiment can be tried by inserting a *tumbler* over a *rose-bud* in a *saucer of water*." (Gardener's Chron.)

Another method by which some flowers may be preserved for many months, is to carefully dip them, as soon as gathered, in perfectly limpid *gum water*, and after allowing them to drain for 2 or 3 minutes, to set them upright, or arrange them in the usual manner in an empty vase. The gum gradually forms a transparent coating on the surface of the petals and stems, and preserves their figure and colour long after they have become dry and crisp.

Faded flowers may be generally more or less *restored* by immersing them half-way up their stems in *very hot water*, and allowing them to remain in it until it cools, or they have recovered. The "*coddled*" portion of the stems must then be cut off, and the flowers placed in *clean cold water*. In this way a great number of faded flowers may be restored, but there are some of the more fugacious kinds, on which it proves useless.

Flowers may be *produced in winter* by taking up the plants, trees, or shrubs in the spring, at the time when they are about to bud, with some of their own soil carefully preserved around the roots, and placing them upright in a cellar till Michaelmas; when, with the addition of *fresh earth*, they are to be put into proper tubs or vessels, and placed in a stove or hot-house, when they must be treated in the usual manner. By this method, in the month of February, *fruits* or *roses* will appear. *Flowers* sown in pots about *Michaelmas*, may thus be made to bloom at *Christmas*.

The apparently *instantaneous flowering of plants*, lately exhibited by M. Herbert to an astonished audience, is, we believe, effected by the heat generated by *fragments of quicklime* concealed in the mould close to, but not in immediate contact with, the roots. The plants selected by M. Herbert, —a *group of geraniums* and a *rose tree*— were planted in two rather deep boxes of garden mould, and were covered with glass shades. The operator commenced by pouring over the roots, from a small watering-pot, a liquid which, uniting to the ingredients already in the earth, caused a great heat, as was shown by an intense steam or vapour, which was evolved within the shades, and allowed, to some extent, to escape through a small hole in the top, which at first was kept closed. The effect upon the geraniums was certainly almost instantaneous: the buds beginning to burst in about five or six minutes, and the plants being in full bloom within ten minutes, when the blossoms were gathered by M. Herbert, and distributed amongst the ladies

present. With the rose tree the exhibitor was less fortunate. The invention may prove useful where ladies require to decorate their drawing-rooms or boudoirs with the beauties of the floral world somewhat earlier in the season than they can otherwise be obtained. It must not, however, be forgotten that the plants are, as it were, parboiled during the process, and die after a few days.

The *collection* and *preservation of flowers* for *medicinal purposes* and *distillation*, will be found noticed under *Vegetable Substances.*

FLOWERS (Artificial). The beauty and value of these pleasing articles of personal decoration mainly depend upon the taste and ingenuity of the maker. The delicate fingers of woman and her ready powers of imitation and invention, combined with her natural affection for the chaste and beautiful, have enabled her the more especially to excel in this manufacture. The productions of the female artificial florists of the French capital, are justly admired everywhere.

The French employ *velvet*, *kid*, and *fine cambric* for the *petals*, and *taffeta* for the *leaves*. Very recently *thin plates* of *bleached whalebone* have been used with great success for some portions of artificial flowers.

As *colours and stains*, the following are employed in Paris:—

Blue. Indigo dissolved in oil of vitriol, and the acid partly neutralized with salt of tartar or whiting.

Green. A solution of distilled verdigris.

Lilac. Liquid archil.

Red. Carmine dissolved in a solution of salt of tartar, or in spirits of hartshorn.

Violet. Liquid archil, mixed with a little salt of tartar.

Yellow. Tincture of turmeric.

The above colours are usually applied to the petals with the finger.

FLOWERS. Syn. *Flores*,—Lat. Among *Chemists* this term is applied to various pulverulent or flower-like substances obtained by sublimation, as *flowers of antimony*, *benzoin*, *zinc*, *sulphur*, &c. The term has been discarded from modern chemical nomenclature, but is still commonly employed in familiar language and trade.

FLOWERS (Candied). See *Candies.*

FLUATES. See *Fluorides.*

FLUID CAMPHOR (Sir J. Murray's). *Prep.* From *camphor* (in powder), 1 dr.; *freshly precipitated carbonate of magnesia*, 2 dr.; *cold distilled water*, 1 pint; the solution is effected by forcing in *carbonic acid gas* under pressure. Each *fl. oz.* contains 3 gr. of *camphor*, and 6 gr. of *carbonate of magnesia.* See *Essence of Camphor.*

FLUID EXTRACTS. See *Essences*, *Extracts*, and *Liquors.*

FLUID MAGNESIA. Syn. *Liquor Magnesiæ Carbonatis*, *L. M. Bicarbonatis*, &c. The preparations sold under this name are mere solutions of *freshly precipitated carbonate of magnesia* in *water*, by means of *carbonic acid gas*, under powerful pressure, and long agitation. Those best known are *Sir J. Murray's* and *Mr. Dinneford's*, each *fl. oz.* of which are *said* to contain about 17½ gr. of the carbonate, but their actual richness in the latter seldom exceeds 10 or 12 gr., and by the time they reach the consumer, is often as low as 5 or 6 gr. *Recently precipitated carbonate of magnesia* placed in a *bottle* or *other suitable vessel*, which is then filled by means of a *soda-water apparatus* with *water fully charged with carbonic acid gas*, readily dissolves on slight and cautious agitation, and the *aerated water* becomes *saturated* with magnesia. A scruple of carbonate of magnesia put into a soda-water bottle, and thus treated, is all taken up in from 20 minutes to half an hour, and the beverage continues beautifully clear.

FLUIDS (Antiseptic). See *Putrefaction.*

FLUIDS (Disinfecting). See *Disinfecting Compounds.*

FLUIDS (Etching). See *Etching.*

FLUMMERY. A species of thick hasty-pudding, made with oatmeal or rice, flavoured with milk, cream, almonds, orange flowers, lemons, &c., according to fancy.

Prep. 1. (*Dutch Flummery.*) From *blanc-mange* and *eggs*, flavoured with *lemon peel* and *sweetened* with *sugar.*

2. (*French Flummery.*) From equal parts of *blanc-mange* and *cream*, *sweetened*, and *flavoured.* The above are poured into forms, and served *cold*, to eat with wine, spirit, cider, &c.

3. (A. T. Thomson.) Take *oatmeal* or *groats*, 1 quart; rub it for a considerable time with *hot water*, 2 quarts; and let the mixture stand until it becomes sour; then add *another quart of hot water*, and strain through a hair sieve. Let stand till a white sediment is deposited, decant the fluid portion, and wash the sediment with cold water. This is now to be boiled with *fresh water*, until it forms a mucilage, stirring the whole time. A light and nutritious food, during early convalescence.

FLUOBORATES. Syn. *Fluoborides*

Borofluorides, Hydrofluoborates. Compounds of fluoboric acid with the salifiable bases. (See *below.*)

FLUOBORIC ACID. Syn. *Terfluoride of Boron.* A peculiar gaseous compound of fluorine and boron, discovered by Gay-Lussac and Thénard.

Prep. A mixture of *vitrified boracic acid*, 1 part; *fluor spar*, 2 parts; and *oil of vitriol*, 12 parts; is exposed to heat in a leaden retort. The gas evolved is collected in glass jars standing over mercury.

Prop., &c. Colourless; transparent; very heavy; fumes in the air; rapidly absorbed by water, forming *liquid fluoboric acid* (Gay-Lussac, Thénard, Dr. Davy), or *borohydrofluoric acid* (Berzelius). It does not attack glass, but rapidly destroys organic substances. Water absorbs fully 700 times its volume of this gas. (Davy.) See *Borofluorides.*

FLUORIC ACID. See *Hydrofluoric Acid.*

FLUORIDES. See *Fluorine.*

FLUORINE. Syn. *Fluorinium*,—Lat. The electro-negative element of *hydrofluoric acid* and the *fluorides.* This substance, though long known in combination, has only been lately obtained in a separate state. The honour of having first obtained it in an isolated form is due to Baudrimont, who procured it by passing *fluoride of boron* over *minium* heated to redness, and receiving the gas in a dry vessel. As thus obtained, it is not *absolutely* pure, being contaminated with small quantities of hydrofluoric and silico-fluoric acids. It has a yellowish colour, and an odour between that of chlorine and burnt sugar. In this state it does not act on glass, but combines directly with gold. With *hydrogen* it forms *hydrofluoric acid*, and with the metals *fluorides.* The well-known mineral, *fluor-spar*, is a fluoride of calcium.

FLUOSILICIC ACID. See *Hydrofluosilicic Acid.*

FLUOTITANIC ACID. See *Titanium.*

FLUX. Syn. *Fluxus, Fluor*,—Lat. A term formerly applied to several diseases attended with a copious discharge, as diarrhœa (*flux*), dysentery (*bloody flux*), English cholera (*bilious flux*), fluor albus (*white flux*), &c. These terms are still current among the vulgar.

FLUX. Syn. (See *above*). A term applied to various substances of easy fusibility, which are added to others which are more refractory, to promote their fusion. The principal fluxes are the following:—

Prep. 1. (Black Flux.) *Nitre*, 1 part; *crude tartar* or *cream of tartar*, 2 parts; mix, and deflagrate, by small quantities at a time, in a crucible, heated to dull redness. The *product* consists of carbonate of potassa, mixed with charcoal in a finely-divided state. *Used* for smelting metallic ores. It exercises a reducing action, as well as promotes the fusion. It must be kept in a dry corked-bottle.

2. (Christison's Flux.) *Carbonate of soda* (cryst), 8 parts; *charcoal* (in fine powder), 1 part; heat the mixture gradually to redness. For reducing arsenic.

3. (Cornish Reducing Flux.) *Crude tartar*, 10 parts; *nitre*, 4 parts; *borax*, 3 parts; triturate together.

4. (Cornish Refining Flux; White Flux.) *Crude tartar* and *nitre*, equal parts; deflagrated together. See *Black Flux.*

5. (Crude Flux.) Same as *black flux*, omitting the deflagration. Reducing.

6. (Fresenius' Flux.) *Carbonate of potassa* (dry), 3 parts; *cyanide of potassium*, 1 part. For the arsenical compounds.

7. (Liebig's Flux.) *Carbonate of soda* (dry), and *cyanide of potassium*, equal parts. As the last. See *Arsenious Acid*, (p. 91.)

8. (Morveau's Reducing Flux.) *Powdered glass* (free from lead), 8 parts; *calcined borax* and *charcoal*, of each, 1 part; all in fine powder, and triturated well together. *Used* as *black flux.*

9. (Lewis Thompson.) See *Copper* (Estim.), p. 288.

10. (White Flux.) See *above.*

11. (Fluxes for Enamels.) See *Enamels.*

12. (Various.) *Borax, tartar, nitre, sal ammoniac, common salt, limestone, glass, fluor spar*, and several other substances, are used as *fluxes* in *metallurgy.*

Obs. On the *large scale* crude tartar is employed in the preparation of fluxes; on the *small scale*, commercial cream of tartar or bitartrate of potassa.

FLY. See *Flies* and *Cantharides.*

FLY PAPERS. See *Birdlime* (Factitious).

FLY POISON. *Prep.* 1. A strong *solution* of *white arsenic* (say 1 *dr.* to the *pint*), sweetened with *moist sugar, treacle*, or *honey.* Sold under the name of "*Fly Water.*"

2. *Treacle, honey*, or *moist sugar*, mixed with about $\frac{1}{12}$th their weight of *King's yellow* or *orpiment.* Both the above are *dangerous preparations*, and should never be employed where there are children.

3. (Redwood.) *Quassia chips* (small), $\frac{1}{4}$ *oz.*; *water*, 1 pint; boil 10 minutes, strain, and add of *treacle*, 4 *oz.* "Flies will drink this with avidity, and are soon destroyed by it." See *Flies, &c.*

FLY POWDER. The dark gray-coloured

powder (*oxide*) obtained by the free exposure of *metallic arsenic* to the *air*. Mixed with *sweets* it is used to kill flies.

FLY WATER. See *above*.

FOILS. These are thin leaves of polished metal, placed under precious stones and pastes, to heighten their brilliancy, or to vary the effect. Foils were formerly made of *copper*, *tinned copper*, *tin*, and *silvered copper*, but the last is the one wholly used for superior work at the present day.

Foils are of two descriptions,—*white*, for diamonds and mock diamonds, and —*coloured*, for the coloured gems. The *latter* are prepared by varnishing or lacquering the *former*. By their judicious use the colour of a stone may be often modified and improved. Thus, by placing a *yellow foil* under a *green stone* that turns too much on the blue, or a *red one* under a stone turning too much on the *crimson*, the hues will be brightened and enriched in proportion.

Prep. 1. *Crystal*, *Diamond*, or *White Foil.* —*a*. This is made by coating a *plate of copper* with a *layer of silver*, and then rolling it into sheets in the flatting mill. The foil is then highly polished, or covered with crystal varnish.

b. The inside of the socket in which the stone or paste is to be set, is covered with *tin foil*, by means of a little stiff gum or size; when dry, the surface is polished and the socket heated, and whilst it is warm, filled with *quicksilver;* after repose for two or three minutes, the fluid metal is poured out, and the stone gently fitted in its place; lastly, the work is well-fitted round the stone, to prevent the alloy being shaken out.

c. The bottom of the stone is coated with a *film* of *real silver*, by *precipitating* it from a solution of the *nitrate* in *spirit of ammonia*, by means of the *oils of cassia* and *cloves*. (See *Silvering*.) This method vastly increases the brilliancy both of real and factitious gems, and the work is very permanent.

2. *Coloured Foils*. The following formulæ produce beautiful coloured effects, when judiciously employed:—

a. (Amethyst.) *Lake* and *prussian blue*, finely ground in *pale drying oil*.

b. (Blue.) *Prussian blue* (preferably *Turnbull's*), ground with *pale*, *quick-drying oil*. Used to deepen the colour of *sapphires*.

c. (Eagle marine.) *Verdigris* tempered in *shell-lac varnish* (alcoholic), with a little *prussian blue*.

d. (Garnet.) *Dragon's blood* dissolved in *rectified spirit of wine*.

e. (Vinegar garnet.) *Orange lake* finely tempered with *shell-lac varnish*.

f. (Green.) — *α*. From *pale shell-lac*, dissolved in *alcohol* (lacquer), and tinged green by dissolving *verdigris* or *acetate of copper* in it.

β. From *sesquiferrocyanide of iron* and *bichromate of potassa*, of each, ½ *oz.;* ground to an impalpable powder, first alone, and then with *gum mastic* (clean and also in fine powder), 2 *oz.;* a little *pyroxilic spirit* is next added, gradually, and the whole again ground until the mass becomes homogeneous and of a fine transparent green. The beauty increases with the length of the grinding. The predominance of the bichromate turns it on the yellowish green; that of the salt of iron, on the bluish green. For use it is to be thinned with pyroxilic spirit. (Chem., iii, 238.) *Used* for *emeralds*.

g. (Red.) *Carmine*, dissolved in *spirit of hartshorn*, or in a *weak solution* of *salt of tartar*, and a little *gum* (dissolved) added.

h. (Ruby.)—*α*. From *lake* or *carmine*, ground in *isinglass*.

β. *Lake* ground in *shell-lac varnish*. Both are used when the colour turns on the *purple*.

γ. From *bright lake* ground in *oil*. *Used* when the colour turns on the *scarlet* or *orange*.

i. (Yellow.)—*α*. Various shades of yellow may be produced by tinging a *weak alcoholic solution* of *shell-lac* or *mastic*, by digesting *turmeric*, *annatto*, *saffron*, or *socotrine aloes* in it. The former is the brightest and is used for *topazes*.

β. From *hay saffron* digested in 5 or 6 times its weight of *boiling water* until the latter becomes sufficiently coloured, and a little *solution of gum* or *isinglass* added to the filtered liquor. When dry, a coating of spirit varnish is applied.

Obs. By the skilful use of the above varnishes, good imitations of the gems may be cheaply made from transparent white glass or paste, and by applying them to foils set under coloured pastes (*factitious gems*), a superior effect may be produced. The pigments employed must be reduced to the *finest state possible* by *patient grinding*, as without this precaution, transparent and beautiful shades cannot be formed. The *palest* and *cleanest mastic* and *lac*, dissolved in *alcohol*, and also the *palest* and *quickest drying oil*, should alone be used when these substances are ordered. In *every case* the colour must be laid on the foil with a *broad soft brush;* and the operation should

be performed, if possible, *at once*, as no part should be *crossed*, or *twice* gone over whilst wet. If the colour turns out too pale, a second coat may be given when the first one has become *quite* dry, but this practice should be avoided, if possible.

FOMENTATION. Syn. *Fomentatio, Fomentum, Fotus*,—Lat. A liquid, either simple or medicated, used for local bathing. *Fomentations* are distinguished from *lotions*, chiefly, in being applied in a heated state, and in larger quantities, and for a longer period at a time.

Fomentations are chiefly *employed* to allay pain or irritation, or to promote suppuration or the healthy action of the parts. As the intention is to convey heat, combined with moisture, to the part fomented, the utmost care must be taken to manage the application so as to promote the object in view as much as possible. *Flannel cloths*, wrung out of the hot or boiling liquid, by means of two sticks turned in opposite directions, form the best vehicles for fomentations. If they are shaken up, and laid lightly over the part, they involve a considerable quantity of air, which, being a bad conductor, retains the heat in them for a considerable time. "In every process of fomenting, there should be two flannels, each (say) three yards long, with the ends sewed together, to admit of the boiling water being wrung out of them; and the one flannel should be got ready whilst the other is applied. The fineness or the coarseness of the flannel is not a matter of indifference. The coarser it is, the less readily does it conduct heat, and the longer it retains its warmth; therefore, it is more efficient for fomenting. *White flannel* also retains the heat *longer* than *coloured flannel.*" (Dr. R. E. Griffith.) More harm than good is frequently done by allowing the patient to become *chilled* during the application. "If only *one* (flannel) is used, the skin becomes chilled during the time occupied in removing the flannel, soaking it in the water, wringing it out, and re-applying it; but if two are used, one of them is ready, and can be applied the moment the other is taken off, by which means the part is never exposed to the air, no matter how long the fomentation is continued. In some diseases, (*rheumatism, peritonitis, &c.*), the patient is scarcely conscious of a degree of heat which scalds the nurse's hands. In this case, the fomenting flannels should be put into a towel, by which means they may be wrung out without being handled by the nurse, and may be applied far hotter than can be done by any other method." (Dr. J. B. Nevins.)

The *quantity of liquid* forming a *fomentation*, as well as the size of the cloths employed, must entirely depend upon circumstances. In some cases, (as in slight affections of the face, &c.,) the application may be effectually made by holding the part in the steam of the hot liquid, and bathing it continually by means of a sponge or cloth. In some instances, ½ pint to a pint of liquid may be found a sufficient quantity; whilst in others, several quarts will be required. Under all circumstances, care must be taken to keep the fomentation as near as possible at the temperature ordered, during the whole time of its application; and, as soon as the operation is finished, to quickly wipe the part dry, and to cover it with ample clothing, in order that the reaction set up may not be prematurely checked.

Fomentations usually *consist of* simple water, or the decoction of some simple vegetable substance, as *chamomiles, elder-flowers*, or *mallows;* but, occasionally, the leaves and flowers of *aromatic* and *narcotic plants*, and *saline matter* are employed under this form. The following formulæ are given as examples:—

FOMENTATION (Anodyne). Syn. *Fotus Anodynus, Fomentatio Anodyna, Fomentum Anodynum*,—Lat. *Prep.* 1. Simple *decoction of poppy-heads.*

2. (Hosp. F.) *Poppy-heads* (without the seeds), 1½ *oz.; water*, 3½ pints; boil to 2½ pints; add of *elder flowers*, ¾ oz.; boil to a quart, and strain. *Used* to allay pain.

3. (Pierquin.) *Opium*, 1 *oz.; wine*, 1 quart; boil to a pint and strain. *Used* in severe gouty, rheumatic, and syphilitic pains.

4. *Opium*, 1 *oz.; water*, 1 quart; boil to ¾ pint, add *pyroligneous acid*, 2 *fl. oz.;* boil for 10 minutes longer, then further add of *sherry wine*, ¾ pint; and as soon as the whole again boils, strain it for *use*. Superior to the last, and cheaper.

5. (Trousseau and Reveil.) *Cyanide of potassium*, 1 dr.; *distilled water*, 6 fl. oz.; dissolve and keep it in a well-closed bottle in the dark. *Used* in neuralgia, especially in that of the face (*tic douloureux*). A compress of lint or soft linen is dipped in it and applied to the part. It must not be used internally or applied to a wounded surface, as it is very *poisonous.*

FOMENTATION (Antineuralgic). Syn. *Fomentatio Antineuralgica*,—Lat. *Prep.* 1. (Mialhe.) *Acetate of morphia*, 2 gr.; *acetic*

acid, 2 or 3 drops; *eau de Cologne*, 2 or 3 dr.; dissolve. In facial neuralgia.

2. See *Anodyne Fomentations*, Nos. 3, 4, and 5, (*above.*)

FOMENTATION (Antiseptic). Syn. *Fomentatio Antiseptica*,—Lat. *Prep.* 1. *Decoction of mallows*, 4 pints; *sal ammoniac*, 2 *oz.*; dissolve, and add of *disulphate of quinine*, 20 gr., dissolved in *camphorated spirit*, 4 *fl. oz.*

2. (Hosp. F.) *Decoction of bark*, 1 quart; *infusion of chamomile*, 1 pint; *camphorated spirit*, 2 fl. oz.; *hydrochloric acid*, 1 fl. dr. Both are used when there is a tendency to gangrene or putrescence.

FOMENTATION (Arnica). Syn. *Fomentatio Arnicæ*,—Lat. *Prep.* 1. *Flowers of arnica*, 1 oz.; *water*, 3 pints; boil to a quart, and strain. *Used* in contusions.

2. (Graefe.) *Flowers of arnica*, 2 oz.; *rue* (leaves), 1 oz.; *boiling water*, q. s. to strain 12 fl. oz. of infusion after an hour's maceration at nearly the boiling temperature. *Used* in contusions and extravasations, especially as an application to *black eyes*.

3. (Radius.) *Flowers of arnica*, ½ oz.; *boiling vinegar*, q. s. to strain 6 fl. oz. of *infusion*, in which dissolve of *carbonate of ammonia*, 2 dr. *Used* in œdema of the scrotum.

FOMENTATION (Aromatic). Syn. *Fomentatio Aromatica, Fotus Aromaticus*,—Lat. *Prep.* 1. *Sea wormwood, southernwood*, and *chamomiles*, of each, 1 oz.; *laurel leaves*, ½ oz.; *water*, 5 pints; boil to ½ gall., and strain. In rheumatism, cutaneous affections, colic, &c.

2. (Augustin.) *Rosemary*, ½ oz.; *red wine* and *water*, of each, 3 fl. oz.; infuse and strain with expression. In contusions, especially *black eyes*.

3. (Hosp. F.) *Cloves* and *mace*, of each, 1 oz.; *opium*, 20 gr.; *red wine* (boiling), 1 pint; digest at near boiling for 1 hour, and strain. *Used* as both the last.

4. (Rideau.) *Bay leaves, rosemary, southernwood*, and *wormwood*, of each, 1 oz.; *water*, 2 quarts; boil 5 minutes and strain. As No. 1.

FOMENTATION (Astringent). Syn. *Fotus Astringens, F. Roborans*,—Lat. *Prep.* 1. *Decoction of oak bark.*

2. To each quart of the last, add of *alum*, 1 dr.

3. (Ph. Chirur.) *Bruised galls*, 1 oz.; *boiling water*, 2½ pints; digest 1 hour, and strain.

4. (Ricord.) *Tannin*, 2½ dr.; *aromatic wine* (hot), ½ pint; dissolve.

5. *Bistort* and *pomegranate peel*, of each, 2 oz.; *sal ammoniac*, ¼ oz.; red wine 1 pint; infuse at a gentle heat. The above are *used* in hemorrhages, piles, prolapsus, &c.

FOMENTATION (Chamomile). Syn. *Fomentatio Anthemidis*,—Lat. *Prep. Chamomiles*, 2 oz.; *water*, 3 pints; boil 10 minutes, and strain with expression. Emollient.

FOMENTATION (Common). Syn. *Fotus Communis*,—Ph. 1746. Same as *aromatic fomentation*, No. 1, (above.) Emollient.

FOMENTATION (Diuretic). Syn. *Fomentatio Diuretica*,—Lat. *Prep.* (Trousseau.) *Tinctures of squills* and *foxglove*, of each, 2 oz.; *hot water*, 6 *fl. oz.*; mix. Applied by lint or linen compresses to the insides of the thighs, in dropsies, when the stomach will not bear diuretics.

FOMENTATION (Elder Flowers). Syn. *Fotus Sambuci*,—Lat. *Prep.* From *elder flowers*, 1 *oz.*; *boiling water*, 2 quarts; digest in a hot place for 1 hour, and express the liquor. Emollient.

FOMENTATION (Emollient). Syn. *Fomentatio Emolliens*,—Lat. *Prep.* 1. *Marshmallow root* and *poppy-heads*, of each, 1 oz.; *water*, 3 pints; boil to a quart, and strain.

2. (P. Cod.) *Emollient herbs*, 1 oz.; *boiling water*, 1 quart; infuse 1 hour, and strain with expression. (See *above.*)

FOMENTATION (Narcotic). Syn. *Fomentatio Narcotica*,—Lat. *Prep.* (P. Cod.) *Narcotic herbs*, 1 oz.; *boiling water*, 1½ pint; infuse as last.

FOMENTATION (Resolvent.) Syn. *Fotus Resolvens*,—Lat. *Prep.* (Richard) *Fomentation of elder flowers*, 8 fl. oz.; *liquor of diacetate of lead*, ½ fl. dr.; mix. *Used* to discuss tumours, &c.

FOMENTATION (Stimulant). Syn. *Fomentatio Stimulans*,—Lat. *Prep.* 1. *Sesquicarbonate of ammonia*, 1 oz.; *tincture of cantharides*, 2 fl. oz.; *warm water*, 1 pint.

2. *Household mustard*, 4 *oz.*; *hot water*, 1½ pint; mix. Both the above are rubefacient and counter-irritant, and excellent in rheumatism, neuralgia, &c.

FOMENTATION (Vermifuge). Syn. *Fomentatio Vermifuga, Fotus Anthelminticus*,—Lat. *Prep. Leaves* and *flowers of tansy, wormwood*, and *chamomile*, of each, 3 oz.; *water*, 1 quart; boil to 1½ pint, and strain. Applied to the abdomen, &c., in worms.

FOOD. Syn. *Cibus, Materia Alimentaria*,—Lat. Anything which feeds or promotes the natural growth of organic bodies, by supplying them with materials which, by assimilation, may be converted into the substances of which they are composed; or which, by their decomposition or slow com-

bustion, maintain the temperature, or some other essential condition of life, at the proper standard. The numerous articles employed as food are all compounds; and in many cases they consist of mechanical mixtures or chemical combinations of two or more compounds. Organized matter, or that which has possessed either animal or vegetable life, or which has been produced by living organs, seems to be alone capable of assimilation, to any extent, by the animal system; and hence it is from the organic kingdom that our aliments (commonly so called) are necessarily derived. Water, iron, earthy phosphates, chloride of sodium, and other salts which form the inorganic constituents of the body, though not of themselves nourishing, are also assimilated when taken in conjunction with organic aliments, and then contribute essentially to nutrition. In the animal and vegetable substances employed as food, these inorganic compounds are provided in small, but sufficient quantities to meet the requirements of the healthy body; and in this state of combination alone can they be regarded in the light of aliments. With respect to water, it is a question with some persons, whether it may not undergo decomposition in the body, and be made directly subservient to the nutrition of the solid parts. Our present knowledge, however, does not afford any evidence in support of this opinion. A complete consideration of this subject embraces not only all the substances used as food, but also those things which when taken with them improve their flavour, promote their digestion, and render them more wholesome and nutritive; and also their preparation for the table in its various relations with health and disease. See *Nutrition*, *Putrefaction*, *Respiration*, *&c.*

FOOD (Farinaceous). See *Farina*, *&c.*

FOOD (of the Gods). See *Assafœtida.*

FOOLS. Cooks give this name to a species of jam made of boiled and crushed fruit, mixed with milk or cream, and sweetened.

Apple Fool. From the *peeled* and *cored fruit*, placed in a jar, with *moist sugar*, q. s. to render it palatable, and a very little *cider* or *perry*; the jar is set in a saucepan of water over the fire, and the heat continued until the apples become *quite soft*, when they are pulped through a colander, and a sufficient quantity of *milk*, a little *cream*, and some *sugar* added to bring them to the proper "palate."

Gooseberry Fool. From *gooseberries*, as the last. Those which are unripe are generally preferred. These preparations, when nicely made, are very pleasant and wholesome. Even now, we look back with envy to our boyish days, when we luxuriated over slices of "home-baked," surmounted with huge piles of *gooseberry* or *apple fool*, which commonly formed our dinner 4 or 5 days a week during the fruit season.

FOOT (Human). See *Feet* (The).

FOOTS. Coarse moist sugar. The scrapings of the sugar hogsheads, refuse sugar, waste, and dirt, is also sold to the publicans under this name, who use it in the adulteration of their beer; chiefly to make it stand more water, and to impart "briskness."

FORCEMEAT. Syn. *Farce*, *Stuffing.* A species of sausage meat, either served up alone, or employed as an ingredient in other dishes.

Mrs. Rundell truly remarks that "at many tables, where everything else is done well, it is common to find very bad forcemeat or stuffing." To avoid this error care should be taken to so proportion the ingredients that "no *one* flavour should predominate; yet if several dishes be served the same day, there should be a marked variety in the tastes of the forcemeats, as well as of the gravies. A general fault is, that the tastes of *lemon-peel* and *thyme* overcome all others; therefore they should only be used in small quantities." Forcemeats should be just consistent enough to cut with a knife, but not dry and heavy. Herbs are very essential ingredients; and it is the copious and judicious use of them that chiefly gives the cookery of the French its superior flavour. "To *force* fowls, meat, &c., is to stuff them." (Mrs. Rundell.)

FORCING. Horticulturalists apply this term to the art of accelerating the growth of plants, so as to obtain fruits or flowers at unusual seasons. *Dung-beds*, *bark-beds*, and *frames*, *pits*, and *houses*, with *glass roofs*, are commonly employed by the gardeners for this purpose.

FORMIATE. Syn. *Formate*, *Formias*, —Lat. The salts of formic acid. The *formiates* are readily obtained, either by direct saturation of the acid, or by double decomposition; most of them are very soluble, and are decomposed by hot oil of vitriol. *Formiate of ammonia* crystallizes in square prisms; *formiate of soda*, in rhombic prisms; *formiate of potassa* is deliquescent and crystallizes with difficulty; the *formiates of baryta*, *lime*, *magnesia*, and *strontia*, form small prismatic crystals; *formiate of lead* assumes the shape of small colourless needles, soluble in 40 parts of water; the *formiates of cobalt*, *iron*, *man-*

ganese, *nickel*, and *zinc* are easily crystallizable, whilst that of copper forms very beautiful, large, bright-blue rhombic prisms; *formiate of silver* is less soluble than the salt of lead, and is decomposed at a gentle heat. See *Formic Acid*.

FORMIC ACID. Syn. *Acid of Ants; Acidum Formicum*,—Lat. The sour liquid ejected by ants when irritated. It was formerly solely prepared from these insects by distilling them along with water. It was discovered by Gehlen, but was first obtained artificially by Doebereiner.

Prep. 1. *Sugar*, 1 part; *water*, 2 parts; *binoxide of manganese*, 3 parts; mix in a retort capable of holding fully 10 times the bulk of the ingredients, and add, cautiously, *oil of vitriol*, 3 parts, diluted with an equal weight of *water;* as soon as the first violent effervescence has subsided, heat may be applied, and the product collected and purified, as *below*.

2. (Doebereiner.) *Tartaric acid*, 2 parts; *peroxide of manganese* and *concentrated sulphuric acid*, of each, 3 parts; *water*, 5 parts; distil in a capacious retort into a well-cooled receiver.

3. (Fownes.) From *dry oxalic acid* and *silicious sand*, equal parts, distilled together. The *product* is scanty, but very strong, and contains a little oxalic acid.

4. (Liebig.) *Starch*, 1 part; *peroxide of manganese* (in fine powder), 4 parts; *water*, 4 parts; mix in an alembic or retort, as before, heat to 104° Fahr., and add, by degrees, *oil of vitriol*, 4 parts; after the frothing is over, apply heat and distil off 4½ parts of liquid.

5. (Liebig.) *Formiate of lead* in fine powder is introduced into a *long glass tube*, one end of which is connected with an apparatus evolving *sulphuretted hydrogen*, and the other, with a receiver. As soon as the salt is entirely decomposed (*blackened*) *a very gentle* heat is applied, and the distilled liquid collected; the product is, lastly, boiled for a minute or less, to expel any adhering sulphuretted gas. This furnishes *chemically pure hydrated formic acid*, containing 1 atom, or 20% of *water*.

6. (Liebig.) *Dry formiate of lead*, 18 parts; *oil of vitriol*, 6 parts; *water*, 1 part; distil in a *chloride of calcium* bath. This hydrate contains 2 atoms, or 40% of water.

7. From *pyroxilic* or *wood spirit* and *platinum black*, as *acetic acid*, No. 25, (p. 9.) In this process, unlike that of alcohol, no intermediate compound corresponding to aldehyde is produced.

8. (C. Watt, Jun.) From *naphtha* or *pyroxilic spirit*, 1 part; *bichromate of potassa* and *sulphuric acid*, of each, 3 parts; the sulphuric acid, diluted with an equal weight of water, being gradually added last. A portion of naphtha distils over with the acid, and may be again treated with *bichromate of potassa* and *sulphuric acid*, when a fresh portion of formic acid will be produced. This process yields a large product.

Prop., &c. The products of the above processes are limpid and colourless; the stronger ones fume slightly in the air, and possess an extremely penetrating odour. The *first hydrate* (No. 5, *above*) boils at 209° Fahr., crystallizes in brilliant scales below 32°, and has the sp. gr. 1·2353. Its vapour is inflammable and burns with a blue flame. The *second hydrate* (No. 6, *above*) boils at 223°, does not solidify at—5°, and has the sp. gr. 1·1167. Both of them are extremely corrosive, and rapidly destroy the texture of living organic substances. The products of the other processes are very dilute, and possess the above properties in only a minor degree. They may all be purified and concentrated by saturating them with pure *carbonate of soda* or of *potassa*, and after subjecting the liquid to a gentle heat for a short time, and liberating the formic acid from the salt by means of dilute sulphuric acid, finally submitting the mixture to distillation, when the hydrated acid will come over perfectly pure.

Formic acid reduces the salts of mercury and silver, and forms salts with the bases termed *formiates*.

Formic acid is readily distinguished from *acetic acid*, which in many points it resembles, by *heating* it with a little *solution of oxide of silver* or *mercury;* the metal is reduced, and precipitated in a pulverulent state, while carbonic acid is extricated. The odours of the two acids also vary.

FORMIC ETHER. See *Ethers*.

FORMOBENZOIC ACID. Syn. *Formiate of Hydruret of Benzyle*. A peculiar acid discovered by Winkler, and obtained by dissolving *crude oil of bitter almonds* in *water*, adding *hydrochloric acid*, evaporating, and treating the dry mass with *ether*, which dissolves out the new acid. It may be decoloured by *animal charcoal*, and obtained in crystals by careful evaporation. It readily combines with the bases forming salts called *formobenzoates*.

FORMOMETHYLAL. Syn. *Formiate of Methyle* (*tribasic*). A light, oily, and very volatile liquid, obtained by Kane, by distilling a mixture of *pyroxilic spirit* and

peroxide of manganese, of each, 2 parts; and *oil of vitriol* and *water*, of each, 3 parts. As soon as the boiling point of the distilled liquor reaches 177° Fahr., the formiate of methyle begins to pass over, and the receiver must be changed. The product is purified by rectification. It has then an agreeable aromatic odour, boils at 170° Fahr., and is soluble in 3 parts of water; sp. gr. 0·855.

FORMULA. Syn. *Formula*,—Lat. *Formule*,—Fr. A prescribed form; a rule, recipe, or prescription. *Chemists* apply this name to the abbreviations or symbols used in the place of the names of substances; more especially for exhibiting in a condensed form the composition and relations of compound bodies. The full consideration of the subject belongs to a work on pure chemistry. See *Equivalents*, *Symbols*, *&c.*

FORMYLE. Syn. *Formule*. A hypothetical organic radical, consisting of two equivalents of *carbon* and 1 eq. of *hydrogen*, of which formic acid is the oxide. Its existence is inferred from the constitution of certain known compounds. (Liebig.) *Iodide*, *bromide*, *chloride*, and *sulphuret of formyle*, have been obtained. Its *terchloride* is chloroform, and its *teroxide* is formic acid.

FORMYLE (Terchloride of). Syn. *Chloroform*,—Dumas; *Chloroformyl*,—Ph. L. *Chloroformum*,—Ph. D. *Chloride of Formyle*, *Perchloride of do.*, *Formyl-chlorid*,—Liebig; *Chloric Ether*, *Terchloride of Carbon*, *Æther Chloricus*,—Obs. *or* unus. An ethereal compound, the composition of which was first accurately determined by Dumas, in 1834, and has since been confirmed by the analysis of Liebig and others. It is rich in synonyms, owing to the different views which were formerly held regarding its composition.

Prep. 1. (Dumas.) *Chloride of lime* (in powder), 4 lb; *water*, 12 lb; mix, in a capacious retort or still, add of *rectified spirit*, 12 fl. oz., and cautiously distil, as long as a dense liquid, which sinks in the water it passes over with, is produced; separate this from the water, agitate it with a little *sulphuric acid*, and, lastly, rectify it from *carbonate of baryta*.

2. (Ph. L.) *Chlorinated lime*, 4 lb; *water*, 10 pints; *rectified spirit*, ½ pint; proceed as last, using a spacious retort that the mixture will only 1-3rd fill, and the heat of a sand bath. "When ebullition commences remove the fire as quickly as possible, lest the retort be broken by the suddenly increased heat,' and "let the solution distil into a receiver as long as there is nothing which subsides, the fire being restored if it be at all needed. Add to the distilled liquid four times as much water, and shake the whole well together;" next "cautiously separate the heavier part as soon as it has subsided, and to this add of *chloride of calcium*, broken into fragments, 1 dr.; and shake occasionally during an hour; finally let the fluid again distil from a glass retort into a glass receiver."

3. (Ph. D.) *Quicklime*, 5 *lb.*, (slaked with) *boiling water*, 1 quart, is put into a sheet iron or copper still, with *chlorinated lime*, 10 *lb.*; *water*, 3¾ gall., previously mixed with *rectified spirit*, 25 *oz.*, and raised to the temperature of 100° Fahr., is then added; heat is now applied, but *withdrawn immediately* the *distillation commences*. The lower stratum of the distilled product, the bulk of which need not exceed a quart, is next agitated, twice in succession, with an *equal volume* of *distilled water*, and then in a *separate bottle* with *half its volume* of *pure sulphuric acid*. Lastly, it is shaken in a matrass with *peroxide of manganese*, in fine powder, ¼ *oz.*; and rectified from off this at a *very gentle heat*.

4. *Hydrate of lime*, 1 part, is suspended in *cold water*, 24 parts, and *chlorine* passed through the mixture until nearly the whole of the lime is dissolved; *hydrate of lime*, q. s. just to restore the alkaline reaction of the liquid is then added; and, afterwards, *rectified spirit of wine* or *wood spirit*, 1 part, is mixed in; the whole, after repose for 24 hours in a covered vessel, is cautiously distilled as before.

Prop., *&c.* Transparent; colourless; odour, fragrant, ethereal, and apple-like; taste, ethereal, sweetish, but slightly acrid; soluble in 2000 parts of water; mixes in all proportions with alcohol and ether; dissolves (readily), bromine, camphor, caoutchouc, gutta percha, iodine, oils, resins, wax, and several other like substances; boils at 141° Fahr.; kindles with difficulty; burns with a greenish flame; and communicates a dull, smoky-yellow colour to the flame of alcohol. Sp. gr. 1·48 to 1·49; density of vapour, 4·2 (4·116,—Fownes).

Pur. Chloroform is frequently adulterated with alcohol and ether; and owing to careless manipulation, is also sometimes contaminated with acetic, formic, or sulphuric acid. The first two may be detected by the odour left on the palm of the hand after the chloroform has volatilized; and the last, by adding a solution of chloride of barium to water which has been previously

agitated with it. When pure it is "free from colour, and of a pleasant odour. Sp. gr. not less than 1·48. It is not perfectly soluble in water; and does not turn the colour of litmus red. Rubbed on the skin, it quickly evaporates, scarcely leaving any odour." (Ph. L.) "The sp. gr. of chloroform is 1·496." (Ph. D.)

Uses, &c. Chloroform is anodyne, antispasmodic, sedative, stimulant, and anæsthetic. *Dose.* 5 to 12 or 15 drops, in water, mixed with a little syrup or mucilage. (See *Chloric Ether.*) It is now chiefly used as an *inhalation* to produce insensibility to pain during surgical operations. The *dose* for this purpose is 1 fl. dr., which is repeated, in a few minutes, if no effect is produced, until 3 fl. dr. have been thus exhibited; the effects being carefully watched, and the source of the chloroform vapour removed as soon as a sufficient degree of anæsthesia is produced, or any unpleasant symptoms develop themselves.

Chloroform in *large doses* depresses the heart's action, and causes profound coma, and death. It is therefore dangerous in all cases complicated with diseases of the heart or brain, or any visceral affections of a congestive character. In other cases, atmospheric air loaded with 4% or 5% of chloroform vapour, may be inhaled with perfect safety until insensibility to pain comes on. When it contains more than 7% of the vapour, it is absolutely dangerous, a fact to which the number of deaths in our hospitals during the last few years bear ample testimony. Dr. Simpson has used as much as "8 fl. oz. in thirteen hours, in a case of labour." Such a dangerous proceeding, however, deserves the severest censure.

The *usual mode of administering chloroform* is by means of an inhaler made for the purpose, but a much simpler and safer plan is, to twist a handkerchief or a napkin into the form of a bird's nest, on the inner surface of which the fluid is to be sprinkled before applying it over the mouth and nose.

The *treatment* of *asphyxia* from chloroform is—the horizontal position, cold affusion to the head and spine, artificial respiration, and, if possible, either the application of electricity, or the inhalation of protoxide of nitrogen or oxygen gas, largely diluted with atmospheric air.

Concluding Remarks. The preparation of chloroform or terchloride of formyle is not unattended with danger, and frequently miscarries in careless or inexperienced hands. This arises chiefly from the violent reaction which immediately follows the application of the heat. On the common plan there is great danger of explosion, or of the liquid in the still being forced over into the receiver, owing to the extraordinary rapidity with which the vapours are eliminated, and the ingredients, in consequence, swell up. The method we have successfully adopted on the *large scale*, is to employ a very broad and shallow capsule-shaped still, having a flat rim round it, with a head or capital furnished with a corresponding rim at its lower part. In use, a flat, endless band of vulcanized Indian rubber is placed between the two rims, which are then held air-tight together by means of small iron clamps. The application of heat is also delayed for some time after the admixture of the spirit with the other ingredients, and the process is interrupted as soon as the first violence of the reaction has subsided, by which time the whole product of chloroform will have passed over into the receiver. If the distillation is continued beyond this point, the remaining product is water. On the *small scale*, a very capacious flat-bottomed retort or cucurbit should be employed. A similar refrigeratory may be used to that noticed under ether. *Chloroform* is also produced when *chloral* is treated with an *aqueous solution of caustic potassa.*

FOUSEL OIL. See *Acetate of Amyle* and *Oils.*

FOXGLOVE. Syn. *Digitalis*,—Ph. L. E. & D. "The recent and dried stem-leaf of the uncultivated" "*digitalis purpurea*" (Ph. L.), or *purple foxglove*. "The leaves (folia),"—Ph. E. & D. "Let it be gathered before the terminal flowers have expanded." "The petiole and mid-rib of the leaf being cut off, dry the lamina." (Ph. L.) The *seeds* (digitalis semina) which were ordered, as well as the leaves, in former pharmacopœias, are said to be in many points preferable to them. When good, the leaves are of a dull-green colour, and possess a feeble narcotic odour, and a bitter unpleasant taste. Both the *dried leaves* and the *powder* should be preserved in corked bottles covered with dark-coloured paper, or in well-closed tin canisters, and kept in a dark cupboard; and the stock should be renewed yearly, as age considerably diminishes the medicinal activity of digitalis.

Foxglove is diuretic, sedative, and antispasmodic, and exerts a specific action over the cerebro-spinal system, promoting the functions of the absorbents, and reducing the force of the circulation in a remarkable manner. It is administered in *fevers* and *inflammations*, to reduce the frequency of

the pulse, and to allay excessive vascular excitement; in *dropsy*, (unless the habit is full and pulse tight and cordy,) as a diuretic, either alone, or combined with squills, calomel, salines, or bitters; in *internal hemorrhages*, as a sedative, when the pulse is full, hard, and throbbing; in *diseases of the heart* and *great vessels*, and in *phthisis*, to reduce the force and velocity of the circulation; in *epilepsy* and *insanity*, to repress vascular excitement; and in *spasmodic asthma*, *scrofula*, and several other diseases, with one or other of the above intentions.

The *greatest caution* is required in the use of foxglove, as its effects accumulate in the system, and the unwary practitioner is occasionally surprised at the sudden demise of his patient, even after he has left off the use of this drug. *Dose.* ½ gr. to 1½ gr., in powder, every 6 hours. See *Extracts*, *Infusions*, *Tinctures*, &c.

FOXING. See *Malt Liquors.*

FOX'S CREAM. *Prep.* From *marrow pomatum* and *oil of almonds*, of each, 2 *oz.*; melt together, and when it has cooled considerably, stir in *huile au jasmin* and *essence of bergamotte*, of each, 1 dr. An excellent soft pomatum.

FRACTURE. Syn. *Fractura*, — Lat. The breaking or disrupture of a bone. When the bone is merely divided into two parts, it is called a *simple fracture*; when the integuments are also lacerated, a *compound fracture*; and when the bone is splintered, a *comminuted fracture.* See *Surgery* (Popular).

FRANKINCENSE. Syn. *Common Frankincense*; *Thus*, — Ph. L. *Abictis Resina*,—Ph. L. 1836. "The turpentine which exudes from the bark" of "*abies excelsa* (Norway spruce fir) and *pinus palustris* (pitch or swamp pine), hardened by the air." (Ph. L.) The gum-resin *olibanum*, which is the produce of the *Boswellia serrata*, is the *odorous frankincense of commerce.*

FRANKINCENSE (Prepared). Syn. *Thus Præparatum*,—Ph. L. *Prep.* (Ph. L.) *Frankincense*, 1 lb; *water*, q. s. to cover it; boil until the resin is melted, and strain through a hair sieve; when the whole has cooled, pour off the water, and keep the frankincense for use. Resembles common resin in its general properties.

FRAXININE. Syn. *Fraxina.* A peculiar, soluble, bitter, neutral, and crystallizable substance, extracted from the bark of *fraxinus excelsior* (Linn.) or *common ash.* It is febrifuge.

FRECKLES. These are round or oval-shaped yellowish spots, similar to stains, developed on the skin. There are two varieties,—*Freckles*, or *summer freckles*, resulting from the action of the sun and heat during the summer season, and disappearing with the hot weather or exposure; and—*Cold freckles*, which occur at all times of the year. The former are chiefly confined to persons of fair complexion, whilst the latter attack persons of all complexions indifferently, and sometimes assume a lively yellow or greenish colour.

Common freckles may generally be removed by the frequent application of *dilute spirits*, *acids*, or *alkaline solutions*; the last two just strong enough to prick the tongue. *Cold freckles* commonly occur from disordered health, or some general disturbance of the system, to which attention should be chiefly directed. In both varieties, the *solution of bichloride of mercury* (Ph. L.), or *Gowland's lotion*, will be found a most useful external application.

FRECKLES (Lotions for). *Prep.* 1. *Bichloride of mercury*, 5 gr.; *hydrochloric acid*, 30 drops; *lump sugar*, 1 *oz.*; *rectified spirit of wine*, 2 *oz.*; *rose water*, 7 *oz.*; agitate together until the *whole* is dissolved.

2. *Petals* or *leaves of red roses*, 1 *oz.*; *hot water*, 12 *fl. oz.*; infuse an hour, and strain, with expression, ½ pint; add of *citric acid*, 30 gr.; dissolve, and in a few hours decant the clear.

3. *Rose leaves* (dried), ¼ *oz.*; *lemon juice* (freshly expressed); and *rum* or *brandy*, of each, ½ pint; digest 24 hours, and squeeze out the liquor for use.

4. (Kittoe's.) *Sal ammoniac*, 1 dr.; *spring water*, 1 pint; *lavender water* or *eau de Cologne*, ¼ *oz.*; mix. The above are applied with the fingers night and morning, or oftener.

FRECKLES (Pomade for). *Prep.* 1. *Citrine ointment*, 1 dr.; *simple ointment*, 7 dr.; *otto of roses*, 3 drops.

2. *Elder flower ointment*, 1 *oz.*; *sulphate of zinc* (levigated), 20 gr.; mix by porphyrization, or by trituration in a wedgwood-ware mortar. Both the above, applied night and morning, are excellent for either *cold* or *summer freckles.*

FREEMAN'S BATHING SPIRITS. *Prep.* 1. *Opodeldoc* or *soap liniment*, coloured with *Daffy's elixir.*

2. (Wholesale.) *Soft soap*, 1¾ *lb.*; *camphor* (small), 3 *oz.*; *rectified spirit* and *water*, of each, 1 gall.; dissolve, and add *spirit colouring*, q. s. Resembles common opodeldoc.

FREEZING MIXTURES. See *Ice* and *Refrigeration.*

FRENCH BERRIES. Syn. *Persian*

Berries, Avignon do.; Graines d'Avignon. The berries or fruit of the *rhamnus infectorius*, (Linn.) They are imported from France and Persia; those from the latter country being esteemed the best. Their decoction dyes cloth, previously mordanted with *alum, tartar*, or *protochloride of tin*, of a *yellow colour;* with *sulphate of copper*, an *olive;* and with *red sulphate of iron*, an *olive-green colour.*

FRENCH POLISH. Several varnishes are used under this name. That most generally employed is a simple solution of *pale shell-lac* in either *rectified spirit* or *wood naphtha.* That made with the former solvent is now only used for the very best work, on account of its costliness. Sometimes a *little* mastic, sandarac, or elemi, or copal varnish, is added to render the polish tougher.

Prep. 1. From *pale shell-lac*, 5½ *oz.; finest wood naphtha* or *pyroxilic spirit*, 1 pint; dissolve.

2. Pale *shell-lac*, 3 *lb.; wood naphtha*, 1 gall. *Rectified spirit* (68 o. p.) may be substituted for the naphtha in each of the above formulæ where expense is no object.

3. *Pale shell-lac*, 5 *oz.; gum sandarac*, 1 *oz.; spirit* (68 o. p.), 1 pint.

4. *Pale shell-lac*, 5½ *oz.; gum elemi*, ¾ *oz.; rectified spirit*, 1 pint.

5. *Pale shell-lac*, 1¼ *lb.; mastic*, ¼ *lb.; rectified spirit*, 2 quarts.

6. *Pale shell-lac*, 2¼ *lb.; mastic* and *sandarac*, of each, 3 *oz.; rectified spirit*, 1 gall.; dissolve, add *copal varnish*, 1 pint, and mix by roughly agitating the vessel. All the above are used in the manner described below.

7. *Shell-lac*, 12 *oz.; wood naphtha*, 1 quart; dissolve, and add of *linseed oil*, ½ pint.

8. *Shell-lac*, ½ *lb.; gum sandarac*, ¼ *lb.; rectified spirit*, 1 quart; dissolve, add of *copal varnish*, ¼ pint; mix well, and further add of *linseed oil*, ½ pint. The last two require no oil on the rubber.

Obs. The preparation of French polish is precisely similar to that of other spirit or naphthalic varnishes. Sometimes it is coloured, in order to modify the character of the wood. A *reddish tinge* is given with dragon's blood, alkanet root, or red sanders wood; and a *yellowish tinge*, by turmeric root or gamboge. When it is simply desired to *darken* the wood, brown shell-lac is employed to make the polish; and when the object is to keep the wood *light coloured*, a little oxalic acid (2 to 4 dr. to the pint) is commonly added. These substances are either steeped in, or agitated with the polish, or with the solvent, before pouring it on the "gums," until they dissolve, or a sufficient effect is produced. French polish is not required to be so clear and limpid as other varnishes, and is, therefore, never artificially clarified. See *Varnishes, &c.*

FRENCH POLISHING. This process, now so generally employed for furniture and cabinet work, is performed as follows:— The surface to be operated on being finished off as *smoothly as possible* with *glass paper*, and placed *opposite* the light, the *rubber* being made as directed below, and the *polish* (see *above*) being at hand, and preferably contained in a *narrow-necked bottle*, the workman moistens the *middle* of the *flat face of the rubber* with the polish, by laying the rubber on the mouth of the bottle and shaking up the varnish against it, *once*, by which means the rubber imbibes the proper quantity to cover a considerable extent of surface. He next *incloses* the *rubber* in a *soft linen cloth*, doubled, the rest of the cloth being gathered up at the back of the rubber to form a handle. The face of the linen is now moistened with a *little raw linseed oil*, applied with the finger to the *middle* of it, and the operation of polishing immediately commenced. For this purpose the workman passes his rubber *quickly* and *lightly* over the surface uniformly in *one* direction, until the varnish becomes dry, or nearly so, when he again charges his rubber as before, omitting the *oil*, and repeats the rubbing, until three coats are laid on. He now applies a *little oil* to the rubber, and two coats more are commonly given. As soon as the coating of varnish has acquired some thickness, he wets the *inside* of the *linen cloth*, before applying the varnish, with *alcohol*, or *wood naphtha*, and gives a *quick, light*, and *uniform* touch over the whole surface. The work is, lastly, carefully gone over with the *linen cloth*, moistened with a *little oil* and *rectified spirit* or *naphtha*, WITHOUT *varnish*, and rubbed, as before, until dry.

The *rubber* for *French polishing* is made by rolling up a strip of *thick woollen cloth* (list) which has been *torn* off, so as to form a soft elastic edge. It should form a coil, from 1 to 3 inches in diameter, according to the size of the work.

FRESCO PAINTING. See *Painting.*

FRETTING IN. See *Wines.*

FRICANDEAU. Among *cooks*, a *ragoût*, or *fricassee of veal.* The same term is also sometimes applied to stewed beef, highly seasoned.

FRICASSEE. A dish prepared by stewing or semi-frying, highly flavoured with herbs, spices, or sauce. Small things, as

chickens, *lamb*, *&c.*, and *cold meat*, are usually formed into fricassees.

FRICTION. In *mechanics*, this is the resistance which the surface of a moving body meets with from the surface of the body on which it moves. The amount of friction is proportionate to the roughness of the surfaces. Bodies *absolutely* smooth offer no resistance to each other of this kind; but *perfect* smoothness is unattainable, even by the most careful polishing. The brilliant surface of the diamond possesses asperities which exercise a similar effect to the rougher surfaces of the metals employed for machinery, although in an immensely less degree. To *lessen* the *amount of friction*, various unctuous substances, as *oil*, *tallow*, *soap*, *blacklead*, *&c.*, are used by engineers. These substances act by imparting smoothness to the points of contact, and thus reduce their resistance to each other. The full consideration of the subject belongs to engineering. See *Anti-attrition* and *Lubrication*.

FRICTION. Syn. *Frictio*,—Lat. Friction, whether simple or conjoined with liniments, is a therapeutical agent of considerable power, and is frequently a most important aid to the more strictly medical treatment of disease. By it, the circulation is promoted in debilitated parts, and medicinal substances (*iodine*, *mercurials*, *opium*, *&c.*) are made to penetrate the pores of the skin. "The benefit of friction, which consists of motion and heat, whether or no the same be raised by rubbing the body with a coarse cloth or the flesh-brush, has advantages inconceivable and scarcely credible, by which the obstructions of the pores and cutaneous glandules are opened, their stagnating juices broken into small particles, dissolved, and rendered fit to be carried off in perspiration, in the room of which, as my Lord Verulam well observes, new juice will succeed with new vigour to the body; and longevity, saith that great naturalist, is this way most certainly promoted." (Daniel Turner.)

Simple friction is performed by the *hand* alone, or with a *piece of flannel*, a *hair glove*, or a *flesh brush*. "If it be properly performed—namely, by short, brisk strokes with the tips of the fingers, and with great celerity, when the naked hand is the agent; and if it be continued for an hour or upwards, and repeated several times a day—its influence in *reducing swelled glands* and *swellings of the joints*, as well as in *alleviating rheumatic pains*, is very great; but, besides being well performed, the friction should be continued for (*at least*) half an hour, in order to render it useful." (Dr. R. E. Griffith.)

Gentle, *slow*, and *equable friction*, by producing a continued repetition of an agreeable impression on the nervous system, acts both as an *anodyne* and *hypnotic*. For this purpose "the operator should sit by the side of the bed, and, introducing the hand under the bed-clothes, rub the legs or the arms (or other parts) gently, with equally lengthened but slow movements. When the invalid is a child, its influence is more powerful when aided by a monotonous, but a soft tune, which, although it operates upon a distinct sense, yet, by combination, renders the friction more soporific." (Griffith.)

When the *friction* is *accompanied* with the use of any *acrid* or *irritating substance*, or is intended to introduce any active remedy into the system, the rubbing should be brisk, and of sufficient force to slightly abrade and inflame the cuticle; and should be continued until the substance, which is usually in the form of an ointment, either wholly or partially disappears, owing to its absorption by the skin. The hand of the operator should, in most cases, be guarded by a glove; otherwise he is likely to share with the patient the effects of the medicine, a result not always agreeable or even safe.

FRIGORIFIC MIXTURES. See *Refrigeration*.

FRITT. The pulverulent materials of glass, heated until they coalesce without melting. See *Enamels*, *Glass*, *&c.*

FRITTERS. Fried batter. A species of pancake, containing fruit, sweetmeats, poultry, meat, or fish.

Prep. 1. (M. Alexis Soyer.) "The following is thirty receipts in one:"—Soak *crum of bread*, 1 *lb.*, in *cold water*, q. s.; take the same quantity of any kind of *boiled* or *roasted meat* (a *little fat*), and chop it into fine dice; press the water out of the bread; put into the pan *butter*, *lard*, or *dripping*, 2 *oz.*, with *chopped onions*, two tea-spoonfuls; fry two minutes, add the bread, stir with a wooden spoon until rather dry, then add the *meat*, and season with *salt*, 1 tea-spoonful; *pepper*, ½ do.; and a *little grated nutmeg*, if handy; stir till quite hot; then further add *two eggs*, one at a time, mix very quickly, and pour it on a dish to cool; next roll it into the shape of *small eggs*, then in *flour*, *egg them*, and bread-crumb them; lastly, fry in abundance of fat to a nice yellow colour, and serve either *plain*, or with any *sharp* or other savoury sauce you fancy. *Innumerable dishes* can

be made in this way; in fact, from everything that is eatable, and at any season of the year,—from the *remains* of *meat*, *poultry*, *game*, *fish*, *vegetables*, &c. The same can be done with *chopped dried* or *preserved fruits*, simply using a ¼ *lb.* more *bread*; and sifting *powdered sugar* and *cinnamon* over them. *Cream* may also be used for *fruits* or *curds*.

Fritters are also (and more commonly) fried in ordinary *batter*, instead of bread-crumbs. "There is no end to what may be done with these receipts." "They can be ornamented, and made worthy the table of the greatest epicure, if the bread be soaked in cream, and spirits or liquor introduced into them." (Soyer.)

2. (Mrs. Rundell.)—*a.* (Apple Fritters.) See *Fruit Fritters*.

b. (Buckwheat Fritters, B. Cakes, Buckings.) Made by beating up *buckwheat flour* to a batter with some *warm milk*, adding a little yeast, letting it rise before the fire for 30 or 40 minutes, then beating in some *eggs* and *milk* or *warm water*, as required, and frying them like pancakes. *Buckwheat fritters*, when well prepared, are excellent. Made without eggs, and served up with *molasses*, they form a common dish in almost every breakfast in the U. S. of America.

c. (Curd Fritters.) From *dried curd*, beaten with *yelk of egg* and a *little flour*, and flavoured with *nutmeg*.

d. (French Fritters.) *Common pancakes*, beaten up with *eggs*, *almonds*, and *flavouring* (sugar, orange-flower water, and nutmeg), and the paste dropped into a stew or frying-pan half full of *boiling lard*, so as to form cakes the size of large nuts, which are cooked till brown.

e. (Fruit Fritters.) From the *sliced fruits*, with *rich batter*.

f. (Soufflé Fritters.) *Rich pancakes*, flavoured with *lemon*.

g. (Spanish Fritters.) From slices of *French rolls* soaked in a *mixture* of *cream*, *eggs*, *sugar*, and *spices*, and fried brown.

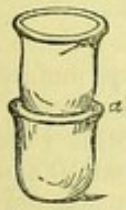
FROG. The esculent variety, in Europe, is the common *green* or *gibbous frog*, the *rana esculenta* of Linnæus, and belongs to the *batrachia*, or fourth order of the *reptilia*. As an aliment it is much esteemed on the Continent. Its *liver* is among the simples of the Ph. L. 1618, and was once considered a useful remedy in certain forms of ague.

FROST-BITES. When those parts of the body in which the circulation of the blood is most languid are exposed to *extreme* cold they quickly become frozen, or as it is called *frost-bitten*. The fingers, toes, ears, nose, and chin, are most liable to this attack. The remedy is *long-continued friction* with the *hands* or *cold flannel*, avoiding the fire, or even a heated apartment. See *Cold*.

FRUIT. Syn. *Fructus*,—Lat. Among *botanists* this is the ovarium or the pistillum arrived at a state of maturity. In *familiar language* the term is applied to any product of a plant containing the seed, more especially those that are eatable.

Fruits are extensively employed as articles of diet by man, both as luxuries and nutriment. The fruit of the *cereals* furnishes our daily bread; that of the *vine* gives us the well-known beverage, wine; whilst *other varieties* enrich our desserts, and provide us with some of our most valuable condiments and aromatics. The *acidulous* and *subacid fruits* are antiseptic, aperient, attenuant, diuretic, and refrigerant. They afford little nourishment, and are apt to promote diarrhœa and flatulency. They are, however, occasionally exhibited medicinally, in putrid affections, and are often useful in bilious and dyspeptic complaints. The *farinaceous fruits*, as already stated, furnish the principal and most useful portion of the food of man. The *oleo-farinaceous* (nuts, &c.) are less wholesome and less easy of digestion than those purely farinaceous. The *saccharine fruits*, or those abounding in sugar, are nutritious and laxative, but are apt to ferment and disagree with delicate stomachs when eaten in excess. *Stone fruits* are more difficult of digestion than the other varieties, and are very apt to disorder the stomach and bowels.

As a rule, *fruit* should never be eaten in large quantities at a time, and only when quite ripe. It then appears to be exceedingly wholesome, and to be a suitable corrective to the grossness of animal food. It also exercises a powerful action on the skin, and is a specific for scurvy in its early stages. Many cutaneous diseases may likewise be removed by the daily use of a moderate quantity of fruit, or other fresh vegetable food. Cases are not uncommon which, after resisting every variety of ordinary medical treatment, yield to a mixed fruit or vegetable diet.



The *farinaceous*, *succulent*, and *aromatic fruits* are probably the *original* and *proper food of man*. The *first*, as nourishment, the *second*, in their juices, and the *third* in their stimulant and corrective tendency, provide him with all that is necessary for his support and well-being.

Fruits should be *gathered* in dry weather,

and preferably about noon, because the dew and moisture deposited on them during the night and earlier part of the morning has then evaporated. They should be quite ripe when gathered, but the sooner they are removed from the tree, after this point is arrived at, the better. *Immature* fruit never keeps so well as that which has ripened on the tree; and *over-ripe* fruit is liable to be bruised and to lose flavour. The less fruit is handled in gathering the better. Some of them, as *peaches, nectarines, grapes, plums, &c.*, require to be treated with great delicacy, to avoid bruising them or rubbing off the bloom. Some fruit, as a few varieties of *apples, pears,* and *oranges, &c.*, are gathered before they are fully ripe, in order that they may the better undergo the perils of transit and storeage.

Ripe fruits are commonly *preserved* in the *fresh state* by placing them in a cool, dry situation on shelves, so that they do not touch each other; or by packing them in in *clean, dry* sand, sawdust, straw, bran, or any similar substance, with like care, to preserve them from the action of air and moisture. An excellent plan, commonly adopted for *dessert fruit* in the country, is to wrap each separately in a piece of *clean, dry paper,* and to fill small wide-mouthed jars or honey-pots with them. The filled pots are then packed one upon another (see *engr.*) in a dry and cold place (as a cellar), where the frost cannot reach them.

1. 

2. 

The space (*a*) between the two pots may be advantageously filled up with *plaster of Paris* made into a paste with *water*. The joint is thus rendered air-tight, and the fruit will keep good for a long time. The mouth of the top jar is covered with a slate. For *use*, the jars should be taken one at a time from the store-room, as wanted, and the fruit exposed for a week or ten days in a warm dry room, before being eaten, by which the flavour is much improved.

Fruit is *preserved* on the *large scale* for the *London market* by placing in a cool situation, *first* a *layer of straw* or *paper, then* a *layer of fruit, next* a *layer of straw,* and so on alternately, to the height of 20 or 25 inches, which cannot be well exceeded, as the weight of the superincumbent fruit is apt to crush or injure the lower layers. Sometimes *alternate layers* of *fruit* and *paper* are arranged in baskets or hampers, which are then placed in the cellar or fruit-room. The baskets admit of being piled one over the other without injury to the fruit. The use of *brown paper* is inadmissible for the above purposes, as it conveys its peculiar flavour to the fruit. Thick *white-brown* paper is the cheapest and the best. See *Putrefaction, Vegetables, &c.*

FRUMENTY. *Wheat* boiled in water until quite soft, then taken out, drained, thinned with *milk*, sweetened with *sugar*, and flavoured with *nutmeg*. When *currants* and *eggs* are added, it forms "*Somersetshire frumenty.*" Some persons boil the wheat like rice. "Eaten with milk, in the evening, for some time, it will often relieve costiveness." (Griffith.)

FRYING. "The frying-pan is, without doubt, the most useful of all kitchen implements, and, like a good-natured servant, is often imposed on, and obliged to do all the work, while its companion, the grid-iron, is quietly reposing in the chimney corner." "The *usual complaint* of food being rendered *greasy* by frying, is totally remedied by *sautéing* the meat in a *small quantity* of fat, butter, or oil, which has attained a *proper degree of heat*, instead of placing it in *cold fat*, and letting it soak while melting." "According to the (common) mode in which all objects are cooked which are called *fried*, it would answer to the French word '*sauté*,' or the old English term '*frizzle*;' but to *fry* any object, it should be *immersed* in *very hot* fat, oil, or butter." "To *frizzle, sauté*, or, as I will now designate it, *semi-fry*, is to place in the pan any oleaginous substance, so that, when melted, it shall cover the bottom of the pan by about two lines; and when *hot*, the article to be cooked is to be placed therein. To do it to perfection requires a little attention, so that the pan shall never get *too hot*. It should also be *perfectly clean*—a great deal depends on this." (Soyer.)

According to the above high authority in all matters connected with the gastronomic art, a *chop* or *steak*, for frying, should be chosen about ¾ of an inch thick, and should "*never exceed* one inch, nor be *less* than half an inch, and to be as near as possible of the same thickness all over." "An *ill-cut* chop (or steak) never can be but *ill-cooked;* you can always equalise them (when badly cut) by beating them out with a chopper."

"The motive of semi-frying food is to have it done quickly; therefore, to fry a *whole* fowl, or even half, (for example) is useless, as it could be cooked in a different

way in the same time; but to *semi-fry* a fowl (in joints, or pieces,) with the object of having it quickly placed on the table, in order to satisfy a good, and perhaps fastidious appetite, it should be done in a similar way to that practised in Egypt some 3000 years since, and of late years for the great Napoleon—that is, *cooked in oil.*"

"In France this dish is called '*Poulet à la Marengo.*' It is related that the great conqueror, after having gained that celebrated victory, ate *three small chickens* at *one meal* done in this way, and his appetite and taste were so good, and he approved of them so highly, that he desired that they might always be served in the same way during the campaign."

"For many objects, I prefer the *frying-pan* to the *gridiron*; that is, if the pan is properly used. As regards *economy*, it is preferable, securing all the fat and gravy, which is often lost when the gridiron is used." "This simple *batterie de cuisine*," may be employed "equally as well in the *cottage* as in the *palace*, or in the *bachelor's chamber* as in the *rooms of the poor*." (Soyer.)

FUCUSAMIDE, *Fucusine*, and *Fucusol*. Compounds obtained by Dr. Stenhouse from several varieties of fucus. See *Furfurine*.

FUEL. Matter used for the production of heat by burning. The principal substances employed as fuel are—*anthracite, charcoal, coal gas, coke, pitcoal, turf*, and *wood*.

TABLE of the *heating power, &c., of* 1 *lb. of the several substances mentioned, expressed in the nearest common numbers.*

NAMES.	Pounds of water heated from 32° to 212° Fahr.	Pounds of water at 212° Fahr. converted into steam.	Weight of atmospheric air at 32° Fahr. consumed.
Alcohol (commercial) . .	52½	9½	11¾
Anthracite	69½	12¼	11
Charcoal of wood (dry) .	73	13¼	11½
„ „ (ordinary)	65¾	12	10½
„ turf or peat .	64½	11¾	15
Coke	65	12	11½
Oil	77	14	15¼
Pitcoal	60¼	11	9½
Tallow	78	14¼	15¼
Turf or peat	30	5½	43¼
Wax	78	14¼	15
Wood (dry)	35	6¼	6
„ (ordinary)	26	4¾	4½

Obs. The above results are scarcely ever obtained in practice, owing to the imperfect construction of boilers, and a large portion of the heat (probably ⅛ to ½) passing up the chimney, and being wasted. 1 *lb.* of coal, with ordinary boilers, is usually reckoned sufficient to convert 7½ *lb.* (9 *lb.*; —Watt.) of *boiling water* into *steam*, or to heat 41¼ *lb.* of water from 32° to 212° Fahr. 1 *lb.* of *fir wood* will evaporate fully 4 *lb.* of *water*, or heat 22 *lb.* to the boiling point.

Engineers commonly reckon the *consumption of coal* in the *furnace of a steam engine*, of good construction, at about 10 to 12 *lb.* per horse-power, the hour; but in the *Cornish pumping-engine*, the quantity has been long reduced to 1½ *lb.* to 2 *lb.*; whilst three or four of those recently constructed, are capable of raising, with only 1 *bushel* (84 *lb.*) *of coal*, from 80 to 100 *millions* of *lb.* of water *one foot high*.

The *evaporative power of fuel*, other circumstances being equal, depends mainly on the extent of the surface of the boiler exposed to its action. With ordinary steam boilers this ranges between 7 and 10 square feet per horse-power; but when economy is an object, it should *not* be *less* than that last mentioned.

FUELS (Economical). Various mixtures have been recommended under this name:—

Prep. 1. *Small coal, charcoal*, or *sawdust*, 1 part; *clay, loam*, or *marl*, 1 part; *sand* or *ashes*, 2 parts; *water*, q. s.; make the mass up wet into balls. For *use*, these balls are piled on an ordinary fire to a little above the top bar. They are said to produce a heat considerably more intense than that of common fuel, and ensure a saving of one half the quantity of coals, whilst a fire thus made up will require no stirring,

nor fresh fuel for ten hours. The quantity of the combustible ingredient in them should be doubled, when they are intended to be used with a very little "foundation of coal."

2. *Peat and turf*, both recent and charred, are commonly used as fuel by the lower classes, in neighbourhoods where they are plentiful.

3. *Fir cones* or *tops*, contain a great quantity of solid woody, in addition to the resinous matter, and are well adapted for domestic fires.

FUELS (Patent). These are numerous. It is, however, very doubtful whether any *artificial fuels* can compete, in economy, on the large scale, with those provided by the hand of nature ready for our use.

Albert's Patent Fuel consists of the *bituminous refuse* from various manufactures, *bituminous schist* (in powder), and *small coal*, of each, 10 parts; *clay* (dry), 5 parts; and *mineral oil* or refuse of the naphtha distilleries, 1½ part; mixed with heat, and ladled whilst soft, into a hole in the ground, near the melting pan.

Grant's Patent Fuel is formed of *coal dust*, 1 cwt., and *coal-tar pitch*, 20 *lb.*, melted together by a heat of 220° Fahr., and moulded into blocks the size of common bricks, under a pressure of 5 or 6 tons. These are, lastly, whitewashed. It is heavier than common steam-coal, and is said to go fully 1-3rd further, by which facility of transport and economy is combined.

FULIGOKALI. *Prep.* (Dr. Polya.) *Caustic potassa*, 1 part; *water*, q. s.; dissolve; add of *wood soot* (powdered, shining, —Deschamps), 5 parts; boil 1 hour, dilute with water, filter, evaporate the filtrate to dryness, and put the product at once into warm, dry bottles. *Dose.* 2 to 3 gr., thrice a day, made into pills, which must be coated with gum and kept from the air. (See *below.*)

FULIGOKALI (*Sulphuretted*). Syn. *Fuligokali Sulphuretum*,—Lat. *Prep.* (Dr. Polya.) *Caustic potassa*, 7 parts; *sulphur*, 2 parts; *water*, q.s.; dissolve with heat, add of *fuligokali*, 30 parts, evaporate to dryness, and preserve it in well-corked dry bottles. *Dose, &c.* As the last.

Obs. M. Gibert has tried both fuligokali and sulphuretted fuligokali on his patients at the Hospital Saint-Louis, both internally and externally, with manifest advantage in various obstinate chronic skin diseases. He made a pommade of 30 grammes (say 1 oz.) of *lead ointment*, and 1 or 2 grammes (say 20 to 25 gr.) of *fuligokali*, in which he *recognised* positive resolvent, detersive, and stimulant properties. (Gaz. des Hôpitaux, 1842.)

FULLER'S EARTH. Syn. *Cimolia, C. Terra, C. Purpurascens*,—Lat. var. A soft, unctuous, friable, greenish or yellowish-gray species of clay, containing 53% of *silica*, 10% of *alumina*, and about 9% of *oxide of iron.* After being dug out of the earth, it is thoroughly dried in ovens, and then thrown into cold water, where it soon falls to powder, and is purified by the common process of edulcoration or washing-over. It is extensively *used* to extract oil and grease from cloth in the process of "fulling;" it forms an excellent filtering powder for oils, and is applied as a cooling and healing dressing by the poor to inflamed breasts, excoriations, &c.

FULLING. Syn. *Milling.* The process of cleaning cloth, and making it compact and firm in a mill. (See *above.*)

FULMINATES. The salts of *fulminic acid.* They are all characterised by the property of exploding with violence by slight heat or friction. (See *below.*)

FULMINATING COMPOUNDS. These are numerous, and are scattered through several distinct classes of bodies. Among the most powerful and dangerous are the *chloride* and *iodide of nitrogen, perchloric ether*, the *fulminates of gold, silver*, and *mercury, fulminating antimony, gun cotton*, and *mixtures* of *chlorate of potassa* and certain *inflammable substances*, as phosphorus, sulphur, carbon, orpiment, &c.

FULMINATING ANTIMONY. Syn. *Fulminating Antimonial Powder; Antimonium Fulminans*,—Lat. *Prep.* 1. (Serullas.) *Tartar emetic* (dried), 100 parts; *lamp black* or *charcoal powder*, 3 parts; triturate together, put it into a crucible that it will 3-4ths fill (previously rubbed inside with charcoal powder), cover it with a layer of *dry charcoal powder*, and lute on the cover; after 3 hours' exposure to a strong heat in a reverberatory furnace, and 6 or 7 hours' repose to allow it to cool, &c., cautiously transfer the solid contents of the crucible, as quickly as possible, without breaking it, to a wide-mouthed stoppered phial, where, after some time, it will spontaneously crumble down into a powder.

2. (Ann. de Chim. 1822.) *Antimony*, 100 parts; *carburetted cream of tartar* (i.e., roasted to blackness), 75 parts; *lamp black*, 12 parts; triturate together, &c., as the last.

Obs. When the above processes are properly conducted, the resulting powders contain potassium, and fulminate violently

on contact with water. A piece the size of a pea introduced into a mass of gunpowder explodes it on being thrown into water, or on its being moistened in any other manner.

FULMINATING BISMUTH. Syn. *Bismuthum Fulminans*,—Lat. *Prep.* From *bismuth*, 120 parts; *carburetted cream of tartar*, 60 parts; *nitre*, 1 part. Very rich in potassium. *Prop., &c.*, resemble those of the last. We have been assured that this is the compound used by the late Capt. Warner for some of his secret fusees.

FULMINATING COPPER. Syn. *Fulminate of Copper; Cuprum Fulminans, Cupri Fulminas*,—Lat. *Prep.* Digest *copper* (in powder or filings) with *fulminate of mercury* or *of silver*, and a *little water*. It forms soluble green crystals that explode with a green flame.

FULMINATING GOLD. Syn. *Auric Fulminate, Aurate of Ammonia, Ammoniuret of Teroxide of Gold; Aurum Fulminans, Auri Fulminas, A. Oxidum Ammoniatum*,—Lat. *Prep.* 1. Recently precipitated *peroxide of gold* is digested in strong *liquor of ammonia* for 24 hours, and the resulting *fulminate* is dried in the open air or at a temperature below 180° Fahr., care being taken to avoid the *slightest* friction lest it should explode. A deep olive-coloured powder.

2. From *terchloride of gold*, digested in *ammonia*, in excess. Brownish yellow.

3. From a solution of *gold* in *aqua regia* (made by dissolving 4 *oz.* of *sal ammoniac*, in 12 or 16 *oz.* of *nitric acid*), precipitated with a *solution of carbonate of potassa*.

Obs. This compound can only be safely made in *very small quantities at a time*, as without *great care* it explodes with extreme violence. This is caused by the *slightest* friction or sudden increase of heat. Its fulminating property may be destroyed by boiling it in pearlash ley, or weak oil of vitriol; and by heating the residuum after washing it in water, *pure gold* will be obtained. *Fulminating gold* is said to be sedative, antispasmodic, and carminative. *Dose.* $\frac{1}{10}$ to 1 gr.; in fevers, nervous diseases, colic, &c. It has been given in larger doses. Its use has "in some cases, produced very serious, and even fatal results." (Pereira.)

FULMINATING MERCURY. Syn. *Fulminate, Fulminate of Mercury, F. of Protoxide of do.; Hydrargyrum Fulminans, Hydrargyri Fulminas*, — Lat. *Prep.* 1. (Berzelius.) *Mercury*, 1 part; *nitric acid*, (sp. gr. 1·375), 12 parts; dissolve, add, at intervals, to this solution, *alcohol* (sp. gr. 0·850), 16·3 parts; apply heat till the effervescence and cloud of gas disappears, adding, gradually, on the action becoming violent, 16·3 parts *more* of *alcohol*. *Product.* 112% of the mercury employed.

2. (Howard.) *Mercury*, 1 part; *nitric acid* (1·36), 12 parts; dissolve, and pour the solution gradually and cautiously into *alcohol* of 80 to 85%, 11 parts, a gentle heat being applied; cool, filter, dissolve in boiling water, and again filter; as the solution cools, crystals of the fulminate are deposited.

3. (Ure.) *Mercury*, 100 parts; *nitric acid* (sp. gr. 1·4), 1000 parts; (or 740 parts by *measure*); dissolve by a gentle heat, and when the solution has acquired the temperature of 130° Fahr., slowly pour it through a glass funnel tube into *alcohol* (sp. gr. 0·830), 830 parts (or 1000 parts by *measure*); as soon as the effervescence is over, and white fumes cease to be evolved, filter through *double paper*, wash with *cold water*, and dry by *steam* (not *hotter* than 212°) or *hot water*. The fulminate is then to be packed in 100 gr. paper parcels, and these stored in a tight box or corked bottle. *Product.* 130% of the weight of mercury employed.

4. (Ure.) *Quicksilver*, 1 *oz.*; *nitric acid* (1·4), 10 *oz.* (or 7½ *fl. oz.*); *alcohol* (0·830), 8·3 *oz.* (or ½ pint); proceed as last.

Prop., &c. Small brownish-gray crystals, which sparkle in the sun; entirely soluble in 130 parts of boiling water, and deposited as the solution cools under the form of beautiful pearly spangles. "An imperial pint of boiling water will dissolve 67 gr. of *pure* fulminate." (Ure.) It greatly resembles fulminate of silver in its appearance and general properties. It explodes violently by both friction and percussion, but unlike the silver-salt, merely burns with a sudden and almost noiseless flash when *kindled* in the open air.

Obs. The formula of Dr. Ure is not only the cheapest but the best and safest. That of Berzelius is more expensive and dangerous. There is "no little hazard in pouring the alcohol into the nitric solution; for at each effusion an explosive blast takes place; whereas, by pouring the solution into the alcohol, as originally enjoined by the Hon. Mr. Howard, the inventor, no danger whatever is incurred." (Ure.) This preparation is used for priming the copper percussion caps for fowling pieces, muskets, &c. Dr. Ure, in his first report to the Board of Ordnance, recommended the use of a *spirituous solution of gum sandarac*, as the best substance for diluting the fulminate, and fixing it in the caps; but in a subsequent report to the same board, he states

that a solution of *mastic in spirit* is to be *preferred.* Less than ¼ gr. of the fulminate is employed for each cap. The French use a mixture of *fulminate*, 10 parts, and *gunpowder*, 6 parts, made into a dough with water by grinding them on a smooth marble table with a wooden muller. 2½ *lb.* are employed to charge upwards of 40,000 of the French caps.

*** *Fulminate of mercury* should only be dried in small parcels at a time, and these should be placed at a distance from each other. The dreadful explosion at Apothecaries' Hall, by which Mr. Hennel, the talented chemist of the Apothecaries' Company, lost his life, was occasioned by the spontaneous detonation of this substance.

FULMINATING PLATINUM. Syn. *Platinum Fulminans*,—Lat. *Prep.* By acting on *sulphate of platinum* with *pure ammonia*, in slight excess. It is analogous to the gold and silver-salt.

FULMINATING POWDER. Syn. *Detonating Powder; Pulvis Fulminans*,—Lat. *Prep.* 1. *Nitre*, 3 parts; *carbonate of potash* (dry), 2 parts; *flowers of sulphur*, 1 part; reduce them *separately* to fine powder, before mixing them. A little of this compound (20 to 30 gr.) slowly heated on a shovel over the fire, first fuses and becomes brown, and then explodes with a deafening report.

2. *Sulphur*, 1 part; *chlorate of potassa*, 3 parts. When triturated, with strong pressure, in a marble or wedgewood-ware mortar, it produces a series of loud reports. It also fulminates by percussion.

3. *Chlorate of potassa*, 6 parts; *pure lamp-black*, 4 parts; *sulphur*, 1 part. A little placed on an anvil, detonates with a loud report, when struck with a hammer. No. 1 is the substance commonly known as *Fulminating Powder.* See *Blasting Powder.*

FULMINATING SILVER. Syn. *Fulminate of Silver*, *Argento-fulminate; Argentum Fulminans*, *Argenti Fulminas*,—Lat. *Prep.* 1. Digest *oxide of silver* (recently precipitated and dried by pressure between bibulous paper) in *concentrated liquor of ammonia*, for 12 or 15 hours, pour off the liquid, and cautiously dry the black powder (*fulminate of silver*) in the air, in divided portions. The *decanted ammoniacal liquor*, when *gently* heated, yields, on cooling, small crystals, which possess a still more formidable power of detonation than the black powder, and will *scarcely bear touching*, even whilst under the liquid.

2. Dissolve *chloride of silver* in strong *liquor of ammonia*, cautiously add *pure potassa* (in fragments), and when effervescence ceases, decant the fluid portion, and wash and dry the powder, as before. Slightly less powerful than the last.

3. (Brugnatelli's.) — *a.* Pour *alcohol*, 1 oz., on *nitrate of silver* (in fine powder), 100 gr., previously placed in a capacious flask or beaker-glass, and shortly afterwards add *strong nitric acid*, 1 oz.; as soon as all the powdered nitrate assumes the form of white clouds, add *cold distilled water*, q. s., to suspend the ebullition, and next collect the powder on a filter, and otherwise proceed as before.

b. (Fownes.) *Metallic silver*, 40 to 50 gr.; *nitric acid* (sp. gr. 1·37), ¾ fl. oz., dissolve by the aid of a *gentle* heat, add, whilst the solution is still hot, *alcohol*, 2 fl. oz., and again apply heat until reaction commences; the fulminate slowly separates from the hot liquid under the form of small, brilliant, white, crystalline plates, which after being slightly washed with a little *cold distilled water*, are to be distributed upon *separate* pieces of filtering paper, in portions not exceeding 1 or 2 gr. each, and left to dry in the air. When dry, the papers are to be folded up, and *carefully* preserved in a box or bottle. A *sixpence* and the strongest *commercial* nitric acid and rectified spirit, answer for the above purpose.

c. (Liebig.) *Grain silver*, 1 part; *nitric acid* (sp. gr. 1·36 to 1·38), 10 parts; dissolve at a gentle heat, and add the solution to *alcohol* of 85%, 20 parts; apply a gentle heat till the liquid begins to boil, then remove it from the fire and set it aside to cool; the *fulminate of silver* is deposited in lustrous, snow-white, acicular crystals, and when washed and dried, equals in weight that of the silver employed. The *products* of the last three formulæ are slightly less explosive than of those wherein ammonia is ordered.

Prop., &c. Fulminating silver occurs either in the form of a dark-coloured powder, or small, brilliant, acicular crystals or crystalline plates, according to the mode of its preparation. It dissolves in 36 parts of boiling water, but the solution deposits the greater portion of the fulminate as it cools. It is one of the most dangerous substances for which we are indebted to modern chemistry. It explodes with unparalleled violence by the *slightest* friction or percussion, or when touched with strong sulphuric acid. This occurs even whilst it is moist, if it is pressed by a hard body; and when *dry*, the touch of a feather is often sufficient to explode it. Indeed, its explosive

tendency is so great, that it can be hardly made, handled, or kept, with safety. We have, nevertheless, with others, succeeded in burning it in a tube, along with oxide of copper, to determine its composition, in a similar manner to that employed in the analysis of other organic substances. Many frightful accidents have happened from the spontaneous explosion of this substance. 1 or 2 gr. are the most that can be exploded with safety, in a building or confined space.

The products of Nos. 1 and 2, probably slightly differ in composition, as they do in explosive power, from Brugnatelli's compound. It has been proposed to call the latter, by way of distinction, "*detonating silver.*" The last is the true *fulminate of silver.*

FULMINATING ZINC. Syn. *Fulminate of Zinc; Zincum Fulminans, Zinci Fulminas,*—Lat. *Prep.* From *fulminate of silver, zinc filings,* and a little *water,* digested together, as *fulminating copper.*

FULMINATION. Syn. *Fulminatio,*—Lat. Detonation. A sudden explosion, accompanied with a loud report and extreme violence. Some *chemists,* without sufficient reason, have endeavoured to confine the application of the term to the explosion of a *fulminate.*

FULMINIC ACID. Syn. *Acidum Fulminicum,*—Lat. A peculiar acid formed by the action of nitrous acid on alcohol in the presence of a metallic salt. It has never been isolated. The *cyanic, fulminic,* and *cyanuric acids,* are isomeric compounds, but differ in their powers of saturation; the first being *monobasic;* the second, *bibasic;* and the last, *tribasic.*

The *existence* of fulminic acid was first pointed out by Gay-Lussac and Liebig. Its salts are the *metallic fulminates.* (See *above*).

FUMARAMIDE. A white insoluble powder, formed by the action of *ammonia* on *fumaric ether.* It closely resembles *oxamide.*

FUMARIC ACID. A peculiar acid, discovered by Lassaigne, and produced by the action of heat on malic acid.

Prep. Pure *malic acid* is kept heated a little higher than its melting point for some time, until it forms a crystalline mass, which is then powdered, and washed with *cold water,* to remove any undecomposed malic acid.

Prop., &c. Small, white, crystalline laminæ; freely soluble in hot water and in alcohol, but requires 200 parts of cold water for its solution; heated in a strong current of air, it sublimes; with the bases it forms salts termed *fumarates;* with alcohol it forms *fumaric ether* or *fumarate of oxide of ethyle.* This acid was originally obtained from *fumaria officinalis,* or *common fumitory.*

FUMIGATION. Syn. *Fumigatio, Suffumigatio,* — Lat. Fumigations (*fumigationes*) are vapours or gases extemporaneously extricated for the purpose of destroying contagious or noxious miasmata or effluvia (*antiloimics, disinficientia*), or to mask unpleasant odours (*odoraments; odorata, odoramenta*), or to produce a medicinal action on those parts of the body with which they are brought in contact.

Fumigations, for the purpose of obviating or masking unpleasant odours in the sick chamber, must never be employed to the neglect of cleanliness and ventilation; for most of them, instead of purifying the air, actually render it less fit for respiration. The common practice of burning *scented paper, pastilles, sugar, juniper berries, benzoin, cascarilla, &c.,* so as to create an odoriferous smoke, is of this character. As *disinfecting agents,* they are utterly useless; and are relics of an ancient custom of burning frankincense, and other odorous substances in vitiated air, to overcome the fetor which is more or less present. The fumes thus diffused through the atmosphere, "disguise unpleasant odours; but they accomplish nothing more. The infection remains not only unaltered by the diffusion of the most powerful aromatic vapours, but its deleterious properties are sometimes augmented by them."

Among the various substances used as DISINFECTING FUMIGATIONS, *chlorine* and the *hypochlorites* (chlorides of lime, soda, and potassa), by almost general consent, hold the first place. Dr. Carmichael Smyth recommended *nitrous acid,* which is even now preferred by Dr. Christison to chlorine; whilst Prof. Graham regards the *fumes of burning sulphur* as more efficacious than either of these substances. The *vapours* of *hydrochloric acid* and of *vinegar,* and the *smoke* of *gunpowder,* which once had their advocates, have now justly sunk into disfavour.

Of all common diseases, *scarlet fever* appears to be the one most requiring fumigation. For this purpose, *chlorine gas* or *heat* should be employed. The infectious matters of certain diseases, especially scarlet fever, are either dissipated, or destroyed, at a heat slightly above that of boiling water. (Dr. Henry.) Contagious diseases are very commonly propagated in this metropolis by

persons having their linen washed by laundresses who perform their operations in the same sinks of dirt and misery in which they live. See *Disinfectants, Inhalations, &c.*, (and *below*.)

FUMIGATION (Acetic). Syn. *Fumigatio Acetica*,—Lat. The *fumes* of *strong vinegar* or *acetic acid*, obtained by heating the liquid over a lamp, or by sprinkling it on a hot shovel. *Aromatic vinegar* in this way yields very refreshing fumes, and was formerly thought more efficacious than simple acetic acid.

FUMIGATION (Anodyne). Syn. *Fumigatio Anodyna*,—Lat. *Prep.* (Trousseau & Reveil.) *Stramonium* and *sage*, equal parts, sufficient to fill a small pipe. Smoked in spasmodic asthma, irritating coughs, &c.

FUMIGATION (Aromatic). See *Balsamic Fumigation.*

FUMIGATION (Balsamic). Syn. *Aromatic Fumigation; Fumigatio Aromatica, F. Balsamica*,—Lat. *Prep.* 1. From *gum benzoin*, either alone, or mixed with *olibanum* or *styrax*, thrown on hot cinders or a heated shovel.

2. (Dr. Dohrn.) *Gum olibanum*, 4 parts; *gum benzoin, styrax*, and *flowers of roses* and *lavender*, of each, 1 part; to be reduced to powder, and used as before.

3. *Amber, mastic*, and *olibanum*, of each, 3 oz.; *benzoin* and *styrax*, of each, 1 oz.; *camphor*, 1 dr. As last. The above are used in hooping-cough, asthma, &c.; a small quantity only being employed at a time.

FUMIGATION (Belladonna). Syn. *Fumigatio Belladonnæ*, — Lat. *Prep.* (M. Schrœder.) From *dried belladonna leaves*, 1 to 2 dr.; as before. In spitting of blood, asthma, tickling cough, &c.

FUMIGATION (Chlorine). Syn. *Disinfecting Fumigation, Guyton-Morveau's do.; Fumigatio Chlorinii, F. Oxymuriatica, Suffumigatio Guytoniana*,—Lat. var. *Prep.* 1. (P. Cod.) *Common salt*, 3 parts; *water* and *oil of vitriol*, of each, 2 parts; *black oxide of manganese*, 1 part; mix in a shallow vessel, placed in the centre of the apartment. This is used to disinfect unoccupied rooms.

2. *Chloride of lime*, either sprinkled on the flour (if *uncarpeted*) or (if *carpeted*) placed about the room in shallow dishes. An old plate or flower-pot saucer answers for this purpose. *Used* for inhabited rooms, and on shipboard, &c.

3. A *solution of chloride of lime* (1 *oz.* of the *chloride* to each quart of *water*). *Used* as the last, but more freely.

Obs. Chlorine fumigations, although so popular, and so much relied on by many medical practitioners, are apparently useless in preventing the progress of certain contagious diseases. "In Moscow, chlorine was extensively tried and found unavailing, nay even injurious, in cholera." (Dr. Pereira.) "At the time that the cholera hospital was filled with *clouds* of chlorine, then it was that the greatest number of the attendants were attacked." (Dr. Albers.) At the Smallpox Hospital, where chlorine was tried, with the view of arresting the progress of erysipelas, "all offensive smell was removed, but the power of communicating the disease remained behind." (Lond. Med. Gaz.) Notwithstanding these marked failures, the confidence of many eminent members of the profession continues unabated. "As a fumigation agent, disinfectant, and antiseptic, chlorine, I believe, stands unrivalled." "For destroying miasmata, noxious effluvia, and putrid odours, it is the most powerful agent known." (Dr. Pereira.) Our own experience leads us to the conclusion that chlorine is more useful in neutralizing the contagious or morbific matter of fevers (especially of scarlet fever) and putrid diseases generally, than of the other diseases in which it has been employed.

FUMIGATION (Hydrochloric). Syn. *Muriatic Fumigation; Fumigatio Muriatica, F. Acidi Hydrochlorici*,—Lat. *Prep.* From *common salt* placed in a cup or saucer, and an equal weight of *oil of vitriol* poured over it. Now seldom used. It rapidly neutralizes ammoniacal fumes.

FUMIGATION (Iodine). Syn. *Fumigatio Iodinii*,—Lat. From *iodine*, 5 to 25 gr., or more, according to extent of surface, placed on a heated iron contained in a box or case in which the limb is enclosed. In the usual skin diseases in which the use of iodine is indicated.

FUMIGATION (Iodine, — Compound). Syn. *Fumigatio Iodinii Composita*,—Lat. *Prep.* (Sellers.) *Iodine*, 20 gr.; *red sulphuret of mercury*, 40 gr.; *sulphur*, 6 dr.; mix and divide into 12 powders. One to be used, as the last, 3 times daily; in lepra, psoriasis, &c.

FUMIGATION (Mercurial). Syn. *Fumigatio Mercurialis*,—Lat. *Prep.* (Bouchardat.) *Olibanum* (in powder), 2 parts; *red sulphuret of mercury*, 3 parts. A little is sprinkled on red-hot coals or a heated shovel held beneath the part; or the fumes are inhaled. *Obs.* Abernethy used the black oxide of mercury (1½ to 2 dr.), and applied it to the whole body, excepting the

head, in a similar way to the sulphur bath, and continued the application for about a quarter of an hour. See *Candles* (Medicated).

FUMIGATION (Muriatic). See *above.*

FUMIGATION (Nitric). Syn. *Nitrous Fumigation, Nitric Acid do.; Fumigatio Nitrica, F. Nitrosa, F. N. Smythianæ, F. Acidi Nitrici, Suffumigatio cum Acido Nitrico,*—Lat. var. *Prep.* (P. Cod.) *Sulphuric acid* diluted with *half its weight of water*, is placed in a porcelain cup (any shallow vessel of glass or earthenware will do), placed over heated cinders, and small quantities of *powdered nitre* added to it from time to time.

Obs. Heat causes the gas to be evolved more rapidly, and thus renders the fumes more offensive, without increasing their efficacy. Equal weights of *oil of vitriol* and *water* are the proportions usually employed. ¼ *oz.* of *nitre* is said to be sufficient for a small room. (Dr. Bateman.) The vessel containing the ingredients should be placed in an elevated position in the centre of the apartment.

Dr. Carmichael Smyth, who introduced nitric acid gas as a fumigation (1799), received a reward of £5000 from Parliament for publishing his formula.

FUMIGATION (Sulphurous). Syn. *Fumigatio Sulphurosa, F. Sulphuris,*—Lat. *Prep.* 1. The *fumes* of *burning sulphur.*

2. *Flowers of sulphur*, 7 parts; *nitre*, 4 parts; *benzoin* and *olibanum*, of each, 2 parts; *camphor*, 1 part; pressed into the bowls of tobacco pipes, and lighted with a quick-match. See *Baths* and *Disinfectants.*

FUMIGATION (Tar). Syn. *Fumigatio Picea, Suffumigatio Picis Liquidæ,*—Lat. *Prep.* 1. *Vegetable tar*, 1 part; *water*, 7 or 8 parts; mix, and let it simmer in an open vessel set over a spirit-lamp placed near the centre of the apartment.

2. (Sir A. Crichton.) *Norway tar*, 1 *lb.*; *powdered carbonate of potash*, ½ *oz.* or 1 *oz.*; mix, and heat it as last. The potash is added to neutralize any volatile acid. Formerly highly thought of in bronchitis and pulmonary consumption.

FUMIGATION (Toothache). Syn. *Fumigatio Odontalgica, F. Anti-neuralgica,*—Lat. *Prep.* 1. From *henbane seeds*, powdered and thrown into a basin of *boiling water*, and the affected part held in the steam. Sometimes a *little of the seed* is placed in a *heated iron spoon*, and the part exposed to the fumes.

2. (Mr. Beasley.) A popular remedy is to throw *henbane seed* on hot cinders, inverting a cup over them to receive the smoke and empyreumatic oil produced. The cup is then filled with *hot water*, and the steam conveyed to the affected side of the mouth.

FUMING LIQUORS. See *Hydrosulphuret of Ammonia*, the *Chlorides of Antimony, Arsenic*, and *Tin*, *&c.*

FUNGI. See *Mushrooms*, *&c.*

FUNGIC ACID. A peculiar compound obtained by Braconnot from certain fungi —the *boletus juglandis, boletus pseudo-igniarius, phallus impudicus, merulius cantharellus, peziza nigra*, *&c.* It is prepared by boiling the *expressed juice*, filtering, evaporating to the consistence of syrup, and digesting *alcohol* on it, the *residuum* is then dissolved in *water*, and precipitated with *acetate of lead*, and the precipitate, after being washed, decomposed with *dilute sulphuric acid* at a gentle heat; the remaining solution is filtered and evaporated. It occurs as a sour deliquescent mass. Its salts are called *fungates.* The *fungate of ammonia* crystallizes in prisms.

FUNGINE. The *fleshy portion* of *mushrooms*, deprived of soluble matter by digestion in *water* and in *alcohol.*

FUNNEL. See *Filtration.*

FURFURINE. A remarkable organic compound discovered by Fownes. It is *prepared* by boiling *furfurolamide* in a *dilute solution of caustic potassa.* The liquid deposits *furfurine*, on cooling, under the form of small, white, silky needles.

Prop., &c. Scarcely soluble in cold water; soluble in 135 parts of boiling water; freely soluble in both alcohol and ether; inflammable; reaction strongly alkaline; it is powerfully basic; with the acids it forms a series of beautiful crystallizable salts which are intensely bitter. This substance is "the nearest approach to the native alkaloids yet made." *Fucusine* is obtained from the fuci by a like process.

FURFUROLAMIDE. A yellowish-white, crystalline, insoluble substance formed by acting on *furfurole*, for some hours, with *liquor of ammonia.* Water decomposes it slowly, and acids instantly.

FURFUROLE. *Prep.* (Fownes.) *Sulphuric acid*, diluted with an equal bulk of *water*, is carefully mixed with *twice* its weight of *wheat-bran*, and the adhesive pasty mass thus obtained, is exposed, in a proper vessel to the action of a current of steam, which is afterwards condensed by a worm and refrigerator; the distillate holds *furfurole* in solution. By redistillation several times repeated, the first half of the liquor only being collected, it may be extracted from the water, and then by

cautions rectification may be obtained in a state of purity. The *product* is much increased by first depriving the bran of soluble matter by steeping it in a *dilute solution of caustic potassa* and then washing it with *cold water*, and drying it in the sun, or by a gentle heat.

Prop., &c. In appearance and odour it greatly resembles oil of cassia; it distils unchanged; dissolves in all proportions in alcohol, and to some extent in water; it boils at 325° Fahr.; strong acids and alkalies decompose it. Sp. gr. 1·165. *Fucusol* is obtained by a like process from the fuci.

FURNACE. The construction of furnaces belongs to engineering. Some useful information on the subject, in its connection with the laboratory, will, however, be found under the heads—*Chimneys, Evaporation, Fuel, Reverberatory Furnace, Smoke, Steam, &c.*, in this work.

FURNISHING. It is essential for the sake of neatness, and for a pleasing effect to the eye, that there should be a harmony of colours, and also a similarity of style in the main articles of furniture. The tints of the *carpet*, of the *paper* or *paint of the walls*, and of the *window-curtains*, should be all in harmony in each room; that is, either possess a general resemblance of colour, or various colours in pleasing contrast and harmony with each other. If the preponderating colour of the curtains is *scarlet*, and the colour of the walls or carpet *blue*, a most inharmonious and unpleasing effect is produced; but *brown* and *green*, or *green* and *gold*, will be in harmony, and may therefore be placed together. *Carpets* being the most expensive articles, it is safest to buy them first, and then to let their colour guide us in the tone and style of the *curtains*, *paper-hangings*, *chair-covers*, *hearth-rugs*, and the various minor articles. It is also economical to buy carpets of the same pattern for several rooms, because in the event of removal to a house with different sized apartments, a piece of one carpet may be taken to alter the size of another.

FURNITURE. See *Oils, Polishes, Varnishes, &c.*

FURS. Of these the most valuable are *ermine* and *sable*. Fur skins when unprepared, or merely dried, go under the name of *Peltry*. (Brande.)

Furs may be *preserved* from *moths* and other *insects* by placing a little *colocynth pulp* (bitter apples), or *spice* (cloves, pimento, &c.) wrapped in muslin among them; *or* they may be washed in a very weak *solution of corrosive sublimate in warm water* (10 or 15 gr. to the pint), and afterwards carefully dried. As well as every other species of clothing, they should be kept in a clean, dry place.

FUSCINE. A brown colouring matter obtained from *empyreumatic oils*. It possesses no practical interest.

FUSEL OIL. See *Amyle, Distillation*, &c.

FUSIBILITY. The property by which solid bodies assume the liquid state under the influence of heat. See *Melting Point* and *Liquefaction*.

FUSIBLE ALLOYS. Syn. *Fusible Metal*. *Prep.* 1. *Bismuth*, 2 parts; *lead*, 5 parts; *tin*, 3 parts. Melts in boiling water.

2. (D'Arcet's.) *Bismuth*, 8 parts; *lead*, 5 parts; *tin*, 3 parts. Melts below 212° Fahr.

3. (Onion's.) *Lead*, 3 parts; *tin*, 2 parts; *bismuth*, 5 parts. Melts at 197° Fahr.

4. To the last, after removing it from the fire, add of *quicksilver* (warm), 1 part. *Liquid* at 172°; *solid* at 140° Fahr.

Obs. The *first three* of the above are used to make toy-spoons, to surprise children by their melting in hot liquors, and to form pencils for writing on asses' skin, or paper prepared by rubbing burnt hartshorn into it, &c.; also as a metal bath in the laboratory. The *last* is used for anatomical injections.

FUSION. Syn. *Fusio*,—Lat. The liquefaction of solid bodies by the action of heat. The term *aqueous fusion* has been applied to the melting of salts in their combined water when heated; and the term *igneous fusion*, to the liquefaction of bodies by heat alone.

The *vessels* in which substances are *fused* are formed of various materials and shapes, according to the properties of the solid operated on, and principally with reference to the degree of heat required for its fusion. In every case the containing vessel should be capable of sustaining the proper degree of heat, *without* either *melting* or *cracking*, and should also be *unacted on* by the substances melted in them. *Crucibles*, made of very refractory clay, are employed for high temperatures, and *metallic* or *earthenware vessels* for lower ones. See *Crucibles, &c.*

FUSTIC. Syn. *Fustic Wood*. Of this dye-stuff there are two varieties—

Old Fustic (bois jaune). The wood of the *morus tinctoria*. Its decoction dyes WOOLLENS *yellow* of different shades, according to the mordant. *Alum*, *tartar*, and *spirits of tin* brighten the tint; *acetate*

and *sulphate of iron* and *common salt*, darken it; with *sulphate of iron* it gives OLIVES and BROWNS; with the *indigo vat* and *sulphate of indigo* GREEN. These colours are very permanent. Its yellow turns on the LEMON when pale, and on the ORANGE when darker. 1 *lb.* of *old fustic* will dye 3 to 5 *lb.* of wool.

Young Fustic (Yellow Fustic; Fustet). The wood of the *rhus cotinus* or *Venice sumach*. It gives a YELLOW turning on the green, but its colours are not very permanent. It is chiefly used in combination with other dye-stuffs.

GALBANUM. Syn. *Gum Galbanum; Galbanum*,—Ph. L. E. & D. The "gum resin" of "*galbanum officinale?*" (Ph. L.) The "concrete gummy-resinous exudation of an imperfectly ascertained umbelliferous plant; probably a species of *opoidia*." (Ph. E.) Its properties are similar to the other fetid antispasmodic gum-resins. It ranks between assafœtida and ammoniacum.

GALBANUM (Strained). Syn. *Prepared Galbanum; Galbanum Colatum; G. Præparatum*,—Ph. L. From *crude galbanum*, as *prepared ammoniacum*. Formerly the common practice was to melt it in the *dry* state, by heat cautiously and quickly applied, and to strain it through a piece of coarse canvass stretched across a wooden frame or "horse." See *Filtration*. The strained galbanum of the shops is seldom pure. The following forms are current in the trade for its "*reduction*," as this species of adulteration is technically termed:—

1. *Galbanum* (true), 9 *lb.*; strain as above, then add, towards the end, *black resin* (clean), 3 *lb.*; and when the whole is melted, further add of *Venice turpentine*, 2 *lb.* *Product.* 12 *lb.*

2. *Strained galbanum* and *black resin*, of each, 6 *lb.*; melt, and add of *strained assafœtida*, 2 *oz.*; *Venice turpentine*, 3 *lb.* *Prod.* 14½ *lb.*

GALBANUM (Strained,—Factitious). Syn. *Galbanum Colatum Factitium*,—Lat. *Prep.* 1. From *black resin*, 4 *lb.*; melt, and add of *Venice turpentine*, 2 *lb.*; *assafœtida*, 2½ *oz.*; *oils of juniper* and *fennel*, of each, 1½ dr.; *water*, ½ pint.

2. As the last, adding *soft soap*, 5 *oz.* Sometimes the small and "waste" of the chests are added to the above to improve them.

GALACTOMETER. See *Lactometer* and *Milk*.

GALL. Syn. *Bile; Bilis, Fel*,—Lat. A bitter fluid secreted by the liver; in part flowing into the intestines, and in part regurgitating into the gall-bladder. Its uses in the animal economy appear to be—to separate the chyle from the chyme, to promote digestion of oleaginous substances, and to assist in exciting the peristaltic action of the intestines. The fæces appear to owe their colour chiefly to the presence of bile, since without, they appear of a dirty pipe-clay colour.

The *gall* of *various animals* was *formerly* used in medicine. From whatever source it was obtained, it was believed to be calefacient, desiccant, detergent, discutient, and parturifacient; but besides these properties, each variety was conceived to possess virtues peculiarly its own. Thus, *bear-gall* (fel ursi) was reputed anti-epileptic; *eel-gall* (fel anguillarum) parturifacient; *hare-gall* (fel leporis), "good in cataract;" and *ox-gall* (fel bovis), "sovereign against stiff joints, rheumatics, angry ulcers, and stomach colics." The gall of the *bat*, *goat*, *hen*, *hog*, *partridge*, *siluris*, *&c.*, were also employed as remedies. At the present time *ox-gall* is the only one used in medicine and the arts.

Ox-gall has been recently re-introduced into medicine by Dr. Allnatt, and others, and in certain cases of dyspepsia and biliary derangement appears to be superior to all other remedies.

Crude ox-gall is extensively employed by the scourers of woollen cloth, clothes renovators, &c. It rapidly extracts grease and oil from textile fabrics, without injuring the colour. See *Constipation*, *Extracts*, *Indigestion*, *Ox-gall*, *Pills*, *&c.*

GALL (Glass). See *Sandiver*.

GALLATE. Syn. *Gallas*,—Lat. The salts of gallic acid. Those of the *alkalies* are soluble. They rapidly suffer decomposition in the presence of excess of the base, and the liquor gradually acquires a blackish colour. The *gallates* of *cobalt*, *iron*, *manganese*, *nickel*, and *zinc*, are also soluble; the rest are *insoluble*. *Gallate of ammonia* is made by neutralizing 1 part of gallic acid with ammonia; and *supergallate of ammonia*, by adding 1 part of acid more, and crystallizing. *Gallate of lead* is obtained by either adding acetate of lead to a warm solution of gallic acid in excess, or by adding the former to the latter at the boiling point. The first is a *supergallate*, the latter a *basic* salt.

GALLIC ACID. Syn. *Acidum Gallicum*,—Ph. L. & D. The "acid prepared from the gall-nut;" in "crystals." (Ph. L.) It may be also obtained from other vegetable

substances. It appears to be a product of the oxidation of tannic acid, and probably does not exist ready formed in recent vegetables.

Prep. 1. (Dumas.) *Nut-galls*, reduced to powder, are moistened with *water*, and exposed to the action of the air, in a warm situation (say 70° to 80° Fahr.), for 2 or 3 months, adding *more water*, from time to time, to make up for that lost by evaporation. At the end of the above period, the mouldy, dark-coloured mass is strongly pressed in a cloth, and the solid portion boiled in a considerable quantity of *water*. The solution (filtered whilst hot), deposits on cooling, crystals of gallic acid, which after being thoroughly drained and pressed dry between bibulous paper, are purified by boiling them along with about $\frac{1}{6}$th of their weight of *prepared animal charcoal*, in 8 parts of *water*, and filtering, &c., as before.

2. (Graham.) A *strong infusion* or *decoction of galls* is precipitated with *sulphuric acid*, in the cold; the resulting thick mass is mixed with *dilute sulphuric acid* (cold), and the liquid expressed; the marc is next treated with *sulphuric acid*, diluted with twice its weight of *water*, and after boiling the mixture for some minutes, the whole is allowed to cool; the resulting crystals are purified as before.

3. (Liebig.) A strong *aqueous solution of tannic acid* (tannin) is added to *sulphuric acid*, as long as a precipitate falls; the powder is collected, washed, and dissolved by the aid of heat in *dilute sulphuric acid;* the solution after being boiled for a few minutes, deposits, on cooling, *crystals of gallic acid* in considerable quantity.

4. (Scheele.) A filtered *decoction of galls* is exposed for some months in an open vessel; after a time it grows mouldy, and becomes covered with a thick glutinous pellicle; in two or three months, the sides of the vessel and the under portion of the pellicle is found to be covered with small yellow crystals of gallic acid, which are purified as directed above. (See No. 1.)

5. (Ph. D.) The Dublin Ph. contains two formulæ for gallic acid, the one being based on that of Dumas or Scheele; the other, on that of Graham or Liebig.—*a.* From *galls* (in coarse powder), 1 *lb.; water*, q. s. to make a stiff paste; a porcelain dish is ordered, and the exposure in the moistened condition is to be continued for 6 weeks; the solution of the first crop of crystals is to be made in 10 fl. oz. of *boiling water*, and when the filtrate has cooled to 80° Fahr., it is to be poured off from the crystals which have formed, which are then to be washed with *ice-cold water*, 3 fl. oz., and dried,—first in blotting paper, and finally by a steam or water heat. By boiling the undissolved portion of the galls with 45 fl. oz. of *fresh water*, more crystals may be obtained.

b. Powdered *gall-nuts*, 1 *lb.;* are steeped for 24 hours in *water*, 1 pint, and after being placed in a porcelain displacement apparatus, are treated with *water*, 1½ pint, added in successive portions; *oil of vitriol*, 5 fl. oz., diluted with an equal volume of *water*, and allowed to cool, is now added to the percolated infusion, and after thorough admixture, the liquid is filtered from the viscid precipitate which forms; *oil of vitriol*, 5 fl. oz. (diluted as before), is then added to the filtrate; the precipitates, enveloped in calico, are submitted to powerful pressure, and subsequently dissolved in *oil of vitriol*, 16 fl. oz., previously diluted with *water*, 56 fl. oz.; the solution is boiled for 20 minutes, and set aside for a week; at the end of this time the deposit which forms, is dissolved in *three times* its weight of *boiling water*, and the solution treated as before.

Prop. Gallic acid forms small, feathery, and nearly colourless crystals, which have a beautiful silky lustre; that of commerce is usually of a pale yellow colour; it is soluble in 100 parts of *cold* water, and in 3 parts of *boiling* water; it is also soluble in alcohol, and *slightly* so in ether; the aqueous solution is decomposed by exposure to the air; dissolved in hot oil of vitriol, it forms a deep, rich, red solution, which when thrown into water, drops the gallic acid, deprived of some of its water. This substance is soluble in the alkalies, and dyes cloth like madder. When strongly heated, gallic acid is converted into *metagallic acid*, *pyrogallic acid*, &c.

Tests. Gallic acid is distinguished from *tannic acid* by not affecting solutions of gelatin, the protosalts of iron, or the salts of the alkaloids, and by giving a deep bluish-black precipitate with the sesquisalts of iron, which disappears when the liquid is heated. It is distinguished from *pyrogallic acid* by its inferior solubility in water, and by its *not* affecting the solutions of the protosalts of iron. To detect *gallic acid* mixed with *tannic acid*, the latter should be removed, either by digesting the substance in ether, or by immersing for some time in its solution a piece of skin depilated by lime, previously to applying the tests.

Pur. "Free from colour; decomposed by heat; soluble in water, and in rectified

spirit. It turns preparations of the sesquioxide of iron, dissolved in water, of a bluish-black colour, but throws down nothing from a solution of isinglass." (Ph. L.)

Uses, &c. The principal use of pure gallic acid is in the art of photography. It has recently been employed in *medicine*, as an internal astringent, in *doses* of 3 to 10 gr., thrice a day, or oftener; in hemorrhage and fluxes, as well as for checking the night sweats in phthisis. Dr. Todd says, that in all cases of internal hemorrhage, or hemorrhagic tendency, it is the best astringent or styptic we possess. As an *external* astringent, it is greatly inferior to tannic acid. It has been given in doses of 15 to 30 gr. in tape-worm, "but without any benefit." (Pereira.)

Obs, Gallic acid, as obtained by either of the above forms, is never quite pure; but it may be rendered *absolutely pure* by combining it with oxide of lead, and decomposing the compound (*gallate of lead*) by sulphuretted hydrogen. The sulphuret of lead acts like animal charcoal in removing the colour. (Liebeg.) Commercial gallic acid "may be rendered nearly white by dissolving it in 20 times its weight of *boiling distilled water*, and causing the solution to traverse a stratum of *prepared animal charcoal* spread upon a calico filter. When the liquid passes through colourless, it should be evaporated to 1-6th its volume, and then suffered to cool, in order to the separation of the crystallized acid." (Ph. D.)

GALLIC FERMENTATION. This name has been given to the peculiar process by which *tannic acid* is converted into *gallic acid*, under the joint influence of moisture and atmospheric oxygen. According to the researches of M. Antoine Larocque, the peculiar ferment of nut-galls which operates this change, also converts sugar into alcohol and carbonic acid, in the same way as yeast does; whilst beer yeast, muscular flesh, and caseous matter, change tannin into gallic acid. The similarity of the gallic and vinous fermentation may hence be reasonably inferred.

GALLS. Syn. *Gall-nuts, Nut-galls; Galla*, —Ph. L. & D. *Gallæ*,—Ph. E. "A swelling of the small twigs of" the "*quercus infectoria*," "excited by the cynipe gallæ tinctoriæ" or gall fly. (Ph. L.) The best galls are "bluish-black, heavy," and "not yet perforated," (Ph. L.) They are imported from Aleppo, and are known in commerce as *black* or *blue galls* (gallæ nigræ, g. cœruleæ). The next quality is termed, from their colour, *green galls* (gallæ virides). Both are gathered before the insect has escaped, and are styptic and powerfully astringent. *White galls* (gallæ albæ) are lighter, less astringent, and inferior.

Uses, &c. Galls are extensively employed in the art of dyeing, and constitute one of the principal ingredients in all the shades of black, and are also employed to fix or improve several other colours. A decoction of galls, to which a little green copperas and gum arabic has been added, forms common writing ink. In *medicine* they are used as an astringent, in hemorrhages and fluxes, in *doses* of 10 to 20 gr.; and *topically*, under the form of infusion or decoction, as a gargle in relaxation of the uvula; as an injection in gleet and leucorrhœa; as a lotion or fomentation in flabby ulcers, prolapsus ani, &c.; and as an ointment in piles, watery ulcers, &c. The infusion or decoction is also used as an antidote to poisoning by the alkaloids, and was formerly given as a tonic in intermittents. See *Gallic Acid*, *Ink*, *&c.*

GALLSTONE. Syn. *Calculus Biliosus, C. Cysticus Bovinus*,—Lat. Formed in the gall-bladder of *neat cattle* in winter, when they are fed upon dry food. *Used* as a yellow pigment, and in medicine. *Dose.* 1 gr. in dyspepsia and flatulency.

GALVANIC BATTERY. See *Voltaic Battery.*

GALVANISM. See *Voltaic Electricity.*

GALVANIZED IRON. See *Iron* and *Zincing.*

GALVANO-PLASTIC. See *Voltatype.*

GAMBOGE. Syn. *Cambogia, Gambogia*, —Lat. "The gum-resin" from "uncertain species of *garciniæ*." (Ph. L.) Gamboge is an active hydragogue and drastic purgative, which occasionally proves useful in torpor of the abdominal and pelvic viscera; but which is highly dangerous in an irritable or inflammatory state of the stomach or bowels, and during pregnancy. It is very apt to induce nausea and vomiting. In large quantities it is a *violent poison.* "The deaths which have occurred from the use of enormous quantities of Morrison's pills, are mainly ascribable to the gamboge contained in those medicines." (Pereira.) *Dose.* 1 to 5 gr., made into pills or mixture, every 4 to 6 hours; in obstinate constipation, in dropsies, in apoplexy and like cerebral affections, and in worms (especially tape-worm), either alone or combined with other cathartics. See *Compound Extract of Colocynth* (and *below*).

GAMBOGIC ACID. Syn. *Gambodic Acid, Gamboge Resin; Acidum Cambogicum*,—Lat. From the *ethereal tincture of gamboge* abandoned to spontaneous evaporation. It forms orange-coloured scales, or a

deep cherry-red resinous mass, which is insoluble in water, very soluble in ether and in alcohol, giving an appreciable yellowness to fully 10,000 times its weight of the latter. With the caustic alkalies it forms dark red-coloured solutions (*alkaline gambogiates*), from which the *gambogic acid* is precipitated unchanged by the stronger acids. Added to a solution of acetate of lead, it throws down a yellow *gambogiate of lead*, and from solutions of the salts of *iron* and *copper*, *gambogiates* of those metals. Its physiological properties are similar to those of gamboge, but much milder and more certain. In *doses* of 3 to 5 gr. it produces copious liquid discharges from the bowels, without pain or inconvenience.

GANGRENE. See *Mortification.*

GANTEINE. A composition used to clean kid and other leather gloves.

Prep. 1. (M. Buhan.) *Curd soap* (in small shavings), 1 part; *water*, 3 parts; mix with heat, and stir in of *essence of citron*, 1 part.

2. (*Saponine*,—M. Duvignau.) *Soap* (in powder), 250 parts; *water*, 155 parts; dissolve with heat, cool, and add of *eau de javelle*, 165 parts; *liquor of ammonia*, 10 parts; and rub the whole to a smooth paste. Patent. A small portion of either of the above is rubbed over the glove with a piece of flannel (always in one direction), until it is sufficiently clean. See *Gloves.*

GARANCINE. See *Madder Red.*

GARDENING. The art of cultivating a garden. It is divided into—"*horticulture*, which comprehends the cultivation of culinary vegetables and fruits;—*floriculture*, which includes the culture of ornamental and curious flowers, shrubs, and trees;—*arboriculture*, which implies the culture of trees and shrubs used for various purposes in the arts and in general economy;—and *landscape gardening*, or the general distribution of the scenery or landscape about a country residence." (Loudon.) Our space precludes a lengthened notice of this subject. Several matters intimately connected with it in its various applications, will be found in this work, under the respective heads.

GARGLE. Syn. *Gargarism*, *Throat-wash*; *Gargarisma*, *Gargarismus*, *Gargarismum*,—Lat. A liquid medicine applied to the back part of the mouth or upper part of the throat. Gargles are applied by allowing a small mouthful, to run as much possible over the affected part, by holding the head backwards, and breathing through it, by which means the liquid is agitated and its action promoted.

Gargles are *not to be swallowed.* It often happens, however, that patients, either by accident or from negligence, do swallow a certain quantity, notwithstanding the instructions given them to the contrary. Care should therefore be taken to avoid making gargles of such substances as may occasion unpleasant symptoms in small doses, though they may not, perhaps, amount to poisoning.

Gargles usually have for their basis either *simple water*, or *milk*, *wine*, or *vinegar*, diluted with *water*, to which, in both cases, *sugar*, *honey*, or *syrup*, is generally added. Their other ingredients vary with the indication, but must, in all cases, be either in the liquid form, or soluble in the liquid used as the excipient.

Gargles are commonly "*dispensed*" in mixture bottles. The quantity used at a time, under ordinary circumstances, may be about 2-3rds of a wine-glassful.

GARGLE. Syn. *Gargarisma*, *G. Commune*, *G. Simplex*,—Lat. *Prep.* (St. B. Hosp.) *Honey* or *honey of roses*, 1½ oz.; *strong vinegar*, 2½ fl. oz.; *barley water*, 1 pint. In common sore throats, &c. The formulæ of several other hospitals are similar.

GARGLE (Acetate of Ammonia). Syn. *Gargarisma Ammoniæ Acetatis*, — Lat. *Prep.* (Wendt.) *Solution of acetate of ammonia* and *honey of roses*, of each, 1 oz.; *elder-flower water*, 8 fl. oz.; mix. In the ulcerated sore-throat of scarlet fever.

GARGLE (Alum). Syn. *Gargarisma Aluminis*, — Lat. *Prep.* 1. (Augustin.) *Oak-bark* (in powder), 1 oz.; *water*, 1½ pint; boil to a pint, filter, cool, and add of *alum*, ½ dr.; *brandy*, 2 fl. oz. In inflammation of the mouth and throat.

2. (Cavarra.) *Alum*, 3 dr.; *water*, 6 fl. oz.; dissolve. In offensive breath.

3. (Foy.) *Alum*, 1 dr.; *tincture of myrrh*, 2 dr.; *tincture of bark*, 4 dr.; *honey of roses*, 2 oz.; *laudanum*, 20 drops; *wine*, ¾ pint. In scurvy.

4. (Grant.) *Alum*, 1 oz.; *tincture of myrrh*, ½ fl. oz.; *peppermint water*, 7 fl. oz. In relaxation of the uvula, &c.

5. (Mid. Hosp.) *Alum*, 1 dr.; *water*, 6 fl. oz. As No. 4.

6. (P. Cod.) *Alum*, 40 gr.; *honey of roses*, 1 oz.; *infusion of roses*, 6 fl. oz. As the last.

7. (Ratier.) *Alum*, 1 oz.; *infusion of red roses* and *barley water*, of each, 3 fl. oz.; *honey of roses*, 2 oz. As No. 4.

8. (Ph. Wirtem.) *Alum* and *nitre*, of each, 3 oz.; *cream of tartar*, 4 oz.; dilute *acetic acid*, 4 lb; dissolve, evaporate to dry-

ness, and powder the residuum. For *use*, ½ oz. of the powder, is dissolved in *water*, 8 fl. oz. Highly recommended in inflammation of the fauces and tonsils. This forms Zobel's *Specific for quinsy*.

GARGLE (Antiscorbutic). Syn. *Gargarisma Antiscorbuticum*, — Lat. *Prep.* (P. Cod.) *Bitter species*, 1 dr.; *boiling water*, 8 oz.; macerate 1 hour, strain, and add *syrup of honey*, 2 oz.; *antiscorbutic tincture*, 1 oz.

GARGLE (Antiseptic). Syn. *Gargarisma Antisepticum*, — Lat. *Prep.* (Fr. Hosp.) *Decoction of bark*, 6 oz.; *camphor*, 20 gr.; *sal ammoniac*, 12 gr. In putrid sore throat, &c.

GARGLE (Astringent). Syn. *Gargarisma Astringens*,—Lat. *Prep.* 1. (Collier.) *Tincture of galls*, 2 fl. dr.; *honey*, ½ oz.; *water*, 6 fl. oz. In relaxation of the uvula and fauces.

2. (Collier.) *Honey*, 4 dr.; *tincture of myrrh*, 3 dr.; *powdered alum*, 40 gr.; *compound infusion of roses*, 5½ fl. oz. As the last, and in fetid sore throat.

3. (Sir A. Cooper.) *Alum*, 2 dr.; *decoction of bark*, 12 oz.; *honey of roses*, 1½ oz.

4. (Dr. A. T. Thomson.) *Infusion of roses*, 7 fl. oz.; *dilute sulphuric acid*, 1 fl. dr.; *tincture of catechu*, 6 fl. dr.; *laudanum*, 1½ fl. dr. For relaxation of the uvula.

GARGLE (Borax). Syn. *Gargarisma Boracis*,—Lat. *Prep.* 1. (Ellis.) *Borax*, 1 dr.; *tincture of myrrh*, 4 fl. dr.; *clarified honey*, 1 fl. oz.; *rose water*, 4 fl. oz.

2. (Fr. Hosp.) *Borax*, 2 dr.; *honey* or *capillaire*, 1 oz.; *rose water*, 7 fl. oz.

3. (Guy's Hosp.) *Borax*, 2 dr.; *honey of roses*, 1 oz.; *barley water*, 7 fl. oz.

4. (Mid. Hosp.) *Borax*, 2 dr.; *simple oxymel*, ½ fl. oz.; *water*, 11½ fl. oz. The above are used in thrush or aphthous sore mouth, ptyalism, &c.

GARGLE (Capsicum). Syn. *Gargle of Cayenne Pepper*; *Gargarisma Capsici*,—*Prep.* 1. (Dr. Griffith.) *Tincture of capsicum*, ½ fl. oz.; *rose water*, 8 fl. oz.

2. (St. B. Hosp.) *Capsicum*, 3 dr.; *common salt*, 1 oz.; *boiling water*, 1 pint; macerate for 12 hours, strain and add of *distilled vinegar*, 1 pint.

3. (U. C. Hosp.) *Tincture of capsicum*, 1 fl. dr.; *vinegar*, 1 fl. oz.; *water*, 6 fl. oz. *Used* in ulcerated sore throat, scarlet fever, &c.

GARGLE (Chlorate of Potassa). Syn. *Gargarisma Potassæ Chloratis*,—Lat. *Prep.* (Beasley.) *Chlorate of potassa*, 1 dr.; *honey of roses*, 1 oz.; *water*, 7 oz.

GARGLE (Chlorate of Soda). Syn. *Gargarisma Sodæ Chloratis*,—Lat. *Prep.* (Radius.) *Chlorate of soda*, 40 gr.; *honey of roses*, 1 oz.; *water*, 3 fl. oz. Both the above are used in malignant sore throat, scarlatina, &c.

GARGLE (Chloride of Lime.) Syn. *Gargarisma Calcis Chlorinatæ*,—Lat. *Prep.* From *chloride of lime*, 1 dr.; *water*, ½ pint; agitate together for 10 minutes, filter through linen, and add of *simple syrup*, 1 fl. oz. *Used* in putrid sore throat, scarlet fever, &c.

GARGLE (Chloride of Soda). Syn. *Gargarisma Sodæ Chlorinatæ*,—Lat. *Prep.* (Copland.) *Liquor of chloride of soda*, 12 fl. dr; *honey*, ½ oz.; *water*, 6 fl. oz. *Used* as the last.

GARGLE (Chlorine). Syn. *Gargarisma Chlorinii*,—Lat. *Prep.* 1. (Fr. Hosp.) *Chlorine water*, ½ fl. oz.; *syrup*, 1 fl. oz.; *water*, 4½ fl. oz.

2. (Mid. Hosp.) *Chlorine water*, 2 fl. oz.; *distilled water*, 10 fl. oz. *Use.* As the last.

GARGLE (Cinchona Bark). Syn. *Gargarisma Cinchonæ*,—Lat. *Prep.* From *decoction of cinchona*, 7 fl. oz.; *simple oxymel*, 1 fl. oz. Antiseptic and astringent; in relaxation, &c.

GARGLE (Common). Syn. *Gargarisma Commune*,—Lat. *Prep.* 1. (Ed. Hosp.) *Water*, 6 fl. oz.; *nitre*, 1 dr.; *honey of roses*, 1 oz. For ordinary sore throat, &c.

2. Instead of *nitre* use *borax*, 2 dr. See *Gargle* (above).

GARGLE (Cyanide of Mercury). Syn. *Gargarisma Hydrargyri Cyanidi*,—Lat. *Prep.* (Brera.) *Cyanide of mercury*, 10 gr.; *honey of roses*, 1 oz.; *barley water*, 1 pint.

2. (Cullerier.) *Cyanide of mercury*, 10 gr.; *linseed tea*, 1 pint. *Used* in the same cases as mercurial gargle.

GARGLE (Detergent). Syn. *Gargarisma Detergens*,—Lat. *Prep.* 1. (P. Cod.) *Alcoholized sulphuric acid*, 1 dr.; *honey of roses*, 2 oz.; *barley water*, 8 oz.

2. (Dr. A. T. Thomson.) *Nitre*, 2 dr.; *honey of roses*, 4 fl. dr.; *infusion of roses*, 5½ fl. oz. In inflammatory sore throat.

GARGLE (Emollient). Syn. *Gargarisma Emolliens*,—Lat. *Prep.* 1. (Buchan.) *Marsh-mallow root*, 1 oz.; *figs*, 2 oz.; *water*, 1 quart; boil to a pint and strain. Demulcent; soothing.

2. (Trousseau & Reveil.) *Barley water*, 8 oz.; *honey*, 1½ oz. Both are used in inflammatory affections of the throat and mouth.

GARGLE (Horseradish). Syn. *Gargarisma Armoraciæ*,—Lat. *Prep.* (Collier.) *Compound spirit of horseradish*, 1 fl. oz.; *honey*, 2 oz.; *water*, 4 fl. oz. A good gar-

gle for scurvy of the fauces and pharynx, vulgarly called the *inward scurvy*.

GARGLE (Hydrochloric Acid). Syn. *Muriatic Acid Gargle; Gargarisma Acidi Hydrochlorici*,—Lat. *Prep.* 1. (Guy's Hosp.) *Hydrochloric acid*, 30 drops; *honey of roses*, 2 oz.; *barley water*, 6 fl. oz.

2. (Ratier.) *Hydrochloric acid*, 2 fl. dr.; *clarified honey*, 2 fl. oz.; *barley water*, 1 pint.

3. (St. B. Hosp.) *Red-rose leaves*, 2 dr.; *boiling water*, 1 pint; *hydrochloric acid*, 1½ fl. dr.; digest 1 hour, and strain. In inflammatory sore throat, ulcerations of the mouth, scarlet fever, &c.

GARGLE (Iodine). Syn. *Gargarisma Iodinii*,—Lat. *Prep.* 1. *Iodine*, 10 gr.; *iodide of potassium*, 12 gr.; *rectified spirit* and *simple syrup*, of each, 1 fl. oz.; *water*, 5 fl. oz. In chronic enlargement of the tonsils, in scrofulous habits.

2. (Dr. Ross.) *Tincture of iodine*, 1½ fl. dr; *tincture of opium*, 1 fl. dr.; *water*, 6 fl. oz. In ulceration of the tonsils.

GARGLE (Mercurial). Syn. *Gargarisma Hydrargyri, G. Mercuriale*, — Lat. *Prep.* 1. (G. Hyd. Bichloridi.) *Corrosive sublimate*, 2 to 5 gr.; *barley water*, 1 pint; *honey of roses*, 2 fl. oz. For syphilitic ulcers in the throat.

2. (Plenck.) *Calomel*, 6 gr.; *quicksilver*, 30 gr.; *powdered gum*, 3 dr.; *syrup of poppies*, ½ oz.; triturate till the globules of metal disappear, and add of *decoction of clematis*, 26 fl. oz.; *honey of roses*, 1 oz.; *essence of myrrh*, 1 dr., (or *tincture of myrrh*, 1 fl. oz.) In syphilitic and putrid sore throat.

GARGLE (Myrrh). Syn. *Gargarisma Myrrhæ*,—Lat. *Prep.* 1. (Ainslie.) *Tincture of myrrh*, 6 fl. dr.; *vinegar*, 1 fl. dr.; *honey of roses*, 1½ fl. oz.; *barley water*, 12 fl. oz.

2. (Ph. Chirur.) *Tincture of myrrh*, ½ oz.; *honey of roses*, 1½ oz.; *lime water*, 6 fl. oz, In scarlatina and putrid sore throat.

GARGLE (Nitre). Syn. *Gargarisma Salis Nitri, G. Potassæ Nitratis*, — Lat. *Prep.* 1. *Nitre*, 2 dr.; *honey* or *syrup*, ½ oz.; *rose water*, 5½ fl. oz.

2. (*Brande.*) *Nitre*, 2 dr.; *oxymel*, 1 fl. oz.; *barley water*, 7 fl. oz. In inflammatory sore throat.

GARGLE (Oak-bark). Syn. *Gargarisma Corticis Quercûs*,—Lat. *Prep.* 1. *Oak-bark*, 2 dr.; *boiling water*, 6 fl. oz.; macerate 1 hour and strain.

2. (Ellis.) *Decoction of oak-bark*, 1 pint; *alum*, ½ dr.; *brandy*, 2 fl. oz. In chronic sore throat, relaxation of the uvula, &c.

GARGLE (Pellitory). Syn. *Gargarisma Pyrethri. Prep.* 1. *Pellitory root*, 4 dr.; *water*, 16 fl. oz.; boil to 8 fl. oz., and add of *liquor of ammonia*, 2 fl. dr.

2. (Swediaur.) *Infusion of pellitory*, 1 pint; *vinegar*, 3 fl. oz.; *sal ammoniac*, 3 dr. To promote the maturation and healing of throat ulcers.

GARGLE (Roses). Syn. *Gargarisma Rosæ, G. Rosarum*,—Lat. *Prep.* (Kendrick.) *Conserve of roses*, 3 oz.; *boiling water*, 16 fl. oz.; infuse 1 hour; add of *dilute sulphuric acid*, 2 fl. dr., and strain. Antiseptic; astringent; *used* in several indications.

GARGLE (Spirit). Syn. *Gargarisma Spiritûs Vini*,—Lat. *Prep.* (Dr. Watson.) *French brandy*, 1 fl. oz.; *water*, ¼ pint. In relaxations and salivation.

GARGLE (Stimulant). Syn. *Gargarisma Stimulans*,—Lat. *Prep.* (Dr. Copland.) *Infusion of roses*, 6½ fl. oz.; *dilute hydrochloric acid*, 40 drops; *tincture of capsicum*, 1½ fl. dr.; *honey*, 3 dr. See *Gargle of Capsicum*.

GARGLE (Tannin). Syn. *Gargarisma Acidi Tannici*, — Lat. *Prep.* 1. (Beral.) *Tannin*, 1 dr.; *honey of roses*, 2 oz.; *rose water*, 2 fl. oz.; *distilled water*, 8 fl. oz.

2. (Jannart.) As the last, but using only *half* the quantity of tannin. In salivation and aphthous ulcerations.

GARGLE (Verdigris). Syn. *Gargarisma Æruginis, G. Cupri Acetatis*,—Lat. *Prep.* (Guy's Hosp.) *Oxymel of verdigris*, 4 dr.; *honey of roses*, 2 oz.; *barley water*, 3½ fl. oz. *Used* as a detergent for ulcers in the throat. If swallowed it produces violent vomiting. The addition of 2½ oz. of water to the above, produces a gargle sufficiently strong for most cases.

GARGLE (Vinegar). Syn. *Oxymel Gargle; Gargarisma Aceti, G. Acidi Acetici*,—Lat. *Prep.* (St. B. Hosp.) *Barley water*, 12 fl. oz.; *acetic acid*, 1½ fl. oz.; *honey*, 6 dr. Antiseptic. For ordinary sore throat.

GARGLE (Zinc). Syn. *Gargarisma Zinci, G. Z. Sulphatis*,—Lat. *Prep.* (Dr. Copland.) *Sulphate of zinc*, 20 gr.; *oxymel*, 1 fl. oz.; *rose water*, 7 fl. oz. In aphthous sores, relaxations, ulceration of the tonsils, &c.

GARLIC. Syn. *Allium*,—Lat. The *allium sativum* of Linnæus. It is diaphoretic, diuretic, expectorant, stimulant, and tonic; and *externally*, irritant, rubefacient, and even vesicant. *Dose.* ½ dr. to 1½ dr.; in enfeebled digestion, chronic diarrhœa, old chronic coughs, atonic dropsies, and worms. An antispasmodic and counter-

irritant liniment is made of the juice, which was formerly esteemed in chest diseases and infantile convulsions. A small clove of garlic, or a few drops of the juice, was formerly introduced into the ear in certain forms of deafness. As a *condiment*, its properties resemble those of the onion, than which it is much more powerful.

GARNET. The finest specimens of "noble garnet" (*Syrian* or *Oriental garnet*) are brought from Pegu. According to chemical analysis, the garnet is a double silicate of alumina and lime, coloured with about $4\frac{0}{0}$ of oxide of iron.

GARNET (Factitious). See *Pastes, Enamels, &c.*

GARUM. A species of pickle prepared of *fish*, in a state of incipient putrefaction, strongly *salted*, and seasoned with *aromatics*. According to Pliny, the Romans used a species of lobster for this purpose.

GAS. Any aëriform or permanently elastic fluid, excepting the compound of oxygen and nitrogen, constituting the atmosphere, to which, in English, the term *air*, is exclusively appropriated. The principal gases are—*ammonia, carbonic acid, carbonic oxide, carburetted hydrogen, chlorine, hydrochloric acid, hydrogen, nitrogen, oxygen, ozone, phosphuretted hydrogen, protoxide of nitrogen, sulphuretted hydrogen*, and *sulphurous acid*. See these substances under their respective heads.

GAS (Coal). Syn. *Light Gas*. Obtained from coal by distillation in iron cylinders or retorts. This gas is a compound of carburetted and bicarburetted hydrogen, more or less pure; its value for the production of light depending on the latter. Good coal gas ought to contain $13\frac{0}{0}$ by measure of bicarburetted hydrogen, and have the sp. gr. 0·650, air being 1; but, as prepared at the gasworks, it varies from about 0·550 to 0·420. The poorest gas made in England was, until very recently, that of the metropolis, which had the average sp. gr. 0·412. The best is that made by the "Liveryool New Gas Company," which has the sp. gr. 0·580. (Hedley.) Owing to the "agitation" on the subject, the opposition of rival companies, and the exposures made by the official chemist, the quality of the gas consumed in the city of London has been greatly improved during the last 2 or 3 years. It is still, however, far from possessing that purity and illuminative power which the public have a right to expect.

It has been proposed to *increase* the *illuminating power* of *ordinary coal gas*, or even *water gas*, and *light carburetted hydrogen*, by passing them through sponges or over trays containing *mineral naphtha* or *benzole*; and a patent has been taken out for this purpose. The gas so treated imbibes or dissolves a portion of the liquid, and burns with increased brilliancy. The method of saturating the gas with the liquid hydrocarbon is as follows:—"The apparatus consists of a brass reservoir or chamber attached to the end of the gas-pipe, near the burner. This reservoir may be in the shape of an oil-flask, made air-tight, with a screw-joint, or other means of supplying any highly volatile oil, turpentine, or mineral naphtha, and should be kept about half full. Into this reservoir the gas-pipe ascends a little above the surface of the oil; a very small jet-pipe of gas, regulated by a stop-cock, is branched off below this chamber, to supply a minute flame, so as to cause a sufficient evaporation from the oil to unite with the gas in the flask receiver. The whole is of course surmounted with the usual burner and lamp glass."

The *illuminating power* of *gas*, as well as of other sources of light, may be directly ascertained by what is termed the "*comparison of shadows*," or indirectly, and more conveniently, by chemical analysis. See *Illumination, Smoke, Ventilation, &c.*

GAYACINE. Resin of guaiacum.

GAZOGENE. Syn. *Ærating Machine*. Under these names several ingenious modifications of what chemists call "Nooth's apparatus" have been recently brought before the public. The "*aerated-water machine*" of Mr. Masters is, however, preferable to *all* others, from the total absence of easily oxidizable metals in its construction. By this simple and inexpensive instrument, *water, wine, ale, &c.*, of the most vapid description, may in a few minutes be fully saturated with carbonic acid gas, and restored to more than its original briskness and piquancy,—to a condition, indeed, not inferior in this respect, to the choicest samples of champagne. By using *fruit syrups*, manufactured from English and foreign fruits, the most delicious aerated summer beverages can be made, resembling those so much esteemed by travellers in the South of Europe, and the sea-bord cities of the Western world. But it is not only in connexion with the *luxuries* of *our households* that this machine must be regarded. Its services in the promotion of *hygiene* and *domestic medicine* are equally important. By its aid that now very expensive, though useful preparation, *fluid magnesia*, may be prepared at the rate of *one penny a quart*,—its present price is 3*s.* 6*d.* In like manner, the various

carbonated saline waters (potash water, soda water, Carara water, &c.) may be made at the rate of *four glasses* a *penny*, and that of equal quality to the best bottled; whilst, when flat, they lack that insipidity and taste of the cork, which is common with all these beverages purchased at the shops.

GEINE. Syn. *Geic Acid.* The name given by Berzelius to the soluble brown matter of vegetable mould. According to Braconnot it resembles ulmin. See *Humic Acid.*

GELATIGENOUS or *Gelatinous principles*, are those alimentary substances which do not contain proteine, and which furnish a jelly, when boiled with water. See *Food*, *Gelatine*, *&c.*

GELATINE. Syn. *Gelatin; Gélatine*, *Grenetine*,—Fr. *Gelatina*,—Lat. Animal jelly, obtained by the action of heat on the organic tissue of the bones, tendons, and ligaments, the cellular tissue, the skin, and the serous membranes, whilst in contact with water. *Glue* and *size* are coarse varieties of gelatine, prepared from hoofs, hides, skins, &c.; and *isinglass* is a purer kind, obtained from the air-bladders and some other membranes of fish.

Prop., &c. Gelatine is insoluble in cold water, but dissolves with greater or less readiness on the application of heat, according to the source whence it is obtained, and in this state forms a tremulous and transparent jelly on cooling; it is insoluble in both alcohol and ether; and is decomposed by the strong alkalies and acids; with tannin it forms *leather;* when acted on by sulphuric acid, it yields *glycicoll* or *gelatine sugar;* and when treated with alkalies it yields *glycicoll* and *leucine*. Chlorine passed into a solution of gelatine occasions a dense white precipitate (*chlorite of gelatine*), which ultimately forms a tough, elastic, pearly mass, somewhat resembling fibrine.

Tests. Its aqueous solution is recognised as follows:—1. It gelatinizes on cooling.—2. It is precipitated by alcohol.—3. Bichloride of mercury gives a whitish flocculent precipitate.—4. A solution of tannin or infusion of galls gives a copious yellowish-white, curdy precipitate, which, on being stirred, coheres into an elastic mass, insoluble in water, and incapable of putrefaction, and which, when dried, assumes the appearance of over-tanned leather.—5. The gelatinizing property is destroyed by nitric acid.—6. It is not affected by either alum or the acetates of lead. In this respect it differs from *chondrine.*

Qual. The goodness of commercial gelatine intended for food, is readily proved by pouring *boiling* water over it, and digesting the two together for a short time. If it is pure and wholesome, its colour remains unaltered, and during its solution it continues entirely free from smell. The resulting solution and jelly are also odourless, neutral to test paper, free from unpleasant taste, and perfectly transparent. If it forms a yellow gluey-looking mass, and evolves an offensive odour, it should be rejected as of inferior quality, and unfit for culinary purposes.

Uses, &c. These are too well known to require a separate notice here. As an article of diet, gelatine appears to be highly nutritious when combined with other food abounding in proteine matter; but *alone*, it appears that, notwithstanding the opinion of ages to the contrary, it is *incapable* of *supporting life.* The commendation of it as an alimentary substance has been too general and lavish, and has led to its employment as an article of diet for the sick, in cases in which it is manifestly improper. "Gelatine may be considered as the least perfect kind of albuminous (?) matter existing in animal bodies; intermediate, as it were, between the *saccharine principles* of *plants*, and *thoroughly developed albumen.* Indeed, gelatine in animals may be said to be the counterpart of the saccharine principle of plants; it being distinguished from all other animal substances by its ready conversion into a sort of sugar, by a process similar to that by which starch may be so converted." (Prout.) The similarity of composition between the *gelatine* and *albumen*, as shown by chemical analysis, is not to be taken as evidence of the existence of like properties; since *gelatine*, in reality more nearly resembles *sugar* than *albumen.* It has *none* of the properties of a compound of proteine. It neither yields proteine when acted on by potassa, nor does it produce a purple colour with hydrochloric acid. (Liebig.) Animals fed exclusively on gelatine *die* of *starvation.* For as gelatine contains no *proteine* it cannot yield *albumen*, *fibrine*, or *caseine*, substances necessary to the composition and support of animal bodies. Blood cannot be produced from gelatine alone; for it does not contain its most essential ingredient. But when *mixed with other food*, especially with *compounds of proteine*, or substances abounding in albumen, caseine, or fibrine, gelatine may be useful as an aliment, and serve directly to nourish the gelatinous tissues. (Liebig.) Hence gelatine is a fitting substance to form part (but only a part) of the diet of con-

valescents, as it conveys nutrition directly to these tissues, without tasking the diminished powers of life for its conversion; but its use should be accompanied by a proper quantity of azotized animal food, to supply the elements to the blood, for the support and increase of the muscular tissue, or fleshy portion of the body. In France the gelatine of bones is extracted and employed as a *part* of the diet in hospitals with the best effect, materially abridging the period of convalescence; but when given *alone* all animals soon become disgusted with it, and die if not supplied with other food. (D'Arcet.)

It has long been a matter of discussion whether gelatine is to be regarded in the light of a *product* or an *educt* of the tissues from which it is obtained. The talented editors of the 3rd vol. of Pereira's "*Materia Medica and Therapeutics*," assert the latter to be the case. "It is an *educt* of the swimming bladder of the sturgeon, and is properly described by the author" (Dr. Pereira), "as a constituent forming from 86 to 93% of isinglass. If an educt of the air-bladder of the sturgeon, it must be equally an educt of the skin of young animals, as of the calf;—*i.e.*, it exists in the skin as such, and is *not* produced from it by the action of boiling water, any more than starch is produced from grain by a similar process. The tissue of the skin is closer than that of the air-bladder; hence it requires a longer continuance of the action of water to separate the gelatine from the other principles. Acetic acid will, however, dissolve gelatine from the skin in the *cold*, and tannic acid (in tanning skins) combines with the gelatinous tissue in the *cold* to form leather. These facts show correctly and truly that *gelatine exists in the skin* as an *independent principle* like albumen." (Vol. iii, p. 2232.) The force of these remarks will be readily admitted, provided it be taken for granted, that the compound in the skin representing gelatine, is precisely similar to that extracted from it by acetic acid, or that either of these compounds are *absolutely identical* with the gelatine extracted from the tissues by the action of heat and water. This we are not prepared to admit, although, for all practical purposes, it may be convenient to take it to be the case.

GELATINE (Animal). Various inferior qualities of gelatine have been sold under this name.

GELATINE (Bone). Obtained from *crushed bones* by coction with *water*, or by the action of *steam* and *water* successively, either with or without pressure; or by maceration in *dilute hydrochloric acid*, to extract the phosphate of lime, the remaining gelatinous mass being well washed in *cold water*, and afterwards dissolved in *boiling water* in the usual manner. A little carbonate of soda is commonly added to the last water. Gelatine has even been extracted from *fossil* bones. "A soup was prepared from one of the bones of the *great mastodon*, by the prefet of one of the departments of France." (Pereira.) Butcher's meat contains on an average 24% of *dry flesh*, 56% of *water*, and 20% of *bone*. The last, will yield, by proper treatment, nearly 1-3rd of its weight of *dry gelatine;* or a quantity equal to about 6% of the meat from which it is cut. This, as well as other varieties of gelatine, is frequently BLANCHED by *sulphurous acid* or *animal charcoal*, and TINGED of *various colours* with the ordinary *vegetable dyes.* Thus, BLUE is given with *sulphate of indigo* or the *juice of blue berries;* GREEN, with the *juice of spinach*; and RED, with juice of *red-beet.*

GELATINE (Cox's Patent). This is a very superior article recently brought before the public, of unusual beauty and purity; whilst it possesses a gelatinizing force superior to that of the best isinglass, to which, for all culinary purposes, it is fully equal.

GELATINE (French). Syn. *Cake Gelatine.* Gelatine done up into small thin cakes, like the finer sorts of glue. A good deal of it is prepared in Paris from the cuttings of the skins used in making kid gloves and slippers.

GELATINE (Nelson's Patent). According to Mr. Nelson's specification, this article is obtained from *glue-pieces*, or cuttings of the hides of beasts and skins of calves; but from the large quantities of *inferior isinglass* which that gentleman buys, it is a natural conclusion that it is principally, if not wholly formed of the latter substance. The crude materials freed from hair, wool, flesh, and fat, after being thoroughly washed and "scored," are macerated for 10 days in a *ley* of *caustic soda*, and are then placed in covered vessels at a temperature varying from 60° to 70° Fahr., until they become tender; they are next washed to free them from alkali, and are then exposed to the *vapour* of *burning sulphur* until they acquire a sensibly acid reaction; they are now dissolved in *water* contained in earthen vessels heated to 150° Fahr., and the solution, after being strained, is put into "settling vessels," and heated to 100° or 120°

Fahr., for 8 or 9 hours; at the end of this time the *clear liquor* is drawn off, and poured on the "cooling slabs" to the depth of about ½ an inch. As soon as the jelly is cold, it is cut into pieces, and washed in water until perfectly free from acid. It is then redissolved in *water* at about 85°, the solution poured out on slabs as before, and when cold, it is cut up, and, lastly, dried on nets.

There are two qualities of this article manufactured by Mr. Nelson, viz. "*first quality*," or "*opaque gelatine*," and "*second quality*," or "*transparent gelatine*." Both varieties are sold cut up in imitation of "picked isinglass," to which, for the preparation of jellies, soups, and blancmanges, they are not much inferior.

GELATINE (Rattray's Patent). From *glue-pieces* steeped in *water* until they begin to putrefy, then washed with *water*, drained, and put for 12 to 24 hours into *water* strongly soured with *sulphurous acid*; they are afterwards washed first with *cold water*, and then in *water* at 120° Fahr., and are lastly converted into *size* by digestion for 24 hours in *water* at 120° Fahr., the resulting solution being filtered through bags of double woollen-cloth.

GELATINE (Rough). Syn. *Gelatine Brut*. From the *skulls of oxen*, the *spongy insides of the horns* and *ribs*, and from several other *soft bony parts* (deprived of fat), by washing them in *water*, digesting in an equal weight of muriatic acid of 6° Baume, in *cold* weather, and 4° or 5° in summer, for 10 days, then in *acid* of only 1° Baume for 24 hours longer; afterwards soaking and washing in successive portions of *cold water* until *all* the acid is washed out, adding an ounce of *carbonate of soda* to the last water. *Used* to make glue, &c. A similar article is prepared from the bones of sheep. The pieces after being treated as above, are steeped in *boiling water* for a few minutes, wiped dry and shaken together in a bag to remove the internal pellicle; after which they are cut into squares or dice to disguise them, and finally dipped into a *hot solution of gelatine* to varnish them. In this state the article is called *gelatine brut fin*. *Used* to make soup. It keeps better than the cakes of portable soup. When less carefully prepared, it is also used to make glue for fine work. See *Bone Gelatine*.

GELATINE (Swinburne's Patent). Syn. *Swinburne's Patent Refined Isinglass*. From common *rough isinglass* or the *cuttings of calves' skins* (thoroughly freed from hair, and cleaned), by treatment with successive portions of *pure water* only, at a temperature ranging between 200° and 212° Fahr., until all the gelatine is removed. The quality of the product is equal to that of any gelatine in the market.

GELEE (pour le Goitre). Syn. *Linimentum Ioduretum Gelatinosum*. A preparation sold at Lausanne, and held in high repute in Switzerland, as a remedy for goitre and other glandular enlargements.

Prep. White *Castile soap* (in shavings), 2 *oz.*; *proof spirit*, 6 fl. oz.; dissolve by placing the bottle in hot water, and whilst still warm add of *iodide of potassium*, 1 *oz.*; (dissolved in) *proof spirit*, 4 fl. oz.; with *perfume*, q. s.

GEMS. Syn. *Jewels; Gemmæ*,—Lat. "Gems are precious stones, which, by their colour, limpidity, lustre, brilliant polish, purity, and rarity, are sought after as objects of dress and decoration. They form the principal part of the crown jewels of kings, not only from their beauty, but because they are supposed to comprise the greatest value in the smallest bulk; for a diamond, no larger than a nut, or an acorn, may be the representative sign of the territorial value of a whole country, the equivalent in commercial exchange for a hundred fortunes, acquired by severe toils and privations." "Among these beautiful minerals mankind have agreed in forming a select class, to which the title of *gems* or *jewels* has been appropriated; while the term *precious stone* is more particularly given to substances which often occur under a more considerable volume than *fine stones* ever do. *Diamonds*, *sapphires*, *emeralds*, *rubies*, *topazes*, *hyacinths*, and *chrysoberyls*, are reckoned the most *valuable gems*;—*crystalline quartz*, pellucid, opalescent, or of various hues, *amethyst*, *lapis lazuli*, *malachite*, *jasper*, *agate*, *&c.*, are ranked in the much more numerous and inferior class of *ornamental stones*." (Ure.)

Tests. The only tests applicable to gems and precious stones, are the determination of their *relative hardness*, and their *specific gravity*. By the first test, *pastes* or *factitious gems* are readily detected, but beyond this, owing to the difficulty of applying it, it ceases to be useful to persons unconnected with the trade. The *determination* of the *specific gravity* is, however, of more general application, as gems are generally dismounted when offered for sale, or are so set that they may be removed from their "mountings" without injury or inconvenience. See *Specific Gravity* (and *below*.)

TABLE *of the Hardness, Specific Gravity, and Refractive Power, of the principal Gems and Precious Stones, and some other Minerals; compiled expressly for this work.*

Name.	Relative Hardness.	Specific Gravity.	Index of Refraction.
Agate	12	2·6	
Amethyst (occidental)	11	2·7	
Calcareous spar	6	2·7	
Chalk	3	2·7	
Chrysolite	10	3·7	
Cornelian	11	2·7	
Crystal	11	2·6	
Diamond (bluish)	19	3·3	2·439
„ (cubic)	18	3.2	
„ (from Ormus)	20	3·7	
„ (pink)	19	3·4	
„ (yellowish)	19	3·3	
„ (average colourless)	19 to 20	3·3 to 3·55	
Emerald	12	2·8	
Fluor spar	7	3 5	1·434
Garnet	12	4·4	1·815
Glass	varies	2·3 to 3·62	1·525 to 2·028
„ (crystal or flint)	varies	3·0 „ 3·6	1·830 to 2·028
„ (plate)	varies	2·5 „ 2·6	1·514 to 1·542
Gypsum	5	2·3	
Jasper (green)	11	2·7	
„ (reddish yellow)	9	2·6	
Onyx	12	2·6	
Opal	10	2·6	
Quartz	10	2·7	1·548
Ruby	17	4·2	1·779
„ (pale, from Brazil)	16	3·5	
„ (spinelle)	13	3·4	1·764
Sapphire (deep blue)	16	3·8	1·794
„ (paler)	17	3·8	
Sardonyx	12	2·6	
Schoerl	10	3·6	
Topaz	15	4·2	
„ (Bohemian)	11	2·8	
„ (whitish)	14	3·5	
Tourmaline	10	3·0	
Zeolite	8	2·1	
Zircon	—	—	1·961

Obs. The relative hardness of the different substances is measured by the power they possess of cutting or scratching the other substances having a smaller number attached to them in the table. Thus no gem but the diamond (20) will scratch either the ruby (17) or the sapphire (16); and, for the same reason, a blue stone that will cut the emerald or the topaz, can be no other than the sapphire. The sp. gr. is ascertained in the usual manner, and will be found sufficiently indicative of the true nature of the stone when considered in connexion with its other characteristics. The *trial by electricity*, another method of testing the gems, is only applicable in a few cases. The *diamond*, when rubbed either in the rough or polished state, exhibits *positive* electricity; *quartz*, the only substitute that possesses much hardness, on being treated in the same manner, exhibits *negative* electricity. When exposed to the sun or the electric spark, the *diamond* becomes *phosphorescent*. The *topaz* also acquires *positive* electricity by friction. The *index of refraction* is a certain key to

quality of the stone, in the hands of those who are capable of determining it, and may be applied to either "mounted" or "unmounted" gems. The most convenient instrument for the purpose is Wollaston's *Reflecting Goniometer.*

GEMS (Factitious). These, with few exceptions, are made of very pure, fusible, highly transparent, and dense glass, usually termed *paste* or *strass*, which is generally formed of *oxide of lead, potassa*, and *silica*, with *small quantities* of other ingredients to increase the brilliancy and clearness. The characteristic tints are imparted by the addition of *metallic oxides.* The beauty of artificial stones and gems, depends, chiefly, upon the tint of the *real* stones being exactly imitated, and upon proper care and skill being exercised in the cutting, polishing, and mounting them. All the coloured glasses, and enamels, may be worked up into artificial gems. See *Enamels, Foils, Pastes, &c.*

GENEVA. See *Gin* and *Hollands.*

GENTIAN. Syn. *Gentiana*,—Ph. L. E. & D. "The root" of "*gentiana lutea*" or *yellow gentian.* (Ph. L.) *Dose.* 10 to 30 gr.; as a simple bitter, tonic, and stomachic, in dyspepsia, loss of appetite, gout, &c. It was formerly a favorite remedy in agues. "Joined with galls or tormentil, and given in sufficient quantity, it has not failed in any intermittents in which I have tried it." (Dr. Cullen.) In excessive doses it is apt to relax the bowels and disturb the system. When taken for some time, it imparts its bitter flavour to the perspiration and urine. See *Decoctions, Extracts, &c.*

GENTIANINE. Syn. *Gentianina*, — Lat. A substance obtained by MM. Henry and Caventou from the root of common gentian.

Prep. 1. *Gentian root* (in powder) is digested for 2 or 3 days in cold *ether*, with agitation, and the filtered tincture evaporated to dryness; the residuum is dissolved in *rectified spirit*, and the solution is again evaporated; the semi-crystalline mass is lastly, redissolved in either *alcohol* or *ether*, and crystallized by careful evaporation.

2. (Magendie.) The *ethereal extract* is exhausted with *cold alcohol* (rectified spirit), as before, and the resulting *tincture* is evaporated to dryness; the residuum is dissolved in *water, calcined magnesia* added in excess, and the whole boiled and filtered; the sediment is digested in *ether*, and the ethereal tincture allowed to crystallize by slow evaporation.

Prop. &c. Gentianine forms golden-yellow needles, scarcely soluble in cold water, but very soluble in alcohol and ether. It is a powerful bitter and stomachic. *Dose.* ½ gr. to 2 gr. According to Trommsdorff and Leconte, the above substance is composed of *gentisin, gentianite*, and *sugar.* See *Tinctures* (and *below*).

GENTIANITE. Syn. *Bitter Principle of Gentian.* This has not been obtained in a state of purity. It may be procured combined with a portion of sugar, by digesting the *alcoholic extract of gentian* in *water*, throwing down the *gentisin* with *solution of diacetate of lead*, passing *sulphuretted hydrogen* through the liquid to remove any traces of lead, filtering, and evaporating. It may be further purified by digestion in *ether.*

GENTISIN. Syn. *Gentisic Acid.* From the *alcoholic extract of gentian*, by digesting it first in *water*, and afterwards in *alcohol;* the *tincture* is gently evaporated to dryness, and the residuum treated with ether. By repeated solutions in *alcohol* it may be obtained under the form of pale yellow needles. It is scarcely soluble in cold water; possesses feeble acid powers; and forms salts with the bases which are called *gentisates.*

GERMAN PASTE. *Prep.* From *pea-meal*, 2 *lb.; sweet almonds* (blanched), 1 *lb.; fresh butter* or *lard*, ¼ *lb.; moist sugar*, 5 *oz.; hay saffron*, ½ dr.; beat to a smooth paste, adding *cold water*, q. s., granulate the mass by passing it through a colander, and expose the product to the air, in a warm place, until quite hard and dry. The addition of 2 or 3 eggs improves it. *Used* to feed *larks, nightingales*, and other *insectivorous birds.* It will keep good for 12 months in a dry place.

GERMAN SILVER. Syn. *Albata, Argentan, Nickel Silver, Tutenag, White Copper.* A well-known alloy, the finer varieties of which nearly equal silver in whiteness and susceptibility of receiving a high polish, whilst they surpass it in hardness and durability. The following formulæ are from the highest authorities, or are the results of actual analysis of the finest commercial samples:—

Prep. 1. *Copper*, 50 parts; *nickel*, 20 parts; *zinc*, 30 parts. Very malleable, and takes a high polish.

2. *Copper*, 50 parts; *nickel*, 26 parts; *zinc*, 24 parts. Closely resembles silver; an excellent sample.

3. *Copper* and *zinc*, of each, 41 parts; *nickel*, 18 parts. Rather brittle.

4. (M. Gersdorff.) *Copper*, 50 parts;

nickel and *zinc*, of each, 25 parts. Very white and malleable, and takes a high polish. Recommended as a general substitute for silver.

5. (Gersdorff.) *Copper*, 60 parts; *nickel* and *zinc*, of each, 20 parts. For castings, as bells, candlesticks, &c.

6. (Gersdorff.) *Copper*, 60 parts; *nickel*, 25 parts; *zinc*, 20 parts. For rolling and wire. Very tough and malleable.

7. (Sample made from the ore of Hilburghausen.) *Copper*, 40½ parts; *nickel*, 31½ parts; *iron*, 2½ parts; *zinc*, 25½ parts. Equal to the best Chinese sample.

8. (Pelouze.) *Copper* and *nickel*, equal parts. Recommended by M. Pelouze as superior to any of the alloys containing zinc.

9. (Pelouze.) *Copper*, 2 parts; *nickel*, 1 part. Not so white as the last, but more malleable.

10. (White Copper from China.)—*a*. *Copper*, 30 parts; *nickel*, 36 parts; *zinc*, 34 parts.

11. (White Copper from China, said to be prepared from native ore.) *Copper*, 41 parts; *nickel*, 32 parts; *iron*, 2½ parts; *zinc*, 24½ parts. Silvery white, takes a high polish, very sonorous, malleable both cold and at a dull red heat, and may be rolled into leaves or formed into wire.

12. (White metal spoon sold as "German Plate.") *Copper*, 55 parts; *nickel*, 24 parts; *zinc*, 16 parts; *tin*, 3 parts; *iron*, 2 parts.

Assay.—*a*. 100 gr. of the alloy is digested in *nitric acid*, q. s., diluted with a *little water*. If the sample is unequally attacked by the acid, and a white external shell is observed which dissolves more slowly than the internal portion, it is *plated* on those parts with *silver*. If this silver shell or casing has a polished surface on both sides, the article has been *electro-plated*; if the contrary is the case, it has most probably been *plated* in the usual way.

b. The solution being completed, heat is applied to expel the excess of acid, and the remainder is largely diluted with *distilled water*; *dilute hydrochloric acid* is now dropped in as long as it occasions a precipitate, and the whole, after being moderately heated for a short time, and cooled, is thrown upon a small paper filter; the precipitate on the filter is next washed with *distilled water*, carefully dried, and ignited in a small porcelain crucible, the filter itself being separately burnt on the cover of the crucible, and the ashes added to its contents prior to ignition. *Every grain* of the resulting *fused chloride* is equal to ¾ gr. of SILVER; or, more accurately, to 0·7533 gr. (See *Silver*.)

c. The filtered liquid (see *b*) is next treated with a *stream* of *sulphuretted hydrogen*, and the black precipitate is collected, washed, and digested in *strong nitric acid*; when the solution is complete, *sulphuric acid* is dropped in, to precipitate the lead (if any is present); if a precipitate is formed, the whole is evaporated to dryness, and the *excess* of sulphuric acid expelled by a rather strong heat applied towards the end; the dry mass is now collected on a filter, washed with *water*, dried, and exposed to *slight* ignition in a porcelain crucible. The resulting *dry sulphate* is equal to 68% of its weight of LEAD; or, more accurately, each gr. represents 0·68367 gr. of that metal. (See *Lead*.)

d. The liquor filtered from the sulphate of lead, or (in its absence) the nitric solution of the precipitate produced by the sulphuretted hydrogen (see *c*) is next treated with *potassa*, &c., as described under the analysis of "*Brass*" (*a*, p. 157). *Each grain* of the *dry protoxide* thus obtained, represents ⅘ gr. of pure COPPER (nearly); or more correctly, 0·7983 gr. (See *Copper*.)

e. The liquor which was filtered from the precipitate produced by the sulphuretted hydrogen (see *c*) is boiled until it loses its offensive odour, and is then precipitated with *carbonate of soda*, in *slight* excess, and again boiled for a few minutes; the precipitate (*mixed oxides* of *nickel* and *zinc*) is collected, washed, and redissolved in *dilute acetic* or *nitric acid*, in excess; a *current of sulphuretted hydrogen* is next passed through the solution, the precipitate collected on a filter, washed, redissolved in *hydrochloric acid*, and the solution again treated with *carbonate of soda*; the last precipitate (oxide) is washed, dried, and gently ignited. *Each grain* of this *oxide* is equivalent to ⅘ gr. of ZINC; or more accurately, 0 8013 gr. (See *Zinc*.)

f. The washings of the precipitated oxides and the liquid filtered from the precipitate occasioned by the sulphuretted hydrogen (see *e*) are mixed together, pure *liquor of ammonia* added in *considerable excess*, and the mixture agitated for some time; the undissolved portion of the precipitate is then collected on a filter, washed with *distilled water*, redissolved in *dilute nitric acid*, again precipitated with *liquor of potassa*, and this last precipitate (*oxide*), washed, dried, ignited, and weighed. *Each grain* represents $\frac{7}{10}$ (*or* 0·700) gr. of IRON. (See *Iron*.)

g. The ammonial solution filtered from

the precipitate of oxide of iron (see *f*) is precipitated with pure *liquor of potassa*, boiled for a few minutes, and, when cold, thrown on a filter; the precipitate is, lastly, washed with *hot water*, dried, ignited, and weighed. *Each grain* of the *oxide*, thus obtained, is equal to $\frac{7}{9}$ gr. of NICKEL; or, more accurately, 0·7871 gr. (See *Nickel*.)

Obs. The manufacture of *nickel* or *German silver* has of late acquired an importance which is second only to that of silver plate itself. The superior quality of this alloy, and the graceful patterns which it is often made to assume in the hands of the accomplished artist, cannot fail to have attracted the admiration of the majority of our readers. The value of correct information regarding the preparation of this alloy, and of a ready method of determining the composition of the most approved commercial samples, will therefore be fully appreciated by every metallurgist who wishes to throw his wares into the arena of public competition. Much that is vended under the name of "*German silver*," is little better than the "*Britannia metal*" or "*plate pewter*" formerly so plentiful in every establishment in this country. The "*Amalgamated silver plate*" recently offered for sale, and so much puffed in handbills and newspaper advertisements, is an inferior variety of "German silver" covered with a thin film of real silver by means of the electrotype.

The union of the metals in the above formulæ is effected by heat, with the usual precautions. When iron is ordered, it is generally added under the form of tin plate. See *Alloy*, *Brass*, *Britannia Metal*, *Bronze*, *&c.*

GERMAN TINDER. See *Amadou.*

GERMINATION. The growth or vegetation of a seed by which a young plant is produced. The conditions essential to germination, are the presence of warmth, air, and moisture. The most favorable temperature is between 60° and 85° Fahr., according to the habitat of the respective plants. Below 40° Fahr. most of the more perfect seeds either refuse to vegetate, or vegetate slowly and feebly; and at or near the freezing point none of them undergo this change. At a temperature above 100° Fahr. the young germ is usually injured, and at about 125°, if it forms, it soon withers and dies. See *Malting*, *Seed*, *&c.*

GHEE. *Butter* melted in a water bath, and allowed to clarify itself by repose; the clear liquid portion is then poured off into su table vessels in which it can be preserved fr m the air. Bottles are commonly used for this purpose in the East Indies, where this process is generally adopted. See *Butter.*

GHERKINS. Syn. *Girkins.* Small cucumbers adapted for pickling. See *Pickles.*

GHOST-LIGHTS. Syn. *Corpse-lights.* The illustrious Reichenbach ascribes the luminous appearances sometimes perceived over graves and sepulchres by highly sensitive subjects, when their external senses are exalted by disease, to the emanations due to the peculiar chemical changes going on in the corpse. See *Phosphuretted Hydrogen.*

GILDER'S PICKLE. See *Gilding Liquors.*

GILDER'S WAX. See *Gilding Wax.*

GILDING. Syn. *Dorure*,—Fr. The art or process of covering the surfaces of bodies with a thin film of gold, for the purpose of increasing their durability or improving their appearance. For the sake of brevity, we shall notice the leading varieties of gilding, and their applications, in alphabetical order.

Burnished Gilding. This is *distemper gilding* to which a face has been given with the "*burnisher.*" It is chiefly employed for the polished portions of the frames of pictures and mirrors, the more prominent parts of statuettes, &c.

Chemical Gilding. Those varieties in which the film of gold is formed on the surface through the agency of *chemical affinity* or the electrotype, in opposition to "*mechanical gilding*," in which the gold is made to adhere by the intervention of some glutinous substance. See *German* and *Voltaic Gilding.*

Cold Gilding. The articles (*copper* or *brass*) to be gilded, after being softened, annealed, and polished, in the usual manner, are rubbed with a little *gilding powder* by means of a piece of cork moistened with a *solution of salt in water*; after which the work is *burnished* with a piece of hematite or polished steel. (See *below.*)

Distemper Gilding. This is applied to wood, plaster, marble, &c. It is commonly performed in this country by giving the wood, *first*, a coating of *good size*, and *next*, several successive coats of *size thickened with finely-powdered whiting*, *Spanish white*, or *plaster of Paris*, until a good face is produced; observing to let each coat become quite dry, and to rub it perfectly smooth with *fine* glass-paper, before the application of the following one. When the proper "*face*" is obtained, the surface is thinly and evenly gone over with

gold size, and when this is *nearly* dry, the *gold leaf* is applied, and afterwards burnished with an *agate*, or a *dog's tooth*. The process, as adopted by the Parisian artists, who greatly excel in this species of gilding, is very complicated, and is divided into at least 17 distinct operations, each of which they declare to be essential to its excellence.

Electro-gilding. See *Voltaic Gilding.*

Friction Gilding. A variety of *Cold gilding.* (See *above.*)

German Gilding. A variety of *Chemical gilding.* (See p. 518.)

Grecian Gilding. In this variety *sal ammoniac* and *corrosive sublimate*, equal parts, are dissolved in *nitric acid*, and a solution of gold made with this menstruum; after slight concentration, the liquid is applied to the surface of *silver*, which immediately becomes black, but on being heated exhibits a rich gilded surface.

Gilding by *Immersion.* This is performed by simply dipping the article (metallic) into a solution of *pyrophosphate of soda* in which *teroxide* or *terchloride of gold* has been dissolved. For other methods, see *Elkington's* and *Talbot's Patent Gilding* (*below*).

Japanner's Gilding. The surface is covered with *oil size* thinned with *spirits of turpentine*, and *gold*, in powder, is gently dabbed on with a *puff of wash-leather.* This gives the appearance of "frosted gold." A coating of varnish is next given, followed by exposure to a gentle heat in the "stove."

Leaf Gilding. This term is commonly applied to the gilding of *paper*, *vellum*, *&c.*, by applying *leaf gold* to the surface, previously prepared with a *coating* of *gum water*, *size*, or *white of egg.* It is usually burnished with an *agate*, or a *dog's tooth.*

Mechanical Gilding. See *Chemical Gilding.*

Mercurial Gilding. See *Wash Gilding.*

Oil Gilding. This species of gilding may be divided into several operations. The following are the abridged instructions of a Parisian artist on the subject:—1. The surface is prepared by a coating of *white-lead* in *drying oil.*—2. Another coat is given, made with *calcined white-lead* or *massicot*, ground in *linseed oil and turpentine.* 3 or 4 coats of this mixture are often given, at intervals of at least 24 hours, observing to carefully smooth off each coat with *pumice stone* or *shave grass* before the application of the following ones.—3. The *Gold Colour*, or *paint*, is next applied. It is usually very adhesive *gold size*, or the bottom of the pot or dish in which painters wash their brushes. For this purpose it is thoroughly ground and strained.—4. When the gold colour becomes partially dry and sufficiently tenacious, the *gold-leaf* is applied and pressed on with a wad of *cotton-wool*, or a *soft brush.* It is now left for several days to harden.—5. A coat of *spirit varnish* is next given, and the object is cautiously passed over a *chafing-dish of charcoal*, observing to avoid stopping the motion of the piece whilst doing so, as the work would then become discoloured and blistered.—6. The work is "finished off" with *pale oil varnish.* For *out-door gilding* and *common work*, the varnishing process is generally omitted. This species of gilding is applied to woodwork, plaster, metal, &c.

Varnish Gilding. This is a mere variety of *oil gilding*, applied to *equipages*, *furniture*, *mirror* and *picture frames*, *&c.*, the surface being *highly* varnished and polished, before it receives the *size* or *gold colour*; and after the gilding has become quite dry, a coat of *spirit varnish*, fumed with the chafing dish as above, is applied, followed by 2, 3, or more coats of the *best copal varnish*, at intervals of 3 or 4 days each. The whole is, lastly, carefully polished with *tripoli-and-water.*

Wash Gilding, *Amalgam do.*, *Mercurial do.*, *Water do.* This consists in the application of a thin coating of *amalgam of gold* to the metallic surface (*brass*, *bronze*, or *copper*,) to be gilded, and the subsequent volatilization of the mercury by heat. It is the usual method of gilding articles of copper and its alloys, and possesses great beauty and durability when skilfully executed. The occupation is, however, an unhealthy one, owing to the continual exposure of the workman to the fumes of mercury. The furnace invented by M. D'Arcet obviates this evil, as the whole of the volatilized mercury is carried off, and again condensed for further use. It should therefore be adopted by every water-gilder who studies economy, and the health of those in his employ.

The *process* of *water-gilding* consists of several distinct operations, and can only be successfully performed by those who have been schooled in the art by an apprenticeship to the trade. It would, therefore, be waste of space to enter into details here. Formulæ for several of the articles employed for the purpose will be found in their alphabetical places in this work.

Water Gilding. See *above.*

Among the *applications* of the *process of*

gilding that deserve a separate notice are the following:—

The *gold letters* and *figures* on the *covers of books* are thus formed:—*Gum mastic*, in fine powder, is dusted over the surface to be gilded; an *iron* or *brass tool* bearing the design upon its face, is then heated to a proper temperature, and gently pressed upon a piece of *leaf gold*, which slightly adheres to it; the two are then transferred to the cover, and the tool is gently pressed on it, by which means the mastic softens, and retains the gold. The loose gold and powdered mastic are then dusted off with a brush. Gold leaf will adhere to leather without the use of mastic, but not so firmly as when it is employed.

The *edges* of the *leaves of books* and *paper* are first cut perfectly smooth, and then washed over with a *solution of isinglass* in *weak spirit*, or with a *varnish* made of *Armenian bole*, 4 parts, and *powdered sugar-candy*, 1 part, mixed up to a proper consistence with *strained white of egg*. The coating is allowed to dry, and is then smoothed with a wet rag, after which the *gold leaf* is applied and polished with the burnisher.

Brass buttons formerly so much in demand, are covered by a rough species of *wash gilding*. The buttons are polished in the lathe, and thrown into a pan with a little *amalgam of gold*, and as much *aqua-fortis diluted with water*, as will wet them all over. Here they are well stirred up, until they assume a *silvery* appearance, when they are washed with clean water. They are then submitted to a sufficient heat in a suitable apparatus, until the mercury is volatilized. The buttons are next cooled and well tossed and rubbed about with a painter's brush; and are, lastly, burnished by washing them well with beer or ale grounds.

Twelve dozen (1 gross) *of buttons*, of 1 inch in diameter, may be *perfectly gilded on both sides* with only 5 gr. of gold. By an Act of Parliament, which is still unrepealed, this is the *smallest* quantity of gold permitted to be used for a gross of buttons of the above size.

Glass, *porcelain*, and *earthenware*, are gilded by blending *powdered gold* with *gum-water* and a *little borax*, and applying the mixture by means of a camel-hair pencil; the article is then heated in an oven or furnace, by which means the gum is burnt, and the borax, vitrifying, cements the gold to the surface. It is afterwards polished with a burnisher. *Names*, *dates*, or any *fancy device* may thus be *permanently* and *easily* fixed on *glass*, *china*, *earthenware*, &c.

Japanned work is gilded by the method explained at p. 516.

Leather is gilded in the same way as the covers of books. (See *above*.) For *common work*, *silver leaf* or even *tin foil*, is applied to the surface, previously covered with *size* or *white of egg*, and after being burnished down and dried, is washed over with *gold-coloured lacquer*.

The *letters of sign-boards* and the *ornamental gilding* for *out-door work*, is done by first covering the design with *yellow paint* then with *oil gold-size*, and when this is *nearly* dry applying the *leaf-gold*, observing to shield it properly from the wind, lest it be blown away or become crumpled before being properly attached. The work is, lastly, varnished.

Polished metals may be gilded by one or other of the methods already noticed. Articles in *silver*, *copper*, *brass*, and *bronze*, are usually coated by the process of *wash* or *water gilding*; or directly, by the application of *gold leaf*, as follows:—The "piece" or article is heated to a bluish tint, and *gold leaf* pressed gently and carefully on it with the burnisher; heat is again applied, and the process repeated with fresh *leaves of gold* until the gilding has acquired the proper thickness and tone. The surface is lastly polished with the burnisher, or is "coloured" in the usual manner at the "stove." This succeeds with *iron*, *steel*, *silver*, *copper* and *its alloys*, &c. *Another method* for *polished articles* in *iron* and *steel*, which, however, is less durable than the preceding, is to apply an *ethereal solution of gold* to the surface with a camel-hair pencil. The *ether* flies off and leaves the surface coated with *gold*; which is then polished as before. In this way, any *fancy device* or *writing* may be executed on steel or iron, with extreme facility.

Silks, *satins*, *woollens*, *ivory*, *bone*, &c., may be readily gilded by immersing them in a *solution of neutral terchloride of gold* (1 of the *salt*, and 3 to 6 of *water*), and then exposing them to the action of *hydrogen gas*. The latter part of the process may readily be performed by pouring some *dilute sulphuric acid* on *zinc* or *iron filings*, in a wide-mouthed bottle, and placing it under a jar or similar vessel, inverted, at the top of which the articles to be gilded are suspended. *Flowers* or *other ornamental designs* may be produced by painting them on the surface with a camel-hair pencil dipped in the solution. The design,

after a few minutes' exposure to the hydrogen, shines with all the splendour of the purest gold, and will not tarnish on exposure to the air, or in washing.

Gilded thread or *gold thread* is merely a thread of *yellow silk* covered with a very thin *flatted wire of gold*, by means of a revolving wheel.

Wire (copper, silver, *or* brass) is occasionally gilded, in coils, by a similar process to that adopted for *buttons;* but more frequently as follows:—*Rods* (usually of *silver*) are covered with *gold foil* of a thickness proportionate to the quality of the intended wire, and the compound bar is then drawn into wire in the usual way. 100 gr. of *gold* was formerly the lowest legal quantity that could be employed for 1 lb. of *silver*.

GILDING (Elkington's Patent). Syn. *German Gilding, Anglo-German do., Bonnet's Gilding Process.* The articles to be gilded, after being *perfectly* cleaned from scale or grease, and receiving a proper "*face*," are suspended, by means of wires, in the "*gilding liquid*" (*boiling hot*) and moved about therein for a period varying from a *few seconds* to a *minute*, or *longer;* the precise time required depending on the newness and strength of the liquid. When sufficiently gilded, the articles are withdrawn from the solution of gold, washed in *clean water*, and dried; after which they undergo the usual operation of "colouring," &c. A "*dead gold appearance*" is produced by the application to the articles of a *weak solution* of *nitrate of mercury* previously to the immersion in the "gilding liquor;" or the *deadening* may be given by applying a *solution of the nitrate* to the *newly-gilded surface*, and then expelling the mercury by heat.

The *Gilding Liquor.* Take of *fine gold*, 5 oz. (troy); *nitro-muriatic acid*, 52 *oz.* (avoirdupois); dissolve by heat, and continue the heat until red or yellow vapours cease to be evolved; decant the clear liquid into a suitable vessel; add of *distilled water*, 4 gall.; *pure bicarbonate of potassa*, 20 *lb.;* and boil for 2 hours. The *nitromuriatic acid* is made with *pure nitric acid* (sp. gr. 1·45), 21 *oz.; pure muriatic acid* (sp. gr. 1·15), 17 *oz.;* and *distilled water*, 14 *oz.*

Obs. This process, though patented by Mr. Elkington in England, and claimed as *his own* invention, was in reality discovered and first practised by M. Bonnet, a foreigner. Articles thus gilded do not bear friction and the operations of being put in colour (*mise en couleur*,) so well as those gilded by the mercurial process, or by the methods of *cold* or *leaf-gilding* as applied to polished metals. For other articles it is, however, both suitable and inexpensive. See *Gilding by Immersion* (and *below*).

GILDING (Talbot's Patent). By this process *polished metallic articles* are *gilded* by simple immersion (as above) in a *solution of gallic acid in water, ether*, or *alcohol*, to which a *solution of gold* has been previously added. *Silvering* and *Platinizing* may be effected in the same manner, by using a *solution* of *either of these metals* instead of one of *gold*.

GILDING AMALGAM. See *Amalgams*.

GILDING LIQUOR. This name has been given to various *solutions of gold*, and to other liquids employed in gilding. The former are noticed elsewhere. Among the latter are the following:—

"*Deading*" *Aquafortis.* From *mercury*, 1 part; *aquafortis* (sp. gr. 1·33), 3 parts; dissolve, and add of *soft water*, 7 parts. *Used* to produce a "*dead-gold*" effect. It is applied (diluted) to the articles, before spreading the amalgam over them, in *water gilding;* or before placing them in the "gilding liquor," in *gilding by immersion.*

Mercurial Solution. From *mercury*, 10 parts, dissolved in *aquafortis* (sp. gr. 1·33), 11 parts, and the solution diluted with 25 times its weight of water. *Used* to moisten the "*scratch brush*" before drawing it over the amalgam, in *mercurial gilding;* also to "deaden" the gilded surface, by moistening the latter with it, and then exposing the "piece" to a heat sufficiently high to drive off the mercury.

Gilder's Pickle. From *alum* and *common salt*, of each, 1 *oz.; nitre*, 2 *oz.;* dissolved in *water*, ½ pint. *Used* to impart a rich colour to gold surfaces, especially of trinkets. Its application should not be too long continued, as it dissolves a small portion of the gold. For common purposes it is best used largely diluted with water.

Vermeil, Vermeil Coating, Or-moulu do. From *annotto* and *salt of tartar*, of each, 2 *oz.; gamboge* and *vermilion*, of each, 1 *oz.; dragon's blood*, ½ *oz.; water*, 1 quart; simmer down to about one fourth, add *saffron*, 20 gr., and, when merely tepid, strain through fine muslin into a bottle. *Used* to give lustre and fire to *distemper gilding.* A little is floated over the surface with a very soft flat camel-hair brush.

GILDING METAL. The metal employed for gilding is usually brass, or a mixture of brass and copper. The following proportions have been recommended:—

1. *Copper*, 6 parts; *brass*, 1 part.
2. *Copper*, 4 parts; *Bristol brass*, 1 part.

3. *Copper*, 13 parts; *old Bristol brass*, 3 parts; *tin*, 14 parts.

GILDING POWDER. *Prep.* 1. *Pure gold*, 5 dr.; *pure copper*, 1 dr.; *aqua regia*, 10 *oz.*; dissolve, moisten clean *linen rags* with the solution, dry them, and burn them to ashes. The latter contain the gold in a state of minute division, and must be carefully collected.

2. *Grain gold*, 1 dr.; *rose copper*, 15 gr.; *aqua regia*, 2 fl. oz.; proceed as last. *Used* in "*Cold Gilding.*"

3. See *Gold* (in powder.)

GILDING SHELLS. See *Gold Shells.*

GILDING SIZE. See *Gold Size.*

GILDING WAX. Syn. *Gilding Varnish*, *Gilder's Wax.* From *bees' wax*, 4 *oz.*; *verdigris* and *sulphate of copper*, of each, 1 *oz.*; melted together.

2. *Bees' wax*, 4 *oz.*; *verdigris*, *red ochre*, and *alum*, of each, 1 *oz.* *Used* to give a red gold-colour to water-gilding.

GIN. Syn. *Geneva.* This is corn spirit flavoured with either oil of juniper or oil of turpentine.

Gin was originally, and, for some time, wholly imported from Holland, and was a rich, soft spirit, flavoured, chiefly, with juniper berries; on which account it had obtained the name of Geneva, from *genièvre*, the French for juniper. After a time the distillation of an *imitation geneva* sprung up in this country, when the foreign spirit came to be called *Hollands*, or *Hollands Gin* or *Geneva*, to distinguish it from the spirit of home manufacture. The English monosyllable "*Gin*," is a corruption of *geneva*, the accented syllable of which, as in numerous other instances, was seized on by the vulgar, and adopted as a short and convenient substitute for the whole word.

The liquor at present known by the name of *gin* in this country, is a very different article to that imported from Holland, and consists of *plain corn-spirit*, flavoured with *oil of turpentine*, and *small* quantities of *certain aromatics.* The *thousand and one* receipts for this article, which have from time to time been printed in books, produce a flavoured spirit, bearing *no resemblance* to the more esteemed samples of English gin; and, if possible, the products are even more unlike genuine Hollands. Any person may easily satisfy himself of the truth of this assertion by actual experiment on the small scale. The cause of this incongruity has arisen chiefly from the writers not being practically acquainted with the subject, and from the disinclination of well-informed practical men to divulge, gratuitously, what they conceive to be valuable secrets. Hence the utter failure of any attempts to produce either gin or Hollands from the receipts usually published. The authors appear to have all imbibed a *juniper-berry mania*—probably from the imbibition of their favorite beverage. *Oil of juniper*, in the hands of these gentlemen, appears to be a perfect *aqua mirabilis* that readily converts whiskey into gin, and imparts the rich creamy flavour of Schiedam Hollands to crude corn or molasses spirit. But theory and experiment sometimes disagree. In practice it is found that the true flavour of *foreign geneva* cannot be imparted to spirit by juniper *alone*, and that the *English gin* of the present day depends for its flavour on *no such a substance.* The following formulæ are merely given as specimens; and it is proper to remark, that every distiller has his own receipt for this notorious beverage. Hence it is, that the gins of *no two* distillers are of *precisely* the same flavour; and this difference is still more marked when the parties reside in parts of the country remote from each other. *Booth's*, *Smith's* and *Nicholson's Gins* have each a characteristic flavour, readily perceived by their respective votaries; whilst the difference between *Plymouth* or *Bristol Gin*, and the *gin of the metropolis*, is as remarkable as that between *Barclay's* XXX and *Guinness' bottled Stout.* These variations in flavour, generally depend on the use of more or less flavouring matter, or of a spirit more or less clean or free from taint; and, less frequently, on the addition of a small quantity of some peculiar aromatic, which exercises a modifying influence on the chief flavouring ingredient. In many cases the flavour has originated from accident, but the consumers having become *accustomed to*, and hence *relishing* that particular "palate," it is found to be unwise, or commercially impossible to alter it. Any change in these matters is therefore looked upon in every distillery as a dangerous innovation, which would prove more prejudicial to the prosperity of its exchequer, than the repeal of the duty on French wines and brandy, or even a frightful conflagration. The distillers, like the brewers, are thorough conservatives in all matters connected with the flavour of their liquors.

In the *preparation* of *gin*, both *sweetened* and *unsweetened*, and indeed of liquors generally, the greatest possible care must be taken to avoid an excess of flavouring. The most esteemed samples are those that consist of *very pure spirit, slightly flavoured.*

Prep. 1. *Clean corn spirit*, at proof,

80 gall.; *newly rectified oil of turpentine*, 1¼ pint; mix well by violent agitation, add *culinary salt*, 14 *lb.*, dissolved in *water* 40 gall.; again well agitate, and distil over 100 gallons, or until the "*feints*" begin to rise. *Product.* 100 gall. of gin 22 u. p., besides 2 gall. contained in the "*feints.*" If 100 gall. at 17 u. p., are required, 85 gall. of *proof spirit*, or its equivalent at any other strength, must be employed.

2. *Proof spirit* (as above), 8 gall.; *oil of turpentine*, 1 fl. *oz.*; *salt*, 1½ *lb.*, dissolved in *water*, 4 gall.; draw over 10 gall., as before. 22 u. p.

3. *Clean corn spirit*, 80 gall.; *oil of turpentine*, 1 pint; *pure oil of juniper*, 3 fl. oz.; *salt*, 21 *lb.*; *water*, 35 gall.; draw over 100 gall., as before. 22 u. p.

4. To the last, before distillation, add of *oil of caraway*, ½ *fl. oz.*; *oil of sweet fennel*, ¼ *fl. oz.*; *cardamoms* (ground), 8 *oz.*

5. To No. 3, add of *essential oil of almonds*, 1 dr.; *essence of lemon*, 4 dr.

6. To No. 1, before distillation, add of *creasote*, 3 fl. dr.

7. To No. 3, add of *creasote*, 2 dr.

8. *Proof spirit*, 80 gall.; *oil of turpentine*, ⅝ pint; *oil of juniper*, ¼ pint; *creasote*, 2 dr.; *oranges* and *lemons*, sliced, of each, 9 in no.; macerate for a week, and distil 100 gall. 22 u. p.

9. To No. 1, add of *rectified fusel oil*, ½ pint.

10. To No. 1, add of *oil of juniper*, ½ pint.

Concluding Remarks. The *oil of turpentine* for this purpose should be of the best quality, and not that usually vended for painting, which always contains resin and often fixed oil. *Juniper berries*, *bitter almonds*, and the *aromatic seeds* may be used instead of the essential oils; but the latter are the most convenient. *Turpentine* conveys a PLAIN-GIN flavour, —*juniper berries* or *oil* gives a HOLLANDS flavour,—*creasote* imparts a certain degree of *smokiness*, or WHISKEY flavour,—*lemon* and the other *aromatics*, a CREAMINESS, FULNESS, and RICHNESS. The flavour imparted by *cardamoms*, when used judiciously, is peculiarly agreeable and appropriate. That from *caraways* is also in general esteem. *Cassia* in *extremely* small proportions also tells well. *Fusil oil* gives a WHISKEY-GIN flavour; and in conjunction with *creasote* or *crude pyroligneous acid*, a full WHISKEY flavour. The only danger in the employment of *all* these articles is "*using too much of them.*" When this misfortune happens, the remedy is to add sufficient *plain spirit* to reduce the flavour to the proper standard. The CREAMINESS and SMOOTHNESS so much admired in foreign geneva results chiefly from *age*. The English rectifier endeavours to imitate this by the addition of a *little sugar*. A rich MELLOWNESS that combines well with *gins* turning on the *Hollands flavour*, is given by a *very small* quantity of *garlic*, and with *Canadian balsam* or *Strasburg turpentine*. The peculiar PIQUANCY, or the property of "BITING THE PALATE," regarded as a proof of strength and quality by the ignorant gin-drinker, is imparted to the liquor by the addition of a little *caustic potassa*. Sliced *horse-radish* gives piquancy as well as mellowness. *Grains of paradise*, *cayenne pepper*, and *sulphate of zinc*, are also commonly added by fraudulent dealers.

Although gin is always *prepared* on the *large* scale by distillation, it may also be made by the simple solution or digestion of the flavouring ingredients in the spirit; but it is, of course, better for distillation. If made in the former way, *no* salt must be employed. The gin produced by the above formulæ is that denominated in the trade "*unsweetened gin*," "*grog gin*," *&c.*; but the gin usually sold in the metropolis is a sweetened spirit, and hence is technically distinguished by the terms "*sweetened*," or "*made up.*" The generality of London gin-drinkers prefer the latter article, even when weaker and inferior, which it usually is; as the addition of sugar permits *adulteration* and *watering* to an enormous extent with absolute impunity. Sweetened spirit *cannot* be easily tested for its strength, and is taken by the Excise at the strength which it is *declared* to possess by the dealer. To *ascertain* whether *gin* is *sweetened* or not, a little may be evaporated in a spoon, over a hot coal or a candle, when, if it is pure, it will leave the spoon scarcely soiled; but if, on the contrary, it has been *sweetened*, a small quantity of syrupy liquid, or sugar, will be obtained, the sweetness of which may be easily recognized by tasting it.

The whole of the *casks* and *utensils* employed for gin should be perfectly clean, and properly prepared, so as not to give *colour*; as if this spirit acquires the *palest* coloured tint its value is lessened, and if *much coloured* it is rendered unsaleable. When gin has once become *much stained*, the only remedy is to re-distil it; when it is only *slightly stained*, the addition of a few *lb.* of *acetic acid* (Ph. L.) to a pipe or butt, a spoonful or two to a gallon, or a few drops to a decanterful, will usually decolour it, either at *once*, or as soon as it is mixed with water to make grog. See *Alcoholo-*

metry, Casks, Distillation, Hollands, Spirits, &c., (and *below.*)

GIN (Cordial). This is gin sweetened with sugar, and *slightly* aromatized.

Prep. Good *gin* (22 u. p.), 90 gall.; *oil of almonds*, 1 dr.; *oils of cassia, nutmeg*, and *lemons*, of each, 2 dr.; *oils of juniper, caraway*, and *coriander*, of each, 3 dr.; *essences of orris root* and *cardamons*, of each, 5 fl. oz.; *orange-flower water*, 3 pints; *lump sugar*, 56 to 60 *lb.*; dissolved in *water*, 4 gall. The *essences* are dissolved in 2 quarts of *spirit of wine*, and added gradually to the gin, until the requisite flavour is produced, when the sugar (dissolved) is mixed in, along with a sufficient quantity of *soft water*, holding 4 *oz.* of *alum* in solution, to make up 100 galls. When the whole is perfectly mixed, 2 *oz.* of *salt of tartar*, dissolved in 2 or 3 quarts of *hot water*, are added, and the liquor is again *well* rummaged up; after which the cask is bunged up, and allowed to repose. In a week, or less, it will have become *brilliant*, and may be either "racked," or drawn from the same cask. *Product.* 100 gall., about 30 u. p.

GIN (Sweetened). *Prep.* From *unsweetened gin* (22 u. p.), 95 gall.; *lump sugar*, 40 to 45 *lb.*, dissolved in *clear water*, 3 gall.; mix well; and fine it down as above. *Product.* 100 gall., at 26 u. p. This, as well as the last, is usually "*permitted*" at 22 or 24 u. p.; which is also done when the gin has been further lowered with water so as to be even 30 or 35 u. p. See *Spirits* (and *above*).

GINGER. Syn. *Ginger Root; Zingiberis Radix; Zingiber*,—Ph. L. E. & D. "The *rhizome*" (rootstock or underground stem) of "*zingiber officinale*, — Roscoe." (Ph. L.) Ginger is an aromatic stimulant and stomachic, very useful in flatulence and spasms of the stomach and bowels, and in loss of appetite and dyspepsia, arising from debility, or occurring in old or gouty subjects. A piece chewed an hour before dinner tends to provoke the *appetite;* as a *masticatory*, it often relieves toothache, relaxation of the uvula, tender gums, and paralytic affections of the tongue. Made into a paste with warm water, and spread on paper, it forms a useful and simple *headache-plaster*, which frequently gives relief when applied to the forehead or temples. As a *condiment* and *flavouring ingredient*, it is perhaps one of the most wholesome of the aromatic kinds, and is less acrid than the peppers. *Dose.* 10 gr. to ½ teaspoonful, stirred up in any simple liquid.

Pur., &c. The best is that known in commerce as "*unbleached Jamaica ginger*," which is an uncoated pale variety, occurring in large bold fleshy pieces ("*races*") which cut soft, bright, and pale-coloured. The inferior varieties occur in smaller pieces, and are darker-coloured, flinty, and shrivelled. The dealers frequently "dress up" the common dark-coloured gingers by washing them in water, drying them, and then "rouncing" them in a bag with a little calcined whiting or magnesia (*washed ginger*); or they bleach them by dipping them into a solution of chloride of lime, or by exposing them to the fumes of burning sulphur (*bleached ginger*); or they dip them into a milk formed of quick-lime or whiting and water (*white-washed ginger*). The last has a chalk-white surface, which cannot be mistaken for the natural one. *Powdered ginger* is with difficulty obtained pure and good. The common adulterants are wheat-flour, or East Indian arrow-root (*curcuma angustifolia*), and plaintain meal (*musa sapientum*). The first may be detected by the microscope, the others by the flavour and action of hot water. See *Lozenges, &c.*

GINGER (Preserved). Syn. *Conditum Zingiberis*,—Lat. An excellent stomachic sweetmeat or preserve. It is chiefly imported from the West Indies and China. See *Candies, &c.*

GINGER (Preserved, — Mock). From the *stalks of lettuce* just going to seed, using a *concentrated syrup, strongly flavoured with Jamaica ginger.* See *Candy, &c.*

GINGER BEER. See *Beers.*

GINGERBREAD. *Prep.* 1. (Dr. Colquhoun.) *Flour*, 1 *lb.; carbonate of magnesia*, ¼ *oz.;* mix; add of *treacle*, ½ *lb.; moist sugar*, ¼ *lb.; melted butter*, 2 *oz.; tartaric acid* (dissolved in a little water), 1 dr.; make a stiff dough, then add of *powdered ginger* and *cinnamon* (cassia), of each, 1 dr.; *grated nutmeg*, 1 oz.; set it aside for half an hour or an hour before putting it into the oven. It *should not be kept longer than two or three hours, at the utmost, before being baked.*

2. *Flour* and *treacle*, of each, 1 *lb.; butter*, 1½ *oz.; carbonate of magnesia*, 1 *oz.;* add *spices* (ginger, cinnamon, nutmeg, allspice, cayenne, corianders, &c.) to taste; mix as last. *Fit for baking in from four to six hours.*

3. *Flour*, 2 *lb.; carbonate of magnesia*, ½ *oz.;* mix; add *treacle*, 1½ *lb.; butter*, 2 *oz.; spice*, q. s.; *tartaric acid*, ¼ *oz.;* mix quickly, and make it into forms. *Ripe for the oven in half an hour to one hour.*

4. Instead of *tartaric acid* in the last formula, use *cream of tartar* (dissolved in water), 2 *oz.* *Ripens in* 40 *or* 50 *minutes.*

5. *Flour* or *fine pollard*, 1 *lb.*; *treacle*, ¾ *lb.*; *salt of tartar*, ½ *oz.*, dissolved in *water*, q. s.; *butter*, 1 *oz.*; *spices*, to palate. *Takes several days to ripen; sometimes a fortnight.*

6. (Extemporaneous.)—*a.* From *flour*, 1¼ *lb.*; *moist sugar* and *treacle*, of each, ½ *lb.*; *butter*, 2½ *oz.*; *baker's salt* (carbonate of ammonia), ¼ *oz.*, dissolved in *cold water*, q. s.; *ginger*, 3 dr.; *nutmeg*, 2 dr.; *cassia*, 1 dr.; *cayenne pepper* (best), ½ dr.

b. From *flour*, 6 *lb.*; *powdered ginger*, 2½ *oz.*; *caraway seeds*, 1 *oz.*; (and other spices to palate;) *candied lemon* and *orange peels*, of each, 2 *oz.*; *moist sugar* and *melted butter*, of each, ½ *lb.*; *treacle*, 4 *lb.*; *volatile salt*, 2 *oz.*; *water*, q. s.; mix as above. *May be baked at once.*

c. From *Jones's Patent flour*, 2 *lb.*; *treacle*, 1 *lb.*; *moist sugar*, ¾ *lb.*; *butter*, 2½ *oz.*; *spice*, q. s.; mix as quickly as possible, and *bake it instantly.* If the dough is *expertly* mixed up, the quality of the product is fully equal, if not superior to that of any of the preceding formulæ.

Obs. Gingerbread is either rolled out into *thin sheets* and cut into cakes or nuts (*gingerbread nuts*) with the top of a wine-glass or canister, or is formed into thick cakes, which are baked in "batches" (ordinary *gingerbread*). Both varieties require a pretty brisk oven; the thinner kinds (*nuts*, *&c.*) especially, must be baked as crisp as possible, without being burnt. The varieties called *lemon gingerbread*, *caraway do.*, *&c.*, have a perceptible predominance of these flavouring ingredients. The addition of a *little alum*, dissolved in *water*, makes the bread both lighter and crisper, and causes it to ripen quicker, but at the same time lessens its wholesomeness.

GINGER CANDY. See *Candy.*

GINGER DROPS. See *Drops* (Confectionary).

GIRAMBING. Syn. *Limoniated Ginger Beer.* A variety of ginger beer in which the flavour of lemon predominates. See *Beers.*

GLAIRE. White of egg. See *Albumen.*

GLAIRINE. Syn. *Barégine*, — Longchamp; *Theiothermine*,—Monheim; *Zoogen*, — Gimbernat. The peculiar glairy, or mucus-like, organic substance, found in certain mineral waters. It is said to give the flavour and odour of flesh-broth to the waters containing it.

GLANDERS. Syn. *Farcinoma*,—Lat. A *contagious* disease, generally confined to the horse, ass, and mule, but communicable to man, in whom it assumes a highly malignant, and often fatal character. This disease appears under two forms—1. *Simple Acute Glanders*, marked by copious discharge of foul mucous matter from the nostrils and adjacent parts; and—2. *Farcy*, *Farcin*, or *Farcy Glanders*, when it attacks the lymphatics of the skin, either generally, producing a distended appearance of the vessels like moles or buttons (*bead* or *button farcy*), or, locally, when it takes the form of dropsical accumulations in the legs (*water farcy*).

Treat. Mr. Youatt considers it useless to attempt the cure of *glandered* horses; but that *farcy* in its earlier stages and milder forms may be often successfully treated. "All the mercurials have been used with *benefit* in farcy; but they must be discontinued as soon as the mouth is sufficiently affected, or sickness, loss of appetite, and like symptoms, are produced." (Blaine.) Feeding the animal entirely on green food appears to be the best mode of treatment in both varieties. The buttons are generally removed with caustic or a red-hot iron.

GLASS. Syn. *Vitrum*, — Lat. This well-known substance is, essentially a compound of silica (*silicic acid*) with the oxide of an alkaline metal, obtained by fusion. In its *usual* form, it is brittle, transparent, non-crystalline, insoluble, and fusible; but it sometimes exhibits other properties.

The manufacture of glass is one of the highest beauty, and considering the comparative worthlessness of the materials of which it is made, and the various purposes of a useful, ornamental, and scientific nature which it subserves, it may be regarded as, perhaps, the most important in the history of inventions. The principle of its production is very simple, although great skill and experience are necessary to ensure its excellence. *Silica* (commonly under the form of *sand*) is heated with *carbonate of potassa* or *of soda*, and *slaked lime* or *oxide of lead*, until the mixture fuses, and combination takes place. After a time the melted mass becomes perfectly limpid and free from air bubbles, when it is allowed to cool until it assumes the peculiar tenacious condition proper for working. The operation of fusion is conducted in large crucibles of refractory fire-clay, which, in the case of lead-glass, are covered with a dome, at the top, and have an opening at the side by which the materials are introduced, and the melted glass withdrawn.

The manufacture of glass is only con-

ducted on the *large scale*, and the precise character and proportions of the ingredients used by the glass-maker, must necessarily greatly depend upon the nature of the raw materials furnished by his locality, or otherwise at his command. The attention of the manufacturer should be directed to the use of his materials in such proportions as will furnish, in the melting pot, the proper quantities of the essential ingredients, as determined from the known composition of the best commercial samples. The purity of the raw materials and the accuracy of his proportions and quantities, are proved or disproved by the excellence of the product; and the cause of error (if any) may be at once determined by carefully ascertaining the quality of the ingredients employed, and the composition of the defective glass.

Prep. The following formulæ exhibit the composition of the leading commercial glasses, as shown by chemical analysis, together with the proportions of the raw materials used in their production.

Bottle Glass. Sp. gr., 2·700 to 2·735.—*a.* (Composition by analysis.) 1. *Silica*, 53·55%; *lime*, 29·22%; *mixed alkali*, 5·48%; *alumina*, 6·01%; *oxide of iron*, 5·74%. Dark green.

2. *Silica*, 52%; *baryta*, 21·6%; *soda*, 26·1%; *oxides of iron* and *manganese*, 0·3%. Pale green; very superior.

b. (Raw materials used.) — 1. *Yellow sand*, 20%; *kelp*, 8%; *lixiviated wood-ashes*, 30%; *fresh wood-ashes*, 8%; *pale clay*, 16%; *cullet* (broken glass), 18%. This is the common mixture for coarse bottles, in Belgium, France, and Germany.

2. To the last add of *black oxide of manganese*, 2½ to 3%. Has a rich yellowish colour; used for Rhenish-wine bottles.

3. *Pale sand*, 51%; *lixiviated wood-ashes*, 33%; *pearl-ashes* (dried), 8%; *common salt*, 7½ %; *white arsenic*, ½ %; *charcoal*, q. s. Very pale green.

4. *Silicious sand* (pale), 68½ %; *potash* (or its equiv.), 4%; *lime*, 23½ %; *heavy spar*, 2½ %; *peroxide of manganese*, 1½ %. This forms the celebrated *flask-glass* of St. Etienne.

Broad Glass, Spread Window Glass. Sp. gr., 2·642.—*a.* (By analysis.) *Silica*, 69·70%; *lime*, 13·30%; *soda*, 15·25%; *oxide of iron* (and loss), 1·75%.

b. (Materials used.) 1. *White sand*, 50%; *dried sulphate of soda*, 22%; *charcoal* (in powder), 9%; *cullet*, 41%; *peroxide of manganese*, a little. Pale.

2. *White sand*, 60%; *potashes* (good), 24%; *common salt*, 10%; *nitre*, 5%; *white arsenic*, 1%; *peroxide of manganese*, a little (1/10 to 1/12 %); *pale cullet*, at will (10 to 30%). Very pale. This is the "*spread*" or *sheet window-glass*, in common use.

Chemical Glass. Sp. gr., 2·390 to 2·396.—*a.* (By analysis.) 1. *Silica*, 72·80%; *potassa*, 16·80%; *lime* (with a trace of alumina), 9·68%; *magnesia*, 0·40%; traces of *oxide of manganese* and *iron* (and loss), 0·32%. This is the difficultly-fusible *Bohemian tube-glass*, so valuable in chemical manipulations.

2. *Silica*, 69·3%; *potassa*, 15·8%; *soda*, 3%; *lime*, 7·6%; *alumina*, 1·2%; *magnesia*, 2%; *oxide of iron*, 0·5%; *oxide of manganese* (and loss), 0·6%. *English chemical glass* (without lead). More fusible than the last.

b. (Materials used.) 1. *Quartz* (hyalin, in powder), 60%; *calcined purified pearlash*, 30%; *fresh-burnt lime* (very pure), 9%; *nitre* (dried), ¾ %; *arsenious acid* or *peroxide of manganese*, ¼ %. Said to be the proportions used in the production of *a*, 1, (above.)

2. (M. Peligot.) *Quartz*, 71½ %; *carbonate of potassa* (or its equiv., dry), 20%; *quicklime*, 8½ %; (*manganese*, a little.) Said to be the formula for the hardest and least fusible *Bohemian tube-glass*. It is very intractable and infusible, except at a very high temperature; but the addition of an exceedingly small quantity of *boracic acid*, *borax*, or *arsenious acid*, causes it to flow into a glass possessing great brilliancy and hardness, and capable of being wrought at the highest heat of the ordinary furnace.

Crown Glass, White Window-glass. Sp. gr., 2·486 to 2·488.—*a.* (By analysis.) 1. *Silica*, 62·8%; *potassa*, 22·1%; *lime*, 12·5%; *alumina* (with traces of oxide of iron and manganese), 2·6%. Crown-glass of Bohemia, according to Dumas. Very beautiful.

2. *Silica*, 72·5%; *soda*, 17·75%; *lime*, 9·75%. English crown-glass; excellent quality, but not so white as the last.

b. (Materials used.) 1. *Finest white silicious sand*, 64%; *purified potashes* (dry), 23%; *lime*, 12%; *white arsenic*, ¾ %; *oxide of manganese*, ¼ %. Said to be used in Bohemia.

2. (Schweigger.) *Pure sand*, 57%; *dry sulphate of soda*, 28½ %; *quicklime*, 11½ %; *powdered charcoal*, 3 or 4%. Corresponds to *a*, 2, *above* (nearly).

3. *Pure sand*, 40%; *soda ash*, 24%; *lime*, 5%; *white cullet*, 31%. Rather superior to the last.

Crystal, Crystal Glass. The crystal glass of *England* is *flint glass* of superior quality; that of *Bohemia* is noticed under *Table glass.*

Flint Glass, Crystal. Sp. gr., 3·000 to 3·620.—*a.* (By analysis.)—1. (Berthier.) *Silica*, 59·19%; *oxide of lead*, 28·68%; *potassa*, 12·13%; *oxides of iron* and *manganese*, traces. Finets colourless English crystal.

2. (Brande; Faraday.) *Silica*, 52·0%; *oxide of lead*, 34·0%; *potassa*, 34·0%. Crystal.

3. (Faraday.) *Silica*, 44·30%; *oxide of lead*, 43·05%; *potassa*, 11·75%; *alumina*, 0·50%; *oxides of iron* and *manganese*, 0·12%; (loss, 0·28%.) Heaviest of three samples of flint glass examined.

b. (Materials used.) 1. *Finest Lynn-sand* (calcined, sifted, and washed), 51%; *litharge* (purest), 28% (or *red lead*, 29%); *refined pearlashes* (calcined before being weighed), 16%; *nitre* (purified), 4¾%; *arsenious acid* and *peroxide of manganese*, of each, ⅛%. Very fine crystal.

2. (M. Payen.) *Fine sand*, 46%; *red lead*, 31%; *purified carbonate of potash*, 23%. French crystal.

3. (Geddes.) *White Lynn-sand*, 51%; *red lead* or *litharge*, 33%; *refined pearlashes*, 13%; *nitre*, 3%; a very little *arsenious acid* and *peroxide of manganese*. Ordinary English flint-glass. *Crystal cullet* may be added at will, to the above. This glass was originally prepared from *powdered flints*, a fact to which it owes its common name.

Optical Glass. 1. (Crown Glass.) *Purest silicious sand*, 55%; *carbonate of soda* (dry), 12%; *chalk* (dry), 11%; *carbonate of baryta*, 22%.

2. (Flint Glass.)—*a.* (By analysis.) *Silica*, 44·30%; *oxide of lead*, 43·05%; *potassa*, 11·75%. This is Guinand's *dense optical glass.*

b. (Materials used.) 1. *Purest quartz*, 42%; *red lead* (finest), 42%; *purified potash*, 14¾%; *purified nitre*, 1¼%. These are the proportions used for the last.

2. (Korner.) *Finest quartz* (reduced to powder, treated with hydrochloric acid, washed, and dried), 47½%; *red lead*, 38¼%; *cream of tartar*, 14½%. The above are used by opticians in the construction of achromatic object glasses.

Plate Glass. Sp. gr., 2·488 to 2·600.—*a.* (By analysis.)—1. (Dumas.) *Silica*, 75·9%; *soda*, 17·5%; *lime*, 3·8%; *alumina*, 2·8%. French mirror-glass.

2. (Mitscherlich.) Silica, 60%; *potassa*, 25%; *lime*, 12·5%; (loss, 2·5%?). Finest Bohemian plate.

b. (Materials used.) 1. *Finest silicious sand*, 45%; *dried carbonate of soda*, 25%; *lime*, 5%; *nitre* (purified), 2%; *plate-glass cullet*, 23%; *peroxide of manganese* and *cobalt azure*, a very little. Ordinary English plate.

2. *Whitish quartz sand*, 60%; *purified carbonate of soda* (dried), 20%; *lime* (slaked by exposure to the air), 9%; *plate-glass cullet*, 11% (or more). Sometimes as much *cullet* as sand is used; but in all cases 1% to 1½% of its weight in *carbonate of soda*, is added with it, besides that ordered in the formula, to compensate for loss of alkali by remelting. *Used* at the celebrated plate-glass works at Saint-Gobain, France. The product possess an amount of excellence which British manufacturers have yet failed to equal.

Table Glass, Bohemian Crystal. Sp. gr. 2·6 to 2·8.—*a.* (By analysis.)—1. (M. Berthier.) *Silica*, 71·7%; *potassa*, 12·7%; *soda*, 2·3%; *lime*, 10·3%; *alumina*, 0·4%; *oxides of iron* and *manganese* (and loss), 2·6%. Very white, hard, and beautiful table glass.

2. (Dumas.) *Silica*, 70%; *potassa*, 20%; *lime*, 4%; *alumina*, 5%; *oxide of iron*, 0·6%; *peroxide of manganese*, 0·4%. A beautiful white wine-glass.

b. (Materials used.) 1. *Finest sand*, 50%; *purified potashes*, 25%; *chalk*, 10%; *nitre*, 2%; *crystal cullet*, 27%; *manganese*, a little (say 1/16%). *Used* in England recently for table glass.

2. *Quartz* (hyalin, in powder), 63%; *purified potashes*, 26%; *slaked lime* (carefully sifted), 11%; *manganese*, a little; *crystal cullet*, at will. *Used* in Bohemia.

3. (M. Perdonnet.) *Powdered quartz*, 44%; *carbonate of potassa*, 33%; *quicklime* (in fine powder), 22%; *nitre*, 1%; and a *very small* quantity of *arsenious acid* and *peroxide of manganese.* Said to be the formula used at Neuwelt, for the glass, *a*, 1, (above.)

Qual., &c. These are denoted by its hardness, transparency, homogeneity, strength, and power of resisting the action of water, air, light, and the stronger acids and alkalies. The power of glass to resist the action of menstrua is readily tried by exposing it to boiling oil of vitriol, and hot, but *dilute* solution of caustic potassa. Neither of these tests should cause the glass to lose its transparency or to become dim.

Pois., &c. Glass and enamel, both in fragments and in powder, have occasionally been swallowed, with different results. These bodies are insoluble in the fluids of the body, and, consequently, any injurious action they may exert upon the system whilst they are retained in it, must entirely depend upon mechanical attrition or irritation. As *treatment*, we must administer an *emetic* and assist its action by thick *mucilaginous liquids*, and afterwards have recourse to antiphlogistics, if necessary.

Anal., or *Assay.*—*a.* A portion of the sample for examination is heated to dull redness, and then suddenly thrown, whilst still hot, into a vessel of cold water. It is next dried, and reduced to fine powder in an agate or hardened-steel mortar.

b. 100 gr. of the *prepared powder* is thoroughly mixed with 200 gr. of *pure potassa*, and the whole is exposed to heat in a silver or platinum crucible or capsule until *perfect* fusion takes place; when cold, the crucible and its contents are boiled in about half-a-pint of *distilled water; nitric acid* is added to the resulting solution, in excess, and the mixture, together with any sediment, is evaporated to dryness, after which, the heat is gradually increased to 400° or 500° Fahr.; the dry residuum is next reduced to powder, and digested in *water acidulated with nitric acid*, until exhausted of soluble matter; the *insoluble portion* is then carefully dried, gently ignited, and weighed. The weight in grains represents the per centage of SILICA in the sample examined.

c. The *mixed liquid* and "*washings*" of (*b*) is next acidulated with *nitric acid*, and treated to a stream of *sulphuretted hydrogen*, which if it produces a precipitate is continued for some time; the precipitate is collected on a *very small* filter, washed, and dried; the filter with the precipitate is next placed in a beaker glass, and strong *fuming nitric acid* is cautiously added, drop by drop, until complete solution takes place; after boiling the solution for a few minutes, and allowing it to cool, it is precipitated with *sulphuric acid*, in excess; this precipitate (sulphate of lead) is washed, dried, slightly ignited in a porcelain crucible, and weighed. The weight in grains, multiplied by 0·7369, gives the per centage of OXIDE OF LEAD OR LITHARGE.

d. The *filtered liquid* from (*c*) is evaporated to dryness, and redissolved in *water* acidulated with *hydrochloric acid*, and treated with a *solution* of *sal ammoniac*, and afterwards with *liquor of ammonia*, in excess; the precipitate (*alumina* and *oxide of iron*) is collected, washed, and boiled in a solution of *caustic potassa;* the undissolved portion is collected on a filter, washed with *boiling water*, ignited, and weighed. This gives the per centage of PEROXIDE OF IRON.

e. The liquid *filtered from the oxide of iron* holds the alumina (if any) in solution; a *solution* of *carbonate of ammonia* is dropped in; the resulting precipitate is washed, dried, ignited, and weighed. This gives the per centage of ALUMINA.

f. The *filtrate* from the *alumina and oxide of iron* (see *d*), after being evaporated to dryness, is redissolved in a large quantity of *distilled water*, and is treated with a solution of *oxalic acid* (a solution of *oxalate of ammonia* is preferable when no baryta is present); the precipitate is washed, dried, gently ignited, and weighed. The weight, in grains, multiplied by 0·56292, gives the per centage of LIME required.

g. The *filtrate* from (*f*) is now mixed with *carbonate of potassa*, in considerable excess, and boiled for a *long time;* the resulting precipitate (if any) is then collected on a filter, slightly washed with *hot water*, dried, and exposed to a *full-red heat* for some time (say 2 hours); the residuum of the calcination is then weighed. This furnishes the per centage value of the sample in MAGNESIA.

h. The *filtrate* from (*f*) is treated with *dilute sulphuric acid* or the *solution of a sulphate*, as long as a precipitate falls; the precipitate (SULPHATE OF BARYTA) is washed, dried, gently ignited, and weighed. The weight, in grains, multiplied by 0·6589 gives the per centage of BARYTA in the sample.

The above may be varied by gently concentrating the liquid filtered from the precipitate of alumina and oxide of iron (see *d*), and precipitating it with *dilute sulphuric acid;* the mixed precipitate is exhausted by digestion in *water* holding *hydrochlorate of ammonia* in solution; the undissolved residuum (SULPHATE OF BARYTA) is washed, dried, and otherwise treated as before; whilst the *solution* with the "*washings*," is treated with a *solution of carbonate of ammonia;* the precipitate is CARBONATE OF LIME, which is to be washed, &c., as directed under (*f*). The liquor, &c., filtered from the lime, is lastly tested for MAGNESIA. (See *g.*)

i. A *second* 100 gr. of the *powdered glass* (see *a*) is mixed with 200 gr. of *fluor spar*, also in powder; the compound is placed in a platinum or leaden capsule, 500 gr. of strong *sulphuric acid* are added, and the whole cautiously stirred together with a silver stirrer or spoon, care being taken to avoid inhaling the fumes; the heat of a spirit lamp is next applied, and at first is kept at about 212° Fahr., but towards the conclusion of the process is raised to 300° Fahr., or even higher, and is continued for at least 2 hours, or until fumes *entirely* cease to be evolved; 5 or 6 fl. oz. of *distilled water* are next poured on the residuary mass, and after thorough agitation, the whole is thrown on a filter, more water being at last poured on to wash out any remains of soluble matter; to the filtrate *carbonate of ammonia* is added in excess, and after a time the earthy salts are removed by filtration; the filtered liquor is now evaporated to dryness, and ignited to *dull*

redness for 2 or 3 minutes; the residuum (*sulphate of potassa* or *soda*, or of *both*), after being weighed (the weight being carefully noted down), is redissolved in *distilled water;* a solution of *chloride of barium* is then added as long as it disturbs the liquor, and after a time the whole is again filtered; the *filtrate* is concentrated by evaporation, and solution of *bichloride of platinum* added in excess; the whole is now gently evaporated to dryness, mixed with *alcohol*, collected on a filter, carefully washed with *weak alcohol*, dried at a temperature under 212° Fahr., and weighed. The weight, in grains, multiplied by 0·1940 gives the per centage of POTASSA sought.

k. The *weight* of *sulphate of potassa* in the ignited residuum in (*i*) is calculated from that of the *potassa* last found (47 parts of the one being equal to 87 parts of the other), and *this weight* is deducted from the *gross weight* of the *ignited sulphates;* the remainder represents the quantity of SULPHATE OF SODA present. The weight of the *latter*, in grains, multiplied by 0·4367, gives the per centage of PURE SODA required.

Concluding Remarks. One of the chief points to which the skilful glass manufacturer directs his attention, is the quality of his materials. Great care is exercised in the selection of the *sand* for all the finer varieties of glass. The usual practice is to test it before using it, by exposing it to a very high temperature. The purest sand is that which is the whitest and freest from iron, and which, consequently, suffers the least alteration by this treatment. The *alkalies* (potash, soda) employed, are purified by solution and crystallization. The *red lead* and *litharge* must be pure and absolutely free from oxide of copper (a common contamination), which gives a green tint to the glass. The former, which is the most costly, is preferable for the finest crystal. Care must also be taken that the *lime*, *clay*, *&c.*, are respectively of proper purity; and that the *cullet* or broken glass, which is almost always remelted with the other materials, is of proper quality, and of the *same* kind as that to which it is added. *Potassa* produces a better glass than soda, although the latter is now very generally employed from its lower price. It is, however, quite inadmissible as an ingredient in the manufacture of the better class of *crystal* and *plate glass*, as however pure it may be, it imparts to the product a slight greenish tinge more or less destructive of its beauty. When *sulphate of soda* (Glauber salt) is used as a source of soda, it is gently calcined to dissipate its water of crystallization, and requires the addition of about 8% of *charcoal* to effect its reduction in the melting-pot. *Common salt* is also employed as a source of soda in the same manner. Sometimes *native sulphuret of lead* (galena) is used to decompose the sulphate of soda, and in lieu of part of the oxide of lead; in which case about 5 parts of the sulphuret are taken for every 9 parts of the calcined sulphate.

To anticipate the results of his processes, and to carry out with certainty his various intentions, the glass-manufacturer, perhaps more than any other person, requires the aid of science and experience. All his most essential operations depend on chemical principles. The products of his furnaces are not formed by the mere mechanical admixture of their several ingredients whilst in the state of fusion, but result from the play of delicate affinities which only act under certain conditions, and when the materials are presented to each other in uniform and definite proportions. Chemically speaking, the glasses are mixed supersilicates of the respective bases which enter into their composition (*potassa*, *lime*, *lead*, *&c.*), and like all other compounds which are formed by elective attraction, obey the common laws of combination, as developed by Dalton, and now so successfully applied in almost every department of industrial art. It has been shown by the most careful analysis, that in all the more valuable and beautiful commercial glasses, the relative proportions of the materials are conformable to these laws, and that several of them are true atomic compounds, as perfect in this respect, as the crystalline bodies commonly denominated salts. In some of the harder glasses of Bohemia the number of atoms or equivalents of silica are to each of the bases with which it is united, nearly as 5 to 1; whilst in a softer glass of German manufacture, the proportions of the two are found to be as 4 to 1. The celebrated plate glass of St. Gobain, is an atomic compound formed of 1 equivalent of trisilicate of soda, united to one equivalent of trisilicate of lime, with a small per centage of alumina in combination with silicic acid (*silica*), also in atomic proportion. Glasses in which the ingredients bear no atomic ratio to each other, are never homogeneous, but always more or less striated and of unequal colour and refractive power. The absence of atomic proportion between the substances entering into its composition, appears to be the

only reason why the best English plate and mirror glass is so greatly inferior to that of France and Germany, that comparison of the two becomes absurd. The only variety of glass in the production of which the English manufacturer excels, is flint glass or crystal, and here he certainly surpasses all his numerous competitors. The subject is doubtless involved in difficulty, owing to the precise temperature necessary to effect the perfect combination of the bases with the silicic acid, varying with the character of the compound, and not being satisfactorily settled by observation or experience. The modifying influence of temperature is shown by the fact that the lower the heat employed in the process, the smaller the quantity of silica which enters into the composition of the resulting glass; whilst at higher temperatures, a part of the base is dissipated in fumes, until such proportions of base and acid result, as are required to produce a permanent atomic compound corresponding to the temperature employed. If the heat is excessive or improperly continued, the loss of base produces an opposite effect, and an opaque, semi-vitrified mass is formed, resembling Reaumur's porcelain. The quality of the resulting glass depends on this change being more or less complete. If the furnace yields the right temperature and the duration of the exposure to its action is neither too short nor too prolonged, nature makes up for the unskilful conduct of the operative, and removes the stumbling blocks which his ignorance had placed in the way of his own attempts at excellence. The proceedings and their results are accidental, but being once obtained, the first are repeated without further trouble or inquiry. This accounts for the same mixture of materials yielding products of different qualities at different times, and in different works, which the operative contents himself with referring to the "going of the furnace." The common plan in this country is to regulate the proportions and firing by experience only, rather than by theory and practice combined. Now, although the chemist has much yet to learn on the precise constitution of the glasses, and although theory may not be able to ensure unvarying success, it is nevertheless certain that, in all cases, it can afford much valuable assistance in that direction. Indeed, it has been asserted by one of the leading Continental chemists, that ingredients that will yield the proper equivalent proportions in the melting pot, *cannot* produce a bad glass, if exposed to such a temperature as to permit of perfect combination taking place.

It is found that those glasses which contain a predominance of alkali are acted on by water, and when this is in great excess, they are perfectly soluble in that fluid. Ordinary *flint glass* is affected by long coction in water, whilst *crown glass*, which contains less alkali, is unaltered by that trial. Glass which contains any considerable quantity of lead, is acted on by sulphuretted hydrogen. This is the cause of the surface of *flint glass*, under certain circumstances, becoming opaque and iridescent. Glasses made of silica and alkali *alone* are incapable of permanently resisting the action of water. The addition of lime or oxide of lead appears to be necessary to give them this quality. Glasses that have a slight greenish or bluish tint may be often *whitened*, or rendered *colourless*, by exposure to light and air. This arises from the peroxidizement of the iron, to whose protoxide they owe their tint. Other glasses become *purpled* by exposure, owing to the peroxidizement of the manganese.

Different colours are communicated to glass by the addition of metallic oxides. Thus, oxide of manganese gives an *amethyst;* oxide of cobalt, a *blue;* oxide of iron, a *brown;* black oxide of copper, a *green;* oxide of gold, a *purple;* suboxide of copper, a *ruby-red;* oxide of tin, a *white;* oxide of silver, a *yellow*, *&c.* These substances are either added to the melted contents of the glass-pot, as in preparing *artificial gems*, *&c.;* or they are applied in a thin layer to the surface of the object, which is then heated until fusion of the coloured compound occurs, as in *enamelling* and *painting on glass.*

Glass is *formed* or *fashioned* into articles by the processes of blowing, casting, drawing, rolling, or spreading. In the process of *blowing glass* the workman begins by collecting a proper quantity of glass in a soft, pasty state, at the end of his *blowpipe* (an iron tube, five or six feet in length, terminated by a mouth-piece of wood), which he then commences blowing through, by which the lump is expanded into a kind of flask, susceptible of having its form modified by the position in which it is held, and the velocity of rotation continually given to the iron tube. If an open-mouthed vessel is to be made, an iron rod, called a "*pontil*" or "*puntil*," is dipped into the glass-pot and applied to the bottom of the flask, to which it thus serves as a handle, the blowpipe being removed by the application of a cold iron to the neck. The vessel

is now re-heated, and the aperture enlarged, and the vessel otherwise altered in figure by the aid of a few simple tools until completed. It is then detached, and carried to the "*annealing oven*," where it undergoes slow and gradual cooling during many hours. In this way bottles, flasks, carboys, and an almost infinite variety of other articles are formed. The large circular *tables* of *crown-glass* are made by a joint process of blowing and spreading. The globular flask at first produced, transferred from the blowpipe to the "pontil," is suddenly made to assume the form of a flat disc by the centrifugal force of the rapid rotatory movement given to the rod. *Spread* or *broad glass* is formed into sheets in a nearly similar manner. *Plate-glass* is cast upon a flat metal table, and after very careful annealing, is ground and polished by suitable machinery. *Tubes* are made by rapidly *drawing* out a hollow cylinder; and from these a great variety of useful small apparatus are constructed with the help of a lamp and blowpipe, or still better, the bellows-table of the barometer-maker. *Glass beads* are made from small tubes chopped into pieces of suitable lengths, which are stirred first, in a mixture of *sand* and *wood-ashes*, in the cold, and afterwards in an iron pan over the fire until they assume a rounded form. *Small tubes* are bent in the flame of a spirit-lamp or gas-jet, and cut by a file, a scratch being made, and the two portions pulled or broken asunder in a way easily learned by a few trials. *Large tubes* require the heat of a powerful blowpipe and lamp, or that of a furnace.

The following *Table of Equivalents*, together with the mode of *assaying glass* (see *above*), will be found of great value by the glass manufacturer desirous of improving the quality of his wares:—

Silica	45·5			Alumina 26
„ (2 atoms)	91·0	are		Baryta 77
„ (3 „)	136·5	equal		Carbonate of potassa (dry). 69
„ (4 „)	182·0			„ soda (do.) 53
„ (5 „)	227·5	to		Chalk 50
„ (6 „)	273·0			Common salt 58·5
				Lime 28
				Litharge 112
				Magnesia 20
				Potassa 47
				Red lead 114
				Soda 31
				Sulphate of baryta 117
				„ soda (dry) 71

GLASS (Management of). The following hints may prove useful to the inexperienced:—

Annealing. The process of annealing glass has been briefly referred to at p. 68. The *extreme brittleness* of *imperfectly annealed wrought glass* may generally be remedied on the *small scale*, by immersing the articles in a *bath of oil*, or a *concentrated solution of chloride of calcium*, or *common salt*, and heating the whole gradually and cautiously to the boiling point, and letting it again cool,—*the slower the better.* By this treatment, the glass will be enabled to bear any alternations of temperature between the two extremes to which it has been exposed.

Blowing. By the ingenious art of *glass-blowing* and *glass-drawing*, as practised on the small scale, with a blowpipe lamp furnace, a variety of articles of ornament and utility may be made, their number being limited only by the ingenuity of the artist. The details of the various operations are, however, too lengthy to describe here. See *Glass* (above).

Cleaning. Windows, looking-glasses, &c., may be quickly cleaned as follows:—Dip a slightly moistened rag or flannel into *whiting*, *fuller's earth*, *wood-ashes*, or *rotten-stone*, in impalpable powder, with which smear the glass, and wipe it off with a dry soft cloth. This does well when the surface is very dirty. In other cases, a little *thumb blue*, *whiting*, or *chalk*, in fine powder, tied up in muslin, may be dusted on the glass, which should then be cleaned off with chamois leather. This gives a fine polish.

Cutting. Glass may be easily cut with a common well-hardened steel file, provided it be moistened with *oil of turpentine*, or plunged *under water*. It may also be perforated with a common steel brad-awl in the same way. *Glass vessels*, as bottles and tubes, may be readily cut or shortened, by placing a heated iron ring over the spot, or a piece of loose string or cotton dipped in

oil of turpentine and set on fire, and immediately on the withdrawal of either, applying *cold water* to the part. Glass vessels or tubes thus treated will generally crack round, and may be readily divided into two parts. The ingenious Faraday, in this manner converts a common Florence oil-flask into an evaporating dish and a funnel. By a little practice a crack may be led in almost any direction, or a new one made, by the point of a *red-hot poker* or a *spring coal* (an ignited crayon of prepared charcoal). The parts may then be separated by a little force or a smart rap; and the divided edges smoothed by the flame of a blowpipe, or by grinding them with *powdered emery-and-water* on a flat stone. In this way many broken articles in glass may be converted into others scarcely less useful.

Engraving, Etching. This has been already noticed. (See p. 397.)

Grinding. This, on the *large scale*, like glass-cutting, forms a distinct occupation. On the *small scale*, glass may be roughed or ground by friction with *powdered emery-and-water* and a flat rubber of wood; care being taken that the article, if a plate, is laid on a perfectly flat surface, or, if hollow, is supported by a *core* of cement or plaster. The *frosted appearance* of ground glass is given to the panes of windows by *gently* dabbing the glass over with a piece of *glazier's putty*, stuck on the ends of the fingers. When applied with *a light and even touch*, the resemblance is considerable. *Another method* is to dab the glass over with thin *white paint*, or *flour paste*, by means of a brush, but the effect is much inferior to the above.

Packing. See *Packing, &c.*

Writing on glass may be performed by a piece of *French chalk* or *crayons* prepared for the purpose; or even with a common pen held nearly perpendicular. *Indian ink*, or when the article will be exposed to damp, *shell-lac ink* or *varnish*, thickened with a little *vermilion* or *lamp black*, is best adapted to this purpose. Common ink is not sufficiently opaque.

GLASS. This term was applied by the *older chemists* to various substances to which a vitreous appearance has been given by heat. Thus, we have *glass of antimony*, *glass of borax*, *&c.* It is now obsolete.

GLASS (Devitrified). See *Glass* and *Porcelain.*

GLASS (Powdered). Syn. *Vitrum Pulverisatum*,—Lat. *Prep.* Heat the glass red hot, throw it into cold water, dry, and powder it. *Used* to filter acids, and glued upon paper as a polishing powder; also to wear down *corns* upon the feet, after the feet have been well soaked, and dried. It has likewise been blown into the eyes to wear down excrescences.

GLASS (Soluble). Syn. *Vitrum Solubule*,—Lat. *Prep.* 1. *Silica* (or its equiv.), 1 part; *carbonate of potassa* or of *soda*, 2 parts; fused together.

2. (Dobereiner). *Carbonate of soda* (dry), 54 parts; *carbonate of potassa* (dry), 70 parts; *silica*, 192 parts; as last. Soluble in boiling water, yielding a fine, transparent, semi-elastic varnish.

3. (Fuchs.) *Carbonate of potassa* (dry), 10 parts; *powdered quartz* or *pure sand*, 15 parts; *charcoal*, 1 part. Soluble in 5 parts of water. The solution, on evaporation, furnishes a transparent glass, permanent in the air.

Uses, &c. The above, in solution, have been used to render textile fabrics less combustible. The potash compound (*silicate of potassa*) has been recommended as a remedy for gouty concretions by Mr. Ure. *Dose.* 10 to 15 gr., in 6 or 8 fl. oz. of water, twice a day.

GLAUBER SALTS. See *Sulphate of Soda.*

GLAUCIC ACID. A compound discovered by Dr. Runge in several species of *dipsacus* and *scabiosa*. It is obtained by adding *ether* to the *tincture of the dry plant*, dissolving the precipitated flocculi in *water*, treating the solution with *acetate of lead*, decomposing the precipitated *glaucate of lead* with *sulphuretted hydrogen*, and evaporating the filtered liquor to expel the water and acetic acid. A brittle yellow mass, forming salts with the bases called *glaucates.*

GLAUCINE. A peculiar substance forming pearly scales, soluble in hot water, alcohol, and ether; discovered by Probst in *glauceum luteum.* It forms neutral salts with the acids.

GLAUCOPICRINE. White scales, soluble in hot water, alcohol, and ether, and having a bitter taste, obtained by Probst from *glauceum luteum.* It forms neutral crystallizable salts with the acids.

GLAZE. *Gravy* or *clarified soup* boiled until it gelatinizes on cooling. It is used as a species of varnish to cover various dishes for the table, and may be spiced and flavoured according to the fancy of the cook.

GLAZES. These are either *white* or *coloured.* The former, by the addition of the colouring ingredients used for enamels are converted into the latter.

Prep. 1. (With lead.) *White lead* (pure),

53 parts; *quartz* or *ground flints*, 36 parts; *Cornish stone* or *felspar*, 16 parts; *white flint glass*, 5 parts; reduce the whole to an impalpable powder, without fritting. For common earthenware.

2. (Without lead.) *Fine Lynn-sand*, 47¾%; *purified potash*, 38%; *slaked lime*, 9½%; *nitre*, 4¾%; powder, mix, heat the mixture until "fritted," and then again reduce it to fine powder. Sometimes about 1% of *oxide of tin* and a *very small* quantity of *oxide of cobalt* are added before "fritting" the ingredients, in order to take off the brown colour, and make the white turn on the azure. For metallic colours and chemical vessels.

3. (Rose.) *Felspar*, 27 parts; *borax*, 18 parts; *finest silicious sand*, 4 parts; *nitre*, *soda*, and *purest china clay* (Cornish), 3 parts; mix, heat to a "frit," powder, and add of *calcined borax*, 3 parts. For porcelain.

4. (Ure.) *White felspar*, 26 parts; *soda*, 6 parts; *nitre*, 2 parts; *borax*, 1 part; "frit" together as last. Of the *product* take 13 parts; *red lead*, 50 parts; *white lead*, 40 parts; *flints*, 12 parts; reduce the whole to powder as before. For painted stoneware.

Obs. Glazes must be reduced to very fine powder. For *use* they are ground with water to a very thin paste or smooth cream, into which the articles, previously baked to the state called "*biscuit*," are then dipped; they are afterwards exposed to a sufficient heat in the kiln to fuse the glaze. *Another method* of applying them is to immerse the "biscuit" in water for a minute or so, and then to sprinkle the dry powder over the moistened surface.

GLIADINE. A peculiar substance contained in the gluten of wheat.

Prep. Rub fresh-made *gluten of wheat flour* with *alcohol*, and evaporate the filtered solution to dryness. The *gliadine* thus obtained may be purified by extracting the colouring matter and oil by means of *ether*.

Prop., &c. A gluey, adhesive substance; hard and translucent, when dry; insoluble in water; soluble in acetic acid and dilute caustic alkali. The presence of gliadine is characteristic of wheat corn. It is *used* to form a test liquor.

GLOBULINE. A species of albumen constituting the principal portion of the blood-globules. See *Hæmatosine*.

GLOVE POWDER. *Prep.* 1. From *Castile soap*, dried by exposure to a warm dry atmosphere for a few days, and then reduced to fine powder in a mortar. *Used* to clean gloves.

2. *Pipe-clay*, coloured with *yellow ochre*, *umber*, or *Irish slate*, q. s., and afterwards scented with a little powdered *orris root* or *cloves*. *Used* to colour gloves made of doe-skin and similar leather.

GLOVES. Although gloves are a less costly article of dress at the present day, than they were during the Middle Ages, the following information may nevertheless be sometimes found of value to their wearers:—

Glove cleaning. 1. (Kid Gloves.)—*a.* Damp them *slightly*, stretch them *gently* over a wooden hand of appropriate size, and clean them with a sponge dipped in recently rectified *oil of turpentine* or *camphine*; as soon as they are dry, withdraw them gently from the "stretcher," and suspend them in a current of air for a few days, or until they cease to smell of the turpentine. Heat must be avoided. If ordinary oil of turpentine is used, a little essence of lemon may be added to it; the scentless or "*sweet oil of turpentine*" needs no such addition. The oil should be used liberally, and the first dirty portion should be sponged off with clean oil. By collecting the "washings" separately, and allowing them to deposit the dirt by standing, the same oil of turpentine may be used over and over again.

b. By employing a *saponaceous compound*. See *Ganteine* and *Saponine*.

2. (Doe-skin *and* Wash-leather Gloves.)—*a.* Stretch them on a hand, or lay them flat on a table, and rub into them a mixture of finely-powdered *fuller's earth* and *alum*; sweep it off with a brush, sprinkle them with a mixture of *dry bran-and-whiting*, and, lastly, dust them well off. This will not do if they are very dirty.

b. Wash them in *luke-warm soft water*, with a little *Castile* or *curd soap*, *ox-gall*, or *bran tea*, then stretch them on wooden hands, or pull them into shape *without wringing them*; next rub them with *pipe-clay* and *yellow ochre*, or *umber*, or a mixture of them in any required shade, made into a paste with *ale* or *beer*; let them dry *gradually*, and, when about *half* dry, rub them well, so as to smooth them and put them into shape; when they are dry, brush out the superfluous colour, cover them with paper, and smooth them with a *warm* (not *hot*) iron.

Glove dyeing. Leather gloves, if not greasy, may be dyed with any of the *ordinary dyes* by brushing the latter over the gloves stretched out smooth. The *surface* alone should be wetted, and a second or third coat may be given after the former one has become dry. When the last coat

has become *thoroughly* dry, the superfluous colour should be well rubbed out, a smooth surface given them by rubbing them with a polished stick or piece of ivory, and the whole gone over with a sponge dipped in white of egg.

GLOVES (Cosmetic). Syn. *Gants Cosmetiques.* These are mock kid or lamb-skin gloves rubbed over, on the *inside*, with the following composition: — *Spermaceti cerate*, 3 *oz.*; melt, add of *balsam of Peru*, ½ dr., stir for 5 minutes, and after a few minutes' repose, pour off the clear portion; to this add of *oil of nutmeg*, 15 drops; *oil of cassia* and *essence of ambergris*, of each, 6 drops; and stir until cold. *Used* by ladies to soften the hands and to prevent or cure chilblains and chaps. They are commonly worn all night in bed.

GLUCIC ACID. Syn. *Kalisaccharic Acid.* A substance produced by the action of alkalies on sugar.

Prep. Saturate a *solution* of *grape-sugar* with *lime* or *baryta*, and set it aside; after some weeks, precipitate the solution with *basic acetate of lead*, filter, wash the precipitate with water, diffuse it in water, decompose it by *sulphuretted hydrogen*, and evaporate the filtered liquor.

Prop., &c. Sour, soluble, deliquescent; its salts (*glucates*) are all soluble, with the exception of the *glucate of protoxide of lead.*

GLUCINA. Syn. *Glycyna, Berylla, Glucine, Oxide of Glucinium, Sesquioxide of do.* A pulverulent white substance, discovered by M. Vauquelin, in 1798, and hitherto found only in the beryl, emerald, and euclase.

Prep. The *beryl*, in fine powder, 1 part; *carbonate of potassa*, 3 parts; expose the mixture to a strong red heat for half an hour, dissolve the calcined mass in *hydrochloric acid*, and evaporate the solution to dryness; redissolve the residuum in *very dilute hydrochloric acid*, and precipitate with *pure liquor of ammonia;* wash the precipitate well, digest it with a large quantity of *carbonate of ammonia*, filter, and boil the solution as long as *carbonate of glucina* subsides. By exposure to a red heat the carbonic acid may be expelled, and the earth rendered anhydrous.

Prop., &c. Glucina closely resembles alumina, from which, however, it is distinguished by its solubility when freshly precipitated, in a cold solution of carbonate of ammonia, from which it is again thrown by boiling. Sp. gr. 2·967. Glucina is classed with the earths. The beryl contains 14% of this substance. (See *below.*)

GLUCINIUM. Syn. *Glycynium, Glucinum, Beryllium.* The metallic base of glucina. It was first obtained by Wöhler, in 1828, by a similar process to that adopted for *aluminium.* It is a grayish-black powder, of difficult fusibility, unacted on by cold water, and burning when heated in the air, producing glucina. It acquires a metallic gloss under the burnisher. See *Aluminum.*

GLUCOSE. See *Grape Sugar.*

GLUCOSIC FERMENTATION. See *Saccharine Fermentation.*

GLUE. Syn. *Colle, Colle Forte,* — Fr. *Gluten, Glutinum,*—Lat. Inspissated animal jelly, or gelatine, used as a cement.

Prep. Glue is principally prepared from the parings and waste-pieces of hides and skins, the refuse of tanneries, and the tendons and other offal of slaughter-houses. These substances, when intended for the glue-maker, are steeped for 14 or 15 days in *milk of lime*, then drained, and dried by exposure to the air. This constitutes what is termed the "*cleansing*" or "*preparation*," and in this state the *glue-pieces*, as they are called, may be kept for a long time, and transported to any distance without suffering decomposition. Before conversion into glue, they are usually again steeped in weak *milk of lime*, and next, well washed, and exposed to the air for 24 to 30 hours. They are then placed in a copper boiler 2-3rds filled with *water*, and furnished with a perforated false bottom to prevent them from burning, and as much is piled on as will fill the vessel and rest on the top of it. Heat is next applied, and the whole gently boiled or simmered together, until the liquor on cooling forms a *firm* gelatinous mass. The clear portion is then run off into another vessel, and a very small quantity of *alum* (dissolved) added; here it is kept hot by a water-bath, and allowed to repose for some hours to deposit its impurities, after which it is run into the *congealing boxes*, and placed in a cool situation. The next morning the cold gelatinous masses are turned out upon boards wetted with water, and are cut horizontally into thin cakes with a stretched piece of brass wire, and then into smaller cakes with a moistened flat knife. The latter are placed on nettings to dry. The dry cakes of glue are next dipped one by one into *hot water*, and slightly rubbed with a brush wetted with *boiling water*, to give them a gloss; they are, lastly, stove-dried for sale. This furnishes the palest and best glue.

As soon as the *liquor* of the *first boiling* has drained off, the undissolved portion of

skins, &c., left in the copper is treated with *fresh water*, and the whole operation is repeated *again* and *again*, as long as any gelatinous matter is extracted. In this way a *second* and other inferior qualities of glue are obtained. The *product* from *dried glue-pieces* is about 50%.

Var. These chiefly depend on the care with which the process is conducted. *Hat-maker's glue* is prepared from the *tendons* of the *legs of neat cattle* and *horses*. It is brown, opaque, and soft; and grows moist in damp weather, but it does not render felt brittle like the other varieties. *Fish glue* is made in like manner from various membranous and solid parts of cetaceous animals. *Parchment glue* is prepared from *shreds* or *shavings of parchment, vellum, white leather*, &c., dissolved by boiling them in *water*. It is scentless and nearly colourless.

Qual. The best glue is transparent, nearly colourless and tasteless, has very little smell, even when melted, and is extremely adhesive. The presence of more than a trace of alum is objectionable; an undue quantity may be easily detected by the usual tests. The strongest glue is that obtained from skins, more especially from the hides of oxen and cows. That obtained from the bones, cartilages, and tendons, is weaker.

GLUE (Liquid). *Prep.* (M. S. Dumoulins.) *Soft water*, 1 quart; *best pale glue*, 2 *lb.*; dissolve in a covered vessel by the heat of a water-bath, cool, and add gradually, of *nitric acid* (sp. gr. 1·335), 7 *oz.*; when cold put it into bottles. Very strong and does not gelatinize. For the "*liquid glue*" sold in the shops, see *Chinese Cement*.

GLUE (Marine). *Prep.* 1. *Indian rubber* (cut small), 1 part; *coal tar* or *mineral naphtha*, 12 parts; digest in a covered vessel with heat and agitation, and when the solution is complete, add of *powdered shell-lac*, 20 parts; continue the heat and stirring until perfect liquefaction has taken place, and pour the fused mass, whilst still hot, on slabs of polished metal or stone, so as to form thin sheets. For *use*, it is heated to its melting point (248° to 250° Fahr.) in an iron vessel, and applied in the liquid state with a brush. Employed in ship-building, &c.

2. *Caoutchouc*, 15 to 20 gr.; *chloroform*, 2 fl. oz.; dissolve, and add of *powdered mastic*, ½ *oz.* It must be kept well-corked and in a cool place, to prevent loss by evaporation. *Used* for small fine work.

GLUE (Portable). Syn. *Bank-note Glue, Mouth do., Indian do.; Colle à bouche*, —Fr. *Prep.* From the *best pale glue*, 1 *lb.*; *water*, q. s.; dissolve in a double glue pot or water bath, add of *pale brown sugar*, ½ *lb.*, continue the heat until the mixture is complete, and pour it into moulds; or pour it on a marble slab, and when cold, cut it into small pieces and dry them in the air. This glue is very useful to draughtsmen, architects, &c., as it dissolves almost immediately in warm water, fastens paper, &c., without the process of damping, and may be softened for many purposes with the tongue. When great strength is not required, 4 *oz.* more of *sugar* may be used.

GLUTEN. Syn. *Vegetable Gluten.* A peculiar substance found in the grain of wheat. According to M. Taddei it is a compound of *gliadine* and *zimome*, but by more recent analysis it appears to consist of *albumen*, *mucin*, and *glutine* (a distinct principle).

Gluten is believed to be eminently nutritious, and to impart to wheat its superiority as an aliment over the grains of the other cereals. It is the presence of gluten in wheaten flour that imparts to it its viscidity or tenacity, and confers upon it its peculiar excellence for the manufacture of *macaroni*, *vermicelli*, and similar pastes. The superiority of wheaten over other bread depends upon the greater tenacity of its dough, which during the *fermentation* is puffed up by the evolved carbonic acid, and retained in its vesicular texture, so as to form a light loaf.

Gluten is grayish coloured, and extensible whilst fresh and moist, like elastic gum. It turns blue when mixed with guaiacum resin. For the mode of obtaining it, see *Flour* (page 476).

GLUTEN BREAD. *Prep.* 1. From *wheat flour* which has been deprived of about 2-3rds of its *starch* by washing it with *water*.

2. From *gluten flour*. Recommended in diabetes.

GLUTEN CHOCOLATE. (*Gentile's.*) A mixture of *cocoa* and *gluten flour*. As a nutritious and appropriate food in diabetes.

GLUTEN FLOUR. *Prep.* 1. From the *waste gluten of the starch works*, washed, dried, and ground.

2. (*Gentile's*). From the last mixed with about an equal weight of *wheat flour*. (See *above*).

GLUTINE. A substance resembling gluten, from which it chiefly differs in being wholly insoluble in alcohol.

GLYCERINE. Syn. *Oxide of Glyceryle; Glycerinum*,—Lat. A sweet syrupy liquid formed during the saponification of oils and fats.

Prep. An almost inexhaustible supply of *crude glycerine* is furnished by evaporating the water used to make lead plaster, and the sweet liquor of the stearine makers. The operative chemist has therefore only to purify one or other of these products to obtain *pure glycerine.* This may be done as follows:—

1. The *water* and *washings* from lead plaster, are mixed together, filtered, and submitted to the action of a *stream* of *sulphuretted hydrogen*, to throw down the lead; the supernatant liquid is decanted from the precipitate, filtered, and evaporated to the consistence of a syrup in a water bath. To render it quite pure it is diluted with *water*, decoloured with a little *animal charcoal*, filtered and again evaporated to the consistence of a thin syrup, after which it is further evaporated in vacuo, or over sulphuric acid, until it acquires the sp. gr. 1·265.

2. (M. Bruère-Perrin.) From the *sweet liquor of the stearine works.* The quantity of *lime* present in the sample is first determined by means of *oxalic acid*, and the proportion of *sulphuric acid* necessary for its saturation, at once calculated, and added; the *crude liquor* is then concentrated in a tinned-copper vessel, evaporation being promoted by brisk agitation, until the sp. gr. sinks to 10° Baumé; it is next cooled and filtered, and *accurately* neutralized (if it is required) with *carbonate of potassa*, after which it is evaporated to the sp. gr. 24° Baumé; on cooling, it deposits gelatinous sulphate of potassa; the whole is now filtered, the deposit on the filter washed with a little very *weak spirit-and-water*, the *filtrate* and "*washings*" mixed together, and evaporated, as before, with agitation, until the sp. gr. 28° Baumé, whilst hot (30° cold), is attained, when the whole is allowed to cool; the clear liquid is, lastly, decanted, and filtered. In this state it has an amber colour, but may be rendered colourless and odourless by re-diluting it with *water*, treating it with *animal charcoal*, filtering, and again evaporating to a proper consistence.

3. By saponifying *olive oil* with *caustic alkali*, decomposing the resulting soap with *dilute sulphuric* or *tartaric acid*, evaporating the aqueous matter to dryness (nearly), dissolving out the *glycerine* with *cold rectified spirit*, and filtering and evaporating the solution as before. The products of all the above are *nearly pure.*

4. (Commercial.) From *sweet stearine-liquor*, by precipitating the lime by a stream of *carbonic acid gas*, or by a solution of *carbonate of soda*, carefully avoiding adding the latter in excess; the liquor is then boiled a little, filtered, evaporated to a syrupy consistence, and again filtered. This is the common glycerine of the shops. It may be further purified as above.

Prop. Pure glycerine is a colourless, odourless, uncrystallizable liquid, sweet to the taste, and of a syrupy consistence; like water, it mixes in all proportions with aqueous liquors, alcohol, and vinegar; it is unctuous and emollient, and softens bodies, like oil, but *without greasing* them; it does not evaporate or change in the air at ordinary temperatures, and is not susceptible of rancidity or spontaneous fermentation; mixed with yeast and kept in a warm place it is gradually converted into *propionic acid;* a strong heat decomposes it, with the production of *acroleine;* it is neutral to test paper, and possesses neither basic nor acid properties; it is easily charged with the aroma of the essential oils, and may be combined with soap, and many other substances, without undergoing change Sp. gr., 1·27.

Uses, &c. Glycerine was discovered by Scheele in 1782, but continued a mere matter of interest to the curious, until comparatively a recent date. At length its value in diseases of the ear was noticed by an English practitioner, and soon afterwards, Dr. Startin announced its efficacy in some cutaneous affections. This led to its action being tested by MM. Bazin and Cazenave, in France; by Mr. Yearsley and Mr. T. Wakley, in London; and in Russia, by Dr. Dallas, of Odessa, by whom its value both as a remedy and a cosmetic has been fully established. It is now extensively employed, either alone, or in lotions, baths, &c., as a soothing emollient, and is added to poultices and dressings, instead of oil, to prevent their hardening. Diluted with water it often succeeds in allaying itching and irritation of the skin when all other means fail. As a *cosmetic*, either made into a lotion or added to soap (*glycerine soap*), or used in small quantities along with the water employed in washing, it imparts a healthy clearness, and a sensation of softness and coolness to the skin, which is very agreeable and refreshing. It is the best remedy known for chapped nipples, hands, lips, &c.; all of which may be prevented by its use as an article of the toilet.

GLYCERYLE. The hypothetical radical of glycerine, according to Liebig.

GLYCION. See *Glycyrrhizine.*

GLYCOBENZOIC ACID. A nitrogenous

compound formed, along with water and pure nitrogen, when *hippuric acid* is treated with *nitrous acid.* It is crystalline, only slightly soluble in water, but freely soluble in alcohol and ether; boiling water resolves it into *benzoic acid* and *glycolic acid.*

GLYCO-CHOLALIC ACID. See *Cholic Acid.*

GLYCOCINE. Syn. *Glycocoll, Glycolamide, Gelatine Sugar.* This substance was originally obtained by the action of cold *concentrated sulphuric acid* upon *gelatine,* but it has been since shown to be formed along with benzoic acid, when *hippuric acid* is treated with boiling *hydrochloric acid.* It is sweet tasted, colourless, crystallizable, freely soluble in water, and unites to form crystallizable compounds with a number of other bodies, like cane and grape sugar.

GLYCO-HYOCHOLALIC ACID. See *Hyocholic Acid.*

GLYCOLAMIDE. See *Glycocine.*

GLYCOLIC ACID. See *Glycobenzoic Acid.*

GLYCYRRHIZINE. Syn. *Glycion, Liquorice Sugar.* An uncrystallizable variety of sugar obtained from the root of common liquorice (*glycyrrhiza glabra,*—Linn.) It is yellow, transparent, soluble in both water and alcohol, and is not susceptible of the vinous fermentation. The stronger acids precipitate it from its solutions.

GLYPHOGRAPHY. An art by which an engraving is produced by voltaic electricity. A drawing having been made through the ordinary etching ground, the plate is etched, and after being dried and covered with a mixture of various substances (*plumbago* answers well), it is suspended in the decomposition cell, and a copper-plate is deposited on it in the usual manner. The design is thus in slight relief, and is intended to be printed from, like a woodcut, by the common system of printing; the lights are, however, apt to take the ink, unless much time and care are spent on them. This fact is well known to the patentee, who refused us a specimen in our pages, unless our printer would permit *him* to "work off" the sheet containing it.

GLYSTERS. See *Enemas.*

GNATS and *Musquitoes.* Smoke and strong fumes of any kind, will drive away these insects. If you only burn a piece of *brown paper* in an enclosed space where they are, they soon after "settle," and appear to become so stupified as to remain inactive for some time after. In those parts of the New World where musquitoes abound, tobacco smoke is commonly had recourse to, in-doors; and large fires made of brush-wood or under-wood, out-of-doors. Old travellers when compelled to bivouac during the season in which they are troublesome, are very careful to keep close on the "lee" of these fires.

GOAT. The *capra* of Linnæus, an animal naturalized almost everywhere. Its *hair* is woven into clothing, and its *flesh* and *milk* furnish us with excellent food. That of the *kid* is much esteemed. The *oriental bezoar* is a concretion found in the stomach and intestines of the goat.

GOITRE. Syn. *Derbyshire Neck; Bronchocele, Tracheocele, Hernia Bronchialis,*—Lat. An indolent tumour on the fore part of the neck, formed by a morbid enlargement of the thyroid gland. It sometimes occurs in Derbyshire, and is endemic in the Alps and several other mountainous districts. *Iodine* and the *iodides* appear to be the only substances capable of curing, or even arresting the progress of this disease.

GOLD. Syn. *Aurum,*—Lat. Gold is the most valuable, and, probably, the longest known of all the metals. From the remotest period it has been esteemed for its beauty and permanence, and has been taken as the standard measure of value amongst all civilized nations. To describe the uses of gold in the arts, and its influence on society in all ages, as a symbol of wealth and an article of ornament and utility, would embrace the whole history of mankind. At the present day it alike contributes to the conveniences, comforts, and luxuries of life, as often exciting the baser passions of the human heart as promoting the cause of benevolence and virtue.

Gold is found only in the metallic state. It occurs as *gold dust* in the sands of various rivers, and in the alluvial soil of auriferous districts, from both of which it is obtained by the simple process of "*washing.*" Traces of it are constantly found in the iron and other pyrites of the more ancient rocks. Sometimes it occurs beautifully crystallized in the cubic form, associated with quartz, oxide of iron, and other substances, in regular veins. In the gold fields of California and Australia lumps of nearly pure gold have been discovered in abundance during the last few years. In the former country a mass of gold weighing 28 pounds was found; whilst in our own colonies, one weighing 106 pounds, was dug out of a quartz rock, near Bathurst. The latter contained upwards of $91\frac{6}{0}$ of *pure*

gold and nearly 8½ % of *silver;* being as pure as the English sovereign, or in trade language, "22 carats fine."

Prep. This consists merely in the separation of the gold and its subsequent purification. *Formerly*, the *auriferous sulphurets*, if very poor, were first roasted, then fused into "mattes" and again roasted; they were next melted with *lead*, and the alloy thus obtained was refined by *cupellation*. When the ores were very rich, the preliminary calcination and fusion were omitted, and the alloy of lead at once formed. This plan (*method by fusion*) does not answer well with auriferous copper pyrites or ores very poor in gold. At the present time the *method by amalgamation* is principally followed. When a *vein-stone* is to be wrought for gold, it is reduced to powder (on the *small scale* by hand, on the *large scale* in stamping mills), and is shaken in a suitable apparatus with *water* and *mercury;* an amalgam of gold is formed, which is then separated from the mixture, and its mercury removed by distillation. The gold is next cast into "ingots." Ores containing less than 1-250,000th part of gold will not pay for working.

Refining. Gold obtained by the *first method* usually contains a little copper and silver, and frequently tin or iron. *Tin* may be removed by adding a little *corrosive sublimate* or *nitre* to the gold melted in a crucible. The *process by amalgamation* commonly leaves no other alloy than *silver*. This metal is removed either in the "*dry way*," by fusing the gold with *sulphur* or *sulphuret of antimony;* or in the "*wet way*," by *quartation* and *parting*. At the Royal Mint, "when gold ingots contain a certain quantity of silver" (say 2% or 3%), "instead of leaving it, as formerly, to constitute a part of the standard alloy, it pays to extract it, and to substitute copper in its place. To get the silver out of the said ingots, they are melted with about 3 parts of *silver*,—the resulting alloy is *granulated* and boiled with *sulphuric acid*,—the gold remains untouched, and all the silver is dissolved and converted into *sulphate*." "The *sulphate of silver* is then decomposed by the immersion of *copper plates;* the silver is precipitated in a fine, crystalline powder, washed, pressed into masses, and melted, and so affords PURE SILVER, which is afterwards made standard by alloying it with *copper*, and is used for coinage. The resulting *sulphate of copper*" (which exists in the solution) "is then crystallized, and sold." (Brande.) By first exhausting the gold with *nitric acid*, and then boiling it in *sulphuric acid*, some two or three thousandth part of silver which escaped the action of the nitric acid is dissolved out, and "*perfectly pure gold* is obtained." (Ure.)

By a foreign invention patented in 1851, by Mr. W. E. Newton, the operations of *separation* and *refining* are conducted by one process. The *argentiferous* substance, whether in the state of *ore* or *bullion*, is reduced to a granulated or spongy state, by fusion along with *zinc*, or some other metal cheaper than silver, and the zinc is subsequently removed, by digesting the resulting granulated, laminated, or pulverulent alloy, in *dilute sulphuric acid*, or other acid. The *zinc*, *&c.*, is recovered by the usual means. This process, carefully conducted, produces metal of great ductility and purity, containing 99% to 99½% of pure gold.

Chemically pure gold is obtained by *dissolving the metal* in *nitrohydrochloric acid*, adding a *solution of protosulphate of iron*, and collecting and washing the precipitate. In this state it is a brown powder, which acquires a metallic lustre by friction or heat.

Prop. The most marked properties of gold are its rich yellow colour, its ductility, malleability, insolubility in all menstrua except aqua regia and aqueous chlorine, and its very slight affinity for oxygen. It melts at a bright red heat (2016° Fahr.,—Daniell), and the fused metal has a brilliant green colour. It forms compounds with chlorine, iodine, oxygen, sulphur, &c.; but its oxides refuse to unite with the acids. The so-called *nitrohydrochlorate* or *nitromuriate of gold* is a true *chloride*. Sp. gr. of *native gold*, 13·3 to 17·7; of *pure gold*, 19·3 (average); its greatest density is 19·5. Gold is the only simple metal which has a yellow colour.

Tests. 1. METALLIC GOLD is characterised by its yellow colour, insolubility in nitric acid, and its ready solubility in aqua regia, forming a rich yellow or amber-coloured liquid, which stains the skin purple.—2. SOLUTIONS OF GOLD exhibit the following reactions:—*a*. Protosulphate of iron gives a brown precipitate, which acquires a metallic lustre when rubbed;—*b*. Protochloride of tin (preferably containing a little perchloride) gives a violet, purple, or blackish precipitate, insoluble in hydrochloric acid;—*c*. Sulphuretted hydrogen and hydrosulphuret of ammonia give a black one insoluble in simple acids;—*d*. Ammonia gives a reddish-yellow precipitate (*fulminating gold*) with tolerably concentrated solutions, either at once or on boiling the liquid;—*e*. Liquor of potassa gives a

reddish-yellow precipitate with neutral solutions of gold, insoluble in excess.

Estim. The *estimation* of the *quantity of gold* in an *alloy* is usually obtained by "*assaying*" the sample, in the manner pointed out at *page* 98. In addition to what is there given on the subject, the following information will be found extremely useful to the young assayer—

TABLE *showing the quantity of lead and silver to be taken for the assay of* 10 gr., *of alloys of different "fineness," when the "cupellation" and "quartation" are performed together.*

Richness of Sample.		Silver required.	Lead required.
Gold per cent.	Gold in 10 gr.		
100	10	30	10
90	9	27	100
80	8	24	160
70	7	21	220
60	6	18	240
50	5	15	260
40	4	12	
30	3	9	285 to 350
20	2	6	
10	1	3	

The *richness in gold* of any substance, whether liquid or solid, when the *quantity is small* (and indeed in all other cases), is most simply and economically performed by the common method of chemical analysis. The gold may be thrown down from its solution by adding a solution of *protosulphate of iron;* the precipitate, after being washed, dried, and gently heated, may be weighed as *pure gold.*

Pois., &c. The soluble preparations of gold (*chlorides*) are violent poisons. The *symptoms* resemble those occasioned by corrosive sublimate, but are somewhat less violent. Metallic gold in a minute state of division is also capable of producing very unpleasant consequences, and even endangering life. The *antidote* is iron filings or a solution of sulphate of iron, given conjointly with an emetic.

Uses. The numerous applications of gold in the arts and the daily transactions of life need only be alluded to here. In *medicine*, gold has been given in the form of powder, in scrofula and syphilis, by Chrestien, Niel, and others, with apparent advantage. *Dose.* ¼ gr. to 1 gr., 3 or 4 times a day, in pills, or as a friction on the tongue and gums. An ointment made of 1 gr. of *powdered gold*, and 30 gr. of *lard*, has been applied by Niel to the skin deprived of the epidermis (endermically), in the above diseases.

GOLD (Ammoniuret of). Syn. *Aurum Ammoniatum, Ammoniæ Auras,* — Lat. *Prep.* By adding *liquor of ammonia* to a *solution of gold* in *aqua regia* (terchloride), as long as a reddish-yellow precipitate (*fulminating gold*) forms; the latter must be collected, washed, and dried with the *greatest possible caution.*

Obs. Ammonia fails to precipitate teroxide of gold from solutions which are not tolerably concentrated, and in those containing free acid or ammoniacal salts, the precipitate only forms upon boiling the solution. Before adding the ammonia, it is, therefore, proper to drive off the excess of acid, if any, by the application of heat.

[We have already cautioned the reader of the danger attending both the preparation and use of this substance. The resources of our materia medica would be limited indeed, if the faculty were driven by necessity to its employment as a medicinal. Happily such is not the case. There is no lack of safe remedies without it. See *Fulminating Gold.*]

GOLD (Chlorides of). Of these there are two :—

GOLD (Protochloride of). A yellowish-white mass, formed when a *solution* of *terchloride of gold* is evaporated to dryness and the residium is exposed to a heat of about 450° Fahr., until fumes of chlorine cease to be evolved. It is insoluble in water, which decomposes it, slowly when cold, but rapidly by the aid of heat, into metallic gold and terchloride of gold.

GOLD (Terchloride). Syn. *Chloride of Gold, Chloruret of do., Perchloride of do., Muriate of do.; Auri Chloridum, A. Terchloridum, A. Murias,*—Lat. *Prep.* (P. Cod.) *Gold*, 1 part; *nitrohydrochloric acid*, 3 parts; dissolve, evaporate until vapours of chlorine begin to be disengaged, then set the solution aside to crystallize.

Prop. Orange-red crystalline needles, or ruby-red prismatic crystals; deliquescent; soluble in water, ether, and alcohol, forming a deep yellow solution; at the heat of 400° Fahr., it suffers decomposition. Protosulphate of iron, oxalic, sulphurous, and phosphorous acids, and most of the metals, decompose its solution with the precipitation of metallic gold. Terchloride of gold combines with several of the metallic chlorides, forming a series of double salts, which are mostly yellow when in crystals, and red when deprived of water. Somewhat under a red heat, both the chlorides of

gold give up their chlorine, and pure gold remains behind.

Uses, &c. It has been employed by Duportal, Chrestien, Niel, Cullerier, Legrand, and others, as a substitute for mercury, in scrofula, bronchocele, chronic skin diseases, &c.; also as a caustic. *Dose.* $\frac{1}{20}$ gr., dissolved in distilled water, or made into a pill with starch; or, in frictions on the gums, in quantities of $\frac{1}{16}$ to $\frac{1}{10}$ gr. The above is the preparation referred to whenever chloride or muriate of gold is spoken of.

GOLD (Soda-chloride of). Syn. *Soda-muriate of Gold; Auro-chloride of Sodium; Sodii Auro-chloridum, Auri* et *Sodii Chloruretum*,—Lat. *Prep.* (P. Cod.) *Terchloride of gold*, 85 parts; *chloride of sodium*, 16 parts; dissolve in a *little* distilled water, evaporate until a pellicle forms, then put it aside to crystallize. It forms beautiful, orange-coloured rhombic prisms.

Dose, &c. $\frac{1}{20}$ to $\frac{1}{12}$ gr., made into a pill with starch or lycopodium, in the same cases in which the terchloride is ordered. Mixed with 2 or 3 times its weight of orris powder, it has been used in frictions on the tongue and gums; and an *ointment*, made with 1 gr. of the *salt*, mixed with 36 gr. of *lard*, has been applied to the skin, deprived of the epidermis by a blister. (See *above.*)

GOLD (Cyanide of). Syn. *Tercyanide of Gold, Cyanuret of do.; Auri Cyanidum, A. Cyanuretum, &c.*,—Lat. *Prep.* 1. Add a *solution of pure cyanide of potassium* to a *neutral solution of pure chloride of gold*, as long as a precipitate forms, carefully avoiding excess; lastly, wash and dry the powder.

2. (Desfosses.) Boil freshly precipitated *teroxide of gold* (washed, but not dried) in *dilute hydrocyanic acid*, until the liquid assumes a beautiful yellow tint, then evaporate it to dryness over a water bath.

Obs. This salt is a pale-yellow powder, insoluble in water, but very soluble in a solution of cyanide of potassium. *Dose.* $\frac{1}{16}$ to $\frac{1}{12}$ gr., made into a pill, in the usual cases in which gold is administered. (See *above.*) The first formula is essentially similar to that of the French Codex, but divested of all unnecessary diffusedness.

GOLD (Fulminate of). See *Ammoniuret of Gold.*

GOLD (Iodides of). Of these there are two:—

GOLD (Protiodide of). Syn. *Iodide of Gold; Auri Iodidum*,—Lat. *Prep.* (P. Cod.) To a *solution* of *terchloride of gold*, add another of *iodide of potassium* (in excess, —Johnston); wash the precipitate in *alcohol*, and dry it.

Obs. This is the *protiodide of gold.* (Johnston; Liebig.) It is a greenish-yellow powder, slightly soluble in boiling water, and freely soluble in dilute hot solution of iodide of potassium, from which it crystallizes on cooling in beautiful golden yellow scales. M. Meillet recommends the use of *hydriodate of ammonia* as the precipitant, in preference to iodide of potassium, as thereby the *whole* of the chloride of gold is decomposed, which is not the case when the latter salt is used. Iodide of gold loses iodine at common temperatures, and should therefore be kept in a cold place, and in a well-stopped phial. *Dose.* $\frac{1}{16}$ to $\frac{1}{12}$ gr., in pills; in scrofula, syphilis, &c. It is also made into an ointment.

GOLD (Teriodide). This compound is formed when the previous process is reversed, and the *solution* of *terchloride of gold* is added to the *solution* of *iodide of potassium.* (Johnson.) It is a dark-green powder, soluble in solutions of hydriodic acid, and the iodides of potassium and sodium. From the latter, dark-brownish red crystals of *auro-iodide of potassium* are deposited on standing.

GOLD (Oxides of). Three oxides have been noticed by chemists, but only one possesses any practical interest. They are:—

GOLD (Protoxide of). This is the precipitate which forms when a *cold solution of potassa* is added to another of *terchloride of gold.* It is also formed when *liquor of potassa* is digested on the *protochloride.* It is a green powder, slightly soluble in liquor of potassa, and spontaneously changing into metallic gold and teroxide of gold.

GOLD (Binoxide of). This name has been given to the purple powder formed by the combustion of gold leaf.

GOLD (Teroxide of). Syn. *Oxide of Gold, Peroxide of do., Auric Oxide, Auric Acid; Auri Oxydum, A. Teroxydum, &c.*, —Lat. *Crocus of Gold, Solis Crocus*,—Obs. *Prep.* 1. (P. Cod.) *Calcined magnesia*, 4 parts; *terchloride of gold*, 1 part; *water*, 40 parts; mix, boil, wash the precipitate *first* with water, *next* with *dilute nitric acid*, and *lastly*, again with water; it must be dried in the shade.

2. (Pesth.) *Neutral chloride of gold*, containing 1 part of gold; *water*, 12 parts; *carbonate of potassa*, 1 part; (dissolved in) *water*, 2 parts; digest together at 170° Fahr., well wash the precipitate with water, dissolve it in *colourless nitric acid* (sp. gr. 1·400), and decompose the resulting solution by admixture with *water.* The precipitate is *pure hydrated peroxide of gold.*

It may be rendered anhydrous by drying it at a heat of 212°. (Liebig.)

Prop., &c. In the state of *hydrate*, teroxide of gold is a reddish-yellow powder, but is dark-brown or black when free from water. It is insoluble in water, and completely decomposed by solar light and a red heat. It dissolves freely in hydrochloric acid and liquid chlorine, and in hydrobromic acid, forming respectively *terchloride* and *terbromide of gold*. It is insoluble in hydrofluoric acid; and in the oxygen acids, with the exception of concentrated nitric acid, from which, however, it is again precipitated on the addition of water. It unites with the alkalies and earths forming salts, which have been termed *aurates*, from the oxide playing the part of an *acid* in their composition.

Uses, &c. Teroxide of gold has been given in scrofula, &c., in *doses* of $\frac{1}{12}$ to $\frac{1}{2}$ gr., or 1 gr., in scrofula, syphilis, &c., made into a pill with extract of mezereon. See *Purple of Cassius* (and *above*).

GOLD (Sulphuret of). Syn. *Sulphide of Gold, Tersulphuret of do.; Auri Sulphuretum*,—Lat. *Prep.* Transmit a current of *sulphuretted hydrogen gas* through a *solution of terchloride of gold* in *water*; or add *hydrosulphuret of ammonia* to the same solution; collect the precipitate, wash it with cold distilled water, and dry it in the shade.

GOLD (Dutch). Syn. *Chrysocal, Hamering, Mannheim Gold, Pinchbeck, Red Brass, Similor, Tombac.* The proportion of zinc in this alloy is altered to suit the colour and other properties to the purposes for which it is intended, and often varies from $\frac{1}{2}$ to $\frac{1}{3}$, or $\frac{1}{6}$ of the weight of the alloy. *Mannheim Gold* contains *copper*, 3 parts; *zinc*, 1 part. At the celebrated works of Hegermühl, near Potsdam, the proportions are *copper*, 11 parts; *zinc*, 2 parts; which produce a metal which is afterwards rolled into sheets for the purpose of making Dutch leaf-gold, and has a very rich, deep gold-colour. See *Brass* and *Mosaic Gold.*

GOLD (Factitious). *Prep.* From *copper*, 16 parts; *platinum*, 7 parts; *zinc*, 1 part; fused together. This alloy resembles in colour, gold of 16 carats fine, or $\frac{2}{3}$, and will resist the action of nitric acid, unless very concentrated and boiling.

GOLD (Grain). Syn. *Aurum Granulatum*,—Lat. *Prep.* From *cupelled gold*, 1 part; *silver*, 3 parts; melted together, and poured in a small stream into *water*; the silver being afterwards dissolved out by digestion in *boiling nitric acid*, and the grains, after being well washed in *water*, heated to redness in a crucible or cupel. *Used* to make preparations of gold.

GOLD (Jeweller's). This term is applied to alloys of gold, used for trinkets and inferior articles of jewellery, ranging from 3 or 4 carats fine, upwards; or which are too inferior to receive the *Hall mark.* The lowest alloy of this class is formed of *copper*, 16 parts; *silver*, 1 to 1½ part; *gold*, 2 to 3 parts; melted together. This is worth only from 8*s.* 6*d.* to 9*s.* 6*d.* the oz.

"It has recently been found that gold of the quality of 12 carats, or less, if alloyed with *zinc* instead of the proper quantity of *silver*, presents a colour very nearly equal to that of a metal at least 2½ or 3 carats higher, or of 8*s.* or 10*s.* an ounce more value; and the consequence has been that a large quantity of jewellery has been made of gold alloyed in this manner; and the same has been purchased by some shopkeepers, very much to their own loss, as well as that of the public: inasmuch as a galvanic action is produced, after a time, upon gold so alloyed; by means of which the metal is split into separate pieces, and the articles rendered perfectly useless. *Gold chains, pencil-cases, thimbles*, and *lockets*, are the articles of which the public and the shopkeepers will do well to take heed, as these have, among some other things, been lately so constructed." (Watherston "*Art of Assaying.*") See *Jewelry, &c.*

GOLD (Leaf). Syn. *Aurum Foliatum, A. in libellis*,—Lat. Gold reduced to leaves by hammering it between thin animal membrane. Its preparation constitutes the trade of the *goldbeater.* These leaves are only 1-282,000th of an inch in thickness. Gilt silver is hammered in the same way, but the leaves are thicker. The latter is called "*party gold.*" Both are *used* by artists and gilders, and by druggists to gild pills, &c.

GOLD (Liquid). Syn. *Ethereal Solution of Gold, Potable Gold; Aurum Potabile*,—Lat. *Prep.* Agitate *ether* with a *solution of terchloride of gold* for some time, allow it to repose, and decant the supernatant portion.

Obs. Naphtha and essential oils possess the same property as ether of taking gold from its solutions; the first has the advantage of cheapness. This liquid was formerly held in great esteem as a cordial medicine. It is now only employed for writing on steel, gilding, &c. As it dries, it leaves a coating of pure gold.

GOLD (Mosaic). Syn. *Aurum Musivum*, —Lat. See *Bisulphuret of Tin.*

GOLD (Mosaic). Syn. *Or-molu, Prince's Metal, Pinchbeck.* These names are applied

to several varieties of fine gold-coloured brass, differing slightly in colour and the proportions of the ingredients.

Prep. 1. (Parker & Hamilton.) *Zinc* is added to an equal quantity of *copper* previously heated to the *lowest temperature* that will fuse it, and the two are stirred together until they are thoroughly mixed; a *further* quantity of *zinc* is then added, in small portions at a time, until the alloy acquires the desired colour. When the process is successfully conducted, the alloy at once assumes a fine brassy-yellow colour, and on the further addition of small portions of zinc, changes to a purple or violet hue, and lastly, becomes perfectly white, which is the proper appearance of the compound in the fused state. It should be at once cast, so as to avoid remelting it, if possible. The *product*, which is very bright coloured, contains from 52% to 55% of zinc.

2. *Copper*, 2 parts; *zinc*, 1 part. Deeper coloured and tougher than the last. See *Gold* (Dutch), and *Brass*.

GOLD (Powdered). Syn. *Divided Gold, Gilding Powder, Gold Bronze, Gold Colour; Auri Pulvis, Aurum Pulveratum, A. Divisum*,—Lat. *Prep.* 1. *Gold*, 1 part; *mercury*, 7 parts; form an amalgam, and expose it to heat until *all* the mercury is volatilized; or, the mercury may be dissolved out with hot *nitric acid*. In either case, the residuum is to be powdered, washed, and dried. If the quantity operated on is considerable, the process should be so conducted as to save the mercury.

2. (P. Cod.) *Gold leaf* is triturated with 10 or 12 times its weight of *sulphate of potassa* (in crystals) until shining laminæ are no longer visible; the mixture is then passed through a fine sieve, and the sulphate of potassa washed out with *boiling water*.

3. From *gold leaf* and *honey* ground together, as the last, by means of a stone and muller. This is the plan commonly adopted in the *small way* by artists.

4. From a *solution of gold* in *aqua regia*, precipitated by *protosulphate of iron*, the resulting powder being washed, dried, and gently heated. This gives pure gold.

Uses, &c. Powdered gold is employed in gilding by japanners and by artists. It is either sold in powder (*gold in powder*), or made up into shells (*gold shells*.) Its use in *medicine*, has been already noticed.

GOLD (Standard). See *Alloy*.

GOLD DUST. The *gold dust* obtained from the sands of rivers and alluvial soil by "washing," generally requires no further preparation, as an article of commerce, before it goes into the hands of the refiner. Indeed, its purity is often greater than that of our "standard gold." That collected in some parts has been found to be 22½ to 23 carats fine. The gold of Giron, New Granada, is said to be of the uniform "fineness" of 23¾ carats. "To those who traffic in gold, it is sufficient to learn the place where it has been collected, to know its title or value." (Humboldt.) See *Gold* (p. 534).

GOLD DETERGENT (Parisian,—Upton & Co.'s). *Prep.* Take *quicklime*, 1 *oz.*; sprinkle it with a little *hot water* to slake it, then gradually add *boiling water*, 1 pint, so as to form a milk. Next dissolve *pearl-ash*, 2 *oz.*, in *boiling water*, 1½ pint; mix the two solutions, cover up the vessel, agitate occasionally for an hour, allow it to settle, decant the clear, put it into flat half-pint bottles, and well cork them down.

Use. To clean gilding, &c., either alone or diluted with water. It is applied with a soft sponge, and then washed off with clean water. It is essentially a weak solution of potassa, and may be extemporaneously prepared by diluting *liquor of potassa* (Ph. L.) with about 5 times its volume of *water*.

GOLD SHELLS. *Gold leaf* or *powdered gold* ground up with *gum-water*, and spread upon the insides of shells. *Used* by artists.

GOLD SIZE. Syn. *Gilding Size, Gilder's do., Gold Colour*. *Prep.* 1. (Oil size.) *Drying* or *boiled oil* thickened with *yellow ochre* or *calcined red ochre*, and carefully reduced to the utmost smoothness by grinding. It is thinned with *oil of turpentine*. Improves by age. *Used* for *oil* gilding.

2. (Water size.) *Parchment* or *isinglass size*, mixed with finely ground *yellow ochre*. *Used* in *burnished* or *distemper* gilding.

GOLD-BEATER'S SKIN is *prepared* from the *peritoneal membrane of the cæcum of the ox*. It is *used* to separate the leaves of gold whilst under the hammer, as a nearly invisible defensive dressing for cuts, as a fabric for *court plaster*, *&c.*

GOLDEN COMPOUND. *Prep.* (Beasley.) *Anhydrous tungstate of soda* (or the salt obtained by fusing 2 equiv. of *tungstic acid* with 1 eq. of *carbonate of soda*) is melted in a porcelain crucible, over a spirit lamp, at a temperature not more than sufficient, and small pieces of *pure tin* added to the melted mass. *Cubes* of a *golden colour* instantly form. The process should not be continued too long, or they acquire a purple hue.

GONG METAL. See *Bell Metal.*

GONIOMETRY. The art of measuring the angles of crystals, by means of a *goniometer;* a most important matter in chemistry and mineralogy. The only accurate and simple instrument of this kind is the *reflective goniometer* invented by Dr. Wollaston. Facility in using this instrument is readily acquired by a few trials.

GONORRHŒA. See *Urethritis.*

GOOSE. This bird, the *anas anser* or *anser domesticus*, is a favorite article of food almost everywhere, and may fairly claim a similar position amongst poultry, to that occupied by "good Sir Loin" among joints of meat. The vulgar inuendos occasionally heard to its prejudice, should be directed against the cook rather than the bird, as it is only when it is unskilfully dressed and too highly seasoned, that it is apt to disagree with that "irascible member of the interior," a delicate or overloaded stomach. Undue susceptibility in that quarter, may, however, be generally allayed by an oblation, in the shape of a little *eau de vie*, used as sauce or gravy. Formerly, almost miraculous virtues were attributed to this bird. Its *flesh* was said to promote longevity, to cure hydrophobia, and to be aphrodisiac. The *fat* (*goose grease; adeps anseris*) mixed with honey, was supposed to be "good against the bitings of a mad dog." At the present day it is occasionally used in clysters, and, when *scented*, as a pommade to make the hair grow, for which purpose it is *said* to be superior to *bear's grease.* In quantity it is an emetic of very easy action. The *large feathers* of the wings (quills) are used for writing. The *small feathers* form the common stuffing of our beds.

GOOSEBERRY. The fruit or berry of *ribes grossularis* (ribes uva crispa,—Linn.) *Unripe fruit*, cold and acidulous; *ripe fruit*, wholesome and slightly laxative; but the seeds and skins should not be eaten, as they are very indigestible; the *juice* is made into wine (*English champagne*); the *pulp* forms an excellent sauce for mackerel and other like fish; the *seeds*, washed and roasted, were formerly used as a substitute for coffee (*gooseberry coffee*). Gooseberries are *preserved* by simply "bottling" them, and keeping them in a very cold place. See *Cheese, Fools, Fruit, &c.*

GOULARD, or *Goulard's Extract.* See *Solution of Diacetate of Lead.*

GOUT. Syn. *Arthritis*,—Lat. A painful disease that chiefly attacks the male sex, particularly those of a corpulent habit and robust frame. Persons who live temperately and take much exercise are seldom troubled with gout. Indolence, inactivity, luxurious habits of life, and free living, are the chief exciting causes of this disease; but excessive study, grief, watchfulness, exposure to cold, and the too free use of acidulous liquors, also occasionally bring it on. In some persons it is an hereditary disease.

Gout, like rheumatism, has been called by different names according to the part attacked:— *Chiragra*, gout in the hand; *Gonagra*, in the knee; *Ischias*, in the hip; *Podagra*, in the feet; &c.

Symp. Gout is generally preceded by unusual chilliness of the feet and legs, and a numbness, or a sensation of prickling along the lower extremities; the appetite fails, flatulency, indigestion, torpor, and languor ensue, and extreme lassitude and fatigue follow the least bodily exercise; the bowels become costive and the urine pallid. The fits usually come on in the night; the patient is awakened by the severity of the pain, generally in the first joint of the great toe, or occasionally in the heel, whole foot, or calf of the leg. The pain resembles that of a dislocated joint, accompanied by a sensation resembling the effusion of cold water; the pain increases, rigors and febrile symptoms ensue, accompanied with local throbbing and inflammation. Sometimes both feet or legs are attacked; at others, only one. Towards morning the patient generally falls asleep, and sinks into a state of copious perspiration, from which he awakes comparatively recovered. This constitutes what is called a *fit of gout.* These fits or paroxysms are apt to return at intervals, commonly every evening, with more or less violence; and when frequent, the disease usually extends its action, the joints become affected, and concretions of a chalky nature (*chalk stones, gout do.*, chiefly *urate of soda*) are formed upon them, and they become stiff and nearly immoveable.

Treat. A plain or vegetable diet, moderate exercise, and the use of warm laxatives, gentle tonics, diaphoretics, and diuretics, are among the best preventives. The moderate use of alkaline remedies, as *potassa* and *magnesia*, has also been recommended. To relieve the *fit of gout*, or to check it at its commencement, the effusion of cold water will be often found effective. The use of the *eau médicinale*, or the *vinum colchici* of the Pharmacopœia, may also be had recourse to; a due dose of which taken at bedtime will frequently carry off the paroxysm, and nearly always mitigate the symptoms. The effects of the above remedies do not greatly differ from each other; for "after taking

about 60 drops of either, the pulse becomes slower, and at length sinks in about 12 hours, from 10 to 20 strokes per minute below its natural number, at which time the inflammation subsides. The action of both medicines is accompanied with great languor, and a deadly nausea or sickness, which terminates in vomiting or a discharge from the bowels, or both." These symptoms have often reached an alarming extent, and in some constitutions follow even a moderate dose. This method of cure should not therefore be unadvisedly and incautiously adopted. It is, however, generally admitted that *colchicum* properly administered, will almost always alleviate the symptoms, and lessen the frequency of the attacks; and numerous instances are on record where the inroads on the constitution were increasing to an alarming extent, and that at an advanced period of life, in which colchicum seems at least to have lessened the severity of the disease, if not to have been the active agent in its removal.

Another remedy for gout brought before the profession some 2 years since, by Drs. Babington and Rees, is *lemon juice*. The results of the trials of this substance at St. Thomas's and Guy's Hospitals, as detailed by Dr. Babington in the 'Lancet' are truly astonishing, and in many points conclusive of its superiority over all other remedies in the cases in which it was given. The *dose* proposed by Dr. O. Rees, who originated this new treatment, was 2 or 3 fl. oz., twice or thrice a day, but the patients themselves often increased it to several times this quantity. Relating only what we have seen, without giving any opinion on the subject, we may state, that in several cases of gout in which lemon juice has been tried, it has proved entirely successful. In one instance, (that of a licensed victualler, a very free liver, who had been a martyr to attacks of this disease for a great number of years, and whose joints were enormously enlarged and several of them covered with chalk stones,) 6 or 7 fl. oz. of *lemon juice* (and sometimes even ½ pint) was taken 4 or 5 times daily, for above a fortnight. The good effects of the remedy were perceptible within 24 hours after the first dose was taken, and within 10 days a perfect cure was effected. The swollen joints gradually resumed their usual size and flexibility, and the chalky matter returned to the liquid form, and was absorbed. The remedy was continued in smaller doses for several weeks afterwards, and lemonade is still a favorite beverage of the same party. We must add, that though nearly two years have elapsed since the above treatment was adopted, no fresh attack has occurred, and the hands of the person alluded to, are now as small, delicate, and symmetrical, as if they had never been disfigured by gouty enlargements. In this case both colchicum and fluid magnesia had been persevered in under the best medical advice, but had entirely failed to prevent the attacks.

To ensure the efficacy of *lemon juice* it must be expressed from the fruit into the glass shortly before being taken. That purchased at the shops is generally stale and disagreeable, and is often worse than useless. In the case above referred to, the juice was taken *undiluted*, but the more common practice is to mix it with about an equal quantity of water. The only unpleasant symptoms that follow such large doses are those common to an equal bulk of any other cold liquid. In one instance, however, a patient of Dr. Babington's experienced fits of shivering and faintness, and was compelled to reduce the dose. See *Rheumatism*, *Colchicum*, *Lemon Juice*, &c.

GOUT CORDIAL. *Prep.* *Rhubarb*, *senna*, *coriander seed*, *sweet-fennel seed*, and *cochineal*, of each, 2 *oz.*; *liquorice root* and *saffron*, of each, 1 *oz.*; *raisins*, 2½ *lb.*; *rectified spirit of wine*, 2 gall.; digest for 14 days, press, and filter. *Used* in gout and rheumatism. Aromatic and slightly laxative. *Dose.* 1 to 3 table-spoonfuls.

GOUT MEDICINE (Duncan's). A mixture of *wine of colchicum*, *wine of opium*, and *tincture of saffron*.

GOUT REMEDY (Alexander's). According to Dr. Paris this contains—*aniseed*, *cumin seed*, *ginger*, *hermodactyls*, *pepper*, and *scammony*.

GOUT SPECIFIC (Murray's). A mixture of *iodide of potassium*, *sulphate of magnesia*, and *wine of colchicum*, disguised with an *aromatic tincture*.

GOUTTES AMERES. See *Drops*.

GRADUATOR. See *Vinegar*.

GRAFTING COMPO'. *Clay* tempered with *water*, to which a little *linseed oil* is sometimes added. *Used* to cover the joint formed by the scion and stock in grafting.

GRAINS OF PARADISE. Syn. *Guinea Grains*, *Malaguetta Pepper*. The seeds of the *amomum grana-paradisi* (Linn.) and *amomum melaguetta* (Roscoe). Grains of paradise are, hot, acrid, and aromatic, and in general properties similar to the other peppers. In some parts of the world they are used as a condiment. They are principally employed in these countries to impart a false strength to wine, beer, spirits, and vinegar,

GRANADINE. Syn. *Grenadine.* A sweet substance found by Latour de Trie in the bark of pomegranate root. It has since been shown to be *mannite.*

GRANILLA. A small inferior variety of cochineal.

GRANULATION. The reduction of metals into grains, drops, or coarse powder. This is done by pouring them, in the *melted state,* into *water.* In many cases they are allowed to run through the holes of a species of colander or sieve to produce minute division; and in order to render the drops spherical, they are allowed to fall from a sufficient height to permit of their acquiring the solid state before striking the water. Lead shot is granulated in this way. Shot towers are often upwards of 100 feet in height. See *Powdering.*

GRANULES. Syn. *Granula,* — Lat. These were introduced into practice by Messrs. Homolle and Quevenne, and are formed of *sugar* and a *medicinal substance* alone. "Their preservation is indefinite, and their solution is always easy. They are intended to supplant common pills, principally in the administration of very active medicines. They generally contain 1 millegramme (1-60 gr.) of the active ingredient." (Trousseau & Reveil.)

GRANULES OF DIGITALINE. Syn. *Granula Digitalinæ,*—Lat. *Prep.* (Homolle.) *Digitaline,* 15½ gr.; *white sugar,* 1½ oz.; *water,* q. s.; beat to a pill-mass, and divide it into 1000 granules. *Dose.* 3 to 6 daily. For other examples see *Pills.*

GRAPES. Syn. *Uvæ,*—Lat. The fruit of *vitis vinifera* (Linn.) or the common *grape vine.* Ripe grapes are cooling and antiseptic, and in large quantities, diuretic and laxative. They are very useful in bilious affections and dyspepsia, and in all febrile, putrid, and inflammatory complaints. The skin and seed, which are indigestible, should be rejected. "Grapes which contain a large quantity of sugar, are, if taken without the husks, the safest and most nutritive of summer fruits." (Cullen.) "The subjects of pulmonary affections, who pass the summer in Switzerland, may try the effects of a course of grapes, '*cure de raisins,*' a remedy held in high estimation in several parts of the Continent." (Sir J. Clark.)

Grapes, in bunches, are *preserved* by wrapping them in *silver paper,* and packing them in *dry bran.* Each bunch is suspended by the stem with the fingers of one hand, whilst the bran is poured round it with the other; the jar being occasionally gently shaken as the process of packing proceeds. Some paper is then laid over the top of the jar, the mouth or cover of which is, lastly, tied firmly over with bladder, to exclude the air and moisture. See *Fruit, &c.*

GRAPHITE. See *Plumbago.*

GRASSES (Fragrant). See *Volatile Oils.*

GRAVEL for *garden walks* is chosen for its fine colour and binding properties. The gravel of Kensington is esteemed the finest in the world.—Gravel walks when once in order may be rendered nearly equal to asphalt by pouring over them *tar* or a *mixture of tar and pitch,* absorption being promoted, if required, by the application of a hot iron.

GRAVIMETER. See *Hydrometer.*

GRAVITY. Weight, heaviness, gravitation. Weight is the measure of gravity. The determination of the relative weights of bodies with reference to a given standard, is explained under "*Specific Gravity.*"

GRAVY. The juice or liquid matter that drains from dressed meat after it is placed on the dish for serving. The common practice among *cooks* is to pour a spoonful or two of *boiling water* or *broth* over the joint, to increase the quantity. The natural gravy that oozes from the meat after it is cut, is the richest and most wholesome. *Made gravies* are prepared by adding *spice* and *flavouring* to the foregoing, or to strong *meat soup.* See *Sauces.*

GRAY DYES. Gray is dyed with the same materials as black, but both the bath and mordant are used in a more diluted state. Sometimes a finishing bath of *archil* or *annotta* is given to soften and beautify them.

GREASE. A general term applied to soft animal fats by the vulgar; as *bear's grease, goose-grease, &c.*

GREASE. An inflammatory affection of the heels of horses, which produces dryness, scurfiness, and stiffness. The *treatment* consists of emollient poultices, accompanied with physic and diuretic balls, to subdue the inflammation, followed by mild astringent lotions or ointments.

GREAVES. Syn. *Graves.* The sediment of melted tallow, consisting chiefly of animal membranes mixed with fat, made up into cakes. *Used* as a coarse food for dogs.

GRECIAN WATER. See *Hair Dyes.*

GREEN DYES. The goods are *first* dyed *blue,* observing to regulate the shade according to that of the intended green; they are then dried, rinsed, and passed

through a *yellow* bath, with the like precautions, until the proper shade is produced. See *Blue Dyes*, *Yellow Dyes*, *&c.*

GREEN PIGMENTS. Several of the green pigments of commerce are obtained from copper. Oxide of chromium furnishes a very beautiful one. Some are formed by the mere mechanical admixture of blue and yellow pigments. The bright blues and yellows, when mixed in this way, produce the *liveliest greens;* orange, or red and blue, and the yellowish browns and blue, the more *dingy greens.* In this way are produced all the *extemporaneous greens* of the artist. Nickel and titanium also furnish green colours, but these are not in common use.

The following list embraces all the best-known and most useful green pigments:—

Arsenical Green. Arsenite of copper. See *Scheele's Green.*

Barth's Green. From *yellow lake*, *Prussian blue*, and *clay*, ground together.

Bice (Green). Same as *mountain green.*

Bremen Green is properly *green verditer*, but other preparations are frequently sold under the name.

Brighton Green. From *sulphate of copper*, 7 *lb.*; *sugar of lead*, 3 *lb.*; each separately dissolved in *water*, 5 pints; mix the solutions, stir in of *whiting*, 24 *lb.*, set the resulting paste on chalk stones, and when dry grind it to powder.

Brunswick Green. This is properly a crude *oxychloride of copper*, but a mixture of carbonate of copper and alumina or chalk, is now commonly sold under the name in the shops.

Prep. 1. A saturated solution of *sal ammoniac*, 3 parts, is poured over *copper filings* or *shreds*, 2 parts, contained in a vessel capable of being closed up, and the mixture is kept in a warm place for some weeks, when the newly formed green pigment is separated from the unoxidized copper, by washing the mixture on a sieve; it is then edulcorated with water, and slowly dried in the shade. Colour very deep and rich. The different shades are produced by the addition of *ceruse*, or *sulphate of baryta.*

2. A *solution* of *crude carbonate of ammonia* or *bone spirit* is added to a *mixed solution* of *alum* and *blue vitriol*, as long as it affects the liquor; in a short time the precipitate is collected, washed, and dried. The various shades of green are produced by using different quantities of alum, which "pales" and "cheapens" it.

Chrome Green. The superb green pigment used by *enamellers* under this name is the *green oxide* or *sesquioxide of chromium.* (See p. 254.) *Caustic ammonia* readily dissolves this oxide when recently precipitated or in the hydrated state, and forms with it a magnificent dark-green liquid, from which, on the addition of spirit of wine, it is again disengaged under the form of a splendid and rather dark-green powder, which was formerly supposed to be *ammonio-chromate of copper* or *cupro-chromate of ammonia.* The readiest way of preparing this permanent and beautiful colour, is to add a *solution of neutral chromate of potassa* to another of *ammoniacal sulphate of copper.*

The *chrome green* of the *oil* and *colour shops* is a *mixture* of *chrome yellow* and *Prussian blue.*

Copper Green. Green bice or mountain green.

Emerald Green. This is an *arsenite of copper*, and for the most part resembles Scheele's green.

Prep. A pulp is formed with *verdigris*, 1 part, and *boiling water*, q.s., and after being passed through a sieve, to remove lumps, is added gradually to a *boiling solution* of *arsenious acid*, 1 part, in *water*, 10 parts, the mixture being constantly stirred until the precipitate becomes a heavy, granular powder, when it is collected on a calico filter, and dried on chalk stones.

Frise or *Friezland Green* resembles Brunswick green.

Gellart's Green is a mixture of *cobalt blue* and *flowers of zinc*, with some *yellow pigment.*

Iris green is prepared by grinding the juice of the *petals* of the *blue flag* (iris nostras) with *quicklime.* It is very fugitive.

Lake (Green). See *Lakes.*

Mineral Green. This is the same as *mountain green.*

Mitis Green is prepared in a precisely similar manner to Scheele's green.

Mountain Green. This pigment is properly the native green carbonate or bicarbonate of copper (*malachite*) ground to powder, either with or without the addition of a little *orpiment* or *chrome yellow.* That of the shops is commonly prepared by adding a *solution of carbonate of soda*, or of *potassa*, to a hot mixed solution of *sulphate of copper* and *alum.* If the solution of copper is employed *cold*, the precipitate has a bluish-green colour. Green verditer is commonly sold for this article.

Prussian Green. The *sediment* of the process of making Prussian blue from bullock's blood or horns, *before* it has had the muriatic acid added to it. It is also pre-

pared by pouring *liquid chlorine* upon *freshly precipitated Prussian blue.*

Rinman's Green resembles that of Gellert.

Sap Green is prepared from the *juice of buckthorn berries.* The berries are allowed to ferment for a week or eight days in a wooden tub. The juice is then pressed out, strained, a *little alum* added, and the whole evaporated to a proper consistence; it is next run into pigs' bladders, and hung up in a dry situation, to harden. An *inferior article* is made from the *juice of black alder*, and of *evergreen privet.* It is a common practice to add ¾ pint of *lime-water*, and ½ *oz.* of *gum arabic* to *every pint* of either of the above juices.

Scheele's Green. This is arsenite of copper.

Prep. 1. *White arsenic* (in powder), 1 part; *commercial potash*, 2 parts; *boiling water*, 35 parts; dissolve, filter, and add the solution gradually, whilst still warm, to a *filtered solution* of *sulphate of copper* (cryst.), 2 parts, dissolved in *hot water*, 50 parts, as long as a precipitate falls; lastly, wash the newly formed pigment with *warm water*, and dry it.

2. (Ure.) *Powdered arsenious acid*, 11 *oz.; carbonate of potassa*, 1½ *lb.; boiling water*, 1 gall.; dissolve, filter, and add the solution, as before, to another solution of *crystallized sulphate of copper*, 2 lb, in *water*, 3 gall. *Prod.* 1½ lb. A very fine grass-green colour.

Schweinfurth Green. This is a superior description of Scheele's green, or arsenite of copper. According to M. Ehrmann, however, it contains fully 10% of combined acetic acid.

Prep. 1. *Acetate of copper* and *arsenious acid*, equal parts, are each dissolved separately in the *least possible* quantity of *boiling water*, and the solutions mixed whilst still as hot as possible; an *olive-green* precipitate falls which is a very permanent colour; but which, by being boiled in the liquor 5 or 6 minutes, changes to a dense granular powder, of a superb green colour.

2. Instead of boiling the solution containing the precipitate, it is allowed to cool and stand for several hours, or until the powder assumes a granular and beautiful tint. Very rich.

3. (Kastner.) *Arsenious acid*, 8 *lb.*, is dissolved in *water* as before; and added to *verdigris*, 9 or 10 *lb.*, diffused through *water*, q. s., at 120° Fahr., the pap of the latter being first passed through a sieve; the mixed ingredients are then set aside till the mutual reaction produces the proper shade.

4. (Dr. Ure.) *Sulphate of copper*, 50 *lb.*, and *lime*, 10 *lb.*, are dissolved in *good vinegar*, 20 gall., and a *boiling hot solution* of *white arsenic*, 50 *lb.*, is conveyed as quickly as possible into the liquor; the mixture is stirred several times, and then allowed to subside, after which it is collected on a filter, dried, and powdered. The supernatant liquor is employed the next time for dissolving the arsenic.

Obs. This is a very fine, permanent, green pigment. The use of a little more *arsenic* turns it on the *yellowish green*, and boiling it with a small quantity of *potash* takes off the *blue colour.* The vessel in which the mixed liquids are set aside should be covered to prevent a premature crystallization on the surface. This pigment is sometimes sold under the name of *Mitis green.* By digesting *Scheele's green* in *vinegar* it is converted into an inferior variety of *Schweinfurth green.*

Verdigris. See *Copper* (Subacetate), and *Verdigris.*

Verditer (Green). This is essentially a mixture of *oxide* and *carbonate of copper*, in uncertain proportions, with *chalk.* Factitious green bice and mountain green have a like composition. See *Verditer.*

Verona Green. The mineral called *green earth.*

Vienna Green. The same as Schweinfurth green.

GREEN SALT (of Magnus). This is obtained by adding *ammonia*, in excess, to a *hot solution* of *protochloride of platinum* and *ammonium;* the salt separates after a time under the form of green crystals, which are insoluble in water. The reactions of this substance are highly interesting to the scientific chemist.

GREEN SICKNESS. See *Chlorosis.*

GREGORY'S SALT. The crude hydrochlorate of morphia, prepared by Gregory's process. It is a double hydrochlorate of morphia and codeia.

GRINDING. The operation of reducing substances to powder by attrition or friction. In the *laboratory*, the term is chiefly applied to powdering by means of a mill or by mechanical power, in opposition to simple pounding or trituration in a mortar or with a slab and muller. All the principal powders, paints, &c., sold by the druggist, drysalter, and colourman, are reduced in the drug or colour mill. Recently machinery has even been applied to the common mortar. An ingenious and very useful contrivance of this kind is the

"*mechanical mortar*" of Mr. H. Goodhall, of 5, Peter's Street, Derby.

GRINDSTONES (Artificial). *Washed silicious sand*, 3 or 4 parts; *shell-lac*, 1 part; melt together, and form the mass into the proper shape whilst warm, with strong pressure. The fineness of the sand must depend on the work the stone is intended for. The same composition is formed upon pieces of wood, as *corn rubbers*, and for the purpose of sharpening knives, and cutting stones, shells, &c. See *Emery*.

GROATS. Syn. *Grits; Grutellum, Avena Decorticata, Avenæ Semina; Avena*, —Ph. L. The common oat deprived of its exterior integuments or husks. This is generally effected in a mill, which, at the same time, cuts them into two or three pieces. When crushed flat, they are denominated *Embden Groats*. The "naked oat" or "pilcorn" (*avena nuda*,—Linn.) is preferred for making groats.

GROSSULINE. The name given by Guibourt to a peculiar principle found in gooseberries and some other acid fruits.

GROUT. *Mortar* reduced to a thin paste with *water*; used to fill up the joints of masonry and brickwork. A finer kind is used to "finish off" the best ceilings.

GRUEL. Syn. *Oatmeal Gruel, Water do.; Decoctum Avenæ*,—Lat. *Oatmeal* or *groats* boiled with *water* to a proper consistence and strained. It is variously flavoured to suit the palate; but the addition of a little white sugar, and finely powdered Jamaica ginger, with or without a glass of wine, is the least likely to offend the stomach. Nutmegs, cinnamon, &c., frequently disagree with invalids. Sometimes *milk* or *butter* is added. *Embden groats* require less boiling than the common groats. Of oatmeal, the *Scotch* is commonly said to be the best.

The following *directions* for *making gruel* from *oatmeal* are from the pen of Dr. A. T. Thomson: —*Oatmeal, 2 oz.; cold water*, 1½ pint; rub the meal in a basin, with the back of a spoon, in some of the water, pouring off the fluid after the grosser particles have subsided, but whilst the milkiness remains; repeat this with fresh water, unite the washings, and boil until a soft, thick mucilage is formed.

GUAIACINE. Syn. *Guaiacic Acid, Pure Guaiacum Resin*. A substance discovered by Trommsdorff in the wood and bark of *guaiacum officinale*. (Linn.)

Prep. The *tincture of guaiacum* is treated with *hydrate of lime*, and the *guaiacate of lime* thus formed is decomposed with dilute *sulphuric acid*; it is purified by dissolving it in *alcohol*.

Prop., &c. Insoluble in water; soluble in alcohol and ether; it unites with the caustic alkalies forming *alkaline guaiacates* (guaiacum soaps); air and light turn it green; gluten, mucilage of gum arabic, &c., turn it blue; nitric acid and chlorine turn it successively green, blue, and brown; tincture of guaiacine added to hydrocyanic acid and sulphate of copper, produces an intense blue colour. (Pagenstecher.) A delicate *photogenic paper* may be formed by washing *unsized paper* with an *alcoholic solution of guaiacum resin*, and afterwards with one of *neutral acetate of lead*. (Johnston.)

GUAIACUM. Syn. *Gum Guaiacum, Guaiacum Resin; Guaiacum*, — Ph. L. *Guaiaci Resina*,—Ph. L. 1836. The "resin prepared by means of fire from the wood" of "*guaiacum officinale*." (Ph. L.) This substance is often adulterated. When pure, its "fresh fracture is *red*, slowly passing to *green*; the tincture slowly strikes a lively blue colour on the inner surface of a thin paring of a raw potato." (Ph. E.) Adulteration with resin may be generally discovered by the odour evolved when the guaiacum is heated. An alcoholic tincture of guaiacum, rendered milky with water, recovers its transparency on the addition of caustic potassa in excess; but this is not the case when resin is present.

Guaiacum is stimulant, sudorific, and alterative. *Dose.* 10 to 20 gr., either in powder, or pills; in chronic rheumatism, gout, obstinate chronic skin diseases, scrofula, syphilis, &c. It forms the active ingredient of the once celebrated "*Chelsea pensioner*," and the "*gout specific*" of Mr. Emerigon. The latter was made by digesting 2 oz. of *guaiacum resin* in 48 fl. oz. of *rum*, for 7 or 8 days. The *dose* of this was a table-spoonful every morning fasting for a twelvemonth. Its other properties are similar to those of *guaiacine*, but are less marked. Sp. gr. 1·20 to 1·22.

GUAIACUM WOOD. Syn. *Lignum Vitæ; Guaiaci Lignum*,—Ph. L. The wood of *guaiacum officinale*, (Linn.) This is employed under the form of shavings, raspings, and saw-dust, in decoctions only. See *Decoctions* and *Balsams*.

GUANINE. A substance closely corresponding to xanthic oxide found in guano. With the acids it forms crystallizable salts.

GUANO. Syn. *Huanho*,—Peruv. This substance, now so extensively used in agriculture, is the excrement of certain aquatic birds, chiefly the common penguin (*alca torda, a. pica*), which congregate in count-

less myriads on the barren and uninhabited islets and rocks on the western coasts of South America, and the coast of Africa. It abounds in ammonia and the phosphates, and is undoubtedly the richest natural manure known. Under judicious application, the increase of the crops of grain, turnips, potatoes, and grass, consequent upon its use, is about 33%; and at its present price of £10 per ton, the cost of this increase is "considerably under the cost of all other manures, whether farm-yard dung and composts, or artificial compounds." "Guano is, moreover, peculiarly adapted to horticultural and floricultural improvement, by its relative cleanliness and facility of application." (Ure.)

In a chemical point of view, guano may be regarded as consisting chiefly of impure uric acid in a remarkable state of decomposition, in which further change is suspended, or at least impeded, by the absence of moisture. In inferior samples, and in those at a lower state of desiccation, this change is in active progress, and then corresponds to the eremacausis or decay of Liebig, which ultimately leads to the destruction of the azotized compound, and, consequently, of the principal value of the guano as a manure.

According to Dr. Ure, the *composition* of a sample of guano from South America (Bolivia), given as a type of that substance in the best state, is as follows:—

Soluble Matter, 31·5%; consisting of	Urea	5·00	representing	Ammonia (*ready formed*) 4·20%
	Sulphate of potassa	7·90		„ (*latent*) 17·05%
	Chloride of sodium	5·00		Total *richness in ammonia* 21·25%
	Biphosphate of ammonia	5·50		
	Oxalate of ammonia	·60		
	Water	6·50		
Insoluble Matter, 69·50%; consisting of	Silica	2·25		
	Subphosphate of lime	9·00		
	Double phosphate of ammonia and magnesia	1·25		
	Urate of ammonia	15·27		
	Undefined azotized organic matter	41·73		
		100·		

The following is the "average result" of numerous "analyses of genuine guano, in reference to its agricultural value," as given by the above authority:—

1. *Azotized animal matter*, including *urate of ammonia*, together capable of affording from 8 to 16% of ammonia by decomposition in the soil	50
2. *Water*	8 to 11
3. *Phosphate of lime*	12 to 25
4. *Phosphate of ammonia*, *sulphate of do.*, and *ammonio-phosphate of magnesia*, together containing from 5 to 9 parts of ammonia	13
5. *Silicious sand*	1
	100

"Among the many samples of '*African Guano*' which I have had occasion to analyse for the importers, none has contained any appreciable quantity of *uric acid*, or by consequence of potential (*latent*) ammonia. The best afforded me 10% of ready-formed ammonia, existing, chiefly, in the state of phosphate. Its specific gravity was so low as 1·57. It contained—

Moisture (separable by a heat of 212° Fahr.)	21·5
Subphosphate of lime	23·0
Magnesian phosphate of ammonia	3·0
Alkaline sulphates and *muriates*	1·5
Silica	1·0
Decayed organic matter, with *phosphate of ammonia*, and a little *carbonate*, equiv. to ½ gr. of ammonia	50·0
	100·

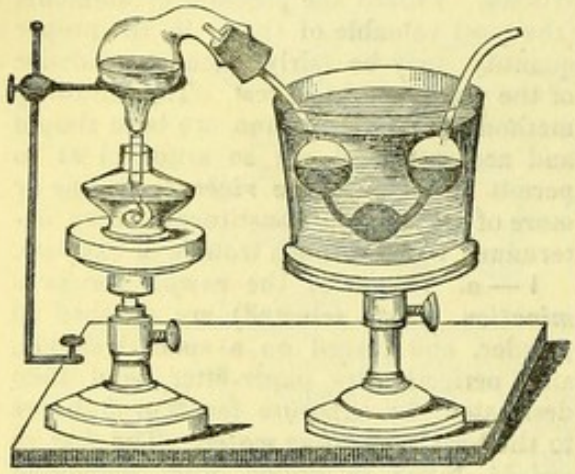
"Other '*African Guanos*' have afforded from 24 to 36% of *moisture; no* uric acid; *no* potential ammonia, but decayed organic

matter; from 5 to 7% of *ready-formed ammonia* (phosphate, and a little carbonate); from 25 to 35% of *subphosphate of lime;* 5 or 6% of *magnesian phosphate of ammonia;* more or less *oxalates* from the decomposition of the uric acid; and 3 to 5% of *fixed alkaline salts.*" (Ure.) It will thus be seen that "*South American*" *guano* is richer in *ammoniacal salts* than "*African guano*;" but the latter contains more *phosphates.*

Pur., &c. Guano, owing to its high price, is very commonly adulterated, or is in an advanced stage of decomposition when sold. Much of what is vended under the name is altogether a *factitious* article. These artificial mixtures are made to look so like genuine guano, that the mere practical man who goes only by their appearance, is very often deceived by them, and owing to the failure of his crops in consequence, is led to distrust the efficacy of guano as a manure. A sample of pretended guano examined by Mr. Johnston, was found to contain, in the state in which it was sold, *more* than *half its weight* of *gypsum*, the *rest* being *peat* or *coal ashes*, with a little *common salt*, *crude sulphate of ammonia*, and either *dried urine*, or the *refuse of the glue manufactories*, to give it a smell. "I could not satisfy myself that it contained a particle of real guano." (*Elem. of Agric. Chem.*) Vessels which sail hence for the guano stations, are now very commonly ballasted with rough *gypsum* or *plaster of Paris.* This substance is mixed with the guano, as it is loaded, and enables the importers to deliver from the vessel, a "nice-looking light-coloured article." Parties purchasing guano are very desirous of having it delivered from the vessel, as they believe they thus obtain it pure. The favorite material for the adulteration of guano, at the present moment, is a variety of *umber*, which is brought from Anglesea in large quantities. The rate of admixture is said to be about 15 *cwt. of umber* to about 5 *cwt. of Peruvian guano*, from which an excellent-looking article is manufactured, which is sold under the name of "*African guano.*"

Pure guano has a pale brown colour, a more or less offensive odour, and the average sp. gr. of 1·63 to 1·64. If the sp. gr. *exceeds* 1·75 it is either damaged or adulterated, and if it is less than 1·62 it contains an undue quantity of moisture. The best is neutral to test paper, and, sometimes, has even an acid reaction; but that of commerce has generally an alkaline reaction, owing to the presence of free ammonia, and in consequence, turns turmeric paper *brown*, and gives white fumes when a glass rod dipped in hydrochloric acid is held over it. Triturated with quicklime or caustic potassa, good guano evolves a powerful odour of ammonia; digested in water fully one half of it is dissolved; dried by the heat of boiling water it does not lose more than from 7 to 9% in weight; and burned upon a red-hot shovel, it leaves a white ash, not a red or dark-coloured one. (See *below.*)

Anal., or *Assay.* The quantitative analysis of guano, so as to exhibit the names and proportions of all its numerous component substances, is an extremely tedious and difficult matter in the hands of persons unaccustomed to chemical manipulations. As, however, its value to the agriculturalist depends, chiefly, on its richness in ammonia, potassa, and phosphoric acid, the analysis of guano for practical purposes, may be reduced to an assay for these articles. Indeed the presence of ammonia (the most valuable of them) in the proper quantity, may be fairly taken as evidence of the presence of the rest. The following methods of testing guano are both simple and accurate, and are so arranged as to permit its *per centage richness* in one or more of its leading constituents to be determined without much trouble or expense.

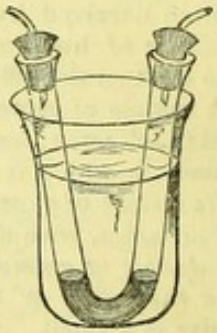


1 — *a.* 100 gr. of the *sample for examination* (fairly selected) are crushed to powder, and placed on a small, weighed, and perfectly dry paper-filter, and then desiccated, by exposure for 2 or 3 hours to the heat of *boiling water.* The *loss in weight*, taken in grains, after deducting 9, indicates the quantity per cent. of WATER *or* MOISTURE which the sample contains in *excess* of that present in good or pure guano.

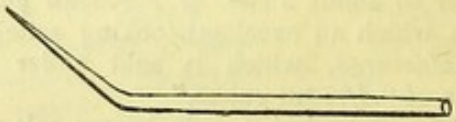
b. The *paper filter, with its contents*, is next suspended for some time over *concentrated sulphuric acid* (oil of vitriol) contained in a wide-mouthed bottle or jar, by means of a thread attached to the cork or stopper; care being taken to exclude the *external* air. The exposure in this way is continued until the guano ceases to diminish in weight, which is ascertained by weighing it at intervals after the first 3 or 4 hours. When this point is arrived at, the filter and its contents are very carefully weighed. The difference between its *present weight* and its *original weight* (before the desiccation in *a*), taken in grains, gives the *gross quantity* of WATER per cent.

c. The *dried guano* from (*b*) is next placed in a weighed, smooth crucible or capsule, and exposed to a low red-heat until

all the organic matter is completely destroyed, and the whole is reduced to a white ash, which is weighed as soon as it has become cold. This *weight*, in grains, gives the gross weight per cent. of NON-VOLATILE MATTER (*alkaline* and *earthy chlorides*, *phosphates*, and *sulphates*); the total *loss of weight* by combustion, denotes the gross per centage of COMBUSTIBLE and VOLATILE MATTER (*urea*, *uric acid*, *ammoniacal salts*, and *organic matter*). The latter should *not* be *less* than 55 to 60%.



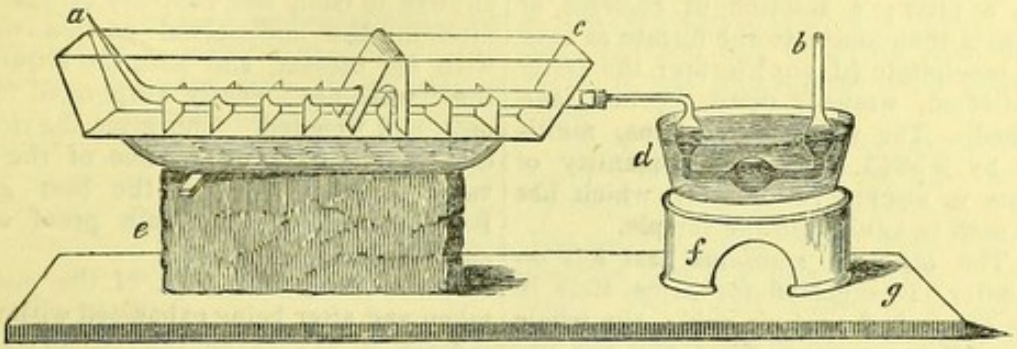
2—*a*. A *second* 100 gr. of the *guano*, selected as before, is distilled along with about 75 gr. of *fresh-slaked quicklime*, and a *little water*, in a small mattrass connected with a tubular, triple bulb-condenser containing cold *distilled water*, and immersed in a basin of *ice-cold water*. (See *Engr.*) The condenser is charged by plunging one



of its extremities into the water, and sucking at the other, until the liquid reaches the level indicated in the margin. A very gentle heat only, cautiously increased, need be employed. After the process is over, the strength of the *solution of ammonia* found in the condenser, is tested, either by taking its density in a small specific-gravity bottle, or by determining its saturating power in the manner described under *Alkalimetry*. This furnishes the per centage of READY-FORMED AMMONIA sufficiently accurate for all ordinary purposes, provided proper care is taken.

When *extreme accuracy* is required, the condenser is charged with a weighed quantity of *dilute hydrochloric acid* of a known strength, instead of water, and after the process is over, this is tested as before. The quantity of *ammoniacal test-liquor* (see *Alkalimetry*) now taken to saturate it, deducted from what it would have taken *before* the exposure in the condenser, gives the per centage sought.

Another method, giving very accurate results, is to use a rather strong *hydrochloric acid* (sp. gr. about 1·13) for the condenser; after the operation is over, the contents of the latter are poured into a glass or porcelain capsule, a solution of *bichloride of platinum* is added, in excess, and the whole is then gently evaporated to dryness; the residuum is rubbed to powder, and exhausted with a *mixture* of *two measures of alcohol* and *one measure of ether*; the undissolved portion is next dried at a heat not exceeding 212° Fahr., and weighed. The *weight*, in grains, of the *ammonio-chloride of platinum* thus obtained, multiplied by 0·0763, gives the per centage of *ready-formed ammonia*, as before. When *hydrochloric acid* is used for the condenser, a simple U tube and beaker glass may be employed, if a bulb-condenser is not at hand. (See *Engr.*) The advantages resulting from the use of acid instead of water, for the condenser, is, that with the former no ammonia can possibly escape being absorbed, whilst little care is required to keep the condenser cool.



b. 25 gr. of the *guano* are next weighed, and after being slightly moistened with a little *dilute hydrochloric acid*, are thoroughly dried by the heat of *boiling water*; the dried sample is then mixed in a warm unglazed porcelain mortar with 10 times its weight of a *mixture* of 2 parts of *quicklime* to 1 part of *hydrate of soda* (both quite dry). This mixture is introduced into a combustion tube of hard Bohemian glass, about 16 or 18 inches long, and ¾ of an inch in diameter. (See *Engr.*) The mortar is rubbed out with a little of the *soda-lime*

mixture, which is also introduced into the tube with that already put there; a little plug of *ignited asbestos* is then loosely placed over the whole, and the tube is *immediately* connected with a tubular bulb-condenser, great care being taken that the joints are made air-tight, which may be determined by the operator sucking a few bubbles out of the apparatus. If, after suction, the liquid remains at a higher level in the furthest bulb (*b*) it is a sign that the con-

nection is sound. This being done, heat is applied to the combustion-tube by means of spirit-lamps; or, more conveniently, by means of the furnace now usually employed in organic analysis. (See *Engr.*) The tube is next gradually surrounded with *red-hot charcoal*, by shifting, by degrees, the screen (*c*) and adding *more charcoal* so as to

gradually expel the ammonia. The disengagement of gas should take place *uninterruptedly*, but not too rapidly, in order that the acid may not ascend into the combustion-tube and spoil the experiment. The non-condensable volatile matters which pass off, furnish a key to the progress of the operation. The heat is at length increased to a full red. When gas ceases to be evolved, and the mixture in the tube has become *quite white*, the experiment is at an end. The point (*a*) of the combustion-tube is broken off, and the ammonia which remains in the tube is expelled by sucking gently at the extremity (*b*) of the bulb-condenser. The latter is then disconnected with the apparatus, and emptied into a glass or porcelain capsule, in order to be tested, as directed under 2, *a*. The quantity of ammonia, in grains, thus found, multiplied by 4, gives the WHOLE QUANTITY of AMMONIA, per cent., both *actual* and *potential*, producible from the sample of guano examined.

c. The quantity of *ready-formed ammonia* (see 2, *a*) deducted from the quantity last found (see 2, *b*), gives the quantity of LATENT or POTENTIAL AMMONIA that will be slowly developed by the decomposition of the guano in the soil, and become available for the food of plants. This is the *most valuable* product of this substance as a manure, and can only be obtained in quantity from well-preserved, dry guano. (See *above*.)

3—*a*. A *third* quantity of 100 gr. of the *guano*, selected as before, is triturated and digested for some time with 12 times its weight of *hot distilled water*, and the whole being thrown on a filter, the undissolved portion is washed with a little *warm distilled water;* the solution and "washings" are then mixed together, and acidulated with *nitric acid;* a solution of *pernitrate of iron* is next added, and afterwards, *solution of ammonia*, in excess; the liquid is next heated for a short time, and the bulky reddish-brown precipitate is collected, washed with hot water, dried, ignited, and weighed. The *weight*, in grains, *less* the *weight of the peroxide of iron* in the *pernitrate* consumed, gives the weight of PHOSPHORIC ACID present in the *soluble phosphates* contained in the sample. The pernitrate of iron is made by direct solution in hot *strong nitric acid*, of *twice* as much *pure iron wire* as there is phosphoric acid suspected to be present in the liquid. A slight excess will not alter the result. The number of grains of metallic iron used to form the solution, multiplied by 1·4286, give the weight of the peroxide of iron which is to be deducted from the gross weight of the precipitate.

b. The *filtrate* and "*washings*" left from 3, *a*, are mixed, and treated with a little *oxalate of ammonia* to throw down any lime, and then carefully evaporated to dryness and ignited; the residuum of the ignition, when cold, after being carefully weighed, is treated with the *smallest* portion of *water* that will dissolve it; the solution is acidified with *hydrochloric acid*, and a solution of *bichloride of platinum* added, in excess; some *strong alcohol* is next poured in, the precipitate carefully collected on a filter, washed with *rectified spirit*, dried at 212° Fahr., and weighed. The *weight*, in grains, multiplied by 0·1940, gives the per centage of POTASSA sought.

c. The *weight of the potassa* multiplied by 1·852, and deducted from the weight of the *ignited residuum* in 3, *b*, already found (see *above*), gives the quantity of CHLORIDE OF SODIUM *or* COMMON SALT (nearly).

4—*a*. The *insoluble residuum* from 3, *a*, dried, and ignited, *or* the *ash* from 1, *c*.,

is digested for 10 or 12 hours in 600 times its weight of *water* (to which a little *common salt* or *sal ammoniac* may be added), after which the whole is thrown upon a filter; a solution of *chloride of barium* is then added to the filtrate as long as a precipitate (if any) forms; the latter is collected, washed, dried, ignited, and weighed. The weight, in grains, multiplied by 0·5843 denotes the quantity of *gypsum* or SULPHATE OF LIME which has been used to adulterate the sample.

b. The *insoluble residuum* last left on the filter, is digested for some time in warm *dilute hydrochloric acid;* the whole is then thrown upon a filter, and the undissolved portion (SILICA or SAND, with, perhaps, a trace of *alumina*) is washed, dried, ignited, and weighed. It should *not weigh more* than 3 to 3½ gr. (3 to 3½ %).

c. The *filtrate* and "*washings*," from *b*, are next mixed together; the mixed liquid is acidified with *dilute sulphuric acid*, and heated until *all* the hydrochloric acid is expelled and the whole reduced to a soft pasty-mass; *rectified spirit* is now poured in, and after active stirring for some time, the mixture is thrown on a filter, and the *solid portion* washed with a little more *rectified spirit;* it is then dried, ignited, and weighed. The weight, in grains, multiplied by 0·7650 gives the quantity of PHOSPHATE OF LIME per cent. required.

d. The *filtrate* from *c*, is diluted with *water*, and after being boiled for a few minutes, *ammonia* is added in slight excess, followed by a solution of *sulphate of magnesia* (previously mixed with as much *sal ammoniac* as will prevent ammonia producing a precipitate in it), slowly dropped in as long as it disturbs the liquor; the whole is now allowed to rest for 10 or 12 hours, when the precipitate is collected on a filter, and washed with *water alkalized with ammonia*, as long as the filtering liquid is rendered turbid by chloride of barium; it is next dried, submitted to *intense* ignition for *some time* in a covered platinum crucible, and when cold, carefully weighed. The weight, in grains, multiplied by 0·6429 indicates the per centage of PHOSPHORIC ACID in the *insoluble phosphates* (phosphates of lime, magnesia, &c.) in the sample examined.

5. A *fourth* 100 gr. of *guano* is weighed, and exhausted by trituration and digestion with *hot water* (see 3, *a*); the solution is evaporated to dryness by a gentle heat, and the residuum of the evaporation, after being weighed, is powdered and enclosed in a stout phial with 8 times its volume of *alcohol*, sp. gr. 0·825 (63 o. p.); the phial is next securely corked and guarded, and exposed for some time, with agitation, to the heat of 212° Fahr.; the whole is then allowed to cool, the contents of the phial filtered, the undissolved portion washed with *hot alcohol*, and both the filtrate and the "washings" gently evaporated to dryness, and weighed. This gives the richness of the sample in UREA, one of the most valuable constituents of the best guano. Its presence is "a certain proof of its entire soundness." (Ure.)

6—*a. Another* 100 gr. of the *guano* is taken and after being exhausted with water, is dried at 212° Fahr., and weighed; it is then digested with heat in 20 times its weight of *borax-water* (containing 1% of borax), or in a *solution of caustic potassa*, and after a time, the whole is thrown on a weighed filter, washed with a little *cold distilled water*, dried by a heat not higher than that of boiling water, and again carefully weighed. The loss, in grains, indicates the proportion per cent. of URIC ACID.

The accuracy of the result may be verified by adding *dilute hydrochloric acid*, in slight excess, to the filtrate, collecting the bulky, crystalline precipitate of uric acid which forms, washing it carefully with a little *rectified spirit*, drying it, and weighing it, as before. This weight, which in general is a *very little* under that denoted above, is the more accurate of the two. The precipitate is shown to be uric acid by its assuming a rich crimson colour when treated with a little nitric acid, which turns to a rich purple (*murexide*) when it is moistened with ammonia water.

b. The quantity of *uric acid* last obtained, multiplied by 1·1012, gives the per centage of URATE OF AMMONIA.

Obs. Amongst the numerous constituents of guano, none are so valuable in an agricultural point of view as the three substances referred to in the last two sections. Indeed almost all the ammonia furnished by this substance to the soil, after the latter, manured with it, has been exposed to the air and rain, is derived from the slow decomposition of *urea*, or *urate of ammonia*. It is these substances from which the store of *latent*, or, as Dr. Ure terms it, *potential* ammonia, is derived. The ammonia existing in the guano under the form of carbonate, or of soluble salts (*ready-formed ammonia*), is either soon dissipated in air or is washed away by heavy rains, and, therefore, forms the least valuable and durable portion of this manure. It may be even added artificially, a matter almost

impossible with the former. An assay, therefore, for the *latent ammonia*, or the UREA, or the *urate of ammonia, any one of them singly*, at once furnishes us, as we have already hinted, with evidence of the quality of the guano examined, without the expense and trouble of a *complete* analysis of this substance. *Urea* and *uric acid* are only to be found in the *very best* samples of guano, and their presence is a positive proof of entire soundness and superior quality. The other valuable portions of guano are *potassa* and *phosphoric acid* (phosphate of lime chiefly); the rest are of little importance. (See 2, *c*, above.)

GUARANA. Syn. *Paullinia*. A powder prepared by the Indians of Para from the seeds of *paullinia sorbilis*. It is tonic and astringent.

GUARANINE. A crystalline substance, discovered by M. Martius, in the fruit (seed) of *paullinia sorbilis*, closely resembling, if not identical with caffeine.

GUDGEON. The *cyprinus gobeo* (Linn.), a small fresh-water fish, common almost everywhere. The "white" is considered the best. It was formerly used in medicine.

GUM. Syn. *Gummi*,—Lat. Inspissated vegetable mucilage. The purest substance of this kind, and the type of a vast number of others, is that called *gum arabic*, or *gum acacia*. The gums are employed as demulcents in *medicine*, and are used as cements, and for giving stiffness and gloss to textile fabrics. Among the vulgar the term is often incorrectly applied to the resins and gum resins.

GUM ARABIC. Syn. *Gum Acacia, Turkey Gum; Gummi Turcicum, G. Arabicum, G. Acaciæ; Acacia*,—Ph. L. "From various species" (of acacia) "yielding gum" (Ph. L. & E.), chiefly *acacia arabica* and *a. vera*. "Whitish or yellowish, transparent or cracked on the surface, and opaque; brittle; it dissolves freely in water." (Ph. L.) It is scentless, and may be bleached by exposure to the sun and air, at the temperature of boiling water. Sp. gr. 1·355. (Ure.) *Barbary* or *Morocco gum* (gummi Barbaricum), *Gum Senegal* (gummi Senegalense), and *East India gum* (gummi Indicum), are inferior commercial varieties of the same substance from other species of acacia.

Powdered gum arabic (pulvis acaciæ) is frequently adulterated with flour or farina, or with Senegal or other inferior gums. The first may be detected by agitating a little of the powder with *cold water*; the pure gum dissolves rapidly, whilst the starch or flour falls to the bottom of the vessel. Or, a little of the powder may be mixed with *boiling* water, and when cold, tested with *tincture of iodine*; if it contains starch or flour, the paste will assume a *blue* colour. If it contains *cherry-tree gum* or *tragacanth*, it will be only partly soluble in cold water, and the paste will be partly coloured, and more or less interspersed with gelatinous clots.

Much of the white *gum arabic* of the shops is formed by *bleaching* gum Senegal, by what is called "*Picciotto's process*." The *gum* is dissolved in *water*, and *sulphurous acid gas* passed through the solution. The liquid is afterwards boiled to expel the sulphurous acid, a little of which, however, still remains behind. To obtain the gum in a still whiter state, *carbonate of baryta* is added, and after agitation, the *mixture* is filtered; it is afterwards shaken with *gelatinous alumina*, again filtered, and evaporated. The product (*bleached gum*) is very white, but lacks the peculiar toughness and adhesiveness of the best gum acacia.

GUM (British). Syn. *Dextrine, Starch Gum; Leicomme; Artificial Gum, Factitious do.* Starch converted by the action of acids, diastase, or heat, into a soluble substance resembling gum.

Prep. 1. *Malt* (crushed small), 1 *lb.*; *warm water*, 2 gall.; mix, heat the whole to 145° Fahr., add of *potato starch*, 5 *lb.*, raise the heat to 160° or 165° Fahr., and mash for about 25 minutes, or until the liquid becomes thin and clear; it must then be *instantly* run off, and raised to the boiling point to prevent the formation of sugar; after boiling for 3 or 4 minutes, the whole must be filtered, and evaporated to dryness by a steam heat.

2. By exposing *dry potato starch*, in a stove, to a heat of about 400° Fahr. Yellow and inferior.

3. (M. Payen.) *Dry starch*, 1 ton; is moistened uniformly with *concentrated nitric acid*, 4½ *lb.*; (diluted with) *water*, q. s., and the paste or dough is made up into small bricks or loaves, and dried in a stove; it is next reduced to coarse powder, and exposed in a stove-room for some time to a current of air at 160° to 165° Fahr.; it is next ground, sifted, and exposed, as before, to a heat of about 228° Fahr.; it is, lastly, ground, and passed through the "bolting machine." Very white and superior. This process has been patented in France by M. Henzé.

4. (Pinel.) *Water*, 100 gall.; *nitric acid*, ½ gall.; and *hydrochloric acid*, ½ pint; are mixed together, and as much *potato starch*

is added as will form a thin paste; in two hours the liquid is drained off, and the solid matter is made up into lumps, which are dried by a gentle heat in a stove-room; they are next coarsely pulverized, and the powder is exposed on three successive days to the respective temperatures of 100°, 150°, and 190° Fahr.; the whole is then sifted, and, lastly, exposed to a heat ranging from 300° to 350° Fahr. Darker coloured than the last. To give it the appearance of *gum arabic*, it is made into a paste with *water containing* 1% *of nitric acid*, and after being spread on copper plates in layers ¾ to 1 inch thick, it is exposed to a stove heat ranging from 240° to 300° Fahr.

Prop., &c. White; insipid; transparent; friable; soluble in cold water, and in *dilute spirit;* insoluble in alcohol and ether; its solution yields a precipitate with acetate of lead (*dextrinate of lead*). Iodine commonly turns *commercial* dextrine *blue*, but does not affect the colour of *pure* dextrine. It is distinguished from ordinary gum by its right-handed polarization of light, and by yielding oxalic but not mucic acid, when treated with nitric acid.

Dextrine is nutritive, emollient, and agglutinant. In France it is largely employed by the pastry-cooks and confectioners, and in *medicine* as a substitute for gum. The French surgeons also commonly employ it as a "*stiffening*" for the splints used for fractured limbs. In this country it is chiefly used as a fine dressing for muslins, silk, and other textile fabrics, and in calico printing. Recently, it has been made up into tear-like masses, and sold for gum arabic, to which, however, it is vastly inferior as an agglutinant. See *Dextrine.*

GUM (Cherry-tree). Syn. *Fruit-tree Gum, Plum-tree do; Gummi Cerasi, G. Pruni,*—Lat. An exudation from the stems of *cherry, plum,* and some other of the *rosaceæ.* It is only partly soluble in cold, but wholly soluble, by long digestion, in boiling water.

GUM RESINS. Syn. *Gummi Resinæ,* —Lat. Inspissated vegetable juices, consisting of extractive or mucilage, and resinous matter. They are partly soluble in water, and partly in alcohol. Many of them form a species of emulsion when triturated with the former fluid. The principal gum resins are—*aloes, ammoniacum, assafœtida, euphorbium, frankincense, galbanum, gamboge, myrrh, olibanum, opoponax,* and *scammony.*

GUM (Seed). Syn. *Gummi Seminum,* —Lat. A species of soluble gum extracted from the *seed* of the *flax* (linseed), *quince, &c.*

GUM TRAGACANTH. Syn. *Tragacanth, Gum Dragon; Gummi Tragacantha, G. Draconis; Tragacantha,*—Ph. L. The gummy exudation of the *astragalus verus* or *tragacanthus,* hardened by the air. When digested in water it swells considerably, a portion is dissolved, and the whole combines to form a thick mucilage. It is totally soluble in boiling water. Sp. gr., 1·384. It is chiefly employed in calico-printing, and by shoemakers and lozenge-makers; by the latter to give toughness to the saccharine mass.

Powdered tragacanth is often adulterated with flour or starch, and not unfrequently with the commoner varieties of gum arabic. According to M. Planche, a mixture of *pulverized tragacanth* and *gum arabic* forms, with *water,* a thinner mucilage than the same quantity of either of these gums alone. This fraud may be detected as follows:—Make a *mucilage* of the *suspected gum,* and add thereto a few drops (2 or 3 to the dr.) of *alcoholic tincture of guaiacum,* taking care to stir it all the while. If the sample contains any gum arabic, the mixture, in the course of a few minutes, assumes a fine blue colour, whilst it does not change colour if the gum tragacanth is pure. 5% of gum arabic can be thus detected. When the quantity is very small, one to four hours may elapse before the colour is developed. Starch and flour are detected in the manner noticed under *Gum Arabic.*

GUN BARRELS. See *Browning.*

GUN COTTON. This is commercial pyroxyline, and must not be confounded with xyloidine, which resembles it in many particulars. See *Collodion* and *Pyroxyline.*

GUN FLINTS. These are now superseded by the *percussion cap,* which see.

GUN METAL. See *Cannon Metal.*

GUNPOWDER. This substance is a mechanical mixture of saltpetre, charcoal, and sulphur. It is seldom prepared on the *small scale.*

Prep. The *saltpetre* having been trebly refined is melted into cakes, which are then brushed to remove any adhering grit or dirt, broken into pieces with a mallet, ground to a fine powder in a mill, and sifted through a fine bolting sieve of brass wire. The *charcoal* is that of the dog-wood, alder, or willow, and is carefully burnt, as described at p. 229, and is then reduced to powder. The *sulphur* is refined and ground to the same fineness as the charcoal and saltpetre. The ingredients are weighed out in the

proper proportions, and mixed by placing them gradually in a wooden vessel, in alternate and equal layers, after which the whole is thoroughly and perfectly mixed together. The mixture is then sifted, and carefully ground to a paste with *water*, and pressed into a hard cake, which is next broken into pieces, granulated by agitation in parchment sieves, and after being glazed by friction, and the dust separated, is dried, with proper precautions, in a stove heated to about 100°.

Theoretical proportion for the best gunpowder	75	13·23	11·77

* These powders also contained from ·5 to 1·1$\frac{0}{0}$ of water.

Obs. The *quality of gunpowder* is best estimated by actual trial of its power and cleanliness in use. It should be dry, hard, and free from dust; the grains should be of an uniform size, and glossy, and the colour a dark-gray or brownish-gray, *not* perfectly black. A very little placed on a piece of paper and fired, should instantly explode with a flash, and neither leave an appreciable residue on the paper, or burn it. Dried by the heat of boiling water, or in vacuo, it should not lose more than $\frac{1}{2}$ to 1$\frac{0}{0}$ of its weight. Damp powder rapidly "fouls" the gun. Gunpowder, containing more than 7$\frac{0}{0}$ of water, does not recover its strength by simply drying it. The sp. gr. ranges between 1·795 and 1·800.

GUNPOWDER (White). Syn. *Blasting Powder*. *Prep.* 1. See *Blasting Powder*, No. 3.

2. *Yellow prussiate of potash* and *white sugar*, of each, 1 part; *chlorate of potassa*, 2 parts; powder each separately, and mix them well, but carefully, with a bone or wooden knife. It may be granulated like gunpowder, by making the powder into a paste with a little water, and pressing the mass through a parchment sieve. For *cautions*, see p. 141.

GUNJAH. See *Indian Hemp*.

GUT (Fishing). Syn. *Silkworm Gut*. This is obtained from the *bombyx mori* (Linn.) or *silkworm caterpillar*. *Prep.* The *silkworms*, when just ready to spin,

are steeped in *strong vinegar* for 12 hours, in warm weather, or 2 or 3 in cold weather, and are then broken in half, and stretched out as far as possible on a board, furnished with slits or pegs to hold them; in this state they are allowed to dry in the sun or a warm place.

Obs. Used by anglers. The worms may be known to be going to spin by refusing food, and by having a fine silken thread hanging from the mouth. (Nobb's *Art of Trolling*.)

GUTTA PERCHA. A species of imperfectly formed caoutchouc brought from Singapore, Borneo, and some other islands of the Indian Archipelago. The honour of its discovery is due to Mr. Thomas Lobb, a talented agent of the well-known florists, Messrs. Veitch, of Exeter. This gentleman, after carefully examining the tree which produced it, sent home specimens of the parts necessary to decide its botanical characters, together with small sections of the dried wood, and of the hardened juice. In April, 1843, Dr. D'Almeida presented some pieces of gutta percha to the Royal Society of Arts, of London, who simply acknowledged the receipt of the gift. Shortly after, Dr. W. Montgomerie, through Mr. Solly, placed before this Society several specimens of the same substance in different stages of preparation, and ere long the Society's gold medal was awarded to the Doctor, "for his very valuable discovery" (?), forgetful of the unpretending botanist, or the less influential foreigner, who by priority was entitled to it. The numerous purposes to which gutta percha was soon afterwards applied, and the rapid development of its manufacture on the large scale are well known.

Prop., &c. Gutta percha is a hydrocarbon which has the same ultimate composition as Indian rubber, from which it chiefly differs in being non-elastic, and in becoming soft and plastic at a heat ranging between 135° and 165° Fahr. At 200° it is soft and ductile, without stickiness, and may be moulded into any form. At 248° it melts, and on cooling continues in a pasty, glutinous state. By distillation it yields a peculiar ethereal oil, identical in chemical constitution with caoutchoucine. It is unacted on by strong alkaline lyes, and by most of the acids, even when concentrated; nitric acid and oil of vitriol, however, rapidly destroy it. Its *best solvents* are chloroform, bisulphuret of carbon, ether, benzole, rectified mineral naphtha, and rectified oil of turpentine. All these dissolve it readily; those having priority on the list, do so with the greatest facility. Immersed in water, buried in damp earth, or exposed in a dark, moist situation, it is very durable; but freely exposed to light and air, it becomes, as it were, resinified, in which state it is brittle and non-elastic, like common resin. This change progresses in exact proportion to the impurity or careless manufacture of the sample. We have a specimen now before us which is several years old, and is still as tough and flexible as ever. Yet we have seen others that after a short exposure might be broken like a stick of sealing wax, or crushed in the hand to powder. One of the large speaking tubes stretched across the court yard of the works in which it was manufactured, broke down, by its own weight, after barely 10 months' exposure to the weather. Unfortunately, most of the substance now sold as gutta percha in the shops, is of this description, notwithstanding all that may be stated to the contrary.

According to M. Payen, the gutta percha of commerce consists of a pecular substance (*gutta* or *gutta percha*, properly so called), which forms fully 75 to 82% of its weight; a crystalline white resin (*crystalbane*, *albane*), forming 16 to 14% of the mass, very soluble in oil of turpentine, ether, chloroform, and bisulphuret of carbon, and fusing at a temperature ranging from 320° to 350° Fahr.; and a yellow resin (*fluavile*) varying in quantity from 6 to 4%, which is freely soluble in *cold* alcohol and the other liquids named above, and which is pasty at 122°, but does not melt below 225° Fahr. Besides these it contains a small quantity of a vegetable acid, and some caseine; hence its cheesy odour in the raw state. Sp. gr., (commercial) 0·970 to 0·975. Its density may be increased by stretching and rolling it, until it equals that of water.

Uses. These are numerous and varied. No substance, perhaps, has been "tortured" to so many different purposes, in so short a time, as gutta percha. For some of these it is admirably suited; for others just the reverse. To the indomitable perseverance and energy of Mr. Samuel Statham, the Manager of the Gutta Percha Works, Wharf Road, the Submarine Electric-telegraph Companies are indebted for that perfect insulation of their wires, which *alone* has rendered their undertakings successful. For this purpose, there is no known substance like gutta percha; but the practical difficulties to be surmounted in its application in this quarter, were so great, that nothing but unusual skill and perseverance,

supported by large capital, could possibly have overcome them.

A solution of *gutta percha* in *chloroform*, or *bisulphuret of carbon* forms an excellent dressing for incised wounds, and a protection for abraded surfaces, burns, &c. It is used in the same way as collodion. See *Traumaticine*.

Dr. Riddell, the officiating superintending surgeon of the Nizam's army, in making experiments on the muddar plant of India (*asclepia gigantea*), had occasion to collect the milky juice, and found that as it gradually dried it became tough and hard, like gutta percha, which substance it exactly resembled in all its properties. The muddar also produces an excellent fibre, useful in the place of hemp and flax. The poorest land suffices for the growth of this tree; and no doubt, if well cultivated, there would be a large yield of juice, and a finer fibre. A nearly similar substance is procurable from the juice of the *euphorbia tirucalli*, only when it hardens after boiling it becomes brittle. The subject is most important; and the discovery, if followed up, will have made a material addition to the productive resources of the country.

GYPSUM. This is native sulphate of lime. When baked, to deprive it of water, and ground, it forms *plaster of Paris*. Gypsum is an excellent manure for certain soils. See *Alabaster*.

HADDOCK. A small sea-fish, allied to the cod, and esteemed an excellent article of food. It is the *gadus æglefinus* of Linnæus. Split, smoked, and dried, it is common in the smaller shops of London.

HÆMATOSINE. A species of albumen on which the colour of the blood is supposed to depend. It may be obtained from *blood*, previously well stirred to separate the fibrine, by mixing it with 6 times its volume of a *saturated solution of sulphate of soda*, filtering, boiling the globules with *alcohol acidulated with sulphuric acid*, again filtering, adding *carbonate of magnesia*, to separate the sulphuric acid, and after filtering, evaporating to dryness. In this state it is a dark reddish-brown mass, soluble in water and in alkaline lyes. The solution has a rich crimson colour. Carbonic and sulphuric acid blacken this solution; oxygen and atmospheric air brighten it; protoxide of nitrogen turns it purple; sulphuretted hydrogen and the alkaline sulphurets change it to a dirty greenish-black.

Hæmatosine differs from the other animal principles in containing, as an essential ingredient, the sesquioxide of iron.

HÆMOPTYSIS. Spitting of blood. It generally arises from extreme fulness of the blood-vessels of the lungs, or the rupture of blood-vessels, as a consequence of ulceration; but sometimes it is induced by excessive exertion or external violence. *Depletion*, *aperients*, *acidulous* and *astringent drinks*, and *nauseants*, are the usual remedies. *Sugar of lead*, in small doses, has been recommended for this affection. When this substance is given, it should be accompanied with a sufficient quantity of *free* acetic acid, to prevent its being converted into the poisonous carbonate of lead in the system.

HÆMORRHAGE. Syn. *Hemorrhage; Hæmorrhagia*,—Lat. A bleeding or flow of blood. Bleeding may be divided into *active*, *passive*, and *accidental*.—*Active hæmorrhage* is that arising from a full state of the vessels, or plethora,—*passive hæmorrhage*, from general debility of the system, and of the blood-vessels in particular,—*accidental hæmorrhage*, from external violence, as blows, wounds, &c. The *first* generally requires depletion, and the *second* the usual treatment to establish the general health and vigour of the body. The *bleeding from wounds*, if extensive, should be arrested by tying the ruptured blood-vessels; or where this cannot be done, and in less important cases, by the application of *styptics*, as *creasote*, *sulphate of iron*, *infusion of galls*, *compound tincture of benzoin*, *&c.*

Artificial hæmorrhage or *bloodletting*, is adopted, under certain circumstances, for the cure or prevention of disease; but the practice is now much less common than formerly in this country, as well as on the Continent, owing to the Faculty distrusting its efficacy, except in peculiar and emergent cases. In America, however, bleeding is carried to a fearful extent. At a discussion between Drs. Draper and Watson, which recently took place in Boston, U. S., the latter *boasted* that he had, during the short period of 4½ years, taken from the citizens of Boston and its vicinity, "*one hundred barrels of blood*, and had exhibited *upwards* of 49 lb of *mercury!*" Astounding, if true! See *Cupping*, *Leeches*, *Venesection*, *&c.*

HAIR. Syn. *Capillus*, *Pilus*,—Lat. The hair of the human head has continually formed a subject for the chisel of the sculptor, the pencil of the artist, and the lay of the poet. Nor is this surprising, since all the features of the face, as well as the head it covers, derive from it additional finish,

and unequalled grace. The hair is, indeed, one of the greatest auxiliaries of personal beauty, and imparts to it some of its principal charms. All nations, in all ages of the world, have been unanimous in their admiration of luxuriant and flowing, or gracefully arranged hair.

Of all organic substances hair is the one least liable to suffer spontaneous change. It is also less affected by aqueous liquids than most other substances. Hence its value in various branches of the useful arts.

The *preservation* of the *hair of the head*, independently of its connection with personal beauty, is a matter of the utmost importance in relation to hygiene. In other parts of this work, we have referred to its management under various conditions, and must here confine our remarks to its *cutting* and *arrangement*. The former is a matter that is commonly little understood, and very carelessly performed. When the hair is in a weakly state, and either falls off or grows feebly, frequently cutting it will be found of the greatest service. In doing this, some attention and trouble are requisite. The *short* and *impoverished* hairs must be cut as well as the *long* ones, with the view of giving them strength and improving their growth. According to the common method adopted by the hair-dressers, the latter only come under the operation of the scissors. Mr. Williams, an ingenious tradesman of Cheltenham, has made this plan the basis of his system of hair-cutting, with the happiest results; but few of his craft have energy or enterprise enough to follow his excellent example.

"In the *arrangement of the hairs* on the surface of the body, it might be inferred, that little existed to excite attention; but this is not the fact, if we are to judge by the careful investigations to which the subject has given rise. The hair-tubes are not placed perpendicularly, but obliquely, in the skin; hence the direction of the hairs, after their escape from the tubes, is in the same sense inclined towards the surface; and the 'set' of the hair, from the root to the point, is governed by a law as precise as that which regulates any other of the secondary vital functions. Thus, on the head, the hair radiates from a single point, the crown, to every part of the circumference, making a gentle sweep, behind, towards the left, and in front, to the right. The direction of this sweep is naturally indicated on the heads of children, and is that in which the hair is turned." (Eras. Wilson.) The same occurs on the face and other parts of the body. In making our toilet, this natural arrangement of the hair should be interfered with as little as possible. Combing it or banding it in an opposite direction to that which it naturally assumes, is highly prejudicial to its healthy growth, and if long persevered in, leads to its premature and rapid decay. The practice now common among ladies, of throwing the hair from the forehead towards the back of the head, is of this reprehensible character.

In addition to our remarks elsewhere, we may here observe, that all the various systems proposed for strengthening, or restoring the hair, depend for their efficacy upon simple "*excitation* or *stimulation* of the skin." Friction with the hair-brush, and the use of the ordinary *hair-oils*, *pommades*, and *washes*, are of this kind. The various advertised nostrums for *reproducing* or *restoring* the hair, are either stimulants or rubefacients of more or less activity, or are emollients, which are directed to be applied by friction, in such a manner as to set up a considerable amount of irritation. When the affection depends on the languid circulation of blood in the part, this treatment often succeeds; but when the hair-bulbs are withered or decayed, or the scalp much attenuated, the restoration of the hair is an impossibility. See *Baldness*, *Hair Dyes*, *Oils*, *&c.*

HAIR DYES. Syn. *Tinctura Capillorum*,—Lat. The practice of dyeing the hair is of great antiquity; and though not so common as formerly, it is still far from infrequent at the present day. The numerous preparations vended for this purpose have generally a basis of lead or silver. Bismuth, pyrogallic acid, and certain astringent vegetable juices, are also occasionally thus employed. The following list embraces all those of any value:—

Prep. 1. *Litharge*, 1 part; *fresh-slaked lime* and *starch*, of each, 2 parts; all in fine powder, and perfectly dry; mix, and keep the compound in well-corked bottles. This powder is to be made into a thin paste or cream with water (for a *black*), or milk (for a *brown*), and applied to the hair, (previously freed from grease with soap-and-water, and dried,) by means of a sponge or brush, or the fingers; observing to rub it well into the roots, and to pass a comb for some time through it, to ensure its coming in contact with every part. The whole must be then covered with a *moist* leaf of cotton wadding, or some brown paper several times doubled and well-damped with hot water, and allowed to remain so for 3 or 4 hours, or even longer;

or an oil-silk cap, or a bladder, may be worn, the object being simply to prevent the evaporation of the moisture. After a sufficient time has elapsed, the powder may be removed by rubbing it off with the fingers, and afterwards washing it out with warm soap-and-water. A little pomatum or hair-oil will restore the usual gloss to the hair. *Another method* of operating is, to apply the cream or paste as before, and then to keep rubbing it about the hair with a brush as long as may be required, occasionally adding a few drops of hot water to preserve the whole moist. In this way the action of the dye is facilitated, and the process concluded in a much shorter time.

2. *Lime* (slaked in the air), 2 parts; *carbonate of lead* (pure white lead), 1 part; mixed and applied as the last.

3. (*Aqua Orientalis.*) From *grain silver*, 2 *dr.*; *steel filings*, 4 *dr.*; *nitric acid*, 1 *oz.*; *soft water*, 1½ *fl. oz.*; digested together, the solution being afterwards diluted with *water*, 3½ fl. oz. and filtered. Applied by means of a fine-toothed comb, or a half-worn tooth-brush to the hair, previously well cleaned with soap-and-water, and dried.

4. (*Argentan Tincture.*) From *nitrate of silver*, 1 dr.; *eau de rose*, 1 fl. oz.; *nitrate of copper*, 2 gr., or q. s. to impart a slight greenish tint. *Used* as the last.

5. (Dr. Cattel.) *Nitrate of silver*, 11 dr.; *nitric acid*, 1 dr.; *distilled water*, 1 pint; *sap green*, 3 dr.; *gum arabic*, 1½ dr.; digest together. *Used* as No. 3.

6. (Chevallier.) *Fresh-slaked lime*, 5 dr.; *water*, 1½ *oz.*; mix, strain through gauze, and pour the milk into a four-ounce bottle. Next dissolve *sugar of lead*, 5 dr., in *water*, 3 fl. oz.; add to this solution, dry *slaked lime*, 1 dr., stir well together, wash the precipitate with a little soft water, drain off the water, then add it to the milk of lime in the bottle, and shake the whole well together, and again before use. Applied as No. 1; but it acts much more quickly.

7. (*Delcroix's.*) From *acetate of lead*, 2 *oz.*; *prepared chalk*, 3 *oz.*; *quicklime*, 4 *oz.*; each in an impalpable powder. *Used* as No. 1.

8. (*Eau d'Afrique*,—Hopekirk's.)—*a. Nitrate of silver* (cryst.), 1½ dr.; *distilled water*, 2 fl. oz.; dissolve, and pour the solution into the bottles labelled "*Solution* No. 1."—*b. Liquor of potassa*, 3 dr.; *hydrosulphuret of ammonia*, 7 dr.; *water*, 1 fl. oz.; mix, and pour the liquid into the bottles labelled "*Solution* No. 2." For *use*, the hair is moistened by means of a small-toothed comb or a tooth-brush, with the solution No. 1, either alone or diluted with a little water; care being taken to avoid touching the skin, if possible. After the lapse of 8 or 10 minutes the solution No. 2, diluted with at least 5 times its measure of water is applied in the same manner, and any spots on the skin removed by rubbing them with the corner of a napkin wetted with the liquid. The skin is then sponged clean with a little warm water, and wiped dry, and the hair is arranged with the comb as usual. It is better to avoid rubbing it or washing it for a few hours. Sometimes the process is reversed, and the liquid No. 2, applied first. In this way, the stains on the skin are more readily removed, but the dye is less permanent than when the other plan is adopted.

9. (*Eau d'Egypte.*) Resembles No. 4, (above).

10. (*Essence of Tyre.*) Resembles the last.

11. (*Grecian Water.*) Resembles No. 3, or 4.

12. (Dr. Hanmann.) *Litharge*, 275 gr. (say, 1 part); *quicklime*, 1875 gr. (or 6¾ parts); *hair powder* (or starch), 930 gr. (or 3½ parts); all in fine powder. *Used* as No. 1.

13. (*Hewlet's*). Resembles *Spencer's.*

14. (*Instantaneous.*) Moisten the hair first with a *solution of nitrate of silver* in *water* (1 to 7 or 8), and then with a *weak solution of hydrosulphuret of ammonia.* The colour of the hair, unaltered by the silver solution, instantly turns black when moistened with the sulphuret. See *Eau d'Afrique.*

15. (*La Forest's.*) See *Washes.*

16. (*Orfila's.*) From *litharge*, 3 parts; *quicklime*, 2 parts; *starch*, 1 part. The original form for this article is as follows:—*Sulphate of lead*, 4 parts; *dry fresh-slaked lime*, 5 parts; *water*, 30 parts; boil 1 hour, collect the paste on a piece of *calico*, and apply it in a similar manner to No. 1.

17. (*Pommade Dye.*)—*a. Nitrate of silver*, 1 part; *nitric acid*, 2 parts; *iron filings*, 2 parts; mix, and let them stand together for 4 or 5 hours, then pour them on *oatmeal*, 2 parts; next add, *lard*, 3 parts; and mix well together.

b. From *nitrate of silver* and *cream of tartar*, of each, 1 dr.; *liquor of ammonia*, 2 dr.; dissolve, add of *lard*, 4 dr., and mix well together.

18. (*Poudre d'Italie.*) Resembles *Orfila's.*

19. (*Pyrogallic Stain.*) A weak solution of *crude pyrogallic acid.* Another article sold under this name, is prepared by distilling *nutgalls* (coarsely powdered) in a

retort, dissolving the *solid acid* which sublimes in a little *hot water*, and after mixing this with the *acid liquid* which also passes over, adding a little *rectified spirit*. The floating oil is then separated and the solution filtered.

20. (Redwood.) *Litharge*, 2 *oz.*; *slaked lime* and *powdered starch*, of each, 1 *oz.*; *liquor of potassa*, 2 dr.; *water*, q. s. to form a thick cream. *Used* as No. 1.

21. (Redwood.) *Liquor of potassa* and *distilled water*, of each, 1 pint; mix, and pass *sulphuretted hydrogen* through the liquid until it is saturated. Of *this solution* take 20 *oz.*; *liquor of potassa*, 4 *oz.*; mix, and label it "*Solution No.* 1." Next dissolve *nitrate of silver*, 1 dr., in *distilled water*, 2 *oz.*; and label the liquid "*Solution No.* 2." *Used* in the same manner as No. 8 & 14.

22. (*Spencer's.*) From *sap green*, ½ dr.; *nitrate of silver*, 1 dr.; *hot water*, 1 *oz.* Applied as No. 3.

23. (*Tinctur zum Schwarzfarben der Haare.*) A strong *tincture* of the *shells of green walnuts*, scented with *oil of lavender*.

24. (Ure.) *Litharge*, *fresh-slaked lime*, and *bicarbonate of potassa*, mixed in various proportions according to the shade of colour desired. *Used* like No. 1.

25. (*Warren's.*) From *litharge*, 1 *oz.*; *white lead*, 2 *oz.*; *quicklime*, (in fine powder), 16 *oz.*; mix, sift through lawn, and at once bottle the mixture. *Used* like No. 1. Mixed with water it is said to dye the hair black; with milk, brown.

26. *White lead*, 1 *oz.*; *fresh slaked lime*, 1½ *oz.*; *litharge* and *ozide of bismuth*, of each, ½ *oz.*; *water*, 1 pint; mix, boil 15 minutes, with frequent agitation, cool, pour it into a bottle, add of *liquor of ammonia*, ¼ fl. oz., shake the whole frequently for some hours, and the next day pour off the liquid portion from the white sediment which forms the dye, *Used* like No. 1. It is applied for 8 or 10 minutes for a *brown*; 30 minutes, or longer, for a *black*. For the first it is washed off with water containing a little common soda.

27. The *juice* of the *bark* or *shell of green walnuts*, applied with a sponge. (Paulus Ægineta.)

28. A *leaden comb* used daily is said to darken the hair, but we have known persons persevere in its use for months without any perceptible change occurring. Premature baldness is a frequent consequence of its use.

Obs. It is right to inform the reader that all those compounds which contain *nitrate of silver* stain the *skin* as well as the hair. These stains may be removed when quite recent, by rubbing them with *water* containing a little *hydrosulphuret of ammonia* (see *above*) or *iodide of potassium* in solution; but as this is attended with some trouble and inconvenience, the best way is to avoid the necessity of doing so. The hair-dressers adopt the plan of smearing *hard pomatum* over the skin immediately surrounding the hair, to protect it from the dye. By very skilful manipulation, and the observance of due precautions, the hair may be thoroughly moistened with the above fluids, without touching the adjacent skin, but this can only be done, in the case of the hair of the head, by a second party. This has led to a preference being given by many to the compounds containing *lead*, as the *plumbite of lead* formed in them, and on which their action depends, does *not stain the skin*. The hue given by the latter (*when pale*), is very apt to possess an unnatural redness; but *all* the shades of colour given by the preparation of silver, are rich and unexceptionable. *Pyrogallic acid*, and the *juice of walnuts*, also stain the skin, although less intensely and permanently than nitrate of silver.

The *detection* of *dyed hair* is often a matter of importance in medico-legal research. The *presence of silver* may be shown by digesting the hair in a little *weak chlorine water* or *hydrochloric acid*, when the resulting chloride of silver may be dissolved out with *liquor of ammonia*, and submitted to the usual tests. *Hair* containing *lead* when digested in dilute nitric acid, gives a solution of nitrate of lead, in which form it is readily detected. See *Lead* and *Silver*.

All the preceding compounds are for dying *living hair* (human); *horse-hair*, *bristles*, *&c.*, and other *dead hair* may be readily stained by steeping them in any of the ordinary liquid dyes; more especially those employed for wool and silk. See *Pommades*, *Washes*, *&c.*

HAIR PAINTS. See *Cosmetique* and *Pommades*.

HALL MARKS. The *Hall Marks* on articles in gold and silver not only inform us of their fineness, but furnish us with other important particulars.

The *Hall Mark* (proper) denotes the place of manufacture or assay, being an anchor for *Birmingham*; a dagger or 3 wheat sheaves, for *Chester*; hibernia, for *Dublin*; castle and lion, for *Edinburgh*; castle with 2 wings, for *Exeter*; tree and salmon with a ring in its mouth, for *Glasgow*; leopard's head, for *London*; 3 cas-

tles, for *Newcastle-on-Tyne;* a crown, for *Sheffield;* and five lion's heads and a cross, for *York.*

The *Duty Mark* is the head of the Sovereign, showing that the duty is paid.

The *Date Mark* is a letter of the alphabet, which varies every year, and with the different companies, thus; the *Goldsmith's Company of London* have used from 1716 to 1755 Roman Capital letters; from 1756 to 1775 small Roman Letters; from 1776 to 1795 old English letters; from 1796 to 1815 Roman Capital letters, from A to U, omitting J; from 1816 to 1835 small Roman letters, a to u, omitting j; from 1836 old English letters.

The *Standard Mark* for *Gold* is, for *England*, a lion passant; *Edinburgh*, a thistle; *Glasgow*, a lion rampant; *Ireland*, a harp crowned. For *silver*, a figure of Britannia. If under 22 carats, gold has the figures 18.

The *Manufacturer's Mark* is the initials of the maker, as S. H., W. T., C. E., &c. See *Gold, Jewellery, &c.*

HALOGENS. A name given by Berzelius to those substances which by their combination with the metals produce saline compounds. Bromine, chlorine, cyanogen, fluorine, &c., are halogens. The compound bodies thus formed are termed *haloid salts.*

HAMS. These are usually prepared from the *legs of bacon pigs*, but those of the *sheep* are also sometimes used for the same purpose. *Smoked ham* is strong eating, and rather fit for a relish than for diet, and should be particularly avoided by the dyspeptic, and by convalescents.

Choice. A sharp knife thrust under the bone should have a pleasant smell when withdrawn. The recently cut fat should be hard and white, the lean fine-grained, and of a lively red. Those short in the hock are the best.

Curing. An ordinary sized ham requires nearly three weeks, if *wet salted*, and about a month if *dry salted*, to cure it perfectly. At the expiration of this time, they are ready for smoking. *Mutton hams* should not lie in pickle longer than 12 or 14 days.

Cooking. Hams should be put into the water *cold*, and should be gradually heated. A ham of 14 *lb.* will take about 4 hours; one of 16 *lb.* will take 4½ hours, and one of 20 *lb.* about 5½ hours to dress it properly. "If it is an old ham it should be soaked for 12 hours previously." (Soyer.)

Pres. Most grocers and dealers in hams enclose them, after being smoked, in *canvass*, for the purpose of defending them from the attacks of the little insect, the *dermestes lardarius*, which, by laying its eggs in them, soon fills them with its larvæ or maggots. This troublesome and expensive process may be altogether superseded by the use of *pyroligneous acid*, applied by means of a painter's brush.

HANDS. *Dirty and coarse hands* are no less the marks of slothfulness and low breeding, than clean and delicate hands are those of cleanliness and gentility. To promote the *softness* and *whiteness* of the skin, mild emollient soaps, or those abounding in oil, should alone be used, by which means chaps and chilblains will generally be avoided. The coarse, strong kinds of soap, or those abounding in alkali, should for a like reason be rejected, as they tend to render the skin rough, dry, and brittle. The immersion of the hands in alkaline lyes, or strongly acidulated water, has a like effect. When the hands are *very dirty*, a little good soft soap may be used with warm water, which will rapidly remove oily and greasy matter. *Fruit* and *ink stains* may be taken out by immersing the hands in *water slightly acidulated* with *oxalic acid* or a *few drops* of *oil of vitriol*, or to which a little *pearlash* or *chloride of lime* has been added; observing afterwards to well rinse them in clean water, and not to touch them with soap for some hours, as any alkaline matter will bring back the stains, after their apparent removal by all the above substances, except the last. The use of a little *chloride of lime* and *warm water*, or *Gowland's lotion*, imparts a delicate whiteness to the skin; but the former should be only *occasionally* used, and should be well washed off with a little clean water to remove its odour. *Glycerine* employed in the same manner renders the skin soft, white, and supple. The use of a little *sand* or *powdered pumice stone* with the soap, will generally remove the roughness of the skin, frequently induced by exposure to cold. The hands may be preserved *dry*, for delicate work, by rubbing a little *club moss* (*lycopodium*), in fine powder, over them. A small quantity of this substance sprinkled over the surface of a basin of water, will permit the hand to be plunged to the bottom of the basin without its becoming wet.

HANGING. In cases of *suspended animation* from *hanging*, the assistance must be prompt and energetic. The body, on its discovery, should be instantly relieved from the state of suspension, and all pressure about the throat. The *remedial treatment* chiefly consists, in the severer cases, in cupping the temples or opening the jugu-

lar vein, and so relieving the head of the blood which is accumulated in its superficial veins in consequence of strangulation. When the body is cold, friction, and the other means used for restoring the animal heat in drowned persons should be resorted to. See *Animation* (*Suspended*) and *Drowning*.

HARDNESS. Compactness; solidity; the power of resisting abrasion. *Mineral substances* are frequently distinguished and identified by their relative hardness. This is ascertained by their power to scratch or be scratched by one another. A valuable table on this subject will be found in the article on *Gems*.

HARMALINE. Syn. *Harmalina*. A basic substance, forming yellow-brown crystals, discovered by Gobell in the seeds of *peganum harmala*. It has a bitter astringent and acrid taste, is soluble in alcohol, and forms yellow, soluble salts with the acids. It has been proposed as a yellow dye. By *oxidation* it yields another compound (*Harmine*), which is a magnificently red dye-stuff, easily prepared and applied. (Göbel.) The seeds are produced abundantly in Russia.

HARNESS POLISH. See *Blacking, &c.*

HARTSHORN. Syn. *Cornu Cervi, C. Cervinum; Cornu*,—Ph. L. The "*horn*" of the "*cervus elephas*" (Ph. L.) or stag. (See *below*.)

HARTSHORN (Burnt). Syn. *Cornu Ustum*,—Ph. L. *Cornu Cervi Ustum*,—Ph. L. 1787. *Prep.* (Ph. L. 1836.) Burn *pieces* of *harts' horns* until perfectly white, then grind and prepare them in the same way as directed for "prepared chalk."

Obs. Finely powdered bone-ash is usually sold for burnt hartshorn, and possesses exactly the same properties. *Dose.* 10 to 30 gr., or more, 2 or 3 times a day, in rickets, &c. See *Phosphate of Lime*.

HARTSHORN SHAVINGS. Syn. *Hartshorn Raspings; Rasura Cornu Cervi, Ramenta C. C.*,—Lat. Obtained from the turners. Boiled in water, it yields a nutritive jelly. *Used* by straw-plait workers to stiffen bonnets, &c.

HATCHETINE. A species of fossil resin found in certain varieties of mineral coal.

HATCHING. See *Incubation*.

HATS. Those should be chosen possessing a *short*, smooth, fine nap, and a good black colour; and sufficiently elastic to resist ordinary wear and tear, without breaking or giving way. The *hat brush* for *daily* use should be made of soft hairs, but a *stiffer one* should be employed *occasionally*, to lay the nap smooth and close. *Grease* may be removed by means of porous brown paper, and pressure with a hot iron.

HEADACHE. Syn. *Cephalalgia*,—Lat. The symptoms of this very general complaint are too well known to require any description. According to pathologists, headache arises, either from a sympathy with the stomach and chylopoietic (chyle-forming) viscera, or from a weakness or exhaustion of the power of the encephalon. The former may be called *sympathetic*, and the latter *nervous headache*. When it attacks only *one* side of the head it is called *Hemicrania*. The TREATMENT of the first form should consist in restoring the healthy action of the stomach, by the administration of *aperients*, and by the use of proper food, and exercise; or when that viscus is overloaded with undigested food, by the exhibition of an *emetic*. For this purpose ¼ to ½ an *oz.* of *ipecacuanha wine* may be taken in a cupful of *warm water*, which will generally relieve the stomach, especially if its action is assisted by drinking *copiously* of warm water. Headache is a common accompaniment of indigestion and stomach disease, and in general it will be found that whatever will remove the one, will also cure the other. *Nervous headaches* are relieved by nervous tonics and stimulants; as *bark, cascarilla, calumba, gentian, camphor, ammonia, ether*, and *wine;* the latter in a state of considerable dilution. A *cup* of *strong coffee* or *strong green tea* often acts like a charm in removing this species of headache. Small doses of *tincture of henbane* have also often a like effect. 20 or 30 drops of *laudanum*, or preferably, half that number of *liquor opii sedativus*, may be taken with advantage as an anodyne, and to induce sleep. Amongst *popular remedies* may be mentioned "*nasal stimulants*," as snuff (cephalic), smelling salts, and aromatic vinegar, the use of which is familiar to every one; and *local applications*, as very cold water, ether, vinegar, strong spirits, Cologne water, &c.; all of which are rubbed over the part of the head affected, with the fingers; or a linen rag dipped in them is laid thereon instead. Pressure on the head has also been used with advantage. *Silence, darkness*, and *repose*, are powerful remedies, alike suitable to every variety of headache; and *change of air, scene*, and *occupation*, are especially beneficial to those resulting from excessive mental anxiety or exertion. *Blisters* are sometimes applied behind the ears in cases of violent headache.

Headache is often *symptomatic* of other diseases, especially those of the inflammatory

and nervous kind, rheumatism, &c. In all these, the primary disease should be sought out and attempted to be cured. In many cases these attacks rapidly yield to a few doses of *compound decoction of sarsaparilla* containing a little *iodide of potassium*. *Headache in pregnancy* may generally be removed by proper attention to the bowels; observing to assist their action, should they require it, by the use of some *mild aperient*, as castor oil, lenitive electuary, seidlitz powders, &c. When the constitution is very robust, blood may be taken. *Headache in bed* may frequently be relieved by washing the head with *cold water*, and discontinuing the use of a nightcap; at the same time preserving the feet warm by wearing worsted socks or stockings.

HEADING. Syn. *Beer Heading*, *Cauliflower do.* *Prep.* 1. *Alum* and *green copperas*, equal parts, both in fine powder.

2. *Alum*, *copperas*, and *common salt*, equal parts.

Used by brewers to make their beer keep its head or froth.

HEALTH. That state of the living body in which all its functions are duly performed. See *Hygiene*.

HEARING. See *Deafness*, *Ear*, *&c.*

HEARTBURN. Syn. *Cardialgia*, *Cordolium*,—Lat. Anxiety and pain about the region of the stomach, generally attended by a sense of gnawing and heat; hence its popular name. Faintness, nausea, and eructation of a thin, acidulous, watery liquid, especially in the morning, are common symptoms of this complaint. The usual *causes* of heartburn are excess in eating or drinking, the use of improper food, and sedentary habits. A *good remedy* is a teaspoonful of *carbonate of magnesia*, or *carbonate of soda*, in a *glass of peppermint* or *cinnamon water*, to which a little *powdered ginger* may be added with advantage. This dose may be taken 2 or 3 times daily until the disease is removed. Articles of food that easily undergo fermentation should at the same time be avoided, and a *dry* diet had recourse to as much as possible. *Soda-water*, *toast-and-water*, and *weak spirit-and-water*, are the most suitable beverages in this complaint.

HEAT. Syn. *Calor*, *Caloricum*,—Lat. The consideration of this subject belongs to *physics* and *chemistry*. Much useful information, in connection with it, will, however, be found in this work, under the heads, *Ebullition*, *Evaporation*, *Expansion*, *Refrigeration*, *&c.*

HEAVY SPAR. Native sulphate of baryta. See *Baryta*.

HECTIC FEVER. Syn. *Febris Hectica*,—Lat. An ill-defined constitutional febrile affection, more or less of an intermittent character, attended by debility, a small quick pulse, paleness, loss of appetite, emaciation, and excessive perspiration. It is often symptomatic of some other disease. When it is an idiopathic affection, sarsaparilla, or the lighter bitter tonics, and mild aperients, judiciously administered, often prove useful; especially when supported with a light and regular diet, regular hours, gentle out-of-door exercise, and warm bathing or the shower bath.

HEDERINE. Syn. *Hederina*. From the *decoction* of the *ground seeds of ivy* (hedera helix), boiled in *water*, along with a little *slaked lime* or *magnesia*, the precipitate being afterwards digested in *rectified spirit*, and the filtered tincture evaporated. Febrifuge and sudorific.

HEDGES. The economising of land in agriculture, is next in importance only to its careful cultivation. The Rev. Mr. Rham calculates the *loss of land* in *hedges* and *ditches* to be 1 acre in 25; by taking the estimates made by Mr. John Grant, in Devonshire, and those made in Kent, it gives the average at 1 acre in 27; and even in a closely-cultivated county, 5 acres were *gained* on a farm of 203 acres by rooting up the hedges; 3 acres were gained on a farm of 180 acres in a similar manner. The advantage, therefore, of substituting fences for hedges, and throwing small enclosures into large ones, can no longer be questioned, however much it may tend to lessen the beauty of our rustic scenery.

HELENINE. Syn. *Elecampane Camphor*. A peculiar substance obtained from the fresh root of *inula Helenium* (elecampane), by digestion in *hot alcohol* or distillation along with *water*. It is crystalline, soluble in alcohol, ether, and essential oils, melts at 162° and boils about 530° Fahr. Its vapour has an odour resembling that of patchouli. Nitric acid converts it into a resin-like substance (*nitrohelenine*.)

HELICINE and *Helicoidine*, are products, along with *anilotic acid*, resulting from the action of *dilute nitric acid* on *salicine*. (M. Piria.)

HELIOGRAPHY. See *Photography*.

HELLEBORE. Syn. *Black Hellebore*; *Helleborus*,—Ph. L. "The rhizome and root" of "*helleborus niger*" (Ph. L.) or black hellebore. It is alterative and emmenagogue, in *small doses* (2 to 8 gr.); and a drastic hydragogue purgative and anthelmintic in *larger ones* (10 to 20 gr.)

HELLEBORINE. Syn. *Soft Resin of*

Hellebore. An odourless, acrid substance, extracted by alcohol from *black hellebore*, and on which, according to Vauquelin, the activity of that drug depends.

HEMATINE. Syn. *Hæmatine, Hæmatoxyline.* A principle obtained by Chevreul from common logwood (*hæmatoxylon campechianum*), and on which its colour appears to depend.

Prep. 1. Infuse *logwood chips* in *water*, at a temperature of about 130° Fahr., for 12 hours, filter, and evaporate to dryness in a water-bath; digest the residuum in *rectified spirit*, for 24 hours, again filter and evaporate; then add a *little* water, again gently evaporate and set aside the solution in a cold place that crystals may form; these must be washed in *rectified spirit* and dried.

2. Digest *powdered hard extract of logwood* in *rectified spirit*, and proceed as last.

Prop., &c. Brilliant reddish-white crystals, soluble in boiling water, forming an orange-red solution which turns yellow as it cools, but resumes its former colour on being heated. Alkalies in excess change its colour successively into purple, violet, and brown; acids brighten it; with the metallic oxides it forms compounds, having a blue, purple, or violet colour.

HEMIDESMIC ACID. Syn. *Hemidesmine; Smilasperic Acid.* A volatile and crystallizable substance obtained by Mr. Garden from the root of *hemidesmus indicus* or *Indian scented-sarsaparilla.* It possesses the taste, odour, and medicinal properties of the root.

HEMIPINIC ACID. Syn. *Semi-opianic Acid.* A new bibasic acid obtained from a mixture of *binoxide of lead, opianic acid,* and *sulphuric acid.*

HEMLOCK. Syn. *Cicuta; Conium,* — Ph. L. E. & D. "The fresh and dried leaf of the wild herb, *conium maculatum*" (Ph. L.) or *spotted hemlock.* The first are used to make the *extract;* the last, the *tincture* and *powder.*

Hemlock is a powerful narcotic acrid poison, occasioning stupor, delirium, paralysis, convulsions, coma, and death. In *small doses* it is anodyne, alterative, resolvent, antispasmodic, and anaphrodisiac, and has been exhibited in cancer, dropsy, epilepsy, rheumatism, scrofula, syphilis, and other diseases. *Dose.* 3 or 4 gr. of the powder, twice or thrice daily, until some obvious effect is produced.

Hemlock, whether in leaf (*conii folia*) or powder (*pulvis conii*) rapidly deteriorates by keeping. When good "the powder, triturated with *solution of potassa*, exhales a powerful odour of conia." (Ph. E.)

In cases of *poisoning* by *hemlock*, the treatment is similar to that noticed under *Aconite.*

HEMP. The common hemp of which cordage is made, is the *cannabis sativa* (Linn.) A variety of this plant, or perhaps the same, simply rendered more active by climate, is the *cannabis Indica* or *Indian hemp*, now so frequently used in medicine. The parts employed in Asia for the purposes of intoxication, and in Europe as medicine, are the *herb* or *leaves* and the *resin.* The *Gunjah* sold in the bazaars, in the East Indies, is the plant, just after flowering, dried and pressed together. *Bang, banga, subjee,* or *sidhee,* consists of the larger leaves and capsules without the stalk. The tops and tender parts of the plant collected after inflorescence, forms *Hashish.* The concrete resinous exudation from the leaves, stems, and flowers, is called *Churrus*, and in this country—*resin of Indian hemp.*

Indian hemp is anæsthetic, anodyne, exhilarant, antispasmodic, hypnotic, and narcotic. In the East it is commonly used as an intoxicant, either by smoking it, like tobacco, or swallowing it. The inebriation produced by it is of an agreeable or cheerful character, exciting the party under its influence to laugh, dance, sing, and to commit various extravagancies. It also acts as an aphrodisiac, augments the appetite for food, and, in some cases, occasions a kind of reverie and catalepsy. In this country its action is less marked. It has here been chiefly administered under the form of alcoholic or resinous extract. See *Cannabine* and *Extracts.*

The *fruit* of common hemp (*hemp seed*) is demulcent and oleaginous. It is said that the plumage of bullfinches and goldfinches fed on it for too long a time, or in too large a quantity, changes from red and yellow to black. (Burnett, *Outlines of Botany.*)

HENBANE. Syn. *Hyoscyamus,* — Ph. L. E. & D. "The *fresh* and *dried* stalk-leaf of the biennial herb, *hyoscyamus niger*" (Ph. L.) or common *biennial* or *black henbane.* The first are used for preparing the *extract;* the *last,* for the *powder* and *tincture.*

Henbane is anodyne, hypnotic, antispasmodic, and sedative. It differs from opium in not being stimulant, and by not confining the bowels; and hence may be administered in cases in which that drug would be improper. In large doses it acts as a powerful narcotic poison; producing

obscurity of vision, dilation of the pupils, delirium, phantasms, coma, &c. *Dose.* 3 to 10 gr., in powder. It is usually given in the form of extract or tincture. The *antidotes, &c.*, are the same as those noticed under *Opium.*

HEPAR. Syn. *Liver.* A name given by the older chemists to various combinations of sulphur, from their brown colour; as *hepar sulphuris*, sulphuret of potassium; *hepar antimonii*, crude oxysulphuret of antimony, *&c.*

HEPATIC AIR. See *Sulphuretted Hydrogen.*

HERBARIUM. Syn. *Hortus Siccus.* A collection of dried specimens of plants; hence called hortus siccus or dry garden. The common plan is to press the branches, flowers, &c., of the plant flat, between porous paper, and after drying them in the sun, or otherwise, to glue or gum them to sheets of paper. The preparation of a herbarium offers an almost endless source of amusement to the ingenious, whilst the specimens so collected, if well preserved, are as useful to the botanist as the living plants.

HERBS. Syn. *Herbæ*,—Lat. The *collection* and *drying of herbs* for medicinal purposes and perfumery, are noticed under *Vegetables.*

Amongst *cooks*, several aromatic herbs, either fresh or dried, are used for seasoning. "In many receipts is mentioned a *bunch* of *sweet herbs*, which consists, for some stews and soups, of a small bunch of *parsley*, two sprigs of *thyme*, and one *bayleaf;* if no parsley, then of four sprigs of *winter savory*, six of *thyme*, and one *bayleaf.*" (Soyer.)

HERNIA. See *Rupture.*

HERPES. See *Tetters.*

HERRING. A well-known small sea-fish, the *clupea harengus*, of Linnæus, belonging to the Cuvierian order, *malacopterigii abdominales.* As an article of food, herrings are of vast importance to a large proportion of the population of Europe. When *recently* caught and dressed by broiling or boiling, they are wholesome and agreeable; but if fried, or long kept, they become strong and oily, and are then apt to offend the stomach. The preparation of salted and dried or smoked herrings (*bloaters, blown herrings, red do.*) furnishes employment for thousands, both in these countries and Holland. Real *Yarmouth bloaters* and *Dutch herrings* are highly esteemed by many as a relish. Salted herrings are said to be diuretic. The *pickle* was formerly used in clysters, dropsies, &c. Mr. Winkles found large quantities of *trymethylamine* in the liquor in which salt herrings are preserved. M. Soyer calls this fish "the poor man's friend," and tells us that after being "cleaned and scaled, and the head removed," it should be "opened in the *back*, and the gut taken out." Also that "the way to ascertain if a herring is too salt, is to take the fish in the left hand, and pull out a few of the fins from the back, and to taste them. You may thus find out the quality and flavour. This plan is adopted by the large dealers."

HESPERIDINE. Syn. *Aurantine?* A peculiar substance obtained from the white portion of the rind of oranges, lemons, &c. It forms crystalline silky needles, is odourless, tasteless, fusible, soluble in alcohol, less soluble in water, and is reddened by oil of vitriol.

HICCOUGH. Syn. *Hickup; Singultus*,—Lat. A convulsive motion of the diaphragm and parts adjacent. The *common causes* are flatulency, indigestion, acidity, and worms. It may generally be *removed* by the exhibition of *warm carminatives, cordials, cold water, weak spirits, camphor julep*, or *spirits of sal volatile.* A *sudden fright* or *surprise* will often produce the like effect. An instance is recorded of a delicate young lady that was troubled with hiccough for some months, and who was reduced to a state of extreme debility from the loss of sleep occasioned by it, that was cured by a fright, after medicines and topical applications had failed. A *pinch of snuff*, a *glass* of *iced soda-water*, or an *ice-cream*, will also frequently remove this affection.

HIERA PICRA. See *Powder of Aloes and Canella.*

HIPPOCRAS. An aromatic medicated wine, formerly much used in England, and still employed on the Continent.

Prep. Lisbon and *Canary wine*, of each, 12 pints; *cinnamon*, 2 *oz.; white canella*, ½ *oz.; cloves, mace, nutmeg, ginger*, and *galangal*, or *cardamoms*, of each, 1 dr.; bruise the spices, and digest them in the wine for three or four days; strain, and add of *lump sugar*, 2½ *lb.*

HIPPURIC ACID. Syn. *Acidum Hippuricum*,—Lat. A compound discovered by Liebig in the urine of the horse, cow, and other graminivora, in which it exists in combination with potassa or soda.

Prep. Concentrate the *urine* by a gentle heat, acidulate it with *hydrochloric acid*, and set it aside to crystallize. It may be decoloured by redissolving it in *boiling water*, and treating it with *animal charcoal*,

or with a little *chloride of lime* along with some *hydrochloric acid*, and re-crystallizing it.

Obs. Hippuric acid, when pure, forms long, slender, milk-white, square prisms; it is soluble in 400 parts of cold water, but is easily dissolved by boiling water; it is also soluble in alcohol. When strongly heated, benzoic acid and benzoate of ammonia distil over in a liquid state, accompanied by a strong odour of Tonka beans, and afterwards of hydrocyanic acid. "The urine of horses or cows, left to itself for some time, or evaporated at a boiling temperature, yields not a trace of hippuric acid, but only benzoic acid." Nitric acid and hot oil of vitriol convert it into benzoic acid. Boiling hydrochloric acid converts it into *benzoic acid* and *glycocoll*. With the bases it forms salts, which are called *hippurates*. See *Benzoic Acid*.

HIPS. Syn. *Heps; Rosa Canina,*—Ph. L. The fresh fruit of the *dog rose* (rosa canina,—*Linn.*) or *wild briar*. *Used* to make a *conserve*.

HIRCIC ACID. A name given by Chevreul to an oily liquid, obtained by saponifying the fat of goats. It is *prepared* in the same way from *goat fat*, as capric, caproic, and butyric acids are from butter. It is soluble in alcohol, and possesses a mixed smell of vinegar and goats. With the bases it forms salts called *hircates*.

HIRCINE. An oily fluid extracted by Chevreul from goat-fat, and which also may be obtained from mutton suet. It smells strongly of the male goat. By saponification it yields *Hircic Acid*.

HOLLANDS. Syn. *Geneva, Hollands Gin, Dutch do. Prep.* 1. The materials employed in the distilleries of Scheidam in the preparation of this excellent spirit, are two parts of the best *unmalted rye*, and 1 part of *malted bigg*, reduced to the state of coarse meal by grinding. About a barrel (36 gall.) of *water*, at a temperature of from 162° to 168° Fahr., is put into the mash tun for every 1½ cwt. of *meal*, after which the *malt* is introduced and stirred, and lastly, the *rye* is added. Powerful agitation is next given to the magma till it becomes quite uniform, when the mash-tun is covered over with canvass, and left in this state for two hours. Agitation is then again had recourse to, and the transparent *spent wash* of a preceding mashing is added, followed by as much *cold water* as will reduce the temperature of the whole to about 85° Fahr. The gravity of the wort at this point varies from 33 to 38 *lb.* A quantity of the *best pressed Flanders yeast*, equal to 1 *lb.* for every 100 gall. of the mashed materials, is next stirred in, and the whole is fermented in the mash tun for about 3 days, or until the attenuation is from 7 to 4 *lb.* (sp. gr. 1·007 to 1·004). During this time the yeast is occasionally skimmed off the fermenting wort. The wash, with the grains, is then transferred to the still, and converted into "*low wines*." To every 100 gall. of this *liquor*, 2 *lb.* of *juniper berries* (3 to 5 years old), and about 1 *lb.* of *salt*, are added, and the whole is put into the *low-wine still*, and the fine spirit drawn off by a gentle heat, one receiver only being employed. The *product* per quarter varies from 18 to 21 gall. of spirit, 2 to 3 *o. p.*

2. (*Best hollands; Brandewyn von Koorn voorloof drie quart.*) Hollands rectified to the strength of 24° Baumé (sp. gr. 0·9125, or about 6 *o. p.*)

3. (*English-made.*)—*a.* From *juniper berries* (at least a year old, and crushed in the hands,) 3 *lb.*; *rectified spirit*, 1½ gall. (or *proof spirit*, 2½ gall.); digest, with agitation for a week, and then express the liquor; after 24 hours' repose, decant the clear portion, add it to *good corn spirit*, at 2 or 3° overproof, 90 or 100 gall., and mix them well together.

b. From *juniper berries*, 2½ *lb.*; *sweet fennel seed*, 5 *oz.*; *caraway seed*, 3½ *oz.*; *proof spirit*, 2 gall.; *corn spirit*, 90 or 100 gall.

c. As the last, with the addition of *Strasburgh turpentine*, or *Canadian balsam*, 1 *lb.*

d. To either of the last two or three, add a very small quantity of *ground cardamoms* or *horse-radish*. Some compounders also add 4 or 5 cloves of *garlic*, or about 15 gr. of *assafœtida*, with 1 gr. of *ambergris* rubbed to a powder with a little *white sand* or *lump sugar*. Good *plain gin* may be advantageously employed in lieu of the corn spirit ordered above, when expense is no object.

Obs. The last four forms, which are only given as examples, produce a very pleasant spirit, if it is kept for some time to "*mellow*." Age is *one* of the principal causes of the "creaminess" of foreign gin, which usually lies in bond for some time before being consumed. The product is, however, much superior if the ingredients are rectified along with 20 gall. of *water*, and about 14 *lb.* of *salt*, by a gentle heat.

It will be seen from the above, that the superior flavour of Hollands spirit depends more on the peculiar mode of its manufacture than on the quantity of

juniper berries employed; 2 *lb.* of them, when new, being barely equivalent to 1 *oz.* of the *essential oil;* and when old, to less than ½ *oz.*, a quantity *wholly insufficient* to flavour 100 *gallons of spirit.* The Dutch distillers, most noted for this liquor, add a little pure *Strasburgh turpentine*, and a handful or two of *hops* to the spirit, along with the juniper berries, before rectification. The former substance has a pale yellowish brown colour, and a very fragrant and agreeable smell, and tends materially to impart that fine aroma, for which the best Geneva is distinguished. At Rotterdam *sweet fennel seed* is commonly added as a flavouring; and at Weesoppe, *Strasburgh turpentine* and *fennel seeds*, or the *essential oil of fennel*, are frequently substituted for a large portion of the juniper berries.

Schiedam Hollands is considered the *best;* the *next quality* is that of *Rotterdam;* after these comes that of *Weesoppe.*

Attempts have been made by Mr. Robert Moore and others, to introduce into general consumption in this country a home-made liquor, resembling, and prepared in the same manner as Foreign Geneva, "but the palates of our gin-drinkers were too corrupted to relish so pure a spirit."

HOMŒOPATHY. A medical hypothesis promulgated at the commencement of the present century by the late Dr. Hahnemann, of Leipsig, according to which, diseases may be cured by the administration of minute doses of medicines capable of producing in healthy persons affections similar to those it is intended to remove. The doctrine that "*similia similibus curantur*," as well as the opposite one of "*antipathy*," had long previously been practically acted on, to a limited extent, in certain cases, in legitimate medicine (*allopathy, heteropathy, &c.*), although not verbally recognized as belonging to its system. The administration of infinitesimal doses is an absurdity which homœopathy, however, alone can claim. According to this method, the *millionth of a grain* is often an excessive dose; whilst *billionths* and *decillionths*, quantities so small as to be vastly beyond human perception, form the *common* doses. This reduces the whole practice of homœopathy to a system of *doing nothing* beyond regulating the diet and habits of the patient. "All judicious practitioners have long been agreed, that there are many cases which are best treated in the manner just mentioned, and in which physic does more harm than good; in which, in short, a sensible physician endeavours to amuse the patient, whilst nature cures the disorder; so that the frequent success of homœopathic treatment may be explained, without admitting the principle upon which it is presumed to be founded." (Brande.) Surely Hahnemann must have intended his theory as a grand satire on the practice of medicine current in his day, rather than as a system of itself!

HONEY. Syn. *Mel*,—Ph. L. E. & D. The sweet substance elaborated by the domestic bee from the juices of the nectaries of flowers, and deposited in the cells of wax forming the honeycomb.

Var.—Pure honey consists of a syrup of uncrystallizable sugar and crystalline saccharine grains, resembling grape sugar.—*Virgin honey* is that which flows spontaneously from the comb.—*Ordinary honey*, that obtained by heat and pressure. The former is pale and fragrant; the latter darker, and possessing a less agreeable taste and smell.—*English honey* (Mel Anglicanum) is chiefly collected from furze and broom flowers, and is more waxy than that from the South of Europe;—*Narbonne honey* (Mel Narbonense), chiefly from rosemary, and other labiate flowers, very fine;—*Minorca honey* (Mel Minorcense);—*East country honey*, inferior and bad tasted;—*Poisonous honey*, found near Trebisond, in Asia, narcotic and poisonous.

Pur. Honey is frequently adulterated with treacle, potato-sugar syrup, potato farina, starch, and wheat flour. The *first* may be detected by the colour and odour; the *second*, in the way noticed under "Sugar;" and the others by the honey not forming *a nearly* clear solution with cold water, and striking a blue colour with iodine. When it contains wheat flour, and is heated, it at first liquefies, but on cooling it becomes solid and tough. "If, when dissolved in *water* by a heat approaching the 170° and cooled again, it be mixed with *iodide of potassium* and *dilute nitric acid*, it exhibits no blue colour." (Ph. L.)

Uses, &c. Honey is nutritive and laxative, but rather apt to gripe. It is employed in the preparation of oxymels and gargles, and also to cover the taste of nauseous medicines, which it does better than sugar. Clarified honey is alone ordered to be used in medicine.

HONEY (Clarified). Syn. *Refined Honey, Strained do.; Mel Depuratum*,—Ph. D. *Mel Despumatum*,—Ph. D. 1826. *Mel Præparatum, Mellitum Simplex, &c.* The honey is simply melted by the heat of a water bath, and strained whilst hot through flannel, (Ph. D.); or—it is melted as last,

and the scum removed, (Ph. U. S., 1830); or—it is melted with 1-3d its weight of *water*, skimmed, strained through flannel, and evaporated until it reaches the sp. gr. 1·261, (P. Cod.)—It is not to be employed without being despumated,—(Ph. L.)

Obs. Clarified honey is less agreeable than raw honey, and has lost the crystalline character of the latter; but it is less liable to ferment and gripe. The use of copper and iron vessels or implements should be avoided, as honey acquires a dark colour by contact with them. Berlin ware, stone-ware, or well-silvered or tinned copper pans should alone be used. On the *large scale*, one or other of the following plans are adopted:—

1. The *honey* is mixed with an equal weight of *water* and allowed to boil up 5 or 6 times without skimming; it is then removed from the fire, and after being cooled, brought on several strong linen strainers, stretched horizontally, and covered with a layer of clean and well-washed sand, an inch in depth; the sand is rinsed with a little *cold water*, and the mixed liquor is finally evaporated to the thickness of syrup.

2. Dissolve the *honey* in *water*, as last, clarify with *white of egg*, and evaporate to a proper consistence.

3. Dissolve in *water*, add 1½ *lb.* of *animal charcoal* to every ¼ cwt. of honey, gently simmer for 15 minutes, add a little *chalk* to saturate excess of acid, if required, strain or clarify and evaporate.

4. *Honey*, 1 cwt.; *water*, 9 gall.; *fresh burnt animal charcoal*, 7 ℔; simmer for 15 minutes, add a little *chalk* to saturate free acid, (if required,) strain or clarify, and evaporate as before.

HONEY (Prepared). Syn. *Mel Præparatum*,—Lat. *Prep.* (Ph. U. S., 1830.) *Clarified honey*, ½ pint; *dilute spirit* (sp. gr. 0·935), 1 pint; mix, add of *prepared chalk*, ½ oz., stir occasionally for 2 hours; heat to boiling, filter, and evaporate over a water bath until the sp. gr. when cold, is 1·32. An expensive and useless preparation.

HONEYS (Medicated). Syn. *Mellita*,—Lat. This is a minor class of preparations, now almost superseded by 'Syrups' (*Syrupi*). The *Mellita* of the Ph. L., including two oxymels, are only four in number.

Honey of Borax, Mellite of do.; *Mel Boracis*,—Ph. L. E. & D. *Prep.* (Ph. L.) *Powdered borax*, 1 dr.; *clarified honey*, 1 oz.; mix. Astringent, detersive, and cooling. It is employed in aphthæ of the mouth, excessive salivation, &c. It is *incompatible* with acids, and is decomposed by compound infusion of roses, with which it is commonly ordered. The formulæ of the other Pharm. are similar.

Honey of Colchicum; Mel Colchici,—Lat. *Prep.* (Beasley.) *Dried colchicum*, 1 part; *water* (at 140°), 16 parts; infuse for 12 hours, strain, let it settle, and boil the clear liquor with *white honey*, 12 parts, to the consistence of a syrup. See *Colchicum.*

Honey of Hellebore; Mel Helleboratum,—Lat. *Prep.* (Ph. L. 1746.) *Hellebore root* (bruised), 1 ℔; *water*, 4 pints; digest for 3 days; boil, strain, add of *honey*, 2 ℔, and boil to a syrup. Cathartic; in mania.

Honey of Liquorice; Mel Glycyrrhizatum,—Lat. *Prep.* (Ph. Hamb.) *Honey* and a *strong infusion of liquorice* boiled to a proper consistence. Emollient, pectoral, and laxative.

Honey of Male Fern; Mel Filicis,—Lat. *Prep.* (Dunglison.) *Ethereal extract of male fern*, 30 gr.; *honey of roses*, 4 dr.; mix. In tape-worm. *Dose.* One-half at bed-time, followed by the remainder in the morning.

Honey (Mercurial); *Mel mercuriale*,—Lat. *Prep.* (Ph. L. 1746.) *Juice of the herb mercury* and *honey*, equal parts; boiled to a proper consistence. Detergent; applied to old ulcers.

Honey of Mercury, Mel Hydrargyri,—Lat. *Prep.* (Bell.) *Quicksilver*, 1 dr.; *honey*, 1 oz.; triturate till the globules disappear. Allard adds of *oil of cloves*, ½ dr. Properties similar to those of mercurial pill. It is chiefly used as an application to ulcers of the throat.

Honey of Roses; Mel Rosæ,—Ph. L. *Mel Rosaceum*,—Ph. L. 1746. *Mel Rosatum*,—Ph. L. 1721. *Prep.* 1. (Ph. L.) *Dried petals of the red rose* (the leaves separated), 4 oz.; *boiling water*, 16 fl. oz.; macerate for 2 hours, lightly press them in the hand, and strain; then add 8 fl. oz. more of *boiling water* to the *roses*, macerate for a short time, and again gently express the liquor; to this add *half* of the *first infusion*, and set aside the other half; next add to the mixed liquors, *honey*, 5 ℔, and evaporate in a water bath, so that the infusion which was set aside, being added, it may become of a proper consistence.

2. (Ph. E.) *Dried rose petals*, 4 oz.; *boiling water*, 2½ pints; infuse for 6 hours, and gently squeeze out the liquor; after the impurities have subsided, decant the clear, add of *honey*, 5 ℔, and evaporate, as before, to a proper consistence; removing the scum which forms. *Used* to make

astringent gargles. It must not be boiled in a copper or iron vessel, as they will spoil the colour. The last form is that commonly adopted in trade.

Honey of Squills; Mel Scillæ, — Lat. *Prep.* 1. *Thick clarified honey*, 3 *lb.*; *tincture of squills*, 2 *lb.*; mix.

2. (Soubeiran.) *Dried squills*, 1 oz.; *boiling water*, $\frac{8}{4}$ pint; infuse 2 hours, strain, add of *honey*, 12 oz., and evaporate to a proper consistence. Resembles oxymel of squills (nearly).

Honey of Violets; Mel Violæ, — Lat. *Prep.* From *clarified honey*, 2 parts; *expressed and depurated juice of violets*, 1 part. Resembles syrup of violets.

HONEY DEW. Syn. *Ros Mellitus*,— Lat. A sweetish matter ejected upon the leaves of plants by certain aphides.

HOOPING COUGH. See *Whooping Cough.*

HOPS. Syn. *Lupulus*,—Ph. L. *Humulus, H. Lupulus*,—Ph. E. & Ph. L., 1824. "The catkins" of "humulus lupulus" (Linn.) or common hop plant. (Ph. L.) The hop or hops of commerce are the strobiles or catkins (*lupuli strobili, l. amenta*) of the hop plant. The *yellow powder* or small lupulinic grains or glands (*lupuline, lupulina*) which are attached to the strobiles, are the portion on which their characteristic qualities chiefly depend. Of this, dried hops yield about 1-6th part of their weight, when rubbed and sifted.

In the *choice of hops*, care should be taken to select those that have large cones or strobiles, that are the most powerfully odorous, and most free from leaves, stems, scaly fragments, and sticks, and which, when rubbed between the hands, impart, in the greatest degree, a yellowish tint and glutinous feeling to the skin. The tightness with which they are packed should also be noticed; as without being *very firmly* pressed together, and *quite solid*, they soon spoil by keeping. The finest flavoured hops are those grown in East Kent, and termed the "*golden bine*;" these possess a lively golden yellow colour, and are principally employed for the finer class of ales. *Mid Kent* and *Sussex hops* are also used for ale, but have an inferior colour and flavour. "*Countrys*" and *Farnham hops* have a greenish yellow colour, and are more expensive than any other variety; they are almost exclusively used for malt liquor that it is intended to keep for a long time, as they do not impart their full flavour to the beer before it has been kept at least a year. They are chiefly employed for ale. The *best hops* are packed in sacks of fine canvass termed "*pockets*," weighing from $1\frac{1}{4}$ cwt. to $1\frac{3}{4}$ cwt. each; and the inferior qualities, in coarse "*bags*," of about double this size. The former are mostly purchased by the ale brewers, and the latter by the porter brewers. When hops are older than of the last season's growth, they are termed "*yearlings*,"—when of the second season's growth, "*olds*,"—and when three years, or older, "*old olds*." See *Extracts, Tinctures, Brewing, &c.*

HORDEINE. This name was given by Proust to the peculiar starchy matter of barley meal; but according to Raspail, it is merely bran more minutely divided than that which remains in the sieve. Dr. Ure says that it is a "mixture of the starch, lignine, and husks, which constitutes barley meal." Others regard it as allied to starch, but to differ from it sufficiently to constitute a distinct substance.

HOREHOUND. Syn. *White Horehound; Marrubium Vulgare*,—Linn. This herb has long been a popular remedy in chronic pulmonary complaints, especially catarrh, and in uterine and liver affections. *Horehound tea* (thea marubii, infusum marubii) is prepared by infusing 1 *oz.* of the herb in boiling water, 1 pint, for an hour;—*syrup of horehound* (syrupus marubii) by thickening the infusion or tea with sugar;—*candied horehound* (marubium conditum) by mixing 1 pint of horehound juice, with 8 or 10 *lb.* of white sugar, boiling the mixture to a candy height, and pouring it, whilst warm, into moulds, or small paper cases, well dusted with finely-powdered lump-sugar; or by pouring it out on a dusted slab, and cutting it into squares.

HORN. For the purposes of the turner and comb-maker, those of the goat and sheep are preferred on account of their superior whiteness and transparency. For medical purposes, those of the stag (*harts-horn*) are ordered to be employed.

Horn is *dyed* with the same dyes, and in a similar manner to bones and ivory.

Horn is *softened*, *bent*, and *moulded* by means of heat and pressure. For these purposes boiling water, and a screw press, are commonly employed.

Horn is reduced to *plates* or *sheets*, by sawing it, and then exposing it to powerful pressure between hot iron plates; the pith having been previously removed, and its texture softened by soaking for some days in water, and subsequent boiling in that liquid.

The *surfaces* and *edges* of *pieces of horn* may be *united* or *cemented* together by softening it by the heat of boiling water,

placing the parts in contact under strong pressure, and exposing the whole thus arranged to the heat of boiling water.

Horn is stained or *party-coloured* to *imitate tortoise-shell*, by a solution of *terchloride of gold*, for the RED portion; *nitrate of silver*, for the DARK BROWN and BLACK; and *nitrate of mercury* (hot), or a paste made of *red lead*, and *potash* or *quicklime*, for the BROWN. When the last is used, the horn must be heated and exposed to its action for some hours.

HORSE. The *equus caballus* (Linn.), belonging to the solipedous family of the pachydermata. (Cuvier.) Of all animals the horse is most useful to man. Independently of its value as a beast of burden and draught, its *skin*, its *hide*, *intestines*, and *bones*, furnish us with leather, the thongs of whips, catgut, grease, bone-black, manure, &c. The *excrement*, *fat*, and *hoof*, were included in the Materia Medica of the Ph. L. 1618. The *flesh* is eaten as beef in some countries, and was formerly esteemed to possess many virtues.

Injuries of a serious character, and even death, are often occasioned by horses "*running away*," or becoming unmanageable. Various methods have been proposed to prevent accidents of this kind, and to place the animal entirely under the power of its rider or driver. In Russia, around the horse's neck, near the neck strap, is placed a cord with a running knot. To this slip-noose is attached a pair of reins, which always lie thrown over the dashboards, ready to be seized at once. When the horse starts, and becomes unruly, the gentleman takes up this cord, and tightens the horse's throat, so that he cannot take breath. The most most furious horse stops instantly, and will not fall or kick.

HORSE BALLS. See *Veterinary Medicine.*

HORSE POWER. This term was employed by Mr. Watt, to express a power capable of raising 33,000 *lb.* one foot high per minute. The effective pressure on the surface of the piston was estimated at 7 *lb.* to the square inch, and hence the *area of the piston*, in square inches, multiplied by 7, gave the gross *effective moving pressure*, and the space passed over by the piston in a minute, gave the *distance* through which this pressure was exerted, or the weight was raised. From these data the horse-power was easily calculated. For—

$$\frac{\text{effective pressure on piston} \times \text{space passed over by piston}}{33{,}000} = \text{nominal horse power.}$$

In process of time, improvements in the formation of boilers and steam engines, increased the effective pressure on the piston, and, consequently, the power of the engine. In modern engines the *actual power* is commonly from 2 to 4 times greater than the *nominal power*, which is, however, still retained as the unit of power in commercial calculations. The actual power can, therefore, be only correctly ascertained by experimentally determining the amount of pressure on the piston by means of an instrument called an "Indicator." The *nominal power* may be determined as follows:—

$$\frac{(\text{diam. of cylinder, in inches})^2 \times \sqrt[3]{\text{length of stroke, in feet}}}{47} = \text{nominal horse power.}$$

HORSE-RADISH. Syn. *Armoracia*,— Ph. L. *Radix Cochlearia Armoraciæ*,— Ph. E. "The fresh root" of "*cochlearia armoracia*," Linn. (Ph. L.) Horse-radish is pungent, acrid, stimulant, and rubefacient. It is also regarded as diaphoretic, diuretic, and antiscorbutic. It forms a useful masticatory in hoarseness, sore-throat, and toothache. As a *condiment*, it provokes the appetite and assists digestion. Reduced to shreds (*scraped horse-radish*) it forms a common and excellent accompaniment to roast beef. The root of aconite or wolfsbane, which somewhat resembles it in appearance, has occasionally been mistaken for it, with fatal results; the two are, however, readily distinguished from each other, as the taste of *horse-radish* is warm and pungent, approaching that of mustard, whilst *aconite* is bitter, and its odour is earthy, and disagreeable, and after a few minutes' contact with the lips, tongue, and fauces, produces a sensation of numbness and tingling. See *Infusions*, *Spirits*, *&c.*

Horse-radish Powder is prepared from the roots gathered in November or December, and dried by a gentle heat or exposure to a current of dry air. *Used* as a condiment.

HORTICULTURE. The cultivation of a garden. The term is commonly restricted to the culture of the *kitchen garden* and *orchard*. According to Loudon, *horticul-*

ture differs from *agriculture*, chiefly in the comparatively limited space over which it extends, and in being conducted by manual labour; whilst the latter is performed jointly by human and animal labour, in fields, or in an extensive tract of land called a farm.

HORTUS SICCUS. See *Herbarium.*

HOSPITAL GANGRENE. Syn. *Phagedæna Gangrenosa*,—Lat. A species of ulcerating mortification, particularly characterised by its infectious nature, and its tendency to attack wounds and ulcers in crowded hospitals, so that often the most trifling operation cannot be performed with safety. Under its influence the parts are rapidly destroyed, not by the formation of ordinary sloughs, as in common mortification, but by their conversion into an ash-coloured viscid substance interspersed with bloody specks. The *treatment* is similar to that noticed under *Mortification*, but here, above all things, thorough ventilation must be established, and persevered in, and when possible, change of situation sought. The recent great loss of life from this affection among our brave soldiers in the East, renders it a subject of painful interest.

HOT BEDS. A cheap and excellent substitute for the glass used in the frames of hot-beds, greenhouses, &c., may be produced by applying, with a common painter's-brush, *boiled oil* or *Canadian balsam* diluted with a little *oil of turpentine*, to the surface of *white calico* previously stretched out and fastened in the position it is intended subsequently to occupy.

HUILE. (Fr.) Oil; a term applied to various substances and preparations on account of their smoothness, consistence, or real or imaginary emollient or oleaginous nature. See *Liqueurs, Oils, Perfumery, &c.*

HUILE ACOUSTIQUE. *Prep.* From *bullock's garlic* and *bay leaves*, of each, ½ oz.; *olive oil*, ½ lb; boiled together for 15 minutes, and strained. *Used* in ear-ache and deafness. A little is dropped on cotton wool and placed in the ear.

HUILE ANTIQUE. See *Hair Oils.*

HUILE LIQUEUREUSE. *Prep.* 1. (*De la rose.*) From *eau de rose*, 1 part; *simple syrup*, 2 parts; mixed together.

2. (*Des Fleurs d'Oranges.*) From *orange-flower water.*

3. (*De Vanille.*) From *essence of vanilla*, 1 dr.; *simple syrup*, 1 pint.

Obs. The above are kept in small decanters, and used to flavour water, grog, liqueurs, &c., instead of sugar or capillaire; also to perfume the breath. Other flavoured syrups, for the same purposes, are prepared in a similar manner.

HUMIC ACID. See *Humus.*

HUMULINE. The narcotic principle of the hop extracted from the *lupulinic grains* by means of *rectified spirit.* It is a mixture of volatile oil, lupulite, and resin.

A beautiful *extract* or *essence of hops* lately vended under the name of Humuline, we find is made as follows:—

A *concentrated tincture of hops* is prepared by percolation with *rectified spirit*; the *same hops* are then exhausted with *water*; the spirit is removed from the *tincture* by careful distillation, and the upper aqueous portion is skimmed off, and added to the infusion, which latter, is then evaporated to the consistence of a soft extract; the *oleo-resinous residuum* of the *tincture* is next added, and well-mixed in; after which the whole is put into pots and carefully tied over for sale. The *product* possesses all the fragrant, tonic, and bitter qualities of the hop in a highly condensed form.

HUMUS. Syn. *Humine.* When wood, or woody fibre, is exposed to the joint action of air and moisture, it suffers eremacausis or decay, and crumbles down into a dark-brown or black powder, commonly called *mould*, and to which chemists have given the name of *humus.* In this state it exists in fertile soils, in which it is derived from the decay of plants. By the action of alkalies this new substance is converted into *humic acid*, which is soluble, and forms salts called *humates.*

HUNGER. The peculiar sensation arising from the want of food. When severe, it increases to actual pain, the coats of the stomach are acted on by its own juices, the respiration becomes less frequent, the circulation languid, and there is a general diminution of the heat of the body and of the secretions. The return of hunger is accelerated by exercise and labour, and by the exposure of the body to a low temperature. Long fasting is injurious, more particularly to the young and the debilitated. See *Appetite, Nutrition, &c.*

HUSBANDRY. The business of the farmer; by some restricted to the joint operations of farming and gardening on the small scale. It is also sometimes used synonymously with agriculture. See *Agriculture, Butter, Cheese, Dairy, &c.*

HYACINTH. Crystallized yellow or brown zircon. See *Gems* and *Zircon.*

HYDRACIDS. Acids which contain hydrogen as one of their essential elements. The substance thus acidified is termed the

radical. Hydrogen (or water) is probably the only universal acidifier. Its presence, even in the oxygen acids (*oxyacids*), appears necessary to the development of their acid properties. Oil of vitriol itself, deprived of *all* its water, or rendered anhydrous, a condition in which it consists of sulphur and oxygen only, ceases to redden litmus, and has lost the other properties of an acid. In this state, if thrown into water, it hisses like a hot iron, from the violence with which combination occurs, and it returns to the normal condition of liquid sulphuric acid (*oil of vitriol*).

HYDRAGOGUES. Syn. *Hydragoga*, —Lat. Medicines which cause the removal of water from any of the cavities of the body. Many cathartics, as *gamboge*, *jalap*, *&c.*, are classed under this head.

HYDRARGYRO - CHLORIDES. Syn. *Hydrargo-Chlorids.* Salts in which bichloride of mercury plays the part of an acid. The only one that has been applied to any useful purpose, is the *hydrargyro-chloride of ammonia*, or the *sal alembroth* of pharmacy. *White precipitate* may also, perhaps, belong to this class. Similar salts have been formed with the chlorides of other metals, to which the names *auro-chlorides*, *cupro-chlorides*, *ferro-chlorides*, *cobalto-chlorides*, *&c.*, *&c.*, have been applied.

HYDRARSINE. An ethereal volatile substance, having an intolerably fetid odour, formed by the action of air on *alkarsine.*

HYDRATES. Compounds containing water in a state of chemical combination and in definite proportion. Thus, slaked lime is a *hydrate of lime;* caustic potassa, a *hydrate of potassa;* and oil of vitriol, a *hydrate of sulphuric acid.* The term *hydrated* is used as an adjective, in the same sense as hydrate is as a substantive. The *latter* is, however, for the sake of euphony, usually applied to simple names, as *hydrate of lime*, *hydrate of potassa*, *&c.;* and the *former*, to compound names, as *hydrated acetic acid*, *hydrated oxide of iron*, *&c.* Many instances of the use of these terms will be found in this work.

HYDRAULIC. See *Cements*, *Expression*, *Press*, *&c.*

HYDRIDE. See *Hydruret.*

HYDRIODATE. Syn. *Hydriodas*, —Lat. A compound formed of hydriodic acid with a base. The *hydriodates* are easily made by saturating the *acid* with the *oxides* or *hydrates* of the bases; or, more economically, by acting on the bases in water, with iodine. When deprived of their water they are true *iodides.* See *Hydriodic Acid*, *&c.*

HYDRIODIC ACID. Syn. *Acidum Hydriodicum*,—Lat. An acid compound of iodine and hydrogen.

Prep. 1. (*Gaseous.*)—*a.* Into a glass tube, closed at one end, introduce a little *iodine*, then a small quantity of *roughly-powdered glass moistened with water*, next a few small fragments of *phosphorus*, and upon this some more *glass;* this order (iodine, glass, phosphorus, glass) is to be repeated until the tube is one half or two thirds filled; a cork and narrow tube are then to be fitted in, a gentle heat applied, and the gas collected over mercury, or passed into *water*, when *liquid hydriodic acid* will be obtained.

b. Pour a little *water* over some *periodide of phosphorus*, previously put into a small glass retort, apply a gentle heat, and collect the gas, as before.

c. (F. d'Arcet.) Evaporate *hypophosphoric acid* until it begins to yield phosphoretted hydrogen, then mix it with an equal weight of *iodine* placed in a retort, and apply a gentle heat, as before.

d. (Dr. Glover.) Place *pure iodide of barium* in a retort, and decompose it with *sulphuric acid.* All the above are chemically pure.

2. (*Liquid.*)—*a. Iodine*, in fine powder, is suspended in water, and a stream of *washed sulphuretted hydrogen* passed through the mixture as long as sulphur is deposited, or until it becomes colourless; the liquid is then gently heated to expel the excess of sulphuretted hyrogen, and either decanted or filtered. A cheap and excellent process.

b. (*Medicinal Hydriodic Acid*, — Dr. Buchanan.) *Tartaric acid*, 264 gr.; *pure iodide of potassium*, 330 gr.; dissolve each separately in *water*, 1½ fl. oz., mix the solutions, and when settled, decant the clear liquid and add *water*, q. s. to make it up to 6¼ fl. oz. The liquid retains a little bitartrate of potassa in solution, but this does not interfere with its medicinal properties. *Dose.* ½ to 1 fl. dr., gradually increased to 2 or 3 fl. dr., twice or thrice daily.

Prop., *&c.* Gaseous hydriodic acid, is colourless, fumes in the air, is very soluble in water, and has a density about 4·4. Liquid hydriodic acid, when strong, is very liable to change, and should be kept in well-stoppered bottles. The latter "possesses all the therapeutical powers of iodine, without its irritating properties." (Pereira.)

HYDROBENZAMIDE. *Prep.* (Laurent.) *Hydruret of benzoyle* (pure oil of bitter almonds) is digested with 20 times its volume of *concentrated liquor of ammonia*,

in a stoppered bottle for 10 or 12 hours, at a temperature of about 120° Fahr.; the resulting crystalline mass is washed with *cold ether*, and dissolved in *alcohol;* the alcoholic solution, by spontaneous evaporation, yields colourless crystals of *hydrobenzamide.*

Prop., &c. Freely soluble in alcohol; insoluble in water; decomposed by heat; by boiling, or by the addition of hydrochloric acid, the solution is resolved into ammonia and hydruret of benzoyle. Hydrobenzamide is chiefly interesting on account of the number of *derivatives* it furnishes when submitted to the action of chemical processes; amongst which *amarine* or *benzoline* is, perhaps, the most important.

HYDROBROMATE. Syn. *Hydrobromas,* —Lat. A salt of hydrobromic acid. In the dry state, they are *bromides.*

HYDROBROMIC ACID. Syn. *Acidum Hydrobromicum,*—Lat. An acid compound of hydrogen and bromine. It is prepared from *bromide of phosphorus, bromide of barium, &c.,* by similar processes to those adopted for *hydriodic acid.* The evolved gas is either collected in dry glass bottles, in the manner directed for chlorine, or over mercury, in the pneumatic trough. When passed into *water* it forms *liquid hydrobromic acid.* Under the first form (*gaseous hydrobromic acid*) it is a colourless, acidulous, and pungent gas; dissolved in water, it forms a limpid and colourless liquid. In both conditions it closely resembles the corresponding compounds of iodine and chlorine. Its salts are the *hydrobromates* or *metallic bromides.* These are formed in a precisely similar manner to the hydriodates and iodides.

HYDROCARBONS. Compounds of carbon and hydrogen. Under the fanciful name of *Carbo-hydrogen*, oil of turpentine or camphine has been lately vended at a price much higher than could possibly be obtained for it, under its common appellation. Dutch liquid is often called *chloride of hydrocarbon.* See *Hydrocarburets* and *Olefiant Gas.*

HYDROCARBURETS. Syn. *Hydrocarbons, Carbo-hydrogens.* Compounds of hydrogen and carbon. The principal of these are—1. *Light carburetted hydrogen,* or the fire-damp of miners, consisting of two equivalents of hydrogen, and one equiv. of carbon; burns with a pale blue flame. —2. *Olefiant gas,* consisting of two equiv. of hydrogen and two equiv. of carbon; burns with a very white and luminous flame.—3. *Light gas* or *coal gas,* consisting of a mixture of the preceding in no definite proportions.—4. *Quadricarburetted hydrogen, quadrihydrocarbon,* or *etherine,* consisting of 4 equiv. each of carbon and hydrogen; it is produced during the destructive distillation of oil, and burns with a dull fuliginous flame.—5. *Bicarburetted hydrogen,* also obtained by the destructive distillation of oil, and consisting of 3 equiv. of hydrogen and 6 equiv. of carbon. See *Hydrogen.*

HYDROCELE. A collection of water or serous fluid between the membranes of the scrotum, or the coats of the testicle and its vessels. Its *treatment* belongs to *pure surgery.*

HYDROCEPHALUS. Syn. *Dropsy of the brain, Dropsy of the head.* There are several forms of this disease noticed by nosologists,—*internal, external, acute, chronic, &c.* The *acute* form of hydrocephalus is almost limited to childhood. The *symptoms* are those of fever; there is pain in the head, accompanied with a sensation of heaviness, and in very young children, there is often actual enlargement. The eyes are irregularly directed, and only partially closed in sleep, and the pupil is more or less dilated. Delirium, coma, convulsions, and paralysis, commonly follow. The *treatment* recommended is bleeding from the temporal artery or jugular vein, cold applications to the head, brisk purgatives (*calomel* combined with *scammony* or *jalap*), a liberal supply of nutriment, and exercise in a pure atmosphere. The bleeding can only be performed by a surgeon, but the other part of the treatment may be safely had recourse to by emigrants and others in the absence of medical assistance.

HYDROCHLORATE. Syn. *Muriate, Chlorhydrate; Hydrochloras, Murias,*—Lat. A salt of hydrochloric acid. See *Chloride* and *below.*

HYDROCHLORIC ACID. Syn. *Chloride of Hydrogen, Chlorhydric Acid, Muriatic do.; Acidum Hydrochloricum,*—Ph. L. & D. *A. Muriaticum,*—Ph. E., & Ph. L. 1824. *Spirit of salt, spiritus salis,*—Ph. L. 1746. *Marine Acid, Acid of Salt, &c.,*—Obs. An acid compound of chlorine and hydrogen, long known in the state of solution, under the name of marine acid or spirit of salt; but first obtained in the pure or gaseous form by Priestly, in 1772.

Prep. 1. (Ph. L. 1836.) *Sulphuric acid,* 20 oz.; *water,* 12 fl. oz.; mix in a retort, and when cold, add of *dried chloride of sodium,* 2 lb., and gradually distil in a sand-bath into a receiver containing *water,* 12 fl. oz. Sp. gr. 1·160. In the *present Ph. L.* this acid is included in the Materia Medica, the same strength being ordered as before.

2. (*A. M. Purum*,—Ph. E.) *Dried purified chloride of sodium* and *pure sulphuric acid*, of each, 3 parts; *water*, 1 part; mix as last, and distil with a gentle heat into a well-cooled receiver containing, *water*, 2 parts, as long as any liquid passes over. Sp. gr. 1·170. Nearly pure.

3. (Ph. D.) Sp. gr., 1·160.

4. (Gregory.) *Pure dried chloride of sodium*, 3 parts; and *pure sulphuric acid*, 5 parts, diluted with *water*, q. s. to reduce the sp. gr. to 1·6 (about 2 parts); are mixed in an alembic furnished with a double-bent tube, the end of which is plunged about $\frac{1}{3}$rd of an inch beneath the surface of the *distilled water* in the receiver (about 3 parts), the latter being surrounded by ice or ice-cold water; a *gentle* heat is now applied and continued as long as any gas comes over. In about 2 hours the process is finished, and the water in the receiver has increased 2-3ds in volume, and has the sp. gr. 1·14 to 1·15. By dividing the water between two receivers, connected together, that in the *first* one will be a fuming acid sp. gr. 1·21; that in the last one, about sp. gr. 1·12.

5. (Winckler.) *Dry* and *pure chloride of sodium*, 24 parts; *pure oil of vitriol*, 44 parts, diluted with *water*, 7 parts, and allowed to cool; mix in a large retort, connect it by a rectangular bent glass tube, at least 3 feet long, with a capacious receiver, containing *distilled water* 20 parts, well cooled, and distil over 44 oz., by weght, of acid of 30%, or sp. gr., 1·14.

6. (*Gaseous.*) This is obtained as above, or by gently heating the *liquid acid* and collecting the evolved gas over mercury.

Prop. Pure hydrochloric acid is a colourless invisible gas, having a pungent odour and an acid taste, and fuming on coming into contact with air. It is irrespirable and uninflammable. Its sp. gr. is 1·2695 (Berzelius.) Under a pressure of 40 atmospheres it is liquid. Water at 40° Fahr. absorbs 480 times its volume of this gas, and acquires the sp. gr. 1·2109 (Davy.) and the volume is increased from 100 to 142. (Ure.) In this state the liquid contains about 42% of real acid. One cubic inch of water at 69° Fahr. absorbs 418 cubic inches, and the sp. gr. becomes 1·1958. (Thomson.)

Pure *liquid hydrochloric acid* is colourless, fumes in the air, evolves a strong odour of hydrochloric acid gas, is intensely sour, reddens vegetable blues, and erodes organic substances. It is entirely separated by heat from the water that holds it in solution. It dissolves many of the metals with the evolution of hydrogen gas; it also dissolves metallic oxides, and the majority of the bases, their hydrates, and carbonates; in each case forming the compounds termed *chlorides*, *muriates*, *chlorohydrates*, or *hydrochlorates*. The acid of the London Pharmacopœia consists of 32·32% of real hydrochloric acid, and 67·68% of water. The *hydrochloric acid* of *commerce* has generally a straw yellow colour, and a sp. gr. ranging between 1·16 and 1·17, and is generally very impure.

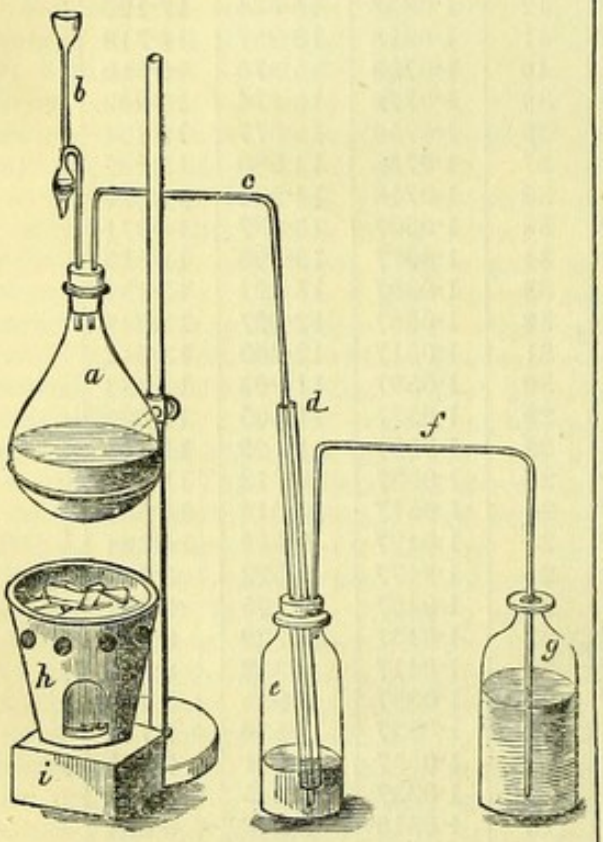
Pur. Pure hydrochloric acid is "free from colour. Exposed to the air, it evolves white and extremely acrid vapours. It is *entirely* dissipated by heat. Diluted with distilled water, no precipitate is formed on the addition of chloride of barium, ammonia, or sesquicarbonate of ammonia. It has no action on gold leaf, even when this is boiled in it, nor does any precipitate fall if protochloride of tin be afterwards added. It does not decolour a solution of sulphate of indigo. Sp. gr., 1·16. 100 gr. are saturated by 132 gr. of crystallized carbonate of soda." (Ph. L.) Sulphuretted transmitted through it, does not produce a yellow or brown colour.

Commercial hydrochloric acid generally contains iron and sulphuric acid, and frequently, chlorine, nitrous acid, bromine, and sometimes, selenious acid. The *first* may be detected by the precipitate it forms when the acid is supersaturated by ammonia,—the *second*, by giving a white precipitate with chloride of calcium or of barium, or with the nitrate of lime or baryta,—the *third*, *fourth*, and *fifth*, by the power the acid possesses of dissolving gold leaf, and decolouring solution of indigo,—and the *last*, by the acid depositing a reddish powder (*selenium*) when long kept.

Uses. Hydrochloric acid is used for various purposes in the arts, in chemistry, and in medicine. It is refrigerant, tonic, and antiseptic, in small doses diluted with water; but corrosive and poisonous in larger doses, and when undiluted. *Dose.* 10 to 20 drops, in a sufficient quantity of any bland diluent; in stomach complaints, typhus fever, syphilitic affections, worms, scrofula, &c. It is also used in gargles and lotions.

Ant. Chalk, whiting, magnesia, or carbonate of soda, mixed with water; or milk, white of eggs, and demulcents of any kind. See *Acids*.

Tests. The *liquid acid* is detected by—1. Its volatility;—2. By giving white fumes when a glass rod dipped in liquor of ammonia is held near it;—3. By giving with nitrate of silver a white cloudy precipitate, which is insoluble in nitric acid, freely soluble in liquor



of ammonia, and blackened by exposure to the light.—4. The *hydrochlorates* or *chlorides* are detected in a similar manner. See *Chloride.*

Estim. The strength of liquid hydrochloric acid is usually estimated from its specific gravity; but it may be more correctly ascertained by the power it possesses of saturating the bases. "In general a good approximation may be found to the per centage of real muriatic acid in any liquid sample, by multiplying the decimal figures of the sp. gr. by 200." (Ure.) See *Acidimetry* and the following *Table:*—

TABLE *of Hydrochloric Acid.* By Dr. URE.

Acid of 1·20 in 100.	Specific gravity.	Chlorine.	Hydrochloric Acid Gas.	Acid of 1·20 in 100.	Specific gravity.	Chlorine.	Hydrochloric Acid Gas.

Concluding Remarks. The hydrochloric acid of commerce is now chiefly obtained from the manufacturers of carbonate of soda, who procure it as a secondary product. For chemical and pharmaceutical purposes, this can only be used after purification. When hydrochloric acid is directly prepared from sea-salt, an iron or stone-ware boiler, set in brickwork over an open fire, furnished with a stone-ware head, and connected with a series of capacious double-necked stone-ware bottles, usually constitutes the distillatory and condensing apparatus. The arrangement resembles that employed in the preparation of liquor of ammonia (see *page* 61). For this, and similar operations, on the *small scale*, the little apparatus, figured in the *engraving*, and which is recommended by Mr. Fownes, will be found to answer admirably.

The simple wash-bottle (*e*) there shown will be found an exceedingly useful contrivance in a great number of chemical operations. It serves in the present, and in many similar cases, to retain any liquid or solid matter mechanically carried over with the gas, and it may be always employed when gas of any kind is to be passed through water or a chemical solution. The open tube (*d*) dipping into the liquid prevents the possibility of absorption, by which a partial vacuum would be occasioned, and the liquid of the second vessel lost by being driven into the first. The formula of the Ph. L. 1836 is defective in ordering too little acid, by which means the product becomes contaminated with a portion of sulphuric acid, and the residuum of the process is rendered so hard and insoluble as to prevent its removal from the retort by ordinary means. It is, therefore, better to use a larger quantity of acid than is there ordered. The products of the other formulæ are pure liquid hydrochloric acid, provided the materials employed are quite free from foreign admixture. The *commercial acid* may be *purified* by diluting it with an equal weight of *water*, gently heating it in a retort, connected with a Liebig's condenser, and receiving the evolved gas into a fresh quantity of pure water. *Iodine* and *arsenic* may be removed by agitating it for a few minutes with some small pieces of bright copper foil, previously to rectification. *Nitrous, nitric, sulphurous,* and *sulphuric acid,* may be removed by a like agitation with a few grains of peroxide of manganese or red lead, in fine powder, and redistilling it as before; observing to reject the first portions that come over, as long as they discolour a weak solution of sulphate of indigo. Ordinary commercial hydrochloric acid may now be bought for less than 0¾*d.* per *lb.*, in quantity.

HYDROCHLORIC ACID (Dilute). Syn. *Acidum Hydrochloricum Dilutum, A. Muriaticum D.*,—Lat. *Prep.* 1. (Ph. L.) *Hydrochloric acid* (Ph. L.), 5 fl. oz. (or, 1 vol.); *distilled water*, 15 fl. oz. (or, 3 vol.); mix. Sp. gr. 1·043. "1 fl. oz. is saturated by 168 gr. of the crystals of carbonate of soda."

2. (Ph. E.) 1 measure of *acid* (Ph. E.) to 3 of *water*. Sp. gr. 1·050.

3. (Ph. D.) 4 measures of *acid* (Ph. D.) to 13 of *water*.

4. (*Henry's.*) Sp. gr. 1·074.

Obs. The first three of the above are used in dispensing. *Dose.* 30 to 60 drops in simple infusion of roses or water. The last is used in assaying mineral waters, &c.

HYDROCHLORIC ETHER. See *Ethers.*

HYDROCOBALTOCYANIC ACID. *Prep.* Pass *sulphuretted hydrogen* through a solution of *cobaltocyanide of lead*, separate the lead by filtration, and evaporate the solution so that crystals may form.

Prop., &c. White, fibrous, acidulous, deliquescent crystals, soluble in water. With the metals it forms compounds termed *cobaltocyanides.* The *cobaltocyanide of potassium* is made by dissolving, by a gentle heat, the pure carbonate or protoxide of cobalt, in a solution of caustic

potassa which has been treated with an excess of hydrocyanic acid, and evaporating the solution. It forms soluble, reddish-yellow crystals which are rendered colourless, or only slightly yellow, by recrystallization. The *cobaltocyanide of lead* is made by treating a solution of acetate of lead with cobaltocyanide of potassium, and adding ammonia, when a white granular precipitate of the salt is formed. *Cobalto cyanide of silver* is prepared by mixing a solution of nitrate of silver with another of cobaltocyanide of potassium; a white granular precipitate subsides. In a similar way several other *cobaltocyanides* may be formed. See *Cobaltocyanogen.*

HYDROCYANATE. Syn. *Hydrocyanas*, —Lat. See *Hydrocyanic Acid.*

HYDROCYANIC ACID. Syn. *Cyanide of Hydrogen, Prussic Acid; Acidum Hydrocyanicum, A. Prussicum, A. Borussicum*,—Lat. This remarkable compound was discovered by Scheele, in 1782; but it was not until 1815 that Gay-Lussac obtained it in a pure anhydrous form, and demonstrated its composition.

Prep. 1. (Gay-Lussac.) *Bicyanide of mercury* (in powder), 3 parts; and *fuming hydrochloric acid*, 2 parts; are mixed in a small tubulated retort, to which is adapted a long tube bent to a right angle at one of its extremities, and containing in its horizontal part some fragments of *carbonate of lime*, succeeded by others of *chloride of calcium;* the free end of the tube is then introduced into a long narrow phial, or, what is better, a test tube, surrounded with *ice-and-salt*, and a gentle heat is applied; the liquid which collects in the receiver is poured into a bottle furnished with a good stopper, which is then covered with black or purple paper, and kept in the *dark*, inverted.

2. (Liebig.) *Pure crystallized ferrocyanide of potassium*, 15 parts; *water* and *sulphuric acid*, of each, 9 parts; are distilled in a glass retort connected with a *well-cooled* receiver containing *chloride of calcium* (in coarse fragments), 5 parts; and the process is stopped as soon as the chloride in the receiver is *perfectly covered* by the distilled fluid; the acid is then decanted into a well-stoppered bottle, as before.

3. (Vauquelin.) *Sulphuretted hydrogen* rendered *perfectly dry* in the usual manner, is passed over *cyanide* or *bicyanide* of *mercury*, in powder, contained in a horizontal glass tube, gently heated, and afterwards over *carbonate of lead* and *fragments of chloride of calcium*, arranged in the manner described above. (See No. 1.) The process should be stopped before *quite* the whole of the bicyanide is decomposed. The *products* of the above formulæ are *pure anhydrous hydrocyanic acid*, provided the instructions are carefully carried out.

Prop., &c. A thin, colourless, and exceedingly volatile liquid, possessing a very powerful odour greatly resembling that of peach kernels or oil of bitter almonds; it boils at 79°, and solidifies 0° Fahr.; sp. gr., 0·7058 at 45°. It possesses a feeble acid reaction, and mixes with water and alcohol in all proportions without suffering decomposition. Mixed with strong hydrochloric acid, the whole solidifies to a crystalline paste of *sal ammoniac* and *hydrated formic acid.* The other strong mineral acids operate a like change. In its anhydrous form this acid can seldom be preserved many days; light facilitates this change. It gradually darkens, and eventually deposits a black substance, and the residual liquor is found to have lost all the characteristic properties of prussic acid.

Pure anhydrous prussic acid is one of the most deadly poisons known. Whether swallowed, or applied to the surface of the body, it produces death so rapidly as to preclude the possibility of antidotes being administered. Even its vapour has a like effect. (See *below.*)

HYDROCYANIC ACID. (Dilute). Syn. *Medicinal Hydrocyanic Acid, M. Prussic do.; Acidum Hydrocyanicum Dilutum*,—Ph. L. & D. *A. Hydrocyanicum*,—Ph. E. *A. Prussicum*,—Ph. D. 1826. *Prep.* 1. (Ph. L.) *Sulphuric acid*, 7 fl. dr.; *water*, 4 fl. oz.; mix, pour the liquid into a retort, and when it has become cold, add of *ferrocyanide of potassium*, 2 oz., previously dissolved in *water*, ½ pint; next adapt the retort to a well-cooled receiver containing *distilled water*, 8 fl. oz.; then apply a gentle heat by means of a sand-bath, and let 6 fl. oz. of acid distil over into the water in the receiver; lastly, add of *distilled water*, 6 fl. oz. more, or q. s., so that 12·59 gr. of nitrate of silver dissolved in distilled water, may be *accurately* saturated by 100 gr. of the newly-prepared acid. It contains 2% of real hydrocyanic acid.

2. (Ph. E.) *Ferrocyanide of potassium*, 3 oz.; dissolved in *distilled water*, 11 fl. oz.; *sulphuric acid*, 2 fl. oz.; diluted with *water*, 5 fl. oz., and allowed to cool; distil over 14 fl. oz., by the heat of a sand-bath or naked gas-flame, and dilute the product with *water*, q. s. to make it exactly measure 16 fl. oz. It contains 3·3% of real acid (Christison;—3·98%,—Pereira.)

3. (Ph. D.) *Ferrocyanide of potassium*, 2 *oz.; oil of vitriol*, 1 fl. oz.; *water*,

12 fl. oz.; proceed as last, and let 8 *fl. oz.* distil over; lastly, add to the liquor in the receiver, *distilled water*, 8 fl. oz., or q. s. to make it up to exactly 16 *fl. oz.* Sp. gr., 0·997. It contains 2½ % of real acid.

4. (Apothecaries' Hall.) *Bicyanide of mercury*, 1 part; *hydrochloric acid*, (sp. gr., 1·15), 1 part; diluted with *water*, 6 parts; the mixture is submitted to distillation until 6 parts have passed over, which are reduced to the standard strength (Ph. L.) with *distilled water*.

5. (Dr. Clark.) *Tartaric acid*, 1 part; *water*, 40 parts; dissolve, add of *pure cyanide of potassium*, 2⅔ parts; agitate, and after repose decant the clear portion. Contains 3% of pure acid and a little bitartrate.

6. (Everitt.) *Cyanide of silver*, 40 gr.; *distilled water*, 7 fl. dr. and 20 minims; *dilute hydrochloric acid* (sp. gr., 1·129), 40 minims; agitate together, and decant the clear into another phial. Contains 2% of pure acid. An ounce of pure medicinal acid (Ph. L.) may be thus obtained for less than a shilling. (Everitt.)

7. (Laming.) *Cyanide of potassium*, 22 gr.; *water*, 6 fl. dr.; dissolve, add of *crystallized tartaric acid*, 50 gr., dissolved in *rectified spirit*, 3 fl. dr.; shake well together, and decant the clear. Each fl. dr. contains 1 gr. of the *pure acid*, or barely 2%. An excellent process when pure cyanide of potassium is at hand.

8. (Magendie.) *Pure anhydrous acid*, 1 fl. oz.; *water*, 6 fl. oz.; (or 1 to 8½ by weight.) Contains 12% of pure acid. It is 6 times as strong as that of the Ph. L.

9. (Scheele.) *Prussian blue* (pure and in fine powder), 10 parts; *red oxide of mercury*, 5 parts; *water*, 30 parts; boil the mixture in a glass vessel until the blue colour has disappeared or turned green, then decant or filter, and wash the solid residuum with *hot water*, 10 parts; to the mixed liquors, add of *iron filings*, 3 parts; *strongest oil of vitriol*, 1 part; agitate well together, and decant the clear liquid from the quicksilver which separates and collects at the bottom of the vessel; lastly, pour the liquid into a retort, and distil over 1-4th part of it for use. The *strength* of the *product* is uncertain, and varies from 3 to 5%. An acid of 4% is now generally sold under the name of "*Hydrocyanic Acid, Scheele's strength.*"

10. (Dr. R. D. Thomson.) *Dilute sulphuric acid* (Ph. L.), 2 fl. dr.; *distilled water*, 6 fl. dr.; mix, and add of *pure cyanide of lead*, 43½ gr.; agitate well, and decant the clear. Contains 2% of pure acid.

11. (Winckler.) *Ferrocyanide of potassium* (pure cryst., in powder), 120 gr.; *solution of pure phosphoric acid* (sp. gr. 1·25), 240 gr.; *alcohol* of 80%, 480 gr.; mix in a retort connected with a receiver containing of rectified spirit, 120 gr.; infuse for 24 hours, with occasional agitation, and then distil over the liquid portion, adding to the distillate, *alcohol*, q. s. to make it up to exactly 1½ oz. Contains 2% of pure acid.

12. (*Foreign Ph.*) Ph. Austr., Baden, Boruss., Hamb., and U. S., as the Ph. L. (nearly); P. Cod., resembles Magendie's, or from 10½ to 12%.

Prop. Medicinal hydrocyanic acid is a colourless, transparent liquid, tasting and smelling of peach kernels or bitter almonds. It is powerfully poisonous, although less intensely so, and less rapid in its action than the stronger acid. Its salts are the *hydrocyanates* and *metallic cyanides*.

Pur. It is "free from colour; by heat it (entirely) escapes in vapour, exhaling a peculiar odour. It turns litmus of a *slight fugitive* red colour. It does not redden on the addition of the iodocyanide of potassium and mercury. Sulphuretted hydrogen does not discolour it. Chloride of barium being added to it, nothing is thrown down." (Ph. L.) "The precipitate" (produced by nitrate of silver) "*entirely* disappears in boiling nitric acid." (Ph. E.)

Tests.—1. It is distinguished by a strong odour of bitter almonds.—2. Neutralized by potassa, and tested with a solution of sulphate or tincture of sesquichloride of iron, it gives a blue precipitate, or one turning blue on the addition of dilute sulphuric or hydrochloric acid. This test may be most successfully applied as follows:—Spread a single drop of solution of potassa over the bottom of a white saucer or porcelain capsule, and invert it over another vessel of the same size containing the matter under examination. After 2 to 5 minutes remove the upper capsule, and add to the potassa on it, a single drop of a solution of sulphate or tincture of iron, and expose it to the air for a few seconds. Next add one or two drops of dilute sulphuric acid, when a blue colour will be developed if hydrocyanic acid is present.—3. Nitrate of silver gives a white clotty precipitate soluble in boiling nitric acid, and which when dried, and heated in a small glass tube, evolves fumes known to be cyanogen, by burning with a violet, or bluish-coloured flame. A watch-glass moistened with this test, and inverted over hydrocyanic acid, as in No. 3, speedily becomes opaque and white from the formation of cyanide of silver.—4. A drop or two of *yellow* hydro-

sulphuret of ammonia is spread on the concave surface of a watch-glass or porcelain capsule, which is then inverted over the vessel containing the suspected matter, as in No. 1; after a few minutes the capsule is removed, and any undecomposed hydrosulphuret evaporated by the application of a *very gentle* heat; a glass rod dipped in a solution of a persalt or sesquisalt of iron is now drawn over the glass, when blood-red streaks of sulphocyanide of iron are formed, if the smallest quantity of hydrocyanic acid has been present; or, if the quantity is considerable, a blood red solution is obtained by placing a drop or two of the iron solution on the glass. If the addition of the iron produces a black colour, the evaporation has been carried hardly far enough. This test originated with Liebig, and is the most delicate yet discovered.—5. Supersaturated with potassa, it gives a greenish blue precipitate with sulphate of copper, which is turned white by the cautious addition of hydrochloric acid.—6. Tincture of guaiacum gives a white precipitate, and when a few drops of a solution of sulphate of copper are added, a blue colour is produced, which is heightened by adding alcohol. (Pagenstecher.)—7. An excess of potassa being added, and, subsequently, red oxide of mercury, the latter dissolves as readily as it would in free hydrocyanic acid, if this acid is present. This is regarded as a test of a most conclusive character.

The above tests apply equally to liquids containing free hydrocyanic acid and the *alkaline cyanides;* but they fail to detect the presence of cyanogen in *cyanide of mercury*. For this purpose the solution is mixed with a little hydrochloric acid and clean iron filings or wire, when metallic mercury separates, and hydrocyanic acid and chloride of iron remain in solution; potassa being now added, and subsequently hydrochloric acid in excess, Prussian blue, recognized by its colour, is at once formed. Or, the solution of cyanide of mercury may be decomposed by sulphuretted hydrogen, and then tested as liquid hydrocyanic acid. Or, like the cyanide of silver, it may be recognized by the colour of its flame. (See No. 3.) Most of the *cyanides of the heavy metals* are decomposed by sulphuretted hydrogen, and by dilute hydrochloric acid, a solution of hydrocyanic acid being formed, which may then be tested in the way already indicated. In cases of poisoning, in which the above tests cannot be applied, the contents of the stomach, or other organic mixture, may be introduced along with a little *sulphuric* or *hydrochloric acid* into a retort, and distilled, and the reagents applied to the distilled liquor.

Estim. The following are the most convenient and reliable of the *cyanogen-metrical processes* now in use:—

1. The liquid acid, diluted with water, if concentrated, is treated with a solution of nitrate of silver as long as a precipitate forms; the latter (*cyanide of silver*) is carefully collected, washed, dried, and weighed. This weight divided by 5, gives the *per centage* of *pure hydrocyanic acid* present, provided 100 gr. have been examined, and the sample is free from hydrochloric acid. The absence of the latter is determined by digesting the weighed precipitate in a concentrated solution of nitrate of silver, or in boiling nitric acid. It should *wholly* dissolve. If any portion remains undissolved, it must be carefully collected, washed, dried, and weighed. In this case the loss in weight gives the quantity of cyanide of silver, which must be divided by 5, as before. The result is the true richness of the sample in pure hydrocyanic acid.

2. (MM. Fordos & Gélis.) This process is founded upon the reaction of iodine upon the cyanides, which consists in the absorption of iodine up to the point of saturation, beyond which the presence of *free iodine* becomes apparent. A *test solution of iodine* (3 gr. to 1 fl. oz.) is gradually added from a pourette to a weighed sample of the *dilute acid*, until a permanent yellow tinge becomes visible, when the *quantity of test liquor consumed*, indicates the strength of the acid examined, (equiv. for equiv.)

3. (Liebig.) *Fused nitrate of silver*, 63 gr., are dissolved in *distilled water*, 5937 gr.; by which a test liquor of 6000 grains is obtained, of which every 300 gr. correspond to 1 gr. of *hydrocyanic acid*. The weight of the bottle containing this silver solution is then accurately taken and noted. A weighed portion of the medicinal hydrocyanic acid under examination is next diluted with three or four times its bulk of *water*, and then mixed with a *solution of caustic potassa* and a few drops of a *solution of common salt*. To this mixture the *silver test solution* is gradually added until a visible turbidity is produced, which does *not* disappear on agitation. The test solution is then again weighed. The loss in weight, divided by 300, gives the quantity of pure hydrocyanic present, per cent., when 100 gr. have been examined. Suppose 60 gr. of medicinal acid are found to require 360 gr. of the silver solution, then the proportion of anhydrous hydrocyanic acid

present in the medicinal acid will be 1·20 gr., or 2%. In testing by this method an error of a grain or two in the quantity of silver solution used is not likely to occur, but even this would not make a difference of more than 1-100th or 1-50th of a grain in the amount of hydrocyanic acid. This test answers equally well "with cherry-laurel and bitter almond water, and solutions of the alkaline cyanides, provided proper care is taken.

4. (Ure.) To 100 gr., or any other convenient quantity of the *acid* contained in a small phial, small quantities of the *red peroxide of mercury*, in fine powder, are added in succession, until it ceases to be dissolved on agitation. The weight of the *oxide* taken up, being divided by 4, gives a quotient representing the quantity of *real hydrocyanic acid* present. By weighing out beforehand, on a piece of paper or a watch-glass, 40 or 50 gr. of the *peroxide*, the residual weight of it shows at once the quantity expended. The operation may be always completed in five minutes, for the red precipitate dissolves as rapidly in dilute prussic acid, with the aid of slight agitation, as sugar dissolves in water. Should the presence of hydrochloric acid be suspected, then the difference in the volatility of hydrocyanate and hydrochlorate of ammonia may be had recourse to with advantage; the former volatilizing at a very gentle heat, whilst the latter requires a subliming temperature of about 300° Fahr. After adding ammonia in slight excess to the acid, if we evaporate to dryness at a heat of 212°, we may infer from the residuary sal ammoniac the quantity of hydrochloric acid present. Every gr. of sal ammoniac corresponds to 0·6822 gr. of hydrochloric acid.

Uses, &c. Medicinal hydrocyanic acid has been administered with apparent advantage in chronic coughs, phthisis, spasmodic asthma, hooping cough, hysteria, the vomiting in cholera and pregnancy, the diarrhœa frequently accompanying pulmonary consumption, &c. It has also been successfully employed as an anodyne in numerous painful affections; as cancer, neuralgia, rheumatism, &c. Also *externally*, in prurigo, and some other skin affections. In gastrodynia and those nameless stomach, nervous, and hysterical affections, in both sexes, arising chiefly from excessive irritability or excitement, over-anxiety, study, &c., in which there appears no well-defined organic ailment, small doses of hydrocyanic acid or the alkaline cyanides are invaluable, and never fail to afford considerable relief, if they do not altogether remove the disease. In some cases the effects appear almost magical. A life of absolute wretchedness —sleepless nights, days of intolerable excitement and irritability—is often changed in a few hours to one of quiet and susceptibility of enjoyment. *Dose.* Of the Ph. L., 1 to 6 drops, 3 or 4 times a day, made into a mixture with water flavoured with gum or syrup. *Externally*, as a lotion, 1 fl. dr. of the dilute acid (Ph. L.) to 3 or 4 fl. oz. of distilled water. A weak lotion of prussic acid, employed both before and after shaving, is very soothing to an irritable face. (Dr. Elliotson.) An eye cup or glass containing a *single drop* of the dilute acid and held against the eye for a few seconds, so that the latter may be exposed to the fumes, is a cosmetic application adopted by certain fashionable ladies and actresses to increase the clearness and brilliancy of their eyes.

Pois., &c. The usual *symptoms* after swallowing prussic acid in *poisonous doses*, are—a bitter, hot taste, faintness, giddiness, unsteady gait, difficult respiration, salivation, tetanic convulsions, and insensibility; the latter continues, followed by profound coma, great muscular relaxation, complete loss of the power of motion, convulsive respiration, severe tetanic spasms, and death. The pupils are generally dilated, but, sometimes, contracted. When the quantity taken has been *very large*, tumultuous palpitation, followed by a few hurried inspirations, and convulsive plunges, an almost imperceptible pulse, insensibility, and profound coma, are the only symptoms that usually precede death. Sometimes convulsions do not occur. When recovery takes place, it is usually very rapid, and in most cases occurs within half an hour after the poison has been taken. In most cases death occurs in about 15 to 20 minutes, but sometimes not for nearly half an hour. Of 7 epileptic patients killed by hydrocyanic acid in one of the hospitals in Paris, some did not die in less than ¾ of an hour. The most characteristic post-mortem appearances are extreme glistening brightness, and staring expression of the eyes; and the venous system is usually gorged with blood, whilst the arteries are empty. The odour of the poison is also generally perceptible. The largest quantity of prussic acid ever swallowed, as far as our knowledge extends, was that of a thirsty carman, who seized a half-gallon jug containing it, which was standing on the laboratory counter, and swallowed between 6 and 7 ounces of it at a gulp, in mistake for cold water.

Ant., &c.—1. *Chlorine water*, or *solution*

of chloride of lime or of *soda*, in doses of 2 or 3 spoonfuls diluted with water, frequently; also applied externally.—2. Inspirations slightly impregnated with the *condensed chloro-vinegar* of M. Mialhe. This is prepared by spreading a thin layer of dry chloride of lime upon a towel, folding this into the form of a cravat, and moistening it with vinegar, which disengages the chlorine by degrees, and allows it to be inspired through the mouth and nostrils.—3. Small quantities of *ammonia water* diluted with 10 or 12 parts of water; also the fumes inhaled. A case is reported of a gentleman who swallowed 2 dr. of the acid (Ph. D.) and in whom insensibility and convulsions had set in, who was cured by this treatment. —4. The joint administration of *carbonate of potassa* and *sulphate of iron*. This has been lately very strongly recommended. —5. *Cold affusion* should be adopted in all cases, and is almost of itself a certain cure, if employed before the convulsive stage is over; and it is often successful even during the stage of insensibility and paralysis. (Herbst.) In all cases, where an emetic can be got down, it should be administered as early as possible, and vomiting promoted by tickling the fauces with the finger or a feather. At a later period a purgative clyster may be administered. Artificial respiration should also be attempted. Unfortunately the poisonous action of prussic acid is so rapid that life is usually extinct before assistance arrives and antidotes can be applied.

Concluding Remarks.—Prussic acid, even when dilute, is very liable to spontaneous decomposition, and this occurs the more speedily under the influence of light and warmth. To *promote* its *preservation*, it is usual to surround the bottles containing it with thick paper (purple on both sides), and to keep them inverted in an obscure situation. The addition of a *very small* quantity of hydrochloric acid renders it much less liable to change, and is now generally made by manufacturers for that purpose; but in testing the strength of such acid by nitrate of silver, it is necessary to deduct the weight of the chloride of silver from that of the mixed precipitate. (See *above*.) The acid prepared by decomposing ferrocyanide of potassium by sulphuric acid, is less liable to change than that prepared by any other process; probably, from a minute quantity of sulphuric acid passing over during the distillation. According to Dr. Christison, it will keep for years. Some of it continued "unchanged for two years and a half, although it was exposed to daylight."

HYDROFERRIC ACID. Same as *Ferric acid*.

HYDROFERRIDCYANIC ACID. Syn. *Hydroferricyanic Acid*, *Ferridcyanic do.*, *Ferridcyanide of Hydrogen*, *Ferrosesquicyanic Acid*. A compound of ferridcyanogen and hydrogen.

Prep. Recently precipitated *ferridcyanide of lead* is decomposed by *sulphuretted hydrogen*, or by *dilute sulphuric acid* carefully added. A yellow solution is thus obtained, which yields a deep brown powder when evaporated by heat, or yellow crystals by spontaneous evaporation.

Prop., &c. With the oxides of the metals this compound forms *ferridcyanides*. These may be made by adding a solution of ferridcyanide of potassium to another of a soluble salt of the base. *Ferridcyanide of potassium* is the salt commonly known as red prussiate of potash. Turnbull's blue is a *ferridcyanide of iron*. See *Ferridcyanogen*, *Potassium*, and *Iron*.

HYDROFERROCYANIC ACID. Syn. *Ferrocyanic Acid*, *Ferrocyanide of Hydrogen*; *Acidum Hydroferrocyanicum*, *A. Ferrocyanicum*,—Lat. *Ferrochyazic Acid*, *Ferruretted do. do.*, *Ferroprussic do.*,—Obs. A peculiar compound of cyanogen, hydrogen, and iron, discovered by M. Porret, and by him named ferrochyazic acid.

Prep. 1. (Berzelius.) *Ferrocyanide of lead* or *copper* (recently precipitated), is diffused through water, and decomposed by passing a *stream* of *sulphuretted hydrogen* through the liquid; the latter is then filtered, and evaporated in vacuo, over sulphuric acid, and the crystals collected, pressed between bibulous paper, and dried. Or, the acid may be obtained from the solution by adding ether as noticed below.

2. (M. Porrett.) *Ferrocyanide of potassium* is dissolved in *water*, and a *solution of sulphuret of barium* added as long as a precipitate falls; this is collected, washed with *cold water*, dried, and dissolved in *cold water*, 100 parts; this solution is then decomposed by adding of *concentrated sulphuric acid*, 30 parts, and the filtered liquid is treated as before.

3. (M. Posselt.) A *concentrated aqueous solution of ferrocyanic acid* (obtained as above) is agitated with a *little ether*; the acid separates immediately, and may be obtained by filtration. If the solution is moderately concentrated, the whole forms a thick mass, and after some time the ferrocyanic acid suspended in the ether separates from the water saturated with ether, and swims on the surface. The water is to be removed by a pipette; the thick mass is to

be put on a filter and washed repeatedly with a *mixture* of *alcohol and ether*, containing a considerable portion of the latter; it is then pressed between the folds of absorbent paper to remove the moisture, and afterwards perfectly dried over sulphuric acid in vacuo.

4. A *concentrated solution of ferrocyanide of potassium*, prepared with *boiled water*, is cooled out of contact with the air, and *hydrochloric acid* added in excess; the mixture is then agitated with *ether* as before; the separated acid is next dissolved in *alcohol* to which a *little* sulphuric acid has been added, the solution filtered if not clear, and agitated with *ether;* the separated acid is lastly collected and dried.

Prop., &c. Crystals or crystalline laminæ, of a yellowish white, or white colour, when pure; soluble in water and alcohol; the aqueous solution has an acid taste and reaction, and decomposes the alkaline carbonates with effervescence; permanent in dry air; but decomposed when heat and moisture are present. With the metallic oxides it forms compounds termed *ferrocyanides, ferrocyanates, hydroferrocyanates*, or *prussiates*. The INSOLUBLE FERROCYANIDES, may all be formed by the mixture of a soluble salt of the metal with a solution of ferrocyanide of potassium. The latter salt is the compound commonly called *yellow prussiate of potash*. See *Ferrocyanogen, Potassium, Iron, &c.*

HYDROFLUORIC ACID. Syn. *Fluoric Acid; Acidum Fluoricum, A. Hydrofluoricum*,—Lat. *Stygian Water, Aqua Stygis*,—Obs. An acid compound of hydrogen and fluorine. It was discovered by Scheele, but was first procured in a pure state by Gay-Lussac and Thénard, in 1810.

Prep. Pour *concentrated sulphuric acid* on half its weight of *fluor spar*, carefully separated from silicious earth, and reduced to fine powder. The mixture must be made in a capacious *leaden* retort, and a gentle heat only applied, and the evolved gas must be collected in a *leaden* receiver, surrounded by ice.

Prop., &c. A colourless fluid below 59° Fahr., which speedily evaporates in dense white fumes when exposed to the air. Its affinity for water exceeds that of sulphuric acid, and its combination with that fluid is accompanied with a hissing noise, and a considerable increase of its sp. gr. up to a certain point. It readily dissolves glass and silica, forming *fluosilicic acid*, for which reason it cannot be preserved in glass vessels. Bottles of lead, silver, platinum, or pure gutta percha, are used to keep it in. It is highly corrosive, instantaneously destroying the skin on contact, and producing deep and serious ulcerations; its vapour is pungent, irritating, irrespirable, and *poisonous*. With the metals it unites to form *hydrofluorates, fluorates*, or *metallic fluorides*. *Hydrofluorate of ammonia* (fluoride of ammonium) is obtained by heating together, in a platinum crucible, over a lamp, 1 part of *dry sal ammoniac*, with a little more than 2 parts of *fluoride of sodium*. The lid of the crucible should be turned upwards, and filled with cold water. The hydrofluorate sublimes and adheres to the lid, forming a mass of small prismatic crystals. It readily acts on glass. The *hydrofluorates* or *fluorides* of the *alkalies, earths*, and *metals*, may most of them be prepared by saturating hydrofluoric acid with the *recently* precipitated oxide, or carbonate of the base.

In the *arts*, hydrofluoric acid is used for etching on glass. (See *page* 397.)

HYDROFLUOSILICIC ACID. *Prep.* From *powdered fluor spar*, and *silicious sand* or *powdered glass*, of each, 1 part; *concentrated sulphuric acid*, 2 parts; mix in a glass retort, apply a gentle heat, and collect the evolved gas over mercury.

Prop., &c. A colourless, incombustible gas, highly corrosive, and poisonous; it does not act on glass vessels, when they are quite dry; water absorbs 365 times its volume of this gas (Dr. Davy); but decomposition ensues, *pure hydrated silicic acid* being deposited in a gelatinous state, and *silicated fluoric acid*, or *silico-hydrofluoric acid*, remaining in solution, By the action of water of ammonia fluosilicic acid gas is completely decomposed. In this way Dr. Davy obtained $\frac{614}{1000}$ of its weight of pure silica.

HYDROGEN. Syn. *Hydrogenium*,—Lat. *Inflammable Air*,—Obs. A chemical element, first correctly described by Cavendish, in 1766, having previously been confounded with other gases, and by some called *phlogiston*, from being supposed to be the matter of heat. It is a substance which, in its combined state, is not perceptible to the senses, and its existence can only be experimentally demonstrated by its pursuit whilst it passes out of one combination into another. It cannot be arrested and exhibited in its passage, but when it presents itself as the component of a new compound, it is immediately recognized by chemical means. It is the lightest of all ponderable matter whose examination belongs to chemistry. According to M. Dumas, it is a metal. "It is a *gaseous metal*, even

as *mercury* is a *liquid metal.* If we suppose that it is impossible to liquefy the vapour of mercury—that it is colourless, inodorous, and transparent as hydrogen—we shall have a correct idea of the views I wish to establish. The *ensemble* of its properties approaches, in fact, to mercury and potassium." (Echo du Monde Savant, Nov. 20, 1842.)

Prep. Hydrogen is always obtained for experimental purposes by the deoxidation of water, by one or other of the following methods:—

1. A tube of iron or porcelain (a *gun barrel*, for instance) containing a quantity of *iron turnings* or *scraps of iron*, is fixed across a furnace, so that its middle portion may be made red-hot; to the one end is attached a retort or other vessel containing water, and to the other, a bent tube connected with a pneumatic trough or gasometer. The tube being now heated to redness, and the water in the retort brought into a state of brisk ebullition, the evolved steam suffers decomposition; the oxygen being absorbed by the iron, and the hydrogen escaping into the gas receiver.

2. *Oil of vitriol*, 1 part, diluted with *water*, 5 parts, is poured on *iron* or *zinc wire* or *filings*, placed in a retort or gas bottle; hydrogen is evolved and is collected, as before. This is the more convenient method of the two, and the one usually adopted in the laboratory.

To ensure the gas being quite pure, *distilled zinc* is employed, and, in both the above cases, the gas is passed, first through *alcohol*, then through a *concentrated solution of pure potassa*, and, lastly, through a *solution of nitrate of silver.* When heat is employed the gas is allowed to cool before proceeding to purify it.

Prop. Gaseous; colourless; tasteless; odourless (when pure); combustible; sp. gr. 0·06935; being 16 times lighter than oxygen gas, and nearly 14½ times lighter than atmospheric air. 100 cubic inches, at 60° Fahr. and 30 inches of the barometer, weigh 2·1371 (say 2·14) gr.; mixed with atmospheric air or oxygen it explodes with extreme violence on the approach of flame, or sudden compression, (Biot.) Brought into contact with spongy platinum, the latter instantly becomes red hot, and the gas is kindled. One measure of *hydrogen*, and 5 or 6 of *atmospheric air;* and 2 of *hydrogen*, and 1 of *oxygen*, are the proportions that explode with the greatest violence. (Doebereiner.) A mixture of 1 volume of *hydrogen*, and 9 volumes of *air*, explodes feebly; and one of 4 volumes of *hydrogen*, and 1 volume of *air*, does not explode at all. (Cavendish.) The electric spark, spongy platinum, the black powder of platinum (Garden), clean platinum foil (Faraday), and some other substances, produce combination, and generally explosion, of the mixed gases. Its slow combustion produces much heat, but little light. A *jet of hydrogen*, burnt in *oxygen gas*, or a jet of these gases (mixed) burnt in the air, with proper precautions, produces the most intense heat known. Water absorbs about $2\frac{0}{0}$ by volume of hydrogen. When hydrogen is prepared from crude zinc it has a slight smell; and, when from iron, its odour is often strong and disagreeable.

Tests. It is recognized by—its combustibility;—the pale colour of its flame;—producing water only when burnt in air or oxygen;—extinguishing the flame of other bodies; and—exploding when mixed with half its weight of oxygen and fired. See *Organic Substances.*

Uses, &c. Pure and uncombined hydrogen is not employed in the arts. *Inhalations* of this gas have, however, been occasionally used in medicine. Dr. Beddoes recommended them in phthisis. *Hydrogen water* has been employed in diabetes. In combination, the uses of hydrogen are almost numberless. Combined with oxygen it forms *water;* with chlorine, *hydrochloric acid;* with iodine, *hydriodic acid;* with bromine, *hydrobromic acid;* with fluorine, *hydrofluoric acid;* with cyanogen, *prussic acid;* with carbon, numerous *hydrocarburets* or *hydrocarbons;* with nitrogen, *ammonia;* with phosphorus, *phosphoretted hydrogen;* with sulphur, *sulphuretted hydrogen;* and with arsenic, tellurium, and potassium, *arseniuretted, telluretted,* and *potassiuretted hydrogens.* It enters into the composition of *all compounds* containing *water* (hydrates, &c.), a multitude of *acids* and *salts*, and into all the various *proximate organic principles* of both the *animal* and *vegetable kingdoms.* It forms one of the ingredients of *coal gas*, and of *all bodies* that *possess the power of burning with flame.* From its extreme lightness it has been used to fill *balloons*, and its *carburet* (coal-gas) is now commonly employed for this purpose. On its property of inflaming in contact with spongy platinum is arranged the popular little instrument for the production of *instantaneous light*, sold by the philosophical instrument makers. The chemist avails himself of the great heat developed by its combustion in oxygen in the formation of the *oxyhydrogen blowpipe.* Indeed, the position occupied and

the offices performed by hydrogen in the material world, as far as our perceptions permit us to judge, appear all but infinite.

1 *oz.* of *zinc*, with 1½ *oz.* of *oil of vitriol* diluted with 5 or 6 times its weight of *water*, produces considerably above 600 cubic inches of hydrogen gas.

HYDROGEN (Amidide of). See *Ammonia.*

HYDROGEN (Aurochloride of). See *Auro-terchlorides.*

HYDROGEN (Binoxide of). Syn. *Deutoxide of Hydrogen, Peroxide of do., Oxygenated Water; Hydrogenii Binoxydum, H. Deutoxydum,*—Lat. This singular fluid was discovered by M. Thénard in 1818.

Prep. 1. *Deutoxide of barium* is mixed with about *twice its weight of water*, and *sulphuric acid* is gradually added until all the deutoxide is converted into sulphate of baryta, observing to avoid excess of acid; the clear liquid is then decanted.

2. (M. Thénard.) *Water*, 6 or 7 fl. oz.; *deutoxide of barium*, 230 gr.; mix, and add gradually as much *pure concentrated hydrochloric acid* as is required to render the deutoxide soluble; then place the containing vessel, which should be of glass, in a *freezing mixture*, or a *vessel of ice*, and add *gradually* and *cautiously* of *deutoxide of barium* (in powder), 185 gr., stirring the liquid with a glass rod, after each addition; as soon as the whole is dissolved, add *sulphuric acid*, q. s. to entirely precipitate the *baryta*; next add a *second portion* of 185 gr. of *deutoxide of barium*, as before; again add *sulphuric acid*, q. s. to precipitate the whole of the baryta, and decant or filter the solution; repeat the same process with *fresh deutoxide of barium*, until about 3 oz. have been employed; lastly, separate the hydrochloric acid by means of *sulphate of silver*, cautiously added, and the sulphuric acid by *pure solid baryta.*

Prop., &c. The liquid prepared by the last formula contains 25 to 30 times its volume of oxygen, and also much simple water, to remove which it must be placed over sulphuric acid, in vacuo, until the sp. gr. reaches 1·452; beyond which it cannot be concentrated, as at this point it begins to volatilize slowly. In this state it is colourless; limpid; tastes metallic; is stable at *low* temperatures; resolved into oxygen and water, at 59° Fahr. It mixes freely with water, and becomes more permanent by the dilution. It bleaches organic substances; is decomposed by all the metals, except iron, tin, antimony, and tellurium, with more or less facility, and by many of the metallic oxides. The peroxides of lead, mercury, gold, platinum, manganese, and cobalt, effect this change instantaneously, and accompanied with extreme violence, during which the glass tube holding the liquid becomes red hot. Its action on oxide of silver is also exceedingly violent. Every drop of the liquid let fall on the dry oxide produces a real explosion, and light and heat is evolved. Gold in powder acts in a similar manner on *pure* oxygenated water; but has no action on this liquid if a little sulphuric acid is first added. Fibrin, and other organic matter, also deoxidize it.

The only use to which *binoxide of hydrogen* has been applied in the arts, is to restore the blackened lights of paintings which have become darkened by sulphuretted hydrogen. It has been proposed by M. de Sondala, as a means of supplying oxygen to the *confined air* of *diving bells* and other limited places; the carbonic acid formed by the lungs being at the same time absorbed by passing the air through hydrate of lime; but for this purpose *ferric acid* is more convenient and effective.

HYDROGEN (Borofluoride of). See *Fluoboric Acid, &c.*

HYDROGEN (Carbides of). See *Carburetted Hydrogen.*

HYDROGEN (Chloramidide of). See *Hydrochlorate of Ammonia.*

HYDROGEN (Oxides of). See *Binoxide of Hydrogen* and *Water.*

HYDROGEN (Sulphides of). See *Sulphuretted Hydrogen.*

HYDROGEN (Antimoniuretted). Syn. *Antimonetted Hydrogen, Antimonide of do.; Hydrogenium Antimoniatum,* — Lat. A gaseous compound of antimony and hydrogen formed under analogous conditions to those under which arseniuretted hydrogen is generated. It burns with a greenish flame, giving rise to dense fumes of teroxide of antimony, and when conducted through a red-hot tube, or the flame is thrown on a cold surface, as a porcelain plate, metallic antimony is deposited. See *Arsenious Acid.*

HYDROGEN (Arseniuretted). Syn. *Hydrogenium Arseniuratum,*— Lat. See *Arsenious Acid, &c.*

HYDROGEN (Carburetted). Syn. *Carbonetted Hydrogen, Carbide of do.; Hydrogenii Carburetum,*—Lat. Besides the hydrocarbons already noticed, two gaseous compounds, of carbon and hydrogen, possess peculiar interest. These are—

1. *Light Carburetted Hydrogen, Heavy Inflammable Air, Subcarburetted do., Dicarburet of do., Fire-damp, Marsh-gas, Gas*

of the Acetates. This is often abundantly disengaged in coal mines, and its combustion occasions those fearful explosions which are so destructive to human life. The mud at the bottom of stagnant pools, on being stirred, suffers bubbles of gas to escape, which, when collected and examined, are found to be a mixture of light carburetted hydrogen and carbonic acid. The latter is easily removed by passing the gas through a *solution of caustic potassa* or *milk of lime.* When a mixture of *acetate of soda* (cryst.) and *hydrate of potassa* (dry), of each, 2 parts, and *quicklime* (in powder), 3 parts, is strongly heated in a flask or retort, this gas, in a state of absolute purity, is disengaged in great abundance, and may be collected over water. (Dumas.) It is colourless; neutral; nearly inodorous; burns with a yellow flame, producing pure water and carbonic acid; explodes when kindled in contact with air or oxygen; and when mixed with atmospheric air may be respired for some time without apparent injury.

2. *Heavy Carburetted Hydrogen, Bicarburetted do.* See *Olefiant Gas.*

3. *Coal Gas, Oil Gas, Rosin Gas.* These are mixtures of the last two in uncertain proportions, obtained respectively from *gas, oil,* and *rosin,* by the action of heat, and used for the purposes of illumination. *Coal gas* purified by passing it through *water,* then agitating it with *moist carbonate of lead,* and again washing it with *water,* has been recommended by Dr. Clanny, and others, as a palliative in pulmonary consumption. It is diluted with its own volume, or twice its volume of common air, and inspired 3 or 4 times daily, in doses of 12 to 15 inches of the mixed gases, gradually increased to 20 or 30 cubic inches.

HYDROGEN (Phosphuretted). Syn. *Phosphoretted Hydrogen, Phosphide of do.; Hydrogenium Phosphoratum,*—Lat. *Prep.* 1. *Hydrated phosphorous acid* is gently heated in a small retort, and the gas collected over water in the pneumatic trough. Pure.

2. From *phosphorus* (in small lumps) boiled in a *solution of caustic potassa* or *milk of lime,* contained in a small retort, as before. When newly prepared by this process, the gas spontaneously inflames on contact with air, owing to the presence of a small quantity of a *liquid phosphide of hydrogen.* (M. Paul Thénard.)

3. As the last, but using *water strongly acidulated with hydrochloric* for the retort.

Prop.,&c. Colourless; very fetid; slightly soluble in water; burns with a white flame; decomposed by light, heat, and strong acids; as commonly prepared, inflames on contact with air, at ordinary temperatures, but when pure, only at the heat of boiling water. Sp. gr. 1·24. It is rendered quite dry by standing over fused chloride of calcium.

HYDROGEN (Seleniuretted). Syn. *Selenietted Hydrogen, Hydroselenic Acid.* This substance is obtained by the action of *dilute sulphuric acid* on the *seleniuret of iron, manganese,* or *potassium.* It is a colourless gas, freely absorbed by water, and in its action on metallic solutions greatly resembles sulphuretted hydrogen. Its most remarkable property is its power of irritating the nose, exciting catarrhal symptoms, and destroying the sense of smell. This has led to the suggestion by Dr. Prout, that the evolution of this substance by volcanoes, and its diffusion through the atmosphere, may be the cause of certain forms of the epidemic disorder called influenza.

HYDROGEN (Sulphuretted). Syn. *Hydrosulphuric Acid, Sulphohydric do., Hydrothionic do., Sulphide of Hydrogen, Hydrothion, Hepatic Air; Hydrogenium Sulphuratum, Acidum Hydrosulphurium, Aer Hepaticus,*—Lat. A compound of hydrogen and sulphur, noticed by Mayer and Ruellius, but first chemically examined by Scheele, in 1777.

Prep. 1. *Tersulphuret of antimony* (in fine powder), 1 part; *strong hydrochloric acid,* 5 parts; mix in a small glass retort, or in a flask furnished with a bent tube, apply the heat of a spirit lamp, and collect the evolved gas either over mercury or water, in the pneumatic trough, or in bottles, as noticed under *chlorine.* Pure.

2. From *protosulphuret of iron* and *oil of vitriol diluted with* 4 *or* 5 *parts of water.* This is the plan commonly adopted in the laboratory.

3. From *sulphuret of calcium* or *sulphuret of potassium,* as the last.

Prop. Gaseous; colourless; very fetid; odour resembling that of rotten eggs; reddens moistened litmus paper; burns with a blue flame; liquefies under a pressure of 17 atmospheres, at 50° Fahr.; freezes into a white crystalline mass at — 122° Fahr.; cold water absorbs about its own volume of this gas, forming *liquid sulphuretted hydrogen* or *sulphuretted hydrogen water;* sp. gr., 1·171; 100 cubic inches weigh 36·33 gr. Its compounds are called *hydrosulphates, hydrosulphurets, sulphurets,* or *sulphides.* It is powerfully poisonous. An atmosphere containing 1-1500th of this gas instantly

killed a small bird; 1-1000th killed a large dog, and 1-250th a horse. (Dupuytren and Thénard.)

Tests. Sulphuretted hydrogen is readily recognized—1. By its odour.—2. By instantly blackening moist carbonate of lead.—3. By tarnishing polished silver.—4. By giving a *yellow* precipitate with arsenious acid.—5. By giving an *orange-red* precipitate with tartar emetic.—6. By giving a *black* precipitate with the salts of lead. Air containing 1-20,000th part of pure hydrogen will sensibly blacken a piece of white paper, moistened with a solution of acetate of lead.

Uses, &c. Sulphuretted hydrogen is chiefly employed as a test in chemical analysis. For this purpose, the best way is to keep a miniature apparatus for generating the gas always at hand. A small bottle or flask, furnished with a closely fitting cork, through which a small bent-tube passes, and containing a *little sulphuret of iron* and *water*, is all that is necessary in this way. When the gas is required for testing, the addition of a *drop* or *two* of *oil of vitriol* will cause it to be at once evolved. Air slightly scented with this gas has been proposed as a sedative, in chronic irritability and inflammation of the lungs during phthisis; but its administration requires the greatest caution. In the form of vapour baths, it has been occasionally employed in obstinate gouty, rheumatic, and cutaneous affections. Under the form of *sulphuretted mineral waters*, it is a common remedy as an alterative and resolvent. *Externally*, sulphuretted hydrogen water has been used as a wash or lotion. Being denser than air, this gas may be poured from its generating bottle into cavities; a scheme successfully employed by M. Thénard to destroy rats and other vermin in their holes. *Hahnemann's test liquor* for detecting lead in wine, is formed of *sulphuretted hydrogen water*, 4 fl. oz., acidulated with *tartaric acid*, 1 dr.

Pois., &c. Sulphuretted hydrogen is one of the most energetic poisons known, especially when it is respired; it is less poisonous when introduced into the stomach or the venous system; it is absorbed without decomposition, and causes great prostration with a change in the texture of organs, and especially of the nervous system.—*Treat.* The first thing is to expose the patient to a free current of air, to loosen the clothing, to use smart and rough friction over the body, and to dash it with *cold vinegar-and-water*. We ought next to make him inspire the condensed chloro-vinegar, noticed under *hydrocyanic acid* (see *page* 579); due care being taken to avoid irritating the lungs. If liquids containing sulphuretted hydrogen or hydrosulphuret of ammonia have been swallowed, a *strong emetic* should be given. Threatened congestion must be met by bleeding. Nervous derangement, spasms, and convulsions, may often be calmed by antispasmodics and the cold bath. If the asphyxia or syncope continues, *mustard* poultices may be applied to the feet and calves of the legs.

HYDROGEN (Sulphuretted,—Solution of). Syn. *Sulphuretted Hydrogen Water, Liquid Sulphuretted Hydrogen, Liquid Hydrosulphuric Acid; Aqua Hydrogenii Sulphureti, A. Acidi Hydrosulphurici, A. Hydrosulphurata, Acidum Hydrosulphuricum aquâ Solutum*,—Lat. var. A solution of sulphuretted hydrogen prepared by passing the gas into cold water. *Used* as a test. (See *above*.)

HYDROGEN (Persulphuretted). Syn. *Persulphide of Hydrogen, Persulphuret of do.* This is prepared by boiling together equal weights of *fresh-slaked lime* and *flowers of sulphur*, in about 6 times their weight of *water*, for 30 or 40 minutes; the resulting deep orange-coloured solution is filtered, and slowly added to an excess of *dilute sulphuric acid*, with constant agitation; a white precipitate of separated sulphur and sulphate of lime makes its appearance, together with a quantity of yellow oily-looking matter, which collects at the bottom of the vessel; this is *persulphide of hydrogen*. It has a very powerful odour; the sp. gr., 1·769; and is a very unstable compound.

HYDROGEN (Telluretted). Syn. *Hydrotelluric Acid.* A peculiar gaseous body discovered by Davy in 1809, and formed in a similar manner to hydrogen, by digesting *hydrochloric acid* on an *alloy of tellurium with zinc* or *iron*. It possesses feeble acid properties, and precipitates *tellurets* from metallic solutions. It is absorbed by water and then forms *liquid hydrotelluric acid*, or *telluretted hydrogen*.

HYDROGURETS. The old name for compounds of hydrogen with a simple inflammable body or a metal.

HYDROKINONE. Two compounds under this name have been obtained by Wöhler from kinone:—

1. (*Colourless Hydrokinone.*) Obtained by the addition of *hydriodic acid, sulphurous acid*, or *telluretted hydrogen* to a *solution of kinone*. Colourless crystals; neutral; odourless; tasteless; soluble both in

water and alcohol; fusible; and volatile by heat.

2. (*Green Hydrokinone.*) This may be obtained by the action of *sesquichloride of iron*, *chlorine*, or *chromic acid* on *colourless hydrokinone*; or, by mixing together *solutions* of *kinone* and *colourless hydrokinone*. It forms slender green crystals of great brilliancy and beauty, which are fusible, and soluble in boiling water.

HYDROLATS. Syn. *Hydrolata.* Medicated waters.

HYDROLEIC ACID. A peculiar fluid compound, discovered by Frémy, and obtained by evaporating the *alcohol used in the preparation of hydromargaritic acid.*

HYDROMARGARIC ACID. A solid, crystallizable compound, formed by melting together one equivalent each of *metamargaric* and *hydromargaritic acids*, and crystallizing the mass from *alcohol.*

HYDROMARGARITIC ACID. Obtained by boiling the *mother-liquor of metamargaric* and *metoleic acids*, when a mixture of *hydromargaritic* and *hydroleic acids* rises to the surface, which, after being washed with *cold alcohol*, leaves the former pure. By heat it is converted into metamargaric acid and water. It is solid and crystallizable, and dissolves in both alcohol and ether. The above three acids, along with *metamargaric*, *metoleic*, *sulphomargaric*, and *sulpholeic acids*, were discovered by M. Frémy, during his researches on the action of sulphuric acid on olive oil.

HYDROMEL. *Prep.* (P. Cod.) *Honey*, 2 oz.; *boiling water*. 32 oz.; dissolve, and strain. A refreshing and slightly laxative drink; in fevers, hoarseness, sore throats, &c.

HYDROMELLONIC ACID. Prepared by dissolving *mellonide of potassium* in *boiling water*, adding *hydrochloric*, *sulphuric*, or *nitric acid*, and collecting, and drying the precipitate. A yellow powder, soluble in water. It forms *mellonides* with the metallic oxides.

HYDROMETER. Syn. *Areometer*, *Gravimeter.* An instrument for ascertaining the specific gravities of liquids, and hence their strength; the latter being either in inverse or direct proportion to their specific gravities. *Spirituous liquors* and *ammonia water* are examples of the one; and *malt wort*, and *syrups*, of the other. The following are those best known:—

Baumé's Hydrometer or *Areometer*, which is now very generally employed on the continent, generally consists of two distinct instruments. The *one* for liquids *heavier* than water; the *other*, for liquids *lighter* than that fluid. The *first* floats at the 0, or zero of the scale, in distilled water, at the temperature of 58° Fahr., and each degree, marked downwards, indicates a density corresponding to one per cent. of common salt. The *hydrometer* for *liquids lighter than water*, is poised, so that the 0 of the scale is at the bottom of the stem, when it is floating in a solution of 1 oz. of *common salt* in 9 oz. of *water*, and the depth to which it sinks in distilled water shows 10°; the space between these fixed points being equally divided, and the graduation continued upwards to the top of the scale.

The *temperature* at which these instruments were *originally* adjusted by Baumé, was 12·5° Centigrade (54·5° Fahr.) They are now commonly adjusted in this country at 58 or 60° Fahr. Hence arise the discrepancies observable in the published tables of the "correspondence between degrees of Baumé and real specific gravities."

Cartier's Hydrometer which is much used in France for light liquids, has the same point for the zero of its scale as Baumé's, but its degrees are rather smaller; 30° *Baumé* being equal to 32° *Cartier.*

Dicas's Hydrometer closely resembles *Sikes's*, and was formerly very generally adopted in this country for testing the strength of spirit.

Fahrenheit's Hydrometer consists of a hollow ball, with a counterpoise below, and a very slender stem above, terminating in a small dish. The middle, or half-length of the stem, is distinguised by a fine line across it. In this instrument every division of the stem is rejected, and it is immersed in all experiments to the middle of the stem, by placing proper weights in the little dish above. Then, as the part immersed is constantly of the same magnitude, and the whole weight of the hydrometer is known, this last weight, added to the weights in the dish, will be equal to the weight of fluid displaced by the instrument, as all writers on hydrostatics prove. And accordingly, the sp. gravities for the common form of the tables will be had by the proportion—

As the *whole weight of the hydrometer and its load, when adjusted in distilled water*, is to the *number* 1000, so is the *whole weight when adjusted in any other fluid*, to the *number expressing its specific gravity.*

Gay-Lussac's Areometer and *Alcoholmeter*, at once indicated on their stems the strength of the liquid examined, which

merely requires correction for temperature.

Guyton-Morveau's Hydrometer resembles *Fahrenheit's.*

Nicholson's Hydrometer is constructed on the same principle as *Fahrenheit's.* It is chiefly intended for taking the sp. gr. of minerals.

Richter's Hydrometer resembles, for the most part, *Gay-Lussac's.*

Sikes's Hydrometer is that adopted by the Revenue authorities in England for ascertaining the strength of spirits, and has been already fully noticed.

Tralles's Hydrometer resembles *Gay-Lussac's* (nearly).

Twaddell's Hydrometer is much used in the bleaching establishments of Scotland, and in some parts of England. According to this scale, 0 is equal to 1000 or the sp. gr. of *distilled water*, and each degree is equal to ·005; so that by multiplying this number by the number of degrees marked on the scale, and adding 1· the real specific gravity is obtained.

Zanetti's Hydrometers exhibit degrees on their scales, which when multiplied by 10, correspond to real specific gravities.

Obs. Hydrometers, unless manufactured with great care and skill, merely afford approximate results, but which are nevertheless sufficiently correct for all ordinary purposes. They also require several ounces of liquid to float them, and hence cannot be used for very small quantities. Those of Fahrenheit, Nicholson, and Sikes, are the most accurate both in principle and application. They are all employed with a long glass tube, termed a *sample*, *test*, or *hydrometer glass*, in the way already noticed, at page 33; but the thermometer for ascertaining the temperature must be covered with a glass case, or arranged with a folding scale to allow of its immersion in corrosive liquids.

Alcoholmeters, *Elæometers*, *Saccharometers*, *Urinometers*, *&c.*, are simply hydrometers so weighed and graduated, as to adapt them for testing *spirits*, *syrups*, *urine*, *&c.* See *Alcoholmetry* and *Specific Gravity.*

HYDROPATHY. Syn. *Water Cure.* A mode of curing diseases by the copious use of *pure cold water*, both *internally* and *externally*, together with *dry sweating*, and the due regulation of diet, exercise, and clothing. This "treatment of diseases undoubtedly includes powerful therapeutic agents, which in the hands of the educated and honorable practitioner, might be most beneficially resorted to as remedial agents." (Pereira.)

HYDROPERSULPHOCYANIC ACID. A reddish yellow crystalline mass, obtained by fusing *sulphocyanide of potassium* in a *stream of dry hydrochloric acid gas*, in a vessel connected with a suitable receiver. It is purified by solution in *hot alcohol*, from which it is deposited on cooling in a semi-crystalline form.

HYDROPHOBIA. Syn. *Canine Madness; Rabies Canina*,—Lat. A disease which is generally considered as the result of a morbid poison being introduced into the system by the bite of a rabid animal. A clear case of idiopathic or spontaneous hydrophobia has never yet been known to occur in the human subject. Prof. Dick, of Edinburgh, denies the existence of this disease in the lower animals. "What commonly goes by that name is simply an *inflammation of the brain;* and, as the lower animals are not subject to this disease, it is clear that they cannot communicate it to others." "The disease in the case of human beings, is caused by an over-excited imagination, worked upon by the popular delusion, out of doors, of the effects of the bite of a rabid animal." Few persons will, we think, agree with the sweeping assertions of the above writer; although it is generally admitted that the imagination may render parties more susceptible to the accession of the disease.

The common *symptoms of hydrophobia*, are great excitability and horror at the sight of water or the attempt to drink, fever, vomiting, excessive thirst, spitting of viscid saliva, difficult respiration, irregular pulse, convulsions, syncope, delirium, and death.

The whole materia medica has been, unfortunately, unsuccessfully sought without the discovery of a single remedy for this disease, or even a palliative of its severer symptoms. At the London Hospital *hydrocyanic* acid has been repeatedly tried without success. In one case, reported in another quarter, the hydrophobic symptoms gave way under the plentiful administration of the acid; but typhus fever immediately followed, and carried off the patient. (*Lancet*, 1839.) This disease is now justly considered as one of the opprobria of medical science.

The *treatment of the recent bites* of venomous animals has been fully explained at page 134, and need not be repeated here. To prevent secondary or constitutional effects arising, the use of *lemon juice*, or *arsenical solution*, has long been popular. (Graham, and others.) Dr. Buchan remarks that "*vinegar* is of considerable use, and should be taken *freely*."

"At Udina, in Friule, a poor man lying under the frightful tortures of hydrophobia was cured with some *draughts of vinegar*, given him by mistake, instead of another potion. A physician at Padua got intelligence of this event at Udina, and tried the same remedy upon a patient in the hospital, administering to him a *pound of vinegar* in the morning, *another* at noon, and a *third* at sunset, and the man was speedily and perfectly cured." (*The Times.*)

The Rev. A. S. Atcheson, who in consequence of his neighbour, Lord Harborough, having been bitten by a rabid spaniel, was led to pay considerable attention to this subject, also reports favorably as to the use of vinegar in hydrophobia. He has kindly handed us the following morceau, which certainly deserves attention. The appearance of pustules under the tongue preceding an attack of this disease, is a symptom that has not been noticed by previous writers.

"The following *treatment* of *hydrophobia* was originally published by Dr. Muller, late of Vienna, and now of Paris, and was received by him from M. Marochetti, a Russian surgeon, who cured 13 out of 14 patients during his residence in the Ukrane, in 1813. It consists in administering about 1½ pint of a *strong decoction of yellow broom*, daily. The under part of the tongue is to be examined twice a day, and any little pimples or pustules discovered there, are to be opened, and cauterized with a red-hot needle; after which the *decoction* is to be gargled, and a portion swallowed. This treatment is to be continued for 6 weeks or more. The 15th person, treated in the ordinary way, by Marochetti, died.

"In 1818 Marochetti had 26 patients bitten by a rabid dog. In 19 of them, pimples under the tongue followed, and were removed at from the 3d to the 9th day *after the bite.* Marochetti conceives that the hydrophobic poison fixes itself under the tongue, at the orifices of the ducts of the submaxillary gland, situated upon the frænum. If these are not opened within 24 hours after their *first* appearance, the patient is lost."

An aged correspondent of one of the American journals asserts that "it has lately been discovered that a strong decoction made of the *bark of the roots of the white ash*, when drunk as medicine, will cure the bite of a mad dog, and the poison of the rattlesnake. The latter can be made more easily to crawl over live fire-coals than over white ash-leaves; and they are never found in the forest where the white ash grows."

Mr. Blaine, the celebrated veterinarian, recommends the following preparation:—*Fresh leaves of the tree box* and *rue*, of each, 2 *oz.*, *sage*, ½ *oz.*, chop them fine, and boil them in *water*, 1 pint, until reduced to one-half; strain, and press out the liquid; next mash the herbs, and boil them in *new milk*, 1 pint, to one-half; then press, strain, and mix the liquors. *Dose.* One third, every other morning fasting, for a man; make double the quantity for 3 doses for a *horse* or *cow;* one-half or two thirds that for a man suffices for a *middle-sized dog*, and a third, for *smaller dogs.* It produces extreme nausea and distress, and must be given with care.

Mr. Youatt recommends for dogs:—*Leaves of the scutellaria lateriflora*, 40 gr.; *belladonna*, 2½ gr.; both in powder; to be given night and morning for 6 weeks, gradually increasing the dose. The scutellaria laterifolia (*Linn.*) is a labiate plant, common in many parts of North America, where it is highly extolled as both a preventive and remedy for hydrophobia, but, apparently, without any sufficient reason. An infusion is made of 1 dr. or 2 teaspoonfuls of the *powder* in a quart of *hot water*, and half-a-pint is taken for a dose night and morning, with an occasional purgative.

HYDROPHTHORIC ACID. Fluorine. (Ampère.)

HYDROSALICYLIC ACID. See *Salicylous Acid.*

HYDROSELENIC ACID. See *Seleniuretted Hydrogen.*

HYDROSTATIC BALANCE. See *Specific Gravity.*

HYDROSULPHATE. Syn. *Hydrosulphas*,—Lat. See *Hydrogen* (Sulphuretted).

HYDROSULPHOCYANIC ACID. Syn. *Sulphocyanic Acid, Sulphuro-prussic do., Sulphuretted Chyazic do., Sulphide of Cyanogen.* A peculiar acid occurring in the seeds and blossoms of the cruciferæ, and in the saliva of man and sheep. It is also produced artificially.

Prep. 1. By decomposing *sulphocyanide of lead* by *dilute sulphuric acid*, avoiding excess, and throwing down the last portion of lead by *sulphuretted hydrogen.*

2. By decomposing a mixture of 1 part of *sulphocyanide of silver* and 100 parts of *water*, by *sulphuretted hydrogen.*

Prop., &c. It forms a colourless fluid, readily undergoing decomposition by the action of air and heat. With the bases it forms compounds termed *sulphocyanides.*

HYDROSULPHURET. Syn. *Hydro-*

sulphuretum,—Lat. See *Sulphuretted Hydrogen*.

HYDROSULPHURIC ACID. Sulphuretted hydrogen.

HYDROTELLURIC ACID. See *Telluretted Hydrogen*.

HYDROTHIONIC ACID. Sulphuretted Hydrogen.

HYDROTHORAX. Dropsy of the chest. The common *symptoms* are, difficulty of breathing when in a recumbent posture, paleness, cough, thirst, swelling of the legs and feet, quick, irregular, or intermittent pulse, a scarcity of urine, and a fluctuation of water in the chest. The *treatment* is the same as that for anasarca or general dropsy, observing to avoid the use of emetics. See *Dropsy*.

HYDROUS. Hydrated; applied to substances containing combined water; just as *anhydrous* is applied to those which are dry or destitute of water. The prefix *hydro-*, is sometimes incorrectly used for *hydrous* or *hydrated;* but is properly confined to compounds of hydrogen, as *hydrochloric acid*, *hydrobromic acid*, acids formed of chlorine, bromine, and hydrogen. See *Hydrate*.

HYDROXANTHIC ACID. The name originally given by Zeise to xanthic acid.

HYDRURET. Syn. *Hydride*, *Hydroguret; Hydridum*, *Hydruretum*,—Lat. A compound of hydrogen with a metal, or a base.

HYGIENE. Syn. *Hygieine*, *Hygieina*. Health; its preservation, promotion, and restoration. That department of medicine and civil government which relates to health. Pressure of other matter on our columns compels us to omit an article we had prepared on this all-important subject. We must, therefore, content ourselves with referring the reader to the various sub-articles—*Air*, *Bathing*, *Exercise*, *Flannel*, *Food*, *Nutrition*, *Sleep*, *Ventilation*, *Warmth*, &c.

HYGRUSINE. A name given by Bizio to the éleoptène of Berzelius, or the liquid and more volatile portion of essential oils.

HYOCHOLALIC ACID. See *Hyocholic Acid*.

HYOCHOLIC ACID. Syn. *Glycohyocholalic Acid*. A compound peculiar to the gall of pigs, discovered by Strecker and Gundelach.

Prep. The *fresh gall of pigs* is mixed with a *solution of sulphate of soda;* the precipitate is dissolved in *absolute alcohol*, and decolorized by *animal charcoal*. From this solution *ether* throws down *hyocholate of soda*, which, on the addition of *sulphuric acid*, yields *hyocholic acid* as a resinous mass, which is dissolved in *alcohol*, re-precipitated by *water*, and dried. When heated with alkaline solutions, *glycocine* and a new crystalline acid (*hyocholalic acid*) are formed. When boiled with acids it yields *glycocine* and *hyodyslysine*.

HYOSCYAMIA. Syn. *Hyoscyamine*, *Hyoscyamina*, *Daturine*, *Daturia*. An alkaloid discovered by Brandes in common henbane (*hyoscyamus niger*), and since found in *datura stramonium*. It is powerfully narcotic. Chevallier, Brault, and Poggiale, eminent and skilful chemists, have failed to procure it. (Jour. de Pharm.) It may, however, be obtained in prisms. With the acids it forms salts. See *Daturine*.

HYPEROXYMURIATES. See *Chloates*.

HYPNOTICS. Syn. *Hypnotica*. Agents or medicines which induce sleep; as *opium*, *morphia*, *henbane*, *Indian hemp*, *lactucarium*, &c. Agents which prevent sleep are called *agrypnotics* (agrypnotica) or *anthynotics* (anthypnotica). Of the latter, *tea*, *coffee*, *digitalis*, *lemon-juice*, and *vinegar*, are the best known. See *Anodynes* and *Sleep*.

HYPOCHLORIC ACID. Syn. *Peroxide of Chlorine; Acidum Hypochloricum*,—Lat. *Prep.* Powdered *chlorate of potassa* is made into a paste with *concentrated sulphuric acid*, and cooled; this is introduced into a small glass retort, and very cautiously heated by *warm water;* a deep yellow gas is evolved, which is the acid, which can only be collected by displacement, like chlorine, since mercury decomposes, and water absorbs it.

Prop. Hypochloric acid has a powerful odour, quite different from that of chlorine itself. It is exceedingly explosive, being resolved with violence into its elements by a temperature short of the boiling-point of water. Its preparation is, therefore, always attended by danger, and should be performed only on a small scale. It may be liquefied by cold. The aqueous solution (*liquid hypochloric acid*) possesses powerful bleaching properties. Salts of this acid have not yet been obtained.

HYPOCHLORITES. See *Hypochlorous Acid*.

HYPOCHLOROUS ACID. Syn. *Protoxide of Chlorine*, *Euchlorine*. A gaseous compound discovered by Davy in 1811.

Prep. 1. (Davy.) By agitating together a *mixture* of *peroxide of mercury*, 1 part; and *water*, 2 parts; contained in a bottle filled with *chlorine gas*. The filtered liquid is *fluid hypochlorous acid*. It may be purified by distillation at a terperature considerably below 212° Fahr., as at that heat it suffers rapid decomposition.

2. (M. Pelouze.) *Red oxide of mercury* (prepared by precipitation, and dried by exposure to a strong heat), is introduced into a cold glass tube, and *well-washed, dry chlorine gas* is slowly passed over it, and the gas collected by displacement. When the flask or bottle in which the gas is received is exposed to artificial cold by the aid of a mixture of ice and salt, the hypochlorous acid condenses to a deep red liquid, slowly soluble in water, and very subject to explosion.

Prop., &c. It bleaches powerfully, and is readily decomposed by light and contact with various substances, especially powdered glass and other angular bodies. The compounds popularly called *chlorides of lime, soda,* and *potash* are genenerally supposed to be *hypochlorites*, but the point is not definitely determined.

HYPOCHONDRIASIS. Syn. *Hypochondriacism.* The hip or hyp, the vapours, depression of spirits, blue devils. This disease chiefly affects persons of the melancholic temperament, and is commonly induced by hard study, irregular habits of life, want of proper social intercourse, living in close apartments, and insufficient out-of-door exercise. The *treatment* may, in most cases, be similar to that recommended for *dyspepsia* and *gastrodynia;* observing, however, that success depends more on amusing and engaging the mind, and in gradually weaning it from old conceits, than in the mere administration of medicine. When the patient is tormented with a visionary or exaggerated sense of pain, or of some concealed disease, or a whimsical dislike of certain persons, places, or things, or groundless apprehensions of personal danger or poverty, or the conviction of having experienced some dreadful accident or misfortune, the better way is to avoid any direct attempts to alter his opinions, but to endeavour to inspire confidence in some method of relief. Greding mentions the case of a medical man who conceived that his *stomach was full of frogs*, which had been successively spawning, ever since he had bathed when a boy, in a pool in which he had perceived some tadpoles; and he had spent his life in endeavouring to get them removed. One patient, perhaps, fancies himself a *giant;* another, as *heavy as lead;* a third, a *feather*, in continual danger of being blown away by the wind; and a fourth a *piece of glass*, and is hourly fearful of being broken. Marcellus Dentatus mentions a baker of Ferrara, who thought himself a *lump of butter*, and durst not sit in the sun, or come near the fire, for fear of being melted. The writer of this article once knew a man who always put on his coat the wrong side in front, because he conceived his face looked behind him. In such cases it is useless to argue with the patient, as it only causes irritation, and increases the malady. The restoration of the bodily health, and a sudden surprise or change of scene will often effect a cure.

HYPONITRIC ACID. See *Nitrous Acid.*

HYPONITROUS ACID. Syn. *Nitrous Acid* (of some writers); *Acidum Hyponitrosum*,—Lat. A highly volatile liquid, gaseous at common temperatures, first obtained by Gay-Lussac, by confining a mixture of binoxide of nitrogen in excess, and *oxygen gas*, in a glass tube over a concentrated solution of pure potassa in the mercurial pneumatic trough.

Prep. 1. *Binoxide of nitrogen*, 4 parts; *oxygen*, 1 part; (both quite dry) are mixed together, and the resulting orange-coloured fumes are exposed to intense cold, which condenses them into a green liquid.

2. (Liebig.) *Nitric acid* (sp. gr., 1·3), 10 parts; is poured on *starch* or *potato farina*, 1 part, contained in a spacious retort, and a gentle heat applied by means of a water-bath, when "pure hyponitrous acid is disengaged," and may either be employed in the state of gas or condensed by cold, as before. This is the method adopted in the preparation of nitrous or hyponitrous ether.

Prop., &c. This acid contains 14 parts (1 equiv.) of nitrogen, and 24 parts (3 eq.) of oxygen. At 0° Fahr. it is a colourless liquid, but is green at higher temperatures, whilst liquid, and rapidly volatilizes in orange-coloured fumes. It is decomposed by contact with water and the bases, and does not unite directly with the metallic oxides. The *earthy* and *alkaline hyponitrates* may, however, be indirectly formed by exposing the corresponding nitrates to a gentle red heat.

HYPOPHOSPHORIC ACID. A name erroneously given by M. Dulong to a mixture of the phosphoric and phosphorous acids.

HYPOPHOSPHOROUS ACID. A peculiar viscid liquid discovered by Dulong, in 1816, and obtained by treating *phosphuret of barium* with *water*, and as soon as the phosphuretted hydrogen has escaped, filtering, throwing down the baryta with *dilute sulphuric acid* and again filtering and evaporating. It is a powerful deoxidizing agent, and forms salts with the bases called *hypophosphites*. The *hypophosphites of the*

alkalies may be prepared by precipitating an earthy hypophosphite with an alkaline carbonate; or by directly neutralizing the acid with those carbonates. The *earthy hypophosphites* may be formed by boiling the earth in a caustic state along with water and a few fragments of phosphorus, filtering, and evaporating. All the hypophosphites are soluble in water, and those of the alkalies, both in alcohol and water; they are all decomposed by heat.

HYPOSULPHATE. Syn. *Hyposulphas*,—Lat. A salt of hyposulphuric acid.

HYPOSULPHITE. Syn. *Hyposulphis*,—Lat. A salt of hyposulphurous acid.

HYPOSULPHOBENZIC ACID. Syn. *Hyposulphobenzidic Acid.* A sour liquid or crystals obtained by decomposing *hyposulphobenzidate of copper* by *sulphuretted hydrogen.* It forms salts with the bases termed *hyposulphobenzidates. Hyposulphobenzidate of baryta* may be formed by saturating fuming oil of vitriol with benzole, adding water, filtering, to separate the *sulphobenzide*, neutralizing the filtered liquid with carbonate of baryta, again filtering, evaporating, and crystallizing. *Hyposulphobenzidate of copper* may be obtained by precipitating the last salt with sulphate of copper, filtering, evaporating, and crystallizing.

HYPOSULPHOBENZOIC ACID. Syn. *Sulphobenzoic Acid. Prep.* Accurately precipitate a *solution of acid hyposulphobenzoate of baryta* with *sulphuric acid*, filter, evaporate first over the open fire, and then *in vacuo* over sulphuric acid. Crystalline, deliquescent, sour; forming salts called *sulphobenzoates* or *hyposulphobenzoates*, with the bases. *Sulphobenzoate of baryta* may be made by conducting the vapour of anhydrous sulphuric acid into a dry receiver, containing crystals of benzoic acid, and placed in a freezing mixture. As soon as a translucent mass is formed, dissolve it in water, decant the clear, neutralize with carbonate of baryta, evaporate, and add some hydrochloric acid, when crystals will form as the solution cools. It may be decoloured by animal charcoal, and purified from hydrochloric acid by repeatedly redissolving and crystallizing it.

HYPOSULPHOINDIGOIC ACID. A name given by Berzelius to one of the acids obtained by precipitating *sulphate of indigo* with *carbonate of potassa.*

HYPOSULPHURIC ACID. Syn. *Dithionic Acid; Acidum Hyposulphuricum*,—Lat. An acid compound of sulphur and oxygen, discovered by Welter and Gay-Lussac. It is prepared by passing *sulphurous acid gas* through *water* holding in suspension *black oxide of manganese*, in fine powder. The manganese is subsequently precipitated with *baryta*, added in excess, and a current of *carbonic acid gas* is passed through the liquid, which is next filtered, and evaporated, when crystals of *hyposulphate of baryta* are obtained. These, when dissolved, and carefully neutralized with *sulphuric acid*, yield a *solution of hyposulphuric acid.* It may be concentrated until its sp. gr. is 1·35. Hyposulphuric acid neutralizes the alkalies and earths forming salts called *hyposulphates*, which are soluble. See *Hyposulphate of Soda, Trithionic Acid, &c.*

HYPOSULPHUROUS ACID. This compound has never been isolated. The *hyposulphites*, or salts formed by its union with the bases, may either be obtained by digesting *sulphur* in *solutions of the sulphites*, or by passing *sulphurous acid gas* into *alkaline solutions.* The *hyposulphites of potassa* and *soda* possess the remarkable property of dissolving a large quantity of chloride of silver, and some other metallic compounds; hence their use in the art of photography. See *Hyposulphite of Soda, &c.*

HYRACEUM. A substance produced by the Cape badger (*hyrax capensis*), and proposed as a substitute for castoreum. "I believe it to be inert and useless." (Dr. Pereira.)

HYSTERICS. Syn. *Hysteria*,—Lat. The *treatment* of this disease varies with the causes and the symptoms. Bleeding, cupping, and depletives, are generally had recourse to, in robust and plethoric habits; and stimulants and tonics, in those of a weakly or relaxed constitution. Affusion of cold water, and nasal stimulants will frequently remove the fit, in mild cases. Exercise, proper amusements, and regular hours and diet, are the best preventives. See *Antihysteric Draught, Hydrocyanic do., &c.*

ICE. Syn. *Glacies*,—Lat. Water, under ordinary conditions, crystallizes or freezes, at 32° Fahr. During this transition it expands with irresistible violence, and separates from all soluble matter previously combined with it. The density of ice is found to be only 0·950; that of water being 1·000. Coloured water and salt water by freezing produce colourless and fresh ice, and clean solid ice, when thawed, furnishes water equal in purity to that which has been distilled. To effect this purification perfectly, the whole mass of water must be slowly and completely frozen, so as to prevent the

accumulation of blebs or air-bubbles, and the entanglement of any uncongealed or ejected matter in its pores.

The *use of ice* in the preparation of *ice-creams, iced-liquors, &c.*, is noticed elsewhere. The confectioner collects his ice as early as possible during the winter, and stores it in a *well-drained* well or excavation, somewhat of the form of an inverted sugar-loaf, contained in a small shed or building called an *ice-house*. This building should always be situated on a dry sandy soil, and, if possible, on an eminence. The door should be on the north side, and the roof should be conical and thickly thatched with straw.

In *medicine*, ice is frequently employed *externally* in inflammation of the brain, to resolve inflammation, to stop hemorrhage, to constringe relaxed parts, and as an anodyne, to deaden pain. For these purposes it is pounded small, in a cloth, and placed in a bladder or bag of gauze (*ice-cap, ice-poultice*) before applying it. *Internally*, ice or ice-cold water has been given with advantage in heartburn, typhus, inflammation and spasms of the stomach, to check the vomiting in cholera, and to arrest hemorrhage, whether bronchial, gastric, nasal, or uterine. Small lumps of ice, or a small glassful of pounded ice-and-water will often temporarily restore the tone of the stomach and nervous system during hot weather, when all other means fail. *Ice-creams*, taken in moderation, act in the same way.

In the warmer climates of Europe an *ice-house* or an *ice-safe* (a *refrigerator*) is a necessary appendage to every respectable dwelling, not merely for the purpose of pleasing the palate with iced beverages, but to enable the residents to preserve their provisions (fish, meat, game, milk, butter, &c.) in a wholesome state from day to day.

ICES. Syn. *Ice-creams.* These are commonly composed of cream or sweetened water, variously flavoured, and congealed by ice or a freezing mixture. Sometimes, instead of cream, the materials of a custard are used. The mixed ingredients are placed in a tin furnished with a handle at top, called a "*freezer*," or "*freezing-pot*," which is then plunged into a bucket containing *salt-and-ice*, (*ice* broken small, and mixed with about half its weight of *common salt*), and is kept in rapid motion, backwards and forwards, until its contents are frozen. As the cream congeals and adheres to the sides, it is broken down with the "*ice-spoon*," so that the whole may be equally exposed to the cold. As the salt and ice in the tub melt, more is added, until the process is finished. The "*ice-pot*" with the cream in it, is next placed in a leaden "*ice-stand*," is at once surrounded with a mixture of ice and salt, and closely covered over. In this state it is carried into the shop. The glasses are filled as required for immediate use, and should have been previously made as cold as possible.

Plain ice-cream or *cream for icing*, is commonly made by one or other of the following formulæ :—

1. *New milk*, 2 pints; *yelks of* 6 *eggs; white sugar*, 4 *oz.*; mix, strain, heat gently, and cool gradually.

2. *Cream*, 1 pint; *sugar*, 4 *oz.*; mix, as above.

3. *Cream* and *milk*, of each, 1 pint; *white sugar*, ½ *lb.*

Flavoured "*ice-creams*" are made by mixing "*cream for icing*" with half its weight of *mashed* or *preserved fruit*, previously rubbed through a clean hair sieve; or, when the flavour depends on the *juice of fruit* or on *essential oil*, by adding a sufficient quantity of such substances. *Raspberry* and *strawberry-ices* are made according to the former method; *lemon, orange, noyeau*, and *almond ices*, by the latter method. In the same way any other article besides cream may be frozen.

Chocolate for Icing is made by rubbing 1 *oz.* of *chocolate* to a paste with a tablespoonful of *hot milk*, and then adding "*cream for icing*," 1 pint.

Coffee for Icing is made of *cream for icing*, 1 quart, to which a small tea-cupful of the *strongest possible clarified coffee* has been added, together with 2 *oz.* of *sugar*, and the *yelks* of 3 or 4 *eggs*.

ICHTHYOSIS. See *Fish-skin Disease.*

ICING (for Cakes). Syn. *Sugar Ice.* The covering of concreted sugar with which the confectioners adorn their cakes. *Prep.* Beat the *white of eggs* to a full froth, with a little rose or orange-flower water; then add, gradually, as much *finely-powdered sugar* as will make it thick enough, beating it well all the time. For *use*, dust the cakes over with flour, then gently rub it off, lay on the icing with a flat knife, stick on the ornaments while it is wet, and place it in the oven for a few minutes to harden, but not long enough to discolour it. It may be tinged of various shades by the addition of the proper "*stains.*"

IDRIALINE. A fusible, inflammable substance, found by Dumas, associated with the native cinnabar of the mines of Idria, in Carniola. It is extracted from the *ore* by means of *oil of turpentine.* It

is only slightly soluble in alcohol and ether. When pure it is white and crystalline.

IDRYLE. A hydrocarbon generally found associated with idrialine.

IGASURIC ACID. Syn. *Strychnic Acid; Acidum Igasuricum*,—Lat. An acid discovered by Pelletier and Caventou, associated with strychnine in St. Ignatius' bean and nux vomica. It may be obtained by digesting the *rasped* or *ground beans* first in *ether*, and then in *boiling alcohol*, evaporating the latter decoction to dryness, diffusing the residuum through *water*, adding a little *carbonate of magnesia*, again boiling for some minutes, filtering, washing the powder with *cold water*, and digesting it in *alcohol*, and filtering. The *igasurate of magnesia* thus obtained is dissolved in *boiling water*, the solution decomposed by *acetate of lead*, and the precipitate (*igasurate of lead*), after being washed and diffused through *distilled water*, is decomposed by *sulphuretted hydrogen*. The solution thus obtained yields crystals (*igasuric acid*) on being evaporated. It is soluble in both water and alcohol.

IGASURINE. A peculiar yellow colouring matter found in the seeds and bark of nux vomica. It is reddened by nitric acid and chlorine. According to M. Desnoix, it is a very energetic base, and is more easily reddened by nitric acid than even brucine itself.

IGNITION. In the *laboratory* this term is commonly applied to the state or act of heating or being heated to redness or luminousness. See *Calcination*.

IGREUSINE. The fluid part of volatile oils.

ILLICINE. Syn. *Illicina*. An unexamined substance obtained from the leaves of the common holly (*ilex aquifolium*,—Linn.)

Prep. The *filtered decoction* is boiled for about 30 minutes with *fresh-burnt prepared animal charcoal*, after which the whole is set aside to cool; when cold the liquid portion is poured off from the charcoal, which is then collected on a filter, drained, washed with a little ice-cold water, and dried; it is next digested for some time in *boiling alcohol*, and the filtered tincture is gently evaporated to dryness. *Dose.* 6 to 18 gr.; in intermittents, gout, &c.

ILLUMINATION. Flame is gas or vapour in a state of combustion. When pure, the light emitted by it is exceedingly feeble. The luminosity of flame depends on the precipitation and ignition of solid carbon within it, a matter which depends both on the nature of the burning material and on the supply of atmospheric oxygen being duly regulated. The flame of substances destitute of carbon, or in which this development of solid matter does not take place, is pale or only feebly luminous. On the other hand, the quantity of heat evolved by the flame of any substance, presuming the combustion is complete, is constantly in inverse ratio to that of the light emitted by it. Pure hydrogen burns with a pale, smokeless flame, but with the production of considerable heat; whilst wax and light gas develope less heat during combustion, but burn with considerable brilliancy. "The light of a flame may be increased by diminishing its heat, or the intensity of its combustion; and conversely, the heat of a flame, may be increased by diminishing its light." To give the greatest degree of luminosity to flame, the supply of air must be proportioned to the character of the burning substance, and be insufficient for the instantaneous combustion of the evolved gases; in which case, the hydrogen takes all the oxygen, and the larger portion of the carbon is precipitated, and burnt in the solid form, at some little distance within the outer surface of the flame. When the supply of air is sufficient for the immediate and complete combustion of the *whole* of the combustible matter, no such precipitation takes place, and the flame is neither white nor brilliant. The richest coal gas mixed with sufficient air to convert all its hydrogen and carbon into water and carbonic acid, explodes with a pale blue flash; yet the same gas, when consumed in the ordinary way, burns with a rich white flame. When the supply of air is insufficient to cause the combustion of the newly-formed solid carbon at the instant of its development, and whilst it is in an incandescent state, the flame becomes red and smoky, and unburnt sooty particles are thrown off. The same occurs when the temperature of any portion of the hydrogen is reduced below that intensity required for the combustion of the newly separated charcoal. Solid bodies, as tallow, oils, and fats, which burn with flame, are converted into the state of gas by the heat required to kindle them, and it is this gaseous matter which suffers combustion, and not the substance which produces it. The existence of these facts may be easily demonstrated by means of a common candle or gas-burner. See *Light* (Artificial), *&c.*

ILLUTATION. See *Mud Bath*.

IMAGINATION. The influence of the imagination both in the production and

cure of disease, has been long admitted by medical practitioners. It is probably the most powerful therapeutic agent known. "Extraordinary cures have been ascribed to inert and useless means, when, in fact, they were referable to the influence of the imagination." (Dr. Pereira.)

IMPERATORINE. A neutral, fusible, and acrid-tasted substance, extracted by means of ether from the roots of imperatoria ostruthium. It is insoluble in water.

IMPERIAL. Syn. *Potus Imperialis, Ptisana I.*,—Lat. *Prep.* 1. *Cream of tartar*, ½ *oz.*; 1 *lemon*, sliced; *lump sugar*, 2 *oz.*; *boiling water*, 1 quart; infuse, with occasional stirring until cold, then pour off the clear portion for use.

2. A *lemon*, sliced; *sugar*, 1 *oz.*; *boiling water*, 1 pint.

3. *Yellow rind* and *juice of lemon*; *citric acid*, 1 *dr.*; *sugar*, 2½ *oz.*; *hot water* (which has been boiled), 1 quart; as No. 1. Refrigerant and slightly diuretic. *Used* as a common drink in fevers, dropsy, &c.; and as a summer beverage.

IMPERMEABLE. A term recently applied to waterproof textile fabrics. See *Waterproofing.*

IMPETIGO. See *Eruptions* and *Tetters.*

IMPLEMENTS (Agricultural). "Almost all the operations of agriculture may be performed by the plough, the harrow, the scythe, and the flail; and these are the sole implements in the primitive agriculture of all countries. With the progress of improvement, many other implements (and machines) have been introduced; the more remarkable of which are the *drill plough*, the *horse hoe*, the *winnowing machine*, the *threshing machine*, the *hay-making machine*, and the *reaping machine*. The object of all these implements and machines is to abridge human labour, and to perform the different operations to which they are applied, with a greater degree of rapidity, and in a more perfect manner than before." (Loudon.) On the *perfection* of *agricultural implements* and *machines* depends much of the improvement of which this art is susceptible. See *Agriculture, &c.*

IMPROVING. The trade name for "doctoring," "adulterating," or "lowering" the quality of any substance with the view of cheapening it, or increasing its bulk. See *Wines, &c.*

INCENSE. *Prep.* 1. *Olibanum*, 2 or 3 parts; *gum benzoin*, 1 part.

2. *Olibanum*, 7 parts; *gum benzoin*, 2 parts; *cascarilla*, 1 part. Placed on a hot plate or burned, it exhales an agreeable perfume. *Used* in some of the rituals of the Roman catholic church.

INCINERATION. The reduction of organic substances to ashes by combustion. See *Calcination.*

INCOMBUSTIBILITY. The quality of being incapable of being kindled, or of being consumed by fire. Substances possessing this property are said to be "*incombustible*" or "*fire-proof.*"

INCOMBUSTIBLE CLOTH. Cloth made of the fibres of asbestos by weaving, will bear a considerable heat without injury. *Cotton* and *linen fabrics* prepared with a *solution* of *borax*, *phosphate of soda*, *phosphate of ammonia*, or *sal ammoniac*, may be placed in contact with ignited bodies without their suffering active combustion, or bursting into flame. These substances act by forming a species of glaze on the surface of the fibres, which excludes them from the air. They do not, however, prevent carbonization taking place, when the temperature is sufficiently high. *Solutions* of *alum*, *sea salt*, *&c.*, have also been used for the same purpose. It is by a knowledge of this property of culinary salt, that *jugglers* are enabled to perform the common trick of burning a thread of cotton whilst supporting a ring or a small key, without the latter falling to the ground. The cotton is reduced to a cinder, but from the action of the salt, its fibres still retain sufficient tenacity to support a light weight.

The addition of about 1 *oz.* of *alum* or *sal ammoniac* to the last water used to rinse a *lady's dress*, or a set of *bed furniture*, or a less quantity added to the starch used to stiffen them, renders them uninflammable, or at least so little combustible that they will not *readily* take fire; and if kindled, are *slowly* consumed *without flame.* Had this precaution been adopted, the late lamentable accident to a talented young actress at one of our national theatres might have been avoided.

Paper, *wood*, *&c.*, may be rendered comparatively incombustible by soaking them in any of the above solutions. See *Asbestos*, *Fires*, *&c.*

INCOMBUSTIBLE STUCCO. *Prep.* From *moist gravelly earth* (or *sand*), previously washed, and sifted to the required degree of fineness, made into *stucco* with the following composition:—*pearl-ashes*, 2 parts; (dissolved in) *water*, 5 parts; *common clay*, 1 part. This is said to cost about 1*s.* 6*d.* per hundred square feet, and to have been tried on a large scale and

found to answer well. It is used for wood, &c.

INCOMPATIBLES. Substances which exert a chemical action on each other, and cannot therefore, with propriety, be prescribed together in the same formula or prescription. The principles on which we should act to avoid falling into the last-named source of error, are briefly developed under the heads "*Affinity*" and "*Decomposition.*" To this we may add, that if a substance is endowed with well marked therapeutical or poisonous properties, independent of those which may exert a chemical effect upon the tissues, its mode of action will neither be changed nor destroyed by the combinations which it forms; provided always that the new compounds are not *insoluble* in water.

"It is not necessary to give two incompatible medicines at the same time, in order to produce decomposition; it is sufficient if they are given within a very short interval of each other. Thus a sick person, who has been treated with *lead* externally, or even internally, will present a discoloration of the skin, if he takes a sulphur bath four or five days after the lead treatment has been discontinued. If a person is rubbed with *iodide of potassium* shortly after having applied *Vigo's plaster* (plaster of ammoniacum with mercury), or the *Neapolitan ointment* (mercurial ointment), iodide of mercury and caustic potash will be formed, which will cause vesication. So also vomiting occurs if *lemonade* made with *tartaric acid* is taken five or six days after the administration of *white oxide of antimony.*" (Trousseau & Reveil.)

Lists of Incompatibles are published in many pharmaceutical and medical works, but are in reality of little use beyond illustrating rules and principles which are familiar to every chemist, and which every prescriber should also be intimately acquainted with.

INCRUSTATION (of Steam Boilers). Many methods have at various times been proposed to prevent the formation of deposits in steam boilers. When water abounding in *earthy carbonates* (as Thames water) is used, the plan recommended by Dr. Ritterband, will, we believe, be found one of the best and least expensive. It consists in simply throwing a little *sal ammoniac* into the boiler, by which carbonate of ammonia is formed, which passes off with the steam, and *chloride of calcium* (muriate of lime), which remains in solution. When the water is permanently hard (*i. e.*, contains sulphate of lime) this method is inapplicable. The *common plan* adopted by working engineers to prevent incrustations from either variety of water, is, on each occasion of cleaning out the boiler, to introduce some substance, which by its mechanical action shall prevent the precipitated earthy matter caking together, or adhering to the boiler plates. Some *common tar*, *bitumen*, or *pitch*, appears to answer well under most circumstances. Mr. Ira Hill recommends the use of 3 or 4 shovelfuls of *coarse sawdust.* He states, that after adopting the use of this article, he never had any difficulty from lime, although using water strongly impregnated with it, and has always found the inside of his boilers as smooth as if just oiled. We have worked a powerful boiler daily for 6 months without opening the "*man-hole,*" after throwing a few pounds of potatoes into it. In all cases, when the earthy matter can be kept in a state of solution, or precipitated in a pulverulent form, it is easily removed from the boiler by what engineers term "priming," which is allowing the hot water to be blown over with the steam, so that, after a sufficient time, the whole original contents of the boiler are removed, and replaced by fresh water. Before doing so, however, it is of consequence to cut off the communication with the cylinders, and to open the waste-steam cock.

INCUBATION (Artificial). This has been practised by the Egyptians from a very remote period. M. Bonnemain has the honour of having introduced this art to Western Europe, in 1775, and having been the first to pursue it successfully on the commercial scale. The source of heat employed by him was a circulatory hot water apparatus, and the temperature maintained by it, 100° Fahr. His plan was to introduce, daily, 1-20th only of the eggs, the apparatus was capable of receiving, so that on the 21st day the first chickens were hatched, and a like number every day afterwards as long as the supply of eggs was kept up. Among the trays containing the eggs, he placed saucers of water, to compensate for the absence of moisture derived in natural incubation by transpiration from the body of the hen. The chickens, as soon hatched, were transfered to a "nursery" or "chick-room," also artificially heated, and were fed with crushed millet seed. Several attempts have been made of late years to introduce artificial incubation into this country, with variable success. Those interested in the subject should pay a visit to Mr. Cantelo's Egg-hatching Exhibition in Leicester Square.

INCUBUS. See *Nightmare.*

INDIAN RUBBER. See *Caoutchouc.*

INDIGESTION. Syn. *Dyspepsy; Dyspepsia,* — Lat. This complaint pervades every rank of society, and is, perhaps, of all others, the most general. Few indeed are there, who wholly escape it, in one or other of its forms. The *common* symptoms of dyspepsia, are—want of appetite, sudden and transient distensions of the stomach, frequent eructations, heartburn, stomachic pains, occasional vomiting, and, frequently, costiveness or diarrhœa. Sometimes the head is affected, and dimness of sight, double vision, muscæ volitantes, and slight vertigo, are experienced, along with a multitude of other symptoms, depending on a derangement of the functions of the *nervous system.*

The *causes* of *dyspepsia* are numerous. In the *higher ranks of society* it is a common consequence of over indulgence in the luxuries of the table, of late hours, or of the want of proper exercise, both of body and mind. In the *studious*, and *those who lead a sedentary life*, it is usually caused by excessive mental exertion or anxiety, or by the fatigues of business, and the want of sufficient bodily exertion, and of pure air. In the *lower orders of society*, it generally results from inebriety, or a deficiency of proper food and clothing, bad ventilation, &c.; and is not unfrequently occasioned by the physical powers being over-taxed, especially soon after meals.

The *treatment* of *dyspepsia* depends less on medicine than on the adoption of regular habits of life. Moderation in eating, drinking, and the indulgence of the passions; early rising, due exercise, and retiring to rest at an early hour, will do much to restore the tone both of the stomach and nerves. Excessive study and mental exertion should be avoided, and recourse should frequently be had to society, and amusements of a lively and interesting character. If the bowels are confined, *mild aperients* should be taken, and if diarrhœa is present, *antacids* and *absorbents* may be had recourse to with advantage. The stomach may be strengthened by the use of *mild bitters*, *tonics*, and *stimulants*, and *sea bathing*, or the *shower* or *tepid bath* may be taken, when convenient, to strengthen the nervous system. When *dyspepsia* is a *secondary* or *symptomatic disease*, the cause should be sought out, and the treatment varied accordingly. *Among* the *aperient medicines* most suitable to dyspepsia, may be mentioned—*Epsom salts*, *phosphate of soda*, and *Seidlitz powders*, each of which should be taken largely diluted with water. An occasional dose of the "*Abernethy Medicines*" (see *page* 1) has also been recommended. Among *antacids*, are the *bicarbonates* and *carbonates of potassa* and *soda*, either of which may be taken in doses of half a tea-spoonful dissolved in water; or if the spirits are depressed, one or two tea-spoonfuls of spirits of *sal volatile* will be more appropriate; and in cases *accompanied* by *diarrhœa*, a little *prepared chalk*. As *bitters*, the *compound infusion of orange peel*, or of *gentian*, are excellent. As *tonics*, small doses of *bark*, or of *disulphate of quinine*, to which *chalybeates* may be added, if there is pallor of countenance, or a low pulse, with no disposition to fever or headache.

When *dyspepsia* is complicated with *hysteria*, *hypochondriasis*, or *chlorosis*, the treatment noticed under those heads may be conjoined to that above recommended. When it depends on *constipation*, or a *deficiency of bile*, the mildest and most effective of all remedies will be found supplied in *inspissated ox-gall.* "In all cases of incipient constipation, ox-gall is a remedy of undoubted efficacy; and even in protracted cases, when hope has almost fled—but where evidences of strangulation are not unequivocally manifested, it should never be omitted by the practitioner. In *habitual* or *chronic constipation*, accompanied by *indigestion*, *clay-coloured stools*, and a *feeling of oppression after food has been taken*, it acts with almost specific certainty. When, however, the liver begins to assume its healthy action, its employment should be discontinued, as it will then produce all the symptoms of regurgitation of bile into the stomach. This state will be readily recognized as a favorable omen of returning power." (Dr. Allnatt, *Lancet*, 1845.) See *Draughts*, *Mixtures*, *Pills*, *&c.*

INDIGO. Syn. *Indicum*, *Pigmentum Indicum*,—Lat. An insoluble blue substance obtained from the leaves and young shoots of several species of *indigofera*, *isatis*, and *nerium*. These are soaked either in *cold water*, or, still better, in *water kept at about* 100° Fahr., until the liquor becomes deep green; the latter is then drawn off, and beaten or churned till blue flakes appear; *lime-water* is next added, and after a time, the yellow liquor is drawn off; the blue sediment is, lastly, dried, and formed into small lumps.

Prop. Tasteless; scentless; of a dark blue colour passing into purple; when rubbed with a smooth hard body, it assumes a coppery hue; insoluble in water, cold alcohol, ether, alkalies, hydrochloric acid,

dilute sulphuric acid, and the cold fixed and volatile oils; slightly soluble in boiling alcohol and oils; freely soluble in concentrated sulphuric acid, and, when decoloured or reduced by contact with deoxidizing substances, in alkaline lyes; soluble in creasote; its colour is destroyed by chromic acid, nitric acid, and chlorine; when suddenly heated it gives off rich purple fumes, which condense into brilliant copper-coloured needles.

Pur. The best indigo (*"fine blue"*) is that which has the deepest purple colour, and assumes the brightest coppery-hue when rubbed with the nail: its fracture is homogeneous, compact, fine-grained, and coppery; its powder is of an intensely deep blue tint, and light enough to swim on water; and it leaves only a fine streak when rubbed upon a piece of white paper. In general, when indigo is in hard, dry lumps of a dark colour, it is considered of bad or inferior quality. Indigo, when in hard or brittle lumps, or in dust or small bits, is often adulterated with sand, pulverized slate, and other earthy substances. The most certain test of its value as a dye-stuff, is an assay for its *indigotine.* (See *below.*)

Assay 1. Take 20 gr. of the *sample of indigo* for examination; 40 gr. of *pure quicklime* (made by burning white marble); and 1000 grains-measure of *distilled water;* with part of the water slake the lime; rub the indigo to an impalpable powder in a clean wedgewood-ware mortar, and gradually add to it a little of the water, so as to form a thin paste; then add the slaked lime, and triturate the mixture for some time, gradually adding more water; next introduce the triturated mass into a large flask, taking great care not to spill or waste anything, and wash out the mortar with the remaining portion of the measured water, and pour the washings into the flask; the latter, with its contents, are then to be exposed for several hours at a temperature ranging from 180° to 190° Fahr., by keeping it immersed in a water-bath heated to near the boiling-point; next add a little (say 30 or 35 gr.) of *protosulphate of iron* (in fine powder), and agitate the little until it is dissolved; then cork up the flask closely, and again place it in the water-bath, and allow it gradually to cool there, occasionally shaking it to assist the reaction of the ingredients on each other; when it has cooled, decant the clear green liquor from the sediment into an open *graduated alkalimeter* up to a certain point, which is then noted; to promote the oxidization of the colouring matter, and to keep the lime and other foreign bodies in solution, a *little hydrochloric acid* should be added; as soon as the liquor has cleared, throw the whole on a *weighed filter*, and collect the precipitate, which is *pure indigo*, wash it, dry it by the heat of boiling water, and then weigh it. The per centage of pure indigo is then ascertained as follows:—Suppose, for example, that 40 divisions (400 grains-measure) have been poured into the alkalimeter, and by oxidation have yielded 3 gr. of indigo, the sample under examination contained 37½ per cent. of *pure indigo.* For

400 gr. : 3 gr. :: 1000 gr. : 7½ gr.

which, being multiplied by 5 (20 gr. only being examined) is equal to 37½ gr.

2. (M. Dana's Process.) This consists in boiling a weighed sample in *water* along with *carbonate of soda*, adding *protochloride of tin* from time to time, and precipitating the clear solution with a *solution* of *bichromate of potassa;* the whole is then thrown on a filter, and the precipitate after being washed, first with *dilute hydrochloric acid*, and next with *pure water*, is dried, and weighed; it is then incinerated; the *weight of the ashes*, deducted from the *original weight of the dried precipitate*, indicates the proportion of *pure indigo.*

3. (*Fritsche's Process.*) 25 gr. each of *indigo*, and *grape sugar*, are put into a bottle capable of containing 1000 gr. of liquor; the bottle is half filled with *boiling alcohol*, and the other half with *alcohol* previously mixed with 37½ gr. of a very concentrated *solution of caustic soda;* the whole is then strongly agitated, and after being left at rest for some time, and becoming bright, is decanted into another bottle; whilst protected from contact with the air, this liquor is of a yellowish-red colour, and so dark that it appears transparent only when held before the light, but as soon as it is exposed to the influence of atmospheric oxygen it becomes purple, and quickly passes through the different shades of red, violet, and blue, until the whole of the *indigotine* is deposited. This appears under the form of minute scales, or of a very fine, light, crystalline powder. This is collected on a filter and washed first with a little *rectified* spirit and then *thoroughly* with *water*, after which it is dried by the heat of *boiling water*, and weighed.

Commercial indigo seldom contains so much as 50% of *indigotine* or *pure indigo blue.*

Uses, &c. Indigo is one of our most valuable blue pigments and dye-stuffs. In

medicine it has been employed in various affections of a spasmodic character, as chorea, convulsions, epilepsy, hysteria, &c. In large quantities it often induces giddiness, vomiting, and diarrhœa; and when continued for some time, muscular twitchings, resembling those arising from strychnine. *Dose.* Beginning at about 15 gr., and gradually increased to 1, 2, or even 3 dr., at which it should be continued for 3 or 4 months; made into an electuary with honey or sugar, to which some aromatic may be added.

Obs. Indigo, though apparently a very simple substance, is composed of several distinct principles, and by the action of acids, alkalies, oxygen, chlorine, &c., yields several other substances possessing considerable interest. The following are the chief of these compounds of which the word indigo constitutes a portion of the name:—

INDIGO (Sulphate of). Syn. *Sulphate of Indigotine, Sulphindylic Acid, Sulphindigotic Acid.* This is prepared by gradually adding *indigo* (in fine powder), 1 part, to *smoking Sulphuric acid*, 5 parts, or *oil of vitriol*, 8 parts, contained in a stone-ware vessel placed in a tub of *very cold water*, to prevent the mixture heating; the ingredients are stirred together with a glass rod at short intervals until the solution is complete, after which the whole is allowed to repose for about 48 hours, by which time it becomes a homogeneous pasty mass of an intense blue colour, which in a dull light appears nearly black. In this state it forms "*Barth's blue*," or the "*chemic blue*" or "*indigo composition*" of the dyer. Diluted with about twice its weight of soft water, it is converted into the "*Saxon blue*" or "*liquid blue*" of the shops, also used for dyeing. If during the addition of the powdered indigo to the acid the mixture becomes heated, a part of the indigo blue is decomposed, sulphurous acid and "*indigo green*" being produced.

Obs. When sulphate of indigo is diffused through a large quantity of water, nearly boiling, and *wool* is macerated in it for some time, the latter absorbs the whole of the indigo-sulphate and is dyed blue, whilst the liquor assumes a greenish-blue colour. Wool so prepared, when well rinsed in water, and boiled for some minutes in a large quantity of that liquid containing $1\frac{0}{0}$ or $2\frac{0}{0}$ of *carbonate of potassa*, or a quantity equal to about 1-3rd that of the indigo originally employed, gives up its blue colour, but retains the indigo-red in its fibres. The liquid is now a rich blue-coloured solution of "*ceruleo-sulphate of potassa*," from which the salt may be obtained by cautious evaporation. This compound is prepared on the *large scale*, by diluting *sulphate of indigo* with about 12 times its weight of *soft water*, and imperfectly saturating the solution with *carbonate of potassa;* the ceruleo-sulphate falls down as a dark-blue coppery-looking powder, soluble in 140 parts of cold water, and in about 90 parts of boiling water. This substance is kept both in the *moist* and *dry state*, and is known in commerce under the respective names of "*distilled indigo*," "*precipitated do.*," "*soluble do.*," "*indigo paste*," "*blue carmine*," "*distilled blue*," "*soluble blue*," &c. It is extensively used in *dyeing;* and when mixed with *starch*, whilst in the moist state, and made into cakes or knobs, it constitutes the finest variety of the "*blue*" used by laundresses for tinging linen. "*Ceruleo-sulphate of ammonia*" and "*ceruleo-sulphate of soda*" may be prepared in the same way as the potash-salt, by substituting the *carbonates of those bases* for carbonate of potassa. The ammonia salt is very soluble. The "*ceruleo-sulphates of lime*" and "*alumina*" are also soluble in water.

INDIGO BLUE. See *Indigotine.*

INDIGO BROWN. Obtained from *powdered indigo* by treating it first with *dilute sulphuric acid*, and then with a hot *strong caustic lye*, which must afterwards be neutralized with *acetic acid*, evaporated to dryness, and digested in *alcohol*, to dissolve out acetate of potassa. A dark-brown substance resembling humic acid.

INDIGO DYES. There are two methods of preparing solutions of indigo for dyeing. —1. By *deoxidizing it* and then *dissolving it in alkaline menstrua.*—2. By *dissolving* it in *sulphuric acid.* The former constitutes the ordinary *indigo vat* of the dyers.

1.—*a.* (*Cold vat.*) Take of *indigo*, in fine powder, 1 *lb.; green copperas* (clean cryst.), $2\frac{1}{2}$ to 3 *lb.; newly slaked lime*, $3\frac{1}{2}$ to 4 *lb.;* triturate the powdered indigo with a *little water* or an *alkaline lye*, then mix it with some *hot water*, add the *lime*, and again well mix, after which stir in the solution of copperas, and agitate the whole thoroughly at intervals for 24 hours. A little *potash* or *soda* is frequently added, and a corresponding portion of lime omitted. For *use*, a portion of this *preparation vat* is ladled into the "*dyeing vat*," as wanted. After being employed for some time the vat must be refreshed with a little more *copperas* and *fresh-slaked lime*, when the sediment must be well stirred up, and the whole

thoroughly mixed together. This is the common "blue vat" of this country.

b. (*Potash vat.*) Take *indigo*, in fine powder, 12 *lb.*; *madder*, 8 *lb.*; *bran*, 9 *lb.*; *potash*, 24 *lb.*; *water* at 125° Fahr., 120 cubic feet; mix well; at the end of about 36 hours add 14 *lb.* more *potash*, and after 10 or 12 hours longer, further add 10 *lb.* of *potash*, and rouse the whole up well; as soon as the fermentation and reduction of the indigo are well developed, which generally takes place in about 72 hours, add a little fresh-slaked lime. This vat dyes very quickly, and the goods lose less of their colour in alkaline and soapy solutions than when dyed in the common vat.

c. (*Pastel Vat.*) As the last, but employing *woad* instead of madder; the vat is set at 160° Fahr., and kept at that temperature until the deoxidizement and solution of the indigo has commenced. The last two are also called the "warm vat."

Obs. Wool, silk, linen, and cotton, may each be dyed blue in the indigo vat. The goods, after being passed through a weak *alkaline solution*, are subjected to the action of the vat for about fifteen minutes; they are then freely exposed to the air; the immersion in the vat and the exposure are repeated until the colour becomes sufficiently deep. Woad and madder improves the richness of the dye. Other deoxidizing substances, beside those above mentioned, may be used to effect the solution of the indigo; thus a mixture of *caustic soda*, *grape sugar*, *indigo*, and *water*, is often employed on the Continent for this purpose; and *orpiment*, *lime*, and *pearlash* are also occasionally used. When properly prepared, the indigo vat may be kept in action for several months by the addition of one or other of its constituents, as required. An excess of either copperas or lime should be avoided.

2. The *sulphatic solution of indigo*, noticed at *pages* 146, 597, &c., is added to *water*, as required, and the goods, previously boiled with *alum*, are then immersed in it, and the boiling and immersion are repeated until the wool becomes sufficiently dyed.

Obs. With the above dye every shade of blue may be dyed, but it is most commonly employed to give a ground to logwood blues. A solution of *soluble indigo* (see *above*), in *water very slightly acid with sulphuric acid*, imparts a very fine blue to cloth, superior in tint to that given by the simple sulphate.

INDIGO GREEN. See *Sulphate of Indigo.*

INDIGO PURPLE. Syn. *Phœnicine.* The name given by Mr. Crum to the purple precipitate obtained by filtration from a *solution of indigo in fuming sulphuric acid*, when largely diluted with *water.*

INDIGO RED. Syn. *Indigo Resin, Red Resin of Indigo.* This is prepared by boiling *alcohol* (sp. gr., 0·830), on *powdered indigo* previously exhausted by digestion in *dilute acids* and in a *strong alkaline solution.* When heated it is converted into a white sublimate (*deoxidized indigo-red*), but recovers its red colour by the action of nitric acid.

INDIGO WHITE. See *Indigogene.*

INDIGOGENE. Syn. *Indicyle, Indigo White, Reduced Indigo, Hydrogenized do.* A name given by Brugnatelli to reduced or deoxidized indigo-blue. It must not be confounded with *aniline* or *crystalline* which has been recently occasionally called indigogene, as the two substances are quite distinct compounds.

Prep. The *yellow alkaline solution* obtained by one or other of the processes noticed under *indigotine* is carefully protected from the air, both before and after precipitation with *hydrochloric acid;* and the precipitate, after being rapidly washed with *recently boiled distilled water*, or with *very dilute sulphurous acid*, is drained on a filter, dried *in vacuo*, and then at once transferred to a well-stoppered bottle.

Prop., &c. A grayish-white mass of minute crystals, generally light-blue on the surface, and rapidly turning blue on exposure to the air; soluble in alkalies, alcohol, and ether, to which it imparts a yellow colour. These solutions deposit indigo blue on exposure to the air. A solution of this substance constitutes the indigo vat of the dyer.

INDIGOIC ACID. See *Anilic Acid.*

INDIGOTINE. Syn. *Ceruline, Indigo Blue.* This is the pure blue principle of indigo. It appears to be the *oxide* of the same organic radical of which indigo-white is probably the *hydrate.*

Prep. 1. *Indigo* (in fine powder) is digested successively in *dilute hydrochloric acid, solution of potassa*, and *alcohol;* the dried residuum is *crude indigotine.*

2. *Indigo* (in fine powder), 1 part; *green sulphate of iron*, 2 parts; *hydrate of lime*, 3 parts; *water*, 15 parts; mix, agitate occasionally until the colour is destroyed, then decant the clear portion, precipitate with *dilute hydrochloric acid*, and wash the powder, *first* with *water*, and then with *boiling alcohol*, until the latter ceases to acquire a yellow colour.

3. *Caustic soda* and *grape sugar*, of each,

1 part; *water*, 20 parts; *powdered indigo*, 5 parts; mix, and proceed as last. The above are essentially the same as the indigo vat., but on the small scale.

4. (Fritsche.) This process has been already explained. (See *page* 596.) It is not only a good process for obtaining indigotine, but the easiest and most correct means of testing the commercial value of indigo, and is well calculated, from its simplicity, for the use of the practical dyer. The product from all the above exceeds 50% of the indigo operated on.

5. (Mr. Thos. Taylor.) *Powdered indigo*, 2 parts; *plaster of Paris*, 1 part; *water*, q. s. to reduce the mixture to a thin paste; spread the mass evenly upon an oblong iron plate to the depth of about ⅛ inch, and dry it by a gentle heat. It must then be held over the flame of a spirit lamp, when a disgusting odour will be evolved, the mass will begin to smoke, and in a few minutes will be covered with a heavy purple vapour, which will condense into brilliant flattened prisms or plates of an intense copper colour, forming a thick velvety coating over the surface immediately exposed to the heat. Should the mass catch fire, it may be instantly extinguished by a drop of water let fall upon it. *Prod.* 15 to 18%. See *Indigo*, *&c.*

INDINE. A peculiar substance produced when *bisulphisathyde* is treated with a cold *aqueous solution of pure potassa*. This substance is isomeric with indigo-white, but is in other respects dissimilar.

INDINIC ACID. Formed by the action of a *boiling solution of potassa* on *indine*. It forms crystalline salts. *Indinate of potassa* forms small black needles.

INDURATION. An increase in the consistence of any portion of the body, usually resulting from chronic inflammation, pressure, or friction. *Corns* and *galls* are of this kind.

INFANCY. "The domestic treatment of infants and children is comprised in the application of the laws of health to the mother as well as to the child. The position of parent is one of serious responsibility, both morally and physically, and the edict has gone forth that 'the sins of the parent shall be visited on the children.' If we could ensure good mothers, we could vastly improve the race of men. The nursing mother of a sick infant must, by following faithfully the rules of health in respect of the four great hygienic principles—*food*, *clothing*, *exercise*, and *ablution*, give health with her milk to her offspring; she must also pay close attention to her mind, avoid all sources of irritation and anxiety, and remember that an angry mother sours her milk, and produces a fractious, and often a diseased infant. I am quite of opinion, that if mothers were sound in constitution, and bestowed the requisite care upon the maintenance of their health, we should hear little of *diseases of children*. In children, as well as in parent, the rules of health must be carried out," and their neglect cannot fail to bring with it a heavy retribution. (Eras. Wilson; *slightly abridged.*) See *Exercise*, *Nursing*, *&c.*

INFANT'S PRESERVATIVE (Atkinson's). *Carbonate of magnesia*, 6 dr.; *white sugar*, 2½ *oz.*; *oil of aniseed*, 20 drops; *compound spirit of ammonia* and *rectified spirit*, of each, 2½ fl. dr.; *laudanum*, 1 fl. dr.; *syrup of saffron*, 1 oz.; *caraway water*, q. s. to make the whole measure 1 pint. Antacid, anodyne, and hypnotic.

INFECTION. Syn. *Contagion*. The communication of disease either by *personal contact* with the sick, or by means of *effluvia* arising from their bodies. Attempts have been made to restrict the term *contagion* to the former, and *infection* to the latter, but this distinction is now discarded by the majority of respectable writers. Indeed, many persons deny the existence of either. The following are the principal diseases which are commonly regarded as contagious:—*chicken-pox*, *cholera*, *cow-pox*, *dysentery*, *erysipelas*, *glanders*, *gonorrhœa*, *hooping-cough*, *hydrophobia*, *itch*, *measles*, *mumps*, *ophthalmia* (purulent), *plague*, *scald-head*, *scarlet fever*, *small-pox*, *syphilis*, *typhus*, *yaws*. See *Chlorides*, *Disinfectants*, *&c.*

INFLAMMABLE AIR. See *Hydrogen*.

INFLAMMATION. Syn. *Inflammatio*,—Lat. The common *symptoms* of inflammation, are *pain*, *swelling*, *heat*, and *redness*, attended with fever and general constitutional derangement when severe. In all cases, the vascular action of the part is excited or augmented; and if the attack does not subside or terminate without an exacerbation of the symptoms, *adhesion*, *suppuration*, *ulceration*, and *obstruction of parts*, follow each other in regular succession. In *external inflammations*, and in those which attack the outer covering of the viscera, these symptoms are the most highly developed and observable; whilst in *inflammations of internal membranes* and deep-seated parts, little pain is often experienced.

The *treatment* of inflammations, whether trifling or serious, is essentially the same in principle, and only differs in degree. This

consists in the adoption of the usual means for lowering the force of the circulation and the frequency of the pulse; of which *bleeding*, *purging*, a *low diet*, and the use of *refrigerant drinks* and *lotions*, form the most important part. The constitutional derangement or symptomatic inflammatory fever, and inflammatory condition of the blood, which always accompany local inflammation, and progress with its intensity, are usually combated by *copious bleeding* from the arm, repeated a second, and even a third time, until some obvious advantage is gained. In inflammations of a more purely local character, *cupping* or *leeching* the part immediately affected, or the parts adjacent to it, is in general more appropriate and successful. In these cases the application of *refrigerant* or *sedative lotions*, *baths*, *&c.*, generally proves of much advantage. In cases in which there is induration or dryness of the part, the use of *warm embrocations* is indicated.

Inflammation often arises from apparently very trifling causes, particularly in persons of a full or bad habit of body, or who indulge in the free use of malt liquors. In some persons, a very trifling local injury, as a slight abrasion, cut, prick, or sprain, produces a considerable amount of tumefaction, attended with severe constitutional excitement. We were once acquainted with a very amiable and beautiful young lady who lost her life from accidentally paring one of her toe nails too close. Had she, on the first occurrence of the irritation and redness which followed, reduced her diet, and taken a dose of aperient medicine, it is probable that she would not have furnished a case in illustration of the danger of neglecting apparently trifling symptoms. Punctured wounds, sprains, and dislocations, commonly furnish the most serious cases of inflammation that depend on mere external injury. See *Abscess*, *Fever*, *Tumours*, *&c.*

INFLAMMATION (of the Bowels). The *common causes* are incautious exposure to cold, the use of improper food, and the presence of acrid substances or hardened fæces in the bowels. The more constant *symptoms*, are pain over the abdomen, thirst, heat, and excessive restlessness and anxiety; sickness, obstinate constipation, and a hard small quick pulse. In the later stages the pain and tenderness of the abdomen especially around the navel, become excessive, and there is difficult micturition. In some cases, the pain suddenly ceases, the belly becomes tumid, the pulse scarcely perceptible, the countenance ghastly, and the patient dies in a few hours. The *treatment* consists in very copious bleeding, leeches to the abdomen, hot bath and fomentations, aperient clysters, and mercurial purges; with effervescing draughts and opium to allay sickness, followed by diaphoretic salines, and gentle aperients. See *Stomach*, *&c.*

INFLAMMATORY FEVER. See *Fever* and *Inflammation*.

INFLUENZA. See *Catarrh*.

INFUSION. Syn. *Infusum*, *Infusio*,— Lat. A liquid medicine prepared by macerating vegetable or animal substances in water, at any temperature below that of ebullition.

The mode of *preparing* infusions, is, with most substances, precisely similar to that pursued for making the almost universal beverage—*tea*. The ingredients are commonly placed in a stoneware pot or vessel (an *infusion pot*) previously made hot; *boiling water* is then poured over them, and the cover being placed on, the whole is allowed to digest together, at first, for a short time, in a warm situation, as on the hob or the fender, and afterwards (the vessel being removed from the heat) until the whole becomes cold. The liquid is then poured from the ingredients, and the latter, being slightly pressed, if necessary, the infusion is strained through a piece of clean linen or a hair sieve for use. During the digestion, the ingredients should be *occasionally stirred*, an important matter often neglected, and not even referred to by most pharmaceutical writers.

The *substances* employed for making infusions receive the same *preliminary treatment* as those intended for making *decoctions*. *Shavings*, *leaves*, and *flowers*, require no previous preparation beyond being pulled asunder; but *roots*, *woods*, and other *solid substances*, must be bruised or sliced, if in the green or recent state, or bruised, or coarsely pulverized, if dry, for the purpose of exposing as large a surface as possible to the action of the menstruum.

The substances extracted by water from vegetables by infusion are chiefly gum, mucus, extractive, tannin, certain vegetable acids, the bitter and narcotic principles, gum-resin, essential oil, and alkaloids. Some of these substances are only sparingly soluble in water at ordinary temperatures; but more readily so in *hot* water, and freely soluble in *boiling water*. The temperature of the water should be therefore proportioned to the nature of the vegetable matter operated on. For mere demulcent infusions, in which fecula and

gum are the chief substances sought to be dissolved out, and when the active principle is scarcely soluble in water, unless at nearly the boiling temperature, *boiling water* alone should be employed; but when the medicinal virtues of vegetables are soluble in water at lower temperatures, it is better to employ *hot water* (165° to 175° Fahr.), and to allow a little longer period for the digestion. In many cases *temperate water* (from 60° to 70°), or *tepid water* (from 80° to 90° Fahr.) may be used with advantage, especially in the preparation of *aromatic bitter infusions*, and in most cases, where it is wished that the product should contain as little inert matter as possible; but when water at low temperatures is employed, the period of the maceration must be proportionately increased. By adopting the method of *maceration in vacuo*, or in an atmosphere of carbonic acid, the menstruum may be allowed to lay in contact with the vegetable matter for an unlimited period, without decomposition taking place.

Infusions, like decoctions, are liable to undergo *spontaneous decomposition* by keeping, especially in warm weather, when a few hours are often sufficient for their passage into a state of active fermentation; they should therefore, when possible, be prepared for use daily, as beyond 24 hours they cannot be depended on. The London College directs a pint only to be made at a time, thus very properly regarding them as extemporaneous preparations.

Concentrated Infusions, now so common in the shops, and unfortunately, so generally used in dispensing, are either made by taking 8 times the quantity of the ingredients ordered in the pharmacopœia, and then proceeding in the usual manner, or by the method of displacement; *or*, by carefully and rapidly *concentrating the simple infusions*, by evaporation in a steam or salt water bath, until reduced to about 1-7th of the original quantity. In either case, the liquid is put into a *strong* bottle, without being filtered, and 10 to 12% of *rectified spirit* added to it, whilst still hot. The cork is then put in and secured down, and the whole agitated for some minutes, after which it is set aside for a week, when the clear portion is carefully decanted from the sediment for sale. *Another method* which answers well with the aromatic bitter vegetables, is to take 8 *times* the *usual quantity of the ingredients*, and to exhaust them with a mixture of *rectified spirit*, 1 part; and *distilled water*, 3 parts; by digestion, or, better still, by percolation. Concentrated infusions made in this way keep well, and deposit scarcely any sediment. Many houses that are remarkable for the "brilliancy" and beauty of these preparations, employ $\frac{1}{3}$ *spirit of wine* and $\frac{2}{3}$ *water* as the menstruum. It may, however, be taken as a general rule, that for vegetable substances that abound in woody fibre, and contain little extractive matter soluble in water (as *quassia*, for instance), $\frac{1}{6}$ to $\frac{1}{5}$ part of *spirit* is sufficient for their preservation; whilst for those abounding in mucilage or fecula, or that readily soften and become pulpy and glutinous in *weak* spirit (as *rhubarb*) $\frac{1}{5}$ to $\frac{1}{3}$ is required.

By adopting the method originally suggested by Mr. Alsop, infusions may be preserved, uninjured, for a year or longer, without the addition of spirit or any other substance. The only precaution necessary is, to keep them in bottles *perfectly filled*, and *hermetically sealed*. (Pharm. Journ. i. 57.) Our own plan is to put a few bruised *cloves* or *seeds of black mustard* into the bottles, which must be only 2-3rds filled, then completely fill them with a condensed atmosphere of carbonic acid gas; and, lastly, to stopper them and seal them over, so as to perfectly exclude the air. A pint of decoction of sarsaparilla, and $\frac{1}{2}$ pint of infusion of calumba treated in this way, kept good for fully 9 years. By simply macerating in the infusion as much *bruised mustard seed* as can be added without flavouring the liquor, along with a little *bruised cloves*, we find that most vegetable infusions may be preserved in bottles which are occasionally uncorked, without either *fermenting or becoming mouldy*, by the use of very little spirit ($\frac{1}{9}$ or $\frac{1}{10}$).

Before adding the spirit to infusions made with *cold* water, or with water which is only *tepid*, it is advisable to heat the liquid to about 185° Fahr., in a water-bath, and after keeping it at that temperature for a few minutes, and allowing it again to become cold, to separate it from the precipitated matter, either by filtration or decantation.

It is often very difficult to render vegetable infusions and decoctions perfectly transparent, a quality always expected in the *concentrated preparations*. Defecation by repose is always better than filtration, owing to the more or less viscidity of the suspended matter. When this is not sufficient, they may be clarified with *white of egg* (2 or 3 to the gall.) previously beaten up with 5 or 6 fl. oz. of water. Most of the vegetable infusions and decoctions will readily pass the filter, after a *very small* quantity of *acetic*, *nitric*, or *sulphuric acid*

has been added to them. The most obstinate may be rendered "*brilliant*," or "*candle bright*," as the "cellarmen" call it, by shaking them up, first with about a drachm of *dilute sulphuric acid*, and afterwards with the *whites of* 3 *or* 4 *eggs*, previously mixed with a few ounces of water, for each gallon of the liquid. This plan is, however, objectionable, for many medicinal preparations.

As many infusions which are occasionally employed in medicine, must necessarily escape being separately noticed in this work, it may be as well to remark, that the *infusions* of all vegetables that do not exert a *very powerful* action on the human frame, as ordinary herbs and roots, may be made by pouring 1 pint of *boiling water* on 1 *oz.* of the *vegetable matter*, and allowing it to macerate for ½ an hour to an hour. The *decoctions* of the same vegetables may be made by simply boiling the above ingredients, in the same proportions, for 10 or 15 minutes, instead of operating by mere infusion. With substances of somewhat greater activity, only half the above quantity should be taken; whilst, with the *narcotic plants*, and those possessing great activity, 1 to 2 dr. to *water*, 1 pint, will be the proper quantity. *The ordinary dose* of such infusions and decoctions is ½ to 1 wine-glassful (1 to 2 *fl. oz.*), two, three, or four times a day, as the case may indicate.

Infusion is preferred for all bodies of a delicate texture, which readily yield their active principles to water; and especially when these are either volatile or liable to be injured by the heat of ebullition.

The *simple infusions* are now less frequently made by the druggist than formerly. In most cases he merely furnishes the ingredients, and the infusions are prepared by either the nurse or patient, by whom they are commonly called "*Teas*."

The following list embraces most of the infusions used in prescribing or noticed in books. Where the proportions of the ingredients are not given, 1 *oz.* of the *medicinal substance*, and 1 pint of *boiling water* are to be taken, and the *dose* is that referred to above.

INFUSION (Agrimony). Syn. *Agrimony Tea; Infusum Agrimonii*,—Lat. From the fresh tops before the flowers are formed. Vermifuge. *Dose.* A teacupful 3 or 4 times a day; also used as an astringent gargle and lotion. For internal use, an equal weight of *liquorice root* (sliced) is commonly added.

INFUSION (Alkaline). Syn. *Infusum Alkalinum*,—Lat. *Prep.* (Beasley.) *Hickory ash*, 1 pint; *wood soot*, ¼ pint; *boiling water*, 1 gall.; in 24 hours decant the clear. "A popular remedy in America for dyspepsia with acidity."

INFUSION (Aloes). Syn. *Infusum Aloës*,—Lat. *Prep.* From *hepatic* or *Socotrine aloes* (in powder), 2 dr.; *carbonate of potassa*, 1½ dr.; *boiling water*, 1 pint.

INFUSION (Aloes,—Compound). Syn. *Infusum Aloës Compositum*,—Lat. *Prep.* 1. As the *compound decoction* (Ph. L.), but using only a pint of *boiling water*.

2. (Fothergill.) *Calumba* and *rhubarb*, of each, 1 oz.; *aloes*, 2 dr.; *lime water*, 16 fl. oz.; *spirit of horse-radish*, 1 fl. oz.; macerate in the cold for 12 hours, and strain. The last three, like the *decoction*, are aperient, antacid, stomachic, tonic, and emmenagogue. *Dose.* 1 table-spoonful to a small wine-glassful, in water. The last one is an admirable medicine in dyspepsia, loss of appetite, and troublesome constipation.

INFUSION (American Calumba). Syn. *Infusum Frazeræ*,—Lat. From the *dried root of American calumba* (Frazera Carolinensis,—*Walter.*) A pure, powerful, and excellent bitter, destitute of aroma, and fully equal to gentian. (Lindley.)

INFUSION (American Centaury). Syn. *Infusum Sabatii*,—Lat. From the herb (*sabbatia angularis*). A pure bitter tonic, without astringency or aroma.

INFUSION (American Senna). Syn. *Infusum Cassiæ Marylandicæ*,—Lat. *Prep.* (Martin.) *Leaves of American* or *wild senna* (cassia Marylandica,—*Linn.*), 1½ oz.; *coriander seed*, 1 dr.; *boiling water*, 1 pint. Purgative.

INFUSION (Angelica). Syn. *Infusum Angelicæ*,—Lat. From the *root of garden angelica.* A warm stomachic and diaphoretic; and, in large doses, aperient. It is a popular remedy in dyspepsia, flatulent colic, and heartburn.

INFUSION (Aniseed). Syn. *Aniseed Tea; Infusum Anisi*,—Lat. Carminative; an excellent adjunct to purgatives to prevent griping; given to infants to relieve colic, &c. Dr. Prout recommends the use of water at 120° or 125° Fahr.

INFUSION (Antiscorbutic). Syn. *Infusum Antiscorbuticum, Mistura Antiscorbutica*,—Lat. *Prep.* (Hosp. F.) *Water trefoil* (menyanthis trifoliata,—*Linn.*), 1 oz.; *orange peel*, 2 dr.; *boiling water*, 1 quart; infuse for 8 or 10 hours, strain, and add of *compound spirit of horse-radish*, 5 fl. oz. In scurvy.

INFUSION (Arnica). Syn. *Infusum Arnicæ*,—Lat. From the *flowers* of *mountain arnica* or *German leopard's bane* (ar-

nica montana,—*Linn.*) Cottereau orders 1 oz., Dr. Pereira ½ oz., and Dr. A. T. Thomson, ¼ oz. of the *flowers* to the pint. The first is the usual quantity. The dose of the first is a tablespoonful; of the second, ½ to 1 fl. oz.; of third, ½ to 1 wine-glassful. See *Decoctions.*

INFUSION (Arnica,—Compound). Syn. *Infusum Arnicæ Compositum,*—Lat. *Prep.* (Ph. Copenh.) *Flowers of arnica,* 1 dr.; *peppermint,* 2 dr.; *chamomiles,* ½ oz.; *boiling water,* ½ pint. *Dose.* 1 fl. oz. As the last.

INFUSION (Arnica-root). Syn. *Infusum Arnicæ Radicis,*—Lat. *Prep.* (Ph. Castr. Ruth.) *Arnica root,* 40 gr.; *water,* 1 lb. *Dose.* 1 fl. oz. As the above.

INFUSION (Astringent). Syn. *Infusum Astringens, Mistura do.,*—Lat. *Prep.* 1. From *oak-bark.*

2. *Infusion of cusparia,* 17 fl. oz.; *tincture of catechu* or *kino,* 1 fl. oz.; *powdered ipecacuanha,* 1 dr.; *powdered opium,* 12 gr.; mix. In diarrhœa, &c. It must be well shaken before pouring out the dose.

INFUSION (Balm). Syn. *Infusum Melissæ,*—Lat. *Prep.* (Plenck.) *Fresh herb,* 5 dr.; *boiling water,* 1 pint; infuse for 15 minutes.

INFUSION (Barberry). Syn. *Infusum Berberis,*—Lat. *Prep.* (Dr. Copland.) From the *bark of the barberry shrub* (berberis vulgaris,—Linn.) In jaundice, biliary fluxes, and other cases where heat and acrimony prevail; either alone or combined with a little carbonate of soda or potassa, and tincture of calumba.

INFUSION (Bark). Syn. *Infusion of Cinchona; Infusum Cinchonæ,*—Ph. L. & E. *Prep.* (Ph. L.) *Yellow cinchona* (bruised), 1 oz.; *boiling distilled water,* 1 pint; macerate for 2 hours in a covered vessel and strain.

2. (Ph. E.) From *any species of cinchona,* as the last; but infusing the bark for 4 hours, and then straining through linen or calico.

Obs. Infusion of bark, is tonic and stomachic, and in very large doses, febrifuge. It is an extremely useful medicine in dyspepsia, debility, and during convalescences, and is often a valuable adjunct to more active remedies. Like the decoction, it is most energetic when strained whilst hot. The addition of 1 fl. dr. of *diluted sulphuric acid* to the water before pouring it on the bark increases its solvent power, and, consequently, the strength of the infusion. *Dose.* 1 to 3 fl. oz.

INFUSION (Bark,—Concentrated). Syn. *Infusum Cinchonæ Concentratum,*—Lat. *Prep.* 1. *Yellow bark* (coarsely powdered), 4 *lb.*; *boiling water,* 8 *lb.*; digest for 12 hours, express the liquid, add *rectified spirit,* 2 *lb.*, and after 24 hours' repose, decant the clear portion.

2. *Yellow bark* (in coarse powder), 4 *lb.*; *cold water,* 8 *lb.*; *rectified spirit,* 2 *lb.*; *dilute sulphuric acid,* 4 fl. oz.; mix the fluids, and either macerate the bark in them for a week in a *closed* vessel, or proceed by the method of displacement. Very superior.

Obs. 1 fl. dr. of either of the above added to 7 fl. dr. of water, produces an extemporaneous infusion of cinchona resembling that of the pharmacopœia. The concentrated preparation of the Ph. L. being more than 8 times the usual strength, is placed amongst *Liquors.*

INFUSION (Pale Bark.) Syn. *Infusum Cinchonæ Pallidæ,*—Ph. L. *Infusum Cinchonæ;* Ph. D., & Ph. L. 1836. *Prep.* 1. (Ph. L.) From *pale bark,* as *infusion of cinchona,* (Ph. L.)

2. (Ph. D.) *Crown* or *pale bark,* 1 *oz.*; *boiling water,* ½ pint; infuse 1 hour in a covered vessel, and strain through paper.

3. (*Inf. Cinch. sine calore,*—Ph. D. 1826.) *Powdered pale bark,* 1 oz.; *cold water,* 12 fl. oz.; triturate the bark with a little of the water, gradually add the remainder, macerate for 24 hours, and decant the clear liquor.

Obs. "This infusion is inferior to the preceding" (inf. of yellow bark) "in activity, and is a very unnecessary one. It is said to oppress the stomach less than that of the other cinchona bark: the reason is obvious,—it is weaker." (Pereira.)

INFUSION (Pale Bark,—Concentrated) Syn. *Infusum Cinchonæ Pallidæ Concentratum,*—Lat. *Prep.* As *concentrated infusion of cinchona,* but using *pale bark.* The concentrated preparation of the Ph. L. will be found under *Liquors.*

INFUSION (Bark,—Compound). Syn. *Infusum Cinchonæ Compositum,* — Lat. *Prep.* 1. (St. B. Hosp.) *Cinchona bark,* 1 oz.; *red-rose leaves,* 3 dr.; *orange peel* (dried), 2 dr.; *boiling water,* 1 pint; macerate 2 hours in a covered vessel, strain, and add of *dilute sulphuric acid,* 1½ fl. dr.

2. (Ph. U. S.) *Powdered bark,* 1 oz.; *aromatic sulphuric acid,* 1 fl. dr.; *water,* 16 fl. oz.; macerate 12 hours, with occasional agitation, and strain.

3. (*Inf. Cinch. cum Aqua Calcis,*—Ph. U. S., 1831.) *Cinchona* (bruised), 1 oz.; *lime water* (cold), 16 fl. oz.; macerate for 12 hours in a covered vessel.

4. (*Inf. Cinch. cum Magnesiæ.*—Ph. U.S. 1831.) *Bruised bark,* 1 oz.; *calcined mag-*

nesia, 1 dr.; *boiling water*, 12 fl. oz.; boil, digest 1 hour and strain. The last two are useless and nearly inert preparations, wisely rejected from the Ph. U. S. 1851.

INFUSION (Bay-leaves). Syn. *Infusum Lauri, Inf. Lauri Nobilis*,—Lat. From the *leaves* or the *berries* of the *sweet bay* (laurus nobilis,—*Linn.*) Aromatic, stimulant, and emmenagogue; in very large doses, emetic and poisonous. It is chiefly given in colic, flatulence, paralysis of the extremities, and obstructed menstruation.

INFUSION (Beef). See *Beef Tea, &c.*

INFUSION (Belladonna). Syn. *Infusum Belladonnæ*, — Lat. *Prep.* 1. (Dr. Paris.) *Leaves of deadly nightshade* (dried), 4 gr.; *boiling water*, 2 fl. oz.; for a dose.

2. (Dr. Saunders.) *Leaves* (dried), ½ dr. *boiling water*, 12 fl. oz.; infuse, strain, and to every 7 fl. oz. of the infusion add of *compound tincture of cardamoms*, 1 fl. oz.

INFUSION (Benne). Syn. *Infusum Sesami*,—Lat. *Prep.* (Dr. Wood). *Fresh leaves of benne* (sesamum Indicum or s. orientale), 4 in no.; *cold water*, 1 pint; infuse until the liquid is sufficiently mucilaginous. *Used* as a demulcent drink in hoarseness, fevers, &c. When the dried leaves are used the water should be warm.

INFUSION (Bistort). Syn. *Infusum Bistortæ*,—Lat. *Prep.* (Radius.) *Bistort* or *snake-weed root* (polygonum bistorta,—*Linn.*), ½ oz.; *boiling water*, 1 pint; infuse 2 hours, and strain. In passive hæmorrhages.

INFUSION (Bitter Purging). See *Compound Gentian Mixture.*

INFUSION (Black Purslane). Syn. *Infusum Euphorbiæ Hypericifoliæ*,—Lat. *Prep.* (Zollickoffer.) *Black purslane* (dried), ½ oz., *boiling water*, 1 pint. *Dose.* In dysentery and diarrhœa, 1 table-spoonful every hour or every other hour; in leucorrhœa and flooding, a wine-glassful thrice daily.

INFUSION (Black Snake-root). Syn. *Infusum Cimicifugæ Racemosæ, I. Acteæ R.*—Lat. In dropsy, rheumatism, and chest complaints.

INFUSION (Blessed Thistle). Syn. *Infusum Centaureæ, Inf. Cardui Benedicti*,—Lat. From the *whole herb.* In small doses it is diaphoretic; in larger ones, tonic, stomachic, and deobstruent; taken warm, it is occasionally given to promote the action of emetics. The properties of carduus benedictus "are such as to lead us to the belief that it has been superseded by other not more efficacious remedies." (Lindley.)

INFUSION (Blood-root). Syn. *Infusum Sanguinariæ*,—Lat. *Prep. Blood-root* (sanguinaria Canadensis,—*Linn.*), ½ oz.; *boiling water*, 1 pint. Stimulant and emetic.

INFUSION (Blue Flag). Syn. *Infusum Iridis Versicoloris*,—Lat. 1. From the *flowers of blue flag* (iris versicolor,—*Linn.*) —2. From the *root* or *rhizomes.* The first is *used* chiefly for its rich colour, as a test, &c.; the second, is diuretic and cathartic, and apt to produce distressing nausea and prostration.

INFUSION (Boneset). Syn. *Infusum Eupatorii*,—Ph. U. S. From the dried *leaves and flowers of boneset* or *thoroughwort* (eupatorium perfoliatum, — Linn.) Diaphoretic, nauseant, and emetic when warm; tonic when cold.

INFUSION (Boneset,—Compound). Syn. *Infusum Eupatorii Compositum*, — Lat. *Prep.* (Ellis.) *Boneset* and *sage*, of each, ½ oz.; *cascarilla*, 1 dr.; *boiling water*, 1½ pint; infuse until cold, and strain. In hectic fever. A wine-glassful of either of the above, given hourly, in these diseases, until perspiration and nausea are induced, has been highly recommended in influenza.

INFUSION (Brazil-wood). Syn. *Infusum Ligni Brasiliensis*,—Lat. From *ground* or *rasped Brazil wood.* When wanted to keep, *rectified spirit*, 3 fl. oz., is added to every pint. *Used* for colouring, and as a test.

INFUSION (Broom). Syn. *Infusum Scoparii*,—Ph. L., 1836. *Prep.* From the *fresh tops of broom* (cytisus scoparius). Diuretic; in dropsy, &c.

INFUSION (Buchu). Syn. *Infusum Buchu*,—Ph. L. & D. *Inf. Bucku*,—Ph. E. *Inf. Diosmæ*,—Ph. L. 1836. Diuretic, sudorific, tonic; in dyspepsia, &c.; but chiefly in chronic affections of the bladder and urethra attended with copious secretion.

INFUSION (Buchu,—Compound). Syn. *Infusum Buchu Compositum, I. iosmæ C.*, —Lat. *Prep.* (Radius.) *Leaves of buchu* and *whortleberry*, of each, ½ oz.; *boiling water*, 8 oz., (say ½ pint); digest for half-an-hour, strain, and add of *syrup of senega*, ½ fl. oz. *Dose.* 1 or 2 table-spoonfuls every hour; in atony of the bladder and mucous discharges.

INFUSION (Buckbean). Syn. *Infusum Menyanthis*,—Lat. From the *herb* or *root of buckbean* or *marsh trefoil* (menyanthes trifoliata,—*Linn.*) Bitter, stomachic, tonic, and diuretic; in *large doses*, purgative, vermifuge, and emetic. It has been recommended in agues, gout, dropsy, scurvy, worms, &c. The chief consumption of this

plant is by the brewers; "2 *oz.* being equal to 1 *lb.* of hops." (Gray.)

INFUSION (Burdock). Syn. *Infusum Arctii*,—Lat. From the *root of common burdock* (lappa minor,—D. C.) Aperient, diuretic, diaphoretic, and tonic; in gout, rheumatism, skin diseases, &c. See *Decoctions* and *Extracts.*

INFUSION (Calumba). Syn. *Infusum Calumbæ*,—Ph. L. & E. *Inf. Colombæ*,—Ph. D. *Prep.* 1. (Ph. L.) *Calumba* (sliced), 5 dr.; *boiling water*, 1 pint; digest for 2 hours in a covered vessel, and strain.

2. (Ph. E.) *Calumba* (in coarse powder), ½ oz.; *cold water*, 1 pint; triturate the powder with a little of the water, so as to moisten it thoroughly, then put it into a percolator, and transmit cold water through it, until 16 fl. oz. of infusion are obtained.

3. (Ph. D.) *Calumba* (in coarse powder), 3 *dr.*; *cold water*, 9 fl. oz.; macerate 2 hours, and strain.

Obs. The infusion prepared by the first of the above formulæ soon spoils, especially in hot weather; but that prepared by the others (*inf. calumbæ cum aquâ frigidâ*) may be kept for some days. In either case it should not be allowed to stand upon the dregs. Infusion of calumba is a good tonic and stomachic bitter. *Dose.* 1 to 3 fl. oz., in dyspepsia, &c., and for restraining vomiting and diarrhœa during pregnancy or dentition. It is preferably joined with small doses of the carbonates of soda, potassa, ammonia, or magnesia, when there is acidity; or with chalybeates, when there is paleness and a low pulse; with all of which substances it may be mixed without suffering any sensible alteration.

INFUSION (Calumba,—Concentrated). Syn. *Infusum Calumbæ Concentratum*,—Lat. *Prep.* 1. *Calumba* (in coarse powder), 5½ *oz.*; *cold distilled water*, 12 fl. oz.; digest, with frequent agitation, for 3 or 4 hours, then express the liquor, and repeat the digestion with 5½ fl. oz. more of tepid *water*; after another hour, express this portion also, using as much force as possible; next mix the liquors, heat them quickly, to the boiling point in a shallow vessel, and pour the infusion, whilst *still hot*, into a strong bottle, and when it has cooled a *little*, add of *rectified spirit*, 4 fl. oz., secure down the stopper or cork, and agitate well for a few minutes; the bottle must now be set aside for a week, after which the clear portion is to be decanted from the dregs. Very superior.

2. (*Wholesale.*) From *calumba* (reduced to coarse powder), 5¼ *lb.*; *rectified spirit*, 5 pints; (diluted with) *water*, 12 pints; digest for a week, or proceed by displacement. Should there be any difficulty in obtaining it free from cloudiness, the *whites* of 4 or 5 *eggs*, previously mixed with about a ¼ pint of *cold water*, may be added to the infusion, which, after being well agitated for about 10 minutes, must be allowed to repose for 7 or 8 days, and then decanted from the dregs. Should it not be perfectly transparent, it may be filtered through blotting paper. *Product.* 20 *lb.*

Obs. The concentrated infusion produced by the above formulæ is of *very superior quality*, and has acquired an extensive sale in the wholesale trade. 1 fl. dr. added to 7 fl. dr. of water makes a perfectly transparent liquid, possessing exactly similar virtues to the *infusion of calumba*, Ph. L.

INFUSION (Cantharides). Syn. *Infusum Cantharidis, Inf. Lyttæ*,—Lat. *Prep.* (Soubeiran.) *Spanish flies* (powdered), 20 gr.; *boiling water*, q. s. (about 3½ fl. oz.) to yield 3 fl. oz., after expression and filtration.

INFUSION (Capsicum). Syn. *Infusum Capsici*,—Lat. *Prep.* 1. (Pereira.) *Capsicum* (powdered), ½ oz.; *boiling water*, 1 pint. *Dose.* ½ fl. oz.

2. (Stephen's *Pepper Medicine*,—Pereira.) *Red pepper* (capsicum fructescens), 2 table-spoonfuls (or 3 of *cayenne pepper*); *common salt*, 2 tea-spoonfuls; *boiling water*, ½ pint; to the strained liquor when cold, add of *very sharp vinegar*, ½ pint. *Dose.* 1 table-spoonful, slowly swallowed, every half hour, in cholera, malignant sore throat, scarlatina, &c.

INFUSION (Caraway). Syn. *Caraway Tea; Infusum Carui*,—Lat. *Prep.* From *bruised caraway seed*, 3 dr.; *boiling water*, 1 pint. In the flatulent colic of infants, and as an adjunct to aperient medicine.

INFUSION (Carrot Seed). Syn. *Infusum Dauci, Inf. Carotæ*,—Lat. Diuretic; in dropsy and nephritic complaints; ½ to 1 pint being taken daily.

INFUSION (Cascarilla). Syn. *Infusum Cascarillæ*,—Ph. L. E. & D. *Prep.* 1. (Ph. L. & E.) *Cascarilla* (bruised), 1½ oz.; *boiling distilled water*, 1 pint; infuse for 2 hours in a closed vessel, and strain.

2. (Ph. D.) *Cascarilla*, 1 *oz.*; *boiling water*, ½ pint. A light, aromatic bitter-tonic. *Dose.* 1 to 3 fl. oz., usually combined with carbonate of soda and tincture of cascarilla. It is an excellent medicine in dyspepsia, debility, diarrhœa, &c.

INFUSION (Cascarilla,—Concentrated). Syn. *Infusum Cascarillæ Concentratum*,—Lat. *Prep.* 1. *Cascarilla* (good and fragrant, bruised), 6½ *lb.*; *rectified spirit of*

wine, 3 pints ; *cold water*, 6 pints; macerate in a close vessel for 14 days, express the liquor, and filter.

2. As the last, but proceeding by the method of displacement.

Obs. If the preceding processes are well managed, the product is 10 *lb.*, and resembles brandy in colour and transparency, and is delightfully fragrant. 1 fl. dr. of *this infusion* mixed with 7 fl. dr. of *water* makes a preparation exactly resembling the *infusion of calumba*, Ph. L.

INFUSION (Cascarilla,—Alkaline). Syn. *Infusum Cascarillæ Alkalisatum*, — Lat. *Prep.* (Ph. Palat.) *Cascarilla*, 3 oz.; *carbonate of potassa*, 2 dr.; *boiling water*, 16 fl. oz. Antacid and tonic. *Dose.* 1 tablespoonful.

INFUSION (Cassia). Syn. *Cassia Tea ; Infusum Cassiæ Fistulæ*, — Lat. *Eau de Casse*,—Fr. *Prep.* (Soubeiran.) *Cassia pods* (bruised), 4 oz.; *boiling water*, 1½ pint. Laxative.

INFUSION (Catechu). Syn. *Compound Infusion of Catechu ; Infusum Catechu*,—Ph. E. *Inf. Catechu Compositum*,—Ph. L. & D. *Inf. Japonicum*,—Obs. *Prep.* 1. (Ph. L.) *Catechu* (powdered), 6 dr.; *cinnamon* (bruised), 1 dr.; *boiling water*, 1 pint; macerate for an hour in a covered vessel, and strain.

2. (Ph. E.) *Catechu*, 6 dr.; *cinnamon*, 1 dr.; *boiling water*, 17 fl. oz.; infuse for 2 hours, strain, and add of *syrup*, 3 fl. oz.

3. (Ph. D.) As the Ph. L. (nearly). Astringent; in diarrhœa, 3 or 4 times a day, or after every liquid dejection.

INFUSION (Cathartic). See *Mixtures.*

INFUSION (Catmint). Syn. *Infusum Catariæ*,—Lat. From *dried catmint* or *catnep* (nepeta cataria,—*Linn.*) Stimulant, carminative, diaphoretic, and emmenagogue. In doses of a tea-spoonful it has been recommended in the flatulent colic of infants.

INFUSION (Cayenne Pepper). See *Infusion of Capsicum.*

INFUSION (Centaury). Syn. *Infusum Centaurii*,—Lat. From the *flowering tops of common* or *lesser centaury* (gentiana centaurium, — *Linn.*) Bitter, febrifuge, stomachic, and vermifuge. A popular remedy in obstructions, jaundice, debility, dyspepsia, &c.; and *externally*, for the itch, and to destroy pediculi. An *infusion* is also made of the root, which is about one-half more powerful than the tops. The plant is "a valuable native medicine; in the places where it grows, it is carefully collected for use in rustic pharmacy." (Lindley.)

INFUSION (Cephalic). Syn. *Infusum Cephalicum*,—Lat. *Prep.* (Edin. Hosp.) *Valerian root*, 2 oz.; *rosemary tops*, 4 dr.; *boiling water*, 1 quart; infuse 12 hours, strain, and add *aromatic water*, 4 fl. oz. As an antispasmodic, and in various affections of the head.

INFUSION (Chamomile). Syn. *Chamomile Tea ; Infusum Anthemidis*,—Ph. L. E. & D. *Inf. Chamæmeli*, — Ph. D. 1826. *Prep.* (Ph. L. & E.) *Chamomiles*, 5 dr.; *boiling water*, 1 pint; macerate 10 minutes (20 minutes,—Ph. E.), and strain.

2. (Ph. D.) *Chamomiles*, ½ *oz.*; *boiling water*, 12 *fl. oz.* Tonic, bitter, and stomachic. It should be drunk cold, as it is emetic when warm. See *Bitters.*

INFUSION (Chamomile,—Concentrated). Syn. *Infusum Anthemidis Concentratum*,—Lat. *Prep.* From *chamomiles*, 5½ oz.; *water*, 1 pint; boil till the mixture weighs exactly 21 *oz.*; express the liquor by means of a powerful tincture-press, cool, and add of *essential oil of chamomile*, 15 drops, dissolved in *rectified spirit*, 5 fl. oz.; agitate well, let it repose until the next day, then decant the clear, and filter. Strongly bitter and odorous, and beautifully transparent. 8 times as strong as the *infusion*, Ph. L.

INFUSION (Cherry-laurel.) Syn. *Infusum Lauro-cerasi*, — Lat. *Prep.* (Dr. Cheston.) Fresh *leaves* of the *common* or *cherry-laurel* (prunus lauro-cerasus,—*Linn.*), 2½ oz.; *boiling water*, 1 pint; infuse, strain, and add of *clarified honey*, 2½ oz. As a lotion in cancer of the lip, and as a wash for malignant ulcers.

INFUSION (Chiretta). Syn. *Infusum Chirettæ, Inf. Chiraytæ*, — Lat. *Prep.* (Ph. E. & D.) *Chiretta*, 4 dr.; *boiling water*, 1 pint ; macerate for 2 hours (1 hour, —Ph. D.), and strain.

Obs. Chiretta is a pure tonic bitter closely allied to gentian, and has been long esteemed in the East Indies as a remedy for acidity, flatulence, and dyspepsia, especially when occurring in gouty or debilitated habits. It is usually given in combination with carbonate of soda or tincture of sesquichloride of iron. The whole of the plant is employed. Dr. Royle recommends the use of water at 180° Fahr., and Mr. Squire recommends *cold water.*

INFUSION (Chiretta, — Concentrated). Syn. *Infusum Chirettæ Concentratum*,—Lat. *Prep.* From *chiretta*, 4 oz., for each pint of the product, prepared as either *infusion of calumba* or *cascarilla.* (See *above.*) 1 fl. dr. added to 7 fl. dr. of *water* makes 1 fl. oz. of the common infusion.

INFUSION (Cinchona). See *Infusion of Bark.*

INFUSION (Cinnamon). Syn. *Cinnamon Tea; Infusum Cinnamoni,*—Lat. In flatulence, dyspepsia, and nervous colics.

INFUSION (Cloves). Syn. *Clove Tea; Infusum Caryophillorum; Inf. Caryophylli,* —Ph. L. E. & D. *Prep.* 1. (Ph. L. & E.) *Cloves* (bruised), 3 dr.; *boiling water*, 1 pint; macerate for 2 hours in a covered vessel, and strain (through calico,—Ph. E.)

2. (Ph. D.) *Cloves*, ¼ *oz.*; *boiling water*, 9 *fl. oz.*; infuse 1 hour. Aromatic, stimulant, and stomachic, either alone or in combination; in colic, dyspepsia, gout, &c.

INFUSION (Cloves, — Concentrated). Syn. *Infusum Caryophylli Concentratum,*— Lat. *Prep.* 1. *Bruised cloves*, 3 oz.; *boiling water*, 16 fl. oz.; infuse as above and strain; when cold add of *rectified spirit*, ¼ pint, and filter.

2. *Bruised cloves*, 1¾ *lb.*; *rectified spirit*, 1 quart; *cold water*, 3 quarts; macerate for 7 days, and express the liquid; sprinkle the *marc* with *water*, 12 fl. oz., and after the lapse of an hour, again submit it to the press; lastly, filter the mixed liquors. Very fine. The above are 8 times the strength of the *infusion of cloves*, (Ph. L.)

INFUSION (Coffee). Syn. *Infusum Caffei,*—Lat. *Prep.* (Dr. McBride.) *Unroasted coffee berries* (bruised), 30 in no.; *cold water*, 1 quart; macerate 2 or 3 hours. In calculus, &c. *Dose.* ½ pint every morning.

Obs. Sir Jno. Floyer and Sir Jno. Pringle cured asthma with a strong infusion of roasted coffee. M. Bouchardat prescribes a strong infusion made by displacement, and mixed with a little brandy, in poisoning by opium and other like narcotics, after the administration of emetics and iodu-retted water. M. Honore also employs very strong made-coffee in albuminuria. Clausen gives it in gout, and Parker employs it as a nervous stimulant in lieu of ammonia and wine, for persons of a highly sensitive and excitable temperament.

INFUSION (Contrayerva). Syn. *Infusum Contrayervæ,*—Lat. *Prep.* (Pereira) *Contrayerva* (in powder), 1 oz.; *boiling water*, 12 fl. oz. Stimulant, tonic, and diaphoretic; in low fevers, &c.

INFUSION (Copalche Bark). Syn. *Infusum Copalchi Corticis,*—Lat. *Prep.* (Dr. Stark.) *Bark of copalche bush* (croton pseudo-china), ½ oz.; *boiling water*, 1 pint; digest 2 hours, and strain. A warm bitter and stomachic.

INFUSION (Corsican Moss). Syn. *Infusum Helminthocorti,*—Lat. *Prep.* (Mr. Farr.) *Corsican moss*, 5 dr.; *boiling water*, 1 pint; macerate for 10 or 12 hours, and strain. Ad libitum, in cancer. See *Decoctions.*

INFUSION (Cusparia). Syn. *Infusion of Angostura Bark; Infusum Cusparia,*— Ph. L. & E. *Inf. Angusturæ,*—Ph. D. 1826. *Prep.* (Ph. L. & E) *Cusparia* (bruised), 5 dr.; *boiling distilled water*, 1 pint; macerate 2 hours, and strain. Stimulant and tonic; in typhus fever, bilious diarrhœa, dysentery, &c.

INFUSION (Daffodil). Syn. *Infusum Narcissi Pseudo-narcissi,* — Lat. *Prep.* (Dufresnoy.) *Flowers of daffodil* (narcissus pseudo-narcissus,—*Linn.*), 3 to 16 in no.; *boiling water*, 1 pint. Expectorant, nauseant, and emetic. In hooping-cough.

INFUSION (Dahlia Petals). From the violet or blue varieties. *Used* for its colour, and as a test.

INFUSION (Dandelion). Syn. *Infusum Taraxaci,*—Lat. From the *sliced root.* Stomachic, resolvent, and tonic. See *Decoctions* and *Extracts.*

INFUSION (Dandelion,—Concentrated). Syn. *Infusum Taraxaci Concentratum,*— Lat. *Prep.* From the root (sliced), 1 *lb.*; exposed to a current of warm dry air until crisp, then coarsely pulverized, and digested for a week in a mixture of *rectified spirit*, 12 fl. oz.; *cold water*, 1½ pint. 8 times the usual strength.

INFUSION (Dandelion, — Compound). Syn. *Infusum Taraxaci Compositum,*— Lat. *Prep.* (Meigs.) *Infusion of dandelion*, 4 fl. oz.; *extract of do.*, 2 dr.; *sesquicarbonate of soda*, ½ dr.; *tartrate of potassa*, 3 dr.; *tincture of rhubarb*, 3 fl. dr.; *tincture of henbane*, 20 drops. In dropsical and visceral affections. *Dose.* 1-3rd part, thrice daily.

INFUSION (Digitalis). See *Infusion of Foxglove.*

INFUSION (Diuretic). Syn. *Infusum Diureticum,*—Lat. *Prep.* 1. *Broom tops*, 1 oz.; *boiling water*, 1 pint; infuse 1 hour, strain, cool, and add of *sweet spirits of nitre*, 3 fl. dr. *Dose.* A wine-glassful every other hour.

2. *Infusion of foxglove*, 4 fl. oz.; *tincture of foxglove*, ½ fl. dr.; *acetate of potassa*, 1 dr.; *laudanum*, 10 drops. *Dose.* 1 table-spoonful twice or thrice a day, carefully watching the effects.

3. *Juniper berries*, 2 oz.; *aniseed*, ¼ oz.; *boiling water*, 1 pint; infuse 1 hour; strain, and when cold, add of *compound spirit of juniper*, 2 fl. oz.; *tincture of squills*, 1 fl. dr.; *nitre*, 1 dr. *Dose.* ½ a teacupful frequently. All the above are used as diuretics in dropsy.

INFUSION (Dogwood Bark). Syn. *Infusum Cornus Floridæ*,—Lat. From the *bark of American dogwood* (cornus Florida, —*Linn.*) See *Decoctions.*

INFUSION (Round-leaved Dogwood). Syn. *Infusum Cornus Circinatæ*,—Lat. Recommended in diarrhœa.

INFUSION (Elder Flowers). Syn. *Elder-flower Tea; Infusum Sambuci Florum*, —Lat. From the *picked flowers*, ½ *oz.*; *boiling water*, 1 pint. Pectoral, expectorant, and diaphoretic, either alone or sweetened with honey. See *Decoctions.*

INFUSION (Elecampane). Syn. *Infusum Inulæ*,—Lat. Diaphoretic, expectorant, and tonic.

INFUSION (Elm-bark, — Compound). Syn. *Infusum Ulmi Compositum*,—Lat. *Prep.* (Cadet.) *Elm-bark, bitter-sweet, burdock,* and *fumitory*, of each, 2 dr.; *boiling water*, 1 pint; digest for 4 hours, strain, and add of *syrup of sarsaparilla*, 1 oz. The whole to be taken in 24 hours, in divided doses, in the chronic exanthemata. See *Decoctions.*

INFUSION (Ergot of Rye). Syn. *Infusum Secalis Cornuti; Inf. Ergotæ*,—Ph. D. *Prep.* 1. (Pereira.) *Ergot*, 1 dr.; *boiling water*, 4 fl. oz.; infuse till cold. *Dose.* One third, every half hour, until the whole is taken.

2. (Ph. D.) *Ergot* (in coarse powder), 2 *dr.*; *boiling water*, 9 *fl. oz.*; infuse 1 hour in a covered vessel, and strain. "The *product* should measure about 8 oz." *Dose.* 1-5th or 1-6th, every ½ hour or hour, as a parturifacient.

INFUSION (Ergot,—Concentrated). See *Liquors.*

INFUSION (Fennel). Syn. *Fennel Tea; Infusum Fœniculi*, — Lat. *Prep.* From *sweet fennel-seeds*, ½ oz.; *boiling water*, 1 pint. In griping and windy colic of infants; a few drops to ½ a tea-spoonful for a dose, or a little by way of enema.

INFUSION (Flax-seed). See *Infusion of Linseed.*

INFUSION (Fleabane). Syn. *Infusum Inulæ Dysentericæ*,—Lat. From *common fleabane* (inula dysenterica,—*Linn.*) Tonic. Formerly *used* in diarrhœa. According to Linnæus, it cured the Russian army under General Keith of dysentery.

INFUSION (American Fleabane). Syn. *Infusum Erigeronis Annui*,—Lat. From the *whole plant* (erigeron annuum). Diuretic; a common remedy in America for the dysuria of children.

INFUSION (Canadian Fleabane). Syn. *Infusum Erigeronis Canadensis*,—Lat. From the *whole plant* (erigeron Canadense). Astringent and diuretic; taken freely in dropsies. See *Extracts.*

INFUSION (Foxglove). Syn. *Infusum Digitalis*,—Ph. L. E. & D. *Prep.* 1. (Ph. L.) *Stem-leaves of foxglove* (dried), 1 dr.; *boiling water*, 1 pint; macerate in a covered vessel for 4 hours, strain, and add of *spirit of cinnamon*, 1 fl. oz. *Dose.* ½ to 1 fl. oz.

2. (Ph. E.) *Foxglove* (dried), 2 dr.; *boiling water*, 18 fl. oz.; *spirit of cinnamon*, 2 fl. oz.

3. (Ph. D.) *Foxglove* (dried and reduced to a coarse powder), 1 *dr.*; *boiling water*, 9 *fl. oz.*; infuse 1 hour. The *product* should measure about 8 fl. oz. The last two are of *double* the strength of the infusion, Ph. L., and the *dose* must consequently be only 2 to 4 fl. dr. "I believe this, when properly made, to be the most effectual of the preparations of foxglove." (Pereira.) See *Foxglove.*

INFUSION (Fumitory). Syn. *Infusum Fumariæ*,—Lat. From the *herbaceous portion* of *common fumitory* (fumaria officinalis,—*Linn.*). Aperient and diaphoretic; in obstinate skin diseases and chronic obstructions of the liver.

INFUSION (Galls). Syn. *Infusum Gallæ*,—Lat. From *Aleppo galls*, coarsely powdered. In diarrhœa, hemorrhages, &c.; also *freely*, in cases of poisoning, by the alkaloids; and diluted with 3 or 4 times its volume of water, for injections, embrocations, gargles, &c.

INFUSION (Galls,—Compound). Syn. *Infusum Gallæ Compositum, Mistura Gallæ*,—Lat. *Prep.* (Ellis.) *Infusion of galls*, 4 fl. oz.; *prepared chalk*, ½ oz.; *powdered gum*, 1 dr.; *tincture of opium*, ½ fl. dr. *Dose.* 1 table-spoonful every 2 hours, in diarrhœa, &c.

INFUSION (Garlick). Syn. *Infusum Allii*,—Lat. *Prep.* (White.) *Garlic* (recent), ½ ℔; *water*, 1 ℔; place them in a covered pot, set it in a very slow oven for 3 or 4 hours, and when cold, express the fluid portion. *Dose.* In epilepsy, 2 tea-spoonfuls before and after every meal; in chronic diarrhœa, a tea-spoonful after every motion.

INFUSION (Gentian). Syn, *Infusum Gentianæ*,—Lat. *Prep.* (Beral.) *Gentian* (bruised), 2 dr.; *boiling water*, 1 pint; infuse 5 or 6 hours, and strain. Stomachic.

INFUSION (Gentian,—Compound). Syn. *Infusum Gentianæ*,—Ph. E. *Inf. Gentianæ Compositum*,—Ph. L. & D. *Prep.* 1. (Ph. L.) *Gentian* (sliced) and *orange peel* (dried), of each, 2 dr.; *lemon peel* (fresh),

4 dr.; *boiling distilled water*, 1 pint; macerate for an hour in a covered vessel, and strain. *Dose.* 1 to 2 fl. oz.

2. (Ph. E.) *Sliced gentian root*, ½ oz.; *bitter orange peel* (dried and bruised), and *coriander seeds*, of each, 1 dr.; *proof spirit*, 4 fl. oz.; digest for 3 hours, then add of *cold water*, 16 fl. oz., and in 12 hours more strain.

3. (Ph. D.) *Gentian* and *dried orange peel*, of each, 2 dr.; *boiling water*, ½ pint; macerate 1 hour and strain. *Dose* of the *last two*, ½ to 1 fl. oz.

Obs. The above are agreeable and useful tonics and stomachics. The infusion of the Edinburgh college will keep for some time in a close vessel; but the others soon spoil, especially in hot weather.

INFUSION (Gentian, — Concentrated Compound). Syn. *Infusum Gentianæ Comp. Concentratum*,—Lat. *Prep.* 1. *Gentian root* (bruised), 4½ *lb.*; *boiling water*, q. s. to cover it; infuse with occasional agitation for 2 hours, express the liquor, wash the *marc* with a little boiling water, and evaporate to 13 quarts; when *cold*, strain through flannel, add of *rectified spirit*, 1 gall., and pour the mixed fluids on *dried orange peel*, 4½ *lb.*; and *fresh lemon peel*, 9 *lb.*; macerate for 1 week, then express the liquor in a powerful press, and filter through paper.

2. *Gentian* and *dried orange peel*, of each, 4½ *lb.*; *fresh lemon peel*, 9 *lb.*; *cold distilled water*, 13 quarts; *rectified spirit*, 1 gall.; macerate for 14 or 15 days, with frequent agitation, then express the liquid, add 1 dr. each of the *essential oils of lemon* and *orange*, agitate well, and filter through paper.

3. *Gentian*, 1¼ *lb.*; *essence of lemon*, 1 dr.; *essence of orange*, ½ dr.; *essence of cedrat*, 15 drops; *rectified spirit*, 1 quart; *cold water*, 3 quarts; digest for 10 days and filter.

Obs. The above formulæ are actually employed at the present time by houses who do largely in concentrated infusion of gentian, and, with proper management, the products possess the brilliancy of brandy, are powerfully bitter, odorous, and aromatic, and keep well; 1 fl. dr., added to 7 fl. dr. of *water*, produces 1 fl. oz. of liquid possessing all the qualities of the *infusion* of the Ph. L. in perfection. The sale of the above preparations is astonishingly large.

INFUSION (Gentian,—with Rhubarb). Syn. *Infusum Gentianæ et Rhei, Mistura Stomachica*,—Lat. *Prep.* From *gentian* and *rhubarb* (bruised), of each, 2 dr.; *boiling water*, 1 pint; digest 1 hour, and strain; to the cold infusion add of *sesquicarbonate of ammonia*, 1 dr. An admirable medicine in dyspepsia, hysteria, loss of appetite, constipation, chronic rheumatism, &c.

INFUSION (Ginger). Syn. *Ginger Tea; Infusum Zingiberis*,—Lat. From the *best unbleached Jamaica ginger*, freshly bruised or grated. In flatulence, colic, and indigestion.

INFUSION (Ginseng). Syn. *Ginseng Tea; Infusum Ginseng, I. Radicis G.*,—Lat. *Prep. Ginseng* (panax quinquefolium,—*Linn.*), ½ oz.; *ginger* (grated), 1 dr.; *boiling water*, 1 pint; macerate 1 hour, then add of *cinnamon* (bruised), ½ dr.; infuse for another hour, and strain. "*Ginseng tea*," made according to the above formula, has a wonderful reputation in China, as a stimulant, restorative, and aphrodisiac. In Europe, however, it is merely regarded as an aromatic demulcent.

INFUSION (Golden Rod). Syn. *Infusum Solidaginis*,—Lat. From the *herbaceous portion* of *common golden rod* (solidago virgo aurea,—*Linn.*) Expectorant, diuretic, and diaphoretic; chiefly used in fevers.

INFUSION (Goldthread). Syn. *Infusum Coptis*,—Lat. From the *root* of *coptis trifolia* (Linn.). Bitter, stomachic; in dyspepsia, and as a mouth-wash in thrush.

INFUSION (Guaco). Syn. *Infusum Guaco*,—Lat. From the *bruised leaves* and *stems* of *guaco* or *huaco* (mikania guaco). Sudorific and vulnerary; reputed in South America to be a powerful remedy for the bites of venomous serpents and for hydrophobia, but the trials in this country do not show it to be of any value in such cases. Dr. Hancock explains this by asserting that the wrong plant has been employed.

INFUSION (Guaiacum). Syn. *Infusion of the Woods; Infusum Guaiaci Compositum, Aqua Benedicta Composita; Aqua Calcis C.*—Ph. D. 1826. *Prep.* (Ph. D. 1826.) *Guaiacum shavings*, 6 oz.; *bruised liquorice root*, 1 oz.; *sassafras bark*, ½ oz.; *coriander seeds*, 3 dr.; *lime water*, 96 fl. oz. (say 5 pints); infuse for 2 days, and strain. *Dose.* 3 to 4 fl. oz., twice or thrice a day, in scrofula, rheumatism, gout, eruptions, &c.

INFUSION (Gum). Syn. *Infusum Acaciæ*,—Lat. *Prep.* From *gum acacia* and *lump sugar*, of each, 2 *oz.*; *boiling water*, 1 pint; macerate until dissolved, then cool, and add of *orange-flower water*, ½ fl. oz. A pleasant demulcent in coughs, hoarseness, &c.

INFUSION (Hedge Hyssop). Syn. *Infusum Gratiolæ*,— Lat. *Prep.* (A. T. Thomson.) *Hedge hyssop* (gratiola offici-

nalis,—*Linn.*), dried, 2 dr.; *boiling water*, 8 fl. oz.. Cathartic, diuretic, emetic, and vermifuge. *Dose.* 3 to 6 fl. dr.; in dropsies, gout, jaundice, &c. See *Extracts.*

INFUSION (Hemlock). Syn. *Infusum Conii, Inf. Conii maculati,*—Lat. *Prep.* (Guy's Hosp.) *Dried leaves of hemlock*, and *coriander seeds*, of each, 2 dr.; *boiling water*, 8 oz.; infuse for 2 hours. Combined with acetate of ammonia, tincture of henbane, and syrup of poppies, in pulmonary complaints, &c.

INFUSION (Hemp Agrimony). Syn. *Infusum Eupatorii Cannabini,*—Lat. From the *herb* (eupatorium cannabinum,—*Linn.*). Reputed aperient, diuretic, pectoral, and vulnerary. The *root* of the plant is used in lieu of jalap.

INFUSION (Henbane). Syn. *Infusum Hyoscyami,*—Lat. From *fresh leaves*, ½ oz.; *boiling water*, 1 pint. As a lotion for painful ulcers, swelled face, &c.

INFUSION (Henbane,—Compound). Syn. *Henbane Fomentation; Infusum Hyoscyami Compositum,*—Lat. *Prep.* (Radius.) *Henbane leaves, poppy heads*, and *mallows*, of each, 1 oz.; *boiling water*, 2 quarts. For painful ulcers, and in facial neuralgia, &c.

INFUSION (Hops). Syn. *Hop Tea; Infusum Humuli; Inf. Lupuli,*—Ph. L. *Prep.* (Ph. L.) *Hops*, 6 dr.; *boiling distilled water*, 1 pint; macerate for 4 hours in a covered vessel (press), and strain. Tonic and anodyne. Well-hopped mild ale is a good substitute.

INFUSION (Horehound). Syn. *Horehound Tea; Infusum Marrubii,*— Lat. From the leaves; demulcent, pectoral; a popular remedy in coughs, colds, hoarseness, and chest affections generally, taken freely.

INFUSION (Horse-radish). Syn. *Infusum Armoraciæ,*—Lat. Diuretic and stomachic.

INFUSION (Horse-radish,—Compound). Syn. *Infusum Armoraciæ Compositum,*—Lat. *Prep.* (Ph. L.) *Horse-radish* (sliced), and *mustard seed* (bruised), of each, 1 oz.; *boiling distilled water*, 1 pint; macerate for 2 hours in a covered vessel, strain, and add of *compound spirit of horse-radish*, 1 fl. oz. Stimulant, stomachic, and diuretic; in dropsies, paralysis, scurvy, chronic rheumatism, &c.

INFUSION (Hyssop). Syn. *Hyssop Tea; Infusum Hyssopi,*— Lat. From the *leaves* of *hyssopus officinalis* (Linn.) Stimulant, stomachic, emmenagogue, and expectorant; in dyspepsia, flatulency, hysterical affections, &c.; also used by boxers as a wash for black eyes.

INFUSION (Hyssop,—Compound). Syn. *Infusum Hyssopi Compositum,*—Lat. *Prep.* (Ratier). *Hyssop leaves*, 2½ dr.; *liquorice*, 2 dr.; *boiling water*, 1 quart. As a demulcent drink in catarrhal affections.

INFUSION (Indian Sarsaparilla). Syn. *Infusum Hemidesmi,*—Lat. From *Indian* or *scented sarsaparilla* (hemidesmus Indicus). Dr. Ashburner orders it to be made with *lime water* (cold); but this plan is seldom followed. *Dose* and *uses*, same as those of infusion of sarsaparilla.

INFUSION (Iron,—Bitter). Syn. *Infusum Ferri Amarum,*—Lat. *Prep.* (Dr. R. E. Griffith.) *Iron filings*, 3 oz.; *gentian* and *ginger*, of each, bruised, 1 oz.; *orange peel*, ½ oz.; *strong old cider*, 1 pint; infuse for a month, frequently stirring, and filter. *Dose.* ½ to 1 dr., 3 or 4 times daily, as a chalybeate tonic.

INFUSION (Juniper Berries). Syn. *Infusum Juniperi, I. Baccæ J.,*—Lat. As a stimulant diuretic, in dropsies, &c.

INFUSION (Juniper Berries,—Compound). Syn. *Infusum Juniperi Compositum,*—Lat. *Prep.* 1. (Guy's Hosp.) *Juniper berries*, 2½ oz.; *boiling water*, 1 pint; to the strained solution, when cold, add of *compound spirit of juniper*, 10 fl. dr.; *bitartrate of potassa*, 1 dr.

2. (Parrish.) *Ginger, juniper berries*, and *mustard seed*, of each, bruised, ½ oz.; *horseradish* and *parsley root*, of each, bruised, 1 oz.; *cider*, 1 quart, infuse, and strain with expression. All the above are used in dropsies.

INFUSION (Justicia). Syn. *Infusum Justiciæ,*—Lat. *Prep.* From the *root of creata* (justicia paniculata), 3 dr.; *boiling water*, 1 pint, Bitter, stomachic, and febrifuge; in dyspepsia, cholera, dysentery, intermittents, &c. See *Drogue Amère.*

INFUSION (Kino). Syn. *Infusum Kino,*—Lat. From *kino*, 5 dr.; *boiling water*, 1 pint. In diarrhœa, and diluted with 4 or 5 times its bulk of water as an *injection* in chronic gonorrhœa.

INFUSION (Lime Flowers). Syn. *Linden-flower Tea; Infusum Tiliæ,*—Lat. From the *flowers* of the *lime* or *linden tree* (tilia intermedia). Antispasmodic, diaphoretic, and cephalic.

INFUSION (Lime Flowers,—Compound). Syn. *Infusum Tiliæ Compositum,*— Lat. *Prep.* (Foy.) *Chamomiles, linden flowers*, and *orange leaves*, of each, 2 dr.; *boiling water*, 1 quart; infuse, strain, and add of *syrup*, 2 fl. oz. In nervous headaches, &c. The above are much used on the Continent.

INFUSION (Linseed). Syn. *Linseed*

Tea, Flaxseed do; Infusum Lini, — Lat. Demulcent and pectoral.

INFUSION (Linseed,—Compound). Syn. *Compound Linseed Tea; Infusum Lini,*— Ph. E. *Inf. Lini Compositum,*—Ph. L.; & Ph. D., 1826. *Prep.* (Ph. L. & E.) *Linseed* (bruised), 6 dr.; *fresh liquorice root* (sliced), 2 dr.; *boiling distilled water*, 1 pint; macerate for 4 hours near the fire, in a covered vessel, and strain. A cheap and useful demulcent in pulmonary and urinary irritation; especially in catarrhs, gonorrhœa, &c.; ad libitum. Dr. Pereira recommends the addition of sliced lemon and sugar-candy, to render it more palatable.

INFUSION (Liquorice). Syn. *Infusum Glycyrrhizæ,*—Lat. From the *fresh root*, sliced. Demulcent and laxative; taken ad libitum.

INFUSION (Litmus). Syn. *Infusum Lacmi,*—Lat. *Used* for its colour, and as a liquid test, and to make test paper.

INFUSION (Lobelia). Syn. *Infusum Lobeliæ, Inf. Lob. Inflatæ.* From *lobelia* or *Indian tobacco.* In asthmas, chiefly. *Dose.* 1 to 2 table-spoonfuls every half-hour, until it occasions nausea.

INFUSION (Logwood). Syn. *Logwood Tea; Infusum Hæmatoxyli,*—Lat. From *logwood chips.* One of the best remedies known for simple diarrhœa arising from weakness; also used as a colour and test.

INFUSION (Maiden-hair). Syn. *Infusum Adianthi,*—Lat. From either *common maiden-hair* (adiantum capillus veneris, —*Linn.*) or *Canadian maiden-hair* (adiantium pedatum, — *Linn.*) They are both slightly bitter, aromatic, and pectoral. The infusion forms an excellent demulcent drink in catarrhs.

INFUSION (Malambo Bark). Syn. *Infusum Corticis Malambo,* — Lat. *Prep.* (Ure.) *Bark*, 2 dr.; *boiling water*, 1 pint. An aromatic tonic and astringent.

INFUSION (Mallow Flowers). Syn. *Infusum Malvæ Florum,*—Lat. Pectoral and laxative. Chiefly used as a test.

INFUSION (Malt). Syn. *Malt Tea; Sweet Wort; Infusum Bynes, Inf. Malti,*— Lat. Prepared with *hot water* (165° to 170° Fahr.) Demulcent and laxative. A useful drink in sore throat, inflammatory fevers, &c. Some persons flavour it with *sliced lemon.*

INFUSION (Marygold). Syn. *Infusum Calendulæ,*—Lat. From the flowers of the *common marygold* (calendula officinalis,— *Linn.*) Carminative, diaphoretic, and emmenagogue. It has been recently recommended in cancerous affections, both internally and as a lotion. Radius adds *syrup of orange-peel* to flavour it.

INFUSION (Matico). Syn. *Infusum Maticonis, I. Maticæ, I. Matico,* — Lat. From the *leaves* of the *matico plant* (artanthe elongata). Aromatic, bitter, stimulant, and reputed hæmostatic; in internal hæmorrhages and mucous discharges. The Indians use it as an aphrodisiac. (Martius.)

INFUSION (Matico,—Compound). Syn. *Infusum Maticonis Compositum,* — Lat. *Prep.* (Watmough.) *Matico* and *senna*, of each, 2 dr.; *boiling water*, 1 pint. In hæmorrhagic and other discharges, piles, &c.; a wine-glassful repeatedly.

INFUSION (May-weed). Syn. *Infusum Cotulæ,*—Lat. From the *dried flowers of may-weed* or *stinking chamomile* (anthemis cotula, — *Linn.*) Bitter, stomachic, and diaphoretic; in large doses, emetic and sudorific; chiefly in hysterical affections, scrofula, &c.

INFUSION (Meadow Rue). Syn. *Infusum Thalictri Flavi,*—Lat. From the herb *meadow rue* (thalictrum flavum,— *Linn.*) In hydrophobia, taken plentifully.

INFUSION (Milfoil). Syn. *Yarrow Tea; Infusum Millefolii,*—Lat. In dropsies, and as a fomentation to bruises. See *Decoctions.*

INFUSION (Mint). Syn. *Mint Tea; Infusum Menthæ Simplex,*—Ph. D. From the *dried leaves of green or spearmint.* Carminative and stomachic; chiefly used as a vehicle for other medicines. A wine-glassful ad libitum.

INFUSION (Mint,—Compound). Syn. *Compound Mint Tea; Infusum Menthæ Compositum,*—Ph. D. 1826. *Prep.* To *mint tea*, 6 fl. oz.; add of *oil of spearmint*, 3 drops, previously triturated with *lump sugar*, 2 dr., and dissolved in *compound tincture of cardamoms*, ½ fl. oz. A useful remedy in colic, flatulence, &c.; as the last.

INFUSION (Mudar). Syn. *Infusum Corticis Mudaris, I. C. M. Giganteæ,*—Lat. From the *root-bark* of *asclepias gigantea*, (Brown.) Resembles infusion of ipecacuanha. *Dose.* 1 to 3 teaspoonfuls, as an alterative; a wine-glassful, as an emetic. In the East Indies it is highly esteemed in epilepsy, hysteria, syphilis, convulsions, and various spasmodic diseases.

INFUSION (Nettle-seed). Syn. *Infusum Urticæ Seminum,*—Lat. *Prep.* (Garde.) *Seed of common nettle* (urtica dioica,— Linn.), 2½ dr.; *boiling water*, 18 fl. oz.; infuse 3 hours, strain, and add of *syrup*, 2 fl. oz. Astringent, diuretic, and pectoral.

INFUSION (Nux Vomica). Syn. *Infusum Nucis Vomicæ*,—Lat. *Prep.* (Hosp. F.) *Nux vomica* (ground or rasped), 1 dr.; *boiling water*, 1 pint; digest 3 hours, and strain. It must be taken with caution, and the effects watched. See *Nux vomica & Strychnine.*

INFUSION (Orange-peel). Syn. *Infusum Aurantii Corticis*,—Lat. Bitter and stomachic.

INFUSION (Orange-peel,—Compound). Syn. *Infusum Aurantii*,—Ph. E. *Inf. Aurantii Compositum*,—Ph. L. & D. *Prep.* 1. (Ph. L. & E.) *Dried bitter-orange peel*, ½ oz.; *fresh lemon peel*, 2 dr.; *cloves* (bruised), 1 dr.; *boiling distilled water*, 1 pint; macerate for 15 minutes in a covered vessel, and strain.

2. (Ph. D.) *Dried orange peel*, 3 *dr.*; *cloves*, ½ *dr.*; *boiling water*, ½ pint; macerate half an hour. An agreeable stomachic. It is chiefly employed as a vehicle for other medicines.

INFUSION (Orange-peel,—Concentrated Compound). Syn. *Infusum Aurantii Concentratum*, *Inf. A. Comp. Conc.*,—Lat. *Prep.* 1. Seville *orange-peel*, (dried), 3¼ *lb.*; *fresh lemon peel*, 1½ *lb.*; *bruised cloves*, ¾ *lb.*; *boiling water*, 9 pints; infuse for 20 minutes, press out the liquor, and, when cold, add of *rectified spirit*, 1 quart; and filter.

2. *Dried orange-peel*, 18 *oz.*; *fresh lemon peel*, ½ *lb.*; *bruised cloves*, ¼ *lb.*; *rectified spirit*, 1 pint; *cold water*, 3 pints; macerate for 1 week, press, and filter. Very superior.

Obs. 1 fl. dr. of either of the above added to 7 fl. dr. of *water*, makes a similar (preferable) preparation to the *compound infusion of orange peel*, Ph. L.

INFUSION (Pareira Brava). Syn. *Infusum Pareiræ*,—Ph. E. & D.; & Ph. L. 1836. *Prep.* 1. (Ph. E., & Ph. L. 1836.) *Velvet leaf* or *pareira brava root*, 6 dr.; *boiling water*, 1 pint; macerate for two hours in a lightly covered vessel, and strain.

2. (Ph. D.) *Pareira* (bruised and torn), ½ *oz.*; *boiling water*, 9 *fl. oz.*; *macerate* 1 hour, and strain. In irritation and mucous discharges from the urinary organs. The corresponding preparation of the Ph. L. will be found among the "*decoctions.*"

INFUSION (Parsley Root). Syn. *Infusum Petroselini*,—Lat. From the *root of garden parsley.* Aromatic, diuretic, and slightly aperient. It has been highly recommended by Dr. Chapman and others in dropsy, in the strangury arising from blisters, &c.; taken freely, either alone, or combined with a little *sweet spirit of nitre.*

INFUSION (Peach Leaves). Syn. *Infusum Persicæ*, *I. P. Folii*,—Lat. *Prep.* (Pereira.) *Peach leaves* (dried), ½ oz.; *boiling water*, 1 pint; macerate an hour, and strain. *Dose.* 1 to 2 table-spoonfuls, twice or thrice a day; to allay irritation of the bladder and urethra, and as a vermifuge.

INFUSION (Pectoral). Syn. *Infusum Pectorale*,—Lat. *Prep.* (Hosp. F.) *Linseed* (bruised), ¾ oz.; *coltsfoot leaves*, ½ oz.; *liquorice root* (sliced) and *poppy-heads*, of each, ¼ oz.; *boiling water*, 1 pint; digest two hours, and strain. In coughs, colds, hoarseness, &c., accompanied with a dose of aperient medicine. See *Species, &c.*

INFUSION (Pennyroyal). Syn. *Pennyroyal Tea; Infusum Pulegii, I. Menthæ Pulegii*,—Lat. A popular remedy for nausea, flatulence, colds, hooping-cough, hysterical affections, obstructed menstruation, &c.

INFUSION (Peppermint). Syn. *Peppermint Tea; Infusum Menthæ Piperitæ*,—Lat. In flatulence, colic, griping, &c., and as a vehicle for other medicines.

INFUSION (Periwinkle). Syn. *Infusum Vincæ Minoris*,—Lat. From the *leaves* of *lesser periwinkle* (vinca minor,—*Linn.*) Astringent and tonic; in diarrhœa, dysentery, &c. Mr. Weathers employs it in passive hæmorrhages, and others have recommended it as an external tonic applied to the perinæum, &c., in piles, relaxation of the genitals, &c.

INFUSION (Persimmon). Syn. *Infusum Persimmonis*,—Lat. From the *bark* of *persimmon* or *pishamin* (diospyros Virginiana,—*Linn.*) Astringent; very valuable in diarrhœa, hæmorrhages, agues, &c.; and as a gargle in ulcerated sore throat.

INFUSION (Peruvian Bark). See *Infusion of Bark.*

INFUSION (Pinkroot). Syn. *Pinkroot Tea, Worm do.; Infusum Spigiliæ*,—Lat. From *Indian pinkroot.* Vermifuge; either combined with, or followed by a purge after the third or fourth dose. The dose for a child, 3 to 5 years old, is 1 to 2 table-spoonfuls.

INFUSION (Pinkroot, — Compound). Syn. *Infusum Spigiliæ Compositum, I. S. cum Sennâ*,—Lat. *Prep.* (Elliss.) *Pinkroot*, ½ oz.; *senna*, 2 dr.; *fennel seed*, 3 dr.; *manna*, 1 oz.; *boiling water*, 1 pint. *Dose*, ½ wine-glassful to a child 2 or 3 years old; in worms. See *Decoctions.*

INFUSION (Pleurisy Root.) Syn. *Infusum Asclepiadis Tuberosæ*,—Lat. From the *root* of *butterfly weed* or *pleurisy root*

(asclepias tuberosa,—*Linn.*) Expectorant and diuretic; in large doses, purgative; in colds, pleurisy, pneumonia, &c. According to Bigelow it is a valuable mild tonic and stimulant.

INFUSION (Poison-oak). Syn. *Infusum Rhois Toxicodendri,*—Lat. *Prep.* From the *dried leaves of the poison-oak* or *poison ivy* (rhus toxicodendron,—*Linn.*), 3 dr.; *boiling water*, 1 pint. Stimulant and narcotic; chiefly in palsy and mania.

INFUSION (Poppy-heads). Syn. *Poppy Tea; Infusum Papaveris,*—Lat. Soothing, anodyne. Sweetened with honey it is a popular remedy for tickling cough, restlessness, &c.; also used *hot*, as an embrocation, in painful tumours, inflammations, &c.

INFUSION (Red Poppy). *Syn. Red-poppy Tea; Infusum Rhœados*—Lat. From the *petals* of the *red* or *corn poppy*. Anodyne and pectoral. Sweetened with sugar or honey, it is a popular remedy in catarrhal affections; but the use of this as well as of the last preparation should be accompanied by a dose of aperient medicine.

INFUSION (Purging Flax). Syn. *Infusum Lini Cathartici,*—Lat. From the *dried leaves of purging flax* (linum catharticum,—*Linn.*) Cathartic. The *dose* should be repeated at intervals of an hour, or an hour and a half, until it operates.

INFUSION (Quassia). Syn. *Quassia Tea; Infusum Quassiæ,*—Ph. L. E. & D. *Prep.* 1. (Ph. L.) *Quassia* (sliced), 40 gr.; *boiling distilled water*, 1 pint; infuse for 2 hours in a covered vessel, and strain.

2. (Ph. E.) *Quassia*, 1 *dr.*; *boiling water*, 1 pint.

3. (Ph. D.) *Quassia* (rasped), 1 *dr.*; *boiling water*, 8½ *fl. oz.*

4. (Ph. U. S.) *Quassia*, 2 dr.; *cold water*, 16 fl. oz; macerate for 12 hours, and strain. As a bitter tonic, in loss of appetite, dyspepsia, &c.; either combined with alkaline carbonates or chalybeates. Sweetened with moist sugar or honey, it forms a common *fly-water* or *fly-poison.*

INFUSION (Quassia,—Compound). Syn. *Infusum Quassiæ Compositum,*—Lat. *Prep.* (Ellis.) *Quassia*, *serpentary*, and *dried orange peel*, of each, ¼ oz.; *boiling water*, 1 pint. A stimulant stomachic.

INFUSION (*Rattle-snake Root.*) Syn. *Seneka Tea; Infusum Senegæ,* — Ph. E. *Inf. Polygalæ,*—Ph. D. *Prep.* 1. (Ph. E.) *Rattle-snake root* (bruised) 10 dr.; *boiling water*, 1 pint; infuse for 4 hours in a covered vessel and strain.

2. (Ph. D.) *Polygala root*, ½ *oz.*; *boiling water*, 9 fl. oz. Stimulant, expectorant, and diuretic, either alone or combined with ammonia; in catarrhs, &c.

INFUSION (Red Cabbage). *Used* as a colour, and to make test paper. It will not keep without the addition of about 1-10th of its weight of *rectified spirit.*

INFUSION (Rhatany). Syn. *Infusum Rhataniæ; Inf. Krameriæ,* — Ph. L. & D. *Prep.* 1. (Ph. L.) *Rhatany root*, 1 oz.; *boiling distilled water*, 1 pint; macerate for 4 hours in a covered vessel, and strain.

2. (Ph. D.) *Rhatany*, ½ *oz.*; *boiling water*, 9 *fl. oz.*; macerate 1 hour, and strain. Astringent and tonic; chiefly in chronic diarrhœa.

INFUSION (Rhatany, — Concentrated). Syn. *Infusum Krameriæ Concentratum,*— Lat. From 8 times the *usual quantity of ingredients*, as *infusion of cascarilla.*

INFUSION (Rhododendron). Syn. *Infusum Rhododendri,*—Lat. From the *leaves of yellow rhododendron* (rhododendron chrysanthum), ½ oz.; *boiling water*, ½ pint. Highly recommended by Pallas and Koelpin in gout, chronic rheumatism, and syphilis. A patient lame from sciatica, and deplorably emaciated, was completely cured by persevering in its use. (Pallas.)

INFUSION (Rhubarb). Syn. *Infusum Rhei,*—Ph. L. E. & D. *Prep.* 1. (Ph. L.) *Rhubarb* (sliced), 3 dr.; *boiling distilled water*, 1 pint; macerate for 2 hours in a covered vessel, and strain.

2. (Ph. D.) *Rhubarb*, 2 *dr.*; *boiling water*, 9 *fl. oz.*; macerate 1 hour.

3. (Ph. E.) *Rhubarb*, (in coarse powder), 1 oz.; *boiling water*, 18 fl. oz.; infuse for 12 hours, add of *spirit of cinnamon*, 2 fl. oz.; and strain through linen or calico. Stomachic and purgative; along with neutral salts or aromatics. The infusion, Ph. E., being fully double as strong as that of the Ph. L. & D., must be taken in proportionate doses.

INFUSION (Rhubarb,—Concentrated). Syn. *Infusum Rhei Concentratum,*—Lat. *Prep.* 1. *Rhubarb* (in coarse powder), 10 *oz.*; *rectified spirit*, 1 pint; *cold distilled watar*, 1 quart; digest 10 days, with frequent agitation, then express the liquor, and filter it; or proceed by the method of displacement.

2. *Rhubarb*, 3 *lb.* 5 *oz.*; *cold distilled water*, 11 pints; *rectified spirit*, 5½ pints; as the last.

Obs. 1 fl. dr. of either of the above, added to 7 fl. dr. of *water*, forms 1 fl. oz. of liquid, resembling, and in many points preferable to the infusion of the Ph. L. The above is the only way a fine, rich-coloured, and transparent concentrated preparation can

be made, that will keep well. Should it not prove perfectly limpid it may be clarified in the way already mentioned.

INFUSION (Rhubarb,—Alkaline). Syn. *Infusum Rhei Alkalinum, I. R. cum Potassâ.*—Lat. *Prep.* (Copland.) *Rhubarb*, 2 dr.; *carbonate of potassa*, 1 dr.; *boiling water*, ½ pint; macerate for 4 hours, strain, and add of *tincture of cinnamon*, ½ fl. oz. In dyspepsia, acidity, heartburn, &c.

INFUSION (Roses). Syn. *Infusum Rosæ*,—Lat. From the *petals of red roses.* Used as colouring and for a test; mixed with vinegar and sweetened with honey it forms a popular gargle in sore throat.

INFUSION (Roses,—Compound). Syn. *Infusum Rosæ*,—Ph. E. *Inf. Rosæ Compositum*,—Ph. L. *Inf. R. Acidum*,—Ph. D. *Tinctura Rosarum*,—Ph. L. 1746. *Prep.* 1. (Ph. L.) *Petals of the red* or *damask rose* (dried and pulled asunder), 3 dr.; *boiling water*, 1 pint; mix, and add of *dilute sulphuric acid*, 1½ fl. dr.; macerate for 2 hours, strain off the liquor, and dissolve in it, *white sugar*, 6 dr. The Edinburgh form is nearly similar.

2. (Ph. D.) *Petals, 2 dr.; boiling water*, ½ pint; infuse 1 hour, strain, and add of *dilute sulphuric acid*, 1 *fl. dr.*

Obs. A vessel of glass or stone-ware should be used to make the infusion in, as metallic vessels injure the colour of the liquid, and are also attacked by the acid. The best plan is to add the dilute sulphuric acid to the water, before pouring it on the leaves. The infusion may be squeezed out of the leaves with the hands.

Infusion of roses is principally used as a vehicle for sulphate of quinine, saline purgatives, and some other medicines. It is astringent and refrigerant, and, when diluted with water, forms a pleasant drink in febrile disorders, phthisical sweats, hæmorrhages, diarrhœa, &c. It also makes a very useful astringent gargle. *Dose.* 1 to 4 fl. oz.; either alone or diluted with water. It is incompatible with the alkalies and earths, and their carbonates and bicarbonates.

INFUSION (Roses, — Concentrated). Syn. *Infusum Rosæ Concentratum*,—Lat. *Prep.* 1. *Rose petals* or *leaves*, 10 *oz.; boiling distilled water*, 3 pints; infuse for 2 hours, with frequent agitation, express the liquid, strain through a clean hair sieve, and add of *dilute sulphuric acid*, 4½ fl. oz.; after agitation for 5 or 6 minutes, and repose for 2 or 3 hours, decant the clear portion, and filter through paper supported on calico; next, dissolve in the liquid 1¼ *lb.* of the *finest white sugar*, broken up into small lumps, but perfectly free from dust and dirt; lastly, pour the infusion into clean stoppered green-glass bottles, and as much as possible keep them from the light, and in a cool place.

2. *Rose petals* or *leaves*, 3¼ *lb.; boiling water*, 2 gall.; *diluted sulphuric acid*, 24 fl. oz.; *finest white sugar*, 6½ *lb.;* as the last.

3. The same quantity of *dilute sulphuric acid* and *cold water*, as before; mix, and infuse the *rose leaves* in the liquid for 48 hours, then express, filter, and add the *sugar.* Product very fine, and keeps well without becoming gelatinous.

Obs. The above infusion is 8 times as strong as that of the Ph. L. Great care should be taken that the utensils are *perfectly clean*, especially the press, if one is employed; and earthenware *glazed with lead* should be *avoided.* The "*pressing*" should also be conducted as rapidly as possible, to avoid the colour being injured by the iron. *Clean wrought iron* does not readily injure the colour of infusion of roses *before* the addition of the acid. When the 3d formulæ is adopted, strong pressure of the leaves with the hands can alone be safely had recourse to. If the infusion does not filter *quite clear* through paper, it should be set aside for a few days, when, in general, it will be found to filter more readily and satisfactorily. Should it be wanted for immediate sale, the addition of the whites of 2 or 3 eggs, diluted with 2 or 3 ounces of water, followed by violent agitation of the liquid for a few minutes, and repose for an hour or two, will usually render it "fine," when it may be either decanted, or filtered should it require it. It will now pass rapidly through ordinary filtering paper, and at once run "clear."

INFUSION (Rue). Syn. *Rue Tea; Infusum Rutæ*,—Lat. Carminative, antispasmodic, emmenagogue, and vermifuge. It is a popular and useful remedy in flatulent colic, infantile convulsions, epilepsy, hysteria, suppressed menstruation, &c.

INFUSION (Rupture-wort). Syn. *Infusum Herniariæ*,—Lat. From the *herb* (herniaria glabra,—*Linn.*) Astringent, diuretic, and saline; formerly supposed to be useful in ruptures.

INFUSION (Sage). Syn. *Sage Tea; Infusum Salviæ*,—Lat. From the *leaves of common garden sage.* Carminative and stomachic. In flatulence and dyspepsia, and diluted with water as a drink, to lessen the night sweats in phthisis and fever, and to stop the secretion of milk after weaning. *Dill tea* (Infusion of dill; Infusum anethi),

which is reputed to promote the secretion of milk, is made in a similar manner.

INFUSION (Sage,—Compound). Syn. *Infusum Salviæ Compositum*,—Lat. *Prep.* (Ellis.) *Sage* and *boneset*, of each, ½ oz.; *cascarilla*, 1 dr.; *boiling water*, 1½ pint; infuse until cold. A wine-glassful every 3 or 4 hours in hectic fever.

INFUSION (Sarsaparilla). Syn. *Infusum Sarzæ; Inf. Sarsaparillæ*, — Ph. U. S. From the *bruised root*. Dr. Hancock adds, ½ fl. dr. of *hydrochloric acid* to each pint of the *water* employed, as the menstruum, by which, he says, the efficacy of the infusion is greatly increased. At St. George's Hospital, a little *liquorice root* and *liquor of potassa* is added for the same purpose.

INFUSION (Sarsaparilla,—Compound). Syn. *Infusum Sarsaparillæ Compositum*,—Lat. *Prep.* (Ph. D., 1826.) *Sarsaparilla root* (washed clean with a little cold water, and sliced), 1 oz.; *lime water* (cold), 16 fl. oz.; macerate for 12 hours, and strain. Inferior to the simple infusion, since both earths and alkalies lessen the solvent action of water on sarsaparilla. *Use* of both the above, similar to that of the decoction.

INFUSION (Sassafras). Syn. *Sassafras Tea; Infusum Sassafras*, — Lat. From *sassafras chips*. Alterative, stimulant, and sudorific; a popular remedy in various cutaneous, rheumatic, scrofulous, and syphilitical affections. Hufeland recommends the addition of a little *liquorice root*.

INFUSION (Savine). Syn. *Savine Tea; Infusum Sabinæ*,—Lat. *Prep.* (Pereira.) *Fresh savine leaves* or *herb*, 1 dr.; *boiling water*, 8 fl. oz.; infuse in a covered vessel. Stimulant, emmenagogue, and vermifuge; in chlorosis, and suppressed menstruation depending on a torpid action of the uterine vessels; in chronic rheumatism, worms, &c. *Dose.* 1 to 2 table-spoonfuls, cautiously administered.

INFUSION (Saxifrage). Syn. *Saxifrage Tea; Infusum Pimpinellæ*,—Lat. From the *root of burnet saxifrage* (pimpinella saxifraga,—*Linn.*) Astringent; in diarrhœa, and *externally* as a wash to remove freckles.

INFUSION (Scutellaria). Syn. *Infusum Scutellariæ*,—Lat. *Prep.* (Dr. Spalding.) *Dried herb* of *scutellaria lateriflora* (Linn), in powder, 1½ tea-spoonful; *boiling water*, 1 pint. By teacupfuls, thrice daily to prevent hydrophobia. (See p. 587.)

INFUSION (Senna). Syn. *Senna Tea; Infusum Sennæ*,—Ph. E. *Inf. Sennæ Compositum*,—Ph. L. & D. *Inf. S. Simplex*,—Ph. L., 1788. *Inf. S. Commune*,—Ph. L., 1746. *Prep.* 1. (Ph. L.) *Senna*, 15 dr.; *ginger* (bruised), 4 scruples; *boiling water*, 1 pint; macerate for an hour in a covered vessel, and strain.

2. (Ph. E.) *Senna*, 1½ oz.; *ginger*, 4 scrup.; *boiling water*, 1 pint.

3. (Ph. D.) *Senna*, ½ *oz.; ginger*, ½ *dr.; boiling water*, ½ pint. Purgative. *Dose.* 1 to 2 wine-glassfuls. It is usually given in doses of 1 to 1½ fl. oz., combined with 3 to 6 dr. of Epsom salts, or other saline purgative, under the name of "*black draught*."

This infusion is very apt to spoil in warm weather, to prevent which "Mr. Squire recommends the addition of 1 gr. of *nitrate of potassa* to each ounce." (Pereira, Elem. Mat. Med. iii, p. 1872.) See *Mixtures*.

INFUSION (Senna, — Concentrated). Syn. *Infusum Sennæ Concentratum*,—Lat. *Prep.* 1. *Senna*, 2 *lb.* 1 *oz.; tepid water*, 1 quart; macerate for 12 hours, frequently stirring with a stick, and express the liquor; to the *marc*, add of *tepid water*, 1¼ pint, repeat the maceration for 3 hours, and again express the liquor with powerful pressure; mix the infusions, and after 2 hours' repose, decant the clear portion, and evaporate it as rapidly as possible, by steam or a chloride of sodium bath, until it measures 1½ pint; pour this into a strong bottle, and when nearly cold, add of *rectified spirit*, ½ pint; *bruised ginger*, 3½ *oz.;* macerate a week with frequent agitation, and after repose for a few days, decant the clear portion, and add *dilute spirit* (1 to 4), q. s. to make the whole measure exactly a quart.

2. Take 8 times the quantity of *senna* and *ginger*, ordered in the Ph. L., put them into a displacement apparatus, either alone, or mixed with *clean washed sand*, and transmit *water*, mixed with ¼th part of *rectified spirit* through the mass, until the proper quantity of infusion is obtained.

3. (Wholesale.) *Alexandrian senna* (best) 7 *lb.; unbleached Jamaica ginger* (finest, bruised), 3 *lb.; rectified spirit* and *water*, of each, 1 gall.; macerate for 14 days, press out the fluid, filter, and set it aside in a well-corked bottle; then take of good *East India senna*, 25 *lb.;* and the "*pressings*" or "*marc*" from the *tincture* (see above), and macerate in the least possible quantity (10 or 12 gall.) of *cold distilled water*, for 12 or 14 hours, employing frequent agitation with a wooden spatula; next press out the liquid, and again macerate the "*marc*" in *cold distilled water* (5 or 6 gall.) for 2 hours; press, mix the two liquors, strain, heat gradually to the boiling point, carefully separate the coagulated albumen, and afterwards evaporate as quickly as possible to

exactly 9 quarts; put the liquid *at once* into a vessel capable of holding 5 gallons, bung close to exclude the air, and when *nearly* cold, add the "*tincture*" obtained from the Alexandrian senna and the ginger; the whole must now be well agitated together, and allowed to stand for a week, when the clear portion must be carefully decanted into bottles (*Winchester quarts*) for sale.

4. As the last, but employing *hot water*, and limiting the period of the infusions to 2 hours, and 1 hour.

Obs. The preceding formulæ are at present employed in the wholesale trade, by nearly all those houses that are most noted for the superior quality of their "*concentrated infusions.*" The products of the whole are excellent. That from No. 3 is very beautiful, and contains all the valuable active matter that it is possible to extract from the ingredients, under the circumstances. It also keeps well. The *last* one like all preparations of senna made with hot water, is apt to drop a large deposit on standing, from which the last portion of the infusion is obtained with difficulty. They each furnish a liquid, of which 1 *fl. dr.* added to 7 *fl. dr.* of *pure water* forms 1 *fl. oz.* of a preparation precisely similar in medicinal qualities to the "*infusion of the Ph. L.*"

From the extreme bulkiness of senna, it has become a common practice with the unprincipled portions of the trade to employ only ⅓ or ¼ of the proper quantity of that drug, and to add *burnt sugar* or *treacle* to bring up the consistence and colour, and *alkaline solution of gamboge* to impart the necessary purgative quality. This fraud may be detected in the way described under "*Extract of Colocnyth*," at *page* 428. *Pure infusion of senna* reddens litmus paper. Concentrated infusion of senna, as generally met with is nearly worthless. This arises from either the employment of *inferior senna*, or the destruction of its active principle, by the lengthened exposure to heat and atmospheric oxygen, during its manufacture.

INFUSION (Senna,—Compound). Syn. *Infusum Sennæ Compositum*,—Ph. E. *Inf. Sennæ cum Tamarindis*,—Ph. D., 1826. *Prep.* (Ph. E.) *Senna*, 3 dr.; *tamarinds*, 1 oz.; *coriander seeds*, 1 dr.; *sugar*, ½ oz.; (if *brown*, 1 oz.); *boiling water*, 8 fl. oz.; infuse for 4 hours, with agitation, and then strain through calico. Pleasanter than the ordinary infusion of senna.

INFUSION (Senna with Coffee). Syn. *Infusum Sennæ cum Caffea*,—Lat. *Prep.* 1. (Foy.) *Senna*, 2 dr.; *roasted coffee* (ground), 1 dr.; *boiling water* and *hot milk*, of each, 3 fl. oz.; infuse for 12 hours (4?), and strain. For an adult; to be taken in the morning fasting.

(Guersand and Blake.) *Senna*, 10 to 30 gr. (according to age); *hot coffee* and *hot milk*, at will; infuse, and when cold, strain, and sweeten it with *sugar*, q. s. As a purge for children.

INFUSION (Senna with Lemon Juice). Syn. *Infusum Sennæ Limoniatum*,—Ph. L. 1746. *Prep.* From *senna*, 1½ oz.; *fresh lemon peel*, 1 oz.; *lemon juice*, 1 fl. oz.; *boiling water*, 16 fl. oz.; infuse.

INFUSION (Senna with Rhubarb). Syn. *Infusum Sennæ et Rhei*,—Lat. *Prep.* (Ellis.) *Senna*, 6 dr.; *manna*, 1 oz.; *rhubarb* and *cardamoms*, of each (bruised), 2 dr.; *boiling water*, 1 pint; infuse 1 hour and strain.

INFUSION (Senna with Tamarinds). See *Compound Infusion of Senna*, Ph. E.

INFUSION (Senna with Tartar). Syn. *Infusum Sennæ Tartarizatum*,—Ph. L., 1788. *Prep.* From *senna*, 1½ oz.; *coriander seeds*, 4 dr.; *cream of tartar*, 2 dr.; *boiling water*, 16 fl. oz.

INFUSION (Serpentary). Syn. *Infusum Serpentariæ*,—Ph. L. & E. *Prep.* (Ph. L.) *Serpentary* or *Virginian snake-root*, ½ oz.; *boiling distilled water*, 1 pint; macerate for 4 hours in a closed vessel, and strain. The form of the Ph. E. is similar. As a stimulating expectorant and diaphoretic; in chronic catarrhs, low fevers, agues, &c.

INFUSION (Serpentary,—Compound). Syn. *Infusum Serpentariæ Compositum*,—Lat. *Prep.* (Guy's Hosp.) *Virginian snake-root* and *contrayerva*, of each, 5 dr.; *boiling water*, 1 pint; macerate 2 hours, strain, and when cold, add of *tincture of serpentary*, 2 fl. oz. As the last.

INFUSION (Silk-weed). Syn. *Infusum Asclepiadis*,—Lat. From the *root-bark* of *common silk-weed* (asclepias Syriaca,—*Linn.*) Expectorant and nauseant; in asthmas, coughs, difficult respiration, &c.

INFUSION (Simaruba). Syn. *Infusum Simarubæ*,—Ph. E. & D.; & Ph. L., 1836. *Prep.* 1. (Ph. E. & Ph. L., 1836.) *Bark of the bitter simaruba* or *mountain damson*, 3 dr.; *boiling water*, 1 pint; macerate 2 hours, and strain.

2. (Ph. D.) *Simaruba bark*, 2 *dr.*; *boiling water*, 9 fl. oz. Tonic, and in large doses, emetic; in chronic diarrhœa and dysentery, either alone or combined with opium; and in agues, dyspepsia, &c.

INFUSION (Simaruba, — Compound). Syn. *Infusum Simarubæ Compositum*,—Lat. *Prep.* (Foy.) *Simaruba bark* and *wormwood*, of each, 2 dr.; *boiling water*, 1 pint; infuse for 15 minutes, strain, and add of *syrup of gentian*, 1 fl. oz. In agues and dyspepsia.

INFUSION (Skunk Cabbage). Syn. *Infusum Dracontii*,—Lat. From the *root* of the perennial *skunk cabbage* (dracontium fœtidum,—*Linn.*) In asthma, hysteria, &c.

INFUSION (Slippery Elm). Syn. *Infusum Ulmi Fulvæ*,—Lat. *Prep.* (Ph. U. S.) *Inner bark of slippery elm* (ulmus fulva), 1 oz.; *boiling water*, 16 fl. oz.; infuse for 2 hours, and strain. Demulcent.

INFUSION (Soap-wort). Syn. *Infusum Saponariæ*,—Lat. From *soap-wort root* (saponaria officinalis,—*Linn.*) Aperient and demulcent; also reputed alterative and antisyphilitic.

INFUSION (Southernwood). Syn. *Southernwood Tea; Infusum Abrotani*,—Lat. From the herb *southernwood* or *old man* (absinthium abrotanum,—*Linn.*) Antispasmodic, tonic, and vermifuge; in hysteria, difficult and painful menstruation, worms, &c.

INFUSION (Stimulant). Syn. *Infusum Stimulans*,—Lat. *Prep.* (Dr. Paris.) *Black mustard seed* (bruised) and *dittander*, of each, ½ oz.; *boiling water*, 16 fl. oz.; macerate for 1 hour, strain, and when cold, add of *spirit of sal volatile*, 1 fl. dr.; *spirit of pimento*, ½ fl. oz. *Dose.* 2 table-spoonfuls, 3 times a day in palsy.

INFUSION (Stinking Hellebore). Syn. *Infusum Hellebori Fœtidi*,—Lat. *Prep.* (Woodville.) *Dried leaves* of *setter-wort* or *helleborus fœtidum* (Linn.), ½ dr. (or *green herb*, 2 dr.); *boiling water*, 16 fl. oz.; macerate 1 hour, and strain. Aperient and vermifuge; and emetic, in large doses. It is chiefly useful against the large round worms of children and females, taken fasting.

INFUSION (Succory). Syn. *Chicory Tea; Infusum Chicorii*,—Lat. From the *dried root.* Aperient, deobstruent, and tonic; either alone or sweetened with honey or sugar.

INFUSION (Sudorific). Syn. *Infusum Sudorificum, Inf. Ayæ-panæ*,—Lat. *Prep.* (Dr. Camera.) *Leaves of Brazilian ayapana* (eupatorium ayapana), 2 dr.; *aniseed*, 1 dr.; *boiling water*, 1 pint. Said to be powerfully alexipharmic and sudorific. It is commonly used in Brazil as an antidote to the bites of venomous reptiles and insects.

INFUSION (Sweet Flag). Syn. *Calamus Tea, Sweet-flag do.; Infusum Acori, Inf. Calami Aromatici*,—Lat. An aromatic stimulant, tonic, and stomachic. See *Acorus Calamus.*

INFUSION (Tamarinds). Syn. *Infusum Tamarindi*,—Lat. Cooling and laxative; in sore throat, febrile affections, &c., taken ad libitum. See *Infusion of Senna.*

INFUSION (Tansy). Syn. *Tansy Tea, Infusum Tanaceti*,—Lat. From the *dried herb*, or the *green herb* using double the quantity. Aromatic, bitter, tonic, and vermifuge.

INFUSION (Tar). Syn. *Tar Water, Tar Tea; Infusum Picis Liquidæ; Aqua P. L.*,—Ph. D. *Prep.* 1. (Bishop Berkeley.) *Wood tar*, 1 quart; *cold water*, 1 gall.; stir with a stick for 15 minutes, then allow the tar to subside, strain, and keep it in well-stoppered jars.

2. (Ph. D.) As the last. Taken to the extent of a pint daily in chronic catarrhal and nephritic affections; also used as a lotion in chronic cutaneous diseases, especially those of the scalp in children.

INFUSION (Thorough-wort). See *Infusion of Boneset.*

INFUSION (Tobacco). Syn. *Tobacco Water; Infusum Tabaci*, — Lat. *Prep.* (Ph. D. 1826.) *Tobacco leaves*, 1 dr.; *boiling water*, 16 fl. oz.; macerate for an hour. *Used* for enemas; in strangulated hernia, obstinate colic, &c., observing not to administer more than one-half at a time; also as a wash to kill pediculi.

INFUSION (Tonic). See *Infusions of Calumba, Cascarilla, Gentian, &c.*, and *Mixtures.*

INFUSION (Trefoil). See *Infusion of Buckbean.*

INFUSION (Tulip-tree Bark). Syn. *Infusum Liriodendri*,—Lat. From the *bark of the tulip tree* (liriodendron tulipifera,—*Linn.*). Diaphoretic, stimulant, stomachic, and tonic; in dyspepsia, fevers, &c.; also used to flavour liquors.

INFUSION (Turmeric). Syn. *Infusum Curcumæ*,—Lat. *Used* as a test and to prepare test-paper. When required for keeping, about 1-7th of its volume of *rectified spirit* must be added.

INFUSION (Valerian). Syn. *Infusum Valerianæ*,—Ph. L. & D. *Prep.* 1. (Ph. L.) *Valerian root*, ½ oz.; *boiling distilled water*, 1 pint; infuse for an hour in a covered vessel, and strain.

2. (Ph. D.) *Valerian, 2 dr.; boiling water*, 9 fl. oz. Antispasmodic and nervine; in hysteria, hypochondriasis, epilepsy, and low fevers.

INFUSION (Valerian,—Compound). Syn.

Infusum Valerianæ Compositum, — Lat. *Prep.* *Yellow cinchona bark*, 1 oz.; *valerian*, ½ oz.; *boiling water*, 1 pint; as before. In debilitated nervous habits.

INFUSION (Vanilla). Syn. *Vanilla Tea; Infusum Vanillæ*,—Lat. *Prep.* *Vanilla*, 1½ dr.; *boiling water*, 1 pint. A stimulant antispasmodic; in hysteria, rheumatism, anaphrodisia, &c.; but chiefly used as a flavouring for liqueurs, confectionery, &c.

INFUSION (Vetiver). Syn. *Vittie-vayr Tea; Infusum Vetiveriæ*,—Lat. From the *roots* of *andropogon muricatus* (vetiver, vittie-vayr, or cuscus). Antispasmodic, diaphoretic, and stimulant, and when warm, diuretic and emmenagogue; in rheumatism, gout, slight febrile cases, &c.; and as a prophylactic of cholera. See *Essences*.

INFUSION (Wall-pellitory). Syn. *Infusum Parietariæ*,—Lat. From the *dried herb* (parietaria officinalis,—*Linn.*) Aperient, diuretic, and pectoral; in asthmas, dropsies, calculous affections, &c.

INFUSION (Walnut Leaves). Syn. *Walnut-leaf Tea; Infusum Juglandis*,—Lat. From the *fresh leaves* of the *common walnut* (juglans regia,—*Linn.*); also from the *inner wood-bark*, and the *green rind of the fruit*. See *Decoctions*.

INFUSION (Water-fennel). Syn. *Infusum Phellandri*,—Lat. *Prep.* (Bird.) *Seeds of water-fennel*, 5 dr.; *boiling water*, 1 pint. *Dose.* 3 to 4 fl. dr., to check excessive expectoration.

INFUSION (Whortleberry). Syn. *Infusum Uvæ Ursi*,—Lat. With alkalies, henbane, or opium, in diseases of the urinary organs; and with sulphuric acid and foxglove, in affections of the lungs. See *Decoctions*.

INFUSION (Wild-cherry Bark). Syn. *Infusum Pruni Virginianæ*,—Lat. *Prep.* (Ph. U. S.) *Wild cherry-tree bark* (prunus Virginiana), ½ oz.; *cold water*, 16 fl. oz.; infuse 24 hours, and strain. A valuable tonic and febrifuge. Wild-cherry bark "also exercises a sedative action on the circulatory and nervous systems, and is much used" (in America) "in a variety of diseases." (Dr. R. E. Griffith.)

INFUSION (Wild Ginger). Syn. *Infusum Asari Canadensis*,—Lat. From the *root* of *wild ginger* or *Canada snake-root* (asarum Canadense,—*Linn.*) A warm stimulant diaphoretic; in the same cases as infusion of Virginian snake-root.

INFUSION (Willow Bark). Syn. *Infusum Salicis*,—Lat. From the *bark* of the *white* or *common willow* (salix alba,—*Linn.*) Astringent, tonic, and febrifuge; often used instead of infusion of cinchona bark.

INFUSION (Winter Green). Syn. *Infusum Pyrolæ*, *Inf. Chimaphilæ*,— Lat. Astringent, tonic, and diuretic; in dropsy, nephritic pains, and chronic affections of the urinary organs. It blackens the urine, like uva-ursi. See *Decoctions*.

INFUSION (Wood Soot). Syn. *Soot Tea; Infusum Fuliginis Ligni*,—Lat. Antacid and stimulant. A similar preparation is also made from *coal-soot*, which is reputed antispasmodic and vermifuge.

INFUSION (Wormwood). Syn. *Wormwood Tea; Infusum Absinthii*,—Lat. From the *fresh tops* of the plant, or from only half the quantity of the dried herb. In loss of appetite, dyspepsia, amenorrhœa, leucorrhœa, gout, worms, &c. See *Bitters*.

INHALATIONS. Syn. *Inhalationes*,— Lat. Vapours or gases inhaled along with the breath, for the purpose of medicating the mucous membrane of the air passages. The *substances* that are to *furnish* the *vapours* or *fumes* are put into a vessel called an "*inhaler*," which is merely a small covered pot or mug of metal or glass, furnished with a short flexible tube, terminating in a small mouth-piece. In many cases, even this simple apparatus may be dispersed with, and the fumes inhaled by holding the head over a vessel containing a little of the substance furnishing them; or, as with chloroform, a little may be dropped on a handkerchief or napkin, which is then held to the nose.

The following are the principal substances that are employed for inhalations at the present day:—

1. *Carbonic acid gas* and *nitrous oxide*; occasionally used in phthisis, by means of a bladder and mouth-piece.

2. *Chlorine gas*; exhibited by adding 5 or 6 drops of aqueous chlorine to the water (tepid) of the inhaler, which should be, in this case, of glass; employed in France for phthisis, but seldom used in England.

3. *Chloroform*; as an anæsthetic.

4. *Vapour of iodine*, administered in the same way as chlorine; occasionally used in phthisis.

5. *Oxygen* and *hydrogen gases*, either alone or diluted with air; employed in asthma and phthisis, by means of a bladder and mouth-piece.

6. *Tar vapour*, obtained by heating tar, mixed with a little carbonate of potash, over a spirit lamp; occasionally employed in bronchitis, and recommended by Sir A. Crighton in phthisis, but appears of little value in the latter.

7. *Steam of hot water;* in bronchitis, and to allay the cough in phthisis; small quantities of the seeds of henbane, opium, poppy-heads, &c., are frequently added to produce an anodyne effect.

INJECTIONS. Syn. *Injectiones*,—Lat. Liquid medicines thrown into the cavities of the body by means of a syringe or an elastic bag. Those thrown into the rectum are commonly called *clysters*, or *enemata*, and are noticed under the latter head. The following are the principal injections employed in medical practice at the present day:—

INJECTION (Acetate of Ammonia). Syn. *Injectio Ammoniæ Acetatis*,— Lat. *Prep.* (Ph. Chirur.) *Solution of acetate of ammonia* (Ph. L.), 1 part; *water*, 3 parts. Refrigerant.

INJECTION (Acetate of Copper). Syn. *Injectio Cupri Acetatis*,—Lat. *Prep.* From *verdigris*, 10 gr.; *oil of almonds* (hot), 4½ oz.; triturate until dissolved, and strain. Detergent.

INJECTION (Acetate of Lead). Syn. *Injectio Plumbi Acetatis*,—Lat. *Prep.* 1. *Sugar of lead*, ½ dr.; *distilled water*, ½ pint.

2. (Dr. Collier.) *Acetate of lead*, 40 gr.; *rose water*, 8 fl. oz. Astringent and sedative.

3. (Wendt.) *Aqueous extract of opium*, 1½ gr.; *mucilage*, 2 dr.; *solution of diacetate of lead*, 4 drops; *water*, 2 fl. oz. Cooling, sedative, and anodyne.

INJECTION (Acetate of Zinc). Syn. *Injectio Zinci Acetatis*,—Lat. *Prep.* 1. (Ellis.) *Acetate of zinc*, 8 gr.; *rose water*, 4 fl. oz.

2. (Brodie.) *Sulphate of zinc*, 1 dr.; *sugar of lead*, 80 gr.; *water*, 1 pint; dissolve separately, mix, and filter. Astringent.

INJECTION (Alkaline). Syn. *Injectio Alkalina*, *Inj. Lithontriptica*,—Lat. *Prep.* (Chevallier.) *Carbonate of soda*, 1 dr.; *Castile soap*, 2 dr.; *water*, 12 fl. oz.; dissolve. In certain forms of calculus.

INJECTION (Alum). Syn. *Injectio Aluminis*, — Lat. *Prep.* 1. (Dr. Collier.) *Alum*, 18 gr.; *rose water*, 6 fl. oz.; dissolve. For the urethra.

2. (Collier.) *Alum*, 3 dr.; *water*, 1 quart. For the vagina.

3. (Ph. Ch.) *Alum*, 4 gr.; *rose water*, 4 fl. oz. The above are all astringent.

INJECTION (Ammonia). Syn. *Injectio Ammoniæ*,—Lat. *Prep.* 1. (Dr. Ashwell.) *Liquor of ammonia*, 1 to 2 fl. dr.; *milk*, 1 pint. In obstructed menstruation.

2. (Lavagna.) *Liquor of ammonia*, 8 to 20 drops; *milk*, 2 fl. oz. As the last, thrice daily, beginning with the least quantity of ammonia.

3. *Liquor of ammonia*, 1 fl. dr.; *mucilage*, 1 oz.; *water*, 9 fl. oz. As the last.

INJECTION (Ammonio-sulphate of Copper). Syn. *Injectio Cupri Ammoniati*, —Lat. *Prep.* (Swediaur.) *Ammonio-sulphate of copper*, 5 gr.; *rose water*, 8 fl. oz. In chronic gonorrhœa.

INJECTION (Astringent). See the names of the respective ingredients.

INJECTION (Bichloride of Mercury). Syn. *Injectio Hydrargyri Bichloridi*,—Lat. *Prep.* 1. *Corrosive sublimate*, 2 gr.; *rose water*, 5 fl. oz.; *hydrochloric acid*, 1 drop.

2. *Corrosive sublimate* and *sal ammoniac*, of each, 5 to 10 gr.; *water*, 1 pint.

3. *Sublimate*, 5 gr.; *rose water*, 2½ fl. oz. *Used* to promote healthy action, and to prevent infection.

INJECTION (Calomel). Syn. *Injectio Calomelanos*, *Inj. Hydrargyri Chloridi*,— Lat. *Prep.* (St. B. Hosp.) *Calomel*, 1 dr.; *mucilage*, 1 fl. oz.; *water*, ½ pint. Some parties order quince mucilage.

INJECTION (Carbonate of Lead). Syn. *Injectio Cerussæ*, *Inj. Plumbi Carbonatis*,— Lat. *Prep.* (Hosp. F.) *Carbonate of lead*, (finely levigated); ½ dr. *sulphate of zinc*, 8 gr.; *mucilage*, 1 oz.; *rose water*, 5 oz. Cooling and astringent.

INJECTION (Chloride of Lime). Syn. *Injectio Calcis Hypochloris*,—Lat. *Prep.* 1. *Chloride of lime*, ½ dr.; *water*, ½ pint; agitate well together, and filter. To prevent infection.

2. (Detmold.) *Chloride of lime*, 2 dr.; *decoction of rhatany*, 13 fl. oz.; dissolve, and filter. In foul discharges, especially in ozœna, or fœtid ulceration of the nose.

3. (Rousse.) *Chloride of lime*, 20 gr.; *water*, 7 fl. oz.; *wine of opium*, 1 fl. oz. In foul discharges, and to allay irritation.

INJECTION (Chloride of Soda). Syn. *Injectio Sodæ Hypochloris*, —Lat. *Prep.* From *solution of chloride of soda*, 1 fl. dr.; *rose water*, 3 fl. oz. As the last.

INJECTION (Chloride of Zinc). Syn. *Injectio Zinci Chloridi*,—Lat. *Prep.* From *chloride of zinc*, 2 gr.; *rose water*, 3 fl. oz.; *hydrochloric acid*, 1 drop. In gonorrhœa.

INJECTION (Copaiba). Syn. *Injectio Copaibæ*, — Lat. *Prep.* 1. (Abernethy.) *Copaiba*, 2 dr.; *thick mucilage*, 5 dr.; *lime water*, 6 fl. oz.; make an emulsion.

2. (Plenck.) *Capivi*, ½ oz.; *yelk of egg*, q. s.; *lime water*, 6 fl. oz.; *honey of roses*, 3 oz.; as the last.

3. (Ricord.) *Capivi*, 6 dr.; *yelk of egg*, q. s.; *decoction of poppies*, 3 to 4 fl. oz. In

ulcers of the rectum, vagina, and urethra; and in gonorrhœa.

INJECTION (Creasote). Syn. *Injectio Creasoti*,—Lat. *Prep.* (Dr. Allnatt.) *Creasote*, 20 drops; *white sugar*, 2 dr.; *liquor of potassa*, 2 fl. dr.; triturate, and add of *water*, 8 fl. oz. In leucorrhœa and piles.

INJECTION (Cubebs). Syn. *Injectio Cubebæ*,—Lat. *Prep.* (Soubeiran.) *Cubebs* (in powder), 1 oz.; *extract of belladonna*, 1 dr.; *boiling water*, 16 fl. oz.; infuse in a covered vessel, and strain. Stimulant and narcotic. In gonorrhœa and leucorrhœa.

INJECTION (for the Ear.) Syn. *Injectio Acoustica*,—Lat. *Prep.* 1. *Ox-gall*, 3 dr.; *balsam of Peru*, 1 dr.; mix. In hardened wax, dryness of membranes, &c.

2. *Oil of almonds* or *olives*, 2 *oz.*; *oil of amber*, 20 drops; *tincture of castor*, 1 fl. dr.; *spirit of camphor*, ½ dr.; *laudanum*, 3 drops; mix. In ear-ache and chronic deafness.

3. (Alibert.) *Balsam of Peru*, 2 dr.; *tincture of musk*, 4 or 5 drops; *otto of roses*, 1 or 2 drops: *decoction of St. John's wort* (warm), 16 fl. oz.; agitate together, and after repose decant the clear. In discharges from the ear.

Obs. Mr. Yearsley, the eminent aurist of Saville Row, states that drops and injections for the ear should be used with very great caution, and only under proper advice, as they otherwise often aggravate the ailment, instead of curing it.

INJECTION (Ergot). Syn. *Injectio Ergotæ*, *Inj. Secalis Cornuti*,—Lat. *Prep.* 1. (Boudin.) *Ergot*, 1 dr.; *boiling water*, 8 fl. oz.; infuse until cold. When the urethra is highly sensitive.

2. (Descrolles.) *Powdered ergot*, 1 oz.; *boiling water*, 1 pint. Both the above are used in chronic inflammation of the vagina, and in gonorrhœa.

INJECTION (Gallic Acid). Syn. *Injectio Acidi Gallici*,—Lat. *Prep.* (Dunglison.) *Gallic acid*, ½ dr.; *water*, 1 pint. In leucorrhœa.

INJECTION (Galls). Syn. *Injectio Gallæ*,—Lat. *Prep.* From *galls* (bruised), 2 dr.; *boiling water*, 1 pint; infuse 1 hour, and strain. Astringent; in leucorrhœa.

INJECTION (Hydrochloric Acid). Syn. *Injectio Acidi Hydrochlorici*—Lat. *Prep.* From *hydrochloric acid*, 10 drops; *soft water*, 5 fl. oz. To prevent and to remove recent infection; also to remove particles of lime and iron from the eye.

INJECTION (Hydrocyanic Acid). Syn. *Injectio Acidi Hydrocyanici*,—Lat. *Prep.* *Medicinal hydrocyanic acid*, 1 fl. dr.; *soft water* or *almond emulsion*, ½ pint. Anodyne; to allay excessive irritability both in chronic ophthalmia and gonorrhœa, and to relieve chordee; but in all cases it must be used with caution, and at first largely diluted with water.

INJECTION (Iodide of Iron). Syn. *Injectio Ferri Iodidi*, — Lat. *Prep.* 1. (Ricord.) *Iodide of iron*, 6 gr.; *water*, 5 fl. oz. In gonorrhœa, gradually increasing the quantity of iodide.

2. (Soubeiran.) *Iodine of iron*, 3 to 4 dr.; *water*, 1 pint. In suppressed and painful menstruation, leucorrhœa, &c. Both are astringent and well adapted to scrofulous patients.

INJECTION (Iodide of Potassium). Syn. *Injectio Potassii Iodidi*, — Lat. *Prep.* (Foy.) *Iodide of potassium*, 3 gr.; *pure water*, 1 pint. As a stimulant to fistulous sinuses and ulcers in persons of scrofulous habits.

INJECTION (Iodine). Syn. *Iodureted Injection*; *Injectio Iodureta*, *Inj. Iodinii*,—Lat. *Prep.* 1. (M. Ameuille.) *Tincture of iodine*, 1 part; *water*, 5 or 6 parts. In refractory fistulæ.

2. (M. Bonnet.) *Iodine*, 1 part; *iodide of potassium*, 2 parts; *water*, 10 parts. In scrofulous hydarthrosis, &c.

3. (Bransby Cooper.) *Compound tincture of iodine*, 2 fl. dr.; *water*, 6 fl. dr. In hydrocele.

4. (Guibourt.) *Iodine*, 4 gr.; *iodide of potassium*, 8 gr.; *water*, 1 pint. To stimulate fistulous sinuses.

5. (Velpeau.) *Tincture of iodine*, 1 fl. dr.; *water*, 3 fl. dr. In hydrocele.

INJECTION (Lithontriptic). Syn. *Injectio Lithontriptica*, *Inj. Vesicalis*,—Lat. *Prep.* (Dr. Hoskins.) *Nitro-saccharate of lead*, 1 gr.; *saccharic acid*, 5 drops; rub together, then add of *distilled water*, 1 fl. oz. As a solvent for phosphatic calculi. See *Alkaline Injection*.

INJECTION (Mercurial). Syn. *Injectio Mercurialis*, *Inj. Hydrargyri*,—Lat. *Prep.* *Quicksilver*, 1 dr.; *gum mucilage*, 1½ oz.; triturate until the globules disappear, and gradually add of *water*, 1½ fl. oz.

2. (Hosp. F.) *Quicksilver* and *balsam of copaiba*, of each, 4 dr.; *yelk of an egg*; *rose water*, ½ pint. An awkward and useless preparation.

INJECTION (Morphia). Syn. *Injectio Morphiæ*,—Lat. *Prep.* (Brera.) *Morphia*, 2 gr.; *oil of almonds* (warm), 1 oz.; triturate together until united. Anodyne and emollient. To ease the pain in ear-ache, acute gonorrhœa, piles, &c.

INJECTION (Nitrate of Silver). Syn. *Injectio Argenti Nitratis*,—Lat. *Prep.* 1. (Acton.) *Nitrate of silver*, 3 gr.; *distilled water*, ½ pint; dissolve.

2. (Dr. Arnott.) *Nitrate*, 12 gr.; *water*, 1 fl. oz.

3. (Dr. Collier.) *Nitrate*, 2 gr; *rose water*, 1 fl. oz.

4. (Dr. Cülverwell.) *Nitrate*, 20 to 30 gr.; *water*, 1 fl. oz.

5. (Dr. Jewell.) *Nitrate*, 12 gr.; *water*, 6 fl. oz.

6. (Ricord.) *Nitrate*, 8 gr.; *water*, 1 fl. oz.

Obs. The weaker solutions are used in chronic gonorrhœa, gleet, and leucorrhœa; those of an intermediate strength to prevent an attack of gonorrhœa following the incipient symptoms of that disease; and the strongest, chiefly in spermatorrhœa. Their use requires great caution.

INJECTION (Opium). Syn. *Injectio Opii, Inj. Opiata*,—Lat. *Prep.* 1. *Tincture of opium* or *wine of opium*, 1 to 2 fl. dr. (according to circumstances); *water*, 5 fl. oz. As an anodyne, in gonorrhœa.

2. (Foy.) *Extract of opium*, 6 gr.; *extract of belladonna*, 1½ dr.; *decoction of wild lettuce*, 16 fl. oz. In neuralgia and hæmorrhages.

INJECTION (Sedative). Syn. *Injectio Sedativa*,—Lat. *Prep.* (Hosp. F.) *Oil of Almonds*, 1 oz.; *solution of diacetate of lead*, 20 drops. Cooling, sedative, and emollient.

2. (Gassincourt.) *Simple emulsion*, 5 fl. oz.; *decoction of poppies*, 16 fl. oz.; *white of* 1 *egg*: mix. In acute gonorrhœa.

INJECTION (Stimulating). Syn. *Injectio Stimulans*,—Lat. *Prep.* (St. Marie.) *Myrrh*, 1 oz.; *quicklime*, 2 oz.; *water*, 1 quart; digest for 2 or 3 days, and decant the clear portion. In fistulous ulcers.

INJECTION (Sulphate of Copper). Syn. *Injectio Cupri Sulphatis*,—Lat. *Prep.* 1. *Sulphate of copper*, 5 gr.; *rose water*, 4 fl. oz. In chronic gonorrhœa.

2. (Hunter.) *Sulphate of copper*, 3 gr.; *water*, 4 fl. oz. As the last.

3. (Swediaur.) *Sulphate of copper*, 6 gr.; *water*, 4 fl. oz.; dissolve, and add *solution of diacetate of lead*, 20 drops. In phymosis.

INJECTION (Sulphate of Iron). Syn. *Injectio Ferri Sulphatis*,—Lat. *Prep.* (Berends.) *Sulphate of iron* and *mucilage*, of each, ½ dr.; *sage water*, 4 fl. oz.; dissolve. In nasal and uterine hæmorrhages.

INJECTION (Sulphuret of Potassium). Syn. *Injectio Potassii Sulphureti*,—Lat. *Prep.* (Wedekind.) *Sulphuret of potassium*, 1 dr.; *water*, ½ pint. In gonorrhœa.

INJECTION (Tannic Acid). Syn. *Injectio Tannini, Inj. Acidi Tannici*,—Lat. *Prep.* (Béral.) *Tannin*, ½ dr.; *distilled water*, 8 fl. oz. (or better, ½ pint). In gleet and leucorrhœa.

INJECTION (Tea). Syn. *Injectio Theæ*,—Lat. *Prep.* (Hosp. F.) *Green tea* (or *rough black tea*), 1 dr. (say 2 teaspoonfuls); *boiling water*, ½ pint. Astringent; in gleet and fluor albus.

INJECTION (Vinous). Syn. *Injectio Vini Rubri, Inj. Vinosa*,—Lat. *Prep.* (Earle.) *Red wine*, 1 part; *water*, 2 or 3 parts. In hydrocele.

INK. Syn. *Atramentum*,—Lat. Coloured liquid employed for writing with a pen. Ink is made of various substances and colours; but in the present article we shall confine ourselves to a notice of the tannogallic compounds to which the term, when standing alone, is almost exclusively applied.

Prep. 1. *Aleppo galls* (well bruised), 4 *oz.*; *clean soft water*, 1 quart; macerate in a *clean* corked bottle for ten days or a fortnight, or even longer, with frequent agitation, then add of *gum arabic* (dissolved in a wine-glassful of water), 1¼ *oz.*; *lump sugar*, ½ *oz.*; mix well, and *afterwards* further add of *sulphate of iron* (green copperas, crushed small), 1½ *oz.*; agitate occasionally for 2 or 3 days, when the ink may be decanted for use, but is better if the whole is left to digest together for 2 or 3 weeks. When time is an object, the whole of the ingredients may be at once put into a bottle, and the latter agitated daily until the ink is made; and *boiling water* instead of *cold water* may be employed. *Product.* 1 quart of excellent ink, writing pale at first, but soon turning intensely black.

2. *Aleppo galls* (bruised), 12 *lb.*; *soft water*, 6 gall.; boil in a copper vessel for 1 hour, adding *more water* to make up for the portion lost by evaporation; strain, and again boil the galls with *water*, 4 gall., for ½ an hour; strain off the liquor, and boil a third time with *water*, 2½ gall., and strain; mix the several liquors, and while still hot, add of *green copperas* (coarsely powdered), 4½ *lb.*; *gum arabic* (bruised small), 4 *lb.*; agitate until dissolved, and after defecation strain through a hair sieve, and keep it in a bunged-up cask for use. *Prod.* 12 gall.; very fine and durable.

3. *Aleppo galls* (bruised), 14 *lb.*; *gum*, 5 *lb.*; put them into a small cask, and add of *boiling soft water*, 15 gall.; allow the whole to macerate, with frequent agitation, for a fortnight, then further add of *green copperas*, 5 *lb*; (dissolved in) *water*, 7 pints; again mix well, and agitate the whole once daily for 2 or 3 weeks. *Prod.* Fully 15 gall. Resembles No. 1.

4. *Galls* (bruised), 9 *lb.*; *logwood chips*

(best Campeachy), 3 *lb.*; boil as in No. 2; to the strained mixed liquors, add of *gum arabic* and *green copperas*, of each (bruised small), 4 *lb.*; simmer or digest until dissolved, and at once strain through a hair-sieve into the store-cask or jars. *Prod.* 16½ gall. Excellent, but inferior to the preceding.

5. *Galls* (bruised), 2 *lb.*; *logwood chips*, *green copperas*, and *gum*, of each, 1 *lb.*; *water*, 7 gall.; boil 2 hours, and strain. *Prod.* 5 gall. A superior ink for retail.

6. *Galls* (bruised), 1 *lb.*; *logwood*, 2 *lb.*; *gum* (common), 1 *lb.*; *green copperas*, ¾ *lb.*; *water*, 8 gall.; proceed as last. *Prod.* 6 gall. Common, but fit for all ordinary purposes.

The following formulæ are for some of the advertised inks, or are those recommended by the authorities, whose names are attached to them :—

7. (*Anti-corrosive.*) Same as "*Asiatic Ink.*"

8. (*Asiatic.*) *Galls*, 4 *lb.*; *logwood*, 2 *lb.*; *pomegranate peel*, 1 *lb.*; *soft water*, 5 gall.; boil as in No. 2, then add to the strained and decanted liquor, when cold, of *gum arabic*, 1 *lb.*; *lump sugar* or *sugar candy*, ¼ *lb.*; dissolved in *water*, 3 pints. *Prod.* 4½ gall. Writes pale, but flows well from the pen, and soon gets black.

9. (Brande.) *Galls*, 6 *oz.*; *green copperas* and *gum arabic*, of each, 4 *oz.*; *soft water*, 3 quarts; by decoction.

10. (Chaptal.) As No. 4 (nearly), adding *sulphate of copper*, ½ *lb.* Full coloured, but less durable and anti-corrosive than the preceding.

11. (M. Desormeaux, jun.) *Galls*, 1 *lb.*; *logwood chips*, 4 *oz.*; *water*, 6 quarts; boil 1 hour, strain 5 quarts, add of *sulphate of iron* (calcined to whiteness), 4 *oz.*; *brown sugar*, 3 *oz.*; *gum*, 6 *oz.*; *acetate of copper*, ¼ *oz.*; agitate twice a day for a fortnight, then decant the clear, bottle, and cork up for use. Writes a full black. (See No. 10.)

12. (*Exchequer.*) *Galls* (bruised), 40 *lb.* (say 4 parts); *gum*, 10 *lb.* (say 1 part): *green sulphate of iron*, 9 *lb.* (say 1 part); *soft water*, 45 gall. (say 45 parts); macerate for 3 weeks, employing frequent agitation. "This ink will endure for centuries."

13. (Guibourt.) Galls (in powder), 50 parts; *hot water*, 800 parts; digest 24 hours, strain, and add of *green sulphate of iron* and *gum arabic*, of each, 25 parts; when dissolved, add the following solution, and mix well:—*Sal ammoniac*, 8 parts; *gum*, 2 parts; *oil of lavender*, 1 part; *boiling water*, 16 parts. Said to be indelible.

14. (Dr. Hare.) As No. 12 (nearly), but substituting "*finery cinder*" for the sulphate of iron. Recommended as anti-corrosive.

15. (*Japan.*) This is a black and glossy kind of ink, which may be prepared from either of the above receipts by calcining the copperas until white or yellow, or by sprinkling it (in powder) with a little nitric acid before adding it to the decoction (preferably the former), by which the ink is rendered of a full black as soon as made. The glossiness is given by using more *gum*. It flows less easily from the pen than other inks, and is less durable than ink that writes paler and afterwards turns black. It is unfitted for steel pens.

16. (Lewis.) *Bruised galls*, 3 *lb.*; *gum* and *sulphate of iron*, of each, 1 *lb.*; *vinegar*, 1 gall.; *water*, 9 quarts; macerate with frequent agitation for 14 days. To produce 3 galls. Fine quality, but apt to act on stee pens.

17. (Old "*Patent.*") As No. 8 (nearly).

18. (*Prerogative Office.*) *Galls*, 1 *lb.* *gum arabic*, 6 *oz.*; *alum*, 2 *oz.*; *green vitriol*, 7 *oz.*; *kino*, 3 *oz.*; *logwood raspings*, 4 *oz.*; *soft water*, 1 gall.; macerate as last. *Said* to write well on parchment.

19. (M. Ribaucourt). *Galls*, 1 *lb.*; *logwood chips* and *sulphate of iron*, of each, ½ *lb.*; *gum*, 6 *oz.*; *sulphate of copper* and *sugar candy*, of each, 1 *oz.*; boil the first two in *soft water*, 2½ gall., to one-half, then add the other ingredients. Full coloured. (See No. 10.)

20. (Dr. Ure.) *Galls*, 12 *lb.*; *green copperas* and *gum Senegal*, of each. 5 *lb.*; as No. 2 (nearly). To produce 12 gall.

21. (Dr. Wollaston.) *Galls*, 1 *oz.*; *sulphate of iron*, 3 *dr.*; *gum*, ¼ oz.; *cold water*, ½ pint; put into a bottle and shaken together every day for a fortnight or longer.

Obs. According to the most accurate experiments on the preparation of black ink, it appears that the quantity of *sulphate of iron* should not exceed ⅓rd part of that of the *galls*, by which an excess of astringent vegetable matter, which is necessary for the durability of the colour, is preserved in the liquid. *Gum*, by shielding the writing from the action of the air, tends to preserve the colour, but if much is employed, the ink flows languidly from *quill pens*, and scarcely at all from *steel pens*. The latter require a very limpid ink. The addition of *sugar* (especially of *moist sugar*) increases the flowing property of the liquid, but makes it dry more slowly, and frequently to pass into an acetous state, in which condition it acts injuriously on the pen. *Vinegar* for a like reason is not calculated for the menstruum,

as it rapidly softens quill or horn, and corrodes iron and steel.

The most permanent (tanno-gallate) inks, are those which contain the proper quantity of oxide of iron, at the *minimum* of oxidizement, in a state of solution or minute suspension, by which means, not only does a larger quantity of the fluid flow from the pen on to a given space, but it also sinks into the substance of the paper, by which the stain is rendered more permanent, and less easily removed by attrition or accident. Such inks are uniformly *pale* until exposed to the air for some days, when they acquire their full colour. When the iron is at the *maximum* of oxidizement, as is the case when *calcined copperas* is employed, the ink writes of a *full black* at first; but from its colouring matter being merely a suspended precipitate, it rests upon the surface of the paper without sinking into it, and may consequently be more easily erased than the former. Its black colour is also more liable to fade by the action of light and atmospheric oxygen.

Another matter of importance connected with the *permanency* of the colour of the tanno-gallic inks, is the use of the *best* Aleppo, or blue nut-galls *only*. No second or inferior quality should be employed. A contrary practice, often adopted for the sake of economy, is nearly always followed by unpleasant results, and often by considerable loss.

The only improvement of importance which has been made in the manufacture of writing ink from the common materials, since the publication of our last edition, is the practice of first *roasting* the *gall-nuts*, which is now adopted by a few of the houses most celebrated for their *copying ink*. In this way, a portion of *pyrogallic acid* is formed, which is very soluble in water, and strikes an intense bluish-black colour with the protosulphate or green sulphate of iron. From galls so treated an ink may be made to write *at once black*, without the trouble and disadvantage of calcining or peroxidizing the copperas, as noticed above. Care must, however, be taken to avoid any loss of materials by volatilization; the process, therefore, requires the exercise of a little skill.

To prevent any tendency to *mouldiness* in ink, a few *bruised cloves*, or a *little oil of cloves*, or, still better, a few drops of *creasote*, may be added. The last two should be previously dissolved in a small quantity of *strong vinegar* or *rectified spirit*. With the same intention some of the large makers allow the ink to become covered with a skin of "mould" in the cask, to render it less liable to undergo the same change when subsequently bottled. Formerly, the practice was to add a little *spirit* for the same purpose.

Sumach, *logwood*, and *oak bark*, are frequently substituted for galls in the preparation of *common* ink. When such is the case, only about $\frac{1}{8}$th or $\frac{1}{7}$th of their weight of copperas should be employed. Inks so made possess little durability.

The very general use of steel pens of late years has caused a corresponding demand for "*easy-flowing inks*," many of which are now vended under the titles of "*writing fluids*," "*steel-pen ink*," "*anti-corrosive ink*," *&c.* The greater number of these are prepared from galls in the preceding manner; but a less quantity of gum is employed, and greater attention is paid than heretofore to avoid every source of "*greasiness*," among which *smoke* and *dirty utensils* are perhaps the principal. The *blue writing fluids* which either maintain their colour or turn black by exposure to the air, are in general prepared from *ferrocyanide of potassium*, or from *indigo*, and are fully noticed in another place. "*Copying ink*," another variety of ink of recent introduction, is characterized by its suitableness to metallic pens, and by furnishing a transcript by means of the *copying press* or *copying machine*.

The inks prepared by the *first four* of the above formulæ are very durable and limpid, and will bear dilution with nearly an equal bulk of *water*, and still be superior in quality to the ordinary inks of the shops. The journals of the editor's father, written with one of them in the Mediterranean, during the early part of the long war, though for some time exposed to the sea air, and now above 60 years old, are still as legible as if newly written. See *Copying Ink*, *Galls*, *Pyrogallic Acid*, *Stains*, *Writing Fluids*, *&c.*

INK (Copying). This is usually prepared by adding a little *sugar* or other *saccharine matter* to ordinary *black ink*, which for this purpose should be *very rich* in colour, and preferably made of galls prepared by heat, as noticed above. Writing executed with this ink may be copied within the space of 5 or 6 hours, by passing it through a *press* (*copying press*) in contact with *thin unsized paper* ("*bank post*") slightly damped, enclosed between two sheets of thick *oiled* or *waxed paper*, when a reversed transcript will be obtained, which will read in proper order when the back of the copy is turned upwards. In the

absence of a *press*, a copy may be taken, when the ink is good and the writing very recent, by rolling the sheets, duly arranged on a ruler, over the surface of a flat smooth table, employing as much force as possible, and avoiding any slipping or crumpling of the paper. Another method is to pass a warm flat-iron over the paper laid upon the writing. The following proportions are employed:—

1. *Sugar candy* or *lump sugar*, 1 *oz.*; or *treacle* or *moist sugar*, 1¼ oz.; *rich black ink*, 1½ pint; dissolve.

2. *Malt wort*, 1 pint; evaporate it to the consistence of a syrup, and then dissolve it in *good black ink*, 1¼ pint.

3. *Solazza juice*, 2 *oz.*; *mild ale*, ¼ pint; dissolve, strain, and triturate with *lamp black* (previously heated to dull redness in a covered vessel), ¼ *oz.*; when the mixture is complete, add of *strong black ink*, 1½ pint, mix well, and in 2 or 3 hours decant the clear.

Obs. After making the above mixtures, they must be tried with a common *steel pen*, and if they do not "*flow freely*" some more unprepared ink should be added until they are found to do so.

INK (Indelible). *Prep.* 1. *Lamp black*, (previously heated to dull redness in a *covered* vessel), ¼ *oz.*; triturate with *good black ink* (gradually added), 1 pint. Resists chlorine, weak acids, and weak alkaline lyes, in the cold.

2. (M. Bezanger.) *Lamp black* ground in a *lye of caustic soda*, combined with a *mixture* of *gelatine* and *caustic soda*. Said to be indelible, and to resemble genuine China ink. (Moniteur Industriel.)

3. (M. Braconnot.) *Dantzig potash*, 4 parts; *tanned leather parings*, 2 parts; *sulphur*, 1 part; *water*, 20 parts; boil them in an iron vessel to dryness, then raise the heat (constantly stirring with an iron rod) until the whole forms a soft mass, observing that it does not ignite; next dissolve the mass in *water*, q. s., and filter the solution through a cloth. Flows freely from a pen, and resists the action of many chemical substances.

4. (*Carbon Ink.*) Genuine *Indian ink*, rubbed down with *good black ink*, until it will flow easily from a pen. Resists chlorine, oxalic acid, and ablution with a hair pencil or sponge.

5. (Coathupe.) *Borax*, 1 *oz.*; *shell-lac*, 2 *oz.*; *water*, 18 fl. oz.; boil in a covered vessel until dissolved, strain, add of *thick mucilage*, 1 *oz.*; and triturate it with *levigated indigo* and *lamp black*, of each, q. s. to give a good colour after 2 hours' repose, decant it from the dregs, and bottle for use. Resists moisture, chlorine, and acids.

6. (*French.*)—*a.* From *Indian ink*, diffused through *water acidulated with hydrochloric acid*. For quills—*b.* From *Indian ink* diffused through *water slightly alkalized with liquor of potassa*. For metallic pens.

7. (Herberger.) *Wheat gluten* (free from starch), q. s., is dissolved in *weak acetic acid* or *good pure vinegar*, 4 fl. oz.; *lamp black* (best), 10 or 12 gr.; *indigo*, 2 or 3 gr.; and *oil of cloves*, 1 or 2 drops, are then added, and the whole is thoroughly incorporated together. The product is inexpensive, has a beautiful black colour, and resists the action of water, chlorine, and weak acids.

8. (Dr. Traill.) Resembles Herberger's (nearly).

9. (Ure.) Similar to No. 4.

Obs. The products of the above formulæ, though called "*indelible ink*" and "*indestructible ink*," are in reality only indelible as compared with common writing ink, as they may all be removed with more or less facility by chemical reagents, assisted by mechanical means. They are intended chiefly for paper, pasteboard, and parchment. No. 5 is also used for glass and metal. See *Marking Ink*.

INK (Horticultural). *Prep.* 1. *Chloride of platinum*, ¼ *oz.*; *soft water*, 1 pint; dissolve, and preserve it in glass. *Used* with a clean quill to write on *zinc labels*. It almost immediately turns black, and cannot be removed by washing. The addition of gum and lamp black, as recommended in certain books, is unnecessary, and even prejudicial to the quality of the ink.

2. *Verdigris* and *sal ammoniac*, of each, ½ *oz.*; *levigated lamp-black*, ¼ *oz.*; *common vinegar*, ¼ pint; mix thoroughly. *Used* as the last, for either *zinc*, *iron*, or *steel*.

3. *Blue vitriol*, 1 *oz.*; *sal ammoniac*, ½ oz.; (both in powder); *vinegar*, ¼ pint; dissolve. A little lamp-black or vermillion may be added, but it is not necessary. As No. 1; for *iron*, *steel*, or *tin-plate*. Some of the preparations described under "*Incorrodible Ink*," are also used by gardeners and nurserymen.

INK (Incorrodible). This name has been given to several preparations of a resinous character capable of resisting the action of damp and acids.

Prep. 1. *Boiled linseed oil*, ground with *lamp-black* and *Prussian blue*, of each, q. s. to impart a deep black colour. It may be thinned with *oil of turpentine*.

2. Good *copal* or *amber varnish*, coloured with either *plumbago* or *vermillion*.

3. *Trinidad asphaltum* (genuine), 1 part; *oil of turpentine*, 4 parts; *colour* (as last), q. s.

4. (Mr. Close.) *Cobalt* (in powder), 25 gr.; *oil of lavender*, 200 gr.; dissolve by a gentle heat, and add of *lampblack*, 3 gr.; *indigo*, 1 gr. (both in impalpable powder); or *vermilion*, q. s.

5. (Mr. Hausmann.) As No. 3 (nearly). Resists the action of iodine, chlorine, alkalies, and acids.

6. (Sheldrake.) *Asphaltum* dissolved in *amber varnish* and *oil of turpentine*, and coloured with *lampblack*.

Obs. The above are also frequently called "*indelible*" or "*indestructible inks.*" They are employed for writing labels on bottles containing strong acids and alkaline solutions. The last four are very permanent, and are capable of resisting the action of iodine, chlorine, alkaline lyes, and acids, together with all the operations of dyeing and bleaching, and at once offer a cheap and an excellent material for marking linen, &c., as they cannot be dissolved off by any menstrua that will not destroy the fabric. They must be employed with *stamps*, *types*, or *stencil plates*, by which greater neatness will be secured than can be obtained with either a brush or pen. See *Horticultural Ink*, *Indelible Ink*, *&c.*

INK (Indian). Syn. *China Ink*; *Atramentum Indicum*,—Lat. *Prep.* 1. *Lamp black* (finest) is ground to a paste with very weak *liquor of potassa*, and this paste is then diffused through *water slightly alkalized* with potassa, after which it is collected, washed with clean water, and dried; the dry powder is next levigated to a smooth, stiff paste, with a *strong filtered decoction of carrageen* or *Irish moss*, or of *quince seed*, a few drops of *essence of musk* and about half as much *essence of ambergris* being added, by way of perfume, towards the end of the process; the mass is, lastly, moulded into cakes, which are ornamented with Chinese characters and devices, as soon as they are dry and hard.

2. A *weak solution of fine gelatine* is boiled at a high temperature in a Papin's digester for two hours, and then in an *open* vessel for 1 hour more; the liquid is next filtered and evaporated to a proper consistence, either in a steam or salt water bath; it is, lastly, made into a paste, as before, with *pure lampblack* which has been previously heated to dull redness in a well-closed crucible. Neither of the above gelatinize in cold weather, like the ordinary imitations.

3. (Gray.) *Pure lampblack* made up with *asses'-skin glue*, and scented with musk.

4. (M. Merimée.) Dissolve *superfine glue* in *water*, add a *strong solution of nut-galls*, and wash the precipitate in *hot water*; then dissolve it in a *fresh solution of glue*, filter, evaporate to a proper thickness, and form it into a paste as before, with *purified lampblack*.

5. (Proust.) As No. 1 (nearly).

6. *Seed lac*, ½ *oz.*; *borax*, 1½ *dr.*; *water*, ½ pint; boil to 8 *oz.*, filter, and make a paste with *pure lampblack*, as before. When dry it resists the action of water.

Obs. The Chinese do not use glue in the preparation of their ink, but an infusion or decoction of certain seeds abounding in a glutinous transparent mucilage, which at once imparts brilliancy and durability to the colour. Starch converted into gum by means of sulphuric acid, or British gum, has been recommended as a substitute. (M. Merimée.) *Indian ink* is chiefly *employed* by artists, but it has been occasionally given as a medicine, dissolved in water or wine, in hæmorrhages and stomach complaints. *Dose.* 1 to 2 dr.

INK (Lithographic). *Prep.* 1. *Mastic* (in tears), 8 *oz.*; *shell lac*, 12 *oz.*; *Venice turpentine*, 1 oz.; melt together, add of *wax*, 1 *lb.*, *tallow*, 6 *oz.*; when dissolved, further add of *hard tallow soap* (in shavings), 6 *oz.*; and when the whole is perfectly combined, add of *lampblack*, 4 *oz.*; lastly, mix well, cool a little, and then pour it into moulds, or upon a slab, and when cold cut it into square pieces.

2. (M. Lasteyrie.) *Dry tallow soap*, *mastic* (in tears), and *common soda* (in fine powder), of each, 30 parts; *shell lac*, 150 parts; *lampblack*, 12 parts; mix as last. Both the above are used for writing on lithographic stones.

3. (*Autographic.*) — *a.* Take of *white wax*, 8 *oz.*; and *white soap*, 2 to 3 *oz.*; melt, and when well combined, add of *lampblack*, 1 *oz.*; mix well, heat it strongly, and then add of *shell lac*, 2 *oz.*; again heat it strongly, stir well together, cool a little, and pour it out as before. With this ink lines may be drawn of the finest to the fullest class, without danger of its spreading, and the copy may be kept for years before being transferred.

b. From *white soap* and *white wax*, of each, 10 *oz.*; *mutton suet*, 3 *oz.*; *shell lac* and *mastic*, of each, 5 *oz.*; *lampblack*, 3½ *oz.*; mix as above. Both the above are used for writing on lithographic paper. When the last one is employed, the transfer must be made within a week.

Obs. The above inks are rubbed down with a little water in a small cup or saucer for use, in the same way as common water-colour cakes, or Indian ink. In winter, the operation should be performed near the fire, or the saucer should be placed over a basin containing a little *tepid* water. Either a steel pen or a camel's hair pencil may be employed with the ink. See *Lithography.*

INK (Marking). Syn. *Indelible Ink, Permanent do.* Of this there are several varieties, of which the following are the most valuable and commonly used :—

1. *Nitrate of silver*, ¼ *oz.*; *hot distilled water*, 7 fl. dr.; dissolve, add of *mucilage*, ¼ *oz.*, previously rubbed with *sap green* or *syrup of buckthorn*, q. s. to colour. The linen must be first moistened with "*liquid pounce*," or "*the preparation*," as it is commonly called, and when it has again become dry, written on with a *clean* quill pen. This ink will bear dilution if the writing is not required very black.

The "*Pounce*" or "*Preparation.*" A solution of *carbonate of soda*, 1½ *oz.*, in *water*, 1 pint, *slightly* coloured with a *little sap green* or *syrup of buckthorn*, to enable the spots wetted with it to be afterwards known.

2. (*Without preparation.*) Take of *nitrate of silver*, ¼ *oz.*; *water*, ¾ *oz.*; dissolve, add as much of the *strongest liquor of ammonia* as will dissolve the precipitate formed on its first addition, then further add of *mucilage*, 1½ dr.; and a little *sap green*, *syrup of buckthorn*, or *finely powdered indigo*, to colour. Writing executed with this ink turns black on being passed over a hot Italian iron, or held near the fire.

3. *Terchloride of gold*, 1½ dr.; *water*, 7 fl. dr.; *mucilage*, 2 dr.; *sap green*, q. s. to colour. To be written with on a ground prepared with a *weak solution of protochloride of tin*, and dried. Dark purple.

4. (Rev. J. B. Reade.) *Nitrate of silver*, 1 oz.; *tartaric acid* (pure), 3 dr.; are triturated together in a mortar, in the dry state; a *little water* is then added, by which crystals of *tartrate of silver* are formed, and the *nitric acid* set free; the latter is then saturated with *liquor of ammonia*, sufficient being added to dissolve all the newly formed tartrate of silver, avoiding unnecessary excess; lastly, a *little gum* and *colouring matter* is added.

5. (Rev. J. B. Reade.) To the last is added an *ammoniacal solution* of a *salt of gold.* Mr. Reade has used for this *purpose* the *purple of Cassius*, the *hyposulphate*, the *ammonio-iodide*, the *ammonio-periodide of gold*, but any other compound of gold which is soluble in ammonia will do as well. The last two substances are new compounds, for which the chemical world is indebted to this gentleman. This ink is unacted on by nearly all those reagents which remove writing executed with solutions of the salts of silver alone; as cyanide of potassium, the chlorides of lime and soda, &c.

6. (Redwood.) *Nitrate of silver* and *pure bitartrate of potassa*, of each, 1 oz. (or, 4 parts), are rubbed together in a glass or Wedgewood-ware mortar, and after a short time, *liquor of ammonia*, 4 oz. (16 parts, or q. s.), is added; when the solution is complete, *archil*, 4 dr. (or, 2 parts); *white sugar*, 6 dr. (or, 3 parts); and *powdered gum*, 10 dr. (or, 5 parts), are dissolved in the liquor, after which *sufficient water* is added to make the whole measure exactly 6 fl. oz., when it is ready to be bottled for use. The last three are used in the same manner as No. 2.

7. (Dr. Smellie.) From *sulphate of iron*, 1 dr.; *vermilion*, 4 dr.; *boiled linseed oil*, 1 oz.; triturated together until perfectly smooth. Used with type.

8. (Soubeiran.) *Nitrate of copper*, 3 parts; *carbonate of soda*, 4 parts; *nitrate of silver*, 8 parts; mix, and dissolve in *liquor of ammonia*, 100 parts. *Used* like No. 2.

9. (Ure.) A *strong solution* of *chloride of platinum*, with a *little potassa*, and *sugar* and *gum*, to thicken.

10. The *fluid* contained between the *kernel* and *shell* of the *cashew nut.* On linen and cotton it turns gradually black, and is very durable. This has been called "*anacardium*" or "*cashew-nut ink.*"

11. *Sulphate of manganese*, 2 parts; *lamp black*, 1 part; *sugar*, 4 parts; all in fine powder, and triturated to a *paste* with a *little water.* Used with types or stencil-plates; the part when dry being well rinsed in water. Brown.

12. *Black oxide of manganese* and *hydrate of potassa*, are mixed, heated to redness in a crucible, and then triturated with an equal weight of *pure white clay*, and *water*, q. s. to give it due consistence. *Used* like the last. Brown.

Obs. The products of the first two of the above formulæ constitute the *marking ink of the shops.* They have, however, no claim to the title of "*Indelible ink*," "*which no art can extract without injuring the fabric*"—as is generally represented. On the contrary, they may be discharged with almost as much facility as common iron-moulds. This may be easily and cheaply effected by means of ammonia, cyanide of

potassium, the chlorides of lime and soda, and some of the hyposulphites, without in the least injuring the texture of the fabric to which they may be applied. The only precaution required, is that of rinsing the part in clean water immediately after the operation. The "*marking ink without preparation*" is more easily extracted than that "*with preparation.*" The former has also the disadvantage of not keeping so well as the latter, and of depositing a portion of fulminating silver, under some circumstances, which renders its use dangerous. The thinner inks, when intended to be used with type or plates, are thickened by adding a *little more gum*, or some sugar.

INK (Marking). Syn. *Packer's Ink.* Ink bottoms. *Used* by packers for marking bales, boxes, &c.

INK (Perpetual). *Prep.* 1. *Pitch*, 3 *lb.*; melt over the fire, and add of *lampblack*, ¾ *lb.*; mix well.

2. *Trinidad asphaltum* and *oil of turpentine*, equal parts. *Used* in a melted state to fill in the letters on tombstones, marbles, &c. Without actual violence it will endure as long as the stone itself.

INK (Printer's). See *Printing Ink.*

INK (Sepia). See *Sepia.*

INK (Sympathetic). Syn. *Diplomatic Ink, Invisible do.* Fluids which, when used for writing, remain invisible until the paper is heated, or acted on by some other chemical agent. Sympathetic inks have been frequently employed as the instruments of secret correspondence, and have often escaped detection; but by heating the paper before the fire until it begins to grow discoloured by the heat, the whole of them may be rendered visible.

The following are the most common and amusing sympathetic inks:—1. *Sulphate of copper* and *sal ammoniac*, equal parts, dissolved in *water*; writes colourless, but turns YELLOW when heated.—2. *Onion juice*; like the last.—3. A *weak infusion of galls*; turns BLACK when moistened with *weak copperas water.*—4. A *weak solution of sulphate of iron*; turns BLUE when moistened with a *weak solution of prussiate of potassa*, and BLACK when moistened with *infusion of galls.*—5. The *diluted solutions of nitrate of silver* and of *terchloride of gold*; become respectively DARK BROWN and PURPLE when exposed to the sunlight.—6. *Aqua fortis, spirits of salts, oil of vitriol, common salt*, or *saltpetre*, dissolved in a *large quantity of water*; turns YELLOW or BROWN when heated.—7. *Solution of chloride* or *nitromuriate of cobalt*; turns GREEN when heated, and disappears again on cooling. If the salt is pure, the marks turn BLUE.—8. *Solution of acetate of cobalt*, to which a *little nitre* has been added; becomes ROSE COLOURED when heated, and disappears on cooling.—9. A *weak solution* of the *mixed chlorides of cobalt* and *nickel*; turns GREEN. The last three are about the best of our sympathetic inks.—10. *Solution of acetate of lead*; turns BROWNISH-BLACK when exposed to the *fumes of sulphuretted hydrogen.*—11. A *weak solution of nitrate of mercury*; turned BLACK by heat and sulphuretted fumes.—12. *Rice water* or *decoction of starch*; turned BLUE by a solution of iodine in *weak spirit*, and by the *fumes of iodine*, if the paper is first slightly moistened by exposure to steam or damp air.

INKS (Coloured). Inks of various colours may be made from a strong decoction of the *ingredients used in dyeing*, mixed with a little *alum* or *other substance* used as a *mordant*, and *gum arabic.* Any of the ordinary *water-colour cakes* employed in drawing, diffused through *water*, may also be used as coloured ink.

Blue Ink. See *Ink* and *Writing Fluids.*

Brown Ink. 1. A strong *decoction of catechu*; the shade may be varied by the cautious addition of a little *weak solution of bichromate of potash.*

2. A strong *decoction of logwood* with a *very little bichromate of potash.*

Gold Ink. From *gold* in the state of an *impalpable powder*, ground up with a little *gum water.* The brilliancy of the writing performed with this ink is considerable, and may be increased by burnishing. (See *page* 539.)

Green Ink. 1. From *sap green* dissolved in very weak *alum water.*

2. A strong solution of *binacetate of copper* in *water*, or of *verdigris* in *vinegar.*

3. (Klaproth.) *Verdigris*, 2 *oz.*; *cream of tartar*, 1 *oz.*; *water*, ½ a pint; boil to one-half, and filter.

4. (Winckler.) *Bichromate of potassa*, 3 parts; *hot water*, 8 parts; dissolve, add of *rectified spirit*, 4 parts, mix, and further add of *sulphuric acid*, q. s. to liberate the *chromic acid*, avoiding excess; next evaporate to one-half, dilute with *water*, filter, and add to the filtrate, *rectified spirit*, 4 parts, together with 3 or 4 drops of *sulphuric acid* (if required) to precipitate any remaining potash-salt; lastly, decant and preserve the liquid until it assumes a rich green colour.

5. A solution of *recently precipitated hydrated oxide of chromium* in *liquor of ammonia*, diluted with *distilled water*, q. s.

A magnificent dark green liquid, perfectly anti-corrosive.

Purple Ink. A *strong decoction of log-wood*, to which a little *alum* or *chloride of tin* has been added.

Red Ink. 1. *Brazil wood* (ground), 4 *oz.*; *white-wine vinegar* (hot), 1¼ pint; digest in glass or a well-tinned copper or enamel saucepan, until the next day, then gently simmer for half an hour, adding towards the end, *gum arabic* and *alum*, of each, ½ *oz.*

2. *Ground Brazil wood*, 10 *oz.*; *white vinegar*, 10 pints; macerate for 4 or 5 days; then boil as before to one-half, and add of *roach alum*, 4½ *oz.*; *gum*, 5 *oz.*; and when dissolved, bottle for use.

3. As the last, but using *water* or *beer* instead of vinegar.

4. *Cochineal* (in powder), 1 *oz.*; *hot water*, ½ pint; digest, and when *quite cold*, add of *spirit of hartshorn*, ¼ pint (or *liquor of ammonia*, 1 *oz.*, diluted with 3 or 4 *oz.* of *water*;) macerate for a few days longer, and then decant the clear. Very fine.

5. (Buchner.) *Pure carmine*, 20 gr.; *liquor of ammonia*, 3 fl. oz.; dissolve, then add of *powdered gum*, 18 gr. Half a drachm of powdered *drop lake* may be substituted for the carmine where expense is an object. Colour superb.

6. (Henzeler.) *Brazil wood*, 2 *oz.*; *alum* and *cream of tartar*, of each, ½ *oz.*; *rain water*, 16 fl. oz.; boil to one-half, strain, add of *gum* (dissolved), ½ *oz.*; and when cold, further add a *tincture* made by digesting *powdered cochineal*, 1½ dr., in *rectified spirit*, 1½ fl. oz.

7. (Redwood.) *Guarancine* and *liquor of ammonia*, of each, 1 *oz.*; *distilled water* (cold), 1 pint; triturate together in a mortar, filter, and dissolve in the solution, *gum arabic*, ½ oz.

Silver Ink. From *silver leaf* or *powdered silver*, as *Gold Ink.*

Violet Ink. The same as *purple ink*, but weaker.

Yellow Ink. 1. From *gamboge* (in coarse powder), 1 *oz.*; *hot water*, 5 *oz.*; dissolve, and when cold, add of *spirit*, ¾ *oz.*

2. Boil *French berries*, ½ *lb.*, and *alum*, 1 *oz.*, in *rain water*, 1 quart, for half-an-hour, or longer, then strain and dissolve in the hot liquor, *gum arabic*, 1 *oz.*

INK POWDERS. *Prep.* 1. *Aleppo galls*, 4 *oz.*; *sulphate of iron*, 1½ *oz.*; *gum arabic*, 1 *oz.*; *lump sugar*, ¾ *oz.*; (all quite dry and in powder); mix, and divide into 3 packets. A pint of *boiling water* poured over one of them produces, in a few hours, a pint of excellent ink.

2. *Aleppo galls*, 3 *lb.*; *copperas*, 1 *lb.*; *gum arabic*, ½ *lb.*; *white sugar*, ¼ *lb.*; all in powder; mix, and divide into two-ounce packets, to be used as the last. *Ink powders* are very useful in travelling.

INOCULATION. Syn. *Inoculatio*,— Lat. The application of poisonous or infectious matter to any part of the body for the purpose of propagating a milder form of disease, and thus preventing or lessening the virulence of future attacks. In this country, the term is generally restricted to the artificial propagation of smallpox. See *Vaccination.*

INOSINIC ACID. An acid said by Liebig to exist in the juice of the flesh of animals, after it has deposited its kreatine.

INOSITE. A species of unfermentable sugar, discovered by Scherer in the juice of flesh. It forms beautiful crystals.

INSANITY. Syn. *Insanitas*, — Lat. Aberration of intellect; madness. Dr. Young divides insanity into the following varieties:—1. *Moral Insanity*, consisting in a morbid perversion of the natural affections, feelings, habits, inclinations, temper, &c.—2. *Monomania*, or partial insanity, in which the mind is influenced by some delusion, or is only disordered in reference to one particular subject.—3. *Mania*, or raving madness, in which the reasoning faculty is either lost or greatly weakened and disordered.—4. *Incoherence* or *dementia*, exhibiting in its different stages, impaired memory, absence of mental volition or reasoning power, deprivation of understanding, and loss of even animal instincts and volition. The consideration of this subject belongs chiefly to medicine and medical jurisprudence. Some remarks that may be useful to the non-professional reader, will be found under *Aberration* (of mind).

INTEMPERANCE. Under this head we refer to habitual indulgence in the use of spirituous or fermented liquors, whether accompanied or not by fits of intoxication or drunkenness.

The action of intoxicating liquors on the human body, in all the numerous relations of cause and effect, has been ably and eloquently treated of, in the "*Anatomy of Drunkenness*," and it would afford both the editor and the reader much pleasure and instruction, did our space permit, to avail ourselves of the mass of facts and judicious remarks collected in that work. As, however, such is not the case, we must confine ourselves to a short notice of certain physical means of removing this vicious habit. The

pernicious influence of intoxicating liquors upon individuals and upon society, and the beneficial effects of temperance, have been so often and ably exposed by the clergy, judges, and magistrates, and by philanthropists of every grade, that it would be folly to do more than merely refer to these points here. Fully one-half of the dark or disreputable deeds of those who fill our gaols, and fully an equal proportion of the poverty and wretchedness which pauperizes our population, and crowds our workhouses, are traceable to that damning vice of the Anglo-Saxon race—*intemperance*. Our judicial authorities appear to be unanimous in their opinion on this subject. *Judge Alderson* has declared that "Drunkenness is the most fertile source of crime; and if it were removed, the assizes of the country would be rendered mere nullities." *Judge Coleridge* has publicly stated, "There is scarcely a crime brought before me that is not, either directly or indirectly, caused by strong drink." According to *Judge Gurney*, "Every crime has its origin, more or less, in drunkenness." *Judge Patteson*, in a recent address, remarked, "If it were not for this drinking, you (the jury) and I would have nothing to do." *Judge Wightman*, in a similar address, observes, "I find in every calender that comes before me, one unfailing source, directly or indirectly, of most of the crimes which are committed — intemperance." Other equally high and competent authorities have expressed themselves in similar language. At the present time more capital is, perhaps, embarked in the manufacture and sale of intoxicating liquors, than in any other similar branch of human industry. And whence comes this enormous capital and the proportionately enormous revenue which its application produces? The reply is, "from the self-imposed taxation of the people, who expend annually in spirits, wine, and beer, fully 70 million sterling; a sum vastly exceeding the whole amount of our exports, and the whole amount of the government taxes, and which is nearly 12 times as great as the sum raised by the poor-rates of the kingdom." Can this enormous expenditure in articles of mere luxury, and which are the chief incentives to the vice, misery, and wretchedness which afflict our land, be judicious, or even useful? Our own opinion is, that there is no vicious habit which has in any equal degree, so tended to corrupt the morals, ruin the character and circumstances, and at once destroy the health and happiness of such multitudes of our fellow-creatures, as *intemperance*. Let every man then avoid, or shake off an habit productive of such frightful consequences. "Poets may sing of the Circean cup—praise in glowing terms the garlands which wreathe it—wit may lend its brilliant aid to celebrate it, and even learning invest it with a charm; but when the poet's song shall have died, and the garlands have all withered; when wit shall have ceased to sparkle, and the lore of ages be an unremembered thing; the baneful *effects* of the intoxicating draught will be felt; and then will the words of wisdom be awfully verified in the miserable doom of the drunkard—'Wine is a mocker—strong drink is raging.' 'At the last it biteth like a serpent, and stingeth like an adder.'" (J. B. Gough.)

To *cure* the "*habit of inebriety*" or "*drunkenness*" various means have been proposed, many of which are more ingenious than useful. Among these the following deserve notice:—

Dr. Kain, an eminent American physician, recommends *tartar emetic*, given in alterative and slightly nauseating doses, for the cure of habitual drunkenness. "Possessing," he observes, "no positive taste itself, it communicates a disgusting quality to those fluids in which it is dissolved." "These liquors, with the addition of a very small quantity of emetic tartar, instead of relieving, increase the sensation of loathing of food, and quickly produce in the patient an indomitable repugnance to the vehicle of its administration. My method of prescribing it has varied according to the habits, age, and constitution of the patient. A convenient preparation of the medicine is 8 gr., dissolved in 4 *oz.* of *boiling water*; ½ an *oz.* (say a table-spoonful) of the *solution* to be put into half a pint, pint, or quart of the patient's favorite liquor, and to be taken daily in divided portions. If vomiting and purging ensue" (which is seldom the case), "I should direct laudanum to allay the irritation, and diminish the dose. In some cases, the change suddenly produced in the patient's habits has brought on considerable lassitude and debility, which, however, were of short duration. In a majority of cases no other effect has been perceptible than slight nausea, some diarrhœa, and a gradual but very uniform distaste to the menstruum." A similar plan has been proposed by Mr. Chambers. The common people in certain parts of the country, have for centuries acted on a similar principle, in infusing *nostoc* or *star-shoot* in the liquor, at drinking which disgust to the menstruum, be it wine, spirit, or beer, is gradually excited. This plant is

the *nostoc commune*, an indigenous species of *alga*.

Dr. Schreiber, a Russian physician, of Brzese-Litewski, confines the drunkard in a room, and furnishes him at discretion with his favorite beverage and coffee as he desires. All the food—the bread, meat, and the *legumes*, are steeped in the same. The poor devil is thus kept continually drunk and "*dort*." On the fifth day of this regime he has an extreme disgust for it, and earnestly requests other diet; but his desire is not yielded to, until he no longer desires to eat or drink; he is then certainly cured of his *penchant* for drunkenness. He acquires such a disgust for his favorite beverage, that he is ready to vomit at the very sight of it.

The following appears in a small treatise on '*Naval Discipline*,' published a few years since:—"Separate for one month every man who is found drunk from the rest of the crew; mark their clothes '*drunkard*;' give them *six-water grog*, or, if beer, mixed with one-half water; let them dine when the crew have finished; employ them in every dirty and disgraceful work, &c. This had such a salutary effect, that in less than six months not a drunken man was to be found in the ship." "The culprits were heard to say, that they would rather receive six dozen lashes at the gangway, and be done with it, than be put into the '*drunkenness*' (for so it was named) for a month."

Dr. Pitcairn, in attempting to break the habit in a highland chieftain, exacted a promise that the latter would every day drop as much sealing-wax into his glass as would receive the impression of his seal. He did so, and as the wax accumulated, the capacity of the glass diminished, and, consequently, the quantity of whiskey it was capable of containing. By this plan he was cured of his bad habit altogether. (Coombe.)

INTERMITTENT FEVER. See *Ague*.

INTOXICATION. Drunkenness; inebriety; the disordered condition of the intellectual functions and volition, produced by taking excessive quantities of alcoholic or intoxicating liquors.

Among the remedies employed to remove the "*fit of drunkenness*," the preparations of ammonia, and the vegetable acids, are the most common and important. About 2 or 3 fl. dr. of *aromatic spirits of ammonia* (spirits of sal volatile), or a like quantity of solution of *acetate of ammonia* (mindererus spirit), mixed with a wine-glassful of water, will in general neutralize or greatly lessen the action of intoxicating liquors. In some cases these fluids produce vomiting, which is, however, a good symptom, as nothing tends to restore an inebriated person so soon as the removal of the liquor from the stomach. Hence tickling the fauces with the finger or a feather, until sickness comes on, is a method very commonly adopted by drunkards to restore themselves to a sober state. The use of aromatic water of ammonia was first suggested by Mr. Bromley. With a like intention, some persons have recourse to *soda-water*, which acts by the free carbonic acid it contains, and also as a diluent, and from its coldness, as a tonic on the coats of the stomach. The *carbonates* and *bicarbonates of soda* and *potassa* are also favorite remedies with habitual drunkards. Among the vegetable acids, *acetic acid* is the one that appears to possess the greatest power of removing intoxication; and after this follow the citric, tartaric, malic, and carbonic acids. These substances are commonly taken by soldiers before going to parade. The usual dose of vinegar is a small tea-cupful. In the West Indies, *lime juice* and *lemon juice* are had recourse to. Both these juices act from the citric acid they contain. The use of *bitter almonds* as a means of lessening or retarding the effects of fermented liquors was known to antiquity, and is still common among heavy drinkers at the present day. Even small doses of *medicinal prussic acid* have been foolishly taken with a like intention.

INULINE. Syn. *Alantine*, *Dahline*, *Datiscine*, *Menyanthine*, *Elecampine*. A peculiar starch-like substance first obtained by Rose from the *root* of *inula helenium* or *elecampane*. It has been found in several other vegetables.

Prep. From the *rasped root*, by the same method that is adopted for arrow-root or potato farina; or by boiling the *sliced root* in 7 or 8 times its weight of *water*, and after filtration, whilst hot, allowing the decoction to repose for a short time.

Prop., &c. Only very slightly soluble in cold water; very soluble in boiling water, but is nearly all deposited as the solution cools; it is precipitated by alcohol.

Inuline is distinguished from *starch* by giving a yellow or yellowish-brown colour with iodine; in the decoction not being precipitated by either acetate of lead or infusion of galls; and by the precipitate formed in the *cold* decoction by an infusion of gall nuts, not disappearing until the liquid is heated to above 212°, while the precipitate from starch redissolves at 122°

Fahr. It appears to be a substance intermediate between starch and gum.

IODATE. Syn. *Oxiodide; Iodas*,—Lat. A salt of iodic acid. The *iodates* closely resemble the chlorates of the corresponding bases. They are *recognized* by the development of free iodine when treated with the *sulphurous*, *phosphorous*, and *hydrochloric acids*, and other deoxydising agents, and by their solutions being converted into iodides when treated with *sulphuretted hydrogen*. They are all of sparing solubility, and many are quite insoluble in water. All the *insoluble iodates* may be obtained from the iodate of potassa, by decomposing it in solution, by a solution of a soluble salt of the base. See *Iodic Acid*, *Iodine*, and *Potassa*.

IODHYDRATE. See *Hydriodate*.

IODHYDRIC ACID. See *Hydriodic Acid*.

IODIC ACID. Syn. *Iodhydric Acid*, *Oxiodine; Acidum Iodicum*,—Lat. An acid compound of iodine and oxygen discovered by Gay-Lussac and Davy.

Prep. 1. *Iodate of soda* is dissolved in *sulphuric acid* in considerable excess, the solution boiled for 15 minutes, and then set aside to crystallize.

2. Decompose *iodate of baryta* by *dilute sulphuric acid*.

3. *Iodine*, 1 part; *nitric acid* (sp. gr., 1·5), 40 parts; mix, keep them at nearly the boiling temperature, for several hours, or until the iodine is dissolved, then evaporate to dryness, and leave the residuum in the open air at a temperature of about 59° Fahr.; when by attracting moisture it has acquired the consistence of a syrup, put it into a place where the temperature is higher and the air drier, when in a few days very fine white crystals of a rhomboidal shape will form. We are indebted for this plan to M. Boursen.

Prop., &c. Iodic acid is decomposed into oxygen and iodine by a heat of about 450 to 500° Fahr., a property of which we avail ourselves for the conversion of the salts of this acid (*iodates*) into iodides. It is very soluble in water and deliquescent, and detonates with inflammable bodies like the nitrates and chlorates. Iodic acid is used as a test for morphia and sulphurous acid. It has been employed by Mr. Monks, the house-surgeon to the Poor-law Schools, at Norwood, as a tonic, stimulant, and alterative, in catarrhal hoarseness, strumous cases, incipient phthisis, &c. *Dose.* 3 to 6 gr.

Test. When iodic acid is mixed with an equal quantity of an alkaloid (preferably *quinine*), on a capsule or watch-glass, and a drop or two of water added, several distinct explosions occur, accompanied by the copious evolution of gas. No other substance exhibits a similar reaction. See *Iodate*.

IODIDE. Syn. *Ioduret*, *Hydriodate; Iodidum*, *Ioduretum*, *Hydriodas*, — Lat. A compound of iodine with a base. The iodides belong to the same class of bodies as the bromides and chlorides, and may be, for the most part, made in the same manner. All the principal iodides are noticed under the names of their respective bases. See *Iodine*, *&c.*

IODIDES (Double). Several of these compounds have been described by Bonsdorff, Boullay, and Liebig, many of which are formed by dissolving the iodides in a solution of iodide of potassium, when crystals of the double salt are deposited as the liquid cools, or on evaporation. They possess little interest in a practical point of view.

IODINE. Syn. *Iodinium*, Ph. L. & D. *Iodineum*,—Ph. E. *Iodium*, *Iodum*, *Iodina*, —Lat. var. An elementary substance accidentally discovered in 1812, by De Courtois, a saltpetre manufacturer at Paris. It was first examined and described by M. Clement, in 1813, and its precise nature was soon afterwards determined by Sir H. Davy and M. Gay-Lussac. It is found in each of the three kingdoms of nature, but exists in greatest abundance in the vegetable family algæ. According to Chatin, all spring water, fresh water, land plants, and every variety of food and beverage contain iodine in minute quantities; and he believes it to be an essential constituent in the organism of all animals, whether fluviatile, marine, or terrestrial. The experiments of Meyric, Marchand, and others, show it to be present everywhere in nature, associated with chlorine. Chatin states that a hen's egg contains more iodine than a litre of milk; whilst milk is richer in this substance than any other food. In atmospheric air, the normal quantity is said to be 1·5 milligramme in every 4000 litres, part of which is absorbed by the organism during respiration. Forcault found that the air of parts where goiture and glandular affections prevailed, was free from iodine. This is confirmed by Chatin in reference to the air of the Alps and of the valley of the Rhone. Oberbeck has detected iodine in the ashes of the ranunculaceæ. Dr. Lohmeyer has endeavoured to throw discredit on these statements, founded on his own experiments, which were, however, of a very inconclusive character. Böttgher has also stated that all (?) nitric acid contains chloride of

iodine, and he hence argues that Chatin may have fallen into this source of error. Althongh we mention it, we do not hold the latter to have been likely.

Prep. Iodine is principally manufactured in the neighbourhood of Glasgow, from the mother-waters of kelp, known as *iodine lye.*

1. *Kelp* (the half-vitrified ashes of seaweed) is exhausted with *water*, and the solution filtered; the liquid is then concentrated by evaporation until it is reduced to a very small volume, the chloride of sodium, carbonate of soda, chloride of potassium, and other salts, being removed as they successively assume the crystalline form; *oil of vitriol* is now added, in excess, to the residual dark-brown mother-liquor (*iodine lye*), and the evolved gases (carbonic acid, sulphurous acid, and sulphuretted hydrogen), are either kindled or allowed to escape by a flue; the liquid is next decanted or filtered from the newly-formed sulphur, heated to about 140° Fahr., and mixed with as much *binoxide of manganese* as there was *oil of vitriol* employed; the whole is then introduced into a cylindrical *leaden still*, furnished with a *very short* head and connected with 2 or 3 large globular glass receivers, and heat is applied, when fumes of iodine are evolved and condensed in the receivers. During the distillation very great care is taken to watch the process, and prevent the neck of the still becoming choked with condensed iodine. For this purpose the head of the still is usually furnished with a moveable stopper, by which the process may be watched, and additions of manganese or sulphuric acid made, if required. To render the product pure, it should be passed between blotting paper, and then resublimed in glass or stoneware.

2. (Soubeiran.) A mixed solution of *sulphate of copper*, 4 parts, and *protosulphate of iron*, 9 parts, are added to the *mother liquor of the soda works*, as long as a white precipitate is thrown down; this precipitate (*diniodide of copper*) is collected, dried, mixed with its own weight of *finely-powdered black oxide of manganese*, and distilled by a strong heat in a retort, when *dry iodine* passes over. By the addition of *sulphuric acid* with the manganese, a less heat is required, but the product is wet with water, like that of the last formula.

3. (Ure.) The *residual liquor of the manufacture of soap from kelp* (or other iodine lye), of the sp. gr. of 1·374, is heated to 230° Fahr., with *sulphuric acid diluted with half its weight of water*, after which the liquid is allowed to cool, and is either decanted or filtered; to every 12 *fl. oz.* of the filtrate, 1000 gr. of *black oxide of manganese*, in powder, are added; the mixture is put into a glass globe or matrass with a wide neck, over which is inverted another glass globe, and heat is applied by means of a charcoal chauffer, when iodine sublimes very copiously, and condenses in the upper vessel; as soon as the latter is warm it is replaced by another, and the two globules are thus applied in succession, as long as violet fumes are evolved. The iodine is washed out of the globes with a little cold water. A thin disc of wood, having a hole in its centre, is placed over the shoulder of the matrass, to prevent the heat from acting on the globular receiver. On the *large scale*, a leaden still, as before described, may be employed, and receivers of either stoneware or glass; and the addition of the sulphuric acid is made in a basin or trough of stoneware or wood. *Prod.* 12 *oz.* yield 80 to 100 gr.

Prop. Iodine is usually met with under the form of semi-crystalline lumps having a semi-metallic lustre, or in micaceous, friable scales, somewhat resembling plumbago or gunpowder. It has a grayish-black colour, a hot acrid taste, and a disagreeable odour, not much unlike that of chlorine. It fuses at 225°, volatilizes slowly at ordinary temperatures, boils at 347°, and when mixed with water rapidly rises along with its vapour at 212° Fahr. It dissolves in about 7000 parts of water, and freely in alcohol, ether, solutions of the iodides, and liquid hydriodic acid. It may be crystallized in large rhomboidal plates, by exposing to the air a solution of it in hydriodic acid, and less perfectly by melting it and allowing it to cool slowly under slight pressure. It bleaches like chlorine, only more feebly. Iodine has an extensive range of affinity: with the salifiable bases, it forms compounds termed *Iodides*, *Iodurets*, or *Hydriodates*, of which several are used in medicine. Its compounds with oxygen are the *iodic* and *periodic acids*. Sp. gr., 4·946 to 4·948. According to Debaugne the addition of syrup of orange-peel or tannin to water, greatly increases its power of dissolving iodine. 2 gr. of the latter will enable 6 fl. oz. of water to take up 10 gr. of iodine. A knowledge of these facts may prove useful to the pharmaceutist.

Pur. It is *entirely* soluble in rectified spirit, and in a solution of iodide of potassium. "On applying heat to it, it first liquefies, and then (wholly) sublimes in violet coloured vapour. (Ph. L.) "39 gr. of *iodine*, with 9 gr. of *quicklime*, and

3 fl. oz. of *water*, when heated short of ebullition, slowly form a perfect solution, which is yellowish or brownish, if the iodine be *pure;* but colourless if it contains more than 2% of water or of other impurity." (Ph. E. & L.) The *iodine of commerce* is usually that of the first sublimation, and generally contains from 12% to 20% of water. Some of the foreign iodine, prepared by precipitation with chlorine, without subsequent sublimation, even contains 1-4th part of water, and has a dead leaden-gray colour, and evolves a sensible odour of chlorine. Coal, plumbago, oxide of manganese, crude antimony, and charcoal, are also frequently mixed with iodine to increase its weight. *Water* may be detected by the loss of weight it suffers when exposed to strong pressure between bibulous paper; or more accurately by drying it in the manner directed below,—*chlorine* may be detected by the odour; and the *other* substances mentioned above, by their insolubility in rectified spirit and in a solution of iodide of potassium. Before *use* as a *medicine*, "it must be dried by being placed in a shallow basin of earthenware, in a small confined space of air, with 10 or 12 times its weight of fresh-burnt lime, till it scarcely adheres to the side of a dry bottle." (Ph. E.) The Dublin College orders their *iodinium purum* to be prepared from commercial iodine as follows: — Place it in a deep circular porcelain capsule, and having covered it accurately with a glass matrass filled with cold water, apply a water heat to the capsule for 20 minutes, and then allow the whole to cool; should the sublimate attached to the bottom of the matrass include acicular prisms of a white colour, and a pungent odour, it must be scraped off with a glass rod, and rejected; the apparatus is then to be again exposed to a gentle and steady heat until the whole of the iodine has sublimed; the sublimate is, lastly, to be collected from the bottom of the matrass, and at once enclosed in a stoppered bottle.

Tests. Free iodine may be recognized by —1. The violet colour of its vapour.—2. Striking a blue colour with starch. This test is so delicate, that water containing only $\frac{1}{450000}$th part of iodine, acquires a perceptible blue tinge on the addition of starch. (Stromeyer.)—3. Nitrate of silver causes a white precipitate in solutions containing iodine.—4. Chloride of palladium causes a black, flaky precipitate; equal in sensibility to starch. (M. Baumann.)—5. It strikes a blue colour with opium and narceine.

Iodine in *combination*, as it exists in *iodic acid* and the *iodates*, does not strike a blue colour with starch, without the addition of some deoxydizing agent, as sulphurous acid or morphia; and as it exists in the *iodides*, not until the base is saturated with an acid (as the nitric, or sulphuric), when iodine being set free, immediately reacts upon the starch. An excess of either acid or alkali destroys the proper action of the test. By mixing the liquid containing the iodine with the starch and acid, and lightly pouring thereon a small quantity of aqueous chlorine, a very visible blue zone will be developed at the line of contact, even in very dilute solutions. (Balard.)

Solutions containing *iodates* yield, with nitrate of silver, a white precipitate soluble in ammonia; the *iodides*, under the same circumstances, give a pale yellowish precipitate with nitrate of silver, scarcely soluble in ammonia; a *bright yellow* one with acetate of lead; and a *scarlet* one with bichloride of mercury. The *iodates* deflagrate when thrown on burning coals, but the *iodides* do not. The *iodates* may also be tested as iodides, by first heating them to redness, by which they lose their oxygen, and are converted into iodides.

Chatin and Gaultier de Claubry, prefer the starch test to all others; and for the liberation of the iodine, either nitric acid, or a mixture of nitric and sulphuric acid. Oberbeck treats a little starch or sugar with nitric acid in a test tube, applying heat until a vigorous disengagement of gas commences, which is then passed into the liquid under examination, previously mixed with a little starch paste. If only 1-1,000,000th *grain* of iodine or iodide of potassium is present, a blue colour is immediately developed.

Estim.—1. By separating it by volatilizing it by heat, and collecting and weighing the sublimate.—2. By solution in rectified spirit, adding water, and collecting the resulting precipitate, which must then be dried and weighed.—3. (Thornton J. Herapath.) 1·309 gr. of perfectly pure iodide of potassium (equal to 1 gr. of iodine) is dissolved in 10,000 gr. of water; this constitutes solution No. 1, and contains a little less than 0·01 of iodine. By diluting this with water, other solutions—Nos. 2, 3, 4, 5, 6, &c., are formed. A weak solution of a salt of palladium is now added drop by drop, until no deepening of colour ensues. The standard solutions so prepared are then corked and sealed up in glass tubes, and are then available in future

investigations. The iodine in the substance to be tested having been converted into hydriodic acid or a soluble iodide, the latter is introduced into a colorometer containing the standard solutions, and is then diluted with water to the necessary degree —that is to say, until it occupies respectively 100, 500, 1000, 10,000, or more water-grain measures, the precaution being taken to first add the solution of palladium as before. The tint is then compared with that of the standard solutions, in which certain known quantities of iodine are contained in the same bulk of water, and the quantity of iodine present inferred from the resemblance in colour, in the same way as is adopted with *Crum's chlorometer*, described at p. 244, "Operating in this way, it is possible to estimate the 1-20,000th of a grain of iodine with the greatest readiness."—4. According to M. Rabourdin chloroform is superior to all other substances for quantitatively determining iodine in organic mixtures. If 10 grammes of any liquid containing $\frac{1}{100000}$th of its weight of *iodine* be treated with 2 drops of *nitric acid*, 15 or 20 of *sulphuric acid*, and 1 gramme of *chloroform*, and agitated, it assumes a distinct violet colour. M. Rabourdin judges of the quantity of iodine present by the tint of violet which the chloroform thus treated assumes.

Uses, &c. Iodine is chiefly used as a medicine, a chemical test, and in photography. Recently it has been employed in the manufacture of writing fluids. In small doses it appears to be both alterative and tonic, rapidly diffusing itself through the body, and exerting a stimulating action on the organs of secretion. It is also said to be diuretic, and in some cases to have produced diaphoresis and salivation. It is said to exert a powerful antaphrodisiac action, and instances are recorded where absorption of the mammæ and testæ have followed its exhibition, (Hufeland's Journ.); but such cases are so very rare as to throw doubt on their having been produced by this medicine. Iodine has been exhibited in the following diseases, as well as in most others depending on an imperfect action of the absorbents, or accompanied by induration or enlargement of individual glands or organs: — *Internally*, in *bronchocele, goitre, Derbyshire neck, scrofula, ovarian tumours, enlargement or induration of the lymphatic, prostate, and parotid glands, amenorrhœa, leucorrhœa, diseases of the muco-genital tissues, phthisis, chronic nervous diseases, lepra, psoriasis, chronic rheumatism, dropsies, hydrocele, &c.*:— *Externally*, in *scrofula, numerous skin diseases (especially the scaly), erysipelas, diseased joints, chilblains, burns, scalds, various wounds, to check ulceration, to promote absorption, &c.* *Dose.* ½ gr. dissolved in spirit, or in water by means of an equal weight of iodide of potassium. It is seldom exhibited alone, being usually combined with the last-named substance, which in fact, is now generally preferred by practitioners. It is applied *externally* in the form of ointment, solution, or tincture.

IODINE (Bromides of). Bromine and iodine unite rapidly by mere mixture. By careful distillation a red vapour is obtained, which, on cooling, condenses into red crystals, of a form resembling fern leaves. This is said to be the *protobromide*. By adding more bromine, these crystals are converted into a fluid, said to be the *bibromide* or *superbromide*.

IODINE (Chlorides of). When dry chlorine is passed over dry iodine, at common temperatures, heat is evolved, and a yellow solid chloride results when the iodine is fully saturated; and an orange red liquid, when the iodine is in excess. They both absorb moisture in the air, are volatile, and very soluble in water, forming a colourless solution, which exhibits acid properties. The solid iodide is decomposed by water into hydrochloric and iodic acids, forming the *chloriodic acid* of Sir H. Davy. The *protochloride of iodine* is said to be formed when chlorine is passed into water holding iodine in suspension. A liquid so prepared has been recommended by Dr. Turnbull as a source of irritating vapour, useful in certain affections of the eyes. The *perchloride* or *terchloride*, by repeatedly distilling the protochloride, or by adding to a solution of the latter a strong solution of corrosive sublimate.

IODOFORM. Syn. *Iodoformum*,—Lat. A solid, yellow, crystallizable substance, obtained by the action of iodine on alcohol.

Prep. 1. An *alcoholic solution of potassa* is added to *tincture of iodine*, carefully avoiding excess; the whole is then gently evaporated to dryness, the residuum is washed with water, and then dissolved in *alcohol;* the alcoholic solution yields crystals by evaporation.

2. (M. Clary.) *Distilled water*, 12 fl. oz.; *rectified spirit*, 2 fl. oz.; *iodine* and *bicarbonate of soda*, of each, 1 oz.; put the ingredients into a flask and apply the heat of a water bath until the colour of the liquid disappears, and bright yellow scales are deposited; these are to be collected on a filter, washed with a little cold water, and

dried. More iodoform may be obtained by adding *fresh iodine* to the same liquor as long as the latter becomes decoloured on repeating the process.

Prop., &c. Nearly insoluble in water; freely soluble in alcohol; the solution is decomposed by alkalies into an iodide and a formiate of the base. *Dose.* ½ gr. to 3 gr.; where the use of iodine is indicated.

IODONITRIC ACID. See *Iodosulphuric Acid.*

IODOPHOSPHORIC ACID. From *iodine* and *phosphoric acid*, as iodosulphuric acid.

IODOSALICYLIC ACID. A dark brown fusible mass, obtained by distilling a *mixture* of *iodide of potassium* and *chlorosalicylic acid;* or by dissolving *iodine* in *salicylic acid.*

IODOSULPHURIC ACID. *Prep.* Drop *sulphuric acid* into a hot concentrated *aqueous solution of iodic acid*, as long as a precipitate falls. When strongly heated, it sublimes, and is decomposed, but by means of a gentle heat, gradually applied, it melts, and crystallizes in yellow rhomboids as it cools. The *iodonitric* and *iodophosphoric acids* may be formed in a similar manner. All of these compounds act with great energy on the metals, and dissolve gold and platinum.

IODOUS ACID. *Prep.* (Sementini.) *Chlorate of potassa* and *iodine*, equal parts; triturate together, until reduced to a homogeneous yellow mass; then heat the mixture over a spirit lamp, in a glass retort connected with a spacious receiver, until vapours are no longer evolved. The oily liquid in the receiver is the iodous acid.

2. (Pleischl.) *Chlorate of potassa*, 3 parts; *iodine*, 1 part; as last.

Obs. Iodous acid, or oxide of iodine, reddens litmus paper, is volatile at 112° Fahr., and dissolves iodine freely. Little is known respecting its precise composition, and some chemists deny its existence as an independent substance.

IPECACUANHA. Syn. *Radix Ipecacuanhæ; Ipecacuanha,* — Ph. L. E. & D. The "root" of "cephaelis ipecacuanha," or the true ipecacuanha plant, one of the rubiaceæ. "Ashy coloured, tortuous, very much cracked, and marked in rings with deep fissures, having an acrid, aromatic, bitterish taste." (Ph. L.) It occurs in pieces, 3 or 4 inches long, and about the size of a writing quill. *Dose.* As an *emetic*, 10 to 20 gr., assisted by the copious use of warm water; as a *nauseant*, 1 to 3 gr.; as an *expectorant* and *sudorific*, ½ to 1 gr. It is undoubtedly the safest and most useful medicine of its class. It has recently been highly recommended in dyspepsia, combined with other bitters or aperients.

IRIDIO-CHLORIDES. Double salts, formed of the *chlorides of iridium* with *other chlorides.* Some of them are crystallizable and soluble.

IRIDIUM. A rare metal, discovered by Descotils in 1803, and by Tennant in 1804, in the black powder left in dissolving crude platinum. This powder is an alloy of iridium with osmium.

Prep. (Wollaston.) The *pulverulent residuum of the ores of platinum* is reduced to fine powder, along with ⅓rd of its weight of *nitre*, and the mixture is heated to redness in a silver crucible, until reduced to a pasty state, and the odour of oxide of osmium becomes perceptible; as soon as the whole is cold, it is powdered and agitated with the smallest possible quantity of *water;* the solution is placed in a retort, acidulated with *oil of vitriol diluted with an equal weight of water*, and rapidly distilled into a clean receiver, as long as fumes of *osmic acid* pass over and condense as a white crust on the sides of the vessel, afterwards liquefying, and sinking beneath the water, forming a flattened globule. By solution in *water*, agitation with mercury, and the addition of *hydrochloric acid*, OSMIUM is obtained as a black porous powder, which exhibits a metallic lustre when rubbed. The undissolved portion is now digested in *hydrochloric acid*, and the solution treated with *any metal* but gold or platinum, when *iridium* is precipitated.

Prop., &c. Brittle, pulverulent, and, when polished, resembling platinum. It is the heaviest, hardest, most infusible, indestructible, and least affected by acids, of all the metals. With *chlorine*, iridium forms 4 compounds:—the *protochloride*, formed by transmitting chlorine over powdered iridium, heated to a dull red, or by digesting the hydrated protoxide in hydrochloric acid;—the *sesquichloride*, by calcining iridium with nitre, digesting in nitric acid, washing with water, and solution in hydrochloric acid;—the *bichloride*, by digesting the sesquichloride in hot *nitrohydrochloric acid;* — the *terchloride*, obtained as a double chloride of potassium. With *oxygen*, iridium forms a *protoxide*, *sesquioxide*, and *teroxide*, each of which may be obtained by precipitating a solution of the corresponding chloride with an alkali. *Metallic iridium* is used for the tips of *gold pens*, *everlasting pens*, *&c.*

IRON. Syn. *Ferrum*,—Ph. L. E. & D. The early history of iron is lost in its antiquity. It is said to have been employed

as a medicine upwards of 3200 years ago. As a remedial agent, when properly exhibited, it acts as a genial stimulant and tonic, and generally proves beneficial in cases of chronic debility, unaccompanied with organic congestion or inflammation. For this purpose, the *protoxide* or *its salts* should be chiefly relied on, as the *peroxide* and *its salts* act, almost universally, as irritant stimulants, occasioning heartburn, febrile symptoms, and accelerated pulse. The powers of the protocarbonate, as it exists in mineral waters, held in solution by carbonic acid in excess, appears to be the form most congenial to the human body; and from its state of dilution, "is rapidly absorbed by the lacteals, and speedily imparts a ruddy hue to the wan countenance." Iron is undoubtedly one of the most valuable articles of the materia medica, and appears from the antiquity of its introduction into medicine, and the number of its preparations, to have been deservedly appreciated.

Prep. Iron is only prepared on the large scale. In Sweden it is extracted from *magnetic iron* and *micaceous iron ore;* and in England, principally from *clay iron ore.* It is obtained by smelting the *ore* along with *coke* and a *flux* (either limestone or clay). The crude iron thus obtained is run into moulds, and then constitutes *cast iron* or *pig iron* (ferrum fusum). By the subsequent processes of *refining* (puddling, welding,) it is converted into *soft iron* or *wrought iron* (ferrum cusum). *Iron filings* (ferri limaturæ), *iron-turnings* (ferri ramenta, ferri scobs), and *iron-wire* (ferrum filum; f. in fila tractum,—Ph. L.), are the forms under which iron is ordered in the pharmacopœias. The last is only used in preparations, but the others are also taken. It is ordered to be "flexible, but not resilient." (Ph. L.) For *medical purposes,* iron-filings and turnings should be purified by washing, drying, and separating them from particles of copper and other metals, by laying a sieve over them, and drawing them through it with a magnet. *Dose.* Of the filings, 5 to 10 gr.

Prop., &c. The properties and uses of iron are too well known to require description. Its applications are almost universal. It is remarkably ductile, and possesses great tenacity, but is less malleable than many of the other metals. Its sp. gr. is 7·788. It is the hardest of all of the malleable and ductile metals, and when combined with carbon or silica (*steel*) admits of being tempered to almost any degree of hardness or elasticity. In dry air it does not oxidize at common temperatures; but at a red heat it soon becomes covered with a scaly coating of black oxide, and at an intense white heat burns brilliantly with the production of the same substance. Pure water, free from air or carbonic acid, does not tarnish the surface of polished iron, but the combined action of air and moisture, especially when a little acid vapour is present, causes its surface to be soon covered with rust, which is hydrated sesquioxide of iron. Nearly all the hydrated acids attack iron; dilute sulphuric and hydrochloric acid do so with considerable energy and the evolution of hydrogen gas. At a red heat, iron decomposes water rapidly, hydrogen being evolved, and the black oxide of iron formed. Iron is magnetic up to a dull-red heat, at which point it loses all traces of that property. It melts at 3300° Fahr. (Daniel.) With oxygen, chlorine, iodine, the acids, &c., it forms numerous important compounds.

Tests. 1. *Metallic iron* is—*a.* Attracted by the magnet.—*b.* Dissolved by dilute hydrochloric and sulphuric acids, with evolution of hydrogen gas, recognised by its inflammability.—*c.* The solution in *b* exhibits the usual reactions of protoxide of iron. (See *below.*)

2. Dry *protoxide of iron* is a black powder; in its hydrated state it is white, and when exposed to air, rapidly absorbs oxygen, assuming first a grayish-green colour, and then a brownish-red, which is much brightened by exposure to a red heat, at the same time that the facility with which it dissolves in the acids is considerably lessened.

3. The *salts of the protoxide of iron* have a greenish colour, but yield nearly colourless solutions, except when concentrated. *Their solutions* are known by—*a.* When *acidulated* they are not precipitated by sulphuretted hydrogen; even *neutral* solutions with weak acids are but incompletely precipitated; whilst *alkaline* solutions are precipitated of a black colour,—*b.* *Neutral* solutions are precipitated black by hydrosulphuret of ammonia.—*c.* Ammonia and potassa give a greenish-white precipitate, gradually becoming green, and then brown in the air. The presence of ammoniacal salts interferes with the action of these tests—*d.* Ferrocyanide of potassium gives a nearly white precipitate, becoming gradually blue in the air, and immediately so on the addition of a little weak nitric acid or chlorine water.—*e.* Ferridcyanide of potassium produces a rich deep blue precipitate, insoluble in hydrochloric acid. In highly dilute solutions the effect is only a deep bluish-green coloration.—*f.* *Auro-chloride of sodium* gives a purple precipi-

tate.—*g.* Phosphate of soda, a blue one. —*h.* Cochineal, freed from fat by ether, and then digested in water (or very weak spirit), gives a solution which is coloured violet by the protosalts of iron. (Kastner.)

4. *Peroxide of iron* is a brownish-red powder; in its hydrated form very soluble in acids; when anhydrous, less so.

5. The *salts* of *sesquioxide* or *peroxide of iron* have for the most part a reddish-yellow colour, yielding deep coloured solutions which exhibit the following reactions: —*a.* They redden litmus paper.—*b.* Sulphuretted hydrogen added to *alkaline* solutions gives a black precipitate.—*c.* Hydrosulphuret of ammonia does the same with *neutral* solutions, or in very dilute solutions only a blackish-green discoloration; the precipitate being in both cases soluble in the hydrochloric and acetic acids.—*d.* Ammonia and potassa produce bulky reddish-brown precipitates insoluble in excess. —*e.* Ferrocyanide of potassium gives a rich blue precipitate, insoluble in hydrochloric acid, and readily decomposed by potassa.—*f.* Ferridcyanide of potassium deepens the colour, but does not give a blue precipitate, as it does with the protoxide.—*g.* Sulphocyanide of potassium gives an intense ruby-red colour to *neutral* or *acid* solutions. This is the most sensitive of all known tests.—*h.* Meconic acid and the meconiates also give a red colour.—*i.* Tincture and infusion of galls strike a black colour.—*k.* Phosphate of soda gives a white precipitate.

Estim. 1. The iron may be thrown down in the state of peroxide or sesquioxide, washed, dried, ignited, and weighed. The weight, in grains, multiplied by 0·7, indicates the weight of metallic iron.

2. (Liebig.) The ore is reduced to fine powder, mixed with a *mixed flux* of *cyanide of potassium* and *carbonate of potassa*, and exposed to a very strong heat in a porcelain crucible. The alumina and silica remain in the scoria; the reduced iron is separated by washing the mass with cold water, and is then dried, and weighed.

3. 50 gr. of the ore are reduced to powder, dissolved in *aqua regia*, with the aid of heat, and the solution filtered in order to separate the silica and a little alumina which sometimes is left in an insoluble state; an excess of ammonia is then added to the filtered liquor, which produces a reddish-brown precipitate of peroxide of iron mixed with alumina, which is collected on a filter, washed, and boiled with a *solution of caustic potassa*, in order to dissolve the alumina; the whole is next thrown upon a filter, on which the peroxide of iron is washed, dried, carefully ignited, and weighed. The above (No. 2 & 3) are well adapted to determine the quantity of iron in clay iron-stone, the most common ferruginous ore in England.

Concluding Remarks. Want of space compels us to omit much useful matter which we had collected together on the analysis of iron ores, and the manufacture of iron. The common crude iron of commerce is thrown as *pig iron* or *cast iron*, which is the melted metal discharged from time to time from the furnaces, and allowed to run into moulds of sand, so as to form lumps called "*pigs.*" Of cast iron there are several varieties, varying in colour, hardness, and composition. They are known as *gray*, *black*, and *white iron*, of which the first is commonly the best. These variations in quality and character of the product depend, chiefly, on the method followed and the fuel used in their production.

The preparations of iron used in medicine and the arts are very numerous. The greater number of them are, however, very easily made, either by direct solution of the metal or its hydrated oxide in the acids, or (as in the case of the insoluble compounds especially) by double decomposition. The following list contains the principal substances of this class:—

IRON (Acetates of). *Prep.* 1. *Protacetate of Iron; Ferri Acetas*,—Lat. From freshly precipitated *protoxide* or *carbonate of iron* dissolved in *dilute acetic acid;* or by adding a *solution of acetate of lime* to another of *protosulphate of iron*, and evaporating the filtered liquid, out of contact with the air. Small, pale greenish needles or prisms, very soluble and prone to oxidation.

2. *Sesquiacetate of Iron, Peracetate of Iron; Ferri Sesquiacetas; Ferri Acetas*,—Ph. D. 1826.—*a.* From *hydrated sesquioxide of iron* dissolved in *acetic acid;* or by adding a solution of *acetate of lime* or of *baryta*, to another of *persulphate of iron.*

b. (Ph. D. 1826.) *Carbonate of iron*, 1 part; *acetic acid* (Ph. D.), 6 parts; digest 3 days and filter. A dark brownish-red uncrystallizable liquid, very soluble, and powerfully astringent. The calcined sesquioxide of iron of the shops, commonly sold as carbonate of iron, does not answer well for this or any of the following compounds, owing to its being with difficulty dissolved by acids, especially by the weaker ones. *Dose.* (Of the last) 10 to 25 drops, in water or wine. See *Iron Liquor.*

IRON (Acetate of,—with Alum). *Prep.*

(Guibourt.) *Alum*, 1 part; *sulphate of iron*, 2 parts; *boiling water*, 10 parts; dissolve, filter the solution, add *solution of diacetate of lead* as long as a precipitate forms, and after a short time filter, and evaporate to the consistence of a jelly. *Used* as *marking ink* by packers, either alone, or stirred up with a little lamp black; it resists alkalies and soap, but not acids.

IRON (Acid of). See *Ferric Acid.*

IRON (Albuminate of). Syn. *Ferri Albuminas*,—Lat. *Prep.* 1. Dissolve well washed *hydrated protoxide* or *peroxide of iron* in *white of egg*, previously diluted with *twice its weight of water*, and filtered.

2. (Lassaigne.) Precipitate a filtered *solution of white of egg* with another of *persulphate of iron*, wash the deposit in *water*, and dissolve it in *alcohol holding caustic potassa in solution.*

Obs. This preparation is highly spoken of by M. Lassaigne and other high authorities, as especially adapted by its nature, on theoretical grounds, for combining with the tissues of the body.

IRON (Ammonio-chloride of). Syn. *Ammoniated Iron*, *Ferro-chloride of Ammonia*; *Ferri Ammonio-chloridum*,—Ph. L. *Ferrum Ammoniatum*,—Ph. L. 1824. *Ferrum Ammoniacale*,—Ph. L. 1788. *Flores Martiales*,—Ph. L. 1775. *Prep.* 1. (Ph. L.) *Sesquioxide of iron*, 3 oz.; *hydrochloric acid*, ½ pint; digest in a sand bath, until dissolved, then add of *sal ammoniac*, 2½ lb, dissolved in *water*, 3 pints; filter the liquid, evaporate to dryness, and reduce the mass to coarse powder. Orange-coloured crystalline grains.

2. Rub *sal ammoniac* with twice its weight of *colcother* or *rust of iron*, sublime with a quick sudden heat, and repeat the sublimation with *fresh sal ammoniac* as long as the flowers are well coloured. Difficult to manage.

Obs. Ammonio-chloride of iron "is totally soluble in proof spirit and in water. Potassa added to the solution throws down sesquioxide of iron, and when added in excess, it evolves ammonia." (Ph. L. 1836.) Ammonia "throws down from 100 gr. of this salt about 7 gr. of sesquioxide of iron." (Ph. L.)

Ammonio-chloride of iron is tonic, emmenagogue, and aperient. *Dose.* 5 to 15 gr.; in glandular swellings, obstructions, &c.

IRON (Ammonio-citrate of). Syn. *Ferro-citrate of ammonia*, *Ferric do. do.*, *Citrate of Iron and Ammonia*; *Ferrico-citras Ammoniæ*; *Ferri Ammonio-citras*,—Ph. L. & D. There are three salts generally known under the name of *citrate of iron—two*, having the peroxide for their base, and *one*, the protoxide. There is also a *fourth*, formed from the magnetic oxide of iron, which has scarcely been introduced into this country, though commonly employed in France, and highly recommended by Béral. The salt at present so much advertised as citrate of iron, is a double citrate of iron and ammonia, and appears to be correctly called *ammonio-citrate of iron* in our pharmacopœia. Several other double citrates of iron may be prepared, but they possess inferior qualities to those just mentioned, and therefore offer no inducement for their manufacture.

Prep. 1. (Ph. L.) *Sulphate of iron*, 12 oz.; *carbonate of soda*, 12½ oz.; dissolve each separately in *boiling distilled water*, 6 pints; mix the solutions whilst still hot, and allow the precipitate to subside; after a time decant the supernatant liquor, wash the precipitate frequently with water (drain it), add of *citric acid* (in powder), 6 oz.; and dissolve by the aid of a gentle heat; when the whole has cooled, add of *liquor of ammonia* (Ph. L.), 9 fl. oz., and gently evaporate to the consistence of a syrup; in this state spread it (very) thinly on flat earthenware dishes (or sheets of glass), dry by a gentle heat, and when dry, keep it in well-stopped bottles.

2. (Ph. D.) *Citric acid*, 4 *oz.*; *distilled water*, 16 *fl. oz.*; *hydrated peroxide of iron*, obtained from *sulphate of iron*, 5 *oz.*; *liquor of ammonia*, 4 *fl. oz.*, or q. s. This differs from the process of the London College chiefly in the precipitate from the sulphate of iron being at once converted into *hydrated sesquioxide of iron* by the addition of *nitric acid*, as noticed below, a trouble and expense uselessly incurred, as the same change occurs spontaneously during the usual process.

3. (*Wholesale.*) A mixture of *iron filings*, and *citric acid*, in powder, with barely sufficient *water* to cover them, are kept in a warm situation for some days, occasionally stirring the mass, and *replacing* the water as it evaporates. A saturated solution is next made in *distilled water*, there being previously added more *citric acid* (about half the weight of the acid first used), as required; it is then neutralized with *liquor of ammonia* (about 1¼ *oz.* of liquor of ammonia, sp. gr. ·882, to every gallon of the solution of sp. gr. 1·025), and the solution is concentrated by evaporation; the process is then completed as in No. 1. The first part of this process produces a salt of the *protoxide of iron*, which is afterwards con-

verted, by exposure to the atmosphere, into a *citrate of the magnetic oxide*, and, lastly, into *citrate of peroxide of iron.*

Obs. This beautiful salt is of a rich ruby colour, and forms glistening transparent scales, very soluble in aqueous menstrua, and the resulting solution is less easily decomposed by reagents, than the solutions of most of the other salts of iron. It is compatible with the alkaline carbonates and bicarbonates, and several other salts, and is nearly tasteless, advantages which have been perhaps overrated by both prescriber and patient. It is doubtful whether this article has not obtained a larger sale from its pleasing appearance than from its medicinal virtues. Several parties who have prepared it in lumps or powder, by the simple evaporation of the solution to dryness, have been unable to sell it under that form, even at a lower price.

The formulæ of the Ph. L. is essentially that of Béral. The third formula is based on Mr. Aikin's process for the preparation of his *ammonio-tartrate of iron.* Pharmaceutical writers have been so diffuse in their disquisitions on the preparation of this salt, as would lead to the inference that there is some difficulty attending it. The contrary is, however, the case. The only care necessary is to spread the syrupy solution *very thinly* on warm sheets of glass to dry, which it will rapidly do, if they are placed in an atmosphere of warm dry air, for which purpose a "*drying closet*" is the most convenient. The dry salt may then be easily detached from the glass, and will form thin scales, or lamellæ, of great brilliancy and beauty. It is also better to use a little more oxide than the acid will dissolve, as the remainder may be employed in a future operation. Less water may be used, or even a larger quantity than that mentioned; but in the first case the liquid will become difficult to filter—in the latter it will require more evaporation. Boiling water dissolves about twice its weight of citric acid, and retain $\frac{13}{20}$th of this quantity in solution when cold, and it takes rather more than twice the weight of the *citric acid* in *most hydrated protoxide of iron*, to produce saturation.

Ammonio-citrate of iron is "soluble in water; the solution neither changes the colour of litmus nor turmeric; nor is it turned blue by ferrocyanide of potassium; but either potassa or lime water being added, it throws down sesquioxide of iron, and ammonia is evolved. From 100 gr. dissolved in water, potassa precipitates about 34 gr. of sesquioxide of iron." (Ph. L.) *Dose.* 3 to 10 gr., in water, wine, or bitter infusions.

IRON (Ammonio-Tartrate of). Syn. *Aikin's Ammonio-tartrate of Iron, Tartrate of Iron and Ammonia, Ferro-tartrate of Ammonia; Ammoniæ Ferro-tartras, Amm. Ferrico-tartras,*—Lat. *Prep.* 1. *Tartaric acid*, 1 part; *iron filings*, 3 parts; digest in a sufficient quantity of *hot water* to barely cover the mixture for 2 or 3 days, observing to stir it frequently, and to add just enough water to allow the evolved gas to escape freely; next add *liquor of ammonia*, in slight excess, stir well, dilute with *water*, decant, wash the undissolved portion of iron, filter the mixed liquors, and evaporate to dryness; dissolve the residuum in water, add a *little more ammonia*, filter, and again gently evaporate to dryness, or to the consistence of a thick syrup, when it may be spread upon hot plates of glass, or on earthenware dishes, and dried in a stove-room, as directed for ammonio-citrate of iron.

2. (W. Procter, Jun.) *Tartaric acid*, 6¼ oz.; *water*, 7 pints; dissolve, neutralize the solution with *sesquicarbonate of ammonia*, and add 6¼ oz. more *tartaric acid;* to the solution heated in a water bath, further add *moist hydrated oxide of iron* (obtained from *sesquioxide of iron*, 53½ dr.; dissolved in *hydrochloric acid*, and precipitated by *ammonia*); when dissolved, filter, and evaporate, &c., as before.

Obs. Glossy, brittle lamellæ, or irregular pieces, of a deep garnet colour, almost black, very soluble in water, and possessing a sweetish and slightly ferruginous taste. By repeated re-solution and evaporation its sweetness is increased, probably from the conversion of a part of its acid into sugar. It contains more iron than a given weight of the sulphate of the same base. It is the most pleasant-tasted of all the preparations of iron, except the ammonio-citrate, last noticed. (Aikin, Lond. Med. Gaz.) *Dose.* 3 to 10 gr.

IRON (Arseniate of). Syn. *Ferri Arsenias, Ferrum Oxydulatum Arsenicum,*—Lat. *Prep.* From a *solution of arseniate of soda, potassa,* or *ammonia*, added to a solution of *protosulphate of iron*, the precipitate being collected, washed in a little cold water, and dried. *Dose.* $\frac{1}{20}$ to $\frac{1}{12}$ gr., made into a pill; in lupus, psoriasis, cancerous affections, &c. (Biett.) *Externally*, combined with 4 times its weight of phosphate of iron and a little water, as a paint to destroy the vitality of cancerous formations. (Carmichael.) An ointment, (20 to 30 gr. to the oz.) is also used for the same purpose. They are all dangerous remedies

in non-professional hands. The *perarseniate* or *sesquiarseniate of iron* is prepared by precipitating *peracetate of iron* with *arseniate of ammonia*, or by boiling nitric acid on the *protarsenite*. It is not used in medicine.

IRON (Arsenite of). Syn. *Protarsenite of iron; Ferri Arsenis*,—Lat. From the *arsenite of potassa, soda*, or *ammonia*, and *sulphate of iron*, as the last. A yellowish brown powder, occasionally used in medicine as a tonic, alterative, and febrifuge. *Dose.* $\frac{1}{16}$ to $\frac{1}{12}$ gr. The *sesquiarsenite* or *perarsenite* is formed in the same way by using the persulphate.

IRON (Benzoates of). Syn. *Ferri Benzoas*,—Lat. Prepared by digesting the corresponding *hydrated oxides* in a *hot solution of the acid;* or from the *benzoate of an alkali* and a *salt of iron*, by double decomposition. The neutral *benzoate of sesquioxide of iron* is soluble; but the basic salt is insoluble.

IRON (Bromide of). Syn. *Ferri Bromidum*,—Lat. *Prep.* 1. (Moir.) *Bromine* and *iron filings*, of each, 1 part; *water*, 3 parts; mix in a stoppered phial, set it aside, occasionally shaking it, for 2 or 3 days, and when the colour of the bromine has disappeared, and the liquid becomes greenish, filter and evaporate to dryness.

2. (Magendie.) As the last, but putting the materials in a flask, and boiling over a sand bath, until the union is complete. *Dose.* 1 to 6 gr., as a tonic, diuretic, and resolvent, in similar cases to those in which iodide of iron is given.

IRON (Carbonate of). Syn. *Protocarbonate of iron; Ferri Carbonas*,—Lat. This preparation is found in a crystallized state in the mineral called *Spathose iron*, and in some chalybeate waters.

Prep. Precipitate a *solution of protosulphate of iron* with a *solution of carbonate of soda*, well wash the green powder with water which has been boiled, and dry it out of contact with the air. On the slightest exposure it is converted into *sesquioxide of iron.* This change is for the most part prevented by combining it with sugar, as in the next preparation.

IRON (Carbonate of,—Saccharine.) Syn. *Carbonate of Iron with Sugar; Klauer's Ferrum Carbonicum Saccharatum; Ferri Carbonas cum Saccharo*,—Ph. L. *Ferri Carbonas Saccharatum*,—Ph. E. & D. *Prep.* 1. (Ph. L.) *Sulphate of iron*, 4 oz.; *carbonate of soda*, 4¼ oz.; dissolve each separately in 1 quart of *boiling water*, and mix the solutions whilst hot; after a time collect the precipitate, wash it frequently with *water*, and add of *sugar*, 2 oz., previously dissolved in *water*, 2 fl. oz.; lastly, evaporate the mixture over a water bath to dryness, and keep it in a well-closed bottle.

2. (Ph. E.) *Sulphate of iron*, 4 oz.; *carbonate of soda*, 5 oz.; proceed as last, collect the precipitate, well wash it with cold water, drain on a cloth, squeeze out as much of the water as possible, and add of *powdered lump sugar*, 2 oz.; mix and dry at a temperature not much above 120° Fahr. The whole operation should be performed as quickly as possible.

3. (Ph. D.) As the last, the desiccation to be conducted under 212° Fahr.

Prop., &c. A sweet-tasted greenish mass or powder, consisting chiefly of carbonate of iron. It is one of the best of the chalybeates. *Dose.* 5 to 10 gr. When pure it should be "easily soluble in hydrochloric acid with brisk effervescence." (Ph. E.)

IRON (Supercarbonate). Syn. *Ferri Supercarbonas*,—Lat. This is iron in the state in which it exists in the carbonated chalybeate mineral waters.

IRON (Carburet of). Syn. *Ferri Carburetum*,—Lat. This is plumbago or black lead. For medical and chemical use it is treated as follows:—

Prep. 1. (Dumas and Stas.) Heat it to redness with *caustic potassa*, in a covered crucible, then wash it well with *water*, boil it in *nitric acid*, and in *aqua regia*, again wash it with water, dry it, and expose it at a white heat to a stream of *dry chlorine gas;* lastly, wash it with *water*, and again heat it to dull redness. In analysis.

2. (Ph. Bor.) *Pure native plumbago*, 1 lb, is boiled in *water* for 1 hour, then drained, and digested, for 24 hours, in a mixture of *water*, 8 oz.; *nitric acid* and *hydrochloric acid*, of each, 2 oz.; it is lastly well-washed with *water*, and dried. See *Plumbago.*

IRON (Chlorides of). *Prep.* 1. *Protochloride of Iron, Muriate of do.; Ferri Chloridum*,—Lat. Dissolve *iron filings* or *scales* in *hydrochloric acid*, evaporate and crystallize. Soluble, green crystals. In this form it is sometimes called *hydrated chloride of iron* (ferri chloridum hydratum).

2. *Sesquichloride of Iron, Perchloride of do., Permuriate of do.; Ferri Sesquichloridum, &c.*,—Lat. Dissolve *sesquioxide* or *rust of iron* in *hydrochloric acid*, evaporate to the consistence of a syrup, and crystallize. Red crystals.

Obs. Neither of the preceding are absolutely pure; but by transmitting dry *hydrochloric acid gas* over iron heated to redness, a pure white crystalline *protochlo-*

ride of iron is obtained; and by the combustion of *iron wire* in *chlorine gas*, or by passing *chlorine* over *heated iron*, the pure *perchloride of iron* is formed. The *protochloride* is volatile at high temperatures, and the *perchloride* is dissipated by a heat a little above 212° Fahr. The latter is soluble in water, alcohol, and ether, and is very deliquescent and corrosive. See *Tinctures*

IRON (Citrates of). *Prep.* 1. *Citrate of Iron, Protocitrate of Iron, Citrate of Protoxide of Iron.* This salt is easily formed by digesting *iron filings* or *wire* with *citric acid*, and evaporating the solution as quickly as possible out of contact with the air. It presents the appearance of a white powder, nearly insoluble in water, and rapidly passing to a higher state of oxidation by exposure to the air. Its taste is very metallic. It is exhibited under the form of pills, mixed with *gum* or *syrup*, to prevent it from being prematurely decomposed.

2. *Citrate of Magnetic Oxide of Iron.* Prepared from the *magnetic oxide of iron*, in the same way as the *percitrate* from the *peroxide.* It may be formed into beautiful transparent scales, or lamellæ, in a similar manner to the ammonio-citrate. Its solution is of a lively green colour, permanent in the air, and possesses an intensely ferruginous taste. For this reason it can only be exhibited under the form of pills or syrup.

3. *Percitrate of Iron, Citrate of Peroxide of do.; Citrate of do.* (?) This may be prepared by either of the methods adopted for the ammonio-citrate, merely *omitting* the addition of the *ammonia.* It much resembles the ammonio-citrate, but is only *slightly* soluble in water, and has a rather less agreeable taste. *Dose.* (Of each of the above.) 3 to 7 gr.

IRON (Ferridcyanide of). See *Turnbull's Blue.*

IRON (Ferrocyanide of). Syn. *Medicinal Prussian Blue; Ferri Ferrocyanidum; F. Ferrocyanuretum,*—Ph. U. S. *F. Percyanidum,*—Ph. L. 1836. *Prep.* (Ph. U. S.) *Sulphate of iron*, 4 oz.; *water*, 1 pint; dissolve, add to the solution, *nitric acid*, 6 fl. dr., in small portions at a time, boiling for a few moments after each addition; next dissolve *ferrocyanide of potassium*, 4½ oz., in *water*, 1 pint, and add this last solution, by degrees, to the first liquid, stirring well each time; lastly, collect the precipitate, wash it with *boiling water*, drain, and dry it. *Dose.* 3 to 5 gr., three or four times daily, as an alterative, febrifuge, and tonic, gradually increasing the quantity until some obvious effect is produced; in agues, epilepsy, and neuralgia. See *Prussian Blue.*

IRON (Gallate of). Syn. *Ferri Gallas,*—Lat. See *Ink* and *Gallic Acid.*

IRON (Iodide of). Syn. *Protiodide of Iron, Ioduret of do., Hydriodate of do., Iodohydrate of do.; Ferri Hydriodas, F. Ioduretum; F. Iodidum,* — Ph. L. E. & D. *Prep.* 1. (Ph. L. 1836.) *Iodine*, 6 oz.; *iron filings*, 2 oz.; *water*, 4½ pints; mix, boil in a sand bath until the liquid turns to a pale green, filter, wash the residuum with a *little water*, evaporate the mixed liquors in an iron vessel at 212° Fahr., to dryness, and immediately put the iodide into well-stoppered bottles.

2. (Ph. E.) As the last nearly, but the solution is not to be filtered until evaporated to ⅛th, *without removing the excess of iron*, and then *as quickly as possible*, and at once put into a basin, surrounded with 12 times its weight of *quicklime*, and placed in some convenient apparatus in which it may be accurately shut in a small space not communicating with the general atmosphere; the whole is then heated in a hot-air press, in a stove or otherwise, until the water is entirely evaporated, when the *iodide of iron* is to be put into small, dry, stoppered-phials.

3. (Ph. D.) *Iodine*, 1 *oz.*, and *clean iron filings* or *turnings*, ½ *oz.*; are put into a Florence flask with *distilled water*, 4 fl. oz., and having applied a gentle heat for 10 minutes, the liquid is boiled until it loses its red colour; it is then at once filtered into a second flask, the filter washed with *water*, 1 fl. oz., and the mixed liquid is boiled down, until it solidifies on cooling.

4. (M. Kop.) *Iodine*, 4 parts, is triturated with *water*, 2 parts, in a large shallow dish or capsule, and *iron filings* (in a state of fine division), 1 part, added *at once*, and the trituration continued; if the heat developed from the mixture is insufficient to cause the disengagement of iodine vapour, the mixture is slightly heated immediately after the addition of the iron filings; the whole, at first liquid, soon becomes solidified, and must be at once put into bottles as before. In the *protiodide of iron* thus prepared, there exists a small quantity of undecomposed iron, which may be easily separated by a filter, when the salt is used in solution, and the *filtered liquid* will then be *colourless*, and free from any admixture of *binodide*, or of *free iodine.* (*Journ. de Chimie Méd.*)

Prop., &c. Iodide of iron "evolves violet

vapours by heat, and sesquioxide of iron remains. When freshly made it is *totally soluble* in water, and from this solution when kept in a badly stoppered vessel, sesquioxide of iron is very soon precipitated; but with iron wire immersed in it, it may be kept clear in a well-stoppered bottle." (Ph. L. 1836.) "Entirely soluble in water, or *nearly* so, forming a greenish solution." (Ph. E.) Its *dilute solution* should be colourless. *Dose.* 1 to 3 gr., or more, as a tonic, stimulant, and resolvent. It has been given with advantage in anæmia, chlorosis, debility, scrofula, and various glandular affections.

Obs. The preparation of the above compound, like that of the *citrates of iron*, has formed a fertile subject during some years, for pharmaceutical amateurs to dilate upon. There is in reality not the *least* difficulty in the process. As soon as *iodine* and *iron* are mixed together under water, much heat is evolved, and if too much water be not used, the combination is soon complete, and the liquor merely requires to be evaporated to dryness, out of contact with the air, at a heat not exceeding 212° Fahr. This is most cheaply and easily performed by employing a glass flask, with a thin broad bottom and a narrow mouth, by which means the evolved steam excludes air from the vessel. The whole of the uncombined water may be known to be evaporated when vapour ceases to condense on a piece of cold glass held over the mouth of the flask. A piece of moistened starch paper occasionally applied in the same way, will indicate whether free iodine is evolved; should such be the case, the heat should be immediately lessened. When the evaporation is completed, the mouth of the flask should be stopped up by laying a piece of sheet Indian rubber on it, and over that a flat weight; the flask must be then removed, and when cold broken to pieces, the iodide weighed, and put into dry and warm stoppered wide-mouth glass phials, which must be immediately closed, tied over with bladder, and the stoppers dipped into melted wax.

Iodine and *iron* have such a powerful affinity for each other, that when rubbed together, even in the dry state, they speedily unite, forming a liquid, which "turns litmus paper green, and which on the addition of water, has the usual acid reaction; thus apparently confirming Davy's original doubt as to the elementary character of iodine." (Rev. J. B. Reade.)

IRON (Iodide of,—Saccharine). Syn. *Saccharum Ferri Iodidi, Ferri Iodidum Saccharatum*,—Lat. *Prep.* 1. (Ph. Bor.) *Iron* (in powder), 1 dr.; *water*, 5 dr.; *iodine*, 4 dr.; obtain a *solution of iodide of iron*, as above, and add to it of *sugar of milk* (in powder), 1½ oz.; evaporate at a temperature not exceeding 122° Fahr., until the mass has a tenacious consistence, then further add of *sugar of milk*, 1 oz., reduce the mixture to powder, and preserve it in a well-stoppered bottle. Every 6 gr. contain 1 gr. of iodide of iron.

2. (Dr. A. T. Thomson.) From *syrup of iodide of iron* exposed in a shallow vessel, in a warm place, until it crystallizes; the crystals are collected, dried, and powdered. A simpler plan is to gently evaporate the whole to dryness, and to powder the residuum. The *saccharated iodide of iron* may be kept for some time in a corked bottle without undergoing decomposition.

IRON (Periodide of). Syn. *Ferri Periodidum*,—Lat. *Prep.* Freely expose a *solution of protiodide of iron* to the air; or digest *iodine*, in excess, on *iron*, under water, gently evaporate, and sublime. A deliquescent, volatile red compound, soluble in water and alcohol.

IRON (Lactate of). Syn. *Protolactate of Iron; Ferri Lactas, Ferrum Lacticum*,—Lat. *Prep.* 1. Boil *iron filings* in *lactic acid* diluted with *water*, until gas ceases to be evolved, and filter whilst hot into a suitable vessel, which must be at once closely stopped; as the solution cools, crystals will be deposited, which after being washed, *first* with a little *cold water*, and then with *alcohol*, are to be carefully dried. The mother-liquor on being digested as before with *fresh iron* will yield more crystals.

2. (Pagenstecher.) *Lactate of lime* (prepared from sour milk) is dissolved in *water*, and *carbonate of ammonia* added until it ceases to produce a precipitate; the liquid is now filtered, and concentrated by heat until it acquires the consistence of syrup; it is then mixed with 6 times its weight of *alcohol* (sp. gr. 0·879), and a concentrated solution of *protochloride of iron* (containing a quantity of the salt equal to 38% of the lactate of lime employed) is added; in about 36 hours the mixed liquid will have deposited all its lactate of iron in minute crystals, which may be obtained by straining and pressure between the folds of bibulous paper.

3. (Wöhler.) Into *sour whey*, 2*lb.*, sprinkle of *sugar of milk* and *iron filings*, of each, in fine powder, 1 *oz.*; digest at about 100° Fahr., until the *sugar of milk* is dissolved, then add a second portion, and as soon as a white

crystalline powder begins to form, boil the whole gently, and filter into a clean vessel; lastly, collect, wash, and dry the crystals, as before.

Prop., &c. Lactate of iron is a greenish-white salt; and when pure forms small acicular or prismatic crystals, which have a sweetish ferruginous taste, and are soluble in about 48 parts of cold, and in 12 parts of boiling water. It has been regarded by many high authorities as superior to every other preparation of iron for internal use, as being at once miscible with the lactic acid of the gastric juice, instead of having to be converted into a lactate at the expense of that fluid, as it is asserted is the case with the other preparations of iron. *Dose.* 2 to 6 gr., frequently, in any form most convenient.

IRON (Magnesio-citrate of). Syn. *Citrate of Iron and Magnesia; Ferri Magnesio-citras, Ferri et Magnesiæ Citras,*—Lat. *Prep.* As *ammonio-citrate of iron*, but using *hydrated carbonate of magnesia* instead of ammonia to neutralize the solution. *Dose.* 2 to 10 gr. It has been recommended as a chalybeate in the dyspepsia of gouty and debilitated habits.

IRON (Malate of, — Impure). Syn. *Ferri Malas Impurus,*—Lat. *Prep.* (P. Cod., 1839.) *Porphyrized iron filings*, 1 part; *juice of sour apples*, 8 parts; digest for 3 days in an iron vessel, evaporate to one-half, strain through linen whilst hot, further evaporate to the consistence of an extract, and preserve it from the air. *Dose.* 5 to 20 gr.; where the use of iron is indicated.

IRON (Muriate of). See *Chlorides of Iron.*

IRON (Nitrates of). *Prep.* 1. *Protonitrate of Iron, Nitrate of Protoxide of Iron; Ferri Nitras,*—Lat. By dissolving *protosulphuret of iron* in *dilute nitric acid*, in the cold, and evaporating the solution in vacuo. Small green crystals, very soluble, and prone to oxidation.

2. *Pernitrate of Iron, Persesquinitrate of do., Nitrate of Sesquioxide of do.; Ferri Pernitras, &c.,*—Lat. By digesting *nitric acid* (diluted with about half its weight of water) on *iron* or *sesquioxide of iron.* A deep-red liquid, apt to deposit a basic salt. It is used in dyeing, and has been recommended in dyspepsia, calculous affections, and chronic diarrhœa. *Dose.* 5 to 10 or 12 drops.

IRON (Oxides of). Iron forms *four* compounds with oxygen. *Protoxide* (or oxide), *sesquioxide* (or peroxide), *protosesquioxide* (black or magnetic oxide, intermediate between, and probably formed by the union of the other two), and *ferric acid*, noticed at *page* 453.

IRON (Protoxide of). Syn. *Ferri Protoxydum,*—Lat. This substance is precipitated from solutions of the *protosalts of iron*, as a white *hydrate* by the *pure alkalies*, and as a white *carbonate* by the *alkaline carbonates;* both of which rapidly absorb oxygen, and turn, first green, and then red by exposure to the air. In both states it readily dissolves in the *acids* forming the *green* or *protosalts of iron.* See *Carbonate of Iron.*

IRON (Deutoxide of). Syn. *Black Oxide of Iron, Magnetic do., Protosesquioxide of do.; Ferri Oxydum Nigrum,*—Ph. E.; *F. O. Magneticum,*—Ph. D. *Oxydum Ferroso-ferricum,* — Berzelius. *Martial Ethiops, Æthiops Martialis,*—Obs. This occurs native, but that used in medicine is prepared artificially.

Prep. 1. *Hydrated.—a.* (Ph. E.) *Sulphate of iron*, 6 oz.; *oil of vitriol*, 160 minims; *nitric acid*, 4 fl. dr.; *liquor of ammonia* (fort.), 4½ fl. dr.; *boiling water*, 3 pints; dissolve half of the sulphate in half of the water, add the oil of vitriol, boil, add the nitric acid gradually, boiling after each addition for a few minutes; dissolve the remaining half of the sulphate of iron in the rest of the boiling water; mix the two solutions, add the ammonia, stirring well (and boil for a short time); collect the precipitate on a calico filter, wash it with water until it ceases to affect a *solution of nitrate of baryta*, and dry at a heat not exceeding 180° Fahr. The formulæ of Gregory and Dr. Jephson are similar.

b. (Ph. D.) *Sulphate of iron*, 8 *oz.*, dissolved in a mixture of *water*, 10 fl. oz., and *sulphuric acid*, 6 fl. dr., is converted into *sesquisulphate* by means of *nitric acid*, 4 fl. dr., diluted with *water*, 2 fl. oz., as last; this solution is then added to another, formed by dissolving *sulphate of iron*, 4 *oz.*, in *water*, ½ pint; the whole is then mixed with *liquor of potassa* (Ph. D.), 2¾ pints, and after being boiled for 5 minutes, is collected on a calico filter, and washed, &c., as before; and is to be preserved in a well-stoppered bottle.

2. *Anhydrous,*—Ph. D. 1826. From the *black scales of iron* (*Ferri oxydi squamæ*) that fall around the smith's anvil, by washing, drying, detaching them from impurities by means of a magnet, and then treating them by grinding and elutriation, as directed for *prepared chalk.* This process is the cheaper of the two, but the product is inferior as a medicine, being less easily soluble in the juices of the stomach.

Prop., &c. A black sand-like substance, consisting of very minute crystals. When pure, it is "attracted by the magnet, and is entirely soluble in hydrochloric acid; and ammonia added to the solution throws down a black precipitate." (Ph. E.) This oxide is the chief product of the oxidation of iron at a high temperature in the air and in aqueous vapour. It is more permanent than the protoxide, but incapable of forming salts. *Dose.* 5 to 20 gr. two or three times a day. It is said to be less irritating than the sesquioxide.

IRON (Sesquioxide of). Syn. *Peroxide of Iron, Red Oxide of do.; Ferri Sesquioxydum, F. Oxydum Rubrum,*—Lat. This substance is found native under several forms, but that employed in the arts is prepared by one or other of the following methods:—

1. From Metallic Iron,—*Rust of Iron, Crude Carbonate of do.; Ferri Sesquioxydum Hydratum Crudum, Ferrugo; Ferri Rubigo,*—Ph. D. 1826, & Ph. L. 1788. From *iron wire* or *clean iron filings* cut into pieces, moistened with *water*, and exposed to the air until completely converted into rust; it is then ground with water, elutriated, and dried, in a similar way to that adopted for chalk. For sale it is usually made up into small conical loaves or lumps.

2. By Calcination,—*Brown Red Colcothar, Crocus, Crocus Martis, Indian Red, Rouge, Jeweller's do., Trip, Caput Mortuum Vitrioli, C. M. Sulphuratus; Ferrum Oxydum Rubrum,*—Ph. D. 1826.—*a.* (Ph. D. 1826.) Calcine *sulphate of iron* until the water of crystallization is expelled, then roast it with a strong fire until acid vapours cease to rise; cool, wash the residuum with *water* until the latter ceases to affect litmus, and dry it.

b. (Berzelius.) *Green sulphate of iron*, 100 parts; *common salt*, 42 parts; calcine, wash well with water, dry, and levigate the residuum. This process yields a cheap and beautiful product, which is frequently sold for the sesquioxide, Ph. L.; but it is less soluble, and therefore unfitted for a substitute for that preparation.

3. By Precipitation,—*Ferri Sesquioxydum,*—Ph. L. & D. *Ferri Oxydum Rubrum,*—Ph. E. *Ferri Carbonas,*—Ph. D. 1826, and Ph. L. 1809. *Ferri Subarbonas,*—Ph. L. 1829.—*a.* By precipitating a *solution of sesquisulphate* or *sesquichloride of iron* with *ammonia*, in excess, and washing, drying, and igniting the resulting *hydrated peroxide.* Pure; anhydrous.

b. (Ph. L.) *Sulphate of iron*, 4 lb; *carbonate of soda*, 4 lb 2 oz.; dissolve each separately in *water*, 3 gall.; mix the solutions whilst hot, set the mixture aside that the precipitate may subside, and subsequently wash and dry it as before. Contains water, and a trace of alkali.

c. (Ph. E.) From *sulphate of iron*, 4 oz.; *carbonate of soda*, 5 oz.; *water*, 4 pints; as the last.

Prop. Sesquioxide of iron, prepared by *precipitation*, is an impalpable powder, of a brownish-red colour, odourless, insoluble in water, freely soluble in acids, and possessing a slightly styptic taste, especially when recently prepared. When exposed to heat, its colour is brightened, its sp. gr. increased, and it is rendered less easily soluble in acids. The sesquioxide prepared by *calcination* is darker and brighter coloured, less soluble, and quite tasteless. It has either a scarlet or purplish cast, according to the heat to which it has been exposed. The finest *Indian red* or *crocus*, usually undergoes a second calcination, in which it is exposed to a very intense heat. It is then known as "*purple brown.*" The best *jeweller's rouge* is prepared by calcining the precipitated oxide until it becomes scarlet. The *rust of iron* contains some combined water, and is more soluble than the oxide prepared by calcination.

Uses, &c. The precipitated oxide is employed in medicine as a tonic, and emmenagogue, in doses of 10 to 30 gr.; and as an anthelmintic, and in tic douloureux, in doses of 1 to 4 dr., mixed up with honey. It is also employed to make some preparations of iron. *Rust of iron* is likewise used in the same way. The *calcined oxide* is employed as a pigment, as an ingredient in a plaster, &c.

Medicinal sesquioxide of iron "is soluble in dilute hydrochloric acid, scarcely effervescing, and is again thrown down by potassa. The strained liquor is free from colour, and is not discoloured by the addition of either sulphuretted hydrogen or ferrocyanide of potassium." (Ph. L.)

IRON (Sesquioxide of,—Hydrated). Syn. *Hydrated Peroxide of Iron; Ferri Peroxydum Hydratum,*—Ph. D. *Ferrugo,*—Ph. E. *Prep.* 1. (Ph. E.) *Sulphate of iron*, 4 oz.; *oil of vitriol*, 3½ fl. dr.; *water*, 1 quart; mix, dissolve, boil, and gradually add of *nitric acid*, 9 fl. dr.; stirring well and boiling for a minute or two after each addition, until the liquor yields a yellowish-brown precipitate with ammonia; it must then be filtered and precipitated with *liquor of ammonia* (fort.), 3½ fl. oz., rapidly added and well mixed in; collect the precipitate,

wash it well with water, drain it on a calico filter, and dry it at a heat not exceeding 180° Fahr. When intended as an antidote for arsenic it should not be dried, but kept in the moist or gelatinous state.

2. (Ph. D.) *Sulphate of iron*, 8 *oz.*; *water*, ½ pint; *sulphuric acid*, 6 fl. dr.; dissolve; oxidize the solution with *nitric acid*, 4 fl. dr., diluted with *water*, 2 fl. oz.; proceed as last, and pour the liquid into *liquor of potassa* (Ph. D.), 1 quart; the precipitate after being well washed, is to be enclosed, in the pasty state, in a porcelain pot, the lid of which is rendered air-tight by *lard*.

Prop., &c. "Entirely and very easily soluble in hydrochloric acid, *without* effervescence; if previously dried at 180° Fahr., a stronger heat drives off about 18% of water." (Ph. E.) We are indebted to Messrs. Bunsen and Berthold for the introduction of this substance as an antidote to arsenic. A table-spoonful of the moist oxide may be given every 5 or 10 minutes, or as often as the patient can swallow it. (Pereira.) When this preparation cannot be obtained, *rust of iron* or even the dry *carbonate* (sesquioxide) may be given along with water instead. According to Dr. Maclagan, 12 parts, and to Devergie, 32 parts of the *hydrated oxide of iron* are required to neutralize 1 part of *arsenious acid*. Fehling says that the value of this substance as an antidote to arsenic is materially impaired by age, even when kept in the moist state. The presence of potassa, soda, ammonia, or their sulphates, chlorides, or carbonates, is not of consequence, and therefore, in cases of emergency, time need not be lost in washing the precipitate, which, in such cases, need only be drained and squeezed in a calico filter. The magma obtained by precipitating *sulphate of iron* with *magnesia*, in excess, and which contains free magnesia and sulphate of magnesia besides hydrated peroxide of iron, precipitates *arsenious acid*, not only *more quickly*, but in larger quantity, than the *hydrated oxide* does when *alone*. It will even render inert *Fowler's solution*, and precipitate both the copper and arsenic from solutions of *Schweinfurth's green in vinegar*, which the pure gelatinous oxide alone will not do. (Fehling, *Archiv der Pharm.*) *Dose.* As a tonic, 5 to 20 gr.

The *rust of iron* is also a hydrated oxide, but is less soluble than that recently precipitated from its solution in an acid. *Hydrated sesquioxide of iron* is best preserved in a well-stoppered bottle filled with *recently* distilled or boiled water.

IRON (Percyanide of). See *Ferrocyanide of Iron* and *Prussian Blue*.

IRON (Phosphate of). Syn. *Protophosphate of Iron, Blue do. do.; Ferrum Phosphoricum Cæruleum, Ferri Phosphas*, —Lat. *Prep.* (Ph. U. S.) *Sulphate of iron*, 5 oz.; *phosphate of soda*, 6 oz.; dissolve each separately in 2 quarts of *water*, mix the solutions, and after repose for a short time, wash, and dry the precipitate.

Prop., &c. A blue powder; insoluble in water; soluble in dilute nitric and hydrochloric acid. *Dose.* 5 to 10 gr.; in amenorrhœa, diabetes, dyspepsia, scrofula, &c.; and *externally*, as an application to cancerous ulcers.

IRON (Sesquiphosphate of). Syn. *Oxyphosphate of Iron, Perphosphate of do., Superphosphate of do., White Phosphate of do.; Ferri Sesquiphosphas, Ferrum Phosphoricum Album, Phosphas Ferricus, &c.*, —Lat. A white powder, obtained by precipitating *sesquichloride of iron* by *phosphate of soda*. *Uses* and *dose*, as the last.

Obs. The synonyms of the phosphates of iron have been very loosely given. We have adopted the above arrangement as the simplest, and the one best understood in medicine and pharmacy, without investigating its scientific accuracy. We find certain recent pharmaceutical writers confound the two preparations. The *oxyphosphate of iron* of Fuzet-Duponget is a mixture of the above two, prepared by using a solution of sulphate of iron which has been rendered brown by exposure to light and air. The *superphosphate* of M. Schobeldt is a mere solution of the sesquiphosphate in aqueous phosphoric acid. The *superphosphate* or *suboxyphosphate of iron* of Rammelsberg, is a brownish-red powder, prepared by boiling sesquiphosphate of iron in a weak solution of potassa. It consists principally of sesquioxide of iron. The nondescript compound called *biphosphate of iron* by Dr. Routh, is formed by adding phosphate of iron to boiling monobasic or glacial phosphoric acid contained in a porcelain capsule, as long as the salt is dissolved. The solution solidifies as it cools. The last is recommended in anæmia, and in debility accompanied by great nervous depression, in doses of 1 to 3 gr.

IRON (Phosphuret of). Syn. *Phosphide of Iron; Ferri Phosphuretum*,—Lat. Not used in medicine. It is frequently an accidental constituent of cast iron, and bar iron, which it renders brittle or *cold-short*.

IRON (Potassio-citrate of). Syn. *Citrate of Iron and Potassa; Ferri Potassio-citras*,

Ferri et Potassæ Citras,— Lat. From *citric acid*, *carbonate of potassa*, and *iron* or *sesquioxide of iron*, by one or other of the processes described under *ammonio-citrate* or *ammonio-tartrate of iron*, the former of which it resembles in many important particulars, and is preferable to it in affections of the stomach and mucous membranes.

IRON (Potassio-tartrate of). Syn. *Tartrate of Potassa and Iron*, *Ferro-tartrate of Potassa*, *Ferric Tartrate of do.*, *Chalybeated Tartar*, *Tartarized Iron*; *Tartrate of Iron* (?); *Ferri Potassio-tartras*,—Ph. L. *Ferrum Tartarizatum*,—Ph. E., & Ph. L. 1824. *Ferri Tartarum*,—Ph. D. *Tartras Ferri et Potassæ*,—Ph. E. 1839. *Prep.* 1. (Ph. L.) *Sulphate of iron*, 4 oz., is dissolved in *water*, 1 pint, previously mixed with *sulphuric acid*, ½ fl. oz.; heat is applied to the solution, and *nitric acid*, 1 fl. oz., gradually added; the solution is boiled to the consistence of a syrup, and then diluted with *water*, 4 gall. (less the pint already used); *liquor of ammonia*, 10 fl. oz., is next added, and the precipitate washed, and set aside for 24 hours; at the end of this time the water being decanted, the still *moist precipitate* is added, gradually, to a mixture of *bitartrate of potassa*, 2 oz., and *water*, ½ pint, heated to 140° Fahr.; after a time the undissolved oxide is separated by a linen cloth, and the clear solution either gently evaporated to dryness or treated in the same manner as ammonio-citrate of iron, (lastly, preserve it in well-stopped bottles.) The formulæ of the Ph. E., D., & U. S., are essentially the same. The Ph. D. orders a heat not beyond 150° Fahr. to be applied to the mixture of the oxide and bitartrate, with occasional stirring for 6 hours, and the desiccation to be conducted at the same temperature.

2. (Ph. D. 1826.) *Thin iron wire* (filings), 1 part; *bitartrate of potassa*, in fine powder, 4 parts; *distilled water*, 8 parts, or q. s.; mix, expose the mass to the air in a shallow vessel for 15 days, occasionally stirring, and adding enough water to keep the mass moist; lastly, boil the magma in *water*, filter, and evaporate.

Obs. This preparation is a double *salt* of *potassa* and *sesquioxide of iron*; it is therefore wrongly called *tartrate of iron*, as is commonly heard. It is "totally soluble in water; the solution is neutral to litmus and turmeric, unaffected by ferrocyanide of potassium, and not precipitated by acids nor alkalies, nor acted on by the magnet." (Ph. L. 1836.) "Heated with potassa, 100 gr. throws down about 34 gr. of sesquioxide of iron." (Ph. L.) "Entirely soluble in *cold* water; taste, feebly chalybeate." (Ph. E.) That of commerce, has generally a feebly inky taste, a *slight* alkaline reaction, is slightly deliquescent, dissolves in 4 parts of water, and is nearly insoluble in alcohol.

Potassio-tartrate of iron is an excellent ferruginous tonic. *Dose.* 10 to 20 gr., made into a bolus with aromatics, or dissolved in water, or other convenient menstruum.

IRON (Quinio-citrate of). Syn. *Ferri Quinio-citras*, *Ferri et Quiniæ Citras*,— Lat. *Prep.* 1. As *ammonio-citrate of iron*, but using *quinine*, recently precipitated, instead of ammonia, to neutralize the acid.

2. (Béral.) *Citrate of iron*, 4 parts; *citrate of quinine*, 1 part; *distilled water*, q. s.; dissolve, gently evaporate, and proceed as directed for ammonio-citrate of iron. *Dose.* 2 to 6 gr.; in cases where the use of both iron and quinine is indicated.

IRON (Silicide of). This compound is found in certain varieties of cast iron, but little is known respecting its chemical constitution.

IRON (Sodio-citrate of). Syn. *Ferri Sodio-citras*, *Ferri et Sodæ Citras*,—Lat. *Prep.* From *citric acid*, *carbonate of soda*, and *iron* or the *hydrated oxide*, as *ammonio-citrate* or *potassio-citrate of iron.*

IRON (Sulphate of). Syn. *Protosulphate of Iron*, *Copperas*, *Green do.*, *Green Vitriol*, *Salt of Steel*; *Ferri Sulphas*,—Ph. L. E. & D. *Shoemaker's Black*, *Vitriolated Iron*, *Sal Martis*, *Sal Chalybis*, *Vitriolum Ferri*, *V. Martis*, *V. Viride*, *V. Ferratum*, *Ferrum Vitriolatum*, *&c.*,—Obs. The crude sulphate of iron or green vitriol of commerce (*Ferri sulphas venalis*,—Ph. L.) is prepared by exposing heaps of moistened iron pyrites or native bisulphuret of iron to the air for several months, either in its unprepared state, or after it has been roasted. When decomposition is sufficiently advanced, the newly-formed salt is dissolved out with water, and the solution crystallized by evaporation. In this state it is very impure. The sulphate of iron employed in medicine is prepared as follows:—

Prep. 1. (Ph. L.) *Sulphuric acid*, 1 fl. oz.; *water*, 4 pints; mix, and add of *commercial sulphate of iron*, 4 ℔; *iron wire*, 1 oz.; digest with heat and occasional agitation until the sulphate is dissolved, strain whilst hot, and set aside the liquor that crystals may form; evaporate the mother-liquor for more crystals, and dry the whole.

2. (Ph. L. 1836.) *Iron filings* (or wire),

8 oz.; *sulphuric acid*, 14 oz.; *water*, 4 pints; dissolve by heat, filter the solution, set it aside to crystallize, and evaporate the mother-liquor for more crystals.

Prop., &c. Sulphate of iron forms pale bluish-green rhombic prisms, having an acid, styptic taste, and acid reaction; it dissolves in two parts of cold, and less than one part of boiling water; it effloresces in the air, loses most of its water at 212° Fahr., and the whole at a somewhat higher temperature; at a dull-red heat it suffers decomposition; sp. gr. 1·82. It is "perfectly soluble in water; a piece of iron put into the solution should not be covered with metallic copper." (Ph. L.) By exposure to the air it is partly converted into sulphate of sesquioxide of iron. *Dose.* ½ to 4 gr., in pills or solution; *externally*, as an astringent or styptic. In the *arts*, sulphate of iron (*copperas*) is extensively used in dyeing, and for various other purposes.

Obs. The *Dublin College* orders *iron wire* to be employed, and the *Edinburgh College* directs the transparent green crystals of the copperas of commerce, to be dissolved in their own weight of boiling water acidulated with sulphuric acid, and re-crystallized.

Crude sulphate of iron is frequently contaminated with the sulphates of copper, zinc, manganese, alumina, magnesia, and lime, which, with the exception of the first, are removed with difficulty. It also contains variable proportions of the neutral and basic sesquisulphates of iron. The preparation obtained by direct solution of iron in dilute sulphuric acid, should, therefore, be alone used in medicine.

In *commerce*, there are four varieties of crude sulphate of iron or copperas known, —*greenish-blue*, obtained from acid liquors, —*pale green*, from neutral liquors,—*emerald green*, from liquors containing sesquisulphate of iron,—and *ochry brown*, which arises from age and exposure of the other varieties to the air. Even the first two of these contain traces of sesquisulphate of iron, and hence give a bluish precipitate with ferrocyanide of potassium; whereas the *pure protosulphate* gives one which is at first nearly white.

IRON (Sulphate of, — Dried). Syn. *Ferri Sulphas Exsiccatum*,—Ph. E. *F. S. Siccatum*,—Ph. D. From *sulphate of iron*, heated in a shallow porcelain or earthen vessel, not glazed with lead, till it becomes a greenish-gray mass, and then reduced to powder. The heat should be that of "an oven," or "not exceeding 400° Fahr." It is chiefly used to make pills. 5 parts of the crystallized sulphate lose very nearly 2 parts by drying.

IRON (Sulphate of,—Granulated). Syn. *Ferri Sulphas Granulatum*,—Lat. *Prep.* (Ph. D.) A solution of *iron wire*, 4 *oz.*, in *oil of vitriol*, 4 fl. oz., diluted with *water*, 1½ pint, after being boiled for a few minutes, is filtered into a vessel containing *rectified spirit*, 8 fl. oz., and the whole stirred until cold, when the granular crystals are collected on a filter, washed with *rectified spirit*, 2 fl. oz., and dried, first, by pressure between bibulous paper, and next, beneath a bell-glass over sulphuric acid, after which they are put into a stoppered bottle, to preserve them from the air.

IRON (Sesquisulphate). Syn. *Persulphate of Iron, Sulphate of Sesquioxide of Iron, Persesquisulphate of do., Oxysulphate of do.; Ferri Persulphas, &c.*,—Lat. *Prep.* By adding to a *solution of sulphate of iron* exactly half as much *sulphuric acid* as it already contains, raising the liquid to the boiling point, and then dropping in *nitric acid*, until the liquid ceases to blacken by such addition. The solution evaporated to dryness, furnishes a buff-coloured mass, slowly soluble in water.

Prop., &c. With the sulphates of ammonia and potassa it unites to form compounds to which the name *iron alums* has been given. It forms the active ingredient in the *liquor oxysulphatis ferri*, of Mr. Tyson, and is said by Dr. Osborne to be a constituent of *Widow Welch's pills*. This salt is also formed when protosulphate of iron is calcined with free exposure to the air. Dissolved in water it is used as a test for hydrocyanic, gallic, tannic, and boletic acid. (See *page* 52.)

IRON (Sulphocyanide of). Syn. *Ferri Sulphocyanidum*,—Lat. By mixing a *solution* of *sulphocyanide of potassium* with a *neutral solution* of *persulphate* or *perchloride of iron*.

IRON (Sulphurets of). Syn. *Sulphides of Iron*. Compounds of sulphur and iron abound in the mineral kingdom, but those employed in chemistry and pharmacy are commonly produced artificially.

Prep. 1. *Sulphuret of Iron, Protosulphuret of do., Sulphide of do., Protosulphide of do.; Ferri Sulphuretum*,—Ph. E. & D. *Chalybs cum Sulphure Præparatus*,—Obs. Lat.—*a.* (Ph. E. & D.) Expose a *bar of iron* to a *full white heat*, and instantly apply a *solid mass of sulphur* to it, observing to let the melted product fall into water; afterwards separate the sulphuret from the sulphur, dry, and preserve it in a closed vessel.

b. From *sublimed sulphur*, 4 parts; *iron filings*, 7 parts; mixed together and heated in a common fire, till the mixture begins to glow, and then removing the crucible from the heat, and covering it up, until the reaction is at an end, and the whole has become cold.

c. (Fownes.) By projecting a mixture of *sulphur*, 2½ parts, and *iron filings*, 4 parts, into a red-hot crucible, excluding the air as much as possible.

2. *Bisulphuret of Iron, Bisulphide of do., Factitious Iron Pyrites.* From *sulphur*, 5 parts; *iron filings*, 4 parts; as the last.

Obs. Several other sulphurets of iron have been prepared and examined by chemists.—*Tetrasulphuret of iron* is made by transmitting hydrogen gas over dry disulphate of peroxide of iron.—*Disulphuret of iron* by a like treatment of the dry protosulphate of iron. (Arfwedson.)—*Sesquisulphuret of iron* by dropping a solution of perchloride of iron into another of hydrosulphate of ammonia, when this compound falls as a black precipitate.—*Bisulphuret of iron* (iron pyrites), is found in large quantities in the mineral kingdom.—*Magnetic iron pyrites*, is a mixed sulphuret of iron found in nature. All the compounds of iron and sulphur, except the *bisulphuret*, yield sulphuretted hydrogen, when treated with sulphuric or hydrochloric acid; hence their frequent employment in chemistry for that purpose. The *bisulphuret* is frequently used for copying medals, &c. It melts easily, and takes sharp casts, and may be coloured red with vermilion. Native iron pyrites is also called *Brass-balls, Horse gold, Copperas-balls, Pyrites Ferri, &c.* (See *below.*)

IRON (Hydrated Protosulphuret of). Syn. *Ferri Protosulphuretum Hydratum,* —Lat. *Prep.* By adding a *solution of hydrosulphuret of ammonia* or of *sulphuret of potassium* to a *neutral solution of protosulphate of iron* made with *recently distilled* or *boiled water;* the precipitate is collected on a filter, washed as quickly as possible with *recently boiled water*, squeezed in a linen cloth, and preserved in the pasty state, *under water*, as directed under *hydrated peroxide of iron.*

Prop., &c. A black, insoluble substance, rapidly decomposed by exposure to the air. Proposed by Mialhe as an *antidote* to the *salts* of *arsenic, antimony, bismuth, lead, mercury, silver*, and *tin*, and to *arsenious acid;* more especially to *white arsenic* and *corrosive sublimate.* "A gargle containing a little hydrated protosulphuret of iron, will instantly remove the metallic taste caused by putting a *little* corrosive sublimate into the mouth." (Mialhe.) On contact with the latter substance it is instantly converted into protochloride of iron and sulphuret of mercury, two comparatively inert substances. It is administered in the same way as the hydrated peroxide of iron. When taken immediately after the ingestion of corrosive sublimate, it instantly renders it innocuous; but when the administration is delayed until 15 or 20 minutes after the poison has been swallowed, it is almost useless. (Orfila.)

IRON (Hydrated Persulphuret of). Syn. *Ferri Persulphuretum Hydratum,*— Lat. *Prep.* By adding, very gradually, a *neutral solution of persulphate of iron* to a *dilute solution of sulphuret of potassium* or *hydrosulphuret of ammonia*, and collecting, &c., the precipitate as above.

Prop., &c. Proposed by Bouchardat and Sandras as a substitute for the last preparation, to which, they say, it is preferable.

IRON (Tannate of). Syn. *Ferri Tannas, Ferrum Tannicum,*—Lat. *Prep.* From *tannin*, 1 part; *boiling water*, 150 parts; dissolve, add of *freshly precipitated sesquioxide of iron* (dried at 212° Fahr.), 9 parts; evaporate by a gentle heat to one-half, filter, add of *sugar*, 1 part, complete the evaporation, and at once put it into bottles. *Dose.* 3 to 5 gr., thrice daily; in chlorosis, internal hemorrhages, &c.

IRON (Tartrates of). *Prep.* By dissolving the corresponding *hydrated oxides* in a *solution of tartaric acid*, employing the former in slight excess, and evaporating, both the *tartrate of protoxide* and of *peroxide of iron*, are easily obtained. (See *above.*)

IRON (Tartrate of). Syn. *Ferri Tartras, Ferri Prototartras,*—Lat. *Prep.* 1. From *iron filings*, 2 parts; *tartaric acid*, 1 part; *hot water*, q. s.; digest together until reaction ceases, agitate the liquid, pour off the turbid solution, and collect, wash, and dry the powder, as quickly as possible, and keep it out of contact with the air.

2. (Soubeiran.) Crystallized *tartrate of potassa* (not bitartrate), 132 parts; *protosulphate of iron*, 139 parts; dissolve each separately, mix the solutions, and collect the precipitate as before. A nearly insoluble powder; seldom used.

IRON (Valerianate of). Syn. *Valerate of Iron; Ferri Valerianas,*—Ph. D. *Prep.* 1. (Ph. D.) By adding a *solution of valerianate of soda* to another of *persulphate of iron* (prepared as directed under hydrated

peroxide of iron), and collecting and washing the precipitate, which is to be dried by placing it for some days folded in bibulous paper, on a porous brick; after which it is to be carefully kept from the air. A reddish-brown amorphous powder. This is *valerianate of sesquioxide of iron.*

2. (Ruspini.) Clean *iron filings*, are put into a wedgewood-ware mortar, and triturated with an equal weight of *valerianic acid*, gradually added; in an hour, *distilled water* is poured in, and in a short time longer, the whole is put into a flask and exposed to a gentle heat; the solution is next filtered and the filtrate exposed to the air out of contact with dust; the surface gradually becomes covered with a crystalline layer of *valerianate of iron*, which is collected, and the liquor again set aside that more crystals may be formed. This is *valerianate of protoxide of iron.*

Prop., &c. Nearly insoluble in water; soluble in rectified spirit, and in the dilute acids with decomposition. Citrate or tartrate of iron, flavoured with oil of valerian, is frequently sold for it. *Dose.* 1 to 3 gr.; in anæmia and chlorosis complicated with hysteria.

IRON AND ALUMINA (Bisulphate of). Syn. *Ferri et Aluminæ Sulphas*,—Lat. *Prep.* (Sir James Murray.) *Alumina* (recently precipitated and well-washed), 10 parts; *wrought-iron filings* (levigated), 3 parts; *carbonate of soda*, 5 parts; *water*, q. s.; mix, and force in *carbonic acid* under strong pressure; to the resulting solution add *dilute sulphuric acid*, in slight excess, and crystallize. A mixed ferruginous alum. *Dose.* 4 to 8 gr.

IRON AND AMMONIA (Sulpho-tartrate of). Syn. *Ferric Sulpho-tartrate of Ammonia; Ferri et Ammoniæ Sulphurico-tartras*,—Lat. *Prep.* (Aikin.) *Sulphate of iron*, 2 parts; *tartaric acid*, 1 part; *water*, q. s.; dissolve, add *ammonia*, in slight excess, filter, and evaporate the solution to dryness. Compatible with alkaline carbonates. *Dose.* 1 to 5 gr.

IRON AND MANGANESE (Saccharine Carbonate of). Syn. *Ferri et Manganesii Carbonas Saccharatum, F. et M. C. cum Saccharo*,—Lat. *Prep.* (Dr. S. T. Speer.) *Sulphate of iron*, 25dr.; *sulphate of manganese*, 1 oz. 20 gr.; *carbonate of soda*, 5 oz.; dissolve each separately in *water*, 1 pint; mix the metallic solutions, then add that of the soda, and after a short time, collect, wash, and drain the precipitate; to this, add of *white sugar*, 2½ oz.; dry at 120° Fahr., and keep it in a well-closed bottle. The whole process is similar to that employed in the preparation of the saccharine carbonate of iron.

Prop., &c. A reddish-brown, tasteless, amorphous mass or powder. *Dose.* 5 to 20 gr.; in amenorrhœa and anæmia, which are said to yield to this remedy much sooner than to the simple chalybeates. It was introduced to medical practice by M. Hannon (Belgium), was subsequently strongly recommended by M. Petrequin (Lyons), and has very recently been employed with success by Dr. Speer (Cheltenham).

IRON ALUM. See *Alums.*

IRON CEMENT. See *Cements.*

IRON FILINGS. Syn. *Ferri Ramenta*,—Ph. L., 1836. *Ferri Limatura*,—Ph. E. *Ferri Scobs*,—Ph. D. The usual method of preparing iron filings for medical purposes is noticed at p. 636; the only way, however, to obtain them pure, is to act on a piece of soft iron with a clean file. The Fr. Cod. orders them to be forcibly beaten in an iron mortar, and to be separated from oxide and dust by means of a fine sieve, and from the grosser parts by means of a coarse hair-sieve. *Dose.* 10 to 30 gr., in sugar or honey, as a chalybeate; in larger doses it is an excellent vermifuge, especially for ascarides or the small thread-worm.

IRON (Levigated). Syn. *Iron in Powder; Ferrum Divisum, F. Pulveratum, Ferri Limatura Lævigata*,—Lat. *Prep.* (P. Cod.) *Prepared iron filings* ground with a muller and porphyry slab, in the dry state, until reduced to an impalpable powder, which is to be preserved from the air in well-stopped bottles.

Obs. It is very difficult to prevent the oxidation of iron filings, and still more so, of levigated iron. Even inclosing them in stoppered bottles, perfectly fitted, is not sufficient. M. Righini has found that when reduced to powder and mixed with an equal quantity of well *dried sugar*, the mixture is of a lead colour, and may be kept even in paper, without its suffering oxidation, provided it is preserved from moisture. Levigated iron filings is an excellent substitute for *Quevenne's Iron*, and is infinitely superior to nearly all that is sold under that name in the shops. *Dose.* 5 to 25 gr., made into an electuary with honey or treacle, either alone or combined, according to the indications.

IRON LIQUOR. Syn. *Pyrolignite of Iron, Dyer's Acetate of do.; Ferri Acetas Venalis*,—Lat. This article, so extensively used in dyeing, is a crude mixed acetate of the protoxide and sesquioxide of iron, in which the latter commonly greatly pre-

dominates. It is usually prepared by one or other of the following methods :—

1. *Old scraps of iron* are left in a cask of *vinegar* or of *pyroligneous acid*, occasional agitation being had recourse to, until a sufficiently strong solution is obtained.

2. A *solution of pyrolignite* or *crude acetate of lime*, is added to another of *green copperas*, as long as a precipitate is formed; after repose, the clear liquor is decanted.

3. (Prof. Runge.) Eight suitable vessels are arranged one above another, like a staircase, so that the top of the upper one may rest a little over the one immediately below it, and so on of the others to the bottom one. The 8 vessels are now filled with *old scraps of iron*, and the upper one with *pyroligneous acid* as well; after half an hour this is drawn off into the vessel next below it, and this again, after the lapse of another half hour, into the *third*, and so on until the last is emptied. The acid is now passed a second time through the vessels in the same way as before, and thus becomes strongly impregnated with iron in a less time than by *any other* means, except the following :—

4. (Dr. Winterfield.) This consists in employing several wooden cylinders, resembling those used in the "*quick process*" of making vinegar; the space between the two perforated bottoms, usually filled with wood shavings, being occupied with *scraps of iron*. Pyroligneous acid is then passed through them, and the same system of ventilation observed as in the manufacture of vinegar.

Obs. Crude pyroligneous acid, or acid of the first rectification, is commonly employed to make iron liquor on the large scale. As soon as the deposit of tarry matter on the surface of the iron hinders the action of the acid, it is burnt off.

IRON (Quevenne's). Syn. *Reduced Iron; Ferrum Reductum; Ferri Pulvis*,—Ph. D. *Fer Reduit*,—Fr. *Prep.* 1. (Ph. D.) Into a gun-barrel, or similar tube of iron, introduce as much *sesquioxide of iron* as will occupy about 10 inches, confining it to the middle portion of the barrel by plugs of *asbestos;* next heat the part containing the oxide to redness, and pass through it a stream of *hydrogen gas* (previously dried by passing it through *oil of vitriol*, and afterwards through a tube containing *caustic potassa*) until it is no longer absorbed or decomposed; then remove the fire, a slow current of the gas being still continued, and when cold, collect the metallic contents of the barrel, and preserve it in an accurately stoppered bottle.

2. (Mr. Arthur Morgan.) *Ferrocyanide of potassium*, 8 oz., after exposure in an oven until all its water is expelled, is reduced to very fine powder, and mixed, by trituration with *precipitated sesquioxide of iron*, 4 oz., and *dried carbonate of potassa*, 3 oz.; the mixture is next introduced, a little at a time, into a red-hot crucible, and the heat is continued until all effervescence has ceased; when the whole is again cold, it is powdered, and thoroughly washed with recently *boiled distilled water*, by agitation with the liquid in a large bottle, after which it is dried as rapidly as possible, out of contact with the air, and preserved as before.

Prop., &c. A fine, dark, gray-coloured powder; soft to the touch; soluble in dilute hydrochloric and sulphuric acid, with the copious evolution of hydrogen gas, which, on being passed through lime water or baryta water, does not occasion a sensible precipitate; the resulting solution is colourless when very dilute, and pale green when concentrated; a solution of ferrocyanide of potassium added to it, gives a nearly white (not a blue) precipitate, whilst a solution of ferridcyanide of potassium gives a deep blue one; sulphocyanide of potassium under the like conditions should not develop a ruby-red colour. In its most perfect condition it is pyrophoric. *Dose.* 5 to 10 gr.; as a mild but certain chalybeate, easily dissolved by the juices of the stomach. See *Levigated Iron.*

IRON WIRE. Syn. *Ferrum in fila tractum*,—Ph. L. *Ferri Filum*,—Ph. E. *Ferri Fila.*—Ph. D. This is the only form of metallic iron retained in the Ph. L. It is used to make preparations of iron. (See *p.* 636.)

ISATHYDE. This name has been given by Erdman to a yellowish-white semi-crystalline powder obtained by adding *hydrosulphuret of ammonia* to a *hot solution of isatine;* sulphur is deposited together with *isathyde* as the liquor cools. By using *sulphuretted hydrogen* instead of hydrosulphuret of ammonia, "*bisulphisathyde*" is obtained. This last is converted by an *alcoholic solution of potassa* into "*sulphisathyde;*" and by cold *aqueous solution of potassa*, into "*indine.*"

ISATINE. A product of the oxidation of indigo, discovered by Erdman and Laurent.

Prep. From *indigo* (in fine powder), 1 part, rubbed to a paste with a *little water*, and then gently heated with a mixture of *bichromate of potassa* and *sulphuric acid*, of each, 1 part; *water*, 30 parts; as soon as a deep yellowish-brown solution is obtained

the whole is allowed to cool, when crystals of impure isatine are deposited; these are purified by carefully washing them with a *little cold water* and by recrystallization, first, in water, and then in alcohol.

Prop., &c. Lustrous, orange-red crystals, soluble in boiling water, and alcohol, and in cold liquor of potassa, forming a rich purple-coloured solution. By boiling the liquid this colour is destroyed, and *isatinate of potassa* formed, which may be obtained in crystals by careful evaporation.

ISATINIC ACID. Syn. *Isatic Acid. Prep.* The crystals of *isatinate of potassa*, obtained as above, are dissolved in *alcohol*, recrystallized, the crystals redissolved in water, and the solution precipitated with *acetate of lead;* the white powder (*isatate of lead*) is next diffused through *water*, and *sulphuretted hydrogen* passed through the liquid, when a solution of isatic acid is obtained, which by spontaneous evaporation, yields *isatic acid.*

Prop., &c. A white semi-crystalline powder, soluble in cold water, but decomposed when the solution is heated. It forms salts with the bases called *isatates* or *isatinates.*

ISERINE. Titaniate of iron.

ISETHIONIC ACID. A new compound discovered by Magnus. It is obtained by boiling a *solution of ethionic acid*, and concentrating the liquid by evaporation. It is a viscid oily liquid, and, as well as its salts (*isethionates*) is rather stable; their solutions may be boiled without suffering decomposition. The *isethionates* of *ammonia*, *baryta*, *copper*, *lead*, *potassa*, and *soda*, are soluble, and crystallize with facility.

ISINGLASS. Syn. *Ichthyocolla*,—Lat. The finest kinds of isinglass are obtained from various species of the genus *acipenser*, that from the *acipenser huso* (Linn.) or *great sturgeon* being perhaps the most esteemed. It is the air-bag, swimming bladder, or sound, dried without any other preparation than opening, folding, or twisting it. The *picked* or *cut isinglass* of the shops, consists of the lumps of *staple isinglass* picked into shreds by women and children, or cut by machines.

Good isinglass is the purest natural gelatine known. Its quality is determined by its whiteness, absence of the least fishy odour, and ready, and almost entire solubility in boiling water; the solution forming a nearly white, scentless, semi-transparent, solid jelly, when cold. It is soluble in weak acids, and this solution is precipitated by alkalies. The aqueous solution is not precipitated by spirit of the common strengths. 1 part of *good isinglass* dissolved in 25 parts of *hot water* forms a rich, tremulous jelly. It is very commonly adulterated. (See *Gelatine.*) A *false isinglass* has been recently imported from Para, which is the dried ovary of a fish commonly called "*gilbriker*" (the *siluris Parkerii*, of Trail.)

ISOLUSINE. A name given by Peschier to a substance found by him in several species of polygala, and which he conceived to be a new principle.

ISOMERISM. Identity of composition, with dissimilarity of properties. *Isomeric compounds* are such as contain the same elements in the same proportions, but which differ from each other in their chemical properties.

ISOMORPHISM. The quality possessed by bodies differently composed of assuming the same crystalline form. *Isomorphous*, as well as *isomeric substances*, are numerous in chemistry, and their resemblance in these respects often furnishes an important indication of other properties and relations.

ISOPATHY. It is Germany which enriches the world with this new benefit. "Homœopathy, magnetism, and phrenology salute their younger sister under the name of isopathy. Dr. Hermann is the prophet of this doctrine, which is based on the following assumed principle:—*Every diseased organ has its remedy in the same organ*—thus, if you have disease of the liver, *eat liver;* if a headache, *eat brain;* if you suffer in the bladder or kidneys, *nourish yourself on bladder and kidneys.* As the organs may not appear very tempting to certain squeamish persons, M. Hermann has made *tinctures* of them, which his patients take in spoonfuls, under the scientific names of *stomachine*, *cystine*, *gesticuline*, *unbria*, *&c.* (*Pharm. Times.*)

ISSUE. Syn. *Fontanel; Fonticulus*,—Lat. A small artificial ulcer formed on any part of the body by means of caustic or the lancet, and kept open by daily introducing an *issue pea* covered with some digestive or stimulating ointment; the whole being duly secured by an appropriate bandage.

ISSUE PEAS. Syn. *Pisæ pro Fonticulis*,—Lat. Those of the shops are the immature fruit of the orange tree (*orange berries*). They are usually smoothed in a lathe. Issue peas are also "turned" from *orris root.* The following are occasionally employed:—

1. *Orris root* (in powder), and *Venice*

turpentine, of each, 1 part; *turmeric*, 2 parts; *bees' wax*, 3 parts; melted together and made into peas whilst warm.

2. *Bees' wax*, 3 parts; melt, add of *Venice turpentine*, 1 part; mix, and further add, of *turmeric*, 2 parts; *orris root* (in powder), 1 part; mix well, and form the mass into *peas* whilst warm. More irritating than the common peas.

3. (Dr. Gray.) *Bees' wax*, 12 parts; *verdigris* and *white hellebore*, of each, 4 parts; *orris root*, 3 parts; *cantharides*, 2 parts; *Venice turpentine*, q. s. *Used* to open issues instead of caustic, but their employment requires care.

ISSUE PLASTERS. See *Plasters.*

ITACONIC ACID. An acid compound, formed along with *citraconic acid*, by the action of heat on *aconitic acid*. It resembles, if it be not identical with pyrocitric acid.

ITCH. Syn. *Psora, Scabies*,—Lat. *Gale*,—Fr. There are four varieties of itch, distinguished by nosologists by the names,—*scabies papuliformis*, or rank itch;—*scabies lymphatica*, or watery itch;—*scabies purulenta*, or pocky itch;—*scabies cachectica*, a species exhibiting appearances resembling each of the previous varieties. Our space will not permit more than a general notice of the common symptoms, and the mode of cure which is equally applicable to each species, and will not prove injurious to other skin diseases simulating the itch.

The *common itch* consists of an eruption of minute vesicles, principally between the fingers, bend of the wrist, &c., accompanied by intense itching of the parts, which is only aggravated by scratching. The *usual treatment* is repeated applications of *sulphur-ointment* (simple or compound), well rubbed in, once or twice a day, until a cure is effected; accompanying its use by the internal exhibition of a spoonful or more of *flowers of sulphur*, mixed with *treacle* or *milk*, night and morning. Where the external use of sulphur is objectionable, on account of its smell, a *sulphur bath*, or a *lotion* or *bath of sulphuret of potassium*, or of *chloride of lime* may be employed instead. See *Baths, Lotions, Ointments, Psoriasis, &c.*

IVORY. The osseous portion of the husks and teeth of the male elephant, the hippopotamus, wild boar, &c. That of the *narwhal* or *sea-horse* is the most esteemed, on account of its superior hardness, toughness, translucency, and whiteness. The dust or shavings (*ivory dust, ivory shavings*) of the turner, form a beautiful *size* or *jelly* when boiled in water. *Vegetable ivory* is the indurated fruit of the *phytelephas macrocarpa* or *Tagua plant.*

Ivory may be *dyed* or *stained* by any of the ordinary methods employed for woollen, after being freed from dirt and grease; but more quickly as follows:—

1. *Black.* The ivory well-washed in an *alkaline lye* is steeped in a *weak neutral solution of nitrate of silver*, and then exposed to the light, or dried and dipped into a *weak solution of hydrosulphuret of ammonia.*

2. *Blue.* Steep it in a *weak solution of sulphate of indigo* which has been nearly neutralized with *salt of tartar;* or in a *solution of soluble Prussian blue.* A still better plan is to steep them in the *dyer's green indigo-vat.*

3. *Brown.* As for black, but using a *weaker* solution of silver.

4. *Green.* Dissolve *verdigris* in *vinegar*, and steep the pieces therein for a short time, observing to use a glass or stone ware vessel; or, in a *solution of verdigris*, 2 parts, and *sal ammoniac*, 1 part, in *soft water.*

5. *Purple.* Steep it in a *weak neutral solution of terchloride of gold*, and then expose it to the light.

6. *Red.* Make an infusion of *cochineal* in *water of ammonia*, then immerse the pieces therein, having previously soaked them for a *few minutes* in *water* very slightly acidulated with aquafortis.

7. *Yellow.—a.* Steep the pieces for some hours in a *solution of sugar of lead*, then take them out, and when dry, immerse them in a solution of *chromate of potassa.*

b. Dissolve as much of the *best orpiment* in *water of ammonia* or *hartshorn* as it will take up, then steep the pieces therein for some hours; lastly, take them out and dry them in a warm place, when they will turn yellow.

Ivory is *etched* or *engraved* by covering it with an *etching ground* or *wax*, and employing *oil of vitriol* as the *etching fluid.*

Ivory is rendered *flexible* by immersion in a solution of *pure phosphoric acid* (sp. gr., 1·13) until it loses, or partially loses its opacity, when it is washed in clean *cold soft water*, and dried. In this state it is as flexible as leather, but gradually hardens by exposure to dry air. Immersion in hot water, however, restores its softness and pliancy. According to Dr. Ure, the necks of infants' sucking bottles (*biberons* or *artificial mothers*) are thus made.

Ivory is *whitened* or *bleached* by rubbing it with *finely powdered pumice-stone and water*, and exposing it to the sun, whilst

still moist, under a glass shade, to prevent desiccation and the occurrence of fissures; observing to repeat the process until a proper effect is produced. Ivory may also be bleached by immersion for a short time in *water* holding A LITTLE *sulphurous acid*, *chloride of lime*, or *chlorine* in solution; or by exposure in the moist state to the *fumes of burning sulphur*, largely diluted with air.

Ivory is *wrought*, *turned*, and *fashioned*, in a similar manner and with similar tools to those used for bone and soft brass.

Obs. Bone for ornamental purposes, is treated in a similar way to ivory, but less carefully, owing to its inferior value. The bones of living animals may be dyed by mixing *madder* with their food. The bones of young pigeons may thus be tinged of a *rose colour* in 24 hours, and of a *deep scarlet* in 3 or 4 days; but the bones of adult animals take fully a fortnight to acquire a rose colour. The bones nearest the heart become tinged the soonest. In the same way *logwood* and *extract of logwood* will tinge the bones of young pigeons *purple*. (Mr. Gibson.)

IVORY BLACK. See *Black Pigments*.

IXINE. A gummy matter which exudes from the wounded roots of the *atractylis gummifera* or *pine thistle*. It is chewed for the purpose of strengthening the gums.

JAGGERIES. These are coarse brown sugar made in India, by the evaporation of the juice of several species of palms.

1. *Cocoa jaggery; Ténné véllum.* From the juice or toddy of the cocoa-nut palm.

2. *Malabar jaggery; Koondee panei véllum.* From Malabar toddy.

3. *Mysore jaggery.* From Mysore toddy; 17 gall. yield 46 *lb.*

4. *Palmyra jaggery; Pannay vellum.* From Palmyra toddy; 6 pints yield 1 *lb.*

JALAP. Syn. *Jalapæ Radix; Jalapa*,—Ph. L., & D. *Jalapium*, — Ph. L., 1745. *Convolvuli Jalapæ Radix*,—Ph. E. "The tuber" of "*Exogonium purga*, Bentham," (Ph. L.; *Ipomea purga*,—Wender; *I. jalapa*, —Royle.) *Jalap* is a powerful stimulant and drastic purgative, producing copious liquid stools; but when judiciously administered, both safe and efficacious. It appears to be intermediate in its action between aloes and scammony. *Dose.* 10 to 25 gr., in powder; in constipation, cerebral affections, dropsies, obstructed menstruation, worms, &c. Owing to its irritant properties, its use is contra-indicated in inflammatory affections of the alimentary canal, and after surgical operations connected with the abdomen and pelvis. It is usually administered in combination with sulphate of potassa or bitartrate of potassa, and ginger; with mercurials, as the case may indicate. The powder is very generally adulterated.

JALAP (Resin of). Syn. *Jalapate of Jalapine; Resina Jalapæ*,—Lat. *Prep.* 1. (Ph. E.) See *Extract of Jalap.*

2. (M. A. Nativelle.) *Jalap root* is digested in *boiling water* for 24 hours, and after being reduced to thin slices, more *water* is added, and the whole boiled for 10 minutes, with occasional agitation; the liquid is then expressed in a tincture press, and the boiling and pressing repeated a *second* and a *third* time (these decoctions by evaporation yield *aqueous extract of jalap*); the *pressed root* is next placed in an alembic, *rectified spirit*, q. s. added, the whole boiled for 10 minutes, and then allowed to cool; the tincture is then pressed out, and the boiling with *fresh alcohol* and expression is repeated twice; a little *animal charcoal* is added to the mixed tinctures, and, after thorough agitation, the latter are filtered; the liquid is now distilled until nothing passes over, the supernatant fluid is poured off the fluid resin, and the latter dried by spreading it over the surface of the capsule, and continuing the heat. The product is a friable and nearly colourless resin, which forms a white powder resembling starch. *Prod.* Fully 10% of pure resin.

3. (M. Planche.) *Resinous extract of jalap* is dissolved in *rectified spirit*, the tincture agitated with *animal charcoal*, and after filtration gently evaporated to dryness.

Pur. The jalap resin of commerce is generally adulterated with scammony, gum guaiacum, or rosin. When in a state of purity, *it does not form an emulsion with milk*, like scammony resin, but runs into a solid mass. It is *insoluble in fixed oils* and *turpentine;* whilst the common resins are freely soluble in those menstrua. Its *alcoholic solution* dropped on a piece of absorbent white paper, and exposed to the action of nitrous gas, *does not acquire a green or blue colour;* if it does, guaiacum resin is present. 2% of this adulteration may be thus detected. (M. Gobley.) It is *insoluble in ether;* but guaiacum resin, common resin, and some others are so; the *decanted ether* should *not become opalescent* when *mixed with water*, and should evaporate without leaving any residuum. *Pow-*

dered jalap resin placed in cold water *does not dissolve*, but forms a semi-fluid, transparent mass, as if it had been melted. *Digested* in a watch-glass with a little *oil of vitriol*, a rich *crimson-coloured solution is obtained*, from which, in a few hours, a brown viscid resin separates. These last two characteristics distinguish it from other resins.

Obs. Earthenware, or well-tinned copper vessels must alone be used in the above processes, as contact with copper or iron turns the resin black, and this tinge can only be removed by redissolving the resin in alcohol, the addition of animal charcoal, and re-evaporation.

Jalap resin is an energetic cathartic. *Dose.* 1 to 5 gr.

JALAP (Resin of,—Factitious). Syn. *Resina Jalapæ Factitia*,—Lat. A substance frequently sold for jalap resin is made by fusing a mixture of *pale yellow rosin* (*white rosin*), and *scammony resin*, and adding, when it has cooled a little, but still semi-fluid, a few drops of *balsam of Peru* or *tolu*; the mixture is then poured into small paper capsules or tin moulds. Its effects resemble those of jalap resin, but it inflames less. (X. Landerer.)

JALAP (Soap of). Syn. *Sapo Jalapæ*, *Sapo Jalapinus*,—Lat. *Prep.* (Ph. Bor.) *Resin of jalap* and *Castile soap*, of each, 1 part; *rectified spirit*, 2 parts, or q. s. to dissolve the ingredients softened by a gentle heat; subsequently evaporate the mixture by the heat of a water bath until reduced to 4½ oz., or it has acquired the consistence of a pill-mass.

Prop., &c. A grayish-brown mass, soluble in rectified spirit. Said to be milder in its action than the resin alone. *Dose.* 5 to 15 gr.

JALAPIC ACID. Syn. *Odorous Principle of Jalap*,—Pereira. *Prep.* Add an *alcoholic solution of acetate of lead* to a *similar solution of jalap resin*, collect the precipitate (*jalapate of lead*), and throw down the *lead* by means of *sulphuretted hydrogen*. (See *Absinthic Acid.*) A brownish, soft, greasy substance, smelling strongly of jalap, soluble in alcohol, and alkalies, and slightly so in ether. Jalap resin contains about 13% of this substance.

JALAPINE. Syn. *Jalapina*, *Rhodeoretine*. Jalap resin is commonly sold under this name, but pure jalapine is prepared by one or other of the following formulæ:—

Prep. 1. The *liquid* filtered from the *jalapate of lead* in preparing jalapic acid, is a solution of *acetate of jalapine*, which after any trace of lead is removed by adding a few drops of *dilute sulphuric acid*, and filtration, yields the whole of its *jalapine*, as a precipitate, on the addition of 5 or 6 times its volume of *water*; this is collected, washed with a little *cold distilled water*, and dried by exposure to a current of warm dry air.

2. (Hume.) *Coarsely powdered jalap* is digested in *strong acetic acid*, for 14 days, the tincture filtered, *ammonia* added in excess, and the whole agitated strongly; the mixture is then filtered, the deposit washed in *cold water*, redissolved in *acetic acid*, reprecipitated by *ammonia*, and again washed and dried.

3. (Kayser.) Pure *jalap resin*, in powder, is digested for some time in *boiling ether*, by which means the *jalapic acid* is removed, and *pure jalapine* remains undissolved.

Prop., &c. A transparent, colourless, scentless, insipid resin, very soluble in alcohol, but insoluble in ether. It is the active purgative principle of crude jalap resin.

JAMAICINE. Syn. *Jamaicina*. A peculiar alkaloid obtained by Huttenschmidt from cabbage-bark (*cortex andiræ inermis*.) It is a brownish-yellow, crystalline substance; soluble in water and alcohol; fusible, and very bitter tasted. It forms salts with the acids, which, in small doses, produce restlessness and trembling; and in larger ones, purging. It is said to be vermifuge.

JAMES'S POWDER. See *Powders.*

JAMS. Conserves of fruit with sugar, prepared by boiling. In the latter respect they differ from the conserves of the apothecary.

Prep. The *pulped* or *bruised fruit* is boiled along with ½ to ⅔ of its weight of *loaf sugar*, until the mixture jellies, when a little is placed on a *cold* plate; the semi-fluid mass is then passed through a coarse hair-sieve whilst hot, to remove the stones and skins of the fruit, and as soon as it has cooled a little, is poured into pots or glasses. It is usual to tie these over, when cold, with paper which has been *dipped* in brandy. The pots must then be placed aside in a dry and rather cold situation.

The following fruits are those from which jams are commonly prepared:—*Apricots*, *cherries* (various), *cranberries*, *currants* (black, red, and white), *gooseberries* (ripe and green), *mulberries*, *Orleans plums*, *raspberries*, and *strawberries*. Red currants are commonly added to the last, to remove insipidity.

JAPAN. See *Varnishes.*

JAPANNING is the art of covering

paper, wood, or metal with a coating of hard, brilliant, and durable varnish. The material employed for this purpose in *Japan*, is the resinous juice of the *rhus vernix* or *poison sumach*, which rapidly blackens and hardens in the air. For *use* it is purified by defecation and straining, and is afterwards mixed with a little oil, and with colouring matter, as required. The *Chinese transparent lacquer* or *japan* is the balsamic juice of the *augia sinensis*. In this country, varnishes of amber, asphaltum, or copal, or mixtures of them, pass under the names of *japan* and *japan varnish*.

Proc. The surface is *coloured* or *painted* with devices, &c., as desired, next covered with a *highly transparent varnish* (amber or copal), then *dried* at a high temperature (135° to 165° Fahr.), and, lastly, *polished*. Wood and paper are first sized, polished, and varnished. For plain surfaces asphaltum varnish or japan is used. See *Varnishing*.

JAPONIC ACID. When catechine is exposed to the air in contact with caustic alkalies, black solutions (*alkaline japonates*) are formed; with carbonated alkalies, red solutions (*alkaline rubinates*); the acid of the former may beseparated. It is a black powder, insoluble in water, soluble in alkalies, and precipitated by acids. *Rubic* or *rubinic acid* forms red insoluble compounds with the earths and some other metallic oxides.

JARAVE. Syn. *Spanish Jarave, Sarsaparilla Beer; Infusum Sarzæ paratum fermentatione, Inf. Sarzæ Hispanicum*,—Lat. *Prep.* From *sarsaparilla* (sliced), ¾ *lb.*; *guaiacum bark* (bruised small), ¼ *lb.*; *guaiacum wood* (rasped) and *liquorice root* (sliced), of each, 2 *oz.*; *aniseed* (bruised), 1½ *oz.*; *mezereon root-bark*, 1 *oz.*; *moist sugar*, 1 *lb.*; *hot water* (not boiling), 2 gall.; mix in a clean stone-jar, and shake it twice a day until active fermentation has set in, when it is fit for use. *Said* to be superior to the other preparations of sarsaparilla as an alterative or purifier of the blood. *Dose*. A small tumblerful 3 or 4 times a day.

JASPER. Syn. *Iaspis*,—Lat. An impure variety of quartz, of various colours; sometimes banded, spotted, or variegated. It was formerly used as an amulet against hæmorrhages and fluxes. It is now extensively worked up into rings, seals, snuff-boxes, vases, &c., for which it is well calculated from its extreme hardness and susceptibility of receiving a fine polish.

JATROPHIC ACID. Syn. *Crotonic Acid, Iatrophic do.* A peculiar fatty acid discovered by Pelletier and Caventou, and originally regarded by them as the cathartic principle of croton oil and croton seeds, but since shown by Redwood and Pereira to be nearly inert.

Prep. The *oil* is saponified by *caustic potassa*, and the resulting soap is decomposed by *tartaric acid*; the fatty matter which floats on the surface of the liquid is then skimmed off the *aqueous portion*, and the *latter* submitted to distillation; the liquid in the receiver is a *solution* of *jatrophic acid*.

Prop., &c. Volatile; very acid; has a nauseous odour; is solid at 23°, and vaporizes at 35° Fahr. It forms salts called *Jatrophates* or *Crotonates* with the bases, none of which possess any practical importance. The *crotonates* of *ammonia*, *baryta*, *magnesia*, *potassa*, and *soda*, have been formed; all of which are soluble in water, and crystallize with more or less difficulty.

JAUMANGE. *Prep.* From *isinglass*, 1 *oz.*; *boiling water*, 12 *oz.*; dissolve, add of any *sweet white wine*, ½ pint; the *yelks* of 2 *eggs* beaten to a froth, and the *grated yellow peel* of 2 *lemons*; mix well, and heat the whole over the fire until sufficiently thickened, stirring all the time; lastly, serve it up, or pour it into moulds.

JAUNDICE. Syn. *Icterus, Morbus Luteolus*,—Lat. A disease characterised by a yellow colour of the eyes and skin, deep-coloured urine, and pale alvine evacuations. It *appears to arise* from a disordered action of the biliary organs. The *treatment* consists of the administration of *saline aperients*, and small doses of *blue-pill*, followed by *tonics* and *diaphoretics*. The action of these remedies should be promoted by the copious use of *diluents* (particularly *saline waters*), and *exercise* in the open air, when possible. When there is much pain and vomiting, *anodynes* (as opium, morphia, &c.) may be administered. Jaundice is not in itself a dangerous disease, but it sometimes lays the patient open to attacks of others which are so.

JELLY. Syn. *Gelly*. A term now very loosely applied to various substances which are liquid or semi-liquid whilst warm, and become gelatinous on cooling.

Jellies are *coloured* by the addition of the usual *stains* used by confectioners, and are rendered *transparent* by clarification with white of egg. See *Stains* (and *below*.)

JELLY (Almond). Syn. *Gelatina amydalarum*,—Lat. *Prep.* From rich *almond milk*, ¼ pint; thick *hartshorn jelly*, ½ pint; *sugar*, 2 oz.; with 2 or 3 *bitter almonds* and a little *lemon-peel*, to flavour, heated together, strained, and moulded.

JELLY (Arrow Root). Syn. *Gelatina Marantæ*,—Lat. From *arrow root* 1½ *oz.*, to *water*, 1 pint. (See p. 85.) *Tous les mois jelly* is made in the same way.

JELLY (Biscuit). *Prep.* From *white biscuit* (crushed beneath the rolling-pin), 4 *oz.*; *cold water*, 2 quarts; soak for some hours, boil to one half, strain, evaporate to 1 pint, and add of *white sugar*, ¾ *lb.*; *red wine*, 4 *oz.*, and *cinnamon*, 1 tea-spoonful. In weakness of the stomach, and in dysentery and diarrhœa, and in convalescences combined with rich beef gravy or soup.

JELLY (Bread). Syn. *Panada*; *Gelatina Panis*,—Lat. *Prep.* Cut a *French roll* into slices, toast them on each side, and boil in *water*, 1 quart, until the whole forms a jelly, adding *more water* if required; strain, and add *sugar*, *milk*, *&c.*, to palate. It may be made with broth from which the fat has been skimmed, instead of water. *Used* as the last.

JELLY (Broth). Syn. *Soup Jelly*. From *broth* or *soup* from which the fat has been skimmed, evaporated until it becomes gelatinous on cooling. A *few shreds* of *isinglass* are commonly added. See *Portable Soup*.

JELLY (Calves' Feet). *Prep.* For *each foot* take of *water*, 3 pints, and boil to one-half; cool, skim off the fat, and again boil for 2 or 3 minutes with the *peel of a lemon* and a *little spice*; remove it from the fire, strain through a *jelly bag*, (see *Filtration*,) add the *juice of a lemon* and a *glass of wine*, and when it has cooled a little, put it into glasses or "forms."

Obs. If this jelly is required to be very transparent, it must be treated as follows:—After the fat is removed, it should be gently warmed, just enough to melt it, next well beaten with the white of an egg and the seasoning, and then brought to a boil for a minute or two, when it will be ready for straining, &c. The calf's feet should not be bought ready boiled, but only scalded. *Cows' feet* or *heels* make nearly as good jelly as that from calves' feet, and are much more economical.

JELLY (Ceylon Moss). Syn. *Gelatina Fuci Amylacei*,—Lat. *Prep.* (Dr. Sigmond.) Boil *Ceylon moss* ½ oz., in *water*, 1 quart, for 25 minutes, or till the liquid jellies on cooling; strain and flavour. Very nutritious; recommended in irritation of the mucous membranes and phthisis.

JELLY (Corsican Moss). Syn. *Gelatina Helminthocorti*,—Lat. *Prep.* (P. Cod.) *Corsican wormweed* or *moss*, 1 oz.; *water*, q. s.; boil for 1 hour, and strain 8 fl. oz.; to this add of *isinglass* (previously soaked in a little water, 1 dr.; *refined sugar*, 2 oz.; *white wine*, a wine-glassful. Vermifuge. See *Decoctions*.

JELLY (Gravy). By evaporating *meat gravies*.

JELLY (Hartshorn). Syn. *Gelatina Cornu Cervi*,—Lat. *Prep.* (P. Cod.) *Hartshorn shavings*, 8 oz.; wash it in water, then boil in *clean water*, 3 pints, till reduced to one-half; strain, press, add of *sugar*, 4 oz.; the *juice of one lemon*; and the *white of an egg* beaten up with a little *cold water*; mix well, clarify by heat, evaporate till it jellies on cooling, then add the *peel of the lemon*, and set it in a cool place. It may be *flavoured* with wine, spices, &c. Very nutritious.

JELLY (Iceland Moss). Syn. *Gelatina Lichenis*,—Lat. *Prep.* (P. Cod.) *Iceland moss*, 2 oz.; soak for 1 or 2 days in *cold water*, then boil for 1 hour in *water*, q. s. to yield a strong solution; strain, decant the clear after repose, apply heat, and dissolve therein of *isinglass*, 1 dr.; evaporate the whole to a proper consistence, put it into pots, and set them in a cool place. Nutritious. Recommended in phthisis. The jelly of Iceland moss and cinchona (*Gelatina lichenis cum cinchona*,—P. Cod.) is made by adding to the above, *syrup of cinchona*, 6 fl. oz.

JELLY (Irish Moss). Syn. *Gelatina Chondri*, —Lat. *Prep.* From *Irish* or *carrageen moss*. See *Decoctions*.

JELLY (Isinglass). Syn. *Confectioners' Jelly*; *Gelatina Icthyocollæ*,—Lat. *Prep.* From *isinglass* dissolved in *water* by boiling, and evaporated till it "jellies" on cooling, adding flavouring, as desired. 1½ *oz.* of good *isinglass* makes fully a pint of *very strong jelly*. See *Blancmange*, *Isinglass*, *Calves'-feet Jelly*, *&c.*

JELLY (Rice). Syn. *Crême de Riz*. From *rice* boiled in *water*, sweetened, and flavoured.

JELLY (Sago). *Prep.* Soak *sago* in *cold water* for 1 hour, strain, and boil in *fresh soft water* until it becomes transparent; then add *wine*, *sugar*, *clear broth*, *milk*, or *spices*, to flavour. 1 *oz.* of sago makes a pint of good jelly.

JELLY (Tapioca). As the last, but using *tapioca* in lieu of sago.

JELLIES (Fruit). These are prepared by boiling the *strained juice of the fruit* mixed with ⅓ to ½ its weight of *refined sugar*, until it "jellies" on cooling, observing to carefully remove the scum as it rises. The process should be conducted by a gentle heat, and it is preferable not to add the sugar until the juice is somewhat con-

centrated, as by *lengthened* boiling the quality of the sugar is injured.

Jellies are sold in pots or glasses, like jams. Both *jams* and *fruit jellies* are refrigerant and laxative; they are, however, mostly employed as relishes, especially during fevers and convalescences. The following are the principal fruit jellies:—

Apple jelly. From *apple juice.*

Barberry jelly. (Gelatina berberorum,—Ph. E., 1744.) From the *juice of barberries.*

Cherry jelly.—a. (Rob de cornis.) From Cornelian cherries.—*b. Kentish cherry jelly* (Rob de cerasis.)

Currant jelly, (Rob de ribes.) From the *juice of currants* (black, red, and white). Black currant juice requires the most sugar; some add twice the above quantity of sugar to either sort.

Elderberry jelly (Rob of elderberries; Rob baccarum sambuci cum saccharo.) From *elder juice.*

Gooseberry jelly. From the *juice.*

Hibiscus jelly. From *juice* and *sugar,* equal parts.

Lemon jelly. From *isinglass,* 2 *oz.; water,* 1 quart; boil, add of *sugar,* 1 *lb.,* clarify, and when nearly cold, add the *juice of* 5 *lemons,* and the *grated yellow rinds of* 2 *oranges* and of 2 *lemons;* mix well, strain off the peel, and put it into glasses.

Noyeau jelly. As *punch jelly,* but strongly flavoured with *bitter almonds.*

Orange jelly. From *orange juice,* 1 pint; let it stand over the *grated yellow rind* of 3 or 4 of the *oranges* for a few hours, then strain, and add of *loaf sugar,* ½ *lb.,* or more; *isinglass,* 2 *oz.,* dissolved in *water,* 1 pint; mix, and put it into glasses before it cools.

Plum jelly (Rob prunorum acidorum). From *unripe plums.*

Punch jelly. From *isinglass,* 2 *oz.; sugar,* 1¾ *lb.; water,* 1 pint; dissolve, add of *lemon juice,* ½ pint; the *peels of* 2 *lemons* and of 2 *oranges; rum* and *brandy,* of each, ¼ pint; keep it in a covered vessel until cold, then liquefy it by a very gentle heat, strain, and pour it into moulds. A pleasant and deceptive way of swallowing alcohol.

Quince jelly (Gelatina cydoniorum; Rob cydoniorum, Ph. E., 1744). *Quince juice,* 3 *lb.; refined sugar,* 1 *lb.;* boil to a jelly.

Raspberry jelly. From the *juice.*

JERVINE. The same as *barytin.*

JESUIT'S BARK. See *Cinchona.*

JESUIT'S DROPS. See *Drops* and *Tinctures.*

JESUIT'S POWDER. Powdered cinchona.

JET. A variety of mineral bituminous carbon, very hard, and susceptible of a fine polish.

JEWELS. See *Diamond, Emerald, Gems, &c.*

JEWELRY. The gold in articles of jewelry, whether solid or plated, which are not intended to be exposed to very rough usage, is generally "*coloured,*" as it is called in the trade. This is done as follows:—

1. (*Red gold colour.*) The article, after being coated with the *amalgam,* is gently heated, and, whilst hot, is covered with *gilder's wax;* it is then "flamed" over a wood fire and strongly heated, during which time it is kept in a state of continual motion, to equalise the action of the fire on the surface. When all the composition has burned away, the piece is plunged into *water,* cleaned with the "*scratch-brush* and *vinegar,* and then washed and burnished. To bring up the beauty of the colour, the piece is sometimes washed with a *strong solution* of *verdigris in vinegar,* next gently heated, plunged *whilst hot* into *water,* and then washed, *first* in *vinegar,* or *water soured with nitric acid,* and then in pure water; it is lastly, burnished and again washed and dried.

2. (*Or-molu colour.*) This is given by covering the parts with a *mixture* of *powdered hematite, alum, common salt,* and *vinegar,* and applying heat until the coating blackens, when the piece is plunged into *cold water,* rubbed with a *brush dipped in vinegar,* or in *water strongly soured with nitric acid,* again washed in *pure water,* and dried. During this process, the parts not to be in "or-molu colour" should be carefully protected.

The *frauds* practised in reference to the "fineness" of the metal used in jewelry, is noticed at *page* 538. The *means of determining* the *quality* of the leading articles of jewelry, are explained under the heads—*Gems, Diamond, Assaying, &c.*

JEW'S PITCH. See *Asphaltum.*

JEW'S STONE. Syn. *Lapis Judaicus, L. Syriacus, Phœnicites.* Small fossil stones found in Palestine, which, when reduced to powder, were formerly in repute as internal remedies for fluxes and urinary complaints.

JUICE (Spanish). See *Extracts* and *Liquorice.*

JUICES. See *Extracts* and *Vegetable Juices.*

JUJUBES. A fruit, resembling a small plum, produced by the *rhamnus ziziphus.* Combined with sugar, it forms the *jujube paste* of the shops, when genuine; but that

now almost generally sold under the name is a mixture of *gum* and *sugar*, slightly coloured and flavoured.

JULEP. Syn. *Julap; Julepum, Julepus, Julapium*,—Lat. A term usually regarded as synonymous with *mixture*; but according to the best authorities, implying a medicine which is used as a vehicle for other forms of medicine. The word comes through the French, from a Persian expression, which signifies "sweet drink." A *julep*, according to Continental writers, is a drink of little activity, generally composed of *distilled waters, infusions*, and *syrups*, to which *mucilages* and *acids* are sometimes added; "but never powders or oily substances, which could interfere with its transparency." In England, the juleps of old pharmacy are now classed under mixtures (*misturæ*,—Ph. L.)

JUNIPER BERRIES. Syn. *Juniperi Baccæ; J. Communis Baccæ*,—Ph. E. *Juniperus*,—Ph. L. "The fruit," of "*Juniperus communis*, Linn." (Ph. L.), or *common juniper tree*. In the old Ph. L., & D., both the tops and berries (*juniperi fructus et cacumina*,—Ph. L., 1836; *juniperus; baccæ, cacumina*,—Ph. D., 1826,) were ordered. The berries are stomachic and diuretic, and have been long employed in dropsies, either alone, or combined with foxglove and squills. The tops (*summitates*) have been highly praised in scurvy and certain cutaneous affections. *Dose*. 1 or 2 dr., made into a conserve with sugar, or in the form of infusion or tea.

JUNKET. Syn. *Devonshire Junket, Curd Jelly*. From *warm milk* put into a bowl, and then turned with a *little rennet*; some *scalded cream* and *sugar* are next added, with a sprinkling of *cinnamon* on the top, without breaking the curd. Much esteemed by "holiday folk" in the western counties, during the hot weather of summer. Sometimes, very strangely, a *little brandy* finds its way into these "trifles."

KAKODYLE. Syn. *Kadodyle, Kadodule, Kakododyle*. A peculiar compound of hydrogen, carbon, and arsenic, discovered by M. Bunsen, and shown by him to be an organic basyle, capable of forming a vast number of combinations, and generally deporting itself like a metal.

Prep. Pure *anhydrous chloride of kakodyle* is digested for about 3 hours, at a temperature of 212° Fahr., with slips of clean *metallic zinc* contained in a bulb blown upon a glass tube, previously filled with *carbonic acid gas*, and hermetically sealed; when the action is complete, and the whole has become cold, the tube is cautiously opened, and the white saline matter which has formed is dissolved in a *little water*; a heavy oily liquid (*kakodyle*) separates, and is purified by distillation from a little *fresh zinc*, in an atmosphere of *carbonic acid gas*. The operation is conducted in a tube having two bulbs blown on it, and bent at right angles, so that one bulb may serve as the retort, and the other, as the receiver; the two extremities being drawn to a point and hermetically sealed.

Prop., &c. A colourless, transparent, thin liquid; extremely fetid and inflammable; inflames on contact with chlorine and oxygen; on the least exposure to atmospheric air, it gives off white fumes and passes first into the state of *oxide of kakodyle*, and then into *kakodylic acid*; it boils at 338°; crystallizes in square prisms when cooled to 21° Fahr.; and is decomposed by a heat much below redness.

Obs. All the preparations of *kakodyle* (except *alkargen*) are *exceedingly poisonous*, and therefore great caution should be exercised in experimenting on them. All the operations connected with them must be conducted in the *open air*, and the *strictest precautions* adopted to avoid the accidental inhalation of the *smallest* quantity of the vapour or its products. Vomiting, numbness of the extremities, fainting, and other alarming symptoms, are the consequences of the most *trifling neglect*. They all evolve a most offensive odour, and this property has led Bunsen to propose the following *test* for *arsenic* and the *acetates*:—The *suspected substance* is boiled with *water* containing a *little potassa*, the resulting liquid is filtered, mixed with *acetic acid*, and evaporated to dryness; the *residuum* heated in a test tube, will evolve the *horrible odour* of *alkarsine*, if arsenic is present. This odour is rendered, if possible, even more offensive by the addition of *protochloride of tin* to the ignited mass. As a *test* for the *acetates*, the addition of a *little arsenic* must be made.

KAKODYLE (Chloride of). *Prep*. A *dilute alcoholic solution* of *oxide of kakodyle* is very cautiously mixed with an *equally dilute solution of bichloride of mercury*, avoiding excess of the latter; the resulting white precipitate is distilled with *concentrated hydrochloric acid*, and the distillate (*hydrated chloride of kakodyle*) is left for some time in contact with some *chloride of calcium* and a *little quicklime*, and is, lastly, rectified alone in an atmosphere of *carbonic acid gas*.

Prop., &c. Limpid; colourless; heavier than water; soluble in alcohol; boils at 215° Fahr.; its vapour inflames on contact with the air, and has the density, 4·56. The latter is more fearful in its effects, and more insupportable in odour, even in the most dilute form, than that of the oxide. It combines with the subchloride of copper to form a white, insoluble, crystalline, double salt (*chloride of kakodyle and copper*); and with alkarsine to form *oxychloride of kakodyle;* crystals of the latter are also deposited when the chloride is exposed to the air.

KAKODYLE (Cyanide of). *Prep.* By distilling *oxide of kakodyle* with *concentrated hydrocyanic acid*, or with *cyanide of mercury*.

Prop.,&c. Lustrous, colourless, four-sided prisms; slightly soluble in water; melts at 91° Fahr.; boils at 285° Fahr. It is, perhaps, the most fearful poison known. A few grains vaporized and diffused through the atmosphere of a large room, produces instantaneous numbness of the hands and feet, vertigo, delirium, and even paralysis and unconsciousness, from which, if the parties be not *instantly* rescued by exposure to a current of cold air, and ammoniacal stimulants, death ensues as an inevitable consequence.

KAKODYLE (Iodide of). Prepared by distilling *oxide of kakodyle* with a *strong solution of hydriodic acid*. A thin, yellowish, fetid, heavy liquid. The yellow crystalline substance which is formed at the same time is said to be *oxy-iodide of kakodyle*. By using hydrobromic acid and hydrofluoric acid, *bromide* and *fluoride of kakodyle* are respectively formed.

KAKODYLE (Oxide of). *Alkarsine, Cadet's Fuming Liquor. Acetate of potassa* and *arsenious acid*, equal parts, are mixed together, and slowly heated to redness in a glass retort, placed in a sand bath, and connected with a tubulated receiver placed in a freezing mixture, and provided with a safety-tube to carry off the non-condensable gases; the heavier liquid that distils over is collected, agitated with *recently-boiled distilled water*, and rectified along with *caustic potassa*, in an atmosphere of *pure hydrogen* or *carbonic acid*. By a second rectification over *lime* or *baryta* it may be obtained anhydrous.

Prop., &c. A colourless liquid, boiling at about 300°; congealing at —10° Fahr., and evolving a very offensive odour, resembling that of arseniuretted hydrogen. "It is *highly poisonous* in every shape." "The minutest quantity painfully affects the eyes and mucous membrane of the nose." In a larger dose it is destructive to life. It possesses feeble basic properties, is soluble in alcohol and ether, sparingly soluble in water, and fumes and inflames spontaneously by exposure to the air. Sp. gr. of the vapour, 7·5.

KAKODYLE (Sulphuret of). Formed by distilling a *mixture of chloride of kakodyle* and *hydrosulphuret of sulphuret of barium*.

Prop., &c. A colourless fetid liquid, heavier than water, with a high boiling point, and very poisonous. It dissolves sulphur forming *tersulphuret of kakodyle* or *sulpho-kakodylic acid*, and combines with the sulphurets of *antimony, bismuth, copper, gold*, and *lead*, forming *sulphur-salts*. A *seleniuret* or *selenide of kakodyle* has also been formed by a similar method to that adopted for the sulphuret.

KAKODYLIC ACID. Syn. *Alkargen, Kadodylic Acid*. This is obtained when *alkarsine* is *gradually* exposed to the air, in the *cold;* as soon as a semi-solid mass is formed, it is treated with *cold water*, the solution evaporated until it solidifies, and then pressed in *bibulous paper*, to remove *hydrarsine;* the residuum is dissolved in *boiling absolute alcohol*, and is again obtained in crystals as the liquid cools; by repeating the process several times with *alcohol*, or by evaporating the *aqueous solution* in a water-bath, and subsequent treatment with *hydrated peroxide of iron*, and a final crystallization from *alcohol*, pure *kadodylic acid* is obtained. *Another method* is to add *oxide of mercury* to *kakodyle* or to *alkarsine*, covered with a *layer of water* and artificially cooled, until the mixture entirely loses its odour, and afterwards decomposing any *kakodylate of mercury* which may have formed, by the *cautious* addition of a *little* more *alkarsine;* the liquid is then evaporated for crystals, as before.

Prop., &c. Brittle, glossy, prismatic crystals, deliquescent, inodorous, tasteless, and soluble in water and alcohol; the solution has an acid reaction; with the bases it forms salts (*kakodylates*). The *kakodylates of potassa* and *soda* are a gummy, amorphous mass; the *kakodylates of mercury* and *silver* are crystallizable. "*Kakodylic acid* is an exceedingly stable compound; it is neither affected by red, fuming nitric acid, aqua regia, nor even by chromic acid in solution; it may be boiled with these substances without the least change." It is, however, deoxidized by phosphorous acid and protochloride of tin. Dry hydriodic acid converts it into *iodide*, and hydro-

chloric acid into *terchloride of kakodyle*. "What is extremely remarkable, this substance (kakodylic acid) is not in the least degree poisonous." (Fownes.)

KALEIDOSCOPE. Syn. *Flower-glass*. A pleasing philosophical toy, invented by Sir David Brewster, which presents to the eye a series of symmetrical changing views. It is formed as follows:—Two *slips of silvered glass*, from 6 to 10 inches long, and from 1 to 1½ inch wide, and rather narrower at one end than the other, are joined together lengthwise, by one of their edges, by means of a *piece* of *silk* or *cloth*, glued on their back; they are then placed in a *tube* of *tin* or *pasteboard*, blackened inside, and a little longer than is necessary to contain them, and are fixed by means of *small pieces of cork*, with their faces at any angle to each other that is an even aliquot part of 4 right angles (*as the* $\frac{1}{6}$, $\frac{1}{8}$, $\frac{1}{10}$, *&c.*) The one end of the tube is then closed with an *opaque screen*, or *cover*, through which a small eyehole is made in the centre; and the other end is fitted, first with a *plate of common glass*, and at the distance of about $\frac{1}{8}$th of an inch, with a plain piece of *slightly-ground glass*, parallel to the former; in the intermediate space or cell are placed the objects to form the images. These consist of *coloured pieces* of *glass*, *glass beads*, or any other *coloured diaphonous bodies*, sufficiently small to move freely in the cell, and to assume new positions when the tube is shaken or turned round. A tube so prepared presents an infinite number of changing and symmetrical pictures, no one of which can be *exactly* reproduced. This toy is so easily constructed, is so very inexpensive, and at the same time, so capable of affording an almost inexhaustible fund of amusement to the young, that we advise our juvenile friends to try their hands at its construction. Any common tube of tin or pasteboard may be used, and strips of glass smoked on one side will answer for mirrors.

KALI. See *Potassa*.

KALISACCHARIC ACID. See *Glucic Acid*.

KALYDOR (Rowlands'). This resembles *Gowland's Lotion*, but is got up in a rather more pleasing style.

KAOLIN. Syn. *Porcelain Clay*. A fine white clay, derived from the decomposition of the felspar of granitic rocks. The potteries and porcelain works of this country are chiefly supplied with this substance from extensive tracts of it which occur near St. Austle, Cornwall.

KAPNOMOR. See *Capnomor*.

KATALYSIS. Syn. *Catalysis*. Dissolution; that condition in which the decomposition, and the recombination of the elements of compound bodies, is excited by the mere presence of, or contact with, other bodies, which do not themselves suffer such a change. The *katalytic* or *catalytic force* is that modification of chemical affinity which determines catalysis. The mode of preparing oxygen gas, by heating a mixture of *chlorate of potassa* and *binoxide of manganese* or *red oxide of lead*, is a familiar example of this force. The salt is decomposed at a temperature very far lower than would be required if it were heated alone; yet the oxide of manganese is not in the slightest degree altered, and is found after the experiment in the same state as it was before. It may, indeed, be employed for the same purpose, any number of times. See *Eremacausis* and *Fermentation*.

KELP. The alkaline ashes obtained by burning various species of sea-weed. Those most valued for the purpose are the *fucus vesiculosus*, *nodosus*, and *serratus*, *laminaria bulbosa* and *digitata*, *himanthalia lorea*, and *chorda filum*.

Kelp seldom contains more than 2% to 5% of real soda. According to Dr. Ure, the best samples contain from 53% to 62% of soluble matter, consisting of—

Sulphate of soda .	8·	19·
Soda (carbonate and sulphuret) . .	8·5	5·5
Muriates of soda and potash . . .	36·5	37·5
	53·	62·

Of late years, the manufacture of kelp, like that of barilla, has been almost abandoned, except as a source of iodine. A few years since, in the Orkney Islands alone, about 20,000 persons were occupied in its manufacture. (Greville.) See *Barilla* and *Alkalimetry*.

KERMES. Syn. *Kermes-grains*, *Alkermes*; *Granum Tinctorium*,—Lat. The dried bodies of the female *coccus ilicis of* Linnæus, a small insect of the order hemiptera, which flourishes on the *quercus ilex*. It has been used as a red and scarlet dyestuff ever since the time of Moses; but is now superseded in this country by cochineal, which gives colours of much greater brilliancy.

KERMES MINERAL. Syn. *Kermes Minerale*, *K. Mineralis*,—Lat. *Prep.* 1. *In the humid way.—a.* (P. Cod.) *Carbonate of soda* (cryst.), 128 parts, (*say*, 21 parts,) is dissolved in *water*, 1280 parts, (*say*, 210

parts,) contained in a cast iron pan; *tersulphuret of antimony* (in fine powder), 6 parts, (*say*, 1 part,) is next added, and the whole boiled for an hour, with constant agitation with a wooden spatula; the boiling liquid is then filtered into a *heated* earthen pan containing a small quantity of *very hot water*, and the solution is allowed to cool as *slowly as possible;* the red powder which is deposited is collected on a cloth, on which it is well-washed with *cold water*, and the superfluous water being removed by pressure, the powder is dried by a gentle heat, and is, lastly, passed through a fine silk-gauze sieve, and preserved from light and air.

b. (*Wholesale.*) From *black sulphuret of antimony*, 4 *lb.*, *carbonate of potassa*, 1 *lb.;* boil in *water*, 2 gall., for half an hour, filter, &c., as before. The undissolved portion of sesquisulphuret of antimony may be boiled again several times with *fresh potassa* and *water*, until the whole is dissolved. Inferior to the last.

c. (*Cluzell's Kermes.*) From *tersulphuret of antimony*, 4 parts; *crystallized carbonate of soda*, 90 parts; *water*, 1000 parts; boil, &c., as in 1, *a*, and dry the powder folded up in paper, at a heat not exceeding 90° Fahr.

2. In the dry way.—*a.* (*Kermes igne paratum*,—P. Cod.) *Carbonate of potassa*, 100 parts; *tersulphuret of antimony*, 50 parts; *sulphur*, 3 parts; mix, fuse in a Hessian crucible, pour the melted mass into an *iron mortar*, and when cold reduce it to powder; next boil it in *water*, 1000 parts, contained in an iron vessel, filter the solution, and otherwise proceed as before. *Product;* large, but of inferior quality.

b. (Fownes.) From *tersulphuret of antimony*, 5 parts; *carbonate of soda* (dry), 3 parts; *water*, 80 parts; fuse, &c., as before. Nearly equal to 1, *a*.

c. (Berzelius.) *Carbonate of potassa* (pure), 3 parts; *tersulphuret of antimony*, 8 parts; *water*, q. s. Resembles the last.

Prop., &c. An odourless, tasteless powder, insoluble in both water and alcohol, and, when pure and carefully prepared, entirely soluble in hydrosulphuret of ammonia. As prepared by the formulæ 1, *a*, & 1, *c*, it is a very dark crimson powder, of a velvety smoothness; but that from the other formulæ has a brownish-red colour, more or less deep. The secret of preparing this compound of a fine and velvety quality, like that imported from the Continent, consists simply in filtering the solution whilst *boiling hot*, and allowing it to cool *very slowly*, by placing the vessel in an appropriate situation for that purpose. Another important point, according to Rose, is to employ sufficient alkali to keep the *whole* of the teroxide of antimony in solution as the liquid cools, instead of allowing a part of it to be deposited with the kermes. This is the reason of the superior quality and mildness of that prepared according to the directions of the French Codex. The liquor decanted from the *kermes mineral* yields the *golden sulphuret of antimony* on the addition of an acid, for which purpose the *acetic* is generally employed.

Kermes mineral is an amorphous tersulphuret of antimony, combined with a small portion (probably accidental) of teroxide of antimony. It is a *hydrated oxysulphuret of antimony*, (Gay-Lussac;) *a hydrated amorphous tersulphuret*, (Berzelius; Fuch;) an *amorphous tersulphuret of antimony* combined with some *sulphantimoniate* of either *sodium* or *potassium*. (Rose.) *Dose.* ½ gr. to 3 or 4 gr.; as a diaphoretic, cathartic, or emetic. It occupies in foreign practice the place of our James's Powder.

KETCHUP. Syn. *Catchup*, *Catsup*, *Katchup*. The juice of certain vegetables strongly salted and spiced, so as to be used as sauce.

Camp ketchup. Take of *good old beer*, 2 quarts; *white wine*, 1 quart; *anchovies*, 4 *oz.;* mix, heat it to the boiling point, remove it from the fire, and add of *peeled shalots*, 3 *oz.;* *mace*, *nutmegs*, *ginger*, and *black pepper*, of each, bruised, ½ *oz.;* macerate for 14 days, with frequent agitation, then allow it to settle, and decant and bottle the clear portion.

Cucumber ketchup. From *ripe cucumbers*, in the same way as *mushroom ketchup*. Very luscious. Mixed with cream, or melted butter, it forms an excellent *white sauce* for fowls, &c.

Marine ketchup. Take of *strong old beer*, 1 gall.; *anchovies*, 1½ *lb.;* *peeled shalots* (crushed), 1 *lb.;* *bruised mace*, *mustard seed*, and *cloves*, of each, ½ *oz.;* *bruised pepper* and *ginger*, of each, ¼ *oz.;* *mushroom ketchup* and *vinegar*, of each, 1 quart; heat the mixture to the boiling point, put it into a bottle, and macerate for 14 days, frequently shaking; then strain through flannel, and bottle it for use. Excellent with anything; like the last, it makes good *white sauce*, and keeps well.

Mushroom ketchup.—a. Sprinkle *mushroom flaps*, gathered in September, with *common salt*, stir them occasionally for 2 or 3 days, then lightly squeeze out the juice, and add to each gallon, *cloves* and

mustard seed, of each, bruised, ½ *oz.*; *allspice*, *black pepper*, and *ginger*, of each, bruised, 1 *oz.*; gently heat to the boiling point in a covered vessel, macerate for 14 days, and decant or strain. Should it exhibit any indications of change in a few weeks, bring it again to the boiling point, with a *little more spice*, and a *table-spoonful* more *salt*.

b. Take of *mushroom juice*, 2 gall.; *pimento*, 2 *oz.*; *cloves*, *black pepper*, *mustard seed*, and *ginger*, of each, bruised, 1 *oz.*; *salt*, 1 *lb.* (or to taste); *shalots*, 3 *oz.*; gently simmer for 1 hour in a covered vessel, cool, strain, and bottle.

c. Take of *mushroom juice*, 100 gall.; *black pepper*, 9 *lb.*; *allspice*, 7 *lb.*; *ginger*, 5 *lb.*; *cloves*, 1 *lb.*; (all bruised;) *salt*, q. s.; gently simmer in a covered tin boiler for 1 hour.

Oyster ketchup. Pulp the *fish*, and to each pint, add of *sherry wine*, or *very strong old ale*, 1 pint; *salt*, 1 *oz.*; *mace*, ¼ *oz.*; *black pepper*, 1 *dr.*; simmer very gently for 10 minutes, strain, cool, bottle, and to each bottle add a spoonful or two of *brandy*, and keep them in a cold situation. *Cockle ketchup* and *muscle ketchup* are made in the same way. *Used* to flavour sauces when the fish are out of season; excellent with rump steak, &c.

Pontac ketchup. Take of the *juice of elderberries* and *strong vinegar*, of each, 1 pint; *anchovies*, ½ *lb.*; *shalots* and *spice*, q. s. to flavour; boil for 5 minutes, cool, strain, and bottle. *Used* to make *fish sauces*.

Tomato ketchup. Prepared from *tomatoes* or *love apples*, like *mushroom ketchup*, except that a little *very strong Chili vinegar* is commonly added. An admirable relish for "high" or rich flavoured viands.

Walnut ketchup.—a. Take of the *expressed juice of young walnuts* when tender, 1 gall.; boil 10 minutes, skim, add of *anchovies*, 2 *lb.*; *shalots*, 1 *lb.*; *cloves* and *mace*, of each, 1 *oz.*; 1 clove of *garlic*, sliced; simmer in a covered vessel for 15 minutes, strain, cool, and bottle, adding a little *fresh spice* to each bottle, and *salt*, q. s. Will keep good in a *cool* place for 20 years.

b. Take of *green walnut-shells*, 16 gall.; *salt*, 5 *lb.*; mix and beat together for a week, press out the liquor, and to *every gallon* add of *allspice*, 4 *oz.*; *ginger*, 3 *oz.*; *pepper* and *cloves*, of each, 2 *oz.*; all bruised; simmer for half an hour, and set aside in a closed vessel and in a cool situation until sufficiently clear.

c. Take of *walnut-juice*, 1 gall.; *vinegar*, 1 quart; *British anchovies* (sprats), 3 or 4 *lb.*; *pimento*, 3 *oz.*; *ginger*, ¼ *oz.*; *long pepper*, ½ *oz.*; *cloves*, 1 *oz.*; *shalots*, 2 *oz.*; boil and bottle, as before.

d. From the *juice of walnut-shells*, 30 gall.; *salt*, 1 bushel; *allspice* and *shalots*, of each, 6 *lb.*; *ginger*, *garlic*, and *horse-radish*, of each, 3 *lb.*; *essence of anchovies*, 3 gall.; as before.

Wine ketchup. Take of *mushroom* or *walnut ketchup*, 1 quart; *chopped anchovies*, ½ *lb.*; 20 *shalots*; *scraped horse-radish*, 2 *oz.*; *spice*, q. s.; simmer for 15 minutes, cool, and add of *white* and *red wine*, of each, 1 pint; macerate for 1 week, strain, and bottle.

Obs. In preparing the above articles vessels of *glazed earthenware*, or *stoneware*, or *well-tinned copper pans* should alone be used to contain them whilst being boiled or heated, as salt and vegetable juices *rapidly corrode* copper, and render the ketchup *poisonous*. Nothing in the shape of *copper*, *lead*, or *pewter* should be allowed to touch them. *Even* a *plated copper spoon* left in a bottle of ketchup for some time will render its contents *poisonous*. Unpleasant and even dangerous fits of vomiting, colic, and diarrhœa, have resulted from the neglect of this precaution. See *Sauces*, *&c.*

KIBES. The vulgar name for ulcerated chilblains. (See *p.* 236.)

KIDNEYS. Syn. *Renes*, — Lat. The kidneys, as almost every one knows, are abdominal viscera which secrete the urine, and form the great channels by which the effete nitrogenous matter is removed from the blood. They are subject to various affections, both functional and organic, chronic and acute, of which some are imperfectly understood, and others only admit of alleviation, but not of being cured. Under the heads "*Urine*" and "*Urinary Organs*" will be found some remarks in connection with this subject which will prove highly serviceable to the emigrant, and to other parties beyond the reach of the assistance of a duly-qualified medical practitioner.

KIDNEYS. Soyer recommends kidneys to be dressed by gently broiling them, having previously split them, "so as nearly to divide them, leaving the fat in the middle," and "run a skewer through them, that they may remain open." After being rubbed with a little *butter*, and seasoned with *salt* and *pepper*, "they may be served on toast, or with any sauce." "You may also egg and bread-crumb them." "Five minutes suffice for a sheep or lamb's kidney of common size." (Soyer.) One

or two lamb's kidneys plainly broiled and served up with the gravy in them, eaten along with a little dry-toasted bread, form a most excellent and appropriate luncheon or dinner for a dyspeptic or convalescent.

KINATE OF CINCHONIA. Syn. *Cinchoniæ Kinas*,—Lat. *Prep.* (Magendie.) By precipitating a *solution of sulphate of cinchonia in rectified spirit* with an *aqueous solution of kinate of lime*, filtering, evaporating the filtrate to dryness, and redissolving it, so as to obtain it in crystals. See *Cinchonia* and *Quinine*.

KING'S CUP. *Prep. Yellow peel of* 1 *lemon; lump sugar*, 1½ *oz.; cold water*, 1 pint; infuse 8 or 10 hours, and strain. The addition of a tea-spoonful of *orange-flower water* is a great improvement. *Used* as a diluent in cases where acid liquors are inadmissible. See *Lemonade*.

KING'S EVIL. See *Scrofula*.

KING'S YELLOW. See *Yellow Pigments*.

KINIC ACID. Syn. *Cinchonic Acid*, *Quinic Acid*. A compound discovered by Hoffmann, in 1790, in the cinchona barks, in which it exists associated with the alkaloids. It is readily obtained from *kinate of lime*, by the action of *dilute sulphuric acid;* the filtered solution evaporated to the consistence of a syrup, gradually deposits large crystals resembling those of tartaric acid.

Prop., &c. It is soluble in 2 parts of water, and in alcohol; and forms salts called *kinates*. *Kinate of lime* is obtained from an acidulated infusion of cinchona bark, by adding an excess of lime, filtering, evaporating to a syrup, and setting the liquid aside to crystallize. These crystals are purified by redissolving them, treating the solution with a little animal charcoal, and crystallizing the salt as before. The *liquid* from which the bark-alkaloids have been precipitated by hydrate of lime, affords an almost inexhaustible supply of this salt. See *Kinone*.

KINO. Syn. *Gum Kino; Kino* (Indicum),—Ph. L. E. & D. "The juice flowing from the incised bark" of the "*pterocarpus marsupium*" or *Indian kino-tree*, "hardened in the sun." (Ph. L.) The "concrete juice of *pterocarpus marsupium*, and of other undetermined genera and species." (Ph. E.) *Dose.* 10 to 30 gr., in powder; as an astringent in chronic diarrhœa, &c. It is regarded as less useful than catechu.

A *factitious kino*, met with in the shops, is made as follows:—*Logwood*, 48 *lb.; tormentil root*, 16 *lb.; madder root*, 12 *lb.;* exhaust by coction with *water*, q. s., to the liquor add of *catechu*, 16 *lb.;* dissolve, strain, and evaporate to dryness. *Prod.* 24 *lb. Extract of mahogany* is also commonly sold for kino.

KINONE. *Prep.* A mixture of *kinic acid*, *binoxide of manganese*, and *sulphuric acid*, are distilled together; the liquid in the receiver is a *solution* of *kinone*, from which crystals may be obtained.

Prop., &c. Yellow; crystallizable; pungent; soluble in water; vapour exceedingly irritating to the eyes; the aqueous solution treated with ammonia, and then exposed to the air, becomes at first brown, and finally black; with chlorine water it strikes a bright green colour. The presence of kinic acid in bark is readily detected by converting it into kinone. (Dr. Stenhouse.)

KINOVIC ACID. Syn. *Chiococeic Acid*, *Kinova Bitter*. A white amorphous substance, almost insoluble in water, but freely soluble in alcohol and ether, found by Hlasiwetz in *calisaya* and *quinquina nova bark*.

KIRSCHWASSER. Syn. *Kirschenwasser*. A spirituous liquor distilled in Germany and Switzerland from *bruised cherries*. From the rude manner in which it is obtained, and from the distillation of the cherry-stones (which contain prussic acid) with the liquor, it has usually a very nauseous *taste*, and is frequently *poisonous*.

KISH. A mixed *carburet of iron and manganese* occasionally produced in iron-smelting furnaces. It closely resembles plumbago in appearance, and is said to possess peculiar efficacy in certain forms of anæmia and chlorosis.

KITCHEN. Our friend Alexis, assures us, that one of the crying faults of our countrymen, is the employment of an apartment for the kitchen, which is either too small or inconveniently situated, and which, in general, is not sufficiently provided with "kitchen requisites." "As a workman cannot work properly without the requisite tools, or the painter produce the proper shade without the necessary colours, in like manner does every person wishing to economize his food, and to cook it properly, require the proper furniture wherewith to do it." The neglect of these matters, which is so general, is, we are told, a mischievous and deceptive economy.

KNEES (Broken). See *Veterinary Medicine*.

KNOX'S POWDER. *Prep.* From *common salt*, 8 parts; *chloride of lime*, 3 parts; mixed together. An ounce of it dissolved in a tumblerful of water, furnishes a solu-

tion which is similar to *Labarraque's disinfecting fluid.*

KŒCHLIN'S LIQUID. *Prep.* From *copper filings*, 96 gr.; *liquor of ammonia*, 2 fl. oz.; digested together until it turns of a full blue colour, and then mixed with *hydrochloric acid*, 5 fl. dr.; *distilled water*, 5 lb. *Dose.* 1 to 2 tea-spoonfuls daily; in scrofula. It is poisonous in large doses.

KOMENIC ACID. Syn. *Comenic Acid, Parameconic do.* A compound resulting from the action of heat on meconic acid. See *Comenic Acid.*

KOOCHLA NUT. See *Nux Vomica.*

KOUMISS. A liquor prepared by the Calmucs, by fermenting *mare's milk*, previously kept until sour, and then skimmed. By *distillation* it yields a spirit called *rack, racky*, or *araka.* 21 *lb.* of *fermented milk* yield about ¾ pint of *low wines*, and this, by rectification, gives fully ¼ pint of *strong alcohol.*

KOUSSO. Syn. *Cusso, Kosso; Brayera Anthelmintica*,—Kunth. This substance is the dried flowers of an Abyssinian tree which grows to the height of about 20 feet, and belongs to the natural order *rosaceæ.* It is one of the most effective remedies known for both varieties of tape-worm. The *dose*, for an adult, is 3 to 5 dr., in powder, mixed with about half a pint of warm water, and allowed to macerate for 15 or 20 minutes. The method prescribed for its successful administration is as follows:—The patient is to be prepared by a purgative or a lavement, and the use of a very slight diet the day before. The next morning, *fasting*, a little *lemon juice* is to be swallowed, or a *portion of a lemon* sucked, followed by the *dose of kousso* (both liquid and powder) at 3 or 4 draughts, at short intervals of each other, each of which is to be washed down with *cold water acidulated with lemon juice.* The action of the medicine is subsequently promoted by drinking weak tea *without* either milk or sugar, or *water flavoured with lemon juice* or *toasted bread;* and if it does not operate in the course of 3 or 4 hours, a dose of *castor oil* or a *saline purgative* is taken.

The flavour of kousso is rather disagreeable and nauseating. Its operation is speedy and effectual; but at the same time, it is apt to produce, in large doses, great prostration of strength, and other severe symptoms, which unfit it for administration to the delicate of both sexes, or during pregnancy, or affections of the lower viscera. Care should be taken not to purchase it in powder, as owing to its high price (40*s.* to 48*s.* per *oz.* retail), it is uniformly adulterated. The *powdered kousso* of the shops, is, in general, nothing more than the *root-bark of pomegranate*, coloured and scented.

KRAMERIC ACID. A peculiar substance found by M. Peschier, of Geneva, in *rhatany root* (krameria triandria), and to which he ascribes its stypticity.

KREASOTE. Syn. *Creasote, Creosote, Kreosote; Kreasoton; Creasoton*,—Ph. L. *Creazotum*,—Ph. E. *Creasotum*,—Ph. D. & U. S. A peculiar substance discovered by Reichenbach, and so named on account of its powerful antiseptic property. It is a product of the dry distillation of organic bodies, and is the preservative principle of wood smoke and pyroligneous acid.

Prep. Creasote is manufactured from wood-tar, in which it is sometimes contained to the amount of 20% to 35%, and from crude pyroligneous acid, and pyroxilic oil.

1. (P. Cod.) *Wood-tar* is distilled in a wrought-iron retort until white vapours of *paraffine* appear; the *heavy oily matter* which forms the *lower layer* of the product, is collected, washed with *water slightly acidulated with sulphuric acid*, and then distilled in a glass retort, rejecting the first portions, which are chiefly *eupione;* the distillate is treated with a *solution of potassa* (sp. gr. 1·12), the mixed liquids being shaken strongly together; after it is settled, the layer of *eupione* which forms, is removed from the surface, and the potash-solution of creasote exposed to the air until it becomes black; it is then saturated with *dilute sulphuric acid*, the watery liquid rejected, and the remainder (consisting of *crude creasote*) submitted to distillation in glass; the treatment by *exposure, potassa, sulphuric acid*, and *distillation*, is repeated three times or oftener, until the combination of *creasote* and *potassa* ceases to become coloured by the action of the air; it is, lastly, saturated with *concentrated phosphoric acid*, and again distilled, rejecting the first portion that comes over.

2. (M. Simon.) A copper still, capable of containing 80 Berlin quarts, is filled to one third with the *oil of wood-tar*, and heat is applied; *first*, the more volatile matters pass over; these do not contain creasote, and are, therefore, rejected; but when, by gradually increasing the temperature, there passes over a very acid liquid, which becomes turbid, and at the same time an oil separates from it when mixed with water, the product is collected, and the distillation continued until the operator notices a squirting in the still, when this part of the

process is complete; the *distilled product* is then *nearly* saturated with *potassa*, and returned to the still, which, in the mean time, has been well cleaned out, and about half-filled with *water*, and the distillation is recommenced; at first an oil comes over, which floats on water, and which consists chiefly of *eupione*, and is, therefore, rejected; as soon, however, as the oil begins to sink in the water which comes over with it, it is charged with creasote, and is carefully collected; the distilling *aqueous* fluid being reintroduced, from time to time, into the still, and the distillation continued so long as any oil continues to come over with it; the heavy oily distillate is now agitated with *liquor of potassa*, sp. gr. 1·120; the portion which remains undissolved is *eupione*, and is skimmed off; the *potassa-solution of creasote* still, however, contains a considerable quantity of *eupione*, the greater portion of which may be separated by dilution and distillation with an *equal quantity*, or with at least $\frac{5}{4}$ths of its volume of *water*, fresh *water* being added from time to time, as long as any *eupione* comes over with the distilled liquor; when this has ceased to pass over, *sulphuric acid* is poured into the still in quantity exactly sufficient to saturate $\frac{1}{3}$rd only of the *potassa* formerly employed, and the distillation is again renewed; *creasote* now distils over, the *first* portions of which, however, still contain *eupione*, after which *pure creasote* follows; that is to say, "a creasote which, when mixed with 6 or 8 times its quantity of a *solution of pure potassa*, furnishes a mixture which, by the addition of any further quantity whatever of water, does not become turbid." The combination of creasote remaining in the still is now mixed with sulphuric acid in slight excess, and the distillation renewed, the water coming over with it being from time to time returned into the still; and when no further oil passes over with the water, the process is complete. The creasote thus obtained is re-distilled with the water which has passed over with it, whilst the distilled water, as before, is allowed from time to time to run back into the still. The creasote thus obtained is then colourless; but it contains a considerable quantity of water in solution, which is separated by distillation in a glass retort. The water distils first, and then creasote, which, after cleaning the neck of the retort from the water, must be received in another dry receiver. If the creasote assumes a red colour after being exposed for some time to the air, it must be re-distilled, and then it keeps very well. Korne found that tar prepared from turf, furnishes much more creasote than that from fir-wood, &c. (Berzelius' Lehr.)

3. (Ure.) In operating upon *pyroligneous acid*, if we dissolve *effloresced sulphate of soda* in it to saturation, at the temperature of 267° Fahr., the creasote separates, and floats upon the surface; it is then decanted, and left in repose for some days, during which it deposits a fresh portion of salt and vinegar; it is next saturated whilst hot with *carbonate of potassa*, and distilled along with water; a pale yellow oily liquid passes over, which is rectified with *phosphoric acid*, *&c.*, like the crude product of creasote from tar.

Prop. Creasote is a colourless, transparent liquid, heavier than water, of a peculiar, unpleasant, penetrating odour, resembling that of smoked meat, and a very pungent and caustic taste; its vapour irritates the eyes; it boils at 397° Fahr., and is still fluid at —16·6° Fahr.; it produces on paper greasy spots, which afterwards disappear; dissolves in 80 parts of water, and mixes in all proportions with spirit of wine, ether, the essential and fatty oils, acetic acid, naphtha, carburet of sulphur, ammonia, and potassa; it dissolves iodine, phosphorus, sulphur, resins, the alkaloids, indigo blue, several salts (especially the acetates and the chlorides of calcium and tin); reduces the nitrate and acetate of silver; is resinified by chlorine, and decomposed by the stronger acids. The aqueous solution is neutral, and precipitates solutions of gum and the white of eggs. It kindles with difficulty, and burns with a smoky flame. When quite pure it is unaltered by exposure to the air. Sp. gr. 1·037, at 68° Fahr.

Pur. The fluid commonly sold in the shops for creasote is a mixture of creasote, picamar, and light oil of tar; in many cases it is little else than impure carbolic acid, with scarcely a trace of creasote. Pure creasote is *perfectly soluble* in both acetic acid and liquor of potassa; shaken with an equal volume of water in a narrow test tube, not more than the 1-80th part disappears; otherwise it contains water, of which creasote is able to assume $\frac{1}{10}$th, without becoming turbid.—If it can be dissolved completely in 80 parts by weight of water, at a medium temperature, it then forms a perfectly neutral liquid.—An oily residue floating on the surface betrays the presence of other foreign products (*eupione*, *capnomor*, *picamar*), which are obtained at the same time with the creasote during the dry distillation of organic substances.

The specific gravity of picamar is 1·095, of paraffine 0·87, of capnomor 0·977, and of eupione 0·655. The first of these is readily detected by agitating the sample with strong liquor of potassa, when, if it is present in any quantity, the mixture solidifies into a mass of crystals in about 24 hours. Eupione may be discovered by its little solubility in liquor of potassa.

Creasote is "devoid of colour, has a peculiar odour, and is soluble in acetic acid. When it is dropped on bibulous paper, and a boiling heat is applied for a short time, it entirely escapes, leaving no transparent stain." (Ph. L.) "Entirely and easily soluble in its own weight of acetic acid." (Ph. E.) Sp. gr. 1·046 (Ph. L.), 1·066 (Ph. E. & D.) The density and boiling-point of absolutely pure creasote is given above. (See *Prop., &c.*)

Uses. Creasote has been recommended in several diseases of the organs of digestion and respiration, in rheumatism, gout, torpid nervous fever, spasms, diabetes, tape-worm, &c.; but its use has not, in general, been attended with satisfactory results. It is given in the form of pills, emulsion, or an ethereal or spirituous solution. *Externally* it has been employed in various chronic diseases of the skin, sores of different kinds, mortification, scalds, burns, wounds (as a styptic), caries of the teeth, &c.; mostly in the form of an aqueous solution (1 to 80); or mixed with *lard* (5 drops to 1 dr.) as an ointment; dissolved in *rectified spirit*, it forms a useful and a popular remedy for toothache arising from decay or rottenness. In the *arts*, creasote is extensively employed to preserve animal substances, either by washing it over them or by immersing them in its aqueous solution. A few drops in a saucer, or on a piece of spongy paper, if placed in a larder, will effectually drive away insects, and make the meat keep several days longer than it otherwise would. A small quantity added to brine or vinegar is commonly employed to impart a smoky flavour to meat and fish, and its solution in acetic acid is used to give the flavour of *whiskey* to *malt spirit*.

KREATINE. Syn. *Creatine.* A crystallizable substance obtained from the juice of the muscular fibre of animals. It was first observed by Chevreul, but has recently been carefully studied by Liebig.

Prep. (Liebig.) *Lean flesh* is reduced to shreds, and then exhausted with successive portions of cold water, employing pressure; the mixed liquid is heated to coagulate the albumen and colouring matter of the blood, and is then strained through a cloth; pure *baryta water* is next added as long as a precipitate forms, the liquid is filtered, and the filtrate is gently evaporated to the consistence of a syrup; after repose for some days in a warm situation, *crystals of kreatine* are deposited; these are purified by redissolving them in water, agitating the solution with animal charcoal, and evaporating, &c., so that crystals may form.

Prop., &c. Brilliant, colourless, prismatic crystals; readily soluble in boiling water, sparingly so in cold water and in alcohol; the aqueous soluton is neutral, bitter tasted, and soon putrefies.

KREATININE. This substance exists in small quantities both in the juice of flesh and in conjunction with kreatine in urine. It is also produced by the action of the *stronger acids* on *kreatine.* It forms colourless prismatic crystals, which are soluble in water, and the solution has a strongly alkaline reaction. It is a powerful organic base, and produces crystallizable salts with the acids.

KRENIC ACID. Syn. *Crenic Acid.* A brown substance, discovered by Berzelius, in certain mineral waters. It is a modification of humus, and is produced by the decay of vegetable matter. *Apocrenic acid* is a nearly similar compound.

KRUMMHOLZOL. Syn. *Oleum Templinum.* An essential oil, obtained in Hungary, from the young branches of the mountain pine (*pinus pumilio*) by distilling them along with *water.*

KRYSTALLINE. The name originally applied by Unverdorben to aniline.

KUSTITIEN'S METAL. *Prep.* Take of *malleable iron*, 3 parts; heat it to whiteness, and add of *antimony*, 1 part; *Molucca tin*, 72 parts; mix under charcoal, and cool. *Used* to coat iron and other metals with a surface of tin; it polishes without a blue tint; is hard, and has the advantage of being free from lead and arsenic.

KYANIZING. A method of preserving *wood* and *cordage* from decay, long known and practised, but patented by Mr. Kyan, a few years since. It consists in immersing the bodies in a solution of *corrosive sublimate*, 1 part, and *water*, 50 or 60 parts, either under strong pressure or the contrary, as the urgency of the case, or the dimensions of the bodies operated on may require.

KYANOL. A substance obtained from *coal-tar oil*, and at first thought to be an independent principle, but since shown to be identical with *aniline.*

LABARRAQUE'S FLUID. See *Chloride of Soda.*

LABDANUM. Syn. *Ladanum.* An odorous, resinous substance found on the leaves and twigs of the *cystus creticus*, a plant growing in the island of Candia, and in Syria. It was formerly much used for making stimulating plasters. The following compound is often vended for it:—

LABDANUM (Factitious). *Prep.* From *gum anime*, *rosin*, *Venetian turpentine*, and *sand*, of each, 6 parts; *Spanish juice* and *gum arabic*, of each (dissolved in a little water), 3 parts; *Canada balsam*, 2 parts; *ivory black*, 1 part; *balsam of Peru*, q. s. to give a faint odour.

LABELS which are *insoluble*, and capable of *resisting* the action of *oils*, *spirits*, *water*, *syrups*, and *dilute acids*, may be obtained as follows:—Lay a coat of *strained white of egg* over the label (an ordinary paper one), and immediately put the vessel into the upper portion of a common steam-pan, or otherwise expose it to a gentle heat till the albumen coagulates and turns opaque, then take it out and dry it before the fire, or in an oven, at a heat of about 212° Fahr.; the opaque white film will then become hard and transparent. The *labels on bottles* containing *strong acids* or *alkaline solutions*, should be either etched upon the glass by means of *hydrofluoric acid*, or be written with *incorrodible ink*. See *Etching* and *Inks.*

LABORATORY. Syn. *Laboratorium*, Lat. A place fitted up for the performance of chemical operations.

It was our intention to have described the best mode of fitting up a chemical and a pharmaceutical laboratory, both on the *small* and *large scale*, and also to have presented the reader with a copper-plate engraving of the celebrated laboratory of Giessen, prepared expressly for this work; but owing to the doubtlessly judicious admonitions of our publisher, on account of the number of our previous pages, we are compelled to withdraw the article and illustrations. We must therefore content ourselves with recommending the reader to consult the last edition of Faraday's '*Chemical Manipulation*,' a work replete with correct and valuable information.

Among *Portable Laboratories*, the cheapest and best arranged which we have lately seen, are those of Messrs. Jackson and Townson, of No. 89, Bishopsgate Street within. The little collection sold by them under the title of "*Professor Stockhardt's Chemical Apparatus*" is truly one that deserves universal patronage. It is, indeed, a miracle of cheapness, and judicious arrangement and selection. Whilst its price places it within the reach of almost the humblest student in chemistry, its intrinsic usefulness adapts it for illustrating all the more valuable facts of chemical science, and performing all the ordinary operations of qualitative analysis. With this tube laboratory, and the collection of tests and chemicals provided by Messrs. Jackson and Townson to accompany it, as a sort of stock-in-trade to operate on, he must be really dull and indifferent who does not become at once fascinated with this delightful science, and, ere long, an adept in its leading operations.

LAC. Syn. *Lacca*,—Lat. A resinous substance combined with much colouring matter, produced by the puncture of the female of a small insect, called the *coccus lacca* or *ficus*, upon the young branches of the *ficus Indica*, *croton lacciferum*, and some other trees. There are several varieties:—Stick lac (*lacca in ramulis*, *lacca in baculis*); seed lac (*lacca in granis*, *lacca in seminis*); lump lac (*lacca in massis*); shell lac (*lacca in tabulis*). The preceding differ chiefly in colour and form. *Shell lac* is the kind most generally used. The palest is the best, and is known as "*orange-lac.*" The darker varieties—"*liver-coloured*," "*ruby*," "*garnet*," *&c.*, respectively diminish in value in proportion to the depth of their colour.

Uses, *&c.* Lac was formerly used in medicine, and was said to be calefacient, attenuant, aperient, diaphoretic, and diuretic. Its only action, if any, was, however, that of a very mild astringent. It is now only used in *dentifrices*, *varnishes*, *lacquers*, and *sealing wax*, and to make *toys* and *trinkets.*

LAC (Bleached). Syn. *White Lac; Lacca Alba.* By dissolving *lac* in a boiling lye of *pearlash* or *caustic potassa*, filtering and passing *chlorine* through the solution until all the lac is precipitated; this is collected, well-washed and pulled in *hot water*, and finally, twisted into sticks, and thrown into *cold water* to harden. *Used* to make pale varnishes and the more delicate coloured sealing wax.

LAC DYE. A colouring substance used to dye scarlet, imported from the East Indies in small cubical cakes. It is prepared by digesting *ground stick lac* in *water*, and evaporating the coloured infusion to dryness.

LAC LAKE. Syn. *Lac Colour*, *East Indian Cochineal.* A superior kind of *lac dye*, also imported, prepared by dis-

solving out the *colour* of *ground stick lac* by means of a *weak alkaline solution*, and then precipitating it along with *alumina* by adding a *solution of alum*.

Obs. Either of the above dissolved in an equal weight of *lac spirit*, by digestion for about 6 hours, and then added to *hot water*, along with about as much *tartar* as lac dye, ½ that quantity of *ground sumach*, and about ⅓rd of *solution of tin*, dyes cloth of a brilliant scarlet colour. 1 *lb.* of good *lac dye* is sufficient for 10 *lb.* of *cloth*. In some cases the stuff is first *yellowed* with *quercitron*.

LAC SPIRIT. See *Solutions of Tin.*

LACCID ACID. A crystalline wine-yellow coloured, sour substance, soluble in water, alcohol, and ether, extracted by Dr. John from stick lac. It forms salts called *laccates* with the bases.

LACCINE. A substance discovered in shell lac by Unverdorben. It is the portion left after all the matters soluble in water, ether, and alcohol, have been dissolved out. It is brittle, yellow, translucent, soluble in caustic potassa and in sulphuric acid.

LACE. See *Muslin.*

LACQUER. A solution of *shell lac* in *alcohol*, tinged with *saffron*, *annotto*, *aloes*, or other *colouring* substances. It is applied to wood and metals to impart a golden colour. See *Varnish.*

LACTALBUMEN. See *Caseine.*

LACTAMIDE. A compound of *lactide* and *ammonia*. It is colourless, soluble, and crystallizable.

LACTATE. Syn. *Lactas*,—Lat. A salt of lactic acid. The *lactates* are characterised by yielding an enormous quantity of perfectly pure *carbonic oxide gas* when heated with 5 or 6 parts of *oil of vitriol*. Most of these salts may be directly formed by the solution of the *hydrated oxide* or *carbonate of the base* in the *dilute acid*. The *lactates* of *ammonia*, *potassa*, *soda*, *lime*, *baryta*, *alumina*, *zinc*, *nickel*, *lead*, *mercury*, *magnesia*, *iron*, *copper*, *silver*, and of some other bases, have been formed and examined, but only those of *iron* and *zinc* have been used in medicine.

LACTATION. See *Infancy*, *Nursing*, *&c.*

LACTIC ACID. Syn. *Acid of Milk; Nanceic Acid*,— Braconnot (?); *Acidum Lacticum*, *A. Lactis*,—Lat. A sour syrupy liquid discovered by Scheele in whey. It is also found in some other animal fluids, and in several vegetable juices, especially in that of beet root.

Prep. 1. Dissolve *lactate of baryta* in *water*, precipitate the *baryta* with *dilute sulphuric acid*, carefully avoiding excess, and gently evaporate to the consistence of a syrup, or until it acquires the density 1·215. *Lactate of lime* may be used instead of lactate of baryta, in which case a *solution of oxalic acid* must be employed as the precipitant. Pure.

2. *Milk* (skimmed or stale), 1 gall.; *bicarbonate of soda*, ½ *lb.*; dissolve, and expose the liquid to the air for some days, until it becomes sour, then saturate the excess of acid with some more *bicarbonate of soda*, and again expose it to the air; repeat this as often as the liquid becomes sour; next heat the liquid to the boiling point, filter, evaporate to the consistence of a syrup, and exhaust the residuum with *rectified spirit*; filter the alcoholic solution, add *sulphuric acid* as long as it causes a precipitate to form, again filter, and evaporate the clear liquid, as before.

3. (Boutron and Fremy.) *Milk*, 3 or 4 quarts; *sugar of milk*, 200 to 300 gr.; mix, and expose for 2 or 3 days in an open vessel at 70° to 80° Fahr., then saturate with *bicarbonate of soda*, again expose at a moderate temperature, saturate with more *bicarbonate of soda*, and repeat the process until the whole of the sugar of milk is decomposed; then coagulate the casein by heat, filter, evaporate, extract the *acid lactate of soda* by *alcohol* of sp. gr. 0·810, and decompose it by the cautious addition of *dilute sulphuric acid*; again filter, distil off the alcohol, and evaporate as before.

4. (Scheele.) Evaporate *sour whey* to ⅛th of its bulk, saturate with *slaked lime*, filter, add 3 or 4 times the quantity of *water*, cautiously precipitate the *lime* with a *solution of oxalic acid*, filter, and gently evaporate to dryness in a water-bath; digest the residuum in strong *rectified spirit*, and again filter and evaporate.

5. (Wholesale.)—*a.* Good *raw cane-sugar*, 7 *lb.*, is dissolved in *milk* (skimmed or stale), 2 gall., and *cheese* (in a moist or putrescent state), ½ *lb.*, and *chalk*, 4 *lb.*, previously rubbed to a cream with *water*, 1½ gall., is then added; the mixture is next exposed in a loosely-covered jar, at a temperature of 80° to 86° Fahr., with occasional stirring, for 2 or 3 weeks, or until the whole is converted into a semi-solid mass of crystals of *lactate of lime*; this is purified either by draining off and expressing the liquid portion, dissolving the residue in water, and evaporating the solution for crystals; or the whole is put into a stone-ware vessel and heated to the boiling point, by which the *caseine* is coagulated, and the *lactate of lime* is dissolved; the solution, fil-

tered whilst hot, furnishes the salt in crystals on cooling; these crystals are subsequently dissolved in *water*, and the filtered solution decomposed by *oxalic acid*, as before.

b. From *cane-sugar*, 4 parts; *moist cheese*, 1 part; *chalk*, 3 parts; *water*, 20 parts; as the last.

Prop. The syrupy liquid obtained as above is *hydrated lactic acid;* it is heavier than water, soluble in water, alcohol, and ether, exhibits the usual acid properties, and forms salts with the bases, called *lactates.* Heated in a retort to 266° Fahr., a small portion distils over, and the residuum on cooling concretes into a yellowish, solid, fusible mass of *anhydrous lactic acid*, which has a very bitter taste, and is nearly insoluble in water. By long boiling in water, this substance is reconverted into hydrated lactic acid. Heated to 480° Fahr., it suffers decomposition, *lactide* (the *anhydrous, concrete*, or *sublimed lactic acid* of former writers) and other products being formed. This new substance may be purified by pressure between bibulous paper and solution in *boiling alcohol*, from which it separates in dazzling white crystals on cooling. By solution in hot water and evaporation to a syrup, it furnishes *pure hydrated lactic acid.*

Uses. Lactic acid has been given in dyspepsia, gout, phosphatic urinary deposits, &c. From its being one of the natural constituents of the gastric juice, and from its power of dissolving a considerable quantity of phosphate of lime, it appears very probable that it may prove beneficial in the above complaints. *Dose.* 1 to 5 gr.; in the form of lozenges, or solution in sweetened water.

Obs. The *products* of the last five of the above formulæ may be rendered quite pure by dilution with *water*, saturation with *baryta*, evaporation, crystallization, re-solution in *water*, and the careful addition of *dilute sulphuric acid* as before; the liquid is, lastly, again filtered and evaporated. *Another plan* is to convert the acid into *lactate of zinc*, and to redissolve this last salt in *water*, and to decompose the solution with a stream of *sulphuretted hydrogen.* In all cases the evaporation should be conducted at a very gentle heat, and, when possible, finished over sulphuric acid, or in vacuo. For very nice purposes, this last product may be dissolved in *ether*, filtered, and the ether removed by a very gentle heat. Care must also be taken to remove the *solid lactate of lime* at the proper period from the fermenting liquid, as otherwise it will gradually redissolve and disappear, and on examination the liquid will be found to consist chiefly of a solution of *butyrate of lime.*

LACTIC FERMENTATION. The peculiar change by which saccharine matter is converted into lactic acid. Nitrogenous substances which in an advanced state of putrefactive change act as alcohol-ferments, often possess, at certain periods of their decay, the property of inducing an *acid* fermentation in sugar, by which that substance is changed into *lactic acid.* Thus, the nitrogenized matter of malt, when suffered to putrefy in water for a few days only, acquires the power of *acidifying* the sugar which accompanies it; whilst in a *more advanced state of decomposition* it converts, under similar circumstances, the *sugar* into *alcohol.* The glutin of grain behaves in the same manner. Wheat flour, made into a paste with water, and left for four or five days in a warm situation, becomes a true *lactic acid ferment;* but if left a day or two longer, it changes its character, and then acts like common yeast, occasioning the ordinary *panary* or *vinous fermentation.* Moist animal membranes, in a slightly decaying condition, often act energetically in developing lactic acid. The rennet employed in the manufacture of cheese, furnishes a well-known example of this class of substances.

In preparing *lactic acid* from *milk*, the acid formed, after a time coagulates and renders insoluble the caseine, and the production of the acid ceases. By carefully neutralizing the free acid by carbonate of soda, the caseine becomes soluble, and, resuming its activity, changes a fresh quantity of sugar into lactic acid, which may be also neutralized, and by a sufficient number of repetitions of this process all the sugar of milk present may, in time, be acidified. This is the rationale of the common process by which lactic acid is obtained. *Cane-sugar* (probably by previously becoming grape-sugar) and the *sugar of milk*, both yield lactic acid; the latter, however, most readily, the grape-sugar having a strong tendency towards the alcoholic fermentation. If the lactic fermentation is allowed to proceed too far, the second stage of the process of transmutation commences, hydrogen gas and carbonic acid gas are evolved, and the *butyric fermentation*, by which oily acids are formed, is established.

LACTIDE. See *Lactic Acid.*

LACTINE. See *Sugar of Milk.*

LACTOMETER. Syn. *Galactometer.* An instrument for ascertaining the quality of milk. The best way of *testing milk* is to

place it in a long *graduated tube* or *lactometer*, and to allow it to remain until all the cream has separated, then to decant off the *clear whey*, and to take its *specific gravity;* the result of the two operations when compared with the known quantity of cream and the density of the whey of an average sample of milk gives the value of the sample tested.

LACTONE. A colourless volatile liquid, boiling at 198° Fahr., formed with *lactide* and other products, when lactic acid is submitted to a heat sufficient for its decomposition. See *Lactic Acid.*

Recently, a useful little instrument has been vended in the shops of London at the low price of 1*s.* each, under the title of "*milk tester.*" It is essentially a hydrometer which sinks to a given mark on the stem in *pure water*, and floats at another mark at the opposite end of the scale, in *pure milk.* The intermediate space indicates the quantity of water (if any) employed to adulterate the article.

LACTUCARIUM. Syn. *Lettuce Opium, Thridace*; *Lactucarium*, — Ph. E. & D. The inspissated milky juice of the *lactuca sativa* (common garden lettuce), or the *lactuca virosa* (strong-scented wild lettuce), obtained, by incision, from the flowering stems, and dried in the air. M. Arnaud, of Nancy, adopts the following method of procuring this substance, which appears to be the most productive and simple of any yet published:— Before the development of the lateral branches, the *stems of twelve plants* are cut, one after another, a little below the commencement of these branches; returning to the *first one*, a *milky exudation* is found on the cut portion, and on that which remains fixed in the earth; this milky exudation is adroitly collected with the end of the finger (or with a bone knife), which is afterwards scraped on the edge of a small glass; the same operation is performed on *twelve other heads*, and so on; on the third day it is repeated on every portion of the plant remaining in the ground, a thin slice being first cut off the top; this is done every day until the root is reached. As soon as the lactucarium is collected, it coagulates; the harvest of each day is divided into small pieces, which are placed on plates, very near each other, but without touching, and allowed to dry for two days, after which they are set aside in a bottle. In this way 15 or 20 times the ordinary product is obtained. (Journ. de Pharm. et de Chim.)

Prop., &c. Lactucarium is anodyne, hypnotic, antispasmodic, and sedative, allaying pain and diminishing the force of the circulation. It has been recommended in cases in which opium is inadmissible, and has been administered with advantage in chronic rheumatism, colic, diarrhœa, asthma, the troublesome cough of phthisis, the irritability and watchfulness in febrile disorders, &c. *Dose.* 2 to 5 gr.; made into pills, lozenges, or tincture.

Obs. The quantity of lactucarium obtained from an average-sized plant of the following species is—*lactuca sativa*, 17 gr.; *l. scariola*, 23 gr.; *l. virosa*, 56 gr. (Schültz, *Buchner's Repert.*, 1823.)

LACTUCERINE. Syn. *Lactucon, Lettuce Wax.* A neutral, crystallizable substance found in lactucarium. It is soluble in alcohol, ether, and the volatile and fixed oils.

LACTUCIC ACID. A substance discovered by Pfaff in the juice of the strong-scented wild lettuce. It closely resembles oxalic acid; from which, however, it differs in giving a green precipitate with the protosalts of iron, and a brown one with sulphate of copper. Walz declares it to be oxalic acid.

LACTUCINE. Syn. *Lactucinum*,—Lat. This is the active principle of lactucarium, and is found in the juice of several species of lettuce.

Prep. Exhaust *lactucarium* with hot *rectified spirit*, agitate the *tincture* with a little *animal charcoal*, filter, add a little *milk of lime*, and evaporate to dryness; digest the residuum in hot *rectified spirit*, filter, and evaporate by a gentle heat, so that crystals may form.

Prop., &c. A nearly colourless, odourless, fusible, neutral, bitter substance; sparingly soluble in cold water and in ether; but freely soluble in alcohol. It possesses feeble basic properties. Good lactucarium contains fully 20% of this substance.

LADANUM. See *Labdanum.*

LADYBIRD. The *coccinella septempunctata* (Linn.) This beautiful little insect was formerly in repute in domestic medicine as an antispasmodic and sedative, in similar cases to those in which cochineal is occasionally prescribed.

LAENNEC'S CONTRA-STIMULANT. See *Draughts.*

LAKE. *Lacca*,—Lat. Animal or vegetable colouring matter, precipitated in combination with oxide of tin or alumina; usually the latter. The term was formerly restricted to *red* preparations of this kind, but is now indiscriminately applied to all compounds of alumina and colouring matter. The term *lake*, when unqualified by

an adjective, is, however, understood to apply exclusively to that prepared from cochineal.

Prep. Lakes are made—1. By adding a *solution of alum*, either alone or partly saturated with *carbonate of potassa*, to a filtered *infusion* or *decoction of the colouring substance*, and after agitation, precipitating the mixture with a *solution of carbonate of potash.*—2. By precipitating a *decoction* or *infusion of the colouring substance* made with a *weak alkaline lye*, by adding a *solution of alum.*—3. By agitating recently *precipitated alumina* with a *solution of the colouring matter*, prepared as before, until the liquid is nearly decoloured, or the alumina acquires a sufficiently dark tint. The *first* method is usually employed for *acidulous solutions* of colouring matter, or for those whose tint is *injured* by alkalies; the *second*, for those that are brightened, or at least *uninjured* by alkalies; the *third*, for those colouring matters that have a great affinity for gelatinous alumina and readily combine with it by mere agitation. By attention to these general rules, lakes may be prepared from almost all animal and vegetable colouring substances that yield their colour to water, many of which will be found to possess great beauty and permanence. The precise process adapted to each particular substance may be easily ascertained by taking a few drops of its infusion or decoction, and observing the effects of alkalies and acids on the colour. The *quantity of alum* or of *alumina* employed, should be nearly sufficient to decolour the dye liquor; and the *quantity of carbonate of potassa* should be so proportioned to the *alum* as to exactly precipitate it without leaving free or carbonated alkali in the liquid. The *first portion of the precipitate* has the *deepest colour*, and the shade gradually becomes paler as the operation proceeds. A beautiful tone of *violet*, *red*, and even *purple*, may be communicated to the *colouring matter* of *cochineal* by the addition of *nitrohydrochlorate* or *perchloride of tin;* the addition of *arseniate of potassa* (neutral arsenical salt) in like manner gives shades which may be sought for in vain with *alum* or *alumina*. After the lake is precipitated, it must be carefully collected, washed with *cold distilled water*, or the *purest rain water*, until it ceases to give out colour, and then carefully dried in the shade. In this state it forms a soft velvety powder. That of the shops is generally made up into conical or pyramidal drops (*drop lake*), which is done by dropping the moist lake through a small funnel on a clean board or slab, and drying it by a gentle heat as before. A very little *clear gum water* is commonly added to the paste to give the drops consistence when dry.

LAKE (Blue). Syn. *Lacca Cœrulea*,—Lat. Prepared from some of the *blue-coloured flowers;* fugitive. The name is also applied to *lump archil* (lacca cœrulea), to *moist alumina coloured with indigo*, and to *mixed solutions* of *pearlash and prussiate of potash*, precipitated with another *solution of sulphate of iron and alum*. These are permanent and beautiful; but are seldom used, in consequence of indigo and prussian blue supplying all that is wanted in this class of colours.

LAKE (Brazil-wood). Syn. *Drop Lake; Lacca in Globulis*,—Lat. *Prep.* 1. Take of *ground Brazil wood*, 1 *lb.; water*, 4 gall.; digest for 24 hours, then boil for 30 or 40 minutes, and add of *alum*, 1½ *lb.*, dissolved in a *little water;* mix, decant, strain, and add of *solution of tin*, ½ *lb.;* again mix well and filter; to the *clear liquid* add, cautiously, a *solution of salt of tartar* or *carbonate of soda*, as long as a deep-coloured precipitate forms, carefully avoiding excess; collect, wash, dry, &c., as directed above.

Obs. The product is *deep red*. By collecting the precipitate in separate portions, lakes varying in richness and depth of colour may be obtained. The first portion of the precipitated lake has the brightest colour. An excess of *alkali* turns it on the *violet*, and the addition of *cream of tartar*, on the *brownish-red*. The tint turns more on the *mellow violet red* when the solution of tin is omitted. Some persons use less, others more alum.

2. Add *washed* and *recently precipitated alumina* to a strong and filtered *decoction of Brazil wood*. Inferior to the last.

LAKE (Carminated). Syn. *Cochineal Lake, Florence do., Florentine do., Paris do., Vienna do.; Lacca Florentina*, — Lat. *Prep.* 1. The *residuum of the cochineal* left in making carmine, is boiled with *repeated portions of water*, until it is exhausted of colour; the resulting liquor is mixed with that *decanted off the carmine*, and at once filtered; some *recently precipitated alumina* is then added, and the whole gently heated, and well agitated for a short time; as soon as the alumina has absorbed sufficient colour, the mixture is allowed to settle, after which the clear portion is decanted, the lake collected on a filter, washed, and dried, as before. The decanted liquor, if still coloured, is now treated with

fresh alumina until exhausted, and thus a lake of a second quality is obtained. Very fine.

2. To the *coloured liquor obtained from the carmine and cochineal* as above, a *solution of alum* is added, the *filtered liquor* precipitated with a *solution of carbonate of potassa*, and the lake collected and treated as before. Scarcely so good as the last.

Obs. Some makers mix a little *solution of tin* with the coloured liquor before adding the *alum* or *alumina:* this brightens the colour. The above lake is a good glazing colour with oil, but has little body. It may be made directly from a decoction of cochineal. (See below.)

LAKE (Cochineal). *Prep.* 1. *Cochineal* (in coarse powder), 1 *oz.; water* and *rectified spirit*, of each, 2½ *oz.;* digest for a week, filter, and precipitate the tincture with a few drops of *solution of tin*, added every 2 hours, until the whole of the colouring matter is thrown down; lastly, wash the precipitate in *distilled water*, and dry it. Very fine.

2. Digest *powdered cochineal* in *ammonia water* for a week, dilute the solution with a *little water*, and add the liquid to a *solution of alum*, as long as a precipitate falls, which is the lake. Equal to the last.

3. *Coarsely-powdered cochineal*, 1 *lb.; water*, 2 gall.; boil 1 hour, decant, strain, add a *solution of salt of tartar*, 1 *lb.*, and precipitate with a *solution of alum*. By adding the alum first, and precipitating the lake with the alkali, the colour will be slightly varied. Some persons use a solution of *cuttlefish-bone* in *dilute muriatic* or *nitric acid;* but this increases the expense, and yields an inferior product. All the above are sold as *carminated* or *Florence lake*, to which they are often superior.

LAKE (Green). Made by mixing *blue* and *yellow lake* together. Seldom kept in the shops, being generally prepared extemporaneously by the artist on his pallet.

LAKE (Lac). *Prep.* Boil *fresh stick-lac* in a *solution of carbonate of soda*, filter the solution, precipitate with a *solution of alum*, and proceed as before. A fine red.

LAKE (Lichen). See *Orceine.*

LAKE (Madder). Syn. *Lacca Rubiæ, L. Columbina,*—Lat. *Prep.* 1. (Sir H. C. Inglefield.) Take of *Dutch grappe* or *crop madder*, 2 *oz.;* tie it in a cloth, beat it well in *a pint of water* in a stone mortar, and repeat the process with *fresh water* (about 5 pints) until it ceases to yield colour; next boil the *mixed liquor* in an earthen vessel, pour it into a large basin, and add of *alum*, 1 *oz.*, previously dissolved in *boiling water*, 1 pint; stir well, and while stirring, pour in gradually of a strong *solution of carbonate of potash* (oil of tartar), 1½ *oz.;* let the whole stand until cold, then pour off the supernatant yellow liquor, drain, agitate the residue with *boiling water*, 1 quart (in separate portions), decant, drain, and dry. *Product*, ½ *oz.* The Society of Arts voted their gold medal to the author of the above formula.

2. Add a little *solution of acetate of lead* to a *decoction of madder*, to throw down the brown colouring matter, filter, add a *solution of tin* or *alum*, precipitate with a *solution of carbonate of soda* or of *potassa*, and otherwise proceed as before.

3. (Ure.) *Ground madder*, 2 *lb.; water*, 1 gall.; macerate with agitation for 10 minutes, strain off the water, and press the remainder quite dry; repeat the process a second and a third time; then add to the mixed liquors, *alum*, ½ *lb.*, dissolved in *water*, 3 quarts; and heat in a water-bath for 3 or 4 hours, adding water as it evaporates; next filter, *first* through flannel, and, when sufficiently cold, through paper; then add a solution of *carbonate of potassa*, as long as a precipitate falls, which must be washed until the water comes off colourless, and, lastly, dried. If the alkali be added in 3 successive doses, 3 different lakes will be obtained, successively diminishing in beauty.

LAKE (Orange). *Prep.* Take of the best *Spanish annotto*, 4 *oz.; pearlash*, ¾ *lb.; water*, 1 gall.; boil for half an hour, strain, precipitate with *alum*, 1 *lb.*, dissolved in *water*, 1 gall., observing not to add the latter solution when it ceases to produce an effervescence or a precipitate; strain, and dry the sediment in small squares, lozenges, or drops. The addition of some *solution of tin* turns this lake on the *lemon yellow;* acids *redden* it. See *Yellow Lake.*

LAKE (Red). *Prep.* Take of *pearlash*, 1 *lb.; clean shreds of scarlet cloth*, 3½ *lb.; water*, 5 gall.; boil till the cloth is decoloured, filter the decoction, and precipitate with a *solution of alum*, as before. See *Brazil-wood, Carminated, Cochineal,* and *Madder Lakes.*

LAKE (Yellow). *Prep.* 1. Boil *French berries, quercitron bark*, or *turmeric*, 1 *lb.*, and *salt of tartar*, 1 *oz.*, in *water*, 1 gall., until reduced to one-half, then strain the decoction, and precipitate with a *solution of alum.*

2. Boil 1 *lb.* of the *dye-stuff* (see *above*) with *alum*, ½ *lb.; water*, 1 gall., as before, and precipitate the decoction with a *solu-*

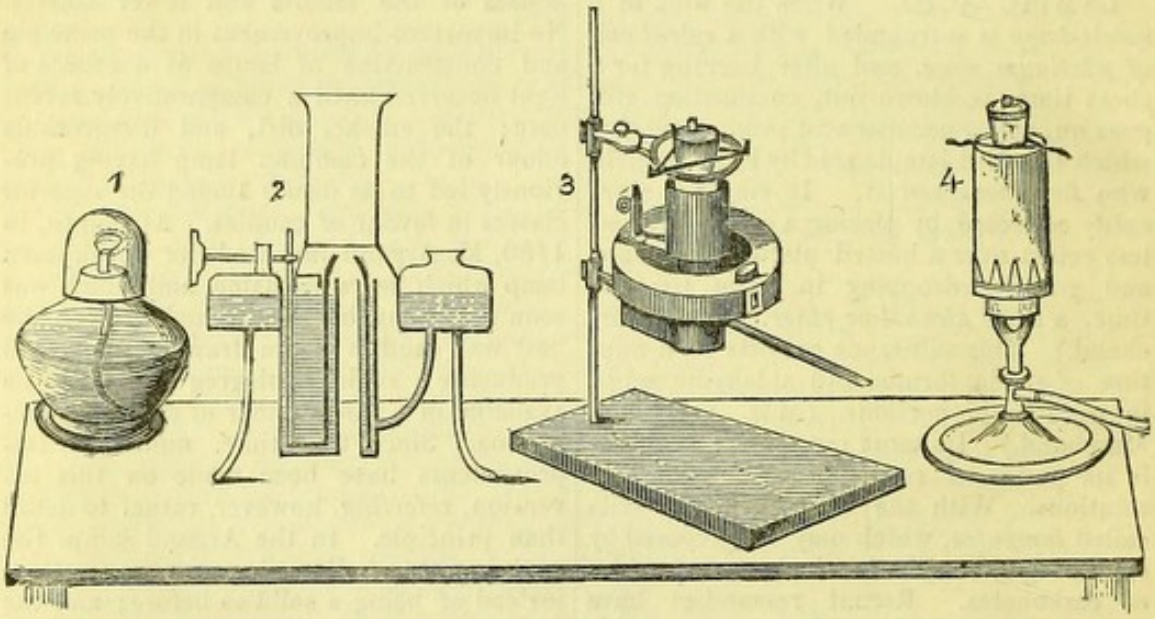
tion of carbonate of potash. See *Orange Lake.*

LAMB in its general qualities closely resembles mutton, of which, indeed, it is merely a younger and more delicate kind. It is well adapted as an occasional article of food for the convalescent and dyspeptic; but it is unequal, for frequent use, more especially for the healthy and robust, to the flesh of the adult animal.

"*Lamb* should be four or five months old, and weigh from thirty to forty pounds; the *fat* ought to be white and light in appearance; the flesh a faintish white, and smooth and firm to the touch." (Soyer.)

LAMINABILITY. That quality of bodies which permits of their extension in surface under a gradually increased pressure. As a property of matter its consideration belongs to *chemistry* and *physics;* whilst the process of *lamination* belongs to *metallurgy* and *engineering.* See *Metals.*

LAMP BLACK. See *Black Pigments.*



LAMPIC ACID. When the wick of a *spirit-lamp* is surrounded with a *spiral coil of platinum wire,* and after burning for a short time, is blown out, combustion still goes on, and a peculiar acid product results, which is called lampic acid by Prof. Daniell, who first observed it. It may be more easily collected by placing a small bottomless retort over a heated platinum capsule, and gradally dropping in, from time to time, a *little alcohol* or *ether.* (R. F. Marchand.) This substance consists of a mixture of acetic, formic, and aldehydic acids, in variable proportions. (MM. Stass and Marchand.) Its most remarkable property is its power of reducing certain metallic solutions. With the bases it forms salts called *lampates,* which may be prepared by saturating the acid with the hydrated oxides or carbonates. Recent researches have shown *lampic acid* (or at least its active portion) and *aldehydic* or *acetylous acid* to be identical.

LAMPREY. Syn. *Great Lamprey, Sea do.* This fish is the *petromyzon marinus* of Linnæus, of the order *pectobranchii.* Its flesh is soft and glutinous, and though esteemed a delicacy, is extremely difficult of digestion, if not otherwise unwholesome. *Potted lampreys* are usually so highly seasoned, as to become a dangerous article of food. Henry I is said to have lost his life by excessive indulgence in this dish.

LAMPS. *Oil lamps* as a source of artificial light, were employed among the nations of antiquity at the earliest period of which any information has been handed down to the present time. The Egyptians, Hebrews, Greeks, and Romans, vied with each other in the taste and elegance displayed in the external form of these useful instruments. The worker in metal made them of the choicest alloys, after patterns furnished by the most skilful artists, and the designs with which they were ornamented, were often equal in execution and beauty to the choicest productions of the modeller and sculptor in the other departments of arts. Strange, however, this care and expenditure was confined almost solely to the external embellishment of the lamp, which, in other respects, was simply a vessel to contain the oil, with a short depression or spout on the one side, on which the wick was laid. Lamps of this rude construction are still common in many countries at the present day; and we remember, that on our first visit to some of the remoter and least frequented parts of the West of England, during our early boyhood, that such lamps were common in the houses of the middle and lower classes. No important improvement in the principle and construction of lamps as a source of light occurred until a comparatively recent date; the smoke, dirt, and disagreeable odour of the common lamp having previously led to its disuse among the superior classes in favour of candles. At length, in 1780, M. Argand invented the well-known lamp which bears his name, and which was soon found capable of superseding even the best wax candles in the drawing-room, and producing a sufficient degree of heat to be available in a vast number of chemical operations. Since that time, numerous improvements have been made on this invention, referring, however, rather to detail than principle. In the Argand lamp, the wick is a thin hollow ring of woven cotton, instead of being a solid as before; and the whole is so arranged that the air passes through the centre of the hollow cylinder whilst the wick is burning, by which air is supplied to the centre of the flame. The whole is surmounted by a cylindrical glass chimney, open at the bottom, and surrounding the flame at a short distance from it, by which another current of air is made to act on the exterior portion of the flame. In this way a due supply of oxygen is secured and sufficient heat generated for the perfect combustion of the gaseous products of the oil, and the smoke and soot which escape from the ordinary lamp are converted into a brilliant and smokeless flame. The *sinumbra, French,* and *iris lamps* (now common as table-lamps), are

mere modifications of the Argand lamp, so arranged as to avoid the shadow of the oil-reservoir falling on objects immediately beneath or around them. In the *Carcel*, *mechanical*, *meteor*, *moderator*, and other like lamps, the oil, instead of being sucked up by the wick, or descending to it by the force of gravity, is driven up by mechanical means from the oil-reservoir contained in the foot or pedestal, by which a more equable supply of oil to the wick is secured. In the *solar lamp*, and lamps fitted on the "*solar principle*," the wick is thicker than in the ordinary Argand lamp, and a greater quantity of oxygen than usual is supplied to the flame. This is effected by means of apertures in the sides of the lamp, and a cap with a deflector, so as to force the two currents of air to impinge on each other. Lamps so constructed will burn camphine, and give a brilliant light even with common fish oil. In the "*Economic hot-oil lamp*" of Mr. Sam. Parker, the oil-reservoir surrounds the upper part of the chimney, and is thus heated by its own flame.

The *Argand lamp* when intended as a source of heat for chemical purposes, is so modified as to adapt it to burn either oil, spirit of wine, or wood spirit, and the combustion is greatly aided by the chimney, which in this case is made of copper. (See *Engr.*, No. 2 and 3.) The lamp itself is also made of metal, and furnished with ground caps to the wick-holder and aperture by which the spirit is introduced, in order to prevent loss of spirit by evaporation when the lamp is not in use. When in use this aperture must always be left open, otherwise an accident is sure to happen; as the heat expands the air in the lamp, and the spirit is forced out in a state of inflammation. *Glass spirit-lamps*, fitted with ground-glass caps, are also very convenient for occasional use in chemical experiments. (See *Engr.* No. 1.)

In those situations in which *coal-gas* is cheap, it may be used with great economy and advantage as a source of heat in small chemical operations. Retorts, flasks, capsules, and other vessels, can be thus exposed to an easily regulated and constant temperature for many successive hours. Small platinum crucibles may be ignited to redness by placing them over the flame on a little wire triangle. The arrangement shown in the *Engraving* (No. 4), consisting of a common Argand gas burner fixed on a heavy and low foot, and connected with a flexible gas-tube of caoutchouc or other material, is found the most convenient in practice.

To *prevent* or *lessen* the *smoking of ordinary lamps* when common oil is burnt in them, the wicks should be well soaked, either in *dilute hydrochloric acid*, and then well washed in water, and dried; or in *strong vinegar*, when they will merely require drying. *Large lamps*, that emit much smoke, should be burnt under a funnel, to carry it off; or a large sponge, dipped in water, may be suspended over them. In all cases, the wicks should not be put up too high, which is in general the cause of their smoking and emitting a disagreeable odour. See *Illumination*, *Gas*, and *Light* (*Artificial*).

LAMP (Flameless). See *Lampic Acid.*

LAMP (Monochromatic). A lamp fed with a *mixture of a solution of common salt* and *spirit of wine*. It gives a yellow light, and makes every object illuminated by it appear either yellow or black. The human features are changed in a remarkable degree; the countenance appearing truly ghastly and unearthly. (Brewster.)

LAMP (Safety). The *safety lamp* of Sir H. Davy consists of a common oil lamp, surmounted with a cylinder of wire gauze, the apertures of which are not greater than the $\frac{1}{20}$th of an inch square, and the wire of which it is made, of the $\frac{1}{40}$th to the $\frac{1}{60}$th of an inch in diameter. The *fire damp* (carburetted hydrogen) of coal mines in passing through the meshes of such gauze, gets cooled by the conducting power of the wire below the point necessary to kindle it. When this lamp is taken into an explosive atmosphere, although the fire-damp may burn within the cage with such energy as sometimes to heat the metallic tissue to dull redness, the flame is not communicated to the mixture on the outside. These appearance are so remarkable, that the lamp becomes an admirable indicator of the state of the air in different parts of the mine, and if its admonitions are attended to, gives the miner time to withdraw before an explosion takes place.

LANA PHILOSOPHICA. See *Oxide of Zinc.*

LANDSCAPE GARDENING. The principles of this art are the same as those upon which a painter proceeds in composing a picture. "Let selected and beautiful nature be constantly your model, and success must follow." (Loudon.)

LANTHANIUM. A rare metal, discovered by Mosander, associated with oxide of cerium. *Oxide of lanthanium* is a pale salmon-coloured powder, unaffected by ignition in open vessels. The *hydrated oxide* has an alkaline reaction, and forms salts which are colourless, astringent, sweet-tasted, and crystallizable. See *Cerium.*

LAPIS CAUSTICUS. See *Potassa.*

LAPIS DIVINUS. Syn. *Divine Stone; Lapis Ophthalmicus,*—Lat. *Pierre Divine,*—Fr. *Prep.* 1. (Beer.) *Verdigris, nitre,* and *alum,* equal parts, melted together.

2. (P. Cod.) *Alum, nitre,* and *blue vitriol,* of each, 3 oz.; *camphor,* 1 dr.; as last.

3. (Woolfuss.) *Blue vitriol, nitre, alum,* and *camphor,* equal parts, melted together, adding the *camphor* last. Astringent and detergent. 1 oz., dissolved in *water,* 1 pint, formed a once celebrated lotion. 1 dr., to *water,* 1 pint, is still used as a collyrium.

LAPIS HIBERNICUS. Irish slate.

LAPIS INFERNALIS. See *Nitrate of Silver.*

LAPIS LAZULI. See *Ultramarine.*

LAPIS LYDIUS. Syn. *Lydian Stone.* A silicious slate, used as a touchstone by jewellers.

LAPIS MEDICAMENTOSUS. Syn. *Medicinal Stone; Lapis Mirabilis,*— Lat. *Prep.* (Ph. L., 1746.) *Alum, litharge,* and *Armenium bole,* of each, 6 oz.; *colcothar of green vitriol,* 3 oz.; *vinegar,* 4 fl. oz.; mix, and evaporate to dryness. Formerly used to make an astringent and detergent lotion:—1 oz. to *water,* 1 pint. Once a popular application to ulcers, and in other cases; now disused.

LAPIS VULNERARIUS. As *lapis divinus* (nearly.)

LARD. Syn. *Hog's Lard, Axunge; Adeps,*—Ph. L. *Axungia,*—Ph. E. *Adeps Suillus,*—Ph. D. *Adeps Porci, A. Præparatus,*—Lat. var. The fat of the pig (*sus scrofa,*—Linn.) melted by a gentle heat, and strained through flannel or a hair sieve. The fat about the loins yields the whitest and hardest lard. "That which has been cured with chloride of sodium is not to be employed." (Ph. L.) "It is not to be used without being first carefully washed with water." (Ph. L. 1836.) *Used,* chiefly, to make ointments, and in cookery.

LARD (Magnetic). See *Magnetic Adeps.*

LARD (Oxygenated). See *Ointment of Nitric Acid.*

LARDING. By many this is regarded as belonging to the higher style of cookery only, and too troublesome and extravagant to be adapted to the kitchens of the middle classes and the poor. This, we are assured, is not the case. "On the contrary, it is an *economical process,* and will make lean meat go much farther than without it." The *process* of *larding* is as follows:—"Get what is called a *larding needle,* that is, a piece of steel from six to nine inches long, pointed at one end, and having four slits at the other to hold a small strip of bacon when put between them. They will, perhaps, cost tenpence. Cut the *bacon* into pieces 2 or 3 inches long, and a

¼ to ½ an inch square; put each one after the other in the pin, insert it in the meat, and leave only about ½ an inch out; using eight pieces to each pound." (Soyer.)

LARICINE. The name given by Martius to the active principle of the larch agaric (*boletus laricis*,—Fries.) It is a white, amorphous, bitter-tasted powder; soluble in alcohol and oil of turpentine, and forming a paste with boiling water.

LARK. The *alauda arvensis* (skylark) and the *alauda cristata* (field-lark), with several other species of the same genus, form a light and nutritious article of food, by many esteemed a delicacy. The last, according to Galen and Dioscorides, eaten either roasted or boiled, "helps the colic." The heart, applied to the thigh, was also regarded to possess the same virtue.

LAUDANUM. This name is now understood to denote, exclusively, the common tincture of opium of the pharmacopœia; but formerly the term was applied to several preparations of opium differing greatly from each other, both in their strength and mode of preparation.

Dutchman's Laudanum. From the *flowers* of bull's hoof or Dutchman's laudanum (*passiflora merucuja*,—Linn.) infused in *rum*. Narcotic. *Used* as a substitute for tincture of opium in the West Indies.

Ford's Laudanum. This is merely the common tincture of opium aromatized with a little *cloves* and *cinnamon*.

Houlton's Laudanum. From *opium*, 2½ oz.; *distilled vinegar*, 1½ pint; digested together for a week, the filtered tincture gently evaporated nearly to dryness, and then redissolved in *weak spirit* (1 of rectified spirit to 7 of water), 1 quart. *Dose.* 10 to 60 drops.

Neumann's Laudanum. A fermented *infusion of opium* evaporated to the consistence of honey.

Quince Laudanum; Extractum Opii Cydoniatum, Laudanum Cydoniatum,—Lat. Extract of opium made with *quince juice*; a few drops of the *oils of cinnamon, cloves*, and *mace*, being added before the mass cools. Now seldom used.

Liquid Quince-laudanum; Laudanum Liquidum Cydoniatum, L. L. C. paratum fermentatione,—Lat. A fermented infusion of opium prepared with *quince juice*, aromatized with *cloves, cinnamon, aloeswood*, and *yellow sandal wood*, and evaporated so as to possess about twice the strength of the ordinary tincture. Now obsolete.

Rousseau's Laudanum. Wine of opium prepared by fermentation. See *Wines*.

Smith's Concentrated Laudanum. Resembles Battley's *liquor opii sedativus*, but possesses about 6 times its strength.

Swediaur's Laudanum. From *extract of opium*, 2 parts, dissolved in a mixture of *alcohol*, 1 part, distilled water, 8 parts. Every five drops contain 1 gr. of opium.

Sydenham's Liquid Laudanum; Laudanum Liquidum Sydenhami,—Lat. Similar to *wine of opium* (Ph. L.), but rather stronger, and aromatized with a little *cloves* and *cinnamon*. Wine of opium is now always sold for it.

Tartarized Laudanum; Laudanum Liquidum Tartarizatum,—Lat. A tincture of opium prepared with spirit alkalized with *salt of tartar*, and flavoured with aromatics. Obsolete.

LAUGHING GAS. See *Nitrous Oxide*.

LAUREL. See *Cherry Laurel* and *Sweet Bay*.

LAUREL FAT. See *Oils*.

LAURINE. Syn. *Bay-berry Camphor*. A fusible, volatile, crystallizable substance, extracted from the berries of the *sweet bay* (laurus nobilis,—*Linn.*) by *boiling strong alcohol* or *ether*. It has an acrid, bitter taste, and an odour resembling that of the expressed oil.

LAVA. The matter thrown out by volcanoes. The beautiful ornamental vases, jugs, and other objects sold under the name, are a superior sort of unglazed coloured porcelain.

LAVEMENTS. See *Enemas*.

LAVENDER. The flowers or flowering tops of *lavandula vera* (lavandula spica,—*Linn.*), or common *garden lavender*. An essential oil, spirit, and tincture, prepared from it, are officinal in the pharmacopœias.

LAVENDER (Red). See *Tinctures*.

LAVENDER (Smith's British). *Prep.* From *English oil of lavender*, 2 *oz.*; *essence of ambergris*, 1 *oz.*; *eau de Cologne*, 1 pint; *rectified spirit*, 1 quart. Very fragrant. See *Lavender Water*.

LAXATIVES. Syn. *Lenitives; Laxativa, Laxantia, Lenitiva*,—Lat. Mild purgatives or cathartics. The principal of these are—*almond oil, cassia pulp, castor oil, confection of senna, cream of tartar, figs, grapes, honey, phosphate of soda, prunes, salad oil, tamarinds, &c.*

LAYERS. Among *gardeners*, a mode of propagating plants, by laying down the shoots or young twigs, and covering a portion of them with the soil, without detaching them from the parent plant. To facilitate the *rooting* of such layers, the part beneath the soil is fractured by twisting or bruising it, or it is partly cut through with a sharp knife, immediately under a bud.

When the layer has taken root, it is divided from the parent stem, and transplanted or potted. In this way, with a little care, nearly all plants may be multiplied.

LEAD. Syn. *Plumbum*,—Lat. This metal, like gold, silver, and iron, appears to have been known in the most remote ages of antiquity. It is only prepared on the *large scale*. The ore from which it is almost exclusively extracted, being the only one found in abundance, is the native *sulphide* or *sulphuret of lead*, called by mineralogists, *galena*. This is roasted in a reverberatory furnace, and afterwards smelted along with coal and lime.

Prop., &c. The general properties of lead are too well known to require notice here. The sp. gr. of that of commerce is about 11·35; but in a state of absolute purity, its greatest density is 11·45. It melts at about 600° Fahr. (612°,—Crighton; 634°,—Kupfer;) and when very slowly cooled, crystallizes in octahedrons. At a white heat it boils, and is volatilized. When exposed to moist air, it soon becomes covered with a gray film, presumed to be the suroxide. It is scarcely acted on by the hydrochloric, sulphuric, and vegetable acids, unless in free contact with air, and then very slowly; but nitric acid rapidly oxidizes it, forming a solution of nitrate of lead. *Pure water*, put into a leaden vessel, and exposed to the air, soon corrodes it, and dissolves the newly-formed oxide; but *river* and *spring water* exert no such influence, the carbonates and sulphates in such water destroying its solvent power. Many other neutral salts act in the same way. Among these, the most certain preservatives are the *phosphates*, *sulphates*, *chlorides*, and *iodides*; their power being in proportion to the relative insolubility of the compound which their acid is capable of forming with lead. It has been found that 1-30,000th part of *phosphate of soda* or of *iodide of potassium*, dissolved in *distilled water*, prevents its corrosive action on this metal. (Christison.) The lead in contact with such water, gradually becomes covered with a superficial film of an insoluble salt of lead, which adheres tenaciously, and prevents further change. From this it appears that ordinary water (*hard water*), which abounds in mineral salts, may be safely kept in leaden cisterns; but *distilled water* and *rain water*, and all other varieties that contain scarcely any saline matter, speedily corrode, and dissolve a portion of lead, when kept in vessels of that metal. When, however, leaden cisterns, have *iron* or *zinc* fastenings or braces, a galvanic action is set up, the *preservative power of saline matter ceases*, and the water speedily becomes contaminated with lead, and unfit for consumption as a beverage. *Water* containing *free carbonic acid* also acts on lead; and this is the reason why the water of some springs, (although loaded with saline matter,) when kept in *leaden cisterns*, or raised by *leaden pumps*, possesses unwholesome properties. Free carbonic acid is evolved during the fermentation or decay of vegetable matter, and hence the *absolute necessity* of preventing the leaves of trees falling into water-cisterns formed of lead. The neglect of this precaution gave rise to the violent ravages of colic that are recorded to have visited Amsterdam about the middle of the last century. (Dr. Frouchin.) The *eau de rose* and the *eau d'orange* of commerce, which are pure distilled water holding in solution small quantities of essential oil, and are imported in leaden canisters, always contain a small quantity of lead, and deposit a sediment, which is not the case when they are kept in glass or incorrodible vessels. *Lead* and *all* its *preparations* are *highly poisonous;* and whether imbibed in almost infinitesimal quantities with our daily beverages and food, or swallowed in larger and appreciable doses, is alike productive of the most disastrous consequences, the real cause, in the former case, being, unfortunately, seldom suspected.

Tests. 1. The *oxides* and *salts of lead*, mixed with a little carbonate of soda, and exposed on a charcoal support to the *reducing flame* of the blowpipe, readily yield a soft and ductile globule of metallic lead, and the charcoal, at the same time, becomes covered with a yellowish incrustation of oxide of lead.—2. Both *metallic lead* and its *oxides* are soluble in nitric acid, furnishing a solution which may be examined by the usual tests.—3. *Solutions of the salts of lead* may be recognized by their behaviour with the following reagents:—*a.* Sulphuretted hydrogen, hydrosulphuret of ammonia, and the alkaline sulphurets, give *black* precipitates, insoluble in the cold dilute acids, alkalies, alkaline sulphurets, and cyanide of potassium.—*b.* Caustic potassa and soda give a *white* precipitate, *soluble* in excess.—*c.* Ammonia (except with the acetate) gives a *white* precipitate, insoluble in excess.—*d.* The carbonates of potassa, soda, and ammonia, give a *white* precipitate, insoluble in excess.—*e.* Dilute sulphuric acid (in excess) and solutions of the sulphates, give a *white* precipitate, *insoluble* in nitric acid, and *soluble* in solution of potassa.—*f.* Chromate of potassa gives a

yellow precipitate, insoluble in dilute nitric acid, and soluble in solution of potassa.—*g.* Iodide of potassium gives a *yellow* precipitate, soluble in acetic acid, solution of potassa, alcohol, and boiling water; from the solution in the last, it is deposited in small, brilliant, golden-yellow scales, as the liquid cools.—*h.* A piece of polished zinc precipitates metallic lead in an arborescent form, hence called the "*leaden tree.*"—*Obs.* A solid supposed to contain lead should be digested in nitric acid, when the solution, evaporated to dryness, and redissolved in water, may be tested as above. *The susceptibility of sulphuretted hydrogen* as a test for lead, ceases when the dilution reaches 500,000 times;—*chromate of potassa*, at 100,000 times;—*carbonates of soda* and *potassa*, at 60,000 times;—*potassa*, at 20,000 times;—*ferrocyanide of potassium*, at 18,000 times;—*iodide of potassium*, at 10,000 times;—and *sulphate of soda* at 5,000 times. (Devergie, *Méd. Lég.*, ii, 779.)

Estim. This has been already referred to under the heads *Brass* and *German silver.* The ores of lead (*galena*) may be digested in *nitric acid*, when the solution may be treated in the manner described at page 514. This is called an assay in the "*wet way.*" The method adopted by practical mineralogists is an assay in the "*dry way*," and is conducted as follows:—*a.* A small but powerful air-furnace, charged with coak, is brought to as high a temperature as possible, and a conical wrought-iron crucible plunged into the midst of it; as soon as the crucible has attained a dull-red heat, 1000 gr. of the galena, reduced to powder, are thrown into it, and stirred gently with a long piece of stiff iron wire flattened at the one end, in order to expose as large a surface of the powdered ore to the air, as possible, observing now and then to withdraw the wire, to prevent it becoming red-hot, in which case some of the ore would permanently adhere to it, and be reduced before the intended time; the roasting is completed in 3 or 4 minutes, and any portion of the ore adhering to the stirrer being detached by a knife, and returned into the crucible, the latter is covered up, and allowed to attain a full cherry-red heat, when about 2 to 3 spoonfuls of *reducing flux* are added, and the whole brought to a full white heat; in 12 to 15 minutes, the portion of metal and scoria adhering to the sides of the crucible, are scraped down into the melted mass with a small stick of *moist green wood*, after which the crucible is again covered, and the heat urged for 2 or 3 minutes longer, so as to keep the mass in a perfectly liquid state during the whole time; the crucible is then removed from the fire with the *crucible-tongs*, and adroitly "tilted" so as to discharge its contents into a small ingot-mould of brass, observing to rake the scoria from the surface to the sides of the crucible, so as to allow the molten lead to be poured out without it; the scoria is then reheated in the crucible with about ½ spoonful of flux, and after being cleansed with a piece of *green wood*, as before, is at once poured out into a second mould, which is instantly inverted; the little button of lead thus obtained is added to the lead in the other mould, and the whole is accurately weighed. The *weight*, divided by 10, gives the *per centage* of *pure lead* in the ore examined.

b. One-half of the *lead* thus obtained is put into a dry *cupel of bone ash*, and placed in the cupelling furnace, and treated as described in the article on *Assaying*; the *metallic button* left on the cupel is then detached and weighed. The *weight*, divided by 5, gives the *per centage* of PURE SILVER.

Obs. The flux commonly employed in the above assay is composed of *red argol*, 6 parts; *nitre*, 4 parts; *borax*, 2 parts; *fluor spar*, 1 part; well pulverized and thoroughly mixed together. When the ore is very refractory, about a spoonful of *potash* should be added for each 1000 grains of ore, in which case the *roasting* may then be dispensed with. The *quantity* of *silver* in argentiferous galena varies from $\frac{3}{10000}$ to $\frac{1}{5}$ part of the whole. Whenever this ore contains above 2 parts of silver in the 1000, it is found to be profitable to extract the latter.

Uses. The uses of lead in the arts are well known. It enters into the composition of many important alloys, it furnishes us with several valuable pigments, and it is extensively used in dyeing. Some of its preparations are employed in *medicine.*

Ant., &c. Administer an *emetic* of *sulphate of zinc* or *sulphate of copper*, and, if necessary, tickle the fauces with the finger or a feather to induce vomiting. Should this not succeed, the stomach-pump may be had recourse to. *Epsom* or *glauber salts*, or *alum, dissolved in water*, or *water acidulated with sulphuric acid*, followed by tea, water gruel, or barley water, are the proper antidotes, and should be taken as soon after the poison has been swallowed as possible. In poisoning by *white lead*, Dr. Alfred Taylor recommends the administration of a mixture of *sulphate of magnesia* and *vine-*

gar, as preferable to the sulphate *alone*. When the *symptoms* are those of *lead colic*, the treatment recommended at *page* 275 should be adopted. In *paralysis arising from lead*, small doses of *strychnia*, *brucia*, and their preparations, may be *cautiously* administered. A *symptom* of *poisoning by lead* is the formation of a narrow leaden blue line, from $\frac{1}{20}$th to $\frac{1}{6}$th of an inch wide, bordering the edges of the gums, attached to the neck of two or more teeth of either jaw. (Dr. Burton.) This discoloration may often be detected or rendered more conspicuous by rinsing the mouth out with *water holding a little sulphuretted hydrogen* or *hydrosulphuret of ammonia in solution*. Chevallier and Rayer recommend the use of sulphurous or hepatic mineral waters, or of artificial solutions of sulphuretted hydrogen or alkaline sulphurets in water, both in cases of *acute* and *chronic poisoning* by lead; but the practical success of this plan does not appear to have been in proportion to theoretical anticipations. The *hydrated sulphurets of iron* are said by their advocates to be infallible, if taken sufficiently early. (See *p.* 648.)

LEAD (Acetate of). Syn. *Sugar of Lead, Neutral Acetate of Lead; Goulard's Powder; Plumbi Acetas*,—Ph. L. E. & D. *Plumbi Superacetas*,—Ph. L. 1809. *Cerussa Acetata*,—Ph. L. 1788. *Saccharum Saturni*,—Ph. L. 1746. *Prep.* 1. (Ph. L. 1836.) *Oxide of lead* (litharge, in powder), 4 lb 2 oz.; *acetic acid* (Ph. L.) and *distilled water*, of each, 4 pints; mix, dissolve by a gentle heat and agitation, strain, evaporate, and crystallize. In the present Ph. L. this preparation is included in the Materia Medica.

2. (Ph. E.) *Litharge*, 14 oz.; *pyroligneous acid* (sp. gr. 1·034), 1 quart; *water*, 1 pint; as above.

3. (Ph. D. 1826.) *Carbonate of lead*, 1 part: *distilled vinegar*, 10 parts; as before.

4. (*Wholesale.*)—*a. Acetic acid* (sp. gr. 1·0843), 23 parts, is gently heated in a copper boiler rendered *electro-negative* by means of a large flat piece of lead soldered within it, and *litharge* (pure, and in fine powder), 13 parts, is sprinkled in; the heat is then continued, with constant stirring, until the acid is saturated, when the mother-waters of a former process (if any) are added, and the whole is heated to the boiling point, and allowed to settle until cold; the clear portion is now decanted, and evaporated in a similar vessel until the liquor has the sp. gr. 1·266 or 1·267, when it is run into salt-glazed stoneware vessels (the edges of which have been well smeared with candle grease), and allowed to crystallize. The *product* is 38 to 38½ parts of *crystallized sugar of lead*. It is found to be advantageous to preserve a very slight excess of acid in the liquid during the boiling and crystallization, to prevent the formation of any basic acetate, the presence of which impedes the formation of regular crystals.

5. From *litharge*, 112 *lb.*; *acetic acid* (sp. gr. 1·057), 128 *lb.* (or its *equiv.*); *Prod.* 180 to 184 *lb.*

Prop. Pure acetate of lead forms colourless, transparent, prismatic crystals, slightly efflorescent in dry air; it is soluble in 8 parts of alcohol, and in 1½ parts of cold water; the aqueous solution has a sweet astringent taste, and feebly reddens litmus, but turns turmeric and the juice of violets green; when gently heated, it melts in its water of crystallization; by continuing the heat, the whole of the water is expelled, and the dry acetate obtained; at a higher temperature the salt suffers decomposition, and acetic acid, acetone, &c., is given off. *Commercial acetate of lead* is in general a confused crystalline mass, somewhat resembling broken lump-sugar. It is powerfully astringent and poisonous.

Pur. Acetate of lead is completely soluble in distilled water acidulated with acetic acid, forming a transparent solution; and when the lead is exactly precipitated with dilute sulphuric acid, or by sulphuretted hydrogen, the clear supernatant liquid is wholly volatilized by heat without residue. "Carbonate of soda throws down a white precipitate; iodide of potassium, a yellow one; by sulphuretted hydrogen it is blackened. Sulphuric acid disengages from it acetic vapours. If to 100 gr. dissolved in water, sulphate of soda be added, 80 gr. of sulphate of lead are precipitated." (Ph. L.)

Uses, &c. Acetate of lead is extensively employed in dyeing and calico-printing. In *medicine* it is used as an astringent, styptic, and hæmostatic; in pulmonary, uterine, and intestinal hæmorrhage, colliquative diarrhœa, phthisical sweats, &c. It is usually combined with morphia or opium, and with acetic acid to prevent it passing into the state of the poisonous carbonate in the stomach. *Dose.* ½ gr. to 2 gr. (Collier); 1 or 2 gr. to 8 or 10 grs., twice or thrice a day (Pereira); 3 gr. to 10 gr. every 6 or 8 hours (A. T. Thomson). *Externally*, as a COLLYRIUM, 10 gr. to water, 8 fl. oz. (A. T. Thomson.); as a LOTION, 20 gr. (A. T. Thomson), 1 dr. (Collier) to water, 8 or 10 fl. oz.; as an INJECTION,

40 gr. to rose water, ½ pint. The lotion is cooling and sedative; and is commonly used in excoriations, local inflammations, &c.

LEAD (Subacetate of). Four *basic acetates of lead* have been examined by chemists, viz., the *hexabasic acetate* (hexacetate), *tribasic acetate* (trisacetate), *bibasic acetate* (diacetate), and the *sesquibasic acetate* (sesquiacetate), having respectively 6, 3, 2, and 1½ equivalents of lead to 1 equiv. of acetic acid. Of these the *diacetate* only is directly employed either in medicine or the arts. The solutions of the whole of them exhibit a strong alkaline reaction, and absorb carbonic acid with great avidity, becoming turbid from the precipitation of basic carbonate. According to some authorities, *Goulard water* (liquor plumbi diacetatis,—Ph. L.) is a solution of *diacetate of lead;* according to others, of *tribasic acetate of lead.* (See *below.*)

Subacetate of Lead, Diacetate of do., Trisacetate of do.; Plumbi Diacetas, P. Subacetas, &c.,—Lat. This is formed—1. When a *cold saturated solution of neutral acetate of lead* is mixed with about ⅙th of its volume of *concentrated liquor of ammonia,* and set aside in a covered vessel. After a time minute, anhydrous, crystalline needles are deposited.

2. *Litharge* (in fine powder), 7 parts; *acetate of lead,* 6 parts; *water,* 30 parts; digest at a moderate heat for some time, with constant agitation. By evaporation out of contact with air, small crystals may be obtained. The crystals from both the above formulæ appear to be those of the *tribasic acetate.* Dr. Thomson (*First Prin. of Chem.*) says, however, that the solid crystalline subacetate obtained from Goulard water is *hydrated diacetate of lead.* See *Solutions.*

LEAD (Arseniate of). Syn. *Plumbi Arsenias,*—Lat. *Prep.* Gradually add a *solution of acetate of lead* to another of *arseniate of soda.* A white insoluble powder. Proposed as an external application in certain forms of cancer.

LEAD (Benzoate of). Syn. *Plumbi Benzoas,*—Lat. A *neutral* and a *basic benzoate of lead* have been formed. Both are freely soluble in cold water. See *Benzoates.*

LEAD (Bromide of). Syn. *Plumbi Bromidum,*—Lat. A white crystalline powder, sparingly soluble in water, formed by precipitating a *solution of neutral acetate* or *nitrate of lead,* with a *solution of bromide of potassium.* It fuses by heat into a red liquid, which turns yellow when cold. It has been used in the same cases as *iodide of lead.*

LEAD (Carbonates of). *Prep.* 1. *Carbonate of Lead, Neutral do.; Plumbi Carbonas,*—Lat. By precipitating a *solution* of either *acetate* or *nitrate of lead* with a *solution of an alkaline carbonate,* observing to well-wash the precipitate and dry it in the shade. This preparation is seldom employed, the *commercial* carbonate (*white lead*) being substituted for it.

2. *Subcarbonate of Lead, Ceruse; Plumbi Carbonas Venalis,*—Lat. See *White Lead.*

LEAD (Chloride of). Syn. *Muriate of Lead; Plumbi Murias; Plumbi Chloridum,*—Ph. L. 1836. *Prep.* 1. (Ph. L. 1836.) Dissolve *acetate of lead,* 19 oz., in *boiling water,* 3 pints; next dissolve *chloride of sodium,* 6 oz., in *boiling water,* 1 pint; mix the two solutions, and when *cold,* wash and dry the precipitate. A white, crystalline powder.

2. Dissolve *finely-powdered litharge* in *boiling dilute hydrochloric acid,* and set aside the filtered solution to cool. Brilliant colourless needles.

Prop. Soluble in 135 parts of cold, and in 22 parts of boiling water; it melts when heated, and solidifies on cooling, forming a horn-like substance (*horn lead; plumbi corneum*). "It is totally dissolved by boiling water, the chloride concreting almost entirely into crystals as the solution cools. On the addition of hydrosulphuric acid it turns black, and by heat yellow." (Ph. L. 1836.)

Uses, &c. In the Ph. L. 1836, chloride of lead was ordered to be employed in the preparation of hydrochlorate of morphia. Mr. Tuson highly recommends it in cancerous affections, to allay pain and restrain morbid action, either in the form of a *lotion* or *ointment.* (*Lancet,* 1844.) *Patent Yellow* is a fused crude chloride of lead.

LEAD (Oxichloride of). Syn. *Plumbi Oxychloridum,*—Lat. According to Mr. H. L. Pattinson's Specification, a *solution of chloride of lead* in *boiling-hot water,* is precipitated by *instantaneous* admixture with an equal volume of *pure lime-water,* by means of two "tumbling boxes" charged with the liquid, and simultaneously upset into a cistern or receiver. *Used* as a white pigment, and said by the patentee to be superior to white lead. The experiments of Mr. Lewis Thompson, lead us, however, to think that such cannot be the case.

LEAD (Chromate of). Syn. *Plumbi Chromas,*—Lat. *Prep.* By adding a filtered solution of *acetate* or *nitrate of lead*

to a like *solution of chromate of potassa*, as long as a precipitate forms, which is collected, washed with water, and dried. The manufacture of this substance on the *large scale*, as a colouring substance (*chrome yellow*), is fully explained under the head, "*Yellow Pigments.*"

LEAD (Dichromate of). See *Red Pigments.*

LEAD (Cyanide of). Syn. *Plumbi Cyanidum, P. Cyanuretum*,—Lat. *Prep.* By adding *hydrocyanic acid* to a solution of *acetate of lead*, as long as a precipitate forms, which after being washed with *distilled water*, is dried by a very gentle heat, and preserved from the light and air. Sometimes used as a source of medicinal hydrocyanic acid.

LEAD (Ferrocyanide of). Syn. *Plumbi Ferrocyanidum*, — Lat. *Prep.* From a *soluble salt of lead* by the addition of a *solution of ferrocyanide of potassium.* A yellowish-white powder.

LEAD (Fluoride of). Syn. *Plumbi Fluoridum*,—Lat. A white powder formed by precipitating a *solution of neutral acetate of lead* with *hydrofluoric acid.* It is very sparingly soluble in water.

LEAD (Gallate of). Syn. *Plumbi Gallas*, —Lat. This salt has been recommended in internal hæmorrhages, &c. See *Gallate.*

LEAD (Iodide of). Syn. *Plumbi Ioduretum; Plumbi Iodidum*,—Ph. L. E. & D. *Prep.* 1. (Ph. L.) *Acetate of lead*, 8 oz.; *water*, 6 pints; dissolve, and add to the solution, *iodide of potassium*, 7 oz., dissolved in *water*, 1 quart; wash the precipitate with *cold distilled water*, dry it, and keep it *without* the *access of light.*

2. (Ph. E.) *Iodide of potassium* and *nitrate of lead*, of each, 1 oz.; dissolve each separately in *water*, ¾ pint; mix the solutions, collect the precipitate on a calico or linen filter, and wash it with water; then boil it in *water*, 3 gall., previously soured with *pyroligneous* (acetic) *acid*, 3 fl. oz.; let the solution settle (still keeping it near the boiling point), and decant the clear portion; as the liquid cools, the iodide subsides in brilliant golden yellow lamellæ, or minute crystals.

Prop., &c. A rich yellow-coloured powder, soluble in acetic acid, alcohol, and boiling water, and in solutions of the alkaline iodides forming *alkaline iodoplumbates* or *plumbo-iodides;* when heated it fuses and volatilizes in yellow vapour, but with a higher degree of heat, violet vapours of iodine are evolved, leaving a residuum (*lead*) which is wholly soluble in nitric acid. "If sulphate of soda be added to 100 gr. of the iodide of lead dissolved in nitric acid diluted with twice its weight of boiling water, after the iodine has been expelled, 66 gr. of sulphate of lead are thrown down." (Ph. L.) "5 grs. of iodide of lead are entirely soluble (by boiling) in 1 fl. dr. of pyroligneous acid, diluted with 1½ fl. oz. of water; and golden crystals are abundantly deposited as the solution cools." (Ph. E.) *Dose.* ¼ gr. to 4 gr. or more, made into a pill, as a deobstruent and resolvent, in enlargements of the cervical, axillary, and mesenteric glands, and in scrofulous affections, and schirrous tumours. See *Ointments.*

LEAD (Oxiodide of). Syn. *Plumbi Oxyiodidum*,—Lat. Prepared by precipitating *subacetate of lead* by *iodide of potassium.*

LEAD (Magistery of). Syn. *Plumbi Magisterium*,—Lat. The old name for precipitated carbonate of lead.

LEAD (Nitrate of). Syn. *Plumbi Nitras*,—Ph. E. & D. *Nitrum Saturninum, Plumbum Nitricum*,—Lat. obs. *Prep.* 1. (Ph. E.) *Litharge*, 4½ oz.; *diluted nitric acid*, 1 pint; dissolve by a gentle heat, and set the solution aside to crystallize.

2. (Ph. D.) *Litharge* (in fine powder), 5 *oz.; pure nitric acid*, 2 fl. oz., diluted with *water*, ½ pint; mix, apply a sand-heat, and evaporate to dryness, occasionally stirring; boil the residuum in *water*, 2½ pints, filter, acidulate with a *few drops* of *nitric acid*, evaporate to a pellicle, and set the liquid aside to cool; lastly, dry the deposited crystals on bibulous paper, and preserve them in a well-closed bottle.

Use, &c. This salt was formerly much esteemed in asthmas, hæmorrhages, and epilepsy. It is now chiefly employed as an external application in cancer, ulcers, wounds, and various cutaneous affections. It is also employed in the preparation of the iodide and other salts of lead. It is the basis of Liebert's celebrated "*Cosmétique infallible*," and of Ledoyen's "*Disinfecting fluid.*" A very weak solution is an excellent application to chapped nipples, lips, hands, &c. *Dose.* ⅛ to 1 gr.; in the form of pill or solution, washed down with a table-spoonful of water *very slightly* acidulated with nitric acid.

LEAD (Oxides of). There are four oxides of lead, of which one only (the protoxide) possesses basic properties and is capable of forming true salts with the acids.

1. *Suboxide of lead, Dioxide of do., Gray Oxide of do.* Prepared by heating *carbonate of lead* or *dry oxalate of lead* to dull redness in a glass tube out of contact with the air. It is also formed on the surface of

metallic lead by long exposure to the air. (Berzelius.) It is a dark gray powder; acids resolve it into the protoxide, which they dissolve, and metallic lead, which remains behind in a pulverulent state. It absorbs oxygen with great rapidity when heated, and also when moistened with water and freely exposed to the air.

2. *Oxide of Lead, Protoxide of do., Yellow Oxide of do., Plumbeous Acid; Plumbi Oxydum, P. Protoxydum,*—Lat. This substance is obtained *perfectly pure* by expelling the acid from *nitrate of lead*, by exposing it to heat in a platinum crucible; or, still better, by adding *ammonia* to a *cold solution of nitrate of lead* until the liquid becomes faintly alkaline, washing the precipitate with *cold water*, drying it, and heating it to moderate redness for 1 hour, as above. It may be obtained in a *crystalline state* by exposing a *concentrated solution of it* in *caustic soda* to the air for some months (M. Houton Labadilliere); or, *still easier*, by mixing an *aqueous solution* of *neutral acetate of lead* with a great excess of *liquor of ammonia*, filtering, and exposing the liquid for a few hours in a well-corked bottle to the sun's rays. If the same solution is kept in the *dark* for some days, stellated crystals of basic acetate of lead, with five atoms of base, are deposited instead of oxide. (W. Behrens.)

Prop., &c. Pure protoxide of lead has a lemon-yellow colour, and is the base of all the salts of lead. It is very heavy, slightly soluble in water, and freely so in acids, particularly when in the hydrated state; the aqueous solution has an alkaline reaction; at a red heat it melts, and assumes a semi-crystalline form on cooling; in the melted state it rapidly attacks and dissolves silicious matter, with which it unites to form glass (*flint glass*); when heated along with organic substances of any kind, it is easily reduced to the metallic state. On the *commercial scale* this oxide is prepared by heating the gray film or dross that forms on the surface of melted lead when freely exposed to the air. When the process is arrested as soon as the oxide acquires a uniform yellow colour, it is called "*massicot;*" when the heat is still further increased until it fuses or partially vitrifies, it forms "*litharge,*" of which there are several varieties. See *Litharge, Massicot,* and *below.*

3. *Red Oxide of Lead, Deutoxide of do., Plumbate of Oxide of do., Plumbeous Suroxide of do.; Plumbi Oxydum Rubrum,* —Lat. This is *prepared* by exposing *unfused protoxide of lead* to a dull red heat. It is a very heavy powder, of a fine red colour, decomposed by a strong heat into protoxide of lead, and oxygen gas, which is evolved. It is probably a mixture of protoxide and binoxide of lead in variable proportions. This substance, manufactured on the *large scale*, forms the *minium* or *red lead* of *commerce* (which see).

4. *Binoxide of lead, Peroxide of do., Puce Oxide of do., Brown do. do., Plumbic Suroxide.* Obtained by putting *red oxide of lead* into *chlorine*, or *dilute nitric acid;* or by fusing a mixture of *protoxide of lead* and *chlorate of potassa*, at a heat a little below redness, and washing the powdered mass in water; or by transmittiug a current of *chlorine gas* through a solution of *neutral acetate of lead.* This oxide gives up half its oxygen at a red heat; acids also decompose it. Its chief use is in chemical analysis, to separate sulphurous acid from certain gaseous mixtures, which it converts into sulphuric acid, which it at the same time absorbs, forming sulphate of lead.

Obs. Besides the above compounds of lead and oxygen, a *sesquioxide* of doubtful existence has been named by some writers. This is an insoluble reddish-yellow powder, formed by adding a solution of *hypochlorite of soda* to another of *protoxide of lead in liquor of potassa.* (Winkelblech.)

LEAD (Hydrated Oxide of). Syn. *Plumbi Oxydum Hydratum,*—Ph. L. 1836. *Prep.* (Ph. L. 1836.) *Solution of diacetate of lead,* 6 pints; *distilled water,* 3 gall.; mix, and add *liquor of potassa* as long as a precipitate forms, avoiding excess; wash with water what is precipitated until nothing alkaline remains.

Obs. This is *dihydrated oxide of lead.* (Mitscherlich.) It is a white powder, and is *used* in preparing disulphate of quinine. "It is totally soluble in dilute nitric acid" (Ph. L.), and in a considerable excess of liquor of potassa.

LEAD (Pyrolignite of). Sugar of lead may be made with rough pyroligneous acid. *Used* in dyeing, chiefly for the preparation of acetate of alumina.

LEAD (Saccharate of). Syn. *Plumbi Saccharas,*—Lat. *Prep.* 1. (Dr. S. E. Hoskins.) *Nitric acid,* 2 parts; *water,* 10 parts; mix in a porcelain capsule, add of *sugar,* 1 part; and apply heat until reaction ceases; then dilute the liquid with *distilled water,* neutralize it with *powdered chalk,* filter, and add to the filtrate a *solution of acetate of lead* as long as a precipitate (*saccharate of lead*) forms; lastly, collect the precipitate on a filter, wash and dry it.

2. Saturate an *aqueous solution of saccharic acid* with moist *hydrated carbonate* or *oxide of lead*, added gradually, and in small portions at a time. *Used* to make the following compound :—

LEAD (Nitrosaccharate of). Syn. *Plumbi Nitrosaccharas*,—Lat. *Prep.* (Dr. S. E. Hoskins.) *Nitric acid*, 1 part ; *water*, 19 parts ; mix ; in this dilute acid, *saccharate of lead* (in fine powder) is to be dissolved, and the solution evaporated by a gentle heat, and set aside that crystals may form, which are to be dried by pressure between the folds of bibulous paper. A weak solution of this salt acidulated with saccharic acid, has been employed by Dr. Hoskins as a solvent for phosphatic calculi, with apparent success. See *Injection* (Lithontriptic).

LEAD (Tannate of). Syn. *Plumbi Tannas*, *Plumbum Scytodepsicum*, — Lat. *Prep.* Precipitate a *solution of acetate of lead* with an *infusion of galls*, and wash and dry the precipitate. Astringent, sedative, and hæmostatic. *Dose.* 1 gr. and upwards made into a pill. It has been highly recommended in the form of ointment and cataplasms, in bedsores, chronic ulcers of the feet, white swellings, &c.

LEAD (Black). See *Plumbago.*

LEAD (Granulated). *Prep.* By melting *new lead*, and pouring it in a small stream, from an iron ladle with a hole drilled in its bottom, into a pail of water. *Used* to make solutions and alloys.

LEAD (Horn). See *Chloride of Lead.*

LEAD (Red). See *Oxides of Lead* and *Minium.*

LEAD (Sheet). The Chinese employ large quanties of sheet-lead in packing their tea, which they make in the following way:—*Melted lead* is poured from a crucible upon a large flat stone, placed upon the ground, and immediately another stone is dashed upon the fluid metal, which is thus pressed out into a very thin plate or leaf. This is instantly removed, and the operation repeated as rapidly as possible. The rough edges of the plates are afterwards cut off, and then soldered together for use. A similar method has been adopted for some years in England, to form the *plates of zinc* for galvanic batteries.

LEAD (White). See *White Pigments.*

LEAD DUST. Syn. *Pulvis Plumbi*, *Plumbum Divisum*,—Lat. *Prep.* By melting *new lead*, adding *bruised charcoal*, mixing by violent agitation, which must be continued until the metal "sets," and then pounding and washing away the charcoal. *Used* by potters.

LEATHER. Syn. *Corium*, *Corius*,—Lat. Leather is the skin of animals which has been prepared by one or other of several processes adopted for the purpose, having the common object of preventing its spontaneous destruction by putrefaction, besides other objects, which are more or less peculiar to each variety of this useful substance.

Leather is only *prepared* on the *large scale*, and primarily, either by the process of "*tanning*" or "*tawing*," in the manner briefly described under those heads.

Curried leather is leather which has been tanned, and sold to the *currier*, who after soaking it in water, and rubbing it to soften it, pares it even with a broad sharp knife, rubs it with a piece of polished stone or wood, and whilst still wet, besmears it with oil or grease (*dubbing*), which gradually penetrates the leather as the moisture evaporates. It next undergoes the operation of "*waxing*," which consists of first rubbing it on the flesh side with a *mixture* of *oil and lamp black ;* it is then "*black-sized*" with a brush or sponge, and when dry, is lastly, *tallowed* with a proper cloth, and "slicked" upon the flesh side with a broad and polished lump of glass. *Leather* curried on the *hair* or *grain side*, termed "*black on the grain*," is blackened by wetting it with *iron liquor*, and rubbing it with an iron "slicker" before applying the oil or grease. The grain is finally raised by the "pommel" or "graining board" passed over it in various directions.

Leather is *dyed* or *stained* by the application, with an ordinary brush, of any of the *strong liquid dyes*, in the cold or only gently heated, to the surface of the skin previously stretched on a board. The surface when dry, is commonly finished off with *white of egg* and the pommel or smoothing stick. *Bookbinders* generally employ copperas water as a *black stain* or *sprinkle ;* a solution of indigo as a *blue one ;* and a solution of salt of tartar or common soda, as a *brown one.* See *Chemic Blue* and *Shoemaker's Black.*

Leather before being *japanned* or *varnished*, as in the preparation of what is called "*enamelled*" and "*patent leather*," is carefully freed from grease by the application of absorbent substances or hard pressure between rollers, and the surface is nicely shaved, smoothed, and polished by appropriate tools ; the varnish is then applied to the *grain side* for the former, and the *flesh side* of the skin for the latter, which is previously stretched out tight on a board to receive it. The whole is lastly, submitted to a gentle stove-heat to harden

the varnish; and the process is repeated, if necessary. See *Japanning* and *Varnishes.*

Uses, &c. These are well-known, and are all but universal. The leather manufacture of Great Britain is equal in importance and utility to any other department of our industry, and inferior in point of value and extent only to those of cotton, wool, and iron. "If we look abroad on the instruments of husbandry, on the implements used in most of the mechanic trades, on the structure of a multitude of engines and machines; or if we contemplate at home the necessary parts of our clothing — breeches, shoes, boots, gloves, — or the furniture of our houses, the books on our shelves, the harness of our horses, or even the substance of our carriages; what do we see but instances of human industry exerted upon leather? What an aptitude has this *single* material in a variety of circumstances for the relief of our necessities, and supplying conveniences in every state and stage of life? Without it, or even without it in the plenty we have it, to what difficulties should we be exposed?" (Dr. Campbell, *Polit. State of G. B.*) Leather is a kind of *natural felt*, but of much closer and firmer texture than that of artificial origin. "The thinner and softer kinds of leather are sometimes used as body-clothing; but its special and proper purpose is the manufacture of coverings for the feet, to protect them from cold and wet." (Eras. Wilson.)

LEATHER (Mountain). See *Asbestos.*

LEAVEN. Dough which has become sour or run into a state of incipient putrefaction. When a small quantity of it is added to recent dough, it excites fermentation, but is apt to produce a disagreeable taste and odour in the bread. It is now superseded by yeast. Both these substances are used in the same way.

LEAVES (Medicated). Syn. *Folio Medicata*,—Lat. On the Continent several preparations of this kind are in use. In many cases the leaves of tobacco deprived of nicotine by soaking them in water, are dried, and then moistened or steeped in a tincture or infusion of the medicinal substance. In this way *belladonna*, *camphor*, and *henbane* are often administered. Cruveillier recommends *opiated belladonna leaves* for smoking in troublesome coughs, phthisis, spasmodic asthmas, &c., to be prepared as follows:—*Belladonna leaves*, 1 oz., are steeped in an *infusion of opium*, 10 gr., in *water*, 1 fl. oz. (or less), and are then carefully dried in the shade. See *Cigars* (Medicinal), and *Vegetable Substances.*

LECANORIC ACID. See *Orsellinic Acid.*

LECANORINE. See *Orsellinic Acid.*

LEECH (Medicinal). Syn. *Bdella; Hirudo*,—Ph. L. &. D. The officinal leech of the Pharmacopœias is the *sanguisuga medicinalis* (Savigny; *hirudo medicinalis*,—Cuv. & Linn.), familiarly known as the *old English* or *speckled leech.* It is also occasionally called the *Hamburg gray* or *Russian leech*, from being imported from those parts. Its *characteristics* are—*Back*, greenish or olive-green, sometimes almost black or intense brown, with 6 rusty-red or yellowish longitudinal stripes, which are mostly spotted with black.—*Belly*, dirty yellow or light olive green, spotted more or less with black. The spots are very variable in size and number; in some cases few, in others so numerous as to form the prevailing tint of the belly. This variety, which is the most valuable of the commercial leeches, is chiefly imported from Hamburg.

Another variety of leech, the *sanguisuga officinalis* (Savigny; *hirudo provincialis*,—Carena; *h. officinalis*,—Geiger.), familiarly known as the *Hamburg* and *French green leech*, are imported from Bordeaux, Lisbon, and Hamburg. Its characteristics are — *Back*, brownish olive-green, with 6 reddish or rusty-yellow longitudinal bands.—*Belly*, light dirty pea-green, or yellowish-green, free from spots, but exhibiting two lateral stripes. This leech is vastly inferior to the preceding variety, and some of those imported from France and Portugal are absolutely useless, from their indisposition to bite, arising from the fraud practised by the collectors and dealers, of gorging them with blood to improve their appearance before sending them to market.

The above are the only species of leech employed in medicine in this country. Other varieties are noticed by writers on the subject, of which the best known is the *hæmopis sanguisorba* (Savigny; *hirudo sanguisuga*,—Linn.), the common horse-leech of our ponds, which although bearing a bad character among the vulgar for producing troublesome wounds, has been shown by a committee of the Council de Salubrité, of Paris, appointed for the purpose, to possess no teeth capable of penetrating the human skin.

Leeches are best *preserved* in water obtained from a pond, and occasionally changed; when kept in spring water, they soon die. The introduction of a hand to which an ill-flavoured medicine or odour adheres into the water in which they are kept, is often sufficient to poison them. The application of saline matter to the skin of

leeches, even in very small quantities, immediately occasions the expulsion of the contents of the stomach: hence a *few grains* of common salt are frequently sprinkled over them to make them disgorge the blood which they have swallowed. The frequent changing of the water in which leeches are kept is injudicious. Once a *month* in winter, and once a *week* in summer, is deemed sufficiently often by the large dealers, unless the water becomes discoloured or bloody, when it should be changed every day, or every other day. When *clean pond water* cannot be obtained, clean rain water that has been well exposed to the air should alone be employed. Mr. J. R. Kenworthy recommends placing in the water a few balls or irregular lumps of *pure clay*, about 2½ inches in diameter; a method which we can recommend as both simple and successful. The *plan* adopted by M. Fée, is as follows: —Place 7 inches of a mixture of *moss*, *turf*, and *charcoal* in a marble or stone trough, over which sprinkle some *small pebbles*. At one end of the trough, and about half way up, place a thin shelf of stone or marble, pierced with small holes, on which put first some *moss*, or portions of *marsh horse-tail* (equisetum palustre, — *Linn.*), and on this a *layer of pebbles* to keep it down; then pour in water sufficiently high just to moisten the moss and pebbles, put in the leeches, and tie over the mouth of the trough with a cloth.

Propag. According to Dr. Wagner, an annual feast on living blood is necessary to render leeches able to grow and propagate. These conditions can only be fulfilled by restoring to the breeding cisterns those which have been already employed. All artificial methods of feeding them by bladders or sponges of blood, have been found to fail. He recommends the employment of *two tanks*, with the bottom formed of *loam*, *clay*, or *turf*, surrounded by an inner border of a similiar substance, and an outer one of sand,—the *one* for leeches fit for medical use,—and the other for *breeding*, or for such leeches as have been applied. No leeches are to be taken from the breeding tank until a year has elapsed after their having been applied and fed with human blood; and their removal to the first tank should take place in September or October, as by this time the breeding season is over. By this plan all leeches that have been applied are to be carefully restored to the breeding tank, without making them disgorge the blood they have swallowed.

LEECHING. This consists in the application of leeches to any vascular part of the body, for the purpose of withdrawing blood from it, and thus allaying local inflammation, distension of vessels, &c. *Leeches* are most conveniently *applied* by means of a common pill-box or a wine-glass. The part should be previously washed perfectly clean, and if covered with hair should be closely shaved. Sometimes leeches are indisposed to bite; in such cases, allowing them to crawl over a piece of dry linen or calico, rolling them in porter, moistening the part with a little milk or sweetened milk, or drawing a little blood by a slight puncture or scratch, will usually make them bite freely. To *stop* the *bleeding* from *leech-bites*, various plans are adopted, among which the application of *nitrate of silver* or *creasote*, or gentle pressure for some hours with the finger, are the most successful. Of late years a piece of *matico leaf* or *soldier's herb*, applied in the same manner as a piece of lint, has been commonly adopted to stop the bleeding of leech bites.

LEEK. Syn. *Porrum*,— Lat. The *allium porrum* (Linn.) Its general properties are intermediate between those of the onion and garlic. The juice is said to be powerfully diuretic, and capable of dissolving phosphatic calculi.

LEGUMINE. Vegetable caseine.

LEMON. Syn. *Limo*,—Lat. The fruit of the *citrus limonum* or *lemon tree*. The *juice*, *peel*, and *essential oil* are officinal. (See *below*.)

LEMON ACID. See *Citric Acid*.

LEMON FLAVOUR. See *Culinary Essences*.

LEMON JUICE. Syn. *Succus Limonum*, —Ph. L. Lemon juice is refrigerant and antiscorbutic, and has long been extensively employed in the preparation of cooling drinks and effervescing draughts, which are justly esteemed as wholesome summer beverages, as well as palliatives in fevers, nausea, &c. In scurvy, there is no remedy equal to *freshly expressed* lemon juice; and in acute rheumatism and gout, according to the united testimony of Dr. Owen Rees, Dr. Babington, and numerous Continental practitioners, it has been exhibited with considerable success. In agues, dysentery, English cholera, nausea and vomiting, heartburn, putrid sore-throat, hospital gangrene, syphilis, and numerous skin diseases, it has proved most serviceable. Its action in most of these cases, especially in scurvy and gout, probably depends on the large quantity of potassa which it contains united to an acid which has only a feeble affinity for

the base; and which hence, readily parts with it in the body, whilst the acid undergoes a change in the organism, by which the formation of uric acid is lessened or prevented. Lemon juice, taken for several days, in very large quantities, is capable of rendering the urine alkaline. Of this no less than three cases have occurred within our knowledge; whilst in others in which the urine was unaffected, no relief was afforded by the juice. See *Citric Acid, Gout, &c,*

LEMON JUICE (Factitious). Syn. *Solutio Acidi Citrici, Succus Limonum Factitius,*—Lat. *Prep.* 1. *Citric acid,* 1¼ *oz.; carbonate of potassa,* 45 *gr.; white sugar,* 2½ *oz.; cold water,* 1 pint; dissolve, add the *yellow peel of a lemon,* and in 24 hours, strain through a hair-sieve or a piece of muslin.

2. As the last, but using 15 or 16 drops of *oil of lemon,* to flavour, instead of the lemon peel.

Obs. The above is an excellent substitute for lemon juice, and keeps well in a cool place. Tartaric acid, and even vinegar, are sometimes used instead of citric acid; but it is evident that it then loses all claim to being considered as an imitation of lemon juice, and to employ it in lieu of which would be absurd.

LEMON PEEL. Syn. *Cortex Limonum,*—Ph. L. "The *fresh* and the *dried* exterior rind of the fruit;" the latter dried "in the month of April or May." (Ph. L.) *Candied lemon peel* (*cortex limonum conditus*) is employed as a dessert, and as a flavouring ingredient by cooks and confectioners. It is reputed stomachic. See *Candies.*

LEMON PICKLE. See *Sauces, &c.*

LEMONADE. Syn. *Lemon Sherbet, King's Cup; Limonadum,*—Lat. *Prep.* 1. *Lemons* (sliced), 2 in no.; *sugar,* 2½ oz.; *boiling water,* 1½ pint; mix, cover up the vessel, and let it stand with occasional stirring until cold, then pour off the clear through a piece of muslin or a clean hair sieve.

2. *Juice of* 3 *lemons: yellow peel* of 1 lemon; *sugar,* ¼ *lb.; cold water,* 1 quart; digest for 5 or 6 hours, or all night, and decant or strain as before.

3. *Citric acid,* 1 to 1½ dr.; *essence of lemon,* 10 drops; *sugar,* 2 *oz.; cold water,* 1 pint; agitate together until dissolved.

Obs. Lemonade is a pleasant cooling summer beverage, and when made as above, may be drank in large quantities with perfect safety. It also forms an excellent refrigerant and antiseptic drink in fevers and putrid diseases generally. *Tartaric acid* is commonly substituted for citric acid from being cheaper. *Oxalic acid* has been used in the same way, but the liquor is thus rendered poisonous. *Lemonade* for *icing* is prepared as above, only using a little more sugar. *Orange Sherbet* or *Orangeade for Icing,* is made in a similar way from oranges.

LEMONADE (Aerated). Syn. *Limonadum Aeratum,*—Lat. *Limonade Gazeuse,*—Fr. *Prep.* 1. (P. Cod.) *Water,* charged with 5 times its volume of carbonic acid gas, 1 pint; *syrup of lemon,* 2 oz.; mix.

2. (*Without a bottling machine.*)—*a.* Into each bottle put *lemon syrup,* 1 to 1½ oz; *essence of lemon,* 3 drops; *sesquicarbonate of soda,* ½ dr.; *water,* q. s. to *nearly* fill the bottle; have the cork fitted and ready at hand, then add of *tartaric acid* (cryst.), 1 dr., *instantly* close the bottle, and wire down the cork; it should be kept inverted in a cool place, and preferably, immersed in a vessel of ice-cold water.

b. As the last, but substituting *lump sugar,* ¾ *oz.,* for the lemon syrup.

c. From *lump sugar,* 1 *oz.; essence of lemon,* 3 drops; *bicarbonate of potassa,* 25 gr.; *water,* q. s., as No. 1; then add *citric acid* (cryst.), 45 gr., and cork, &c., as before. The last is most wholesome, especially for the scorbutic, dyspeptic, gouty, and rheumatic.

Obs. The best aerated lemonade of the London makers is prepared by putting 1½ fl. oz. of rich *lemon syrup* into each bottle, which is then filled up with *aerated water* at the bottling machine.

LEMONADE (Antimoniated). Syn. *Limonadum Antimoniatum,*—Lat. *Prep.* By adding *tartar emetic,* 1 gr., to each pint of ordinary lemonade. *Dose.* A wine-glassful, every ½ hour or hour, as a diaphoretic and expectorant. See *Potassio-tartrate of Antimony.*

LEMONADE (Aperient). Syn. *Limonadum Laxativum,*—Lat. *Prep.* 1. *Sugar,* 1 *oz.; lemon juice,* ¾ *fl. oz.; sulphate of soda,* 3 dr.; *water,* 8 fl. oz.; put them into a soda-water bottle without shaking, have the cork ready fitted, add of *sesquicarbonate of soda* (in cryst.), ½ dr., and instantly cork the bottle, wire it down, and keep it in a cool place inverted. For a *dose.*

2. *Heavy carbonate of magnesia,* 1½ dr.; *refined sugar,* 1 *oz.; essence of lemon,* 5 or 6 drops; *water,* 8 fl. oz.; bottle as last, then add of *citric acid* (cryst.), 3 dr., and instantly cork, &c., as before. For a *dose.* It should be kept for at least 24 hours before being taken.

LEMONADE (Lactic). Syn. *Limonadum Lacticum*,—Lat. *Prep.* (Magendie.) *Lactic acid*, 1 to 4 dr.; *syrup*, 2 oz.; *water*, 1 pint; mix. Recommended in dyspepsia, &c.

LEMONADE (Milk). Syn. *Limonadum Lactis.* Take of *sugar*, ½ *lb.*; *water*, 1 pint; dissolve, add the *juice of* 3 *lemons*; *milk* or *whey*, ½ pint; stir the whole together and strain through a hair sieve. Some persons add a *glassful of sherry.*

LEMONADE (Mineral). On the Continent, under the name of *limonade minerale*, is included *water* acidulated with the *mineral acids* and sweetened with *sugar.* Thus we have *limonade chlorhydric, nitrique, phosphorique, sulphurique, &c.*, all of which are used as cooling drinks in fevers, inflammations, skin diseases, &c.

LEMONADE (Portable). See *Powders* and *Lemon Sugar.*

LEMONADE POWDERS. See *Powders, &c.*

LEMONATED KALI. See *Citrate of Potassa.*

LENITIVES. See *Laxatives.*

LENSES. A description of these articles belongs to a work on optics. It may, however, be useful to the chemical student to remark here, that the Coddington and Stanhope lenses, which may now be bought at any of the opticians, neatly mounted and of great power, for a few shillings, will be found of the greatest service in examining minute crystals, precipitates, &c.; and for all ordinary purposes offer a cheap and efficient substitute for more complicated microscopes. An extemporaneous instrument, possessing considerable power, may be made by simply piercing a small circular hole in a slip of metal, and introducing into it a drop of water, which then assumes a spherical form on each side of the metal while the latter is held in a horizontal position. The ingenious little *toy microscopes* sold about the streets of London under the form of a perforated pill-box, at one penny each, consist of such a lens made with *Canada balsam*, instead of water, which has the property of hardening without losing its transparency after exposure for a few hours to the air. A *still simpler substitute* for a lens, is a piece of *blackened card-paper* with the smallest possible needle-hole pierced through it. Any very small object held in a *strong light*, and viewed through this hole at the distance of about an inch, will appear quite distinct, and from 10 to 12 times larger than its usual size. We have often found this little instrument of incalculable service in situations and under circumstances in which a more powerful or complicated apparatus was unattainable or could not be applied.

LENTILS Syn. *Massoor; Lens Vulgaris.* The seeds of the *ervum lens* (Linn.; *lens esculenta*,—Mönch.), a plant of the natural order *leguminosæ.* Lentils resemble beans in their general properties, but are vastly inferior, and are reputed difficult of digestion, apt to disorder the bowels, and injurious to the eyes. They are chiefly cultivated as food for domestic animals. Such is the character of lentil seeds, yet, strange to say, the public have been now for years gulled with pretended preparations of them, vended at enormous prices as cures for dyspepsia, constipation, &c., and indeed, as *panaceas* that are capable of shortly removing disease and suffering from the world, and establishing a golden era in which the physician's vocation would be like "Othello's occupation"—"gone." *Nevill's Lentil Powder* is said to consist of *lentil flour*, 3½ *lb.*; *curry powder*, 1 *oz.* According to the 'Lancet,' the advertised article contains fully 1-3rd of its weight of *barley flour*, and in many cases consists entirely of *pea* or *bean flour*, mixed with ½ of its weight of the *flour of Indian corn*, with about 1 *oz.* of *common salt* to each *lb.* of the composition. See *Ervalenta* and *Revalenta.*

LEPROSY. Syn. *Lepra*,—Lat. A scaly eruption of the skin, characterized by patches of a circular form, and distinguished from the rashes and pimples by the alteration of the scarf-skin which covers the inflamed part. The cuticle becomes reddish and scaly; at first upon one spot, often the knee, and thence gradually spreads over the body, the parts attacked becoming stiff and uncomfortable, and generally, most disagreeable in appearance. By the time the patches reach the size of a shilling or half-a-crown, the scales usually fall off, and very frequently the surface looks red and angry, and remains bare until the eruption declines altogether. This variety is the "*lepra vulgaris*" of medical writers. The "*lepra alphos*," another variety, and one not uncommon in this country, is so named, because the patches when they cease to enlarge, after attaining a size about that of a sixpenny-piece, become depressed in the centre, and within the depression minute white powdery scales may be observed, whilst the surrounding border continues raised, and of the same red colour as at first. This variety usually commences at the elbow, but soon involves the fore-arm, and often the back of the hand. In the "*lepra*

nigricans," the colour of the patches is dark and livid, and their central portion is not depressed, as in lepra alphos. In other respects it resembles lepra vulgaris. In "*lepra guttata*" the appearance of the eruption is that of a number of drops of water hanging to the skin. The little scale increases in thickness by the addition of fresh layers to its under surface, and has a bright, silvery lustre, which is due to the extreme thinness of the layers of scarf-skin, and the sponginess of its texture. "The eruption does not, however, constantly retain its early spotted character; more frequently, the spots increase in dimensions, and spread out into the form of circular patches, having the size of a shilling, half-a-crown, or crown-piece. This enlarged growth naturally requires time; and in proportion to the period occupied in growth is the thickness of the laminated scale; the latter, however, never exceeds in thickness a piece of moderately thick paper, and always preserves its beautiful silvery aspect. There are no humours, no irregular unsightly crusts, no excoriated surfaces in this eruption; in fact, there is nothing repulsive; but, on the contrary, if it were the general, instead of being the exceptional, it would be thought very beautiful, and would become highly fashionable." (Eras. Wilson.)

The *treatment of leprosy* consists chiefly of frictions, and warm vapour or sulphur baths, followed by the use of slightly stimulating ointments or liniments, with a light but nutritious diet of fresh meat, vegetables, and fruit, and entire abstinence from wine, spirits, and internal stimulants generally. A course of sulphureous mineral waters is generally sufficient of itself to remove ordinary cases.

The administration of *solution of potassa*, or of *arsenite of potassa*, or *bichloride of mercury*, has also been recommended, and is often useful. Sir Alex. Crichton employed the decoction of the leaves and twigs of solanum dulcamara (*bitter sweet* or *woody nightshade*), in doses of 2 or 3 fl. oz. thrice a day, gradually increased until at least a pint a day was taken. This is declared by the editors of the Lexicon Medicum to be "one of the most effectual remedies for lepra, under all its varieties." In delicate and relaxed habits, especially in females, chalybeates have often been given with much advantage. Perhaps, however, of all others, the most active and certain remedy is Donovan's solution of hydriodate of arsenic and mercury (*liq. hydriod. arsen. et hydrarg.*)

Leprosy appears to have been of much more frequent occurrence in ancient than in modern times. It is often spoken of in Holy Writ, and it occupied the particular attention of the Jewish lawgiver. But it is generally believed that the lepers mentioned by both the sacred and profane historians, were afflicted with a disease more nearly resembling the *elephantiasis* of modern writers, than leprosy.

LEROY'S VOMITIF-PURGATIF. *Prep.* Take of *tartar emetic* (in fine powder), 1 dr.; *white wine*, ½ pint; *sugar candy*, q. s. to colour; dissolve, and label the bottle "*Vomitif.*" Next dissolve of *resin of jalap*, 7 dr., in *rectified spirit*, ½ pint; and label the bottle "*Purgatif.*" A popular nostrum in France, but its use requires caution.

LETHARGY. Syn. *Lethargus*,—Lat. A heavy unnatural sleep, sometimes bordering upon apoplexy, with scarcely any intervals of waking, from which the patient is with difficulty aroused, and into which he again sinks as soon as the excitement is withdrawn. It frequently arises from plethora, in which case depletion is indicated; or from the suppression of some usual discharge or secretion, which it should then be our business to re-establish. It also often arises from over mental fatigue, and nervous debility, when relaxation from business, the use of a liberal diet, and ammoniacal stimulants and antispasmodics, are found useful. When depending on a determination of blood to the head, cupping may be had recourse to, and all sources of excitement avoided. In all cases the bowels should be moved as soon as possible by means of mild purgatives.

LETTUCE. Syn. *Lactuca*,—Lat. The early leaves or head of the *lactuca sativa* (Linn.) or *garden lettuce*, form a common and wholesome salad. They are reputed slightly anodyne, laxative, hypnotic, and antaphrodisiac, and have been recommended to be eaten at supper by those troubled by watchfulness, and in whom there exists no tendency to apoplexy. The "flowering herb" (*lactuca*) is officinal in the Ph. L.; the "inspissated juice," in the Ph. E.; and the "inspissated juice" and "leaves," in the Ph. D. The "inspissated juice" of *lactuca virosa* (Linn.) or *strong-scented wild lettuce*, is also officinal in the Ph. E.; and both the "leaves" and "inspissated juice" of the same variety are ordered in the Ph. D. The last species is more powerful than the cultivated lettuce. See *Extracts* and *Lactucarium*.

LEUCINE. M. Braconnot has given this name to a white pulverulent substance, obtained by the action of *dilute sulphuric*

acid on *muscular fibre*. It is also obtained when *albumen*, *fibrine*, or *caseine*, are boiled in a *concentrated solution of potassa* as long as ammoniacal vapours are evolved; the liquid neutralized with *ammonia*, gently evaporated to dryness, and the residuum exhausted by *boiling alcohol*, furnishes a mixed solution of *protide*, *erythroprotide*, and *leucine*. The last is a crystallizable substance, forming small scales or lamellæ, which are colourless, tasteless, odourless, volatile when heated, soluble in both water and alcohol, and in oil of vitriol without decomposition. With nitric acid, it forms *nitroleucic acid*.

LEUCOLINE. See *Chinoleine*.

LEUCORRHŒA. Syn. *Fluor Albus*,—Lat. The *symptoms* of this disease, popularly called the "*whites*," are well known to most adult females. The common *causes* are debility, a poor diet, excessive use of hot tea, profuse menstruation or purgation, late hours, immoderate indulgence of the passions, frequent miscarriages, protracted or difficult labours, or local relaxation. Occasionally it is symptomatic of other affections. The *treatment*, must be directed to the restoration of the general health, and imparting tonicity to the parts affected. Tepid or sea bathing, or shower baths; bark, chalybeates, and other tonics; with *local affusions* of *cold water*, and *mild astringent injections*, as those of *black tea* or *oak bark*, are generally found successful in ordinary cases.

LEUKOL. A substance, accompanied by *kyanol*, separated from *coal-oil* by agitating large quantities of that liquid with *hydrochloric* or *dilute sulphuric acid*, and then distilling the acid along with *caustic potassa* or *quicklime*, in excess. The mixed product is separated into its component substances by distillation. Recent researches have shown leukol to be identical with *chinoleine*.

LEVANT NUT. See *Cocculus Indicus*.

LEVIGATION. Syn. *Levigatio*,—Lat. The process of reducing substances to *fine* powder, by making them into a paste with water, and grinding the mass upon a hard smooth stone or slab, with a conical piece of stone having a flat, smooth, undersurface, called a "*muller*." Levigation is resorted to in the preparation of paints on the small scale, and in the elutriation of powders. The term is also, sometimes, incorrectly applied to the lengthened trituration of a substance in a marble or wedgewood-ware mortar.

LEVORACEMIC ACID. See *Racemic Acid*.

LIBAVIUS'S LIQUOR. See *Bichloride of Tin*.

LICHEN. A dry papulous or pimply eruption of the skin, terminating in scurfy exfoliations. "*Lichen* exhibits great variety in its outward characters in different individuals; in *one*, the pimples are brightly red; in *another*, of debilitated constitution, they are bluish and livid; in a *third*, they are developed around the base of hairs; in a *fourth*, they appear as circular groups, and increase by their circumference, while they fade in the centre, forming so many rings of various size; in a *fifth*, a modification of the preceding, they have the appearance of flexuous bands; while in a *sixth*, they are remarkable for producing intensity of suffering, or unusual disorganization of the skin. They are all *occasioned* by constitutional disturbance, sometimes referable to the *digestive*, and sometimes to the *nervous system*. In some instances, however, they depend upon a *local cause*. I have had a crop of lichenous pimples on the backs of my hands from rowing in hot weather; and in hot climates that annoying disorder called *prickly heat* is a lichen." (Eras. Wilson.) The *treatment* of this affection is noticed under "*Eruptions* (Papular)."

LICHEN GUM. A strained *infusion* or *decoction* of several species of *lichen*, evaporated to dryness. It closely resembles gum arabic. 1 cwt. of *lichen coralloides* yields 14 *lb.*; of *lichen esculentus*, about 13 *lb.* (Gray.) See *Gum*.

LICHENIC ACID. An acid compound first noticed by Pfaff in Iceland moss. According to Brande it is identical with malic acid; but others who have examined it represent it as fumaric acid.

LICHENINE. Syn. *Lichen Starch*. A species of starch extracted from Iceland moss.

LICHENS. *Lichenes*,—Juss. *Lichenales*,—Lind. These are *cryhtogamous plants* which appear under the form of thin, flat crusts, covering rocks and the barks of trees. Some of them, like Iceland moss, are esculent and medicinal, and employed either as medicine or food; and others, when exposed in a moistened state to the action of *ammonia*, yield purple or blue colouring principles, which, like indigo, do not pre-exist in the plant. Thus, the *rocella tinctoria*, the *variolaria orcina*, the *lecanora tartarea*, &c., when ground to a paste with water, mixed with putrid urine or solution of carbonate of ammonia, and left for some time freely exposed to the air, furnish the *archil*, *litmus*, and *cudbear* of

commerce, very similar substances, differing chiefly in the details of their preparation. From these the colouring matter is easily extracted by water or very dilute solution of ammonia. See *Archil*, *Cudbear*, and *Litmus*.

LIFE. Syn. *Vita*,—Lat. Life is only a general term expressive of the power by which the vital phenomena are produced. Treviranus, following in the footsteps of Needham and Buffon, asserts that there is in nature a matter which is ever moving, by which all living beings, animal and vegetable, possess life, and which, though immutable in its essence, is notwithstanding, variable in its form, and is incessantly changing it: that this matter or essence is deprived of form itself, but nevertheless ready to take that which we denominate *life;* that it maintains a determinate form under the influence of external causes; that it only continues in that form so long as these causes are active, and it takes another as soon as new causes influence it: that the matter capable of life, and the living principle, exist reciprocally, and that death is only a passage of certain forms of this matter or essence to certain others, which may resemble it in character, or be absolutely different. The researches of De Blainville and Tiedemann, demonstrate that life, as far as our limited knowledge extends, is a power of reaction, modified in every part according to its texture, and called into operation in each texture by appropriate and peculiar stimuli. The consideration of these questions belongs to physiology and philosophy, and their solution is a task which will probably never be accomplished by man.

LIGATURE. A small waxed piece of cord or string formed of silk or thread, employed for the purpose of tying arteries, veins, and other parts, to prevent hæmorrhage, or to cause their extirpation. To be safe and useful, they should be round, smooth, and sufficiently strong to permit of being tied with security without incurring the danger of breaking or slipping. There are many cases recorded in which emigrants, soldiers, and travellers have lost their lives, from the simple inability of those around them to apply a ligature.

LIGHT. Syn. *Lumen*, *Lux*, — Lat. Light acts as a vivifying or vital stimulus on organized beings; just as privation of light, or darkness, disposes to inactivity and sleep. "In maladies characterised by imperfect nutrition and sanguinification, as scrofula, rickets, and anæmia, and in weakly subjects with œdematous (dropsical) limbs, &c., free exposure to solar light is sometimes attended with very happy results. Open and elevated situations probably owe part of their healthy qualities to their position with regard to it." On the contrary, "in diseases of the eye attended with local vascular or nervous excitement, in inflammatory conditions of the brain, in fever, and in mental irritation, whether attended or not with vascular excitement, the stimulus of light proves injurious, and, in such cases, darkness of the chamber should be enjoined. After parturition, severe wounds, and surgical operations, and in all inflammatory conditions, exclusion of strong light contributes to the well-doing of the patient." (Pereira, *Elem. Mat. Med.*, *&c.*, i, 8-9.)

LIGHT (Artificial). Some interesting matter connected with this important subject will be found under the heads, *Gas*, *Illumination*, *Lamp*, *Photometry*, *&c.* Dr. Ure asserts that "by *narrowing* the top of a long glass chimney over an argand flame either from oil or coal gas, the light could be doubled, at the same cost of material. The very tall chimneys used by the Parisian lampists are very wasteful. I find that with a narrow chimney of *half* the length of theirs, I can have as good a light, and save 30 per cent. of the oil." A few years since Faraday demonstrated the fact, that by *widening* the *top* of a lamp chimney, a similar result was obtained.

TABLE *showing the relative cost of the same amount of light obtained from different sources referred to a common standard. Prepared expressly for this work.*

Rayner & Carter's paragon camphine lamp . .	2
Young's vesta . . .	2

It appears from calculation, that two wax candles in burning vitiate the atmosphere of a room to an equal degree with the respiration of an averaged-sized man. The effect of tallow candles affording the same light is rather greater; whilst gas, from the impurities it is commonly loaded with, may be regarded to vitiate the air fully *four* times as fast as wax candles. According to Dr. Ure, "when a *tallow candle* of 6 to the *lb.* is not snuffed, it loses in intensity, in 30 minutes, 80% ; and in 39 minutes, 86% ; in which *dim state* it remains *stationary*, yet still consuming nearly the same proportion of tallow."

LIGHT (Bude). This name was originally given to a *gas* or *oil lamp*, supplied with a current of *oxygen gas*. It has since been applied to the concentric argand burner patented by Mr. Gurney.

LIGHT (Drummond). This is produced by directing a stream of *oxygen gas*, passing through the flame of a *spirit lamp*, upon a small *ball* of *quicklime* of about ¼ inch in diameter. Such is the intensity of this light, that when placed in the focus of a parabolic mirror, it has been distinctly seen at the distance of 60 miles.

LIGHT (Instantaneous). See *Matches, &c.*

LIGHT (Oxyhydrogen). This resembles the last in intensity. It is produced by directing the flame of the *oxyhydrogen blowpipe* on a piece of *quicklime*.

LIGNINE. Syn. *Cellulose*. This is woody fibre deprived of all foreign matter. It forms about 95% of baked wood, and constitutes the woody portion of all vegetable substances. Fine linen and cotton are almost entirely composed of lignine, the associated vegetable principles having been removed by the treatment the fibres have been subjected to during the process of their manufacture.

Pure lignine is tasteless, inodorous, insoluble in water and alcohol, and absolutely innutritious; dilute acids and alkaline solutions scarcely affect it, even when hot; oil of vitriol converts it into dextrine or grape sugar, according to the mode of treatment. When *concentrated sulphuric acid* is added *very gradually* to about half its weight of *lint*, *linen rag*, *old cordage*, or any similar substance shreded small, and contained in a glass vessel, with constant trituration, the fibres gradually swell up and disappear, without the disengagement of any gas, and a tenacious mucilage is formed, which is entirely soluble in water. If, after a few hours, the mixture be diluted with *water*, the acid neutralized by the addition of *chalk*, and, after filtration, any excess of lime thrown down by the cautious addition of a *solution of oxalic acid*, the liquid yields, after a second filtration, and the addition of *alcohol*, in considerable excess, a gummy mass, which possesses all the characters of *pure dextrine*. If, instead of at once saturating the diluted acid solution with chalk, we boil it for 4 or 5 hours, the dextrine is entirely converted into *grape sugar*, which, by the addition of *chalk* and filtration, as before, and evaporation by a gentle heat to the consistence of a syrup, will, after repose for a few days, furnish a concrete mass of crystallized sugar. By strong pressure between folds of porous paper or linen, redissolving it in *water*, agitation with *animal charcoal*, and recrystallization, brilliant colourless crystals of *grape sugar* may be obtained. Hemp, linen, or cotton, thus treated, yield fully their own weight of gum, and 1⅛ of their weight of grape sugar. During the above transformation, the sulphuric acid is converted into *ligno-sulphuric acid*, and may be procured in a separate state. Strong nitric acid dissolves *sawdust*, and when the solution is diluted with *water*, a white insoluble powder (*xyloidine*) is deposited, which explodes when heated. (Robiquet.)

LIGNONE. Syn. *Xylite*. A light inflammable fluid, obtained with other products during the destructive distillation of wood. According to Berzelius, it is a mixture of pyroxilic spirit and acetate of methyle.

LIGNO-SULPHURIC ACID. Syn. *Sulpholignic Acid*. See *Lignine*.

LIGNUM VITÆ. See *Guaiacum Wood*.

LILAC DYES. These are modifications of violets or purples. See *Dyeing, &c.*

LILACINE. Syn. *Lilacina, Syringine.* A bitter crystallizable principle obtained from the *syringa vulgaris* (Linn.) or *common lilac.*

Prep. (M. Meillet.) The *leaves*, or, preferably, the *seed-vessels of syringa vulgaris*, are bruised, boiled twice with *water*, the mixed decoction is evaporated to one-half, and *basic acetate of lead* is added; the liquor is next evaporated to a syrup, and treated with *calcined magnesia*, in excess; the whole is then dried, pulverized along with a little *carbonate of magnesia*, digested in water at about 100° Fahr., and the undissolved portion treated with *boiling rectified spirit.* The solution thus obtained is decoloured with *animal charcoal*, filtered, evaporated to one-half, and placed aside; the *lilacine* crystallizes out as the spirit cools.

Prop., &c. Lilacine forms white fasciculi of acicular crystals, or prisms; it has a bitter taste, and is insoluble in water and many acids. (Jour. de Pharm. 1842.) It is tonic and febrifuge, and has been proposed as a substitute for quinine.

LIME. Syn. *Oxide of Calcium, Protoxide of do.; Calcii Oxydum, &c.*—Lat. *Calx*, —Ph. L. E. & D. An oxide of calcium, obtained by exposing limestone or chalk, which are carbonates of lime, to a red heat. The substance thus obtained is called *quicklime, caustic lime, burnt lime*, or "*stone lime*," (*calx viva, c. usta, c. u. recens.*) When water is sprinkled on quicklime it becomes very hot, and crumbles down into a dry white powder, which is "*hydrate of lime*," (*calcis hydras, calx extincta,*) popularly known as "*slaked*" or "*slacked lime.*" Oyster-shells, and other fish-shells, are also converted into quicklime by burning, which are then called "*shell lime*," (*calx è testis*,—Ph. L. 1824.) *Milk of lime* is slaked lime mixed up with water, as in the preparation of common "*whitewash.*"

Prep. Lime is included in the Materia Medica of the present Ph. L.; by which we should infer the quicklime of commerce is intended, did not the college add "*freshly prepared from chalk.*" In the Ph. L. 1836, both commercial lime, and lime prepared by burning *chalk*, broken into small pieces, for 1 hour, in a "very strong fire," are ordered. The Ph. E. directs small fragments of *white marble* to be placed "in a covered crucible, and kept at a full red-heat for 3 hours, or until the residuum, when slaked and suspended in water, no longer effervesces on the addition of muriatic acid." *Iceland spar, white Carrara marble*, and the *black bituminous marble* of Derbyshire or Kilkenny, yield nearly pure lime by calcination. *Perfectly pure lime* can only be obtained by heating to whiteness, in a platinum crucible, a *carbonate of lime* prepared by precipitating *nitrate of lime* with *carbonate of ammonia.*

Prop. Pure lime has a sp. gr. of about 2·3; it is highly acrid, alkaline, and caustic, and rapidly destroys organic matter in the presence of moisture; it is soluble in 635 parts of water at 32°, but requires 778 parts at 60°, 972 parts at 130°, and 1270 parts at 212° Fahr. for its solution, (Wollaston); a pint of water at 32° dissolves 13·25 gr.; at 60°, 11·6 gr.; and at 212°, 6·7 gr. (Phillips); hence, the propriety of employing *cold water* for the solution of lime; exposed to the air, it rapidly attracts carbonic acid, and passes into the state of carbonate (*chalk*); when strongly heated it becomes phosphorescent, and emits a brilliant light; and on this account is sometimes employed for illumination, as in the *Gurney*, or *Lime Light.* Lime readily unites with the acids, and forms salts, nearly all of which may be made by directly neutralizing the acid with *hydrate* or *carbonate of lime.* They may also be made by double decomposition.

Pur. "Water being added, it crumbles into powder. It is (entirely) dissolved by dilute hydrochloric acid, without effervescence. Ammonia being added to this solution, in excess, throws down nothing." (Ph. L.)

Tests. 1. The alkaline carbonates, phosphates, oxalates, and sulphates occasion white precipitates in solutions of lime. The precipitates produced by the *first three* tests are soluble in dilute nitric and hydrochloric acid; that by the *last* is insoluble in those menstrua, but soluble in a solution of common salt, and is not reprecipitated by dilute sulphuric acid. (Wackenroder.) *Oxalate of ammonia* is the most delicate test for lime. If the substance under examination is a solid, it must be dissolved by digestion in hydrochloric acid, the resulting solution filtered, evaporated to dryness, the residuum redissolved in water, and the new solution tested as above.—2. Caustic potassa and ammonia, perfectly free from carbonic acid, do not disturb solutions of the salts of lime.—3. All the soluble salts of lime tinge the flame of alcohol of an orange colour; but this may be confounded with the colour produced by the salts of strontia.

Lime, in solution, is distinguished from *baryta* by *not* being precipitated by hydro-

fluosilicic acid;—from *strontia*, by not being precipitated by neutral chromate of potassa;—from *alumina* and *magnesia*, by the comparative insolubility of its sulphate; and from both baryta and strontia, by the liquid being unaffected by a solution of sulphate of lime, and yielding, in weak solutions, a white precipitate with oxalate of ammonia, after the removal of those earths (if present) by the cautious addition of a solution of sulphate of potassa.

Estim.—1. The lime may be thrown down by *oxalate* or *carbonate of ammonia*, and the precipitate washed, dried, calcined, and weighed. Each grain is equivalent to 0·5629 gr. of pure lime.—2. The washed precipitated as last, is calcined with excess of sulphuric acid, which converts it into sulphate of lime. In this case each gr. represents 0·41176 gr. of lime.—3. When mixed with alumina, baryta, or magnesia, the plan noticed under Glass (see *p.* 525) must be had recourse to.

Uses. Lime is corrosive, antacid, and depilatory. It is employed in *surgery* as a caustic, and in *chemistry* and *pharmacy* to make lime water, to render the alkalies caustic, to make several calcareous salts, abstract water from various substances, &c. It is largely used to make mortars and cements, and as a manure in *farming*, *&c.* In large doses it is poisonous. The *antidotes* are, water acidulated with vinegar or lemon juice, and demulcents.

LIME (Acetate of). Syn. *Calcis Acetas*,—Lat. *Prep.* 1. *Acetic acid* is neutralized by *prepared chalk*, and the filtered solution, evaporated by a gentle heat, and allowed to crystallize. Very soluble. *Dose.* 10 to 20 gr.; as a diuretic in dropsies, &c.

2. See *Pyrolignite of Lime.*

LIME (Carbonate of). A white powder, insoluble in water, but freely soluble in water holding carbonic acid in solution, which thus becomes temporarily hard. By boiling, the carbonic acid is expelled, and the carbonate again precipitated. See *Chalk*, *Limestone*, *Marble*, *&c.*

LIME (Chloride of). See *Hypochlorite of Lime.*

LIME (Chromate of). Syn. *Calcis Chromas*,—Lat. This salt is now used in large quantities as a source of chromic acid.

Prep. (Chas. Watt, jun.) The *residual liquor of the process of bleaching with chromic acid*, which is rich in oxide of chromium, is placed in a wooden vessel, and *slaked lime* is cautiously added until the sulphuric or hydrochloric acid present is saturated, carefully avoiding excess, as oxide of chromium would be then precipitated; after an hour's repose the clear portion is decanted, and finely *slaked lime* added, with constant agitation, until all the oxide is thrown down; known by the liquor becoming clear when allowed to settle; after sufficient repose, the liquid portion is decanted, the precipitate is washed with *clean water*, and drained; the residual mixture of *oxide of chromium* and *lime* is then placed about 2 inches thick upon a large flat iron plate set evenly over a fire, and turned every half hour until the process of roasting is completed, and the whole is converted into *chromate of lime*, which is known by the mass assuming a yellow colour, instead of the grayish one which it previously possessed; during the operation, care must be taken not to employ too much heat, as the product is readily decomposed, and assumes a green colour, in which case it is rendered useless. See *Chromic Acid.*

LIME (Hydrate of). See *above.*

LIME (Hydrochlorate of). See *Chloride of Calcium.*

LIME (Hypochlorite of). Syn. *Bleaching Powder*, *Chlorinated Lime*, *Chloride of do.*, *Chlorite of do.*; *Calcis Hypochloris*; *Calx Chlorinata*,—Ph. L. & E. *Chloruret of Lime*, *Oxymuriate of do.*, *Calcis Oxymurias*, *Calcaria Hypochlorosa*, *Subchloris Calcicus*, —Obs. The precise constitution of this compound is still undetermined, but it is now generally conceived that the characteristic properties of this substance, as well as of the corresponding preparations of potassa and soda, depend on the presence of hypochlorous acid, a substance as remarkable for its bleaching powers and chemical activity as chlorine itself. This opinion is borne out by the discovery of M. Gay-Lussac, that when the bleaching chlorides are distilled along with sulphuric or nitric acid, in quantity insufficient to decompose the whole, *hypochlorous acid* is evolved; but where the acid is added in excess, chlorine alone is disengaged. (*Ann. Chim. et Phys.*)

Prep. 1. (Ph. L. 1836.) *Hydrate of lime* is thinly spread out in a proper vessel and exposed to an *atmosphere* of *chlorine gas* until it is saturated. In the present Ph. L., it is included in the Materia Medica.

2. (M. Labarraque.) *Hydrate of lime* (fresh), 20 parts; *common salt*, 1 part; are mixed together and the powder placed in long earthenware vessels into which *chlorine* is passed until the mixture begins to grow damp, or until one part of it dissolved in 130 parts of *water*, is capable of

decolouring 4½ parts of *sulphate of indigo*, when the whole is transferred to dry bottles.

3. (*Wholesale.*) The *chlorine* is generated from the usual materials mixed in *leaden vessels*, heated by steam, and the gas, after passing through *water*, is conveyed by a *leaden tube*, into an apartment built of *silicious sandstone*, and arranged with *shelves* or *trays*, containing dry *fresh slaked lime*, placed one above another, about an inch asunder. The process, to produce a *first-class article*, is continued for 4 or 5 days. During this time the lime is occasionally agitated by means of iron rakes, the handles of which pass through *boxes of lime* placed in the walls of the chamber, which thus act as valves.

Prop., &c. "It is soluble in dilute hydrochloric acid, emitting chlorine." (Ph. L.) "Pale grayish white; dry; 50 gr. are nearly all soluble in 2 fl. oz. of water, forming a solution of the density of 1·027, and of which 100 measures, treated with an excess of oxalic acid, give off much chlorine, and if then boiled, and allowed to rest for 24 hours, yield a precipitate which occupies 19 measures of the liquid." (Ph. E.) Good chloride of lime contains on the average from 32% to 36% by weight of chlorine, of which, however, not more than 25% to 30% are available or capable of being easily liberated by an acid.

Tests. It is recognized by the above properties, and by its power of destroying vegetable colours. When heated it evolves oxygen gas, together with a little chlorine.

Estim. See *Chlorimetry.*

Uses. Chloride of lime is employed in *medicine* as an antiseptic and disinfectant. An ointment of chloride of lime has been used in scrofula (Cima), and a lotion or bath, moderately dilute, is one of the cleanest and readiest ways of removing the *itch*, and several other skin diseases. As a *disinfectant*, it may be used either in substance or solution. A small quantity of the powder spread on a flat dish or plate, and placed on the chimney piece, and a like quantity in an opposite part of the room, will continue to evolve sufficient chlorine or hypochlorous acid to disinfect the air of an apartment for several days. The evolution of chlorine is promoted by occasionally renewing the exposed surface, by stirring it with a piece of stick, and after it becomes scentless, by the addition of a little acid, as *strong vinegar*, or *spirits of salts* or *oil of vitriol*, largely diluted with *water*. The most extensive consumption of chloride of lime is, however, for bleaching textile fabrics. When employed for this purpose, the goods are first immersed in a *dilute solution* of this compound, and then transferred to a vat containing *dilute sulphuric acid*. The chlorine thus disengaged in contact with the cloth, causes the destruction of the colouring matter. This process is generally repeated several times, it being unsafe to use strong solutions. *White patterns* may thus be imprinted upon coloured cloth; the figures being stamped with *tartaric acid thickened with gum-water*, the stuff is immersed in the chloride bath, when the parts to which no acid has been applied remain unaltered, while the printed portions are bleached white.

Concluding Remarks. Chloride of lime is now scarcely ever made on the *small scale*, as it can be purchased of the large manufacturer of better quality and cheaper than it could possibly be made by the druggist. Messrs. Tennants, of Glasgow, are the largest manufacturers of this article in the United Kingdom. Berzelius and Balard, the two best authorities on the subject, regard this substance as consisting of *hypochlorite of lime*, *chloride of calcium*, and *water*. The only *secret* in the manufacture of good bleaching powder is maintaining the temperature of the ingredients rather low.

Keller has proposed chloride of lime as a source of oxygen gas. 1 *oz.* of this substance boiled in about 4 fl. oz. of *water*, furnish about 340 cubic inches of OXYGEN; and with the addition of ½ its weight of *black oxide of manganese*, considerably above 500 cubic inches, by the same treatment. The gas is contaminated with some chlorine, from which, however, it is easily freed.

LIME (Lactate of). Syn. *Calcis Lactas*, —Lat. See *Lactic Acid.* It has been recommended in stomach affections, accompanied with heartburn and acidity.

LIME (Muriate of). See *Chloride of Calcium.*

LIME (Oil of). See *Chloride of Calcium.*

LIME (Oxalate of). Syn. *Calcis Oxalas*, —Lat. A white powder, *insoluble* in acetic acid, *easily* soluble in nitric acid. A red heat converts it into carbonate of lime. See *Oxalic Acid.*

LIME (Oxymuriate of). See *Hypochlorite of Lime.*

LIME (Phosphates of). There are several distinct compounds of lime and phosphoric acid, but only two are of any practical importance. They are all insolu-

ble in water, but dissolve readily in dilute acids, even the acetic.

1. *Bone Phosphate of Lime, Tribasic do., Subphosphate of do.; Calcis Subphosphas, C. Triphosphas, &c.*, Lat.—*a.* (*Bone ash, bone earth; terra ossium, ossa calcinata*,—Lat.) From *bones* calcined in contact with the air, until the whole of the carbonaceous matter is destroyed. It consists of tribasic phosphate of lime, mixed with a little carbonate and a trace of sulphate of lime. (See *page* 148.)

b. Precipitated phosphate of lime; calcis phosphas præcipitatum,—Ph. D. *Bone ash* (in powder), 4 *oz.*; *hydrochloric acid*, 6 fl. oz.; diluted with *water*, 1 pint; digest 12 hours, filter, add to the filtrate, *water*, 1 pint, and precipitate the solution with *solution of ammonia*, 11 fl. oz., or q. s. to render the liquid slightly alkaline; lastly, collect the precipitate on a calico filter, well wash it, and dry it by exposure to a warm atmosphere. *Dose.* 10 to 30 gr., twice or thrice a day, either alone or combined with saccharine carbonate or sesquioxide of iron; in rickets, ulcers, fractures, &c.

2. *Superphosphate of Lime, Biphosphate and Sulphate of do.; Calcis Superphosphas*, —Lat. *Prep.* From *burnt bones* (crushed small), 2 parts; *oil of vitriol*, 1 part; *water*, 3 parts; mix, and macerate together for some days, frequently stirring. Mixed with water, dry earth, or sand, it forms an excellent manure. See *Bone Dust* and *Manures.*

LIME (Pyrolignite of). This is impure *acetate of lime* made with *crude pyroligneous acid.* By exposing it to a heat insufficient for its decomposition, much of the tar and empyreumatic matter is destroyed or rendered insoluble. It is used to make *crude acetic* or *pyroligneous acid*, and *acetate* or *pyrolignite of lead.*

LIME (Sulphate of). Syn. *Calcis Sulphas*,—Lat. This compound exists native in *gypsum* and *selenite*, and when baked or deprived of water by roasting, forms the substance popularly known as *plaster of Paris.* Its applications in this form are well known. It is soluble in about 500 parts of water, and in a much less quantity of water holding chloride of sodium, sal ammoniac, or nitre in solution. The solution, in all cases, is precipitated by alcohol. It is this substance which imparts *permanent hardness* to *spring* and *river water.*

LIME (Sulphuret of). See *Sulphuret of Calcium.*

LIME (Tartrate of). Syn. *Calcis Tartras*, —Lat. Insoluble in water. See *Tartaric Acid.*

LIMES. The *fruit* of *citrus acida* (Roxburgh; *C. lima*,—Macfadyen) or *lime tree.* For the most part they resemble lemons. The juice (*lime juice, limetta do.*,) is, however, much more acid, and when undiluted, is said to be even acrid.

LIMESTONE. The value of *chalk, limestone, marble, &c.*, for hydraulic mortars and cements may be determined as follows:—

1. A given weight (say 100 gr.) of the sample is reduced to powder and digested in *hydrochloric acid* diluted with about an equal weight of *water*, with frequent agitation for an hour or longer; the mixture is then diluted with thrice its volume of *water*, thrown upon a filter, and the undissolved portion washed, dried, ignited, and weighed. This *weight* indicates the *per centage* of CLAY and SILICA or SAND; and the *loss* that of the LIME, MAGNESIA, and IRON present in the substance examined. In most cases these results will be sufficient to show the quality of the limestone for the purpose of making mortar or cement.

2. The *filtrate* and the *washings* are mixed together, and *ammonia* is added in excess; the bulky, reddish-brown precipitate, is collected, washed, dried, ignited, and weighed. This gives the *per centage* of SESQUIOXIDE OF IRON.

3. The *filtrate, &c.*, from (2) is then treated with *oxalate of ammonia*, and the quantity of LIME determined in the manner described at *page* 693.

4. The *liquid filtered* from the precipitate in (3) is boiled for some time with *carbonate of potassa* until ammoniacal fumes are no longer evolved; the precipitate is then collected on a filter, washed with hot water, dried, and *strongly* ignited for 3 or 4 hours, and lastly, weighed. This gives the *per centage* of MAGNESIA.

5. The respective proportions of *caustic lime* and *carbonate of lime* or *chalk* in a mixture of the two, are determined as follows:—

a. 100 gr. of the *sample for examination* are mixed with 200 gr. of *sal ammoniac*, both in fine powder, and the mixture is treated as described under *Guano* (p. 548, 2 *a*, or 2 *b*). The weight of *ammonia*, thus found, multiplied by 1·65, the product deducted from 100, and the difference multiplied by 2·273, gives the *per centage* of CHALK (nearly). Or—

b. 100 gr. of the sample are tested in the *alkalimeter* of Fresenius and Will, described at *page* 42, and figured at *p.* 19. The car-

bonic acid evolved, in grains, multiplied by 2·273, gives the *per centage* of CHALK, as before. The difference between this *weight* and 100, indicates the *per centage* of QUICKLIME.

LINCTUS. Syn. *Looch, Lohoch, Linc-ture, Lambative; Elegma, Illinctus, &c.* A medicine of the consistence of honey, intended to be licked off a spoon. This form of medicine is well adapted to females and children, but is not much used in England at the present time. Those employed in modern pharmacy and prescribing are included under the heads *Confections, Conserves,* or *Electuaries.* The *dose,* when it is not otherwise stated, is a tea-spoonful occasionally.

LINCTUS (Cacao). Syn. *Linctus Cacao, Lohoch C.,*—Lat. *Créme de Tronchin,*—Fr. *Prep.* From *cocoa-nut butter,* 2 oz ; *white sugar* (in powder), *syrup of capillaire,* and *syrup of tolu,* of each, 1 oz.; mix. Demulcent and pectoral; in coughs, sore throats, hoarseness, &c.

LINCTUS (Common). Syn. *Lohoch Commune,*—Ph. E. 1744. *Prep.* From *oil of almonds* and *syrup of tolu,* of each, 1 oz.; *powdered white sugar,* 2 dr. As the last.

LINCTUS (Cough). Syn. *Linctus Pectoralis,*—Lat. *Prep.* (Dr. Latham.) *Compound ipecacuanha powder* (Dover's powder), ½ dr.; *compound tragacanth powder,* 2 dr.; *syrup of tolu, confection of hips,* and *simple oxymel,* of each, 1 oz. *Dose.* 1 tea-spoonful, 3 or 4 times a day. "This linctus has been extensively used, as a remedy for coughs, in the West-end of London, having been found to be a safe and generally efficacious remedy." (Redwood.) The preceding as well as the following are also useful preparations.

LINCTUS (Demulcent). Syn. *Linctus Demulcens,*—Lat. *Lohoch de Tronchin,*—Fr. *Prep.* From *oil of almonds, syrup of capillaire, manna,* and *cassia pulp,* of each, 2 oz.; *powdered gum tragacanth,* 20 gr.; *orange-flower water,* 2 fl. oz. As the last. The above is the quantity for two days, which is as long as it will keep.

LINCTUS (Emollient). Syn. *Oily Emulsion; Lohoch Oleosum, Emulsio Oleosa,*—Lat. *Looch Huileux,*—Fr. *Prep.* (P. Cod.) *Oil of almonds, powdered gum,* and *orange-flower water,* of each, 4 dr.; *syrup of marshmallow,* 1 oz.; *water,* 3 fl. oz. or q. s.; for an emulsion. In troublesome coughs.

LINCTUS (Expectorant). Syn. *Linctus Expectorans, Lohoch E.,*—Lat. *Prep.* 1. *Oxymel of squills, confection of hips, syrup of marshmallows,* and *mucilage of gum arabic* (thick), equal parts. Demulcent and expectorant.

2. (Dr. Copland.) *Oil of almonds* and *syrup of lemons,* of each, 1 fl. oz.; *powdered ipecacuanha,* 6 gr.; *confection of hips,* 1 oz.; *compound powder of tragacanth,* 3 dr.

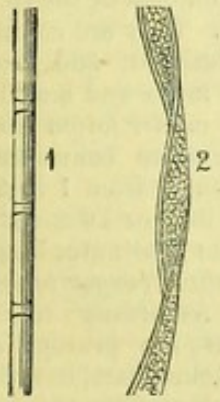
3. (Zanetti.) *Kermes mineral,* 4 gr.; *manna,* 6 oz.; *oil of almonds, syrup of squills,* and *syrup of senega,* of each, 2 dr. Laxative, demulcent, and expectorant. The above are useful in hoarseness, tickling coughs, sore throats, &c.

LINCTUS (Pectoral). Syn. *Fox Lungs; Linctus Pectoralis, Lohoch e pulmone Vulpium,*—Lat. *Prep.* From *spermaceti* and *Spanish juice,* of each, 8 *oz.; water,* q. s. to soften the liquorice; make a thin electuary, and add of *honey,* 3 *lb.; oil of aniseed,* 1 *oz.;* mix well. A popular and excellent demulcent in coughs. It formerly contained the herb *fox lungs,* but spermaceti is now substituted for that article.

LINCTUS (Turpentine). Syn. *Linctus Stimulans, L. Terebinthinæ, Lohoch Anthelminticum,*—Lat. *Prep.* (Recambier.) *Oil of turpentine,* 2 dr.; *honey of roses,* 3 oz.; mix. *Dose.* A tea-spoonful, night and morning, followed by a draught of any weak liquid; in worms, more especially tape-worm.

LINCTUS (White). Syn. *Linctus Albus, Mistura Alba, Lohoch Album,*—Lat. *Looch Blanc,*—Fr. *Prep.* (P. Cod.) *Jordan almonds,* 4½ dr.; *bitter almonds,* ½ dr.; blanch them by steeping them in *hot water* and removing the skins, add of *white sugar,* ½ oz.; *gum tragacanth,* 20 gr.; beat to a smooth paste, and further add of *oil of almonds* and *orange-flower water,* of each, 4 dr.; *pure water,* 4 fl. oz. A pleasant demulcent in tickling coughs.

LINEN. Syn. *Linteum,*—Lat. Linen is a textile fabric made of the fibrous portions of the *bark* of the *linum usitatissimum* (Linn.) or *common flax,* a plant which from time immemorial has been cultivated for this purpose. It is remarkable for the smoothness and softness of its texture, and is hence highly esteemed in temperate climates as an elegant and agreeable article of clothing to be worn next the skin. Its fibres are better conductors of heat, more porous, and more attractive of moisture than those of cotton, which render it less adapted for body linen in cold weather as well as in hot weather and hot climates, than calico. The latter, however, lacks the luxurious softness and freshness of linen, whilst the peculiar twisted and jagged character of its fibres render it apt to excite irritation in extremely delicate



skins. The common prejudice in favour of old linen and flax lint for dressing wounds is thus shown to have reason on its side, and like many other vulgar prejudices, to be supported by the investigations of science.

Identif. Linen fabrics are commonly sophisticated with cotton, which is a much less costly, and a more easily wrought material. Various plans have been proposed to detect this fraud, many of which are too complicated and difficult for practical purposes. The following commend themselves for their simplicity and ease of application :—

1. (Dr. Boettger.) A *small strip* (a square inch for instance) of the *suspected cloth* is immersed for 2 or 3 minutes in a *boiling mixture* of about equal parts of *hydrate of potassa* and *water*, contained in a vessel of silver, porcelain, or hard glass; after which it is taken out and pressed between the folds of *white blotting paper* or *porous calico*. By separating 8 or 10 threads in each direction, their colour may be readily seen. The *dark* yellow threads are LINEN, the *white* or *pale yellow* ones are COTTON.

2. (M. Kindt.) A *small strip of the cloth* previously well washed, dried, and *weighed*, is immersed for 1 to 2 minutes in *oil of vitriol;* it is then withdrawn, boiled for a few minutes in *water* to dissolve out the gummy portion, and then washed, *first* with *water holding a little salt of tartar in solution*, and *next* with *pure water;* the strip is lastly, dried and weighed. The *loss of weight* indicates the quantity of cotton which was originally present in the sample. The number of fibres or threads so lost may be readily determined by simple inspection.

3. (*By the microscope.*) The indications afforded by both the previous tests, although quite visible to the naked eye, are rendered still more palpable by the use of a magnifying glass of small power, as the common pocket lens. Under a good *microscope* the presence of *cotton* in a *linen tissue* is very perceptible. The *fibres of cotton* present a distinctly flat, and shrivelled appearance, not unlike that of a narrow, twisted ribbon, with only occasional joints; whilst those of *flax* are round, straight, and jointed. The fibres of cotton after being exposed to the action of strong alkaline lyes (*alkalized cotton, mercurized do.*) untwist themselves, contract in length, and assume a rounded form, but still continue distinct in appearance from the fibres of linen. The *engraving* represents a fibre of *linen* and *cotton* as they appear when magnified 155 diameters. The difference between the two may be perceived, although less distinctly, through a good Stanhope or Coddington lens, provided the object be well illuminated.

Dyeing. Linen and cotton from the similarity of their behaviour with dye-stuffs are treated in nearly the same manner. The affinity of their fibres for colouring matter is very much weaker than that of the fibres of silk and woollen. On this account they are dyed with greater difficulty than those substances, and the colours so imparted are, in general, less brilliant and permanent under similar conditions. The yarn or cloth after being *scoured* and *bleached* in the usual manner, requires to have an additional tendency given to it, by chemical means, to condense and retain the materials of the dye-bath in its pores. This is effected by steeping the goods in solutions (*mordants*) which have at once an affinity for both the fibres of the cloth and the colouring matter. A similar process is employed in dyeing most other substances; but with cotton and linen, attention to this point is essential to the permanency of the dye. These matters are more fully explained under the heads, *Dyeing* and *Mordants.*

The *domestic management* of *linen* may here receive a few moments' attention. *Fruit stains, iron-moulds,* and other spots on linen, may, in general, be removed by applying to the part, previously washed clean, a *weak solution* of *chlorine, chloride of lime, spirits of salts, oxalic acid,* or *salts of lemons,* in *warm water,* and frequently by merely using a little *lemon juice.* When the stain is removed, the part should be thoroughly rinsed in clear *warm water* (without soap) and dried. *Recent iron-moulds* or *ink spots* on starched linen, as the front of a shirt, may be conveniently removed by allowing a drop or two of *melted tallow* from a *common candle* to fall upon them before sending the articles to the laundress. The oxide of iron combines with the grease, and the two are washed out together. If the spot is not *entirely* removed the first time, the process should be repeated. *Linen* that has acquired a *yellow* or *bad colour* by careless washing, may be restored to its former whiteness by working it well in water to which some

strained solution of *chloride of lime* has been added, observing to *well rinse* it in *clean water*, both before and after the immersion in the bleaching liquor. The attempt to bleach *unwashed* linen should be avoided, as also using the liquor too strong, as in that case the linen will be rendered rotten. See *Chlorometry*, *Bleaching*, *Hypochlorite of Lime*, *&c.*

LING. The *gadus molua* (Linn.), an inferior species of the cod-fish tribe, common in the Northern seas, and used as a coarse article of food by the poor.

LINIMENT. Syn. *Linimentum*,—Lat. A semifluid ointment, or soapy application to painful joints, swellings, burns, &c. The term is also occasionally extended to various spirituous and stimulating external applications. A medicine of a thinner consistence, but similarly employed, is called an "*embrocation.*" These terms are, however, frequently confounded together, and misapplied. *Liniments* are generally *administered* by friction with the hand or fingers, or with some substance (as a *piece of flannel*) capable of producing a certain amount of irritation of the skin. Sometimes a piece of linen rag dipped in them is simply laid on the part. In most cases in which liniments are found beneficial, the advantage obtained from them is attributable rather to the friction or local irritation, than to any medicinal power in the preparation itself. The greater number of *cerates* and *ointments* may be converted into *liniments* by simply reducing their consistence with *almond* or *olive oil*, or *oil of turpentine*.

LINIMENT (Acid). Syn. *Linimentum Acidum*, *L. Acidi Sulphurici*,—Lat. *Prep.* 1. (Sir B. Brodie.) *Salad oil*, 3 oz.; *oil of vitriol*, 1 dr.; mix, then add of *oil of turpentine*, 1 oz., and agitate the whole well together. As a counter-irritant, in rheumatism, stiff joints, &c. It closely resembles the "*Guestonian Embrocation.*"

2. (Hosp. F.) *Olive oil*, 3 oz.; *oil of turpentine*, 2 oz.; *sulphuric acid*, 1 fl. dr. An excellent alterative, stimulant, discutient, and counter-irritant, in chronic rheumatism, stiff joints, indolent tumours, and various chronic diseases of the skin.

LINIMENT (Amber-oil). Syn. *Linimentum Succini*,—Lat. *Prep.* From *olive oil*, 3 parts; *oils of amber* and *cloves*, of each, 1 part. Resembles *Roche's Embrocation.*

LINIMENT (Amber,—Opiated). Syn. *Linimentum Succini Opiatum*,—Lat. *Prep.* From *rectified oil of amber* and *tincture of opium*, of each, 2 fl. oz.; *lard*, 1 oz. Anodyne, antispasmodic, and stimulant. A once popular remedy in cramp, stiff joints, &c.

LINIMENT (Ammonia). Syn. *Volatile Liniment*, *Ammoniacal do.*, *Oil and Hartshorn*; *Linimentum Ammoniæ*,—Ph. L. E. & D. *Lin. A. Fortius*, — Ph. L. 1824. *Oleum Ammoniatum*,—Ph. E. 1839. *Prep.* 1. (Ph. L. & E.) *Liquor of ammonia* (sp. gr. 0·960), 1 fl. oz.; *olive oil*, 2 fl. oz.; shake them together until they are mixed.

2. (Ph. D.) To the last add of *olive oil*, 1 fl. oz. Stimulant and rubefacient. *Used* in rheumatism, lumbago, neuralgia, sore throat, spasms, bruises, &c. When the skin is irritable more oil should be added, or it should be diluted with a little water.

LINIMENT (Ammonia,—Camphorated). Syn. *Linimentum Ammoniæ Camphoratum*, *Embrocatio Amm. Camphorata*, — Lat. *Prep.* 1. (Hosp. F.) *Olive oil*, 3 oz.; *camphor*, ½ oz.; dissolve by a gentle heat, and when cold, add of *liquor of ammonia*, 1 fl. oz.

2. *Soap liniment*, 2 oz.; *olive oil* and *liquor of ammonia*, of each, 2 dr. As the last; more especially for sprains, bruises, chilblains, &c.

LINIMENT (Ammonia, — Compound). Syn. *Dr. Granville's Counter-irritant* or *Antidynous Lotion*; *Linimentum Ammoniæ Compositum*,—Ph. E. *Prep.* (Ph. E.) —*a.* (*Stronger.*) From *liquor of ammonia* (sp. gr. 0·880), 5 fl. oz.; *tincture of camphor*, 2 fl. oz.; *spirit of rosemary*, 1 fl. oz.; mix. It should be kept in a well-stoppered bottle and in a cool situation.

b. (*Weaker.*) *Liquor of ammonia* (0·880), 5 fl. oz.; *tincture of camphor*, 3 fl. oz.; *spirit of rosemary*, 2 fl. oz.

Obs. The above formulæ are nearly identical with the original ones of Dr. Granville; the principal difference being in his ordering liquor of ammonia of the sp. gr. 0·872, instead of 0·880. They are counter-irritant, rubefacient, vesicant, and cauterizing, according to the mode and length of their application. The *milder lotion* is sufficiently powerful to produce considerable rubefaction and irritation in from 1 to 5 or 6 minutes; vesication, in 8 or 10 minutes; and cauterization, in 4 or 5 minutes longer. For the latter purpose the *stronger lotion* is generally employed. According to Dr. Granville, these lotions are prompt and powerful remedies in rheumatism, lumbago, cramp, neuralgia, sprains, swollen and painful joints, headache, sore throat, and numerous other affections in which the use of a powerful counter-irritant has been recommended. They are ordered to be *applied*

by means of a piece of linen, 6 or 7 times folded, or a piece of thick, coarse flannel wetted with the lotion, the whole being covered with a thick towel, and firmly pressed against the part with the hand. The *stronger lotion* is only intended to be employed in apoplexy, and to produce cauterization. See *Counter-irritants.*

LINIMENT (Sesquicarbonate of Ammonia). Syn. *Linimentum Ammoniæ Sesquicarbonatis*,—Ph. L. *Lin. Amm. Subcarbonatis*,—Ph. L. 1824. *Lin. A. Carbonatis*,—Ph. L. 1809. *Lin. Ammoniæ*,—Ph. L. 1788. *Lin. Volatile*,—Ph. L. 1746. *Prep.* (Ph. L.) *Solution of sesquicarbonate of ammonia*, 1 fl. oz.; *olive oil*, 3 fl. oz.; shake them together until mixed. This preparation resembles *liniment of ammonia* in its general properties, but it is much less active, owing to the alkali being carbonated. It is the "*oil and hartshorn*" and the "*volatile liniment*" of the shops.

LINIMENT (Anodyne). See *Liniments of Belladonna, Morphia, Opium, Soap, &c.*

LINIMENT (Antispasmodic). Syn. *Linimentum Antispasmodicum, Lin. Cajeputi Compositum*, — Lat. *Prep.* (Hufeland.) *Oils of cajeput* and *mint*, of each, 1 part; *tincture of opium*, 3 parts; *compound camphor liniment*, 24 parts. Anodyne, stimulant, and rubefacient.

LINIMENT (Arceus's). Compound elemi ointment.

LINIMENT (Belladonna). Syn. *Linimentum Belladonnæ*, — Lat. *Prep.* 1. (Cazenave.) *Extract of belladonna*, 1 dr.; *oil of almonds*, 2 oz.; *lime water*, 4 fl. oz. In eczema, and some other cutaneous affections, to allay irritation, &c.

2. (Cutan. Hosp.) *Extract of belladonna*, 4 dr.; *glycerine*, 1 oz.; *soap liniment*, 6 oz. As the last.

3. (Guy's Hosp.) *Extract of belladonna*, 1 oz.; *soap liniment*, 8 fl. oz.

4. (Phœbus.) *Extract of belladonna*, 40 gr.; *rectified ether*, 1 dr.; *cherry-laurel water*, 2 fl. oz. As a friction to the abdomen in lead colic.

Obs. The above are reputed excellent stimulants, anodynes, antispasmodics, and resolvents, in various diseases, as rheumatism, neuralgia, painful affections of the skin and joints, tumours, &c. &c.

LINIMENT (Cajeput Oil). Syn. *Linimentum Olei Cajuputi*, — Lat. *Prep.* 1. (Dr. Copland.) *Compound camphor liniment* and *soap liniment*, of each, 1½ fl. oz.; *oil of cajeput*, 1 fl. oz.

2. (Dr. Williams.) *Oil of cajeput*, ½ fl. dr.; *castor oil*, 1 fl. dr.; *olive oil*, 4½ fl. dr. A warm antispasmodic diffusible stimulant and rubefacient; in spasmodic asthma, colic, chronic rheumatism, spasms, chest affections, &c.

LINIMENT (Camphor). Syn. *Camphorated Oil, Camphor Embrocation; Linimentum Camphoræ*,—Ph. L. E. & D. *Oleum Camphoratum*,—Ph. E. 1839, & Ph. D. 1826. *Prep.* (Ph. L. & E.) *Camphor*, 1 oz.; *olive oil*, 4 fl. oz.; gently heat the oil, add the camphor (cut small), and agitate until dissolved. The Dublin College orders only ½ the above camphor. Stimulant, anodyne, and resolvent; in sprains, bruises, rheumatic pains, glandular enlargements, &c.

LINIMENT (Camphor, — Compound). Syn. *Linimentum Camphoræ Compositum*, —Ph. L. & D. *Lin. Camphoræ*,—Ph. L. 1788. *Prep.* 1. (Ph. L.) *Camphor*, 2½ oz.; *oil of lavender*, 1 fl. dr.; *rectified spirit*, 17 fl. oz.; dissolve, then add of *stronger liquor of ammonia*, 3 fl. oz.; and shake them together until they are mixed.

2. (Ph. L. 1836.) *Liquor of ammonia*, 7½ fl. oz.; *spirit of lavender*, 1 pint; distil off 1 pint, and dissolve in it, *camphor*, 2½ oz. The formula of the Ph. D. 1826, was nearly similar.

3. (*Wholesale.*) *Camphor* (clean), 21 *oz.*; *English oil of lavender*, 3¾ *oz.*; *liquor of ammonia*, 2¾ *lb.*; *rectified spirit*, 7 pints; mix, close the vessel, and agitate occasionally until the camphor is dissolved. Powerfully stimulant and rubefacient. It closely resembles, and is now almost universally sold for *Ward's "Essence for the Headache."*

LINIMENT (Cantharides). Syn. *Liniment of Spanish Flies; Linimentum Lyttæ; Lin. Cantharidis*,—Ph. D. & U. S. *Prep.* 1. (Dr. Collier.) *Tincture of cantharides* and *soap liniment*, equal parts.

2. (Ph. D.) *Cantharides* (in fine powder), 3 *oz.*; *olive oil*, 12 fl. oz.; digest for 3 hours over a water bath, and strain through flannel, with expression.

3. (Ph. U. S.) *Spanish flies*, 1 oz.; *oil of turpentine*, 8 fl. oz.; proceed as last. The above are irritant, and rubefacient; but should be used cautiously, lest they produce strangury.

LINIMENT (Chloride of Lime). Syn. *Linimentum Calcis Chlorinatæ*, — Lat. *Prep.* 1. *Chloride of lime*, 1 dr.; *water*, (added gradually), 3 fl. oz.; triturate together in a glass mortar for 10 minutes, pour off the liquid portion, and add of *oil of almonds*, 2 fl. oz.

2. (Kopp.) *Solution of chloride of lime* (ordinary), 1 part; *olive oil*, 2 parts.

3. (Waller.) *Chloride of lime* (in fine powder), 1 part; *soft soap*, 2 parts; *soft water*, q. s. to make a liniment.

Obs. The above are cleanly and excellent applications in itch, scald head, herpes, lepra, foul ulcers, &c.

LINIMENT (Chloroform). Syn. *Linimentum Chloroformi*, — Lat. *Prep.* 1. *Chloroform*, 1 fl. dr.; *almond oil*, 7 fl. dr.; mix in a phial, and agitate it until the two unite.

2. (Tuson.) *Chloroform*, 1 fl. dr.; *soap liniment*, 2 fl. oz.; as the last. *Used* as an application in neuralgic pains, rheumatism, &c.

LINIMENT (Cod-liver Oil). Syn. *Linimentum Olei Morrhuæ, Lin. O. Jecoris Aselli*,—Lat. *Prep.* (Dr. Brach.) *Cod-liver oil*, 2 fl. oz.; *liquor of ammonia*, 1 fl. oz.; mix. Resolvent, dispersive; applied to glandular tumours, scrofulous enlargements, &c.

LINIMENT (Croton Oil). Syn. *Linimentum Crotonis*,—Ph. D. *Lin. Olei Crotonis, L. O. Tiglii*,—Lat. var. This article is now introduced into the Irish Pharmacopœia.

Prep. 1. (Ph. D.) *Croton oil*, 1 fl. oz.; *oil of turpentine*, 7 fl. oz.; mix by agitation.

2. (J. Allen.) *Croton oil* and *liquor of potassa*, of each, 1 fl. dr.; agitate until mixed, then add of *rose water*, 2 fl. oz.

3. (Pereira.) *Croton oil*, 1 part; *olive oil*, 5 parts.

Obs. The above are used as counter-irritants; in rheumatism, neuralgia, bronchial and pulmonary affections, &c. When rubbed on the skin, redness and a pustular eruption ensue, and in general the bowels are acted on.

LINIMENT (Diuretic). Syn. *Linimentum Diureticum*,—Lat. *Prep.* 1. (Dr. Calini.) *Squills* (in fine powder), 1 dr.; *gastric juice of a calf*, 2 oz.; mix.

2. (Dr. Christison.) *Soap liniment*, *tincture of foxglove*, and *tincture of squills*, equal parts. In dropsies; rubbed over the abdomen or loins, twice or thrice a day.

LINIMENT (Emollient.) Syn. *Linimentum Album, Lin. Emolliens*,—Lat. *Prep.* From *camphor*, 1 dr.; *Peruvian balsam*, ½ dr.; *oil of almonds*, 1 fl. oz.; dissolve by heat, add of *glycerine*, ½ fl. oz., agitate well, and when cold, further add of *oil of nutmeg*, 15 drops. Excellent for chopped hands, lips, nipples, &c.

LINIMENT (Garlic). Syn. *Linimentum Allii*,—Lat. *Prep.* From *juice of garlic*, 2 parts; *olive oil*, 3 parts; mix. In hooping-cough, infantile convulsions, &c.

LINIMENT (Ginger). Syn. *Linimentum Zingiberis*,—Lat. *Prep.* (Dr. Turnbull.) *Ginger*, 1 part; *rectified spirit*, 2 parts; make a tincture or essence. For *short-sightedness.* A few drops are occasionally rubbed on the forehead for 8 or 10 minutes at a time. How this *tincture* came to be called a *liniment* we are at a loss to determine.

LINIMENT (Hungarian.) Syn. *Linimentum Hungaricum*,—Lat. *Prep.* (Soubeiran.) *Powdered cantharides* and *sliced garlic*, of each, 1 dr.; *camphor*, *bruised mustard seed*, and *black pepper*, of each, 4 dr.; *strong vinegar*, 6 fl. oz.; *rectified spirit*, 12 fl. oz.; macerate a week, and filter. An excellent rubefacient and counter-irritant.

LINIMENT (Hydrochloric Acid). Syn. *Linimentum Muriaticum, Lin. Acidi Muriatici, L. A. Hydrochlorici*,—Lat. *Prep.* 1. (Hosp. F.) *Olive oil*, 2 oz.; *white wax*, 2 dr.; dissolve by a gentle heat, add of *balsam of Peru*, 1 dr.; *hydrochloric acid*, 2 dr.; mix well. An excellent application to chilblains before they break.

2. (W. Cooley.) *Olive oil*, ¼ pint; *white spermaceti* (pure) and *camphor*, of each, ½ oz.; mix with heat, add of *hydrochloric acid*, ½ fl. oz., and proceed as before. Equal to the last, and cheaper. This was extensively employed among the seamen of the Royal Navy, by the Editor's father during the long war, with uniform success.

LINIMENT (Iodide of Potassium.) Syn. *Linimentum Ioduretum Gelatinosum*,—Lat. *Gelée pour le Goitre*,—Fr. *Prep.* (Foy.) *Iodide of potassium*, 4 dr.; *proof spirit*, 2 oz.; dissolve, and add the liquid to a solution of *curd soap*, 6 dr., in *proof spirit*, 2 oz., both being at the time gently warm; lastly, aromatise with *rose* or *neroli*, pour it into wide-mouthed bottles, and keep them closely corked. In goitre, &c.

LINIMENT (Iodine). Syn. *Iodurettted Liniment; Linimentum Iodinii, L. Ioduretum*,—Lat. *Prep.* 1. (Cutan. Hosp.) *Compound tincture of iodine* and *laudanum*, equal parts.

2. (Dr. Copland.) *Soap liniment*, 1 oz.; *iodine*, 8 to 10 gr.

3. (Guibourt.) *Iodide of potassium*, 1 dr.; *water*, 1 fl. dr.; dissolve, and add it to *white soap* (in shavings) and *oil of almonds*, of each, 10 dr., previously melted together. Some perfume may be added. In scrofula, glandular enlargements, rheumatism, &c.

LINIMENT (Lead). Syn. *Linimentum Plumbi*,—Lat. *Prep.* (Gaozey.) *Acetate of lead*, 40 gr.; *soft water*, 12 fl. oz.; *olive oil*, 6 oz.; mix, and agitate well. Astringent and refrigerant. Useful in excoriations; especially when accompanied with inflammation.

LINIMENT (Lime-water). Syn. *Lini-*

ment for Burns, Carron Oil; Linimentum Calcis,—Ph. L. E. & D. *Lin. Aquæ Calcis* or *Oleum Lini cum Calce*,—Ph. E. 1839. *Prep.* From *olive oil* (linseed oil,—Ph. E.) and *lime water*, equal parts, shaken together until they are mixed. Very useful in burns and scalds.

LINIMENT (Lime,—Compound). Syn. *Linimentum Calcis Compositum*, — Lat. *Prep.* 1. (*Camphorated*, — W. Cooley.) *Camphor liniment* and *lime water*, equal parts.

2. (*Opiated*,—W. Cooley.) *Lime-water* and *camphor liniment*, of each, 1 oz.; *extract of opium*, 5 gr.; mix. Both the above are used as anodynes to allay pain and irritation in severe burns, chilblains, &c., for which purpose they are excellent. All the above liniments with lime water should be used as soon as possible after being prepared, as the ingredients separate by keeping.

LINIMENT (Mercurial). Syn. *Liniment of Mercury; Linimentum Hydrargyri*,—Ph. L. *Lin. H. Compositum*,—Ph. L. 1836. *Prep.* (Ph. L.) *Camphor*, 1 oz.; *spirit of wine*, 1 fl. dr.; sprinkle the latter on the former, powder, add of *lard* and *mercurial ointment* (stronger), of each, 4 oz.; rub them well together, then gradually add of *liquor of ammonia*, 4 fl. oz.; and mix well. Stimulant and discutient. It resembles mercurial ointment in its effects; but though milder in its operation, it more quickly produces salivation.

LINIMENT (Morphia). Syn. *Linimentum Morphiæ*,—Lat. *Prep.* (W. Cooley.) *Pure morphia*, 3 gr.; put it into a warm mortar, add very gradually, of *oil of almonds* (warm), 1 fl. oz., and triturate until the morphia is dissolved, then add of *camphor liniment*, 1 oz. An excellent topical anodyne and antispasmodic, which often allays pain when other means have failed.

LINIMENT (Mustard). Syn. *Linimentum Sinapis*,—Lat. *Prep.* 1. *Flour of mustard* (best), 1 *oz.*; *water* (tepid), 2 fl. oz.; mix and add of *glycerine*, *liquor of ammonia*, and *olive oil*, of each, 1 fl. oz.

2. (Béral.) *Carbonate of ammonia* (in fine powder), 1 part; *camphor* (in powder), 2 parts; *oil of lavender*, 4 parts; *tincture of mustard*, 6 parts; mix, dissolve by agitation, add of *simple liniment* (warm), 56 parts; and again agitate until the whole is perfectly incorporated.

3. *Black mustard seed* (ground in a pepper-mill or otherwise well bruised), ½ *lb.*; *oil of turpentine*, 1 pint; digest, express the liquid, filter, and dissolve in it, *camphor*, ¼ *lb.* Stimulant and rubefacient. A popular and useful remedy in rheumatic pains, lumbago, colic, chilblains, &c. The last is a close imitation of *Whitehead's "Essence of Mustard."* See *Essences.*

4. (*Lin. Olei Volatilis Sinapis.*)—*a.* From *volatile oil of black mustard seed*, ½ dr.; *oil of almonds*, 1 fl. oz. As a rubefacient.

b. From *volatile oil*, 1 part; *alcohol* (sp. gr. 0·815), 1 to 2 parts. As a vesicant.

LINIMENT (Nitrate of Mercury). Syn. *Citrine Liniment; Linimentum Hydrargyri Nitratis*,—Lat. *Prep.* (Sir H. Halford.) *Ointment of nitrate of mercury* and *olive oil*, equal parts, triturated together in a glass mortar, or mixed by a gentle heat. This liniment is stimulant, discutient, and alterative, and in its general properties resembles the ointment of the same name. For most purposes the quantity of oil should be at least doubled.

LINIMENT (Nux Vomica). Syn. *Linimentum Nucis Vomicæ*, — Lat. *Prep.* (Magendie.) *Tincture of nux vomica*, 1 fl. oz.; *liquor of ammonia*, 2 fl. dr.; mix. As a stimulating application to paralysed limbs. The addition of 1 fl. dr. each, of *glycerine* and *salad oil* renders it an excellent application in chronic rheumatism and neuralgia.

LINIMENT (Opium). Syn. *Anodyne Liniment; Linimentum Opii*,— Ph. L. & E. *Lin. Opii* or *Lin. Anodynum*,—Ph. D. *Lin. Saponis cum Opio*,—Ph. D., 1826. *Prep.* 1. (Ph. L.) *Tincture of opium*, 2 fl. oz.; *soap liniment*, 6 fl. oz.; mix.

2. (Ph. E.) *Castile soap*, 6 oz.; *opium*, 1½ oz.; *rectified spirit*, 1 quart; digest for three days, then filter, add of *camphor*, 3 oz., *oil of rosemary*, 6 fl. dr., and agitate briskly.

3. (Ph. D.) *Soap liniment* and *tincture of opium*, equal parts.

4. (*Wholesale.*) *Soft soap*, 1¼ *lb.*; *powdered opium* and *camphor*, of each, ¼ *lb.*; *rectified spirit*, 1 gall.; digest a week.

Obs. This preparation is an excellent anodyne in local pains, rheumatism, neuralgia, sprains, &c.

LINIMENT (Phosphorus). Syn. *Linimentum Phosphoratum*,—Lat. *Prep.* (Augustin.) *Phosphorus*, 6 gr.; *camphor*, 12 gr.; *oil of almonds*, 1 oz.; dissolve by heat; when cold, decant the clear portion, and add of *strongest liquor of ammonia*, 10 drops. A useful friction in gout, chronic rheumatism, certain obstinate cutaneous affections, &c.

LINIMENT (Simple). Syn. *Linimentum Simplex*,—Ph. E. *Prep.* (Ph. E.) *White wax*, 1 oz.; *olive oil*, 4 fl. oz.; melt

together and stir the mixture until it is cold. Emollient; resembles spermaceti ointment in all except its consistence.

LINIMENT (Soap). Syn. *Opodeldoc, Camphorated Tincture of Soap, Balsam of do.; Linimentum Saponis,*—Ph. L. E. & D. *Lin. S. Compositum,*—Ph. L. 1824. *Lin. Saponaceum,*—Ph. E. 1839, and Ph. L. 1745. *Tinctura Saponis Camphorata,* — Ph. E. 1839. *Tinct. S. Composita, Balsamum Saponis,*—Lat. var. *Prep.* 1. (Ph. L.) *Castile soap* (cut small), 2½ oz.; *camphor* small), 10 dr.; *spirit of rosemary*, 18 fl. oz.; *water*, 2 fl. oz.; digest with frequent agitation until the solid substances are dissolved.

2. (Ph. E.) *Castile soap*, 5 oz.; *camphor*, 2½ oz.; *oil of rosemary*, 6 fl. dr.; *rectified spirit*, 1 quart.

3. (Ph. D.) *Castile soap* (in powder), 2 *oz.; camphor*, 1 *oz.; proof spirit*, 16 fl. oz.

4. (*Liniment Savonneau,*—P. Cod). *Tincture of soap* (P. Cod.) and *rectified spirit* (·863 or 41 *o. p.*), of each, 8 parts; *olive oil*, 1 part.

Obs. This article, prepared according to the directions of the pharmacopœia, from "soap made of olive oil, and soda" (*Castile soap*), is apt to gelatinize in cold weather, and to deposit crystals of elaidate and stearate of lime. This may be avoided, when expense is not an objection, by first well drying the soap, employing a spirit of at least 85°, and keeping the preparation in well-closed bottles. A cheaper and better plan is to substitute the *soft soap* of the Ph. L. ("soap made with *olive oil* and *potassa*") for the Castile soap ordered by the College. The *soft soap of commerce* imparts to the liniment an unpleasant smell. The following formula, one of those commonly adopted by the *wholesale druggists*, produces a very good article, though much weaker than that of the pharmacopœia:—*Camphor* (cut small), 1½ *lb.; soft soap*, 7 *lb.; oil of rosemary*, 3 fl. oz.; *rectified spirit of wine* and *water*, of each, 3½ gall.; digest with occasional agitation for a week, and filter. This is the "*opodeldoc*" or "*soap liniment*" of the shops.

Uses. Soap liniment is stimulant, discutient, and lubricating, and is a popular remedy in rheumatism, local pains, swellings, bruises, sprains, &c.

LINIMENT (Soap,—with Opium). See *Liniment of Opium.*

LINIMENT (Soap,—Sulphuretted). Syn. *Linimentum Saponis Sulphuretum, Lin. Sulphuro-saponaceum,*—Lat. *Prep.* (Jadelot.) *Sulphuret of potassium*, 3 oz.; *soap*, 12 oz.; *water*, q. s.; melt together, and add of *olive oil*, 12 oz.; *oil of origanum*, 1 fl. dr.; mix well. An excellent remedy for the itch and some allied skin diseases.

LINIMENT (St. John Long's). Syn. *Linimentum Terebinthinæ Aceticum,*—Lat. *Prep.* (Dr. Stokes.) *Oil of turpentine*, 3 oz.; *rose water*, 2½ fl. oz.; *acetic acid*, 5 dr.; *oil of lemons*, 1 dr.; *yelk* of 1 egg; make an emulsion. As a counter-irritant, in phthisis, &c.

LINIMENT (Sulphuret of Carbon.) Syn. *Linimentum Carbonis Bisulphureti,*—Lat. *Prep.* 1. From *bisulphuret of carbon*, 1 dr.; *camphorated oil*, 1 oz.; mix.

2. (Lampadius.) *Camphor*, 2 dr.; *bisulphuret of carbon*, 4 fl. dr.; dissolve, and add of *rectified spirit*, 1 fl. oz. In rheumatism, gouty nodes, &c.

LINIMENT (Sulphuric Acid). See *Acid Liniment.*

LINIMENT (Tripharmic). Syn. *Linimentum Tripharmicum,* — Ph. L. 1746. *Prep.* Take of *lead plaster* and *olive oil*, of each, 4 oz.; melt, add of *strong vinegar*, 1 fl. oz., and stir until cold. Cooling and desiccative; in excoriations, burns, &c.

LINIMENT (Turpentine). Syn. *Kentish's Liniment; Linimentum Terebinthinæ,* — Ph. L. & D. *Lin. Terebinthinatum,* — Ph. E. *Prep.* 1. (Ph. L.) *Soft soap*, 2 oz.; *camphor*, 1 oz.; *oil of turpentine*, 16 fl. oz.; shake them together until mixed. Stimulant; in lumbago, cholera, colic, &c.

2. (Ph. L. 1824.) *Resin cerate*, 6 oz.; *oil of turpentine*, 4 fl. oz.; mix. An excellent application to burns.

3. (Ph. E.) *Resin ointment*, 4 oz.; *camphor*, 4 dr.; dissolve by a gentle heat, and stir in *oil of turpentine*, 5 fl. oz.

4. (Ph. D.) *Oil of turpentine*, 5 fl. oz.; *resin ointment*, 8 *oz.;* mix by a gentle heat. This forms Dr. Kentish's celebrated application to burns and scalds. The parts are first bathed with warm oil of turpentine or brandy, and then covered with pledgets of lint smeared with the liniment.

LINIMENT (Turpentine,—Compound). Syn. *Linimentum Terebinthinæ Compositum*—Lat. *Prep.* 1. (*Acetic.*) See *St. John Long's Liniment.* In phthisis.

2. (*Ammoniated,* — Debreyne.) *Lard*, 3 oz.; melt, and add of *oil of turpentine* and *olive oil*, of each, 1 oz.; when cold, further add of *camphorated spirit*, 4 fl. dr.; *liquor of ammonia*, 1 fl. dr. In sciatica, lumbago, &c.

3. (*Opiated,*—Recamier.) *Oil of turpentine*, 1 fl. oz.; *oil of chamomile*, 2 fl. oz.;

tincture of opium, 1 fl. dr. In neuralgia, &c.

4. (*Sulphuric*, — Ph. Castr. Ruthena.) *Oil of turpentine*, 2 oz.; *olive oil*, 5 oz.; mix, and add of *dilute sulphuric acid*, 1½ dr. See *Acid Liniment*.

LINIMENT (Veratria). Syn. *Linimentum Veratriæ*,—Lat. *Prep.* (Brande.) *Veratria*, 8 gr.; *alcohol*, ½ fl. oz.; dissolve, and add of *soap liniment*, ½ fl. oz. In neuralgic and rheumatic pains, gout, &c.

LINIMENT (Verdigris). Syn. *Oxymel of Verdigris; Linimentum Æruginis*, — Ph. L. *Oxymel Æruginis*,—Ph. L. 1788, & Ph. D. 1807. *Mel Ægyptiacum*,—Ph. L. 1746. *Unguentum Æ.*, — Ph. L. 1720. *Oxymel Cupri Subacetatis*,—Ph. D. 1826. *Prep.* (Ph. L.) *Verdigris* (in powder), 1 oz.; *vinegar*, 7 fl. oz.; dissolve, filter through linen, add of *honey*, 14 oz., and evaporate to a proper consistence.

Obs. This preparation is wrongly named a liniment. The College, after "beating about the bush" for nearly a century, found a right name for it in 1788; but, as in many other cases, soon abandoned it for another less appropriate.

Oxymel of verdigris is stimulant, detergent, and escharotic. It is applied to indolent ulcers, especially of the throat, by means of a camel-hair pencil; and, diluted with water, it is used as a gargle. Care must be taken to avoid swallowing it, as it occasions vomiting and excessive purging. This application of it, although sanctioned by centuries, is unworthy of medical science.

LINIMENT (Vermifuge). Syn. *Linimentum Anthelminticum, Lin. Vermifugum*, —Lat. *Prep. Castor oil*, 1 oz.; *essential oils of wormwood* and *tansy*, of each, ½ oz.; *Dr. Peschier's ethereal tincture of pennyroyal buds*, 20 drops; mix. Employed in frictions on the abdomen in cases of worms in children. Its activity may be still further increased by the addition of a little *garlic juice*. (Journ. de Méd.) An excellent medicine.

LINIMENT (Ware's). *Prep.* From *camphor liniment*, 1 oz.; *solution of carbonate of potassa*, 1 dr. In amaurosis.

LINIMENT (White). The old name for *spermaceti ointment*.

LINIMENT (Wilkinson's). *Prep.* (Phœbus.) *Prepared chalk*, 20 gr.; *sulphur*, *lard*, and *tar*, of each, ½ oz.; mix, and add of *Boyle's fuming liquor*, 10 or 15 drops. In certain chronic skin diseases, neuralgia, &c.

LININE. A bitter principle obtained from the *linum catharticum* or *purging flax*.

LINSEED. Syn. *Flax Seed; Lini Semina*, — Lat. "The seed" of "*linum usitatissimum* (Linn.) or *common flax*." (Ph. L.) Oily, emollient, demulcent, and nutritive. Ground to powder (*linseed meal; farina lini*,) it is used for poultices. The cake left after expressing the oil (*linseed cake; lini placenta*,) is used for feeding cattle. Under the form of *tea* or *infusion*, it is used as a diluent, and to allay irritation in bronchial, urinary, and other like affections. See *Infusions, Linen, &c.*

LINT. Syn. *Linteum*,—Lat. Old *white linen-cloth* scraped by hand or machinery, so as to render it soft and woolly. It is used for dressing ulcers, either alone, or smeared with some suitable ointment or cerate.

LINT (Medicated). Syn. *Linteum Medicatum, L. Nigrum, L. Infernale*,—Lat. *Prep.* 1. *Nitrate of silver*, 20 to 30 gr.; *distilled water*, 1 fl. oz.; dissolve, saturate *dry lint*, ½ oz., with the solution, and expose it in a saucer or capsule to the light and air, until it has become black and dry.

2. From *nitrate of silver* and *nitrate of copper*, of each, ½ dr.; *lint*, 1 oz.; *water*, 1½ fl. oz.; as the last. *Used* to dress old and indolent ulcers.

LIPAROLES. Liparolés (*graisses médicamenteuses*,— P. Cod.) are preparations of a fatty nature, destitute of resinous matter, and generally aromatized. See *Pommades*.

LIPIC ACID. One of a series of new acids, discovered by Laurent, and obtained by the action of *nitric acid* on *oleic acid*. See *Adipic Acid*.

LIPS (The). See *Lip Salves, &c.*

LIQUATION. The process of "sweating out" by heat the more fusible metals of an alloy. *Metallurgists* avail themselves of this method in *assaying* and *refining* the *precious metals*, and procuring *antimony* and some other metals from their ores.

LIQUEFACIENTS. Syn. *Resolvents; Liquefacientia, Resolventia*,—Lat. A term applied to substances or agents which promote secretion and exhalation, soften and loosen textures, and promote the absorption or removal of enlargements, indurations, &c. To this class belong the *alkalies, antimony, bromine, chlorine, iodine, mercury, sulphur, &c.*, and their preparations.

LIQUEFACTION. The assumption of the liquid form. It is usually applied to the conversion of a solid into the liquid state, which may arise from increase of temperature (*fusion*), absorption of water from the atmosphere (*deliquescence*), or the action of a body already fluid (*solution*).

The *liquefaction* of *gases* and *vapours* is effected by pressure and cold.

LIQUEUR DE LA MOTTE. See *Drops* and *Tinctures.*

LIQUEUR DOREE. *Prep.* Take of *cinnamon, bitter orange peel,* and *Peruvian bark,* of each, ½ *oz.; hay saffron,* ¼ *oz.; brandy* and *Malaga wine,* of each, 3 quarts; digest for a week, strain, and add of *lump sugar,* 2 *lb.* Tonic, stomachic, and stimulant; chiefly used as an agreeable alcoholic dram.

LIQUEUR DE PRESSAVIN. *Prep.* From *oxide of mercury* (freshly precipitated), and *cream of tartar,* of each, 1 oz.; *hot water,* 1 quart; dissolve and filter. For *use,* 2 spoonfuls of *this liquor* are added to 1 quart of *water. Dose.* A wine-glassful 3 or 4 times a day, avoiding the use of common salt. This is simply a *solution* of *potassio-tartrate of mercury,* and may be taken in the usual cases in which mercury is administered.

LIQUEURS. Syn. *Cordials.* Stimulating beverages, formed of weak spirit, aromatized and sweetened. Their manufacture constitutes the trade of the "compounder," "rectifier," or "liquoriste."

The *materials* employed in the preparation of liqueurs or cordials, are *rain* or *distilled water, white sugar,* and *clean, flavourless spirit.* To these may be added the substances employed as "*finings,*" when artificial clarification is had recourse to.

The *utensils* and *apparatus* required in the business, are those ordinarily found in the wine and spirit cellar; together with a copper-still, furnished with a *pewter* head and a *pewter* worm or condenser, when the method "by distillation" is pursued. A barrel, hogshead, or rum puncheon, sawn in two, or simply "unheaded," as the case may demand, forms an excellent vessel for the solution of the sugar; and 2 or 3 *fluted funnels,* with some good *woollen filtering paper,* are occasionally found useful for filtering the aromatic essences used for flavouring. Great care is taken to ensure the whole of the utensils, &c., being *perfectly* clean and "sweet," and well "seasoned," in order that they may neither stain nor flavour the substances placed in contact with them.

In the *preparation* or *compounding of liqueurs,* one of the first objects which engages the operator's attention, is the production of an alcoholic solution of the aromatic principles which are to give them their peculiar aroma and flavour. This is done, either by simple *solution* or *maceration,* as in the manufacture of tinctures and medicated spirits; or by *maceration* and subsequent *distillation.* The products, in this country, are called *essences* or *spirits,* and by the French, *infusions,* and are added to the solution of sugar (*syrup* or *capillaire*) or to the *dulcified spirit,* in the proportions required. *Malt* or *molasses spirit* is the kind usually employed for this purpose in England. As before observed, it should be of the best quality; as, if this is not the case, the raw flavour of the spirit is perceptible in the liquor. *Rectified spirit of wine* is generally very free from flavour, and when reduced to a proper strength with *clear soft water,* forms a spirit admirably adapted for the preparation of cordial liquors. Spirit weaker than about 45 o. p., which has been freed from its own essential oil, by careful rectification, is known in trade under the title of "*pure,*" "*flavourless,*" "*plain,*" or "*silent spirit.*" Before macerating the ingredients, if they possess the solid form, they are coarsely pounded, bruised, sliced, or ground, as the peculiar character of the substance may indicate. This is not done until shortly before submitting them to the action of the menstruum; as, after they are bruised, they rapidly lose their aromatic properties by exposure to the air. When it is intended to keep them for any time in the divided state, they should be preserved in well-corked bottles or jars. The practice of *drying* the ingredients before pounding them, frequently adopted by ignorant and lazy workmen, for the sake of lessening the labour, is, of course, even more destructive to their most valuable qualities than mere exposure to the air. The length of time the ingredients should be digested in the spirit should never be less than 5 or 6 days, but a longer period is preferable when distillation is not employed. In either case the time may be advantageously extended to 10 days or a fortnight, and frequent agitation should be had recourse to during the whole period. When *essential oils* are employed to convey the flavour, they are first dissolved in a little of the *strongest rectified spirit of wine,* in the manner explained under "*Essences;*" and when added to the spirit, they are mixed up with the whole mass as rapidly and as perfectly as possible, by laborious and long-continued agitation ("*rummaging.*") In *managing the still,* the *fire* is proportioned to the ponderosity of the oil or flavouring substance, and the receiver is changed before the faints come over; as these are unfitted to be mixed with the cordial. In many cases the addition of a few pounds of *common salt* to the liquor in

the still facilitates the process and improves the product. Ingredients which are *not volatile*, are, of course, *always* added after distillation. The *stronger spirit* is reduced to the desired strength by means of either *clear soft water*, or the *clarified syrup* used for sweetening. The *sugar* employed should be of the finest quality, and is preferably made into *capillaire* or *syrup* before adding it to the aromatized spirit; and not until this last has been rendered *perfectly "fine"* or transparent, by filtration or clarification, as the case may demand. Some *spirits* or *infusions*, as those of aniseed, caraway, &c., more particularly require this treatment, which is best performed by running them through a *clean wine bag*, made of rather fine cloth, having previously mixed them with a spoonful or two of *magnesia;* but in all cases clarification by simple repose should be preferred, and first attempted. Under proper management, liqueurs or cordials prepared of good materials, will be found perfectly "clear" or "bright" as soon as made, or will become so after being allowed a few days for defecation; but in the hands of the inexperienced operator, and when the spirit employed is insufficient in strength or quantity, it often happens that they turn out "foul" or "milky." When this is the case, the liquid may be *"fined down"* with the *whites* of 12 to 20 *eggs* per hogshead; or a little *alum*, either alone or followed by a little *carbonate of soda* or *potassa*, both dissolved in water, may be added, in the manner described at *page* 463.

An *excellent* and *easy way* of *manufacturing cordial liquors*, especially when it is inconvenient to keep a large stock on hand, is by simply *aromatizing* and *colouring*, as circumstances or business may demand, *spirit of the strength of* 60 *or* 64 *u.p.*, kept *ready sweetened* for the purpose. To do this to the best advantage, *two* descriptions of sweetened spirit should be provided, containing respectively 1 *lb.* and 3 *lb.* of *sugar* to the gallon. From these, spirit of any *intermediate sweetness* may be made, which may be flavoured with any *essential oil dissolved in alcohol*, or any *aromatized spirit* or *"infusion,"* prepared either by digestion or distillation. As a general rule, the *concentrated essences*, made by dissolving 1 *oz.* of the *essential oil* in 1 pint of the *strongest rectified spirit of wine*, will be found admirably adapted for this purpose. These essences, which should be kept in well-corked bottles, are employed by *dropping* them *cautiously* into the *sweetened spirit* until the desired flavour is produced. During this operation, the liquor should be frequently and violently shaken to produce complete admixture. If by any accident the essence is added in too large a quantity, the resulting *"milkiness"* or *excess of flavour* may be removed by the addition of a little more spirit, or by clarification. In this way the majority of the *cordial liqueurs* in common use may be produced *extemporaneously*, of nearly equal quality to those prepared by distillation. For those which are *coloured*, simple digestion of the ingredients is almost universally adopted. The "process by distillation" should, however, be always employed to impart the flavour and aroma of volatile aromatics to the spirit, when expense, labour, and time, are of less importance than the production of a superior article.

The *French liquoristes* are proverbial for the superior quality, cream-like smoothness, and delicate flavour of their cordials. This chiefly arises from the employment of *very pure spirit* and *sugar* (the former in a larger proportion than that adopted by the English compounder), and in the judicious application of the flavouring ingredients. The French liquoristes distinguish their cordials into two classes; viz.,—*eaux* and *extraits* (waters, extracts), or liqueurs which though sweetened are entirely devoid of viscidity; and—*baumes*, *crêmes*, and *huiles* (balms, creams, oils), which contain sufficient sugar to impart to them a considerable degree of consistence. The greatest possible attention is given to the preparation of the aromatized or flavouring essences, in France called *"infusions."* These are generally made by macerating the aromatic ingredients in spirit at about 2 to 4 u. p. (sp. gr. 0·922 to 0·925), placed in well-corked glass carboys, or stoneware jars or bottles. The maceration is continued, with occasional agitation, for 3, 4, or even 5 weeks, when the aromatized spirit is either distilled or filtered; generally the former. The *outer peel* of *cedrats*, *lemons*, *oranges*, *limettes*, *bergamottes*, *&c.*, are alone used by our Continental neighbours, and is obtained either by carefully peeling the fruit with a knife, or by converting it into an *oleosaccharum*, by rubbing it off with a lump of hard white sugar. *Aromatic seeds* and *woods* are bruised by pounding, before being submitted to infusion. The substances employed in France to *colour liqueurs* are, for—BLUE, *soluble Prussian blue*, *sulphate of indigo* (nearly neutralized with chalk), and the *juice* of *blue flowers* and *berries;*

—AMBER, FAWN, and BRANDY COLOUR, *burnt sugar* or *spirit colouring*;—GREEN, *spinach* or *parsley leaves* (digested in spirit), and mixtures of *blue* and *yellow*;—RED, *powdered cochineal* or *brazil wood*, either alone or mixed with a *little* alum;—VIOLET, *blue violet petals*, *litmus*, or *extract of logwood*;—PURPLE, the same as *violet*, only deeper;—YELLOW, an *aqueous infusion* of *safflowers* or of *French berries*, and the *tinctures* of *saffron* and *turmeric*.

A frequent cause of *failure* in the *manufacture* of *liqueurs* and *cordials* is the addition of *too much flavouring* matter. Persons unaccustomed to the use of strong aromatic essences and essential oils, seldom sufficiently estimate their power, and, consequently, are very apt to add *too much of them*, by which the liquor is rendered not only disagreeably high flavoured, but from the *excess* of oil present, also "*milky*," or "*foul*," either at once, or what is nearly as bad, on the addition of water. This source of annoyance, arising entirely from bad manipulation, frequently discourages the tyro, and cuts short his career as a manufacturer. From the consistence or viscidity of cordials, they are less readily "*fined down*" than unsweetened liquor, and often give much trouble to clumsy and inexperienced operators. The most certain way to prevent disappointment in this respect is to use *too little*, rather than *too much* flavouring; for if the quantity proves insufficient, it is readily "*brought up*" at any time; but the contrary is not effected without some trouble and delay.

A careful attention to the previous remarks will render this branch of the rectifier's art far more perfect and easy of performance than it is at present, and will, in most cases, produce at *once* a satisfactory article, "*fine*, *sweet*, and *pleasant*."

The *cordials* of respectable British "*compounders*" contain fully 3 *lb.* of *white lump sugar* per gallon, and are of the *strength* of 60 to 64 u. p. The *baumes*, *crémes*, and *huiles* imported from the Continent, are richer both in spirit and sugar than ours; and to this may be referred much of their superiority. Mere *sweetened* or *cordialized spirits* (*eaux*, of the Fr.) contain only from 1 to 1½ *lb.* of *sugar* per gallon.

The *purity* of *liqueurs* is determined in the manner noticed under *Brandy*, *Spirits*, *Wines*, *&c.*

The following list embraces nearly all the *cordials* and *liqueurs*, both native and imported, met with in trade in this country:—

Alkermes. This liquor is highly esteemed in some parts of the South of Europe.

Prep. 1. *Bay leaves* and *mace*, of each, 1 *lb.*; *nutmegs* and *cinnamon*, of each, 2 *oz.*; *cloves*, 1 *oz.*, all bruised; *cognac brandy*, 3½ gall.; macerate for 3 weeks, frequently shaking, then distil over 3 gall., and add of *clarified syrup of kermes*, 18 *lb.*; *orange flower water*, 1 pint; mix well and bottle. This is the original formula for the *alkermes de Santa Maria Novella*, which is much valued.

2. *Spice*, as last; *British brandy*, 4 gall.; *water*, 1 gall.; macerate as before, and draw over 4 gall., to which add of *capillaire*, 2 gall., and *sweet spirit of nitre*, ¼ pint. Cassia is often used for cinnamon. Inferior to the last.

Aniseed Cordial. From *aniseed*, 2 *oz.*, (or *essential oil*, 1½ dr.), and *sugar*, 3 *lb.* per gallon. It should not be made weaker than about 45 u. p., as at lower strengths it is impossible to produce a full-flavoured article without its being milky or liable to become so. See *Peppermint Cordial.*

Anisette de Bourdeaux. This is merely a variety of aniseed cordial.

Prep. 1. (Foreign.) *Aniseed*, 4 *oz.*; *coriander* and *sweet fennel seeds*, of each, 1 *oz.*; (bruised); *rectified spirit*, ½ gall.; *water*, 3 quarts; macerate for 5 or 6 days, then draw over 7 pints, and add of *lump sugar*, 2½ *lb.*

2. (English.) *Oil of aniseed*, 15 drops; *oils of cassia* and *caraway*, of each, 6 drops; rub them with a *little sugar*, and then dissolve it in *spirit* (45 u. p.), 3 quarts, by well shaking them together; filter, if necessary, and dissolve in the clear liquor, *sugar*, 1½ *lb.*

Balm of Molucca. From *mace*, 1 *dr.*; *cloves*, ½ *oz.*; *clean spirit*, (22 u. p.), 1 gall.; infuse for a week in a well-corked carboy or jar, frequently shaking, colour with *burnt sugar*, q. s., and to the *clear tincture* add of *lump sugar*, 4½ *lb.*, dissolved in *pure soft water*, ½ gall. On the Continent this takes the place of the "*cloves*" of the English retailer.

Bitters. These have generally from 1 to 1½ *lb.* of *sugar* per gallon. (See *page* 135.)

Caraway Cordial. Generally from the *essential oil*, with only 2½ *lb.* of *sugar* per gall. 1 fl. dr. of the *oil* is commonly reckoned equal to ¼ *lb.* of the *seed*. The addition of a *very little oil of cassia*, and about half as much of *essence of lemon* or of *orange*, improves it. See *Caraway Brandy.*

Cedrat Cordial. From *essence* (oil) *of cedrat*, ¼ *oz.*; *pure spirit* (at proof), 1 gall.; dissolve, add of *water*, 3 pints, agitate well; distil 3 quarts, and add an equal

measure of *clarified syrup*. A delicious liqueur.

Cinnamon Cordial. This is seldom made with cinnamon, owing to its high price, but with either the *essential oil* or *bark of cassia*, with about 2 *lb.* of *sugar* to the gall. It is preferred coloured, and therefore may be very well prepared by simple digestion. The addition of 5 or 6 drops, each, of *essence of lemon* and *orange peel*, with about a spoonful of *essence of cardamoms* per gallon improves it. 1 *oz.* of *oil of cassia* is considered equal to 8 *lb.* of the *buds*, or *bark*, 1 *fl.dr.* of the *oil* is enough for 2½ gall. It is coloured with *burnt sugar*.

Citron Cordial. From the *oil* or *peel*, with 3 *lb.* of *sugar* per gall. as above. (See *below*.)

Citronelle; Eau de Barbades. 1. From *fresh orange peel*, 2 *oz.; fresh lemon peel*, 4 *oz.; cloves*, ½ *dr.; corianders* and *cinnamon*, of each, 1 dr.; *proof spirit*, 4 pints; digest for 10 days, then add of *water*, 1 quart, and distil ½ gall.; to the *distilled essence* add of *white sugar*, 2 *lb.*, dissolved in *water*, 1 quart.

2. *Essence of orange*, ½ dr.; *essence of lemon*, 1 dr.; *oil of cloves*, and *cassia*, of each, 10 drops; *oil of coriander*, 20 drops; *spirit* (58 o. p.), 5 pints; agitate until dissolved, then add of *distilled* or *clear soft water*, 3 pints; well mix, and filter it through blotting paper, if necessary; *lastly* add of *sugar* (dissolved), q. s.

Clairet; Rossalis des six graines. From *aniseed, fennel seed, coriander seed, caraway seed, dill seed*, and *seeds of daucus creticus*, (athamanta cretensis, — *Linn.*), of each, bruised, 1 *oz.; proof spirit*, ½ gall.; digest for 1 week, strain, and add of *loaf sugar*, 1 *lb.*, dissolved in *water*, q. s.

Cloves, Clove Cordial. From *bruised cloves*, 1 *oz.*, or *essential oil*, 1 fl. dr. to every 3 gall. of *proof spirit*. If distilled, some *common salt* should be added, and it should be drawn over with a pretty quick fire. It requires fully 3 *lb.* of *sugar* per gall., and is generally coloured with *poppy-flowers* or *burnt sugar*. The addition of 1 dr. of *bruised pimento*, or 5 drops of the *oil* for every *oz.* of *cloves*, improves this cordial.

Coriander Cordial. From *corianders*, as the last. A few *sliced oranges* improve it.

Crême d'Anise. As *aniseed cordial*, only richer.

Crême des Barbades. As *citronelle*, adding some of the *juice* of the *oranges*, and an additional *lb.* of *sugar* per gall.

Crême de Cacao. Infuse *roasted caracca cacao nuts* (cut small), 1 *lb.*, and *vanilla*, ½ *oz.*, in *brandy*, 1 gall., for 8 days; strain, and add of *thick syrup*, 3 quarts.

Crême de Cedrat, Huile de Cedrat. From *spirit of citron*, 1 pint; *spirit of cedrat*, 1 quart; *proof spirit*, 3 quarts; *white sugar*, 16 *lb.*, dissolved in *pure soft water*, 2 gall.

Crême de Macarons. 1. From *cloves, cinnamon*, and *mace*, of each, bruised, 1 dr.; *bitter almonds* (blanched and beaten to a paste), 7 *oz.; spirit* (17 u. p.), 1 gall.; digest a week, filter, and add of *white sugar*, 6 *lb.*, dissolved in *pure water*, 2 quarts.

2. *Clean spirit* at 24 u. p. (sp. gr. 0·945), 2 gall.; *bitter almonds*, ¾ *lb.; cloves, cinnamon*, and *mace*, of each, in coarse powder, 1½ dr.; infuse for 10 days, filter, and add of *white sugar*, 8 *lb.*, dissolved in *pure water*, 1 gall.; lastly, give the liqueur a *violet tint* with *infusion* or *tincture of litmus* and *cochineal*. An agreeable nutty flavoured cordial; but from containing so much bitter almonds, should be only drank in small quantities at a time. The English use only *one-half* the above quantity of almonds.

Crême de Naphe. From *sweetened spirit* (60 u. p.) containing 3½ *lb.* of *sugar* per gall., 7 quarts; *orange flower water* (foreign), 1 quart. Delicious.

Crême de Noyeau. See *Noyeau.*

Crême d'Orange. From *oranges*, sliced, 3 dozen; *rectified spirit*, 2 gall.; digest for 14 days; add of *lump sugar*, 28 *lb.* (previously dissolved in water, 4½ gall.); *tincture of saffron*, 1½ *fl. oz.;* and *orange flower water*, 2 quarts.

Crême de Portugal. Flavoured with *lemon*, to which a little *oil of bitter almonds* is added.

Curaçoa. From *sweetened spirit* at 56 u. p., containing 3½ *lb.* of *sugar* per gall., flavoured with a *tincture* made by digesting the *oleosaccharum* prepared from *Seville oranges*, 9 in number; *cinnamon*, 1 dr.; and *mace*, ¾ dr., in *rectified spirit*, 1 pint. It is coloured by digesting in it for a week or 10 days, *Brazil wood* (in powder), 1 *oz.*, and afterwards mellowing the colour with *burnt sugar*, q. s.

Delight of the Mandarins. From spirit (22 u. p.), 1 gall.; *pure soft water*, ½ gall.; *white sugar* (crushed small), 4½ *lb.; anisum chinæ*, and *ambrette* or *musk seed*, of each, bruised, ½ *oz.; safflower*, ¼ *oz.;* digested together in a carboy or stone bottle, capable of holding double, and agitated well every day for a fortnight.

Eau de Cedrat, Cedrat Water. As *crême de cedrat*, but using *less sugar*.

Eau de Chasseurs. See *Peppermint Cordial.*

Eau de Vie d'Andaye, Eau de vie d'Anis; Aniseed Liqueur Brandy. From *brandy* or *proof spirit*, 1 gall.; *sugar*, ¾ *lb.*; dissolved in *aniseed water*, 1 pint.

Extrait d'Absinthe de Suisse; Swiss Extract of Wormwood. From the *tops of absinthum majus*, 4 *lb.*; *tops of absinthum minus*, 2 *lb.*; *angelica root*, *calamus aromaticus*, *seeds of anisum chinæ*, and *leaves of dittany of Crete*, of each, 15 gr.; *brandy* or *spirit* at 12 u. p., 4 gallons; macerate for 10 days, then add *water*, 1 gall.; distil 4 gall. by a gentle heat, and dissolve in the distilled spirit of *crushed white sugar*, 2 *lb.* Tonic and stomachic. Served round at some tables after wine has been taken freely, to recruit the stomach, and enable it to bear more.

Gold Cordial. From *angelica root* (sliced), 1 *lb.*; *raisins*, ½ *lb.*; *coriander seeds*, 2 *oz.*; *caraway seeds* and *cassia*, of each, 1½ *oz.*; *cloves*, ½ *oz.*; *figs* and *sliced liquorice root*, of each, 4 *oz.*; *proof spirit*, 3 gall.; *water*, 1 gall.; digest 2 days, and distil 3 gallons by a gentle heat; to this add of *sugar*, 9 *lb.*, dissolved in *rose water* and *clean soft water*, of each, 1 quart; lastly, colour the liquid by steeping in it of *hay saffron*, 1¼ *oz.* This cordial was once held in much esteem. It derives its name from a small quantity of *gold leaf* being formerly added to it.

Huile d'Anis. See *Créme d'Anis.*

Huile de Vanille. Flavoured with *essence* or *tincture of Vanilla.* It is kept in a decanter, and used to flavour liqueurs, grog, &c.

Huile de Venus. From the *flowers of the wild carrot* (daucus silvestris,—*Linn.*) 2½ *oz.*, and *sugar*, 3 *lb.* to the gall. It is generally coloured by infusing a little *powdered cochineal* in it.

Jargonelle, Jargonelle Cordial. Flavoured with *essence of jargonelle pear* (acetate of amyle). *Pine-apple cordial* and *liqueurs* from some other *fruits* are also prepared from the new fruit essences. See *Essences*, *Ratafias*, and *Oils* (Volatile).

Lemon Cordial. Digest *fresh* and *dried lemon peel*, of each, 2 *oz.*, and *fresh orange peel*, 1 oz., in *proof spirit*, 1 gall. for a week; strain with expression, add of *clear soft* water, q. s. to reduce it to the desired strength, and *lump sugar*, 3 *lb.* to the gallon. The addition of a little orange flower or rose water improves it.

Liquodilla. Flavoured with *oranges* and *lemons*, of each, sliced, 3 in number; with *sugar*, 2½ *lb.* per gall.

Lovage Cordial. From the *fresh roots of lovage* (ligusticum levisticum,—*Linn.*), 1 *oz.*, to the gallon. A *fourth* of this quantity of the *fresh roots of celery* and *sweet fennel* are also commonly added. In some parts a little *fresh valerian root* and *oil of savine* are added before distillation. It is much valued by the lower classes in some of the provinces for its stomachic and emmenagogue qualities.

Oil of Cedrat. See *Crême de Cedrat.*

Orange Cordial. Like *lemon cordial* or *créme d'orange*, from *fresh orange peel*, ½ *lb.* to the gallon.

Parfait Amour, Perfect Love. Flavoured with the *yellow rind* of 4 *lemons*, and a teaspoonful of *essence of vanilla* to the gallon, with *sugar*, 3 *lb.*, and *powdered cochineal*, q. s. to colour.

Peppermint, Peppermint Cordial, Sportsman's do., X. Mint; Eau de Chasseurs. This well-known compound is in greater demand in every part of the kingdom than all the other cordials put together.

Prep. 1. From *peppermint water*, and *gin* or *plain spirit* (22 u. p.), of each, 1 pint; *lump sugar*, ¾ *lb.*

2. (*Wholesale.*) *English oil of peppermint*, 5 *oz.*, is added to *rectified spirit of wine*, 3 pints, and the mixture is agitated well together for some time in a corked bottle capable of holding 4 pints or more; it is then emptied into a cask having a capacity of *upwards* of 100 gall., and *perfectly white and flavourless proof spirit*, 36 gall., is poured in, and the whole well agitated for 10 minutes; a solution of the *best double refined lump sugar*, 2¾ cwt., in about 35 gall. of *pure filtered rain water*, is then added, and the contents of the cask "well rummaged up," in the usual manner, for at least 15 minutes; sufficient *clear rain water* to make up the whole quantity to *exactly* 100 gallons, and holding in solution *alum*, 5 *oz.*, is next added, and the whole is again well agitated for at least a quarter of an hour, after which the cask is bunged down, and allowed to repose for a fortnight before it is "broached" for sale.

Obs. The last formula produces a beautiful article, provided the ingredients are of good quality. Care on this point is particularly necessary in reference to the *essential oil*, which should only be purchased of some *known respectable dealer.* That prepared at Mitcham, Surrey, and hence called "*Mitcham oil of peppermint*," is not only the strongest but the best flavoured, and though more than double the price of the foreign oil, is, in the long run, much the cheapest. The *sugar* should be sufficiently pure to dissolve in a wine glassful of clear soft water without injuring its *transparency*, and the *cask* should be a fresh-

emptied gin pipe, or one properly prepared for gin, as, if it "gives colour," it will spoil the cordial. When these particulars are attended to, the product is a "*bright*" *transparent* liquor as soon as made, and does not require fining. Should there be be the slightest opacity, the addition of 2 *oz.* of *salt of tartar* dissolved in a quart of *hot water*, will have the effect of "clearing it down" in the course of a few days. The *product* is 100 gall. of cordial at 64 u. p.

Pimento, Pimento Cordial, Pimento Dram. Rather strongly flavoured with *allspice* or *pimento.* It has obtained a great repute in the West Indies in diarrhœa, cholera, and bowelly complaints generally.

Raspberry Cordial. From *raspberry brandy, capillaire,* and *water,* equal parts. A still superior article is prepared by flavouring *sweetened spirit* with the new "*raspberry essence.*"

Ratifias. These are numerous, and are noticed in another part of this volume. The same remark applies to *Shrub* and *Usquebaugh.*

Shrub. See *above.*

Sighs of Love.—a. From *proof spirit flavoured with otto of roses* and *capillaire,* equal parts.

b. From *sugar,* 6 *lb.; pure soft water,* q. s. to produce a gallon of syrup, to which add of *eau de rose,* 1 pint; *proof spirit,* 7 pints. It is stained of a pale pink by *powdered cochineal.* A very pleasant cordial. A drop or two (not more) of essence of ambergris or vanilla improves it.

Tears of the Widow of Malabar. As *balm of Molucca,* but employing *cloves* (bruised), ½ *oz.*, *mace* (shreded), 1 dr., and a teaspoonful of *essence of vanilla* for flavouring. Some add of *orange-flower water,* ¼ pint. It is slightly coloured with *burnt sugar.*

Tent. From *plain spirit* (22 u. p.) and *port wine,* of each, 1 quart; *sherry* and *soft water,* of each, 1 pint; *orange-flower water* and *lemon juice,* of each, ¼ pint; *essence of ambergris,* 2 drops (not more); *sugar,* 2 *lb.* See *Wines.*

Usquebaugh. See *above.*

LIQUID COLOURS. See *Stains, Show Colours, &c.*

LIQUODILLA. See *Liqueurs.*

LIQUOR. Syn. *Liquor,*—Lat. *Liqueur,*—Fr. This term is applied in the London Pharmacopœia to those aqueous solutions commonly, though improperly, called *waters;* as *liquor ammoniæ, liquor potassæ, &c.;* which, being simple solutions of pure potassa and gaseous ammonia, would be more correctly and intelligibly called "*solutions.*"

The term "*liquor*" has also, of late years, been applied to certain concentrated preparations, most of which would be more correctly termed "*fluid extracts,*" as they merely differ from *good* extracts in their consistence, and from *ordinary* extracts in containing less starchy matter, albumen, and gum. There is also usually a little spirit added to them, to prevent decomposition. *Liquors of this kind* may be *prepared* of the finest quality, by the same processes that are required for the preparation of good soluble extracts; observing to stop the evaporation as soon as the consistence of treacle is acquired, and when cold, to add 1-4th or 1-5th part of their *then weight* in *rectified spirit.* The addition of 3 or 4 drops of the *oils of cloves* and *mustard seed,* dissolved in the spirit, will secure them from any risk of "*moulding*" or *fermenting;* in fact, with this addition many of them will keep well *without* spirit, provided they are evaporated sufficiently, and kept in a cool place. The *liquors* which are *merely concentrated infusions* or *decoctions,* and which, in their consistence, do not even approximate to extracts, may be made in the manner directed at pages 309 and 601.

Much confusion would be prevented if the term *concentrated decoction, infusion, &c.,* were adopted for those vegetable preparations possessing 8 times the usual strength; *liquors,* for those of a higher strength, but still sufficiently liquid, to be treated as such, in dispensing, &c.; and *fluid extracts,* for those possessing considerable consistence, and approaching the common extracts in their degree of concentration and mode of preparation. See *Decoctions, Infusions, Essences, Extracts, Solutions, &c.*

The following formulæ present some illustrations of the preparation of this class of medicines.

LIQUOR (Anodyne,—Hoffman's). See *Spirit of Ether* (Compound).

LIQUOR (Anodyne,—Vegetable). See *Spirit of Acetic Ether.*

LIQUOR (Antinephritic). Syn. *Liquor Antinephriticus,* — Lat. *Prep.* (Adams.) *Poppy heads,* 6 oz.; *water,* 1½ pint; boil to one third, strain with pressure, and add of *nitrate of potassa,* 1 oz. *Dose.* 1 to 2 teaspoonfuls night and morning; in gravel and painful affections of the kidneys and bladder.

LIQUOR (Antipodagric, — Beguin's). Syn. *Hoffman's Gout Liquid; Liquor Antipodagricus Hoffmannii,*—Lat. *Prep.*

From *Boyle's fuming liquor*, 1 part; *spirit of wine*, 3 parts. Sudorific. *Dose.* 20 to 30 drops; or *externally*, in gout, and other painful affections, either alone or combined with camphor. See *Perhydrosulphuret of Ammonia.*

LIQUOR (Antipsoric). Syn. *Liquor Antipsoricus, Lotio A.*,—Lat. *Prep.* (Van Mons.) *Sulphuret of sodium*, 1½ dr.; *hydrochlorate of ammonia*, 75 gr.; dissolve each separately in *water*, ½ pint, mix the solutions, and filter. In itch, and other moist skin diseases.

LIQUOR (Bleaching). See *Solution of Chloride of Lime.*

LIQUOR (Boyle's Fuming). See *Perhydrosulphuret of Ammonia.*

LIQUOR OF CALUMBA. Syn. *Liquor Calumbæ*,—Lat. Same as *concentrated infusion of calumba.*

LIQUOR OF CAMPHOR. See *Essences.*

LIQUOR OF CHIRETTA. Same as *concentrated infusion of chiretta.*

LIQUOR OF CINCHONA. Syn. *Liquor of Bark; Concentrated Infusion of Bark, Inspissated do. do.; Infusum Cinchonæ Spissatum*,—Ph. L. *Prep.* 1. (Ph. L.) *Yellow cinchona bark* (bruised), 3 lb, is macerated in *distilled water*, 6 pints, at two successive operations, as directed under *extract of cinchona*, Ph. L.; the mixed infusions are evaporated by the heat of a water-bath to one fourth, and placed aside to settle; the clear portion is decanted, the remainder strained, and the mixed liquid again evaporated until its sp. gr. reaches 1·200; to this, when cold, *rectified spirit* is dropped in, by degrees, "so that 3 fl. dr. may be added to each fl. oz. of the liquor;" lastly, allow it to repose for 20 days, that the dregs may subside.—*Obs.* It is not at all clear whether the college means *3 fl. dr. of spirit* to be added to *each fl. oz. of the liquid before its addition*, or that it is to be added so that *each fl. oz. of the product* shall contain that quantity. We presume the former. 1 fl. dr. of this preparation is said to represent fully 4 fl. oz. of the *infusion of cinchona*, Ph. L.; but it is obvious that it must be liable to great variations in strength. "In a general way, 1 fl. dr. may be considered equal to 3 fl. oz. of the infusion." (Pereira.) As commonly met with, this preparation is nearly destitute of the cinchona alkaloids.

2. *Yellow cinchona bark*, bruised, 56 *lb.*; and *water*, holding in solution *sulphuric acid*, 1½ *lb.*; are macerated together, with occasional agitation in a covered earthen vessel for 48 hours, after which the liquid is expressed, and the residuum or marc is treated with *fresh water*; the mixed strained liquid is then evaporated as rapidly as possible in earthenware, to exactly 6 *lb.*; to this *rectified spirit*, 1¼ *lb.*, is added, and the whole is set aside for a week or 10 days; the clear portion is, lastly, decanted and preserved in well-closed bottles. The *product* is very rich in quinine. It is 96 times as strong as the *decoction of cinchona*, Ph. L., and 12 times as strong as the *concentrated infusion* or *decoction of cinchona*, Ph. L. This preparation resembles the *liquor cinchonæ* sold by certain houses in the trade, at 24*s.* per *lb.*, wholesale.

3. Exhaust the *bark* as above, by maceration in 3 successive *waters without acid*, filter, evaporate the mixed liquors to 7 *lb.*, and proceed as before. Inferior to the last, and less rich in the cinchona alkaloids. Very thick; scarcely liquid.

LIQUOR OF PALE CINCHONA. Syn. *Liquor Cinchonæ Pallidæ; Infusum Cinchonæ Spissatum*,—Ph. L. From *pale bark*, as the last.

LIQUOR (Disinfecting). See *Solutions of the Chlorides of Lime, Soda,* and *Zinc,* and *Disinfecting Compounds.*

LIQUOR OF ERGOT. Syn. *Essence of Ergot of Rye, Concentrated Infusion of do.; Essentia Secalis Cornuti, Liquor Ergotæ, Infusum Ergotæ Concentratum*,—Lat. *Prep.* Recent *ergot of rye* (reduced to coarse powder by pounding, or preferably by grinding it in a pepper-mill), 1½ *lb.*, and *boiling distilled water*, 4 *lb.*, are digested together in a closed vessel, with frequent agitation until cold, and then put into a wide-mouthed bottle, along with *rectified spirit*, 2 *lb.*; the whole is then allowed to macerate for a week, after which the liquor is expressed and filtered. 4 fl. dr. of *this essence* are equal to 1 dr. of *ergot* in substance. It is 8 times the strength of the infusion (as usually prepared according to the formula of Pereira and others), and 2½ times the strength of the *tincture of ergot* of the London Apothecary's Hall. This is the only *essence* or *liquor of ergot* known in the wholesale trade.

LIQUOR OF FLINTS. See *Solutions.*

LIQUOR (Libavius's). Bichloride of tin.

LIQUOR OF MATICO. Syn. *Concentrated Infusion of Matico; Liquor Maticonis, Infusum Maticonis Concentratum*,—Lat. *Prep.* From *matico leaves*, 1 *lb.*; *rectified spirit*, ½ pint; *distilled water*, 32 fl. oz.; digest 10 days, express, and filter. 1 fl. dr. added to 7 fl. dr. of water is equal to 1 fl. oz. of the common infusion.

LIQUOR OF MYRRH. Syn. *Solution of Myrrh; Liquor Myrrhæ, Loco Liquaminis Myrrhæ*,—Lat. *Prep.* (Ph. Bor.) *Extract of myrrh* (Ph. Bor.), 1 oz.; *distilled water*, 5 fl. oz.; mix thoroughly, decant, and strain. It should be of a brownish-yellow colour, and turbid. *Dose.* ½ to 1 fl. dr.

LIQUOR OF OPIUM. Syn. *Liquor Opii, Liq. O. Concentratus, Liq. Opiatus*, —Lat. *Prep.* 1. See Black drop.

2. (Messrs. Smith.) *Opium*, 4 oz., is made into an *extract* and denarcotized by *ether;* it is then dissolved in alcohol, filtered, evaporated nearly to dryness, and redissolved in *water*, q. s. to furnish 12 oz. of solution; to this is added of *rectified spirit*, 2¾ oz., with *water*, q. s. to make the whole up to 16 oz. *Dose.* 3 to 12 drops.

LIQUOR OF OPIUM (Acetic). Syn. *Liquor Opii Aceticus*,—Lat. *Prep.* (Mr. Houlton.) See *Houlton's Laudanum.*

LIQUOR OF OPIUM (Citric). Syn. *Liquor Opii Citricus*,—Lat. *Prep.* 1. *Powdered opium*, 1½ oz.; *lemon juice*, 1½ pint; *evaporate* to one-half, cool, add of *rectified spirit*, 5 fl. oz., and the next day decant or filter; same strength as laudanum.

2. (*Liquor Morphiæ Citratis*,—Dr. Porter.) *Opium*, 4 oz.; *citric acid*, 2 oz.; triturate, and add of *boiling water*, 16 fl. oz.; digest with agitation for 24 hours, and filter. This last has above three times the strength of laudanum. It is sadly misnamed.

LIQUOR OF OPIUM (Hydrochloric). Syn. *Solution of Muriate of Opium; Liquor Opii Hydrochloricus*,—Lat. *Prep.* (Dr. Nichol.) *Powdered opium*, 1½ oz.; *distilled water*, 1 pint; *hydrochloric acid*, 1½ fl. oz.; digest a fortnight, and strain with expression. Same strength as laudanum. According to Dr. Nichol this is preferable to every other preparation of opium.

LIQUOR OF OPIUM (Sedative,—Battley's). Syn. *Sedative Solution of Opium; Liquor Opii Sedativus*,— Lat. *Prep.—a. Hard aqueous extract of opium* (bruised), 3 *oz.*, is boiled in *water*, 1½ pint, until dissolved; to the solution, when cold, *rectified spirit*, 6 *oz.*, is added, together with *water*, q. s. to make the whole measure *exactly* 1 quart.; the liquor is, lastly, filtered.

b. From *hard extract of opium*, 22 *oz.; boiling water*, 13 pints; *rectified spirit*, 3 pints; as the last.

c. From *extract of opium* (Ph. L.), 4¼ *oz.; water*, 1 quart, boil till reduced to 34 fl. oz.; cool, filter, and add of *rectified spirit*, 6 fl. oz. and *water*, q. s. to make up exactly 1 quart.

Obs. The first two formulæ, which vary only in their quantities, are identical with that employed by Mr. Battley, as we have already mentioned at *page* 438. As hard extract of opium is not always at hand, we have introduced a formula in which the ordinary extract is ordered. It gives a precisely similar product to the others, provided the *cold aqueous decoction* is filtered before adding the spirit. Battley's *liquor opii sedativus* is an excellent preparation, less exciting than opium or laudanum. *Dose.* 10 to 30 drops. Dr. Christison states that 20 drops of Battley's *solution* are equal to 30 drops of the common tincture.

LIQUOR OF RHUBARB. Syn. *Liquor Rhei, Infusum Rhei Concentratum*,— Lat. *Prep.* 1. *Rhubarb* (well bruised), 6¾ *oz.*; *water*, q. s.; *rectified spirit*, ½ pint; proceed as for *infusion of calumba* (conc.); to produce a quart. 8 times the usual strength.

2. See *Infusion of Rhubarb* (Concentrated).

LIQUOR OF SARSAPARILLA. Syn. *Fluid Extract of Sarsaparilla; Liquor Sarzæ, Essentia Sarsaparillæ*,—Lat. *Prep.* Either *the simple* or the *compound liquor of sarsaparilla* may be made from the corresponding decoction, or, preferably, the *infusion prepared with water* at 125° Fahr., by carefully evaporating it until sufficiently concentrated, and then straining it through flannel, and adding a *little spirit.* Jamaica sarsaparilla should be alone employed, as the other varieties, especially the Honduras, not only possess less medicinal virtue, and yield less extract, but are very liable to ferment, and get mouldy, unless an undue proportion of spirit is added to them. See *Extracts* (p. 441-2).

LIQUOR OF SENNA. Syn. *Liquor Sennæ*,—Lat. Both the *fluid extract* and the *concentrated infusion of senna* are called by this name, but more generally the former. The following are additional formulæ:—

1. (Duncan.) *Senna*, 15 *lb.; boiling water*, 5 gall.; proceed by the method of displacement, evaporate the product to 10 *lb.*, add of *molasses*, 6 *lb.* (previously concentrated over a water bath until it begins to congeal on cooling), dissolve, and further add of *rectified spirit*, 1¼ pint, together with *water*, q. s. to make the whole measure exactly 12 pints. Every fl. oz. represents 1 oz. of senna.

2. (Dr. Tweedy.) As the last, but using

tincture of ginger (prepared with rectified spirit), 1½ pint; instead of the spirit there ordered.

LIQUOR OF SOAP. Syn. *Liquor Saponis*,—Lat. See *Tinctures*.

LIQUOR (Styptic). Syn. *Liquor Stypticus*,—Lat. *Prep.* (Ph. Slesvico-Holsat. 1831.) *Alum* and *sulphate of copper*, of each, 1½ oz.; *sulphuric acid*, 1 oz.; *water*, 1 ℔; dissolve, and filter.

LIQUOR OF TARAXACUM. Syn. *Fluid Extract of Dandelion; Extractum Taraxaci Fluidum, Liquor Taraxaci*,—Lat. *Prep.* 1. *Dandelion roots* (dried), 28 *lb.*, are rinsed in *clean cold water*, to remove dirt, and then sliced small, and macerated in enough *cold water* to cover them, for 24 hours; the liquid is next pressed out, and after the fecula has subsided, the clear portion is decanted, and heated to 180° or 190° Fahr., to coagulate the albumen; the liquid is then filtered while hot, and evaporated by steam, or preferably by a current of warm air, until it is reduced to 22½ *lb.*; to this *rectified spirit* 6 *lb.*, is added, and after thorough agitation, the vessel is set aside for a week or a fortnight, after which the clear portion is gently poured from the sediment and preserved in well-closed bottles in a cool place. A very fine article. It represents an equal weight of the root.

2. The *expressed juice of dandelion* is heated to near the boiling point, strained, and evaporated as the last to a proper consistence; ¼th or ⅓th of *rectified spirit* is then added, and the liquid is otherwise treated as before. Very odorous and pale coloured.

3. *Dried root* (coarsely powdered), 1 *lb.*; *water*, 1¼ pint; *rectified spirit*, ½ pint; digest a week, express the liquor, pass it through a hair sieve into a bottle, and in 10 days decant the clear portion.

4. (Ph. Bor.) *Extract of dandelion*, 3 parts; *water*, 1 part (or q. s.); triturated together.

5. (Mr. W. Procter.) *Fresh root*, 2 *lb.*, is sliced and reduced to a pulp, and macerated with ⅛th of its bulk of *rectified spirit* for 24 hours; it is then subjected to strong pressure, the *marc* is treated with *water containing a little spirit*, 1 pint, and the liquid is again expressed; the mixed product is evaporated to 12 fl. oz., and when cold, *rectified spirit*, 4 fl. oz., is added, and the whole filtered.

Obs. Liquor of taraxacum has a very large sale. The *dose* is 1 to 2 fl. dr. See *Extracts*.

LIQUOR OF VALERIAN. Syn. *Fluid Extract of Valerian; Liquor Valerianæ, Extractum V. Fluidum*,—Lat. *Prep.* See *Extracts*. 1 fl. oz. is equal to ½ oz. of the root.

LIQUOR OF VANILLA. Syn. *Fluid Extract of Vanilla; Liquor Vanillæ, Extractum V. Fluidum*,—Lat. *Prep.* 1. *Vanilla* (sliced), 1 *lb.*; *rectified spirit*, 3 pints; prepare a tincture either by displacement or maceration, and reduce it by distillation at the lowest possible temperature, to 1½ *lb.*; put this into a strong bottle whilst hot, add of *white sugar candy* (in powder), ½ *lb.*, cork down, and agitate the whole until it is nearly cold. Very fine. *Used* chiefly for its odour and flavour. It represents half its weight of vanilla.

2. (W. Procter.) *Vanilla* (cut into thin transverse slices), 1 oz.; *sugar*, 3 oz.; triturate until reduced to fine powder, put it into a strong pint bottle, along with *syrup*, ½ pint; *water*, 2 oz. ;tie down the cork, and set the bottle for nalf an hour in *boiling water*; cool, strain, and treat the residue in a like manner with a mixture of *water*, 6 fl. oz., and *rectified spirit*, 1 fl. oz.; lastly, mix the two products. Greatly inferior to the last.

LIQUORS (Medicated Vinous). See *Wines*.

LIQUORICE. Syn. *Stick Liquorice; Liquoritia; Glycyrrhizæ Radix; Glycyrrhiza*,—Ph. L. & D. *G. Glabra*,—Ph. E. "The recent and the dried root of *glycyrrhiza glabra*," Linn., or common liquorice. "The fresh root is to be kept buried in dry sand for use." (Ph. L.) It has a sweetish taste, and is slightly aperient, expectorant, and diuretic. It is a popular demulcent and pectoral. As a masticatory it allays thirst and irritation. Its *extract* is the common *liquorice*, *Spanish liquorice*, or *Spanish juice* of the shops. See *Extracts*, *&c.*

LIRIODENDRINE. A white crystallizable principle, obtained from the *root-bark* of the *liriodendron tulipifera* (Linn.) or *tulip tree* of North America. It has a bitter taste, is soluble in alcohol, slightly so in water, and closely resembles boracic acid.

LISBON DIET-DRINK. The original formula for this article is given at *page* 328.

LIST. The *border* or *selvage* torn off a piece of cloth. It is used by the *French* polisher and law stationers to form their rubbers, and for numerous other purposes.

LITHARGE. Syn. *Semi-vitrified Oxide of Lead; Plumbi Oxydum*,—Ph. L. *Plumbi*

Oxydum Semi-vitreum,—Ph. D. *Lithargyrum*,—Ph. E. The litharge of *commerce* is semivitrified protoxide of lead, obtained chiefly by scraping off the *dross* that forms on the surface of *melted lead* exposed to a current of air (*dross of lead; plumbum ustum*), and heating it to a full red, to melt out any undecomposed metal. The *fused oxide* in cooling forms a yellow or reddish semi-crystalline mass, which readily separates into scales; these, when ground, constitute the *powdered litharge* of the shops. Litharge is also prepared by exposing red lead to a heat sufficiently high to fuse it, and *English litharge* is obtained as a secondary product by liquefaction, from argentiferous lead ore, when it is often called *silver stone*.

Pur. "Entirely, or almost entirely, soluble in dilute nitric acid. This solution is blackened by sulphuretted hydrogen. Potassa throws down a white precipitate, which is re-dissolved by adding the same in excess. If sulphate of soda be added to 100 gr. of this oxide dissolved in nitric acid, 135 gr. of sulphate of lead are precipitated." (Ph. L.) "50 gr. dissolve *entirely*, and without effervescence, in 1½ fl. oz. of pyroligneous acid; and the solution precipitated by 53 gr. of phosphate of soda, remains precipitable by more of the test." (Ph. E.) The solution in both acetic and nitric acid should be colourless. It is of great importance to the pharmaceutist to obtain pure litharge, as the slightest impurity will often colour and spoil his lead plaster (*emp. plumbi*), and solution of diacetate of lead (*liq. plumbi diacetatis*).

Uses. Litharge is employed *in pharmacy*, to make plasters and several other preparations of lead; by *painters* as a "*drier*" for oils; and for various other purposes in the arts.

Obs. The *litharge* of *commerce* is distinguished by its colour into *Litharge of gold* (lithargyrum auri, l. aurium, l. chrysitis), which is dark coloured and impure, and *Litharge of Silver* (silver stone; lithargyrum argenti, l. argenteum, l. argyritis), which is purer, and paler coloured. The dark colour of the former is generally said to be owing to the presence of red lead; but this we find is not the case, the increased colour depending chiefly on its being more slowly cooled. *Foreign litharge* generally contains copper and iron; and, not unfrequently, a little silver and silica. These are readily detected by the usual tests. In *grinding litharge* about 1 *lb.* of *olive oil* is usually added to each 1 cwt., to prevent dust. The *best solvents* of litharge are *nitric acid* and *acetic acid*. As it slowly absorbs the carbonic acid of the air, it generally effervesces slightly when treated with acids, and this effervescence is stronger in proportion to its age.

LITHIA. Syn. *Oxide of Lithium*. An alkali or alkaline earth, discovered in 1818, by M. Arfwedson, in a mineral called *petalite*. It has since been found in a few other minerals, and in minute quantities in some mineral springs.

Prep. (Berzelius.) *Petalite* or *spondumene* (in fine powder), 1 part; *fluor spar*, 2 parts; mix, add *oil of vitriol*, 10 parts, and heat the mixture as long as acid vapours are evolved; dissolve the residuum in *pure water of ammonia*, boil, filter, evaporate the solution to dryness, and heat the dry mass to redness. The matter left is pure *sulphate of lithia*, from which *pure lithia* may be obtained by decomposing it by *acetate of baryta*, and expelling the acetic acid from the filtered solution by heat; at first *carbonate of lithia* is formed, from which the carbonic acid is expelled as the temperature increases.

Prop., &c. Lithia is caustic, alkaline, and sparingly soluble in water. One of its most remarkable properties is its power of corroding platinum. It is distinguished from POTASSA and SODA by its *phosphate* and *carbonate* being only sparingly soluble in water,—from BARYTA, STRONTIA, and LIME, by forming crystallizable and soluble salts with *sulphuric acid* and *oxalic acid*,—and from MAGNESIA, by the solution of its *carbonate* exhibiting an alkaline reaction. Heated on platinum it tinges the flame of the blowpipe carmine red. With the acids, lithia forms SALTS, most of which may be made by the direct solution of *itself* or *carbonate* in the *dilute acids*.

LITHIA (Carbonate of). Syn. *Lithiæ Carbonas*,—Lat. *Prep.* To an *aqueous solution of sulphate of lithia*, add a *strong solution of sesquicarbonate of ammonia*, collect the precipitate, drain and press it, wash it with a little *rectified spirit*, and dry it. By dissolving it in *boiling water*, and slowly evaporating the solutions, crystals may be obtained.

Prop., &c. It resembles carbonate of magnesia in appearance; is soluble in about 100 parts of cold water, and in considerably less of boiling water. It has been proposed by M. Lipowitz and others, as a solvent for uric acid deposits. According to Biswanger, 1 part of carbonate of lithia in 120 parts of water, takes up, at blood-heat, nearly 4 parts of uric acid. Mr. Alexander Ure recommends a dilute solution of this substance as

an injection in lithic calculus, as it is a better solvent of uric acid than either borax or the alkaline carbonates. "Of all the various menstrua hitherto recommended, none appear to promise more favorably than the carbonate of lithia." "If by means of injections" (of this solution) "we can reduce a stone at the rate of a grain or more an hour, we shall not merely diminish the bulk of the calculus, but further loosen its cohesion, disintegrate it, so to speak, causing it to crumble down, and be washed away in the stream of urine." (Mr. A. Ure.) *Dose.* 2 to 5 gr., twice or thrice a day; as an *injection*, 1 gr. to *warm water*, 1 fl. oz. See *Earths.*

LITHIC ACID. See *Uric Acid.*

LITHIUM. The metallic base of *lithia*, first obtained by Sir H. Davy by exposing *hydrate of lithia* in contact with *mercury* to galvanic action, and decomposing the resulting *amalgam* by distillation. Its existence as a metal is so transient, that its properties cannot be fully examined. It is a white-coloured metal, like *sodium*, and exceedingly oxidable.

LITHOCHOLIC ACID. A name given by Wöhler to an acid found by him in a biliary concretion. It possesses no practical interest.

LITHOFELLIC ACID. Syn. *Lithofellinic Acid.* An acid discovered by Göbel, in a biliary concretion. It forms the chief portion of the substances called *oriental bezoar-stones.* It is obtained by digesting the *calculus* in *boiling alcohol* of 98%, evaporating, and re-digesting the residuum first in *cold*, and then in *boiling alcohol;* from the latter solution the acid is procured by slow evaporation. Colourless crystals, when pure, forming salts with the bases termed *Lithofellinates.* According to Taylor *lithofellic acid* is identical with *ellagic acid.*

LITHOGRAPHY. Want of space renders our notice of this beautiful and useful art necessarily brief.

There are two methods of lithography in general use. In the *one*, a drawing is made on the *stone* with a *lithographic crayon*, or with *lithographic ink;* in the *other* method, the design is made on *lithographic paper*, which, on being moistened and passed through the press, leaves its design on the surface of the stone, reversed. In either method, *water acidulated with oil of vitriol* or with *hydrochloric acid*, is poured over the stone, and by removing the alkali from the chalk or ink, leave the design on it in a permanent form, at the same time that it "etches" away a portion of the lights, and renders the surface more absorbent of water.

The *process* of *lithographic printing* is as follows:—*water* is thrown over the stone, the "*roller*" charged with *printing ink* is passed over the surface, the *paper* is applied, and a copy is obtained by the action of the *lithographic press.* The same process must be had recourse to for *each* copy. The nature of the stone is such that it retains with great tenacity the resinous and oily substances contained in the ink or crayon employed to form the design, and also absorbs water freely; this, combined with the peculiar affinity between resinous and oily substances, and their mutual power of repelling water, occasions the ink on the printing roller to *adhere to the design*, and to *leave untouched the lights.*

The *stones* are *prepared for lithography* by polishing in the ordinary way; the style of work for which they are intended determining the degree of labour bestowed upon them. For *crayon drawings*, the surface should have a fine grain, but the finish of the stone must depend upon the desired softness of the intended drawing; for *writing* or *drawing on in ink*, the surface must receive a higher polish, and must be finished off with *pumice stone and water.*

The *best lithographic stones* are obtained from Solenhofen, near Munich, and from Pappenheim, on the banks of the Danube. The white lias which lies immediately under the blue, near Bath, also yields good lithographic stones, and furnishes the principal portion of those employed in this country. See *Crayons*, *Inks*, and *Papers.*

LITHONTRIPTICS. Under this head are included numerous substances (*lithics; lithica*) used to prevent the formation of urinary calculi, or to dissolve them when already formed. Those employed with the former intention are more correctly termed *antilithics* (antilithica), and those with the latter, *lithontriptics*, or *lithonlytics* (lithontriptica, lithonlytica). In cases exhibiting a lithic diathesis, much depends on the regulation of the diet of the patient. When there is a superabundant secretion of uric acid, the food should contain as little nitrogen as possible, and should therefore be mainly of a vegetable nature; but, at the same time, care must be taken that the healthy action of the stomach is not impaired by the sudden or undue privation of the usual or necessary diet. *Indigestible substances*, as new bread, pastry, salt meat, and even soup, should be avoided; nor should malt liquors or acid wines be allowed. When the *white sand deposits* or

the *phosphates* occur, an acid system of diet is beneficial, with abstinence from alkalies, soda water, &c.; whilst lemon juice, the acid wines, and fruits in moderation, may be taken with advantage.

The following are the principal substances included under this head by pharmacological writers:—*Alkalies and their carbonates, benzoic acid, borax, carbonate of lithia, carbonic acid, carrot, cinnamic acid, diluents* (generally), *diuretics* (generally), *juniper, malic acid, Malvern waters, mineral acids, nitrosaccharate of lead, opium, phosphate of soda, phosphoric acid, poppies, turpentines, uva ursi, vegetable acids, vegetable astringents, vegetable bitters, Vichy waters, wall pellitory, water* (pure).

LITMUS. Syn. *Turnsole; Lacmus, Lacca Cærulea, L. Musiva, L. Musci,*—Lat. A blue substance prepared by the united influence of *water, air, ammonia,* and either *potassa* or *soda,* from *rocella tinctoria, lecanora tartarea,* or any of the other *tinctorial lichens* capable of yielding archil, by a process essentially similar to that adopted for the latter substance, except that *chalk* is generally used to form the paste, which is moulded into cakes and dried.

Pur., &c. "Soluble in both water and alcohol. Its blue colour is reddened by acids, and is restored by the addition of alkalies." (Ph. L. 1836.) It is extensively used by the *dyer* as a red and crimson colouring matter, and by the *chemist* as a test for acids. See *Archil, Cudbear, &c.*

LIVE-LONG. See *Candies.*

LIVER. Syn. *Hepar,*—Lat. A large abdominal viscus, the exclusive duty of which, until recently, was stated by physiologists to be *to secrete bile;* but the secretion of sugar for combustion in the lungs or capillaries is now said to be one of its chief duties. The *liver* is subject to several *diseases,* both functional and organic, among which *inflammation* or *hepatitis* holds the most important place. The *acute form of this disease* is ushered in with pain in the region of the liver, with sickness, costiveness, and a strong, hard, and frequent pulse, with great pain about the clavicle and shoulders. There is cough, oppressed breathing, and often vomiting of bilious matter. The urine is scanty, and of a saffron-yellow colour, and the skin and eyes are also tinged yellow. The *treatment* consists chiefly in bleeding, purging with salines accompanied with mercurials, the use of antimonials, and a blister applied over the region of the liver. Bitter tonics, as calumba, cascarilla, and gentian, may afterwards be had recourse to; and if the patient resides in a hot climate, a change to a temperate one should be made if possible. *Chronic hepatitis* requires similar treatment, but of a less active character. The more usual *causes* of diseases of the liver, besides those common to the other viscera, are residence in a hot climate, and the excessive use of highly seasoned food and alcoholic liquors.

LIVER. Syn. *Hepar,*—Lat. A term formerly applied to numerous substances, on account of their colour; as *liver of antimony* (hepar antimonii), *liver of sulphur* (hepar sulphuris), &c.

LIVERWORT. The *marchantia conica* and *polymorpha* (Linn.); on account of their supposed value in diseases of the liver. This name is now often given to Iceland moss.

LIVE-STOCK. The *choice, employment, breeding,* and *fattening* of *domestic animals* for the purposes of labour and profit, form most important objects in the successful management of a farm, and receive the especial attention of every scientific agriculturist. Want of space precludes us from doing more than to call attention to the necessity of selecting those breeds only which are most suited to the object in view, and so treating them as to enable them to return us the greatest amount of useful labour, or become the soonest ready for the market.

LIXIVIATION. The process of dissolving out or extracting the saline matter of bodies, more especially of ashes, the residua of distillations, &c., by means of ablution or digestion in water. The solution so obtained is called a *lye, ley,* or *lixivium,* and the salts resulting from the evaporatiom of such solutions, *lixivial salts.*

LOADSTONE. Syn. *Magnetic Iron-stone.* Native crystallized magnetic oxide of iron. See *Iron* (Oxides of).

LOAM. A native mixture of *clay, sand,* and *oxide of iron,* with more or less chalk. *Loamy soils* are of this description. They are called *heavy* or *light,* according to the proportion of clay; and *sandy, calcareous,* or *gravelly,* just as sand, gravel, or chalk form a characteristic portion of them.

LOBELIA. Syn. *Indian Tobacco; Lobelia,*—Ph. L. E. & D. "The flowering herb" of "*lobelia inflata,*"—Linn. (Ph. L.), or *bladder-podded lobelia.* This herb has an unpleasant odour, and an acrid, burning, nauseous taste, somewhat resembling that of tobacco. In *small doses* (1 to 3 gr.) it is expectorant and diaphoretic; in *larger ones* (5 to 15 gr.), nauseant and emetic;

and in *excessive* doses, poisonous. According to Dr. Pereira, its principal value is that of an antispasmodic. It has been highly recommended by Dr. Elliotson in spasmodic asthma. He commences with small doses, and gradually increases them, unless headache or nausea occurs. Others give a full dose at or before the commencement of the fit. It has been also tried in croup, hooping-cough, and other diseases of the respiratory organs, with variable effect.

Lobelia is the panacea of Dr. Coffin, the author of the pretended system of medicine irreverently called "Coffinism."

LOBELIANINE. Syn. *Oil of Lobelia, Odorous Principle of do.* This name has been given by Dr. Pereira to the butyraceous volatile oil obtained by distilling Indian tobacco (*lobelia inflata*) along with water.

LOBELIC ACID. The acid existing in decoction of lobelia. It closely resembles gallic acid. It reddens litmus, and is precipitated by several metallic salts.

LOBELINE. Syn. *Lobeline, Lobelina.* A light yellowish-brown oily substance, found by Dr. Colhoun in lobelia inflata. It is volatile, soluble in alcohol, ether, and water; and in oil of turpentine, oil of almonds, and some other fixed oils; with the acids it forms crystallizable salts which are soluble. It resembles, and is probably identical with the nicotine of Berzelius. It may be *obtained* by the action of *alcohol* on the *seeds*, evaporation, digestion of the residue in *dilute acid*, and subsequent precipitation. 1 *oz.* of the seeds furnishes 2 gr. When perfectly pure, 1 gr. will kill a large dog.

LOBSTERS. See *Shell Fish.*

LOCKSOY. Rice boiled to a paste and drawn into threads. *Used* to thicken soups. It is imported from China.

LOCOFOCOS. See *Matches.*

LOCUSTIC ACID. A sour liquid obtained from the grasshopper. It is impure acetic acid.

LOGWOOD. Syn. *Sapan Wood; Hæmatoxylum*,—Ph. L. E. & D. *Hæmatoxyli Lignum, Lignum Campechense, L. Campechianum, L. Campescanum, L. Indicum, L. Sappan*,—Lat. var. The wood of *hæmatoxylon campechianum* (Linnæus). It is a valuable astringent, and its decoction, extract, and infusion are useful remedies in chronic diarrhœa and dysentery, and in hæmorrhages, &c. The extract is an efficient substitute for catechu and kino.

Logwood is extensively employed in *dyeing* and *calico printing* for the production of *reds, violets, purples, blacks, drabs,* &c. It readily yields its colour both to spirit and boiling water. The colour of its infusion is a fine red, turning on the purple or violet; *acids* turn it on the YELLOW, and *alkalies* DEEPEN it. To *stuffs mordanted* with *alum*, it gives various shades of VIOLET and PURPLE, according to the proportions of the materials. By using *solution of tin* as the mordant, various shades of RED, LILAC, and VIOLET, may be obtained. The addition of a little *Brazil wood* is commonly made to *brighten* the red. With a *mordant* of *sulphate* or *acetate of iron*, it dyes BLACK; and with the addition of a little *sulphate of copper*, GRAYS of various shades. It is, however, chiefly employed, in conjunction with *gall-nuts*, for blacks, to which it imparts a lustre and velvety appearance. *Silk* is usually turned through the cold decoction, but for *wool* the decoction is used either hot or boiling. Logwood is one of the cheapest and most easily managed of the dye stuffs. It is also used to make ink. See *Hematine, Inks,* &c.

LOHOCH. See *Linctus.*

LOLIINE. A pulverulent grayish-white substance obtained from *lolium temulentum* (Linn.) or *bearded darnel.* It is soluble in water and hot alcohol, has an acid reaction, and is very acrid. It has been proposed as a remedy in headache, neuralgia, sciatica, &c.

LOOCH. See *Linctus.*

LORICA. A species of lute applied as a coating to chemical vessels before exposing them to the fire. Its application is called *lorication.* See *Lutes.*

LOTION. Syn. *Lotio*,—Lat. An external application, or wash, consisting of water holding in solution medicinal substances. Lotions may be *prepared* of any soluble medicaments that are capable of exerting their action by contact with the skin. Writers on *pharmacology* have arranged them in classes, as sedative, anodyne, stimulant, &c., according to their effects. *Sedative* and *refrigerant* lotions are commonly employed to allay inflammation;—*anodyne* and *narcotic* lotions, to relieve pain;—*stimulant* lotions, to induce the maturation of tumours, &c.;—*detergent* lotions, to clean foul ulcers;—*repellent* and *resolvent* lotions, to discuss tumours, remove eruptions, &c.; *counter-irritant* lotions, to excite a secondary morbid action, with the intention of relieving one already existing. *Lotions* are usually *applied* by wetting a piece of linen with them and keeping it on the part affected; or, in slight cases, by moistening the part with the fingers previously dipped into them. Lotions

are more agreeable if made with *rose water*, but are not thereby rendered more efficacious. In all cases, *distilled water*, or *filtered soft water*, is alone admissible as the solvent.

As *lotions* are, in general, mere *extemporaneous* or *magistral preparations*, it will, of course, be only necessary here to give the formulæ for a few of those which are the most useful or the most frequently employed. These will serve as examples from which others may be prepared. As a GENERAL RULE, the *medium dose* of any substance dissolved in a *fluid ounce* of *distilled water*, forms a lotion of the proper strength, under all ordinary circumstances; or, what is the same thing, the *medium dose in grains*, taken in *scruples*, is sufficient for a *pint* of such a lotion. Thus; the dose of *sulphate of zinc*, is 1 to 3 gr., therefore— $\frac{1+3}{2} = 2$ gr., which is the proportion of sulphate of zinc to be taken for 1 *fl. oz. of water*, or 40 gr. for 1 *pint*. Again, the dose of *bichloride of mercury* is $\frac{1}{8}$ to $\frac{3}{4}$ gr., therefore— $\frac{\frac{1}{8}+\frac{3}{4}}{2} = \frac{7}{16}$ gr.; or nearly $\frac{1}{2}$ gr. per *fl. oz.*, and $8\frac{1}{2}$ gr. *per pint*. In this method, extreme or unusual doses, as, for instance, those of sulphate of zinc, as an emetic, in poisoning, &c., are not taken into the calculation. In all cases in which lotions are intended for extremely susceptible parts, it is proper to dilute them with an equal bulk of water. When intended for *collyria* they should be diluted with at least 3 to 4 times their bulk of water. See *Embrocations, Liniments, &c.*

LOTION (Acetate of Ammonia). Syn. *Lotio Ammoniæ Acetatis*,—Lat. *Prep.* 1. *Solution of acetate of ammonia*, 1 part; *water*, 2 parts.

2. (Hosp. F.) *Solution of acetate of ammonia*, *rectified spirit*, and *water*, equal parts. Discutient and refrigerant. In ordinary inflammations.

LOTION (Acetate of Lead). Syn. *Lotio Plumbi Acetatis*, — Lat. *Prep.* (Collier.) *Sugar of lead*, 1 dr.; *distilled water*, 8 fl. oz. Sometimes a little *vinegar* is added. In excoriations, burns, sprains, contusions, &c. See *Solution of Diacetate of Lead.*

LOTION (Acetate of Zinc). Syn. *Lotio Zinci Acetatis*,—Lat. *Prep.* (Béral.) *Acetate of zinc*, $1\frac{1}{2}$ dr.; *water*, 1 pint. Astringent; similar to lotion of sulphate of zinc.

LOTION (Acetic). Syn. *Lotio Aceti*,—Lat. *Prep.* 1. *Vinegar*, 1 part; *water*, 2 or 3 parts. For bruises, contusions, &c., and as a general refrigerant application to sound parts.

2. *Vinegar*, 1 fl. oz.; *cold water*, $\frac{1}{2}$ pint; as a wash in chronic ophthalmia, &c.

LOTION (Acid). See *Lotions of Acetic, Nitric*, and *Phosphoric Acid, &c.*

LOTION (Aconitine). Syn. *Lotio Aconitinæ*,—Lat. *Prep.* (Turnbull.) *Aconitina*, 8 gr.; *rectified spirit*, 2 fl. oz. In neuralgia; applied by means of a small piece of sponge mounted at the end of a stick. It must never be employed when the skin is broken or abraded; and it would be wise, in most cases, to dilute it with double its volume of proof spirit.

LOTION (Alkaline). Syn. *Lotio Alkalina, L. Potassæ Carbonatis*,—Lat. *Prep.* (P. Cod.) From *salt of tartar*, 1 oz.; *water*, 1 pint. Stimulant and detergent. Diluted with an equal bulk of water it forms an excellent cosmetic wash to remove scurf from the hair. Sometimes it is made with *almond milk* instead of water.

LOTION (Alum). Syn. *Lotio Aluminis*, —Lat. *Prep.* 1. From *alum*, $1\frac{1}{2}$ dr.; *distilled* or *rose water*, 1 pint. Astringent. For sore gums, nipples, excoriations, &c.

2. (*Compound*,—Cadet de Gassicourt.) *Alum* and *sulphate of zinc*, of each, 1 dr.; *plantain water*, 1 pint. As a wash for wounds and bleeding ulcers.

LOTION (Ammoniacal). Syn. *Lotio Ammoniæ, L. Ammoniacalis*,—Lat. *Prep.* 1. *Liquor of ammonia*, 3 fl. dr.; *cold water*, 5 fl. oz. As a stimulant to indolent ulcers, and in certain skin diseases.

2. (Swediaur.) *Liquor of ammonia, spirit of thyme*, and *spirit of camphor*, equal parts. In headaches; applied to the forehead and temples, and in other cases, as a counter-irritant. In most cases, it should be used diluted.

3. (*Opiated*,—Dr. Kirkland.) *Sal volatile*, $3\frac{1}{2}$ fl. oz.; *tincture of opium*, $\frac{1}{2}$ fl. oz.; *water*, 4 fl. oz. Anodyne, stimulant, and resolvent.

LOTION (Antiphlogistic). Syn. *Lotio Antiphlogistica*,—Lat. *Prep.* 1. (Copland.) *Solution of diacetate of lead*, 3 fl. dr.; *solution of acetate of ammonia*, 2 fl. oz.; *distilled water*, 1 pint. Refrigerant, sedative, and repellent. *Used* to allay inflammation, &c.

2. (A. T. Thomson.) *Opium*, 2 dr.; *distilled vinegar*, $\frac{1}{2}$ pint. Anodyne and refrigerant; in swelled joints, &c.

LOTION (Arnica). Syn. *Lotio Arnicæ*, —Lat. *Prep.* 1. *Tincture of arnica*, 1 fl. dr.; *rose water*, $2\frac{1}{2}$ fl. oz. In contusions, bruises, extravasations, &c.

2. (Niemann.) *Arnica flowers*, $\frac{1}{2}$ oz.; *hot vinegar*, 3 fl. oz.; *boiling water*, 5 fl. oz.; infuse until cold, and strain. In acute hydro-

YORKSHIRE COLLEGE

cephalus; or with *water*, q. s. to measure a pint, as a common lotion.

LOTION (Arsenical). Syn. *Lotio Arsenicalis, L. Acidi Arseniosi,*—Lat. *Prep.* 1. *Arsenious acid*, 5 gr.; *water*, 1 pint. In psoriasis, &c.

2. (Compound,—M. le Febre.) *Arsenious acid*, 8 gr.; *boiling water*, 16 fl. oz.; dissolve, and add of *extract of hemlock*, 1 oz.; *solution of diacetate of lead*, 3 fl. oz.; *tincture of opium*, 1 fl. dr. Every morning in cancer.

LOTION (Astringent). Syn. *Lotio Astringens,*—Lat. See *Lotions of Alum, Sulphate of Zinc, &c.*

LOTION (Barlow's). *Prep.* From *sulphuret of potassium* (in powder), 3 dr.; *soap* (sliced), 1½ dr.; *lime water*, 7½ fl. oz.; *proof spirit*, 2 fl. oz.; dissolve. In itch, ringworm, &c.

LOTION (Bateman's). *Prep.* From *bichloride of mercury*, 2 gr.; *compound spirit of lavender*, 1 fl. oz.; dissolve, and add of *distilled water*, 4 fl. oz. In obstinate cutaneous eruptions, more especially those of a papular character.

LOTION (Belladonna). Syn. *Lotio Belladonnæ,*—Lat. *Prep.* (Graefe.) *Extract of belladonna*, ½ dr.; *dilute solution of diacetate of lead*, ½ pint. Applied to tumours and glandular enlargements.

LOTION (Bichloride of Mercury). Syn. *Lotio Hydrargyri Bichloridi, L. H. Chloridi Corrosivi,*—Lat. *Prep.* 1. *Corrosive sublimate*, 5 to 10 gr.; *distilled water*, 1 pint. The addition of 5 or 6 gr. of *hydrochlorate of ammonia*, or as many drops of *hydrochloric acid*, increases the solvent action of the water, and renders the preparation less liable to change. Some persons dissolve the sublimate in 1 or 2 fl. dr. of *rectified spirit* before adding it to the water; but this is unnecessary. In obstinate eruptions, glandular swelling, obstinate sores, &c.; also as an injection.

2. (Good.) *Corrosive sublimate*, 1 dr.; *sal ammoniac*, 2 dr.; *nitre*, 4 dr.; *water*, 6 fl. oz.; dissolve. In itch, &c. For use, it should be diluted with about 3 times its bulk of water.

3. (*Lotio Hydrargyri Amygdalina,*—St. B. Hosp.) *Blanched bitter almonds*, 1 oz.; *water*, 1 pint; make an emulsion, and add of *bichloride of mercury* (dissolved in a little rectified spirit), 10 gr. This resembles *Gowland's lotion*, and may be used for it.

LOTION (Black). See *Mercurial Lotions.*

LOTION (Borax). Syn. *Lotio Boracis, L. Boracica.*—Lat. *Prep.* 1. (Dr. Abercrombie.) *Borax*, 2½ dr.; *distilled vinegar*, ¼ pint. In ringworm.

2. (Copland.) *Borax* (in powder), 1 dr.; *rose water* and *orange-flower water*, of each, 3 fl. oz.; dissolve. A fragrant and effective application to sore gums, sore nipples, excoriations, &c.

3. (Dr. Johnson.) *Borax*, 2 dr.; *precipitated chalk*, 1 oz.; *rose water* and *rectified spirit*, of each, 3 oz. For sore nipples.

4. (Dr. Meigs.) *Borax*, ½ oz.; *sulphate of morphia*, 6 gr.; *rose water*, 8 fl. oz. To allay itching and irritation, especially pruritus vulvæ.

LOTION (Bromine). Syn. *Lotio Brominii,*—Lat. *Prep.* (Dr. Glover.) *Bromine*, 1 dr.; *water*, 1 pint. As an application to scrofulous ulcers.

LOTION (for Burns). See *Liniments.*

LOTION (Camphorated). See *Evaporating Lotion.*

LOTION (Capsicum). Syn. *Lotio Capsici,* —Lat. *Prep.* (Griffith.) *Tinctures of capsicum* and *camphor*, of each, 4 fl. oz.; *liquor of ammonia*, 2 fl. oz. A powerful rubefacient and counter-irritant.

LOTION (Carbonate of Soda). Syn. *Lotio Sodæ Carbonatis,*—Lat. *Prep.* From *carbonate of soda*, ½ oz.; *water*, 1 pint. To allay itching and irritation. See *Alkaline Lotion.*

LOTION (Cherry Laurel). Syn. *Lotio Lauro-cerasi,* — Lat. *Prep.* 1. *Cherry-laurel water* (distilled), 1½ fl. oz.; *distilled water*, ½ pint. Anodyne; useful to allay irritation, &c. Some persons with delicate skin employ it as a wash after shaving.

2. *Cherry-laurel water* (distilled), 4 oz.; *rectified spirit* and *ether*, of each, 1 fl. oz.; *extract of belladonna*, 2 dr.; agitate well together in the cold. An excellent application in neuralgia, painful tumours, &c.

LOTION (for Chilblains). See *Chilblains, Liniments, &c.*

LOTION (Chlorate of Soda). Syn. *Lotio Sodæ Chloratis,*—Lat. *Prep.* (Darling.) *Chlorate of soda*, 5 dr.; *water*, ½ pint. In pruritus, &c.

LOTION (Chloride of Lead). Syn. *Lotio Plumbi Chloridi,*—Lat. *Prep.* (Mr. Tuson.) *Chloride of lead*, 1 dr.; *hot distilled water*, 1 pint; dissolve. In cancerous ulcerations, painful neuralgic tumours, &c.

LOTION (Chloride of Tin). Syn. *Lotio Stanni Chloridi,*—Lat. *Prep.* (M. Nauche.) *Chloride of tin*, 1 gr.; *distilled water*, 2 to 3 fl. oz. In cancerous ulcerations.

LOTION (Chloride of Zinc). Syn. *Lotio Zinci Chloridi,*—Lat. *Prep.* 1. *Chloride of zinc*, 10 gr. (or *solution*, ½ fl. dr.); *water* 1 pint. As a disinfectant and preventive lotion.

2. (Voght.) *Chloride of zinc*, 8 gr.; *extract of aloes*, 40 gr.; *distilled water*, 4 fl. oz. In atonic and foul ulcers.

LOTION (Chlorinated). Syn. *Lotio Chlorinata*,—Lat. *Prep.* 1. *Lotio Calcis Chlorinatæ.—a.* From *chloride of lime*, 3 dr.; *water*, 1 pint; agitate together for some time, and strain through muslin.

b. (Derheims.) *Chloride of lime*, 1 oz.; *water*, 1 quart; triturate and filter.

2. (*Lotio Sodæ Chlorinatæ.*) From *chloride of soda*, as the last. They are both excellent washes for foul ulcers, the itch, &c.; and, when diluted, for the teeth, to sweeten the breath, remove the smell of tobacco smoke, to prevent infection, and for various similar purposes. When intended for application to very tender or abraded surfaces, they must be largely diluted with water.

LOTION (Chloroform). Syn. *Lotio Chloroformi*, — Lat. *Prep. Chloroform* (pure), 1½ fl. oz.; *rectified spirit* and *cold distilled water*, of each, ½ pint. Anodyne. A piece of oiled silk should be laid over the rag to prevent evaporation. The lotion made with *water*, as commonly prescribed, is inert.

LOTION (for Corns). See *Corns.*

LOTION (Creasote). Syn. *Lotio Creasoti*,—Lat. *Prep.* 1. *Creasote*, 2 fl. dr.; *liquor of potassa*, 3 fl. dr.; *water*, ½ pint.

2. *Creasote*, 3 fl. dr.; *vinegar* and *water*, of each, ½ pint. In burns, itch, phagedenic ulcerations, ringworm, chancre, &c.

LOTION (Cyanide of Potassium). Syn. *Lotio Potassii Cyanidi*, — Lat. *Prep.* 1. (Cazenave.) *Cyanide of potassium*, 10 gr.; *emulsion of bitter almonds*, 6 fl. oz. In chronic eruptions and other cases attended with much itching or irritation.

2. (Foy.) *Cyanide of potassium*, 8 gr.; *distilled water*, 1 fl. oz. In neuralgia, acute rheumatism, &c.; applied by means of compresses of linen. Both the above are poisonous if swallowed. Malherbe has employed a very much stronger solution, but its use is attended with so much danger that we think it unsafe to publish the formula for it.

LOTION (Delphinia). Syn. *Lotio Delphiniæ, Embrocatio D.*,—Lat. *Prep.* (Dr. Turnbull.) *Delphinia*, 20 to 60 gr.; *rectified spirit*, 2 fl. oz. *Used* as lotion of veratria.

LOTION (Detergent). Syn. *Lotio Detergens*,—Lat. Several lotions of this character will be found under the names of their leading ingredient.

LOTION (Diacetate of Lead). Syn. *Goulard's Lotion; Lotio Plumbi Diacetatis*, —Lat. The dilute liquor of diacetate of lead, Ph. L. See *Solutions.*

LOTION (Evaporating). Syn. *Lotio Evaporans, L. Vaporans, L. Spiritus Diluti*,—Lat. *Prep.* 1. (Copland.) *Sulphuric ether, rectified spirit*, and *solution of acetate of ammonia*, of each, 1½ fl. oz.; *rose water*, 3½ fl. oz.

2. (Guy's Hosp.) *Rectified spirit*, 1 part; *water*, 5 parts.

3. (Erasmus Wilson.) *Rectified spirit*, 1 part; *water*, 4 to 6 parts.

4. (*Camphorated*, — Ware). *Camphor*, ½ dr.; *elder flowers*, ½ oz.; *rectified spirit*, 4 oz.; digest 24 hours and strain.

Obs. The above are *soothing* and *refrigerant*, if allowed to evaporate by free exposure; *stimulant*, if the evaporation is prevented by covering the part with the hand, or a piece of oiled silk. They are useful applications in nervous headaches, restlessness, itching and irritability of the skin, &c. "A little *rose water* added to the simple water makes an agreeable addition, and sometimes *camphor water* (julep), or a *little Goulard's extract*, may be deemed advantageous, when a greater degree of calming effect is required." (Eras. Wilson.) *Eau de Cologne*, diluted with an equal quantity of water, is often used as an evaporating lotion.

LOTION (Gall-nuts.) Syn. *Lotio Gallæ*,—Lat. *Prep.* From *gall-nuts* (bruised), ½ oz.; *boiling water*, 1 pint; infuse until cold, and strain. Astringent. An excellent application to sore nipples, or to strengthen them before suckling; *spirit of wine*, 3 fl. oz., may be advantageously added to the cold infusion, and a like portion of water omitted. See *Decoctions.*

LOTION (Glycerine). Syn. *Lotio Glycerini, L. Glyceriniæ*,—Lat. *Prep.* 1. *Glycerine*, 1 oz.; *water*, 1 pint. To allay itching, and remove dryness, &c., in various skin diseases; also in chaps of the nipples, lips, and hands. For the latter purpose the addition of 2 to 3 dr. of *borax* is recommended by some writers.

2. *Glycerine*, 1 oz.; *thick mucilage*, 2 oz.; *lime water*, 7 oz. In burns, scalds, chaps, excoriations, &c.

3. (Mr. Startin.) *Glycerine*, 1 oz.; *extract of belladonna*, 1 dr.; *soap liniment*, 3 oz.; triturate together. In bruises, sprains, and swelled joints; gouty, neuralgic, and rheumatic pains, &c.

4. (Mr. Startin.) *Trisnitrate of bismuth*, ½ dr.; *tincture of foxglove* and *dilute nitric acid*, of each, 1 fl. dr.; *glycerine*, 4 dr.; *rose water*, 8½ fl. oz. To allay the itching in prurigo, and some other skin diseases.

YORKSHIRE COLLEGE

LOTION (Goulard's). See *Lotion of Diacetate of Lead.*

LOTION (Gout). Syn. *Lotio Antarthritica*,—Lat. *Prep.* 1. *Glycerine*, 1 oz.; *extract of belladonna*, 3 dr.; *veratrine*, 10 gr., dissolved in *rectified spirit*, 2 fl. oz.; mix, and further add of *water*, 17 fl. oz. It is poisonous if swallowed.

2. (*Scudamore's.*) From *camphor mixture*, 9 fl. oz.; *rectified spirit*, 3 fl. oz. The above are applied on rags or compresses, or are poured on the surface of poultices. (See *below.*)

LOTION (Gowland's). This celebrated nostrum is prepared as follows:—Take of *Jordan almonds*, 1 oz.; *bitter almonds*, ½ oz.; blanch them, and make an emulsion in *soft water*, 1 pint; to this add of *bichloride of mercury*, 15 gr., previously dissolved in *rectified spirit*, 2 fl. dr., together with enough *water* to make the whole measure 1 pint, and put it into bottles.

Obs. This preparation is chiefly used as a cosmetic to improve the complexion; and also as a wash for obstinate eruptions and minor glandular swellings and indurations. As a beautifier of the complexion it is employed by simply wetting the skin with it, either by means of the corner of a napkin or the fingers dipped into it, after which it is gently wiped off with a dry cloth. Dr. Paris represents this nostrum to contain ½ dr. of corrosive sublimate in every pint, which is not the case; but even the smaller quantity which is employed is in part decomposed by the organic matter in the emulsion.

LOTION (Granville's Counter-irritant). See *Liniment of Ammonia* (Compound).

LOTION (Hannay's Preventive). *Water* alkalized with *potassa*. *Used* against infection.

LOTION (Hemlock). Syn. *Lotio Conii*, —Lat. *Prep.* (Mid. Hosp.) *Extract of hemlock*, 3 dr.; *opium*, 1 dr.; *boiling water*, 1 pint; digest until cold, and strain. Anodyne and resolvent; in glandular enlargements, painful ulcers, cancer, indurations, rheumatism, neuralgia, &c.

LOTION (Hooping Cough,—Struve's). *Lotio antipertussica*,—Lat. *Prep.* (Paris.) *Potassio-tartrate of antimony*, 1 dr.; *tincture of cantharides*, 1 oz.; *water*, 2 oz. This is a powerful counter-irritant, and should be used with caution, as it is apt to induce a troublesome eruption on the parts to which it is frequently applied.

LOTION (Hydriodate of Arsenic and Mercury). Syn. *Lotio Arsenici et Hydrargyri Hydriodatis*,—Lat. *Prep.* From *Donovan's solution*, 1 part; *water*, 9 parts. In lepra, psoriasis, and other scaly skin diseases.

LOTION (Hydrochlorate of Ammonia). Syn. *Lotio Ammoniæ Hydrochloratis*,—Lat. *Prep.* 1. (*Weaker.*) From *sal ammoniac*, 1 to 4 dr.; *water*, 1 pint. As a wash in itch, ulcers, tender feet, swelled joints, &c.

2. (*Stronger.*) From *sal ammoniac*, 1 to 2 oz.; *water*, 1 pint. In contusions, chronic tumours, extravasations, chilblains, &c., when the skin is not broken. Both are stimulant and resolvent or discutient. *Vinegar* is often substituted for the whole or part of the water; and sometimes a fifth or sixth part of *rectified spirit* is added.

LOTION (Hydrochloric). Syn. *Lotio Acidi Hydrochlorici*,—Lat. *Prep.* 1. *Hydrochloric acid*, 1 fl. oz.; *water*, 1 pint. In *lepra*, and several other skin diseases.

2. (Foy.) *Hydrochloric acid*, 1 part; *water*, 16 parts. In chilblains, when the skin is unbroken.

LOTION (Hydrocyanic). Syn. *Lotio Hydrocyanica*, *L. Acidi Hydrocyanici*,—Lat. *Prep.* 1. (Magendie.) *Medicinal hydrocyanic acid*, 1 to 2 fl. dr.; *lettuce water*, 1 pint. In hepatic affections.

2. (Sneider.) *Medicinal acid*, 1½ fl. dr.; *rectified spirit* and *water*, of each, 6 fl. oz.

3. (A. T. Thomson.) *Medicinal acid* and *rectified spirit*, of each, 2 fl. dr.; *acetate of lead*, 16 gr.; *distilled water*, 7½ fl. oz. In impetigo, &c.

Obs. Lotions of prussic acid are employed to allay pain and irritation in various chronic skin diseases, especially the scaly and itchy eruptions; and in cancer, &c., with variable success. See *Hydrocyanic Acid.*

LOTION (Hyposulphite of Soda). Syn. *Lotio Sodæ Hyposulphitis*,—Lat. *Prep.* (Mr. Startin.) *Hyposulphite of soda* and *alum*, of each, 1½ dr.; *eau de Cologne*, ½ fl. oz.; *rose watar*, 7½ fl. oz. In the advanced stages of acne.

LOTION (Iodide of Potassium). Syn. *Lotio Potassii Iodidi*,—Lat. *Prep.* 1. From *iodide of potassium*, 1 to 2 dr.; *water*, 1 pint. In the usual cases in which ioduretted preparations are employed.

2. (Dr. O. Ward.) *Iodide of potassium*, 1 dr.; *water*, ¾ pint. In Itch.

LOTION (Iodide of Zinc). Syn. *Lotio Zinci Iodidi*,—Lat. *Prep.* (Ross.) *Iodine*, 1½ dr.; *zinc filings*, 1 dr.; *water*, 8 fl. oz.; digest with heat until the liquid becomes coloured, then filter. In enlarged tonsils.

LOTION (Iodine). Syn. *Lotio Iodinii*, —Lat. *Prep.* From *iodine*, 2 gr.; *rectified spirit*, 1 fl. dr.; dissolve, well agitate the

solution with *distilled water*, 1 pint, and filter. An excellent wash for scrofulous ulcers, and in chronic ophthalmia, cutaneous scrofula, and several chronic skin diseases, particularly in highly sensitive habits.

LOTION (Ioduretted). Syn. *Lotio Iodureta*,—Lat. *Prep.* 1. *Iodide of potassium*, ½ dr.; *iodine*, 15 gr.; *water*, 1 pint. This is the common and best form of ioduretted lotion; but for *certain* cases it is used much stronger.

2. (Cazenave.) *Iodide of potassium* and *iodide of sulphur*, of each, 1 dr.; *water*, 1 pint. In itch; either alone or diluted with an equal bulk of water.

3. (Dauvergne.) *Iodine*, 3 dr.; *iodide of potassium*, 6 dr.; *water*, 3 fl. oz.; dissolve, and label the bottle No. 1. *Sulphuret of potassium*, 4 oz.; *water*, 8 fl. oz.; dissolve. For use, a tea-spoonful of No. 1, and a table-spoonful of No. 2, are to be added to about a pint of water. In itch, and several other skin diseases.

4. (Lugol.) *Iodine*, 1 to 3 gr.; *iodide of potassium*, 3 to 6 gr.; *water*, 1 pint. In scrofulous ophthalmia, fistulas, &c.; and as a wash in numerous skin diseases.

5. (Righini.) *Chloride of lime*, 4 dr.; *water*, 2½ fl. oz.; triturate together, filter into a stoppered bottle, and add of *tincture of iodine*, 1 dr. With a pint of *water* it forms an effective application in itch.

6. (Soubeiran.) *Iodide of potassium*, 1 oz.; *iodine*, ½ oz.; *water*, 6 oz.; dissolve. *Used* as *iodine paint*; also as a caustic to touch the surfaces of scrofulous ulcers, and the eyelids in scrofulous ophthalmia.

LOTION (Itch). Syn. *Lotio Antipsorica*, Lat. *Prep.* (Cazenave.) *Sulphuret of potassium*, 1 dr.; *soft soap*, 2 dr.; *water*, 8 fl. oz.; dissolve. An excellent remedy for the itch. It leaves little smell behind, and does not soil the linen. (See *above*.)

LOTION (Kirkland's). See *Lotion of Myrrh*.

LOTION (Lemon Juice). Syn. *Lotio Succi Limonis*,—Lat. *Prep.* From the *freshly expressed juice of lemon*, diluted with 4 or 5 times its bulk of *water*. To render it more agreeable, *rose water* may be employed, or a few drops of *eau de Cologne* added. It is cooling and detergent, and forms an excellent application to foul ulcers, and to allay the itching in numerous cutaneous affections.

LOTION (Lime Water). Syn. *Lotio Calcis Spirituosa*, — Lat. *Prep.* (Ph. Chirur.) *Rectified spirit*, 4 oz.; *lime water*, 8 fl. oz. See *Evaporating Lotion*.

LOTION (Mammillary). Syn. *Lotio Balsami Peruviani Composita*,—Lat. *Prep.* (Iverg.) *Balsam of Peru*, 1 dr.; *yelk of* 1 *egg*; make an emulsion, and add of *spirit of wild thyme*, 3 fl. oz. For sore nipples; to be followed, whilst still wet, by a "dusting" with a powder composed of *Peruvian bark*, 1 dr.; *gum arabic*, 2 dr.

LOTION (Mercurial). *Prep.* 1. (*Black Wash, Black Lotion, Mild Phagedænic do.; Lotio Nigra, L. Hydrargyri Cinerea, L. H. Nigra, L. H. Chloridi cum Calce, L. Mercurialis N., Aqua Phagedænica Mitis*,—Lat. var.—*a*. From *calomel*, 1 dr.; *lime water*, 1 pint; well shaken together. These are the usual proportions.

b. (Mid. Hosp.) To the last add of *thick mucilage*, 1 fl. oz.

Obs. Black wash is a favorite application to all kinds of syphilitic and scrofulous sores. The bottle should be well shaken before the lotion is applied. At Guy's Hospital the proportions are *calomel*, 1 dr., to *lime water*, 8 fl. oz.

2. (*Yellow Wash, Yellow Lotion, Phagedænic do.; Lotio Flava, L. Phagedænica, Aqua Ph., Lotio Hydrargyri Flava, L. H. Bichloridi cum Calce*,—Lat. var.—*a*. From *corrosive sublimate*, ½ dr.; *lime water*, 1 pint; well shaken together. This is the usual strength.

b. (St. B. Hosp.) *Corrosive sublimate*, 20 gr.; *lime water*, 6 fl. oz. *Used* as the last, but it is stronger and more active, from containing a little undecomposed bichloride.

LOTION (Myrrh). Syn. *Kirkland's Lotion; Lotio Myrrhæ*,—Lat. *Prep.* (Dr. Kirkland.) *Tincture of myrrh* and *lime water*, equal parts. In scorbutic ulcers and gums.

LOTION (Myrrh,—Compound). Syn. *Lotio Myrrhæ Composita*,—Lat. *Prep.* (Ph. Chirur.) *Honey of roses* and *tincture of myrrh*, of each, 2 fl. dr.; *lime water*, 2½ fl. oz. As the last; also used as a dentifrice.

LOTION (Nitrate of Bismuth.) Syn. *Lotio Bismuthi Nitratis*,—Lat. *Prep.* (Cutan. Hosp.) *Subnitrate* or *trisnitrate of bismuth*, ½ dr.; *corrosive sublimate*, 12 gr.; *spirit of camphor*, ½ fl. dr.; *water*, 1 pint. In itch, and some other eruptions.

LOTION (Nitrate of Silver). Syn. *Lotio Argenti Nitratis*, — Lat. *Prep.* 1. *Nitrate of silver*, 15 gr.; *nitric acid*, 10 drops; *distilled water*, ½ pint. As a wash for indolent ulcers, sore legs, &c.

2. (Mr. Jackson.) *Nitrate of silver*, 10 gr.; *water*, 1 fl. oz. For bed-sores; applied, at first, twice or thrice a day.

3. (Schreider.) *Nitrate of silver*, ½ dr.; *nitric acid*, 10 drops; *water*, 1½ fl. oz. In chilblains, soft corns, &c.

LOTION (Nitre). Syn. *Lotio Potassæ*

YORKSHIRE COLLEGE

Nitratis,—Lat. *Prep.* 1. *Nitre*, 3 dr.; *vinegar*, ¼ pint; *water*, ¾ pint.

2. *Nitre*, 2 dr.; *sal ammoniac*, 1 dr.; *vinegar* and *water*, of each, ½ pint. In sprains, contusions, extravasations, tender feet, chilblains, &c. Diluted with an equal bulk of water it is a popular application to "black eyes."

LOTION (Nitric Acid). Syn. *Lotio Acida*, *L. Acidi Nitrici*,—Lat. *Prep.* 1. (Collier.) *Nitric acid*, ½ fl. oz.; *water*, 1 pint. In lepra and other scaly skin diseases.

2. (Copland.) *Nitromuriatic acid*, 1¼ dr.; *water*, 1 pint. In gangrene and mortification.

3. (Phœbus.) *Nitric acid*, 1 fl. dr.; *laudanum*, 1½ fl. dr.; *rose water*, ½ pint. For venereal ulcers.

LOTION (Nux Vomica). Syn. *Lotio Nucis Vomicæ*,—Lat. *Prep.* 1. *Alcoholic extract of nux vomica*, 10 gr.; *rectified spirit* and *water*, of each, 2½ fl. oz. In amaurosis.

2. (Radius.) *Alcoholic extract of nux vomica*, 8 gr.; *liquor of ammonia* (stronger), ½ fl. oz.; *rectified spirit*, 2 fl. oz. In paralysed limbs.

LOTION (Opium). Syn. *Lotio Opii*, *L. Opiata*,—Lat. *Prep.* 1. (Christison.) *Opium*, 40 gr.; *water*, ¼ pint; infuse, add to the filtered liquid a solution of *sugar of lead*, 40 gr., in *water*, ¼ pint, and filter.

2. (St. B. Hosp.) *Opium*, 1½ dr.; *boiling water*, 1 pint; triturate and strain. Anodyne; the first is also refrigerent and discutient.

LOTION (Oxide of Zinc). Syn. *Lotio Zinci Oxydi*,—Lat. *Prep.* 1. (Augustin.) *Oxide of zinc*, 1 dr.; *elder flower water*, 1½ fl. oz. In pustular erysipelas.

2. (Hosp. F.) *Oxide of zinc*, ½ dr.; *mucilage*, 2 fl. dr.; *water*, 6 fl. dr. As an astringent and desiccant, in scrofulous eruptions, excoriations, moist chaps, &c.

LOTION (Phagedænic). See *Mercurial Lotion.*

LOTION (Phosphoric Acid.) Syn. *Lotio Acidi Phosphorici*,—Lat. *Prep.* (Pereira.) *Dilute phosphoric acid* (Ph. L.), 1 fl. oz.; *water*, ½ pint. In caries and fistula.

LOTION (Potassa). Syn. *Lotio Potassæ*,—Lat. *Prep.* From *liquor of potassa*, 1 fl. oz.; *water*, 1 pint. Detergent; in scorbutic eruptions and foul ulcers, and to prevent infection.

LOTION (Potassio-tartrate of Antimony). Syn. *Lotio Antimonialis*, *L. Antimonii Potassio-tartratis*, *L. Rubefaciens*,—Lat. *Prep.* 1. *Tartar emetic*, 1 dr.; *tincture of camphor*, 2 fl. dr.; *water*, 1 pint. As a local stimulant. Diluted with twice or thrice its weight of water it is employed as a collyrium in chronic ophthalmia, and in specks on the cornea.

2. (Sir Wm. Blizard.) *Tartar emetic*, 20 gr.; *boiling water*, 1 fl. oz. *Used* to cleanse foul ulcers, to repress fungous growths and warts, and in ringworm, &c.

3. (Pereira.) *Tartar emetic*, 1 dr.; *boiling water*, 1½ fl. oz.; dissolve. *Employed* as a local irritant instead of the ointment. All the above are rubefacient and counter-irritant. See *Potassio-tartrate of Antimony.*

LOTION (Quinine). Syn. *Lotio Quinæ*, *Embrocatio Quinæ*,—Lat. *Prep.* From *disulphate of quinine*, 1 dr.; *rectified spirit*, 5 fl. oz. Applied over the spine in intermittents.

LOTION (Red). See *Mercurial Lotion.*

LOTION (Rubefacient). See *above.*

LOTION (Saponaceous). Syn. *Lotio Saponis*; *L. Saponacea*,—Ph. L. 1746. *Prep.* From *liquor of carbonate of potassa*, ½ oz.; *olive oil*, 4 oz.; *rose water*, 12 oz.; agitated together. Emollient; chiefly as a cosmetic.

LOTION (Saviard's). *Prep.* (Foy.) *Caustic potassa*, 1 dr.; *camphor*, 20 gr.; *sugar*, 1 oz.; *water*, 1 pint. As a wash for indolent ulcers.

LOTION (Struve's). See *Hooping Cough Lotion.*

LOTION (Sulphate of Copper). Syn. *Lotio Cupri Sulphatis*,—Lat. *Prep.* 1. *Blue vitriol*, 1 dr.; *camphor julep*, 1 pint. For phagedænic ulcers, and in itch, &c.

2. (Dr. Graves.) *Sulphate of copper*, 10 gr.; *water*, 1 fl. oz. In chilblains, ring-worm, &c.

3. (Mr. Lloyd.) *Sulphate of copper*, 1 oz.; *water*, 1 pint. In itch; either alone or diluted.

LOTION (Sulphate of Zinc). Syn. *Lotio Zinci Sulphatis*,—Lat. *Prep.* 1. *Sulphate of zinc*, ¾ dr.; *water*, 1 pint. Astringent; in some chronic skin diseases, as a wash for loose flabby granulations, and for ulcers that discharge profusely, &c.

2. (Collier.) *Sulphate of zinc*, 2 dr.; *water*, 1 pint. As a counter-irritant in pains of the joints, periosteum, old sprains, &c.

LOTION (Tar). Syn. *Lotio Picis Liquidæ*,—Lat. *Prep.* (Saunders.) *Quicklime*, 6 oz.; *water*, 2½ pints; slake, add of *tar*, 4 oz., and boil to one half. This liquid consists of a solution of pyrolignite of lime, and pyrogenous oil and resin. It may be advantageously employed in various chronic skin diseases, especially those affecting the heads of children. See *Tar Water.*

LOTION (Valerian). Syn. *Lotio Valerianæ*, *Embrocatio Antihysterica*, *E. Emmenagoga*,—Lat. *Prep.* From *tincture of*

YORKSHIRE COLLEGE

valerian and *proof spirit*, equal parts. In hysteria, suppressions, &c.

LOTION (Veratrine). Syn. *Lotio Veratriæ*,—Lat. *Prep.* (Dr. Turnbull.) *Veratrine*, 20 to 60 gr.; *rectified spirit*, 2 oz. In gout, rheumatism, &c. It is extremely poisonous, and must only be used where the skin is sound, and then with great caution.

LOTION (Verdigris). Syn. *Lotio Æruginis, L. Cupri Acetatis*,—Lat. *Prep.* From *verdigris*, 3 dr.; *vinegar*, ¼ pint; *water*, ¾ pint. As a wash for indolent scrofulous, and venereal ulcers.

LOTION (Vinegar). See *Lotion* (Acetic).

LOTION (Yellow). See *Mercurial Lotion.*

LOVE APPLES. See *Tomatoes.*

LOZENGE. Syn. *Troche; Trochiscus, Tabella*,—Lat. *Tablette*,—Fr. A small cake, often medicated, consisting principally of powdered sugar, made into a mass with some glutinous liquid, without the aid of heat, and dried. The form given to lozenges (*troches; tabellæ, trochisci; tablettes*) is generally that of a small round tablet or flattened cylinder; but, originally they were exclusively made in the shape of a lozenge or rhomb, from which circumstance their familiar name is derived. *Lozenges* are distinguished from *drops* or *pastilles* by the non-employment of heat in their preparation; and from *pastes*, by the latter being formed of vegetable juice or pulp, and having a softer consistence.

In the *preparation* of *lozenges*, the *dry ingredients* separately reduced to a *very fine* powder, are first *perfectly* mixed together, and then beaten into a stiff paste with the *glutinous liquid* employed to give them form; the mass is next rolled out to a proper thickness, and cut into pieces of the desired shape by means of a small cylinder or punch of steel or tin-plate, called a *lozenge-cutter*. The newly formed lozenges are lastly *dried* by placing them on an inverted sieve or frame covered with paper in a dry, warm, and airy situation, and are frequently turned until they become hard and brittle; due care being taken to preserve them from dust and dirt. To prevent the mass *adhering* to the fingers and utensils during the process of manufacture, a little finely powdered starch, or a very little *olive oil* scented with the same aromatic as that contained in the lozenges may be used. *Mucilage* of *gum arabic* or of *gum tragacanth, thin isinglass size*, or the *strained white of egg*, are the substances usually employed to make the pulverulent materials adhere together. A *strained decoction of Irish moss* is now frequently used for the same purpose, for "inferior qualities." The larger the proportion of gum which enters into the composition of lozenges, the slower they dissolve in the mouth; hence *powdered gum* is frequently added to the other materials to increase their quality in this respect, as well as to give additional solidity to those, which like *chalk*, for instance, are of a peculiarly dry or crumbly nature. *Starch* and *potato flour* are often added to lozenge-masses in lieu of a portion of the *sugar*, and even *plaster of Paris* is not unfrequently employed to give them weight; frauds which are readily detected in the manner noticed under *Gums, Sugar*, and *Sweetmeats.*

Lozenges as a *form of medicine* are now so seldom ordered by the faculty in this country, and those of the *confectioner* are so much superior in appearance to the corresponding articles prepared by the English druggist, that the London and Dublin Colleges have wisely expunged them from their pharmacopœias. On the Continent, however, this class of preparations is extensively employed, and pharmaceutical works groan under the load of formulæ published for their manufacture, which exhibit an amount of luxuriance in detail and repetition, which is amusing on account of its utter uselessness and the gravity with which the subject is treated.

As a general rule *medicated lozenges* should weigh from 8 to 10 gr. each, and a *medium* dose of their active ingredient should be distributed through the bulk of 6 to 8 of them, in which case 3 to 5 of them may be safely taken as a dose, or sucked during the lapse of 3 or 4 hours. This will be useful in the preparation of those for which no established proportions are given. In "sending out" compounds of this class containing *active medicaments*, as morphia or opium, the retailer as well as the manufacturer should be careful that the *quantity contained in each lozenge* is *plainly marked on the label.*

In *lozenges* intended for *mouth cosmetics*, or to *perfume the breath*, ambergris is generally regarded as the most appropriate perfume; but *hard smokers* frequently prefer cloves and cinnamon, and some ladies give the preference to roses, orange flowers, and orris or violets.

Lozenges are *coloured* with the same stains as are used for *liqueurs* and *sweetmeats.*

Lozenges, as well as *all other articles of confectionery*, should be *preserved* in well-closed glass bottles, or jars, or in tin ca-

nisters, so as to be *perfectly excluded* from the *air* and *damp*.

A *list* of the *principal lozenges*, both of the apothecary and the confectioner, is given below, together with formulæ for many of them, which will serve as examples for others.

LOZENGES (Absorbent). *Trochisci Antacidi*,—Lat. *Prep.* 1. Take of *precipitated chalk*, ¼ *lb.*; *gum arabic*, 2 *oz.*; *double refined white sugar*, 14 *oz.*; all in impalpable powder; *oil of nutmeg*, ½ fl. dr.; pass the mixture through a fine sieve, beat it up with *mucilage*, q. s., roll the mass into a thin sheet, and cut it into lozenges; lastly, dry these by exposing them on a sheet of white paper to the air, out of contact with dust.

2. As the last, but substituting *heavy carbonate of magnesia*, 1½ *oz.*, for an equal weight of chalk. In diarrhœa, heartburn, acidity, &c. See *Chalk Lozenges*, *Magnesia do.*, *Soda do.*, *&c.*

LOZENGES (Acacia). See *Gum Lozenges.*

LOZENGES (Acidulated). Syn. *Acidulated Lemon Lozenges*, *Tartaric Acid do.*; *Trochisci Acidi Tartarici*,—Ph. E. *Prep.* From *tartaric acid*, 2 dr.; *oil of lemon*, 10 drops; *white sugar*, 8 oz.; *mucilage*, q. s. to make a lozenge-mass. The same ingredients mixed with heat form *acidulated* or *acid drops*. Both are useful in coughs, hoarseness, sore throats, &c. See *Cayenne Lozenges*, *Citric Acid do.*, *Rose do.*, *&c.*

LOZENGES (Alkaline). See *Soda Lozenges*, *Vichy do.*, *&c.*

LOZENGES (Alum). Syn. *Trochisci Aluminis*,—Lat. Each lozenge contains 1½ gr. of *alum*. As an astringent. (See *below.*)

LOZENGES (Aniseed). Syn. *Trochisci Anisi*,—Lat. *Prep.* From *oil of aniseed*, 1½ fl. dr.; *finest white sugar*, 1 *lb.*; *mucilage*, q. s. Carminative and stomachic. In colic, griping, &c.; and as a pectoral.

LOZENGES (Anthelmintic). See *Worm Lozenges.*

LOZENGES (Antimonial). Syn. *Trochisci Antimoniales*, *Morsuli Stibii Kunkelii*, — Lat. *Tablettes de Kunkel*, — Fr. *Prep.* (P. Cod.) *Levigated sulphuret of antimony* and *cardamom seeds*, of each, 1 oz.; *almonds* (blanched), 2 oz.; *cinnamon*, ½ oz.; *sugar*, 13 oz.; *mucilage of tragacanth*, q. s.; to be divided into 15-gr. lozenges. As an alterative.

LOZENGES (Aperient). Syn. *Trochisci Aperientes*,—Lat. Each lozenge contains 1 gr. each of *calomel* and *scammony*, and 2 gr. of *jalap*; or instead of the last ¼ gr. of *jalapine*. 2 to 3 for a *dose*.

LOZENGES (Astringent). Syn. *Trochisci Astringentes*,—Lat. Each lozenge contains 1½ gr. of *alum* and 2 gr. of *catechu*. In spitting of blood, relaxed uvula, sore-throat, &c.

LOZENGES (Bark). Syn. *Trochisci Cinchonæ*,—Lat. *Prep.* (P. Cod.) *Cinchona*, 2 oz.; *cinnamon*, 2 dr.; *white sugar*, 14 oz.; *mucilage of gum tragacanth*, q. s.; mix, and divide into 16-gr. lozenges. Tonic.

LOZENGES (Bath). Syn. *Dawson's Lozenges.* From *extract of liquorice* and *gum arabic*, of each, 1½ *oz.*; *sugar*, 17 oz. It is both rolled into lozenges and formed into pipes. Demulcent; in tickling coughs, &c.

LOZENGES (Bismuth). Syn. *Trochisci Bismuthi*,—Lat. *Prep.* (Trousseau.) Each lozenge contains 1 gr. of *trisnitrate of bismuth.* Tonic and antispasmodic; in chronic dyspepsia, gastrodynia, nausea, cramp of the stomach, &c.

LOZENGES (Black Currant). *Trochisci Ribis Nigri*,— Lat. *Prep.* From *inspissated juice of black currants* and *sugar*, of each, in powder, 1 *lb.*; *tartaric acid*, ¼ *oz.*; *mucilage*, q. s. In hoarseness, &c.

LOZENGES (Borax). Syn. *Trochisci Boracis*, — Lat. Each lozenge contains 3 gr. of *borax*. One occasionally in aphthous sore mouth, sore throat, &c.

LOZENGES (Burnt Sponge). Syn. *Trochisci Spongiæ*, *T. S. Ustæ*,—Lat. *Prep.* (P. Cod.) *Burnt sponge*, 4 oz.; *sugar*, 12 oz.; *mucilage of tragacanth*, q. s.; divide into 12-gr. lozenges. In scrofula, glandular enlargements, &c.

LOZENGES (Cacao). Syn. *Trochisci Butyri Cacao*,—Lat. Each lozenge contains 1-3rd of its weight of *pure cacao-nut butter.* In habitual constipation; and in phthisis, scrofula, &c., instead of cod-liver oil; taken ad libitum. They are usually scented with roses.

LOZENGES (Caffeine). Syn. *Trochisci Caffeinæ*,—Lat. Each lozenge contains ¼ gr. of *caffeine*, and ½ gr. of *citric acid.* In hemicrania, hypochondriasis, &c.

LOZENGES (Calomel). Syn. *Worm Lozenges*; *Trochisci Calomelanos*, *T. Hydrargyri Chloridi*,—Lat. *Prep.* (P. Cod.) Each lozenge contains 1 gr. of *calomel.* Alterative, &c. They afford a simple way of introducing mercury into the system. During their use, salt food and acid liquors should be avoided. When given for *worms* they should be followed, in a few hours, by a purge.

LOZENGES (Camphor). Syn. *Trochisci*

Camphoræ—Lat. Each lozenge contains ¾ gr. of (finely powdered) *camphor*. They must be kept in a well-corked bottle.

LOZENGES (Carbonate of Lime). See *Chalk Lozenges*.

LOZENGES (Catechu). Syn. *Cachou Lozenges; Trochisci Catechu, Tro. de Terra Japonica*,—Lat. *Tablettes de Cachou*,—Fr. *Prep.* (Ph. E. 1744.) *Catechu*, 2 oz.; *tragacanth*, ½ oz.; *white sugar*, 12 oz.; *rose water*, q. s.

2. (P. Cod.) *Extract of catechu*, 4 oz.; *sugar*, 16 oz.; *mucilage of gum tragacanth*, q. s.; for 10-gr. lozenges.

3. (*Tro. Catechu et Magnesiæ*,—P. Cod.) *Magnesia*, 2 oz.; *powdered catechu*, 1 oz.; *sugar*, 13 oz.; *mucilage of gum tragacanth* (made with cinnamon water), q. s. to mix.

4. (*Perfumed.*) See *Cachou Aromatisé* and *Pastils*.

Obs. All the above are taken in diarrhœa, in relaxation of the uvula, in irritation of the larynx, and as cosmetics to fasten the teeth, and disguise a stinking breath. The one containing magnesia (No. 3) is also sucked in dyspepsia, acidity, and heartburn.

LOZENGES (Cayenne). Syn. *Trochisci Capsici*,—Lat. Flavoured with *essence* or *tincture of capsicum* or *cayenne*, with a *very concentrated chilli vinegar*, or a little pure *soluble cayenne pepper*.

2. (*Acidulated.*) To each *lb.*, add of *tartaric acid*, ½ *oz.* Both are used in dyspepsia, and to promote digestion and create an appetite. They have also been recommended in temporary deafness arising from exposure to cold. They are generally tinged of a light pink or red colour.

LOZENGES (Chalk). Syn. *Heartburn Lozenges; Trochisci Cretæ, T. Cardialgici, Tabellæ Cardialgicæ*,—Lat. *Prep.* (Ph. E.) *Prepared chalk*, 4 oz.; *gum arabic*, 1 oz.; *nutmeg*, 1 dr.; *white sugar*, 6 oz.; *rose* or *orange flower water*, q. s. Antacid and absorbent. 3 or 4 sucked ad libitum in heartburn, dyspepsia, diarrhœa, acidity of the stomach and bowels, &c.

LOZENGES (Charcoal). Syn. *Trochisci Carbonis*,—Lat. *Prep.* 1. (P. Cod.) *Prepared charcoal*, 4 oz.; *white sugar*, 12 oz.; *mucilage*, q. s. to mix. In diarrhœa, cholera, dyspepsia, &c.

2. (*Tro. Carbonis cum Chocolata*,—M. Chevallier). *Charcoal* and *white sugar*, of each, 1 oz.; *chocolate*, 3 oz.; *mucilage of gum tragacanth*, q. s. to mix. Nutritious; *used* as the last.

LOZENGES (Ching's Worm). *Prep.*—*a.* (*Yellow.*) From *saffron*, ½ *oz.*; *boiling water*, 1 pint; infuse, strain, add of *calomel*, 1 *lb.*; *powdered white sugar*, 28 *lb.*; mix well, make a mass with *mucilage of tragacanth*, and divide it into 7000 lozenges. Each lozenge contains 1 gr. of *calomel*.

b. (*Brown.*) From *calomel*, 7 *oz.*; *resinous extract of jalap*, 3½ *lb.*; *white sugar*, 10 *lb.*; *mucilage of tragacanth*, q. s.; mix, and divide into 6125 lozenges. Each lozenge contains ½ gr. of *calomel* and 3½ gr. of *resinous extract of jalap*. 1 to 6 of the *yellow* lozenges over night, as a vermifuge, followed by an equal number of the *brown* ones the next morning fasting. See *Patent Medicines*.

LOZENGES (Chlorate of Potassa). Syn. *Trochisci Potassæ Chloratis*,—Lat. Each lozenge contains 1½ gr. of *chlorate of potassa*. In phthisis, sore throat, &c. 6 to 12 a day.

LOZENGES (Chloride of Gold). Syn. *Trochisci Auri Chloridi*,—Lat. Each lozenge contains $\frac{1}{10}$ gr. of *neutral chloride of gold*. 2 to 4 daily, in scrofula, cancer, &c. (See *p.* 536.)

LOZENGES (Chloride of Gold and Soda). Syn. *Trochisci Auri et Sodii Chloridi, T. Sodii Auro-chloridi*,—Lat. (Chrestien.) Each lozenge contains $\frac{1}{16}$th gr. of *soda-chloride of gold*. Two daily; as the last. (See *p.* 537.)

LOZENGE (Chloride of Lime). Syn. *Trochisci Calcis Chloridi, T. C. Chlorinatæ*,—Lat. Each lozenge contains ¼ gr. of dry *chloride of lime*. They are frequently tinged with a little carmine. *Used* to sweeten the breath, and whiten the teeth. They do not keep well.

LOZENGES (Chocolate). Syn. *Trochisci Chocolatæ*,—Lat. From *vanilla chocolate*, pressed into sheets and cut into pieces whilst hot.

LOZENGES (Cinchona). Syn. *Trochisci Cinchonæ Extracti*,—Lat. Each lozenge contains 1½ gr. of *dry extract of bark*. A little *cinnamon* or *nutmeg* is often added. See *Bark Lozenges*.

LOZENGES (Cinnamon). Syn. *Trochisci Cinnamomi*,—Lat. From *cinnamon* (in fine powder), 1 *oz.*, or the *essential oil*, 1 fl. dr., to each *lb.* of *sugar*. Carminative and stomachic. "*Cassia Lozenges*" are made in the same way, and are frequently substituted for them.

LOZENGES (Citrate of Iron). Syn. *Trochisci Ferri Citratis*,—Lat. Each lozenge contains 1½ gr. of *ammonio-citrate of iron*. As a mild chalybeate tonic. They are sometimes made with equal parts of *sugar* and *vanilla chocolate*.

LOZENGES (Citrate of Magnesia). Syn.

Trochisci Magnesiæ Citratis,—Lat. Each 15-gr. lozenge contains 5 gr. of *pure citrate of magnesia*. Laxative.

LOZENGES (Citric Acid). Syn. *Trochisci Acidi Citrici*,—Lat. *Prep.* (P. Cod.) *Citric acid*, 3 dr.; *sugar*, 16 oz.; *essence of lemon*, 16 drops; *mucilage of tragacanth*, q. s.; mix, and divide into 12-gr. lozenges. In coughs, hoarseness, &c.

LOZENGES (Clove). Syn. *Trochisci Caryophilli*,—Lat. From *cloves* (powdered along with sugar), 2 oz., or *essential oil*, 1 fl. dr., to each *lb.* of *sugar*. They are frequently coloured. Carminative and stomachic; also *used* as a restorative after fatigue, added to chocolate to improve its flavour, and sucked to sweeten the breath.

LOZENGES (Colocynth). Syn. *Prepared Colocynth; Trochisci Alhandel, Colocynthis Præparata*,—Lat. *Prep.* (Ph. Bor. & Hamb. Cod.) *Colocynth pulp* (free from seeds and cut), 5 oz.; *gum arabic*, 1 oz.; *water*, q. s.; make a paste, dry, powder, and preserve it in a well-closed bottle. *Dose.* 2 gr. This must not be confounded with any of the previous preparations, and ought to have been inserted at *p.* 276. See *Colocynth.*

LOZENGES (Copaiba). Syn. *Trochisci Copaibæ*,—Lat. Each 16-gr. lozenge contains 1 drop of *balsam of copaiba*, flavoured with *oil of peppermint*. In urinary affections. A useless preparation.

LOZENGES (Cough). Syn. *Pectoral Lozenges, Pulmonic do.; Trochisci Anticatarrhales*,—Lat. *Prep.* 1. *Black currant lozenge-mass*, 1 *lb.*; *ipecacuanha* (in very fine powder), 2 dr. For 12-gr. lozenges.

2. To the last, add of *powdered opium* and *camphor*, of each, 1½ dr.

3. To either No. 1 or 2 add of *oil of aniseed*, 1½ fl. dr.

4. (*Tablettes de Tronchin.*) From *powdered gum arabic*, 8 oz.; *oil of aniseed*, 16 drops; *extract of opium*, 12 gr.; *Kerme's mineral*, 1 dr.; *pure extract of liquorice*, 2 oz.; *white sugar*, 32 oz.; *water*, q. s.; mix and divide into 10-gr. lozenges.

5. (*Tablettes de Vandamme.*) From *benzoic acid*, 1 dr.; *orris powder*, 2 dr.; *gum arabic* (powdered), 1 oz.; *starch*, 2 oz.; *sugar*, 16 oz.; *water*, q. s.; mix and divide into 15-gr. lozenges.

6. Each lozenge contains ½ gr. of *lactucarium*, ⅛ gr. of *powdered ipecacuanha*, and 1/12 gr. of *powdered squills*, together with ⅓rd of their weight of *pure extract of liquorice.*

Obs. To render the above serviceable in coughs, hoarseness, &c., the bowels should be kept gently open with some mild aperient, and a light diet adopted, with abstinence from stimulating liquors. See *Emetine Lozenges, Ipecacuanha do., &c.*

LOZENGES (Crab's Eyes). Syn. *Trochisci Cancrorum Oculorum*,—Lat. From *crab's stones*; now superseded by *chalk lozenges.*

LOZENGES (Croton Oil). Syn. *Trochisci Crotonis*,—Lat. *Prep.* (Soubeiran.) *Croton oil*, 5 drops; *powdered starch*, 40 gr.; *white sugar*, 1 dr.; *chocolate*, 2 dr.; divide into 30 lozenges; 5 or 6 generally prove cathartic.

LOZENGES (Cubebine). Syn. *Trochisci Cubebini*,—Lat. *Prep.* (Ph. Hamb.) *Copaiba* and *extract of cubebs*, of each, 6 oz.; *yelk of* 3 *eggs*; mix, add of *powdered marshmallow root*, 6 oz.; make it into pipes of 12 gr. each, and roll them in *sugar.* In gleet, &c., and in affections of the mucous membranes of the throat and fauces. Lablonye orders them to be made of *sugar*, and flavoured with *oil of peppermint.*

LOZENGES (Cubebs). Syn. *Trochisci Cubebæ*,—Lat. *Prep.* (Spitta.) *Cubebs*, 2 dr.; *balsam of tolu*, 6 gr.; mix, and add of *extract of liquorice*, 1 oz.; *syrup of tolu*, 1 dr.; *powdered gum*, q. s.; divide into 10-gr. lozenges. One of these, allowed to melt gradually in the mouth, is said to alleviate the obstruction in the nose, in coryza.

LOZENGES (D'Arcet's). See *Vichy Lozenges.*

LOZENGES (Digestive). See *Rhubarb Lozenges, Ginger do., Digestive Candy, &c.*

LOZENGES (Edinburgh). *Prep.* From *extract of poppies*, 2 *oz.; powdered tragacanth*, 4 *oz.; sugar*, 10 *oz.; rose water*, q. s. to form a lozenge mass.

LOZENGES (Emetine). Syn. *Trochisci Emetinæ*,—Lat. *Prep.* (Magendie.)—*a.* From *impure* or *coloured emetine*, 32 gr. (or *pure emetine*, 8 gr.); *white sugar*, 2 oz.; *mucilage*, q. s. to mix; divide into 64 lozenges. Emetic. *Dose.* 1 for a child, and 4 for an adult. They are generally tinged of a pink colour with carmine.

b. From *impure* or *coloured emetine*, 32 gr. (or *pure emetine*, 8 gr.); *sugar*, 4 oz.; *mucilage*, q. s.; divide into 256 lozenges. Pectoral. 1 every hour or oftener, for an adult. The last are intended to take the place of ipecacuanha lozenges, but are rather stronger.

LOZENGES (Escharotic). Syn. *Trochisci Escharotici*,—Lat. *Prep.* (P. Cod.) *Corrosive sublimate*, 2 dr.; *starch*, 4 dr.; *mucilage of tragacanth*, q. s.; mix, and divide into 3-gr. oat-shaped granules. For *external use* only. See *Caustic* (Zinc).

LOZENGES (Ferrocyanide of Iron). Syn. *Trochisci Ferri Ferrocyanidi, T. Cærulei,*—Lat. Each lozenge contains 1½ gr. of *pure prussian blue.* Alterative, febrifuge, and tonic; in epilepsy, intermittents, diseases of the ganglionic system, &c.

LOZENGES (Fruit). *Prep.* From *juice of black currants* (boiled to the consistence of an extract), 1 *lb.; do. of red currants,* ½ *lb.; powdered gum tragacanth,* ¼ *lb.; sugar,* 3 *lb.; raspberry syrup,* q. s.; *pear essence,* a few drops. Resemble *black currant lozenges,* but are more agreeable.

LOZENGES (Ginger). Syn. *Trochisci Zingiberis,*—Lat. From the best *unbleached Jamaica ginger,* and *gum arabic,* of each, in very fine powder, 1½ *oz.; double refined lump sugar,* 1 *lb.; rose water* (tinged with *saffron*), q. s. A still finer quality may be made by using an equivalent proportion of *essence of ginger,* instead of the powder. *Inferior qualities* are prepared with *coarser sugar,* to which some *starch* is often added. *Ginger lozenges* are carminative and stomachic, and are useful in flatulency, loss of appetite, dyspepsia, &c.

LOZENGES (Gold). Syn. *Trochisci Auri,*—Lat. Each lozenge contains $\frac{1}{10}$th gr. of *pulverulent gold.* (See *above.*)

LOZENGES (Gum). Syn. *Trochisci Acaciæ, T. Gummi Arabici, T. Gummosi,*—Lat. *Prep.* 1. (Ph. E.) *Gum arabic,* 4 oz.; *starch,* 1 oz.; *white sugar,* 12 oz.; (all in very fine powder); *rose water,* q. s.

2. (P. Cod.) *Gum arabic,* 1 ℔; *sugar,* 3 ℔; *orange flower water,* 2 fl. oz.

3. (*Transparent.*) From the same materials, but employing a gentle heat. Demulcent; *used* to allay "tickling coughs."

LOZENGES (Gum Tragacanth). Syn. *Trochisci Tragacanthæ, T. Gummi T.,*—Lat. *Prep.* (Ph. E. 1744.) *Compound powder of tragacanth,* 3 oz.; *sugar,* 12 oz.; *rose water,* 4 fl. oz. Resemble the last; but are more durable in the mouth.

LOZENGES (Heartburn). See *Chalk Lozenges, &c.*

LOZENGES (Iceland Moss). Syn. *Trochisci Lichenis,*—Lat. (P. Cod.) Contain half their weight of dried and powdered *lichen jelly.* Resemble gum lozenges.

LOZENGES (Indian Hemp). Syn. *Trochisci Cannabis, T. C. Indici,*—Lat. (M. Ebriard.) Each lozenge contains $\frac{1}{12}$ gr. of *extract of Indian hemp.* (See *p.* 562.)

LOZENGES (Iodide of Iron). Syn. *Trochisci Ferri Iodidi,*—Lat. Each lozenge contains ½ gr. of dry *iodide of iron.* 12 to 20 daily; in amenorrhœa, chlorosis, scrofulous debility, &c. They are generally flavoured with a little nutmeg or cinnamon.

LOZENGES (Iodide of Potassium). Syn. *Trochisci Potassii Iodidi,*—Lat. Each lozenge contains 1 gr. of *iodide of potassium,* flavoured with *nutmeg* or *cinnamon.* 10 to 15 daily; in scrofula, indurations, &c. One of the best ways of taking iodide of potassium.

LOZENGES (Ipecacuanha). Syn. *Trochisci Ipecacuanhæ,*—Lat. *Prep.* 1. (P. Cod., Hamb. do., and Ph. U. S.) Each lozenge contains ¼ gr. of *ipecacuanha.*

2. (*Tro. Ipecac. cum Camphora.*) Each lozenge contains ½ gr. of *camphor,* and ¼ gr. of *ipecacuanha.*

3. (*Tro. Ipecac. cum Chocolata,*—P. Cod.) Each lozenge contains 1 gr. of *ipecacuanha,* and 12 gr. of *chocolate à la vanille.* The above are pectoral and expectorant, and are very useful in tickling and chronic coughs, hoarseness, &c.

LOZENGES (Iron). Syn. *Trochisci Ferri, T. Chalybeati,*—Lat. Each lozenge contains 1 gr. of *Quevenne's iron.*

2. (*Tro. Ferri Carbonatis.* Each lozenge contains 1½ gr. of *saccharine carbonate of iron.* They are both mild and excellent chalybeates. See *Steel Lozenges.*

LOZENGES (Jujube). See *Jujube Paste.*

LOZENGES (Kermes Mineral). Syn. *Trochisci Kermetis,*—Lat. *Prep.* 1. (P. Cod.) Each lozenge contains ⅛ gr. of *Kermes mineral,* and about ¾ gr. of *gum,* made up with *sugar* and *orange flower water.* Diaphoretic and expectorant.

2. (*Compound.*) As the last, but with the addition of ⅛ gr. of *opium,* ¼ gr. of *squills,* and ½ gr. of *ipecacuanha.* Anodyne and expectorant; both are very useful in catarrhs.

LOZENGES (Lactate of Iron). Syn. *Trochisci Ferri Lactatis,*—Lat. *Prep.* (M. Cap.) Each lozenge contains 1 gr. of *lactate of iron.* Tonic. *Useful* in debility, accompanied with a diseased state of the organs of digestion.

LOZENGES (Lactic Acid). Syn. *Trochisci Acidi Lactici,*—Lat. Each lozenge contains 1 gr. of *lactic acid* to about 12 gr. of *sugar.* They are best flavoured with *vanilla* or *nutmeg.* In dyspepsia, &c., especially in gouty subjects. Those prepared by Magendie's formula contain a larger proportion of acid, but are much too sour for frequent use.

LOZENGES (Lactucarium). Syn. *Trochisci Lactucarii,*—Lat. *Prep.* (Ph. E.) Prepared with *lactucarium* in the same manner as the *opium lozenges,* Ph. E. Each of these lozenges contains from ⅛ to ⅐ gr. of lactucarium. Anodyne and demulcent. *Used* to allay tickling coughs, &c.

LOZENGES (Lavender). Syn. *Trochisci Lavandulæ*,—Lat. From ¾ fl. dr. of *Mitcham oil of lavender* to each *lb.* of *sugar*, and tinged red with *liquid lake* or *carmine*; or violet, with *litmus* or *indigo*. *Used* chiefly to scent the breath. Those of the shops are generally deficient in odour.

LOZENGES (Lemon). Syn. *Trochisci Limonis*, *T. Limonum*,—Lat. *Prep.* 1: From 1½ fl. dr. of *oil of lemon* to each *lb.* of *double refined white sugar*.

2. (*Acidulated.*) See *Citric Acid* and *Tartaric Acid Lozenges*.

Obs. Lemon lozenges and drops are agreeable sweetmeats, and those that are acidulated are often very useful to promote expectoration, ("*cut the phlegm*," as it is commonly called,) in coughs, &c. The last are also made into drops as well as lozenges, when they form the "*acidulated lemon drops*" of the shops. Those that are made with citric acid are by far the most wholesome. Both lemon lozenges and drops are generally coloured with *infusion of saffron* or *turmeric*.

LOZENGES (Lettuce). Syn. *Trochisci Lactucæ*,—Lat. *Prep.* From *extract of lettuce*, *extract of liquorice*, *gum*, and *sugar*, equal parts. Anodyne and demulcent; in obstinate coughs, without expectoration.

LOZENGES (Lichen). See *Iceland Moss Lozenges*.

LOZENGES (Liquorice). Syn. *Black Lozenges*; *Trochisci Glycyrrhizæ*, *T. G. Glabræ*, *T. Bechici Nigri*,—Lat. *Prep.* (Ph. E.) *Extract of liquorice* and *gum acacia*, of each, 6 oz.; *white sugar*, 12 oz.; dissolve in *water*, q. s.; evaporate to a paste, and form into lozenges. Pectoral and demulcent. Useful to allay tickling coughs, and remove hoarseness.

LOZENGES (Liquorice,—with Opium). See *Opium Lozenges*.

LOZENGES (Magnesia). Syn. *Heartburn Lozenges*; *Trochisci Magnesiæ*,—Lat. *Prep.* 1. (Ph. E.) *Carbonate of magnesia*, 6 oz.; *powdered white sugar*, 3 oz.; *oil of nutmeg*, 20 drops; *mucilage of tragacanth*, q. s. to mix.

2. (Ph. U. S.) *Calcined magnesia*, 4 oz.; *sugar*, 12 oz.; *nutmeg*, 1 dr.; *mucilage of tragacanth*, q. s.; for 10-gr. lozenges.

3. (*Wholesale.*) *Calcined magnesia*, 3 *oz.*; *powdered gum tragacanth*, 1 *oz.*; *double refined lump sugar*, ¾ *lb.*; *rose* or *orange-flower water*, q. s. to make a lozenge mass.

Obs. Magnesia lozenges are very useful in heartburn, acidity, and indigestion. The confectioners generally omit the nutmeg, and make their mucilage with either *rose* or *orange-flower water*, or else add the dry gum to the mass, and then mix up the powders with one or other of these liquids. It is also an improvement to use calcined magnesia, which is about twice as strong as the carbonate, and consequently less need be employed.

LOZENGES (Manna). Syn. *Trochisci Mannæ*,—Lat. *Prep.* (Van Mons) *Powdered tragacanth*, 1 dr.; *white sugar*, 12 oz.; *manna*, 3 oz.; *orange-flower water*, q. s. to mix. Demulcent, and in large numbers slightly laxative.

LOZENGES (Marsh-mallow). Syn. *Trochisci Althææ*,—Lat. *Tablettes de Guimauve*,—Fr. *Prep.* (P. Cod.) *Marsh-mallow root* (decorticated and finely powdered), 2 oz.; *sugar*, 14 oz.; *mucilage of tragacanth* (made with *orange-flower water*), q. s. Demulcent and expectorant. *Useful* to allay the irritation in cough, &c. The preparations of marshmallow have always been highly esteemed as pectorals by the vulgar.

LOZENGES (Minium). Syn. *Trochisci Minii*,—Ph. E. 1744. *Prep.* From *red lead*, 1 dr.; *corrossive sublimate*, 2 dr.; *crum of bread*, 1 oz.; *rose water*, q. s.; to be made up into oat-like grains. For external use only.

LOZENGES (Morphia). Syn. *Trochischi Morphiæ*, *T. M. Hydrochloratis*,—Lat. *Prep.* (Ph. E.) *Hydrochlorate of morphia*, 20 gr.; *tincture of tolu*, ½ fl. oz.; *powdered white sugar*, 25 oz.; dissolve the hydrochlorate in a *little warm water*, mix it with the tincture and the sugar, make a mass with *mucillage of gum tragacanth*, q. s., and divide it into 15-gr. lozenges. *Each lozenge* contains about $\frac{1}{40}$ gr. of hydrochlorate of morphia. *Used* as opium lozenges, but are pleasanter. The *morphia lozenges* of the *shops* generally contain $\frac{1}{24}$ gr. of *hydrochlorate of morphia*. (Pereira.)

LOZENGES (Morphia and Ipecacuanha). Syn. *Trochisci Morphiæ et Ipecacuanhæ*, —Lat. *Prep.* (Ph. E.) As the last, adding of *ipecacuanha*, 1 dr. Each lozenge contains about $\frac{1}{40}$ gr. of *hydrochlorate of morphia*, and $\frac{1}{13}$ gr. of *ipecacuanha*. Anodyne and expectorant; in tickling coughs, &c., and to allay pain.

LOZENGES (Naphthaline). Syn. *Trochisci Naphthalinæ*,—Lat. *Prep.* (Dupasquier.) Each lozenge contains about $\frac{1}{7}$ gr. of *naphthaline*, and is flavoured with *oil of aniseed*. Expectorant; from 15 to 20 daily.

LOZENGES (Nitre). Syn. *Trochisci Nitri*, *T. e. Nitro*,—Lat. *Prep.* (Ph. E. 1783.) *Nitre*, 3 oz.; *white sugar*, 9 oz.; *mucilage of tragacanth*, q. s. to mix. Diu-

retic; but chiefly sucked, without swallowing, to remove incipient sore-throat.

LOZENGES (Nitre, — Camphorated). Syn. *Trochisci Nitri Camphorati*,— Lat. *Prep.* (Chaussier.) Each lozenge contains $\frac{1}{8}$ gr. of *opium*, $\frac{1}{2}$ gr. of *camphor*, and 1 gr. of *nitre*. In hoarseness, sore-throat, &c.

LOZENGES (Nutmeg). Syn. *Trochisci Myristicæ*,—Lat. From *oil of nutmeg*, 1 fl. dr. to each *lb.* of *sugar*, and coloured with *infusion of saffron*. Carminative and stomachic; in colic, &c.

LOZENGES (Opium). Syn. *Anodyne Lozenges; Trochisci Opii, T. Glycyrrhizæ cum Opio*,—Lat. *Prep.* 1. (Ph. E.) *Opium* (strained), 2 dr.; *tincture of tolu*, $\frac{1}{2}$ oz.; triturate together, add of *powdered sugar*, 6 oz.; *extract of liquorice* (soft) and *powdered gum acacia*, of each, 5 oz.; mix, and divide into 10-gr. lozenges. *Each lozenge* contains $\frac{1}{6}$ to $\frac{1}{7}$ gr. of opium. *Used* to allay tickling cough, and irritation of the fauces, and as an anodyne and hypnotic.

2. (Ph. U. S.) *Opium* (in fine powder), 2 dr.; *extract of liquorice*, *gum arabic*, and *sugar*, of each, 5 oz.; *oil of aniseed*, $\frac{1}{2}$ fl. dr.; *water*, q. s.; divide into 6-gr. lozenges. Each lozenge contains $\frac{1}{10}$ gr. of opium. As the last.

LOZENGES (Orange). Syn. *Trochisci Aurantii*,—Lat. From *oil of orange*, 1½ fl. dr. to each *lb.* of *sugar*, and *infusion of saffron* for colouring. By adding *citric or tartaric acid*, 3 dr., "*acidulated orange lozenges*" will be formed.

LOZENGES (Orange Flowers). Syn. *Trochisci Aurantii Florum*,—Lat. *Prep.* (P. Cod.) *Powdered sugar*, 1 *lb.*; *neroli*, 1 dr.; *orange-flower water*, q. s.; make it into drops (*pastilli*); or, omit the water and make it into lozenges with *mucilage of tragacanth* made with *orange-flower water*. Delightfully fragrant.

LOZENGES (Orris-root). Syn. *Trochisci Iridis*,—Lat. *Prep.* From *orris-root* (in very fine powder), 1 *oz.*; *sugar*, 1 *lb.*; *mucilage of tragacanth*, q. s. to mix. *Used* to perfume the breath.

LOZENGES (Oxalate of Potassa). Syn. *Trochisci Potassæ Oxalatis, T. P. Superoxalatis*,—Lat. As acidulated lozenges, but using *quadroxalate of potassa* (salt of sorrel) instead of tartaric acid.

LOZENGES (Oxalic Acid). Syn. *Trochisci Acidi Oxalici*,—Lat. As acidulated lozenges, but using *oxalic acid* instead of tartaric acid. The last two are refrigerant, but their use is objectionable, especially for patients who labour under the oxalic diathesis. In large quantities they are *poisonous*.

LOZENGES (Paregoric). Syn. *Trochisci Paregorici*,—Lat. Medicated with 2 fl. oz. of *paregoric*, and 2 dr. of *tartaric acid*, to each *lb.* of *sugar*, and tinged of a pink colour with lake or cochineal. As a pectoral in catarrhs, &c.

LOZENGES (Paullinia). Syn. *Trochisci Paullinia, T. Guaranæ*,—Lat. *Prep.* (Dr. Gavrelle.) Each lozenge contains nearly ½ gr. of *extract of guarana* or *paullinia*, and is flavoured with *vanilla*. 12 to 20 daily, as an alterative and tonic; in chlorosis, diarrhœa, &c.

LOZENGES (Pectoral). Syn. *Trochisci Pectorales, T. Bechici*,—Lat. *Prep.* 1. (Black; *T. Bechici Nigri.*) See *Liquorice Lozenges.*

2. (Dr. Grunn.) *Powdered squills*, 4 parts; *extract of lettuce*, 8 parts; *ipecacuanha*, 18 parts; *manna*, 125 parts; *sugar*, 250 parts; *mucilage of tragacanth*, q. s. to mix.

3. (Magendie.) See *Emetine Lozenges.*

4. (*Yellow; Tro. Bechici Flavi*). *Powdered orris root*, 6 dr.; *starch*, 4 dr.; *liquorice powder*, 3 dr.; *saffron*, 2 dr.; *sugar*, 8 oz.; *mucilage of tragacanth*, q. s. to mix.

5. (*White; Tro. Bechici Albi*,—Ph. L. 1788.) *Orris root*, 4 dr.; *liquorice powder*, 6 dr.; *starch*, 1½ oz.; *sugar*, 18 oz.; *mucilage of tragacanth*, q.s. to make a lozenge mass.

Obs. All the above are used as demulcents in coughs, colds, &c. The *second* and *third* are anodyne as well as demulcent. For other formulæ see *Cough Lozenges, Liquorice do., Opium do., &c.*

LOZENGES (Pellitory). Syn. *Trochisci Pyrethri*, — Lat. *Prep.* From *pellitory*, *mastic*, and *tragacanth*, of each, in fine powder, equal parts; *orange flower water*, q. s. to mix. In toothache.

LOZENGES (Peppermint). Syn. *Trochisci Menthæ Piperitæ*,—Lat. *Prep.* 1. (P. Cod.) *Oil of peppermint*, 1 dr.; *powdered sugar*, 16 oz.; *mucilage of tragacanth*, q. s.

2. (Ph. U. S.) *Oil of peppermint*, 1 fl. dr.; *sugar*, 12 oz.; *mucilage of tragacanth*, q. s.

3. (Wholesale.) 1 fl. dr. of the *finest Mitcham oil of peppermint* to each *lb.* of the *finest double refined white sugar*, with *mucilage* of either *gum arabic* or *tragacanth* to mix.

Obs. The best peppermint lozenges are made of the *very finest double refined sugar*, and of *English* oil of peppermint only, carefully mixed up with *very clean* mucilage. The *commoner qualities* are made by employing inferior lump sugar and foreign oil of peppermint, or what is better, English oil of peppermint, but in a

less proportion than for the better sorts. The addition of starch, in quantity varying from $\frac{1}{6}$th to $\frac{2}{3}$ths of the whole mass is also commonly made to them; and in the *cheapest varieties* even *plaster of Paris* or *chalk* is occasionally introduced by unprincipled makers. The addition of a *very small* quantity of *blue smalts*, reduced to an impalpable powder, is commonly made to the sugar, to increase its whiteness. "*Transparent*" or "*semi-transparent peppermint lozenges*" are made from the same materials as the opaque ones; but the sugar is not reduced to quite so fine a powder, and the cake is rolled thinner before cutting it. A *little oil of almonds* or of *olives* is also occasionally mixed with the ingredients, to promote the transparency; but it tends to render the lozenges less white.

Peppermint lozenges and *drops* are useful in flatulency, nausea, and griping; and judging from the enormous and constantly increasing demand for them, they are more highly esteemed by the public than all other lozenges and confections.

LOZENGES (Pontefract). These are made of the *purest refined juice* or *extract of liquorice*, and have long been esteemed as a demulcent.

LOZENGES (Poppy). Syn. *Trochisci Papaveris*,—Lat. *Prep.* From *extract of poppies*, 3 *oz.*; *sugar*, 15 *oz.*; *powdered gum tragacanth*, 2 *oz.*; *rose water*, q. s. to mix. *Used* in coughs as an anodyne and demulcent, in lieu of opium lozenges.

LOZENGES (Pulmonic). See *Cough Lozenges*, *Pectoral do.*, *Wafers*, *&c.*

LOZENGES (Quinine). Syn. *Trochisci Quininæ Sulphatis*,—Lat. *Prep.* (Soubeiran.) Each lozenge contains about $\frac{1}{16}$th gr. of *sulphate* (disulphate) *of quinine*. Tonic, and stomachic, in dyspepsia, &c.; but to render them useful the quantity of the alkaloid should be doubled.

LOZENGES (Rhubarb). Syn. *Digestive Lozenges*, *Rhubarb Tablettes*; *Tabellæ de Rheo*, *Trochisci Rhei*,—Lat. *Prep.* (P. Cod.) *Powdered rhubarb*, 1 oz.; *sugar*, 11 oz.; *mucilage of tragacanth*, q. s.; divide into 12-gr. lozenges. Stomachic and laxative. Sucked before dinner they excite the appetite, and after it, promote digestion. They are frequently aromatized with a little *cinnamon* or *vanilla*.

LOZENGES (Rhubarb,—Aromatized). Syn. *Trochisci Rhei Aromatici*,—Lat. See *Digestive Candy* (and *above*).

LOZENGES (Rose). Syn. *Trochisci Rosæ*,—Lat. *Prep.* 1. (*Acidulated*; *Tro. R. Acidæ.*) From *otto*, 5 to 10 drops; *citric* or *tartaric acid*, 3 *dr.*; *sugar*, 1 *lb.*; *mucilage*, q. s.

2. (Ph. E. 1746.) *Red-rose leaves* (powdered), 1 oz.; *sugar*, 12 oz.; *mucilage*, q. s.

3. (*Pâte de Rose Lozenges*, *Pati Rosa do.*) As No. 1, omitting one-half of the acid.

4. (*Red*; *Tro. R. Rubri.*) As No. 1; but coloured with *liquid lake*, or an *infusion of cochineal*.

Obs. Some makers add of *starch*, 4 *oz.*, substitute *oil of rhodium* for otto of roses, and use *mucilage made with rose water*; but the quality of course suffers. They are chiefly used to perfume the breath.

LOZENGES (Saffron). Syn. *Trochisci Croci*,—Lat. *Prep.* From *hay saffron* (in fine powder), 1 *oz.*; *white sugar*, 1 *lb.*; *mucilage of gum tragacanth*, q. s., to mix. Anodyne, pectoral, and emmenagogue; but chiefly used to raise the spirits in hypochondriasis.

LOZENGES (Santonine). Syn. *Tasteless Worm Lozenges*; *Trochisci Santonini*,—Lat. *Prep.* (M. Calloud.) Each lozenge contains $\frac{1}{2}$ gr. (nearly) of *santonine*. 5 to 10 daily, as a vermifuge.

LOZENGES (Soda). Syn. *Trochisci Sodæ Bicarbonatis*,—Lat. *Prep.* 1. (Ph. E.) *Bicarbonate of soda*, 1 oz.; *powdered gum arabic*, $\frac{1}{2}$ oz.; *sugar*, 3 oz.; *mucilage*, q. s.

2. (*Wholesale.*) From *bicarbonate of soda* and *powdered gum tragacanth*, of each, 2 *oz.*; *double refined lump sugar*, $\frac{3}{4}$ *lb.*; *rose water*, q. s. to mix. In acidity, heartburn, &c. See *Vichy Lozenges*.

LOZENGES (Soda and Ginger). Syn. *Trochisci Sodæ et Zingiberis*,—Lat. To the last, add of *ginger* (in very fine powder), $1\frac{1}{2}$ *oz.*; *powdered gum*, $\frac{1}{2}$ *oz.*

LOZENGES (Squills). Syn. *Trochisci Scillæ*,—Lat. Each lozenge contains $\frac{1}{8}$ gr. of *powdered squills*, and 2 gr. of *extract of liquorice*.

LOZENGES (Squills and Ipecacuanha.) Syn. *Trochisci Scillæ et Ipecacuanhæ*,—Lat. As the last, adding for each lozenge $\frac{1}{4}$ gr. of *powdered ipecacuanha*. Both the above are useful cough lozenges.

LOZENGES (Starch). Syn. *Trochisci Amyli*, *T. Bechici Albi*,—Lat. See *Pectoral Lozenges*.

LOZENGES (Steel). Syn. *Trochisci Ferri*, *T. Chalybeati*,—Lat. *Prep.* (P. Cod.) *Levigated iron filings*, 1 oz.; *sugar*, 10 oz.; *cinnamon*, 2 dr.; *mucilage of tragacanth*, q. s.; mix, and divide into 480 lozenges. Tonic. See *Iron Lozenges*.

LOZENGES (Sulphur). Syn. *Trochisci Sulphuris*,—Lat. *Prep.* (P. Cod.) From *sulphur* (pure precipitated), 2 oz.; *sugar*, 16 oz.; *mucilage of tragacanth* (made with

rose water), q. s. to mix. Useful in piles and some skin diseases. The "*tro. e sulphure*," Ph. L. 1788, was made with washed sulphur, and "*tro. diasulphuris*," Ph. E. 1744, contained *benzoic acid*.

LOZENGES (Tartaric Acid). See *Acidulated Lozenges*.

LOZENGES (Tolu). Syn. *Balsamic Lozenges; Trochisci Tolutani, T. Balsamicæ*,—Lat. *Prep.* 1. (P. Cod.) *Balsam of tolu* and *rectified spirit*, of each, 1 oz.; dissolve, add of *water*, 2 fl. oz., heat the mixture in a water bath, and filter; make a mucilage with the filtered liquid, and *gum tragacanth* (in powder), 80 gr.; add of *sugar*, 16 oz., make a mass, and cut it into lozenges.

2. (*Wholesale.*) As the last, but using only *one-half* the weight of *balsam of tolu*. Pectoral and balsamic.

LOZENGES (Tronchin's). Same as *Tablettes de Tronchin*. (See *p.* 726.)

LOZENGES (Vanilla). Syn. *Trochisci Vanillæ*,—Lat. *Prep.* 1. *Essence of vanilla*, 3 fl. dr., to each *lb.* of *sugar*.

2. (Guibourt.) From *vanilla* triturated to a fine powder with 7 times its weight of *sugar*. Antispasmodic, nervine, and stomachic. *Used* to sweeten the breath, to flavour chocolate, &c.

LOZENGES (Vichy). Syn. *D'Arcet's Lozenges; Trochisci Sodæ*,—Lat. *Pastilles de Vichy*,—Fr. *Prep.* 1. (P. Cod.) *Bicarbonate of soda*, 1 oz.; *powdered sugar*, 19 oz.; *mucilage of gum tragacanth*, q. s.; mix, and divide into 20-gr. lozenges.

2. (M. D'Arcet.) As the last, adding a little *oil of peppermint* to give a slight flavour. Antacid or absorbent; in heartburn, &c.

LOZENGES (Violet). Syn. *Trochisci Violæ, T. Violarum*.—Lat. *Prep.* Orris lozenges coloured with the *juice of violets*. (See *p.* 729.)

LOZENGES (Wistar's Cough). *Prep.* *gum arabic, extract of liquorice*, and *sugar*, of each, 2½ oz.; *powdered opium*, 1 dr.; *oil of aniseed*, 40 drops; for 60 lozenges. One, three or four times a day.

LOZENGES (Worm). Syn. *Trochisci Anthelmintici, Morsuli contra Vermes*,—Lat. 1. Most of the advertised nostrums under this name have a basis of *calomel* (about 1 gr. per lozenge), and require to be followed by a purge a few hours afterwards.

2. (*Ching's*). (See *p.* 725.)

3. (Ph. Austr. 1836.) *Ethereal extract of wormseed*, 1 dr.; *jalap, starch*, and *sugar*, of each, 2 dr.; *mucilage of gum tragacanth*, q. s.; divide into 60 lozenges.

4. (Ph. Dan. 1840.) *Wormseed*, 1 oz; *ethiops mineral* and *jalap*, of each, 3 dr.; *cinnamon*, 2 dr.; *sugar*, 7 oz.; *rose water*, q. s.

5. (Ph. Hamb. 1845.) As No. 3.

6. (*Tasteless*). See *Santonine Lozenges*.

LOZENGES (Zinc). Syn. *Trochisci Zinci, T. Z. Sulphatis*,—Lat. *Prep.* (Dr. Copland.) Each lozenge contains ½ gr. of *sulphate of zinc*. Antispasmodic, expectorant, and tonic; and in quantity emetic.

LUBRICATING COMPOUNDS. See *Anti-attrition*.

LUCIFERS. See *Matches*.

LUMBAGO. Rheumatism of the loins. It is distinguished from *nephritis*, or inflammation of the kidneys, by the pain being aggravated on stooping. The *treatment* consists of strong stimulant embrocations or liniments, or of blisters over the part affected, with active aperients, warmth, and diaphoretics (as *Dover's powder*) at bedtime. The *hot* or *vapour bath* often gives almost immediate relief. See *Rheumatism*.

LUMINOUS PHIAL. See *Phosphorus*.

LUNA CORNEA. Fused chloride of silver.

LUNAR CAUSTIC. See *Nitrate of Silver*.

LUNCH or *Luncheon*. Among the middle classes this is a slight repast between breakfast and dinner; but among the higher or fashionable classes it constitutes the midday meal. See *Dinner* and *Meals*.

LUNGS. See *Stays* and *Respiration*.

LUPININE. A name given by M. Cassola to a species of gum obtained from *lupins*.

LUPINITE. A bitter substance extracted from the leaves of *lupinus albus* or *white lupin*.

LUPULINE. Syn. *Lupulina, Lupulinic Grains, L. Glands*. The yellow powder obtained from the *dried strobiles* or *catkins of the hops*, by gently rubbing and sifting them. *Dose.* 5 to 10 gr.; as an anodyne, tonic, &c. See *Hops*.

LUPULITE. Syn. *Hop Bitter* (Pure). The aromatic bitter principle of hops.

Prep. The *aqueous extract of the yellow powder* or *lupulinic grains of the strobiles*, along with a *little lime*, are treated with *rectified spirit;* the filtered tincture is evaporated to dryness, re-dissolved in *water*, and the solution is again filtered, and evaporated to dryness; the residuum is, lastly, washed with *ether*, and allowed to dry.

Prop., &c. A yellowish-white, bitter, uncrystallizable substance, soluble in 20 parts of water, very soluble in alcohol, and slightly so in ether. The yellow powder above alluded to is improperly called *lupuline;* a name which appears more appropriate to this compound than to the *lupulinic grains*.

LUPUS. A disease affecting the skin, remarkable for eating away the parts which it attacks with extreme rapidity. It is generally confined to the face, and commences with small spreading ulcerations, which become more or less concealed beneath bran-like scabs, and end in ragged ulcers, which gradually destroy the skin and muscular tissue to a considerable depth. Sometimes it assumes a form resembling that of ring-worm; in others, to the inexperienced eye, it simulates cancer. In its most malignant shape (*noli me tangere*) it frequently attacks the cartilages of the nose, when the whole of that organ is often destroyed by its ravages. Lupus is a disease of a most obstinate character and most difficult to cure, and, in many cases, appears to be even aggravated by medication. The only *treatment* besides that of a constitutional character, consists in the use of escharotic lotions, or in the separation of the diseased from the sound parts by caustic applications or the knife. Among internal remedies the *solutions of arsenic, chloride of barium*, and *hydriodate of arsenic and mercury* (Donovan's solution), appear to be the most beneficial.

LUSTRE. See *Plumbago.*

LUTE. Syn. *Luting; Lutum, Cæmentum*,—Lat. A composition employed to secure the joints of chemical vessels, or as a covering to protect them from the violence of the fire.

Prep. 1. *Linseed meal*, either alone, or mixed with an *equal weight of whiting*, and made into a stiff paste with water. It soon becomes very hard and tough.

2. *Ground almond cake*, from which the oil has been pressed, mixed up as the last. Both the above are much used for stills, resorts, and other vessels that are not exposed to a heat higher than about 320° Fahr. They are capable of resisting the action of the fumes of volatile oils, spirits, weak acids, &c., for some time.

3. *Fresh-slaked lime* made into a paste with strained *bullock's blood* or *size*. As the last.

4. *Plaster of Paris* made into a paste with *water*, and at once applied. It bears a nearly red heat, but becomes rather porous and friable.

5. *Powdered clay* or *whiting* made into putty with *water* and *boiled linseed oil*. This is commonly known as "*fat lute*."

6. A mixture of *powdered clay* and ground *bricks*, made up with *water* or a *solution of borax*. For joining crucibles, &c., which are to be exposed to a strong heat.

7. *Pipe-clay* and *horse-dung*, made into a paste with *water*. As a coating for glass vessels, to preserve them from injury from exposure to the fire. This composition is used by the pipe-makers, and will stand unharmed the extremest heat of their kiln for 24 hours. It is applied by spreading it on paper.

8. As the last, but employing *shredded tow* or *plumbago* for *horse-dung*.

Obs. For the joints of small vessels, as *tubes, &c.*, especially those of glass or earthenware, pieces of *vulcanized Indian tubing* slipped over and tied above and below the joint, are very convenient substitutes for lutes, and have the advantage of lasting for a long time, and bearing uninjured the heat at which oil of vitriol boils. Flat rings or "*washers*" *of vulcanized rubber* are also excellent for still heads, &c., whenever the parts can be "pinched together" by screws or clamps.

LUTEOLINE. Syn. *Luteoleine*. A yellow colouring matter, discovered by Chevreul in *reseda luteola* (Linn.) or *weld*. It is crystallizable and volatile. It may be obtained in beautiful, transparent, yellow needles by sublimation. See *Weld.*

LYCOPODIUM. Syn. *Club Moss, Common do. do.; Lycopodium clavatum*—Linn. The seed (*pollen*) of this plant is exceedingly combustible; thrown suddenly from a powder puff or bellows across the flame of a candle, it produces the imitation flashes of lightning of our theatres. *Rosin* (in fine powder) which is often used for the same purpose, is much less effective. The powder is also employed as a "dusting powder" in excoriations, and to roll up boluses and pills. The herb is very astringent, and where it is plentiful, has long been used for the restoration of ropy wine and beer. See *Hands, &c.*

LYNCH'S REMEDY (for Rheumatism). See *Embrocations.*

MACARONI. This only differs from vermicelli in the size of the pipes, which are about as large as a goose quill. When properly dressed it is very wholesome and nutritious. A *pleasant dish* may be made by boiling *macaroni* in *water* until soft, either with or without a *little salt*, draining off the water, and then stewing it with a *little butter, cream*, or *milk*, and *grated cheese*, adding *spice* to palate. It may be made into a "form" and browned before the fire.

MACAROONS (English). *Prep.* Take of *sweet almonds*, 1 *lb.*; blanch and beat

them to a paste, add of *lump sugar*, 1¼ *lb.*; *whites of* 6 *eggs*; the *grated yellow peel* of 2 *lemons*; mix well, make it into "forms," cover with *wafer paper*, and bake in a moderate oven.

MACE. Syn. *Macis*,—Lat. The aril or tough, unctuous, membranous envelope of the nutmeg. After being separated from the fruit it is dipped into *brine* and dried in the sun. It has a flavour and odour more agreeable than that of nutmeg, which in its general properties it resembles. It is used as a flavouring by cooks, confectioners, and liquoristes; and in medicine as a carminative. See *Oils*, *&c.*

MACERATION. Syn. *Maceratio*,—Lat. The steeping of a substance in cold water, for the purpose of extracting the portion soluble in that menstruum. The word is also frequently applied to the infusion of organic substances in alcohol or ether, or in water, either alkalized or acidulated.

MACHINES. The *construction* and *management of machinery* does not come within the province of this work. For some information in connexion with the subject, see *Anti-attrition*, *Evaporation*, *Fuel*, *Horse-power*, *&c.*

MACKEREL. The *scomber scombrus* (Linn.), a well-known spiny-finned sea-fish, much esteemed at certain seasons for the table. Though nutritious, is is very apt to disagree with delicate stomachs, and occasionally induces symptoms resembling those of poisoning. It keeps worse than, perhaps, any other fish, and hence the privilege granted by an old statute to hawk it about the streets on Sundays. The use of mackerel was formerly regarded as beneficial in liver affections.

MACQUER'S SALT. Binarseniate of potassa.

MADDER. Syn. *Rubia*, *Rubiæ Radix*, —Lat. The root of *rubia tinctorum* (Linn.) or *dyer's madder*. The best madder has the size of a common goose quill, a reddish appearance, and a strong odour. As soon as the roots are taken from the ground they are picked and dried; and before use, they are ground in a mill. Levant, Turkey, and Smyrna madder, is imported *whole*,—French, Dutch, and Zealand madder *ground*. The finest quality of ground madder is called "*crop*" or "*grappe*;" "*ombro*" and "*gamene*" are inferior sorts, and "*mull*" the worst.

Madder contains several distinct principles, as—*madder red*, or *alizarine*;—*madder purple*, or *purpurine*;—*madder orange*, or *rubiacine*, a substance very soluble in ether and in hot alcohol;—*madder yellow*, or *xanthine*, which is very soluble in water and in alcohol; and—*madder brown*, a substance little known; — *rubian*, a peculiar bitter substance, and several resins, &c.

Pur. Madder is frequently adulterated with logwood, Brazil wood, and other dye-stuffs of inferior value; and also, not unfrequently, with brick dust, red ochre, clay, sand, mahogany saw-dust, bran, &c. These admixtures may be detected as follows:—

1. When dried at 212° Fahr., and then incinerated, not more than 10% to 12% of ash should be left.

2. It should not lose more than 50% to 56% by exhaustion with cold water.

3. When assayed for alizarine (see *below*) the quantity of this substance obtained should be equal to that from a sample of the same kind of madder which is known to be pure, and which has been treated in precisely the same manner. The operation may be conducted as follows:—500 gr. of the *sample* are weighed, and after being dried by the heat of *boiling water* or *steam*, are gradually added to an equal weight of *concentrated sulphuric acid* contained in a glass vessel, and stirred with a glass rod; after a few hours the charred mass is washed with *cold water*, collected on a filter, and dried by the heat of boiling water; the carbonized mass (*commercial garancine*) is next powdered, and treated with successive portions of *rectified spirit to which a little ether has been added*, at first in the cold, and afterwards with heat, until the liquid is no longer coloured by it, when the mixed tincture is filtered, and evaporated (distilled) to dryness; the weight of the residuum divided by 5, gives the *per centage* of RED COLOURING MATTER present. Or,—The dried *carbonized matter* is exhausted by boiling it in a *solution* of 1 part of *alum* in 5 or 6 parts of *water*, and the decoction, after being filtered whilst in the boiling state, is treated with *sulphuric acid* as long as a precipitate falls, which is washed, dried, and weighed as before.

Uses, *&c.* Madder has been given in jaundice and rickets, and as an emmenagogue. It imparts a red colour to the bones of animals which are fed on it. *Dose.* ½ dr. to 2 dr., twice or thrice a day. It is principally employed as a dye stuff. See *Red Dyes*, *Ivory*, *&c.*

MADDER RED. Syn. *Alizarine*, *Garancine*, *Lizaric Acid.* The red colouring principle of madder, first obtained in a separate form by Robiquet.

Prep. 1. By cautiously exposing *dried*

and *powdered madder* or *commercial garancine* to heat, and collecting the sublimate, which may then be crystallized from *alcohol.*

2. The *aqueous decoction of madder* is treated with *dilute sulphuric acid* as long as a precipitate falls, which after being washed, is boiled in a *solution of sesquichloride of aluminum* as long as it gives out colour; the liquid is then filtered, precipitated with *hydrochloric acid*, and the precipitate washed and dried. It may be purified from a little adhering purpurine, by dissolving it in *alcohol*, again throwing it down with *hydrate of alumina*, boiling the precipitate with a *strong solution of soda*, and separating the alizarine from its combination with alumina by means of *hydrochloric acid;* it is lastly crystallized from *alcohol.*

3. (A. Meillet.) *Alum*, 3 parts, is dissolved in *water* at 140° Fahr., 30 parts, and *madder*, 13 parts, added to the solution; the whole is then gently boiled for 30 or 40 minutes, after which, it is thrown upon a filter, and submitted to strong pressure; this treatment is repeated with fresh solutions a *second* and a *third* time; the mixed filtrates are then decanted, and when nearly cold, *oil of vitriol*, 1 part, diluted with twice its bulk of *water*, is added, care being taken to stir the liquid all the time; the supernatant fluid is next decanted, and the residuum well washed, and lastly, dried in the air. If required *quite pure*, it is dissolved, whilst still moist, in a *solution* of 1½ times its weight of *carbonate of potassa* in 15 parts of *water*, and after reprecipitation with *sulphuric acid*, is washed and dried as before.

4. (Robiquet & Colin.) *Powdered madder* is exhausted with *water* of a temperature not exceeding 68° Fahr., and after being dried, 1 part of it is boiled for 15 or 20 minutes in a solution of *alum*, 8 parts, in *water*, 40 parts; the liquid is filtered whilst boiling, the marc well-washed with a fresh *solution of alum*, the mixed liquids precipitated with *sulphuric acid*, and the precipitate washed and dried, as before.

5. *Madder* exhausted by 2 or 3 macerations in 5 or 6 times its weight of *cold water*, is submitted to strong pressure, to remove adhering water, and the *marc*, whilst still moist, is mixed with ½ its weight of *oil of vitriol diluted with an equal quantity of water;* the whole is kept at the temperature of 212° for an hour, and after being mixed with *cold water* is thrown on a linen strainer, well-washed with *cold water*, and dried.

6. From *powdered madder* and *oil of vitriol*, equal parts, without heat, as described at *p.* 733.

7. (Mr. F. Steiner.) The "*used madder*" of the dye-works is run into filters, and precipitated with *sulphuric acid;* the matter thus obtained is put into bags and rendered as dry as possible by hydraulic pressure; the pressed cake is next crumbled to pieces, placed in a leaden vessel, and treated with 1-5th of its weight of *oil of vitriol*, afterwards assisting the action of the acid by introducing steam to the mixture; the resulting dark-brown carbonized mass is, lastly, well washed, dried, powdered, and mixed with about 5% of *carbonate of soda*, when it is ready for sale. *Patent*, dated Aug., 1843. The *last three formulæ* produce the *garance* or *garancine* of commerce now so extensively used in dyeing.

Prop., &c. Pure *anhydrous alizarine* crystallizes in magnificent orange-red crystals, which may be fused and sublimed; it is freely soluble in alkaline solutions, which it colours purple or violet; and in oil of vitriol, giving a rich red colour; water throws it down from the last unchanged; it is also soluble in hot alcohol, a hot solution of alum, and less freely, in hot water. *Hydrated alizarine* occurs in small scales resembling mosaic gold. When impure, it generally forms shining reddish-brown scales. *Commercial garancine* is a deep brown or puce-coloured powder, and will probably, ere long, entirely supersede crude madder for dyeing. The properties of garancine as a dye-stuff are precisely similar to those of madder. A *solution of alum* added to a *solution of alizarine*, and precipitated by *carbonate of potassa*, furnishes a *rose lake*, which, after being washed with *water*, and dried, possesses a most charming tint.

MADDERIC ACID. One of two colourless acids found by Runge in madder.

MADEIRA. See *Wines.*

MADNESS. See *Insanity.*

MAGILP. Syn. *Meggellup.* A mixture of *pale linseed oil* and *mastic varnish*, employed by artists as a vehicle for their "glazings." The proportions vary according to the work. It is thinned with turpentine.

MAGISTERY. Syn. *Magisterium*,—Lat. The old name of precipitates obtained by diluting certain solutions with water. The following are the principal substances to which this term has been applied:—*Magistery of alum*, hydrate of alumina; *m. of bismuth*, trisnitrate of do.; *m. of diaphoretic antimony*, materia perlata; *m. of opium* (Ludolph's), crude morphia; *m. of lapis calaminaris; m. of zinc*, hydrated oxide of

zinc; *magisterium marcasitæ*, trisnitrate of bismuth.

MAGNESIA. Syn. *Calcined Magnesia, Oxide of Magnesium; Magnesia*,—Ph. L. E. & D. *Mag. Calcinata; M. Usta*,—Ph. L. 1788. *Burnt Magnesia, Caustic do., Bitter Earth, Talc do.*,—Obs. A light white substance, classed with the earths.

Prep. 1. (Ph. L. E. & D.) Expose *carbonate of magnesia* in a crucible (earthen or platinum) to a full red heat for 2 hours, or until the powder suspended in water does not effervesce on the addition of *dilute sulphuric* or *hydrochloric acid*.

Prop. A very light, white, odourless, tasteless, powder; sp. gr. 2·3; when moistened it slightly acts on turmeric paper; soluble in 5142 parts of cold water, and in 36,000 parts of boiling water. It slowly absorbs carbonic acid from the atmosphere. With the acids it forms salts, most of which may be made by the direct solution of the earth, or of its hydrate or carbonate.

Pur. "Being moistened with water, it slightly changes the colour of turmeric to brown. It dissolves in hydrochloric acid without effervescence. Neither bicarbonate of potassa, nor chloride of barium, throws down anything from this solution." (Ph. L.) "Fifty grains are entirely soluble in 1 fl. oz. of hydrochloric acid; an excess of ammonia occasions in the solution only a scanty precipitate of alumina: the filtered liquid is not precipitated by oxalate of ammonia." (Ph. E.) Distilled water, which has been boiled on it, is not affected on the addition of either chloride of barium or nitrate of silver.

Tests. Magnesia is precipitated—1. By the pure alkalies as a bulky white hydrate, which is insoluble in water, but freely soluble in dilute acids.—2. As a bulky white carbonate, by the carbonates of potassa and soda. Both the above precipitates readily dissolve in dilute nitric and hydrochloric acids, forming salts which are very deliquescent, and which are soluble in alcohol.—3. Solutions of magnesian salts are not precipitated by the alkaline sulphates or sulphuric acid, nor, when very dilute, by oxalate of ammonia.—4. Ammonia only throws down part of the magnesia present, the remainder uniting to form a double salt, which is not decomposable by the addition of ammonia in excess; but the whole of the magnesia is thrown down on the addition of carbonate of potassa, and boiling the mixture for some time. By the above tests, magnesia is readily distinguished and separated from the *other earths*. Its insolubility in alkaline solutions distinguishes it from *alumina*. In all cases ebullition promotes the formation of the precipitate.

Estim. It may be thrown down in the form of carbonate, and after being washed, dried, and strongly ignited in a platinum crucible for 2 hours, may be weighed as pure magnesia.

Uses, &c. Calcined magnesia is chiefly employed in medicine. It is antacid and laxative, and its general action resembles that of the alkalies. It is exhibited in heartburn, diarrhœa, constipation of children, gout, &c. Its continued use, however, is not unaccompanied with danger, as instances are recorded in which it has accumulated in the intestines, and produced very serious consequences. *Dose.* As an *antacid*, a teaspoonful; as a *purgative*, ½ dr. to 2 dr. or more. Combined with rhubarb it is a favorite purge for infants.

Obs. Calcined magnesia is now seldom prepared by the retail druggist. On the *large scale*, covered crucibles made of porous earthenware are employed as the containing vessels, and the heat is applied by placing them side by side, in a sort of furnace, or rather oven, heated with coke. The process is known to be complete when the magnesia presents a peculiar luminous appearance, technically called "brightening." After calcination, the crucibles, still covered, are allowed to cool, when their contents are at once passed through a fine sieve, and preserved in well-corked bottles or jars, as it quickly absorbs carbonic acid from the air. *Prod.* 42 to 43%.

MAGNESIA (Heavy). Syn. *Heavy Calcined Magnesia, Condensed do. do.; Magnesia Ponderosa, M. Calcinata P.*,—Lat. *Prep.* From the *heavy carbonate* by calcination in the usual manner. For this purpose the mixed solution of the *sulphate of magnesia* and *alkaline carbonate* is generally at once evaporated to dryness and calcined, the alkaline sulphate resulting from the decomposition being afterwards removed by careful washing.

Prop., &c. Heavy magnesia resembles the ordinary calcined magnesia of the shops (*light calcined magnesia*) in all except its density. The assertion, however, that 1 part of the *former* is equal to 3 of the *latter*, which frequently appears on the labels, is a gross exaggeration.

MAGNESIA (Henry's Calcined). This, for the most part, resembles the last preparation.

MAGNESIA (Acetate of). Syn. *Magnesiæ Acetas*,—Lat. Very soluble, deliquescent, and difficultly crystallizable.

MAGNESIA (Carbonate of). Syn. *Subcarbonate of Magnesia, Hydrated do. do.; Light Carbonate of do.; Magnesiæ Carbonas,*—Ph. L. E. & D. *M. Subcarbonas,* Ph. L. 1824. *M. Alba,*—Ph. L. 1788. *Magnesia,*—Ph. D. 1807. *M. Subcarbonas Hydrata, M. Anglica, M. Salis Amari, M. Hydrico-carbonica, Carbonas Magnesicus cum Aquâ, Comitissæ Palmæ Pulvis,*—Lat. var. *Prep.* 1. (Ph. L.) *Sulphate of magnesia,* 4 lb, and *carbonate of soda,* 4 lb 9 oz.; *boiling distilled water,* 4 gall.; dissolve the salts separately in one half the water, filter, mix the solutions, and boil for 2 hours, constantly stirring with a spatula, *distilled water* being frequently added to compensate for that lost by evaporation; lastly, the solution being poured off, wash the precipitated powder with *boiling distilled water,* and dry it. The formulæ of the Ph. E. & D. & Ph. L. 1836, are essentially the same, except that the ebullition is limited to from 10 to 20 minutes.

2. (Ph. D. 1826.) *Sulphate of magnesia,* 25 parts; *carbonate of potassa,* 24 parts; *boiling water,* 400 parts; as the last, but merely boiling for "a short time."

3. Add a *solution of carbonate of potassa* or *soda* to the *bittern* or *residuary liquor* of the sea salt works, and well wash and dry the precipitate as before. This is known in commerce as "*Scotch magnesia.*"

Prop. Carbonate of magnesia is a white, inodorous, tasteless powder, possessing similar properties to calcined magnesia, except effervescing with acids, and having less saturating power. An ounce measure is filled by 45 to 48 gr. of the powder lightly placed in it.

Pur. "It is soluble in dilute sulphuric acid. From this solution, when the effervescence has ceased, nothing is thrown down by bicarbonate of potassa. Water in which it has been boiled does not change the colour of turmeric paper to brown, nor is any thing thrown down on the addition of chloride of barium or nitrate of silver." (Ph. L.) By solution in dilute sulphuric acid, 100 parts lose 36·6 parts by weight." (Ph. L. 1836.)

Obs. The carbonate of magnesia of commerce is usually made up into cakes or dice, while drying; or it is permitted to drain and dry in masses, which are then cut into squares with a thin knife. It is powdered by simply rubbing it through a wire sieve. The presence of iron in the solution of the sulphate of magnesia, when the crude salt is employed, and which is destructive to the beauty of the preparation, may be got rid of by the addition of *lime water* until the liquor acquires a slight alkaline reaction, and subsequent decantation after repose. *Dose.* As an *antacid,* ½ to a whole teaspoonful 3 or 4 times daily; as a laxative, ½ dr. to 2 dr. It is commonly taken in milk. It is apt to produce flatulence, but in other respects is preferable to calcined magnesia.

MAGNESIA (Heavy Carbonate of). Syn. *Maynesia Carbonas Ponderosa,* — Lat. *Prep.* 1. (Apothecaries' Hall.) A *saturated solution of sulphate of magnesia,* 1 part, is diluted with *water,* 3 parts, and the mixture heated to the boiling point; a *cold saturated solution of carbonate of soda,* 1 part (*all by measure*) is then added, and the whole is boiled with constant agitation until effervescence ceases; *boiling water* is next freely poured in, and after assiduous stirring for a few minutes, and repose, the clear liquid is decanted, and the precipitate thrown on a linen cloth and thoroughly washed with hot water; it is, lastly, drained, and dried in an iron pot.

2. (Ph. D.) Dissolve *sulphate of magnesia,* 10 *oz.,* in *boiling distilled water,* ½ pint; and *carbonate of soda* (cryst.), 12 *oz.,* in *boiling distilled water,* 1 pint; mix the two solutions, and evaporate the whole to dryness by the heat of a sand bath; then add of *boiling water,* 1 quart, digest with agitation for half an hour, and wash the insoluble residuum as before; lastly, drain it, and dry it at the temperature of boiling water.

Obs. The above preparations, although commonly called carbonates of magnesia, appear to be a compound of carbonate with hydrate, in proportions, which are not perfectly constant. On account of the excess of base in its composition, it was formerly regarded as a subsalt. A great deal has been written uselessly respecting the preparation of these carbonates, about which, however, there is neither mystery nor difficulty, as some writers would lead their readers to suppose. If the solutions are very dilute, the precipitate is exceedingly light and bulky; if otherwise, it is denser. By employing nearly saturated solutions, and then heating them and mixing them together whilst very hot, a very heavy precipitate is obtained, but it is apt to be gritty or crystalline. The same occurs when cold solutions are mixed, and *no* heat is employed. The lightest precipitate is obtained from cold highly dilute solutions, and subsequent ebullition of the mixture. Mr. Pattinson, a chemist of Gateshead, prepares a very beautiful and pure heavy carbonate from magnesian limestone. The

latter is calcined at a dull red heat (not hotter) for some time, by which the carbonic acid is expelled from the carbonate of magnesia, but not from the lime, which hence continues insoluble. The calcined mass is next reduced to a milk with water in a suitable cistern, and the carbonic acid resulting from its own calcination, forced into it under powerful pressure. The result is a saturated solution of magnesia, the lime remaining unacted on, so long as the magnesia is in excess. The solution by evaporation yields the *heavy carbonate*, whilst carbonic acid is expelled, and may be again used in the same manufacture. 154 to 160 gr. of the heavy carbonate are required to fill an ounce measure when lightly placed in it, by which it appears to be fully thrice as dense as the light carbonate. The *dose* is of course proportionate.

MAGNESIA (Carbonate of,—Henry's). This is ordinary carbonate of magnesia, the washing of which has been finished with a little rose water.

MAGNESIA (Bicarbonate of). Syn. *Magnesiæ Bicarbonas*,—Lat. This name has been applied to the small prismatic crystals of *hydrated neutral carbonate of magnesia* which are deposited when "fluid magnesia" is exposed for some time to the air, under an error as to their constitution. A similar mistake is made by Pereira and others, who state that "this salt is obtained in solution only;" whereas, the solution of magnesia to which they refer is simply a solution of the common carbonate in an excess of carbonic acid, or in highly carbonated water, without any chemical union taking place. It might with more propriety be called a supercarbonate, as analysis proves its composition to vary in different samples.

MAGNESIA (Citrate of). Syn. *Magnesiæ Citras*,—Lat. *Prep.* 1. By saturating a *dilute solution of citric acid* with either *calcined magnesia* or *carbonate of magnesia*, with heat, avoiding excess, and crystallizing by evaporation in the usual manner.

2. (Dorvault.) *Citric acid* (cryst.), 100 parts; heat it in a capsule until it liquefies, then stir in of *calcined magnesia*, 29 parts (or, *carbonate*, 64 parts), and after the mass has become solid and cold, reduce it to powder, and preserve it from the air.

3. (Thevenot.) *Citric acid* (dried and powdered), 3 parts; *calcined magnesia*, 1 part; mix, and preserve it in well-closed bottles.

Prop., &c. Citrate of magnesia is a mild and agreeable laxative; its secondary effects resemble those of the carbonate. *Dose.* As a purgative, ½ to 1 oz. A solution of this salt in water, sweetened and flavoured, forms *Magnesian Lemonade.*

MAGNESIA (Citrate of,—Effervescing). Syn. *Magnesiæ Citras Effervescens*,—Lat. *Prep.* 1. *Citric acid* (dried and powdered), 7 parts; *heavy carbonate of magnesia*, 5 parts; mix, and preserve in well-corked bottles.

2. (*Extemporaneous.*) *Citric Acid* (cryst.), 20 gr.; *carbonate of magnesia*, 14 gr.; mix in a tumbler of *cold water*, and drink the mixture whilst effervescing. A pleasant saline.

Obs. The dry white powder sold as citrate of magnesia in the shops, is quite a different preparation to the above, and *does not contain a particle of citric acid.* The following formula is that of a wholesale London drug-house that does largely in this article:—

Calcined magnesia, 1¼ *lb.* (or *carbonate*, 2 *lb.*); *powdered tartaric acid*, 1½ *lb.*; *bicarbonate of soda*, 1 *lb.*; dry each article by a gentle heat, then mix them, pass the mixture through a fine sieve in a warm dry room, and keep it in well-corked bottles. A few drops of *essence of lemon*, and 3 *lb.* of *finely powdered sugar* are commonly added to the above quantity. This addition renders it more agreeable. If *citric acid* was employed in this preparation, instead of tartaric acid, it would be unobjectionable. Its sale as *citrate of magnesia* is a gross fraud.

MAGNESIA (Boro-citrate of). Syn. *Magnesiæ Boro-citras*,—Lat. *Prep.* (Cadet.) *Boracic Acid* (in powder), 113 gr.; *calcined magnesia*, 80 gr.; mix in a porcelain capsule, and add enough of a solution of *citric acid*, 260 gr., in *water*, 3½ pints, to form a thin paste; then add the remainder of the citric solution, and gently evaporate, with constant stirring, to dryness. A cooling saline, and in small doses, emmenagogue and lithontriptic. *Dose.* As an aperient, 3 to 6 dr.

MAGNESIA (Phosphate of). Syn. *Magnesiæ Phosphas*,—Lat. *Prep.* 1. From the mixed solutions of *phosphate of soda* and *sulphate of magnesia*, allowed to stand for some time. Small, colourless, prismatic crystals.

2. (Niemann.) By saturating *dilute phosphoric acid* with *carbonate of magnesia*, and evaporating the solution to dryness. An amorphous mass.

Obs. The above compounds somewhat differ from each other in composition, and in solubility. The neutral phosphate is

soluble in about 15 parts of cold water, and less of boiling. Phosphate of magnesia exists in the grains of the cereals, and in considerable quantity in beer. It is also found in guano. *Dose.* 10 to 20 gr.; in caries, rickets, &c.

MAGNESIA (Ammonio-phosphate of). Syn. *Magnesiæ et Ammoniæ Phosphas*,—Lat. This compound falls as a white crystalline precipitate whenever *ammonia* or its *carbonate* is added, in excess, to a solution of a *salt of magnesia* which has been previously mixed with a *soluble phosphate*, as that of soda. It subsides immediately from concentrated solutions, but only after some time from dilute ones.

Prop., &c. Ammonio-phosphate of magnesia is very slightly soluble in pure water; when heated it is resolved into *bibasic phosphate* or *pyrophosphate of magnesia*, and is vitrified at a strong red heat. It is found in wheaten bran, guano, potatoes, &c., and occasionally forms one of the varieties of urinary calculi.

MAGNESIA (Potassio-tartrate of). Syn. *Magnesiæ Potassio-tartras, M. et Potassæ Tartras*,—Lat. *Prep.* From *cream of tartar* (in powder), 7 parts; *carbonate of magnesia*, 2 parts; *water*, 165 parts; boiled until the solution is complete, and then evaporated and crystallized. A mild aperient. *Dose.* 1 to 5 dr.; in scurvy, &c.

MAGNESIA (Silicate of). There are several *native silicates of magnesia*, more or less pure, of which, however, none is directly employed in medicine. *Meerschaum* and *steatite* or *soap-stone* are well-known varieties. *Serpentine* is a compound of silicate and hydrate of magnesia. The minerals *augite* and *horneblende* are double salts of silicic acid, magnesia, and lime, with some protoxide of iron. The beautiful crystallized mineral called *chrysolite* is a silicate of magnesia, coloured with protoxide of iron. *Jade* is a double silicate of magnesia and alumina, coloured with sesquioxide of chromium.

MAGNESIA (Sulphate of). Syn. *Epsom Salt; Sal Epsomensis; Magnesiæ Sulphas*,—Ph. L. E. & D. *Physical Salt, Bitter Purging do., Salts, Epsom Salts*,—Vulgo. *Vitriolated Magnesia, Sal Catharticum, S. C. Amarum, S. Anglicum, S. Seidlitzense, Magnesia Vitriolata*,—Obs. var. This compound was originally extracted from the saline springs of Epsom, Surrey, by Dr. Grew, in 1695. It is now exclusively prepared on the *large scale*, and from either is magnesian limestone, or the residual liquor the the sea-salt works.

rid o*rep.* 1. From *Dolomite* or *Magnesian lime-stone.*—*a.* The *mineral*, broken into fragments, is heated with a sufficient quantity of *dilute sulphuric acid* to convert its *carbonates* into *sulphates;* the *sulphate of magnesia* is washed out of the mass with *hot water*, and the solution, after defecation, is evaporated and crystallized.

b. The *lime-stone*, either simply broken into fragments, or else, calcined (burnt), and its constituent quicklime and caustic magnesia converted into *hydrates* by sprinkling (slaking) it with *water*, is treated with a sufficient quantity of *dilute hydrochloric acid* to dissolve out *all* the lime without touching the magnesia; the residuum of the latter, after being washed and drained, is dissolved in *dilute sulphuric acid*, and crystallized as before.

c. The *mixed hydrates* (see *b*) are digested in a *solution of sulphate of iron*, with agitation, until *all* the magnesia is dissolved; from the solution crystals of *sulphate of magnesia* are obtained, as before. The last two methods are included in the patent of Dr. William Henry, of Manchester, (1816,) and are admirable in situations in which hydrochloric acid may be obtained at an exceedingly low rate, as in the neighbourhood of soda works.

2. From *Bittern.*—*a.* The *residual liquor* or *mother-water of sea-salt* is boiled for some hours in the pans which are used during the summer for the concentration of brine; the saline solution is then skimmed and decanted from some common salt which has been deposited, after which it is concentrated by evaporation, and, finally, run into wooden coolers; in about 36 hours, 1-8th part of Epsom salts usually crystallizes out. This is called "*singles.*" By re-dissolving this in *water*, and re-crystallization, "*doubles*," or Epsom salts fit for the market are obtained. A *second crop* of crystals may be procured by adding *sulphuric acid* to the *mother-liquor*, and re-concentrating the solution, but this is seldom had recourse to in England. Bittern yields fully 5 parts of sulphate of magnesia for every 100 parts of common salt that has been previously obtained from it.

b. A *concentrated solution of sulphate of soda* is added to *bittern*, in equivalent proportion to that of the chloride of magnesium in it, and the mixed solution is evaporated at the temperature of 122° Fahr. (Ure); cubical crystals of *common salt* are deposited as the evaporation proceeds, after which, by further concentration, and repose, regular crystals of sulphate of magnesia are obtained.

c. A sufficient quantity of *calcined* and

slaked magnesian lime-stone is boiled in *bittern* to displace the hydrochloric acid from the magnesia, and the liquid is evaporated, &c., as before. This is a very economical process.

Prop. Small acicular crystals, or (by careful crystallization) large four-sided rhombic prisms; colourless; odourless; transparent; slightly efflorescent; extremely bitter and nauseous; when heated it fuses in its water of crystallization, the larger portion of which readily passes off, but one equivalent of water is energetically retained; at a high temperature it runs into a species of white enamel; it dissolves in its own weight of cold water, and in 3-4ths of that quantity of boiling water; it is insoluble in both alcohol and ether. Sp. gr. 1·66.

Pur. Sulphate of magnesia is soluble in an equal weight of water at 60° Fahr., by which it may be distinguished from sulphate of soda, which is much less soluble. Shaken in the cold with water and carbonate of baryta or of lime, an alkaline solution of carbonate of soda is obtained when Glauber salt is present. Digested in alcohol, the filtered liquid does not yield a precipitate with nitrate of silver, nor burn with a yellow flame, and evaporates without residue. "Not deliquescent in the air." (Ph. L.) "Sulphuric acid dropped into the solution should not expel any fumes of hydrochloric acid. 100 gr. dissolved in water, and mixed with a boiling solution of carbonate of soda, yield 34 gr. of carbonate of magnesia when dried." (Ph. L. 1836.) 100 gr. of the pure crystallized sulphate yield 16¼ gr. of calcined magnesia. (Pereira.) "10 gr., dissolved in 1 fl. oz. of water, and treated with a solution of carbonate of ammonia, are not *entirely* precipitated by 280 minims of solution of phosphate of soda." (Ph. E.)

Uses, &c. Sulphate of magnesia is an excellent cooling purgative, and sometimes proves diuretic and diaphoretic. *Dose.* 1 *dr.* to 1 *oz.*, as a purgative, or an antidote in poisoning by lead. Large doses should be avoided. Instances are on record of their having proved fatal. Dr. Christison mentions the case of a boy 10 years old, who swallowed 2 *oz.* of salts, and died within 10 minutes. The best *antidote* is an emetic. A small quantity of Epsom salts, largely diluted with water (as a drachm to ½ pint or ¾ pint), will usually purge as much as the common dose. This increase of power has been shown by Liebig to result rather from the quantity of water than the salt. *Pure* water is greedily taken up by the absorbents; but water holding in solution saline matter is rejected by those vessels, and consequently passes off by the intestines.

Obs. The selection of the process for the preparation of sulphate of magnesia must, necessarily, chiefly depend on the locality, and on the resources of the manufacturer. In all cases, however, the proper quantity of the materials employed to effect decomposition (*hydrochloric acid, sulphuric do., sulphate of soda, &c.*) must be determined by previous trials on the small scale, without which, loss and disappointment is almost sure to be experienced.

Oxalic acid has occasionally been mistaken for Epsom salt, with fatal results. They may be readily distinguished from each other by the following characteristics:—

Epsom Salt.	Oxalic Acid.
Tastes extremely bitter and nauseous.	*Tastes* extremely sour.
Turns milky when dissolved in water and mixed with carbonate of soda or carbonate of potash; and after a time, a white sediment subsides.	*Effervesces* when mixed with carbonate of soda or carbonate of potash, and the liquid in a few seconds becomes transparent.

MAGNESIA (Ferro-sulphate of). Syn. *Magnesiæ Ferro-sulphas*,—Lat. *Prep.* 1. *Epsom salt*, 1¼ *lb.*; *water*, 1 fl. oz.; melt in a porcelain vessel, add of *protosulphate of iron* (cryst., powdered), 1 *oz.*, stir until the whole is liquefied, then remove the vessel from the fire, and allow it to cool very slowly.

2. *Sulphate of iron*, 1 *oz.*; *water*, 1¼ fl. oz.; dissolve, in the cold, and stir the solution with *Epsom salt*, 1 *lb.*; lastly, throw the crystals on a sieve to drain. A chalybeate aperient. *Dose.* 1 to 8 dr.

MAGNESIA (Tartrate of). Syn. *Magnesiæ Tartras, Magnesia Tartarica*,—Lat. *Prep.* By saturating a *solution of tartaric acid* with *carbonate of magnesia*, and gently evaporating to dryness. It is only very slightly soluble in water. *Dose.* "20 to 60 gr., or more;" "in painful chronic maladies of the spleen." (Pereira, ex Radmacher.) The *effervescing tartrate of magnesia* commonly sold under the name of "*citrate*," is noticed at *page* 737.

MAGNESIA AND QUININE (Ferro-sulphate of). Syn. *Magnesiæ et Quinæ Ferro-sulphas*,—Lat. *Prep.* Take of *sulphate of quinine*, 1½ dr.; *rectified spirit*,

1 fl. oz.; *dilute sulphuric acid*, q. s.; dissolve, add of *syrup*, 1 fl. dr., and stir the mixture with *ferro-sulphate of magnesia* (cryst.), 1 *lb.*; lastly, partially dry it on an inverted hair-sieve, and preserve it from the air. As an aperient in debilitated habits. *Dose.* 1 *dr.* to 1 *oz.* The last two preparations are not definite compounds, and are undeserving of the names given to them.

MAGNESIA AND POTASSA (Boro-tartrate of). Syn. *Magnesiæ et Potassæ Boro-tartras*,—Lat. *Prep.* (M. Garod.) *Boro-tartrate of potassa*, 100 parts; *water*, 600 parts; *carbonate of magnesia*, 24 parts; dissolve by heat, filter, and gently evaporate to dryness. It is made into a medicinal lemonade with a little *citric acid* or *lemon juice*, and some *syrup of lemon peel.*

MAGNESIAN APERIENT (Effervescing). *Prep.* 1. *Heavy carbonate of magnesia*, 2 *lb.*; *tartaric acid* and *double refined lump sugar*, of each, 1½ *lb.*; *bicarbonate of soda* (dried without heat), 1 *lb.*; each separately dried and in very fine powder; *essential oils of orange and lemon*, of each, ½ fl. dr.; mix well in a warm dry situation, pass the whole through a sieve, put it into warm dry bottles, and keep them well corked.

2. As the last, but substituting *calcined magnesia*, 1 *lb.*, for the heavy carbonate, and adding *sugar*, ¾ *lb.* The preceding furnish a very pleasant effervescing saline draught.

3. (*Moxon's.*)—*a.* Take of *sulphate of magnesia*, 2 *lb.*; dry it by a *gradually increased* heat, powder, add of *tartaric acid* (also dried and powdered), 1¼ *lb.*; *calcined magnesia*, ½ *lb.*; *finely powdered white sugar*, 3 *lb.*; *bicarbonate of soda* (dried without heat), 1 *lb.*; *essence of lemon*, 1 dr.; mix, and proceed as before.

b. (Durande.) *Carbonate of magnesia*, 1 part; *bicarbonate of soda*, *tartrate of soda and potassa* (sel de Seignette), and *tartaric acid*, of each, 2 parts; mix as before.

c. (Pharm. Journ.) *Sulphate of magnesia* and *bicarbonate of soda*, of each, 1 *lb.*; *tartaric acid*, ½ *lb.*; mix as before. The last two are much less agreeable than the others.

4. (M. Rogé's.) *Carbonate of magnesia*, 2 parts; *calcined magnesia*, 4 parts; *citric acid*, 13 parts: *lump sugar*, 25 parts; *essence of lemon*, q. s. to flavour. Very agreeable. This is known as *Rogé's Purgatif.*

Obs. The above are very useful and popular medicines in indigestion, heartburn, nausea, habitual costiveness, dyspepsia, &c. *Dose.* ½ to 2 dessert-spoonfuls, thrown into a tumbler 3 parts filled with cold water, rapidly stirred and drunk whilst *effervescing*, early in the morning fasting, or between breakfast and dinner.

MAGNESIAN LEMONADE. A solution of *citrate of magnesia*, flavoured with *lemon*, and *sweetened.* The effervescing citrate and tartrate of magnesia are frequently called "*effervescing magnesian lemonade.*" See *Lemonade* (Aperient), and *above.*

MAGNESIUM. Syn. *Magnium*, *Talcium.* The metallic base of magnesia. The existence of this metal was demonstrated by Sir H. Davy, in 1808; but it was first obtained in sufficient quantity to examine its properties, by Bussy, in 1830.

Prep. 5 or 6 pieces of *potassium* or *sodium*, about the size of peas, are introduced into a test tube, and covered with small fragments of *chloride of magnesium*; the latter is then heated to near its point of fusion, when the flame of the lamp is applied to the potassium, so that its vapour may pass through the stratum of heated chloride; when the vivid incandescence that follows is over, and the whole has become cold, the mass is thrown into *water*, and the insoluble metallic portion collected and dried.

Prop., &c. In colour and lustre it resembles silver; it is malleable; fusible at a red heat; unaffected by dry air and by cold water; burns with brilliancy in oxygen gas, yielding *oxide* or *protoxide of magnesium* (*magnesia*); inflames spontaneously in chlorine, yielding *chloride of magnesium*; it dissolves in the acids with the evolution of hydrogen gas, and pure salts of magnesia result.

MAGNESIUM (Bromide of). Syn. *Magnesii Bromidum*,—Lat. *Prep.* By dissolving *calcined magnesia* in *hydrobromic acid*; or by adding *calcined magnesia*, in excess, to a solution of *bromide of iron*, gently heated; the solution is filtered and gently evaporated to dryness. Alterative and resolvent properties have been attributed to it.

MAGNESIUM (Chloride of). Syn. *Muriate of Magnesia*; *Magnesiæ Hydrochloras*, *Magnesii Chloridum*,—Lat. *Prep.* (Liebig.) By dissolving *magnesia* in *hydrochloric acid*, evaporating to dryness, adding an *equal weight* of *hydrochlorate of ammonia*, projecting the mixture into a red hot platinum crucible, and continuing the heat till a state of tranquil fusion is attained. On cooling it forms a transparent, colour-

less, and very deliquescent mass, which is anhydrous, and soluble in alcohol.

Obs. Without the addition of the hydrochlorate of ammonia, it is impossible to expel the last portion of the water, without at the same time driving off the chlorine, in which case nothing but magnesia is left. The fused mass should be poured out on a clean stone, and when solid, broken into pieces, and at once transferred to a warm dry bottle. The P. Cod. orders the *hydrochloric solution* to be evaporated to the sp. gr. 1·384, and to be put, whilst still hot, into a wide-mouthed flask to crystallize. *Dose.* 1 to 4 dr.; as a laxative.

MAGNESIUM (Fluoride of). *Prep.* By direct solution of *magnesia* or its *carbonate* in *hydrofluoric acid.*

MAGNESIUM (Iodide of). Syn. *Magnesii Iodidum,*—Lat. *Prepared* in the same manner as the *bromide,* from *hydriodic acid* and *magnesia.*

MAGNESIUM (Sulphuret of). Syn. *Magnesii Sulphuretum,*—Lat. *Prep. Calcined magnesia,* 5 parts; *sulphur,* 4 parts; fuse together in a covered crucible. *Dose.* 4 to 12 gr.; in chronic exanthemata, hooping-cough, &c.

MAGNET. Syn. *Magnes,*—Lat. Besides its application to the loadstone, this name was formerly given to several compounds used in medicine.—*Arsenical magnet* (*magnes arsenicalis*), a substance once used as a caustic, consisted of *common antimony, sulphur,* and *arsenious acid,* fused together until they formed a sort of glass. *Magnes epilepsiæ* was native cinnabar.

Magnets have been *used* with apparent advantage in toothache, neuralgia, rheumatism, spasmodic asthma, and several other diseases. For the first, a single *bar* or *staff magnet* is commonly applied to the tooth or gum; but in the others a *compound magnet* or *magnetic* battery is employed. *Magnetic rings, bracelets, collars, girdles, &c.,* are made of several artificial magnets, with their opposite poles placed in contact, and inclosed in silk or linen.

MAGNETIC ADEPS. This substance is made by pouring *melted lard,* in a small stream, into *cold water,* placing the thin fragments thus obtained in a sieve covered with paper, or other suitable apparatus, and exposing it to the air for 3 or 4 months, or longer. *Used* to make mercurial ointment. It speedily "*kills*" 30 or 40 times its weight of quicksilver.

MAHOGANY. This is the wood of *Swietenia mahogoni* (Linn.), a native of the hotter parts of the new world. The *extract* is astringent, and has been used in tanning, and as a substitute for cinchona bark. The *wood* is chiefly employed for furniture and ornamental purposes, and, occasionally, in shipbuilding.

Imitations of *mahogany* are made by staining the surface of the inferior woods by one or other of the following methods:—

1. Warm the *wood* by the fire, then wash it over with *aquafortis,* let it stand 24 hours to dry, and polish it with *linseed oil* reddened *by digesting alkanet root* in it; or instead of the latter, give the wood a *coat of varnish,* or *French polish* which has been tinged of a mahogany colour with a little *aloes* and *annotta.*

2. *Socotrine aloes,* 1 *oz.: dragon's blood,* ½ *oz.; rectified spirit,* 1 pint; dissolve, and apply 2 or 3 coats to the *surface of the wood,* previously well smoothed and polished; lastly, finish it off with *wax* or *oil tinged with alkanet root.*

3. *Logwood,* 2 *oz.; madder,* 8 *oz.; fustic,* 1 *oz.; water,* 1 gall.; boil 2 hours, and apply it several times to the wood boiling hot; when dry, *slightly* brush it over with a *solution of pearlash,* 1 *oz.,* in *water,* 1 quart; dry, and polish as before.

4. As the last, but using a *decoction* of *logwood,* 1 *lb.,* in *water,* 5 pints. The tint may be BRIGHTENED by adding a little vinegar or *oxalic acid,* and DARKENED by a *few grains* of *copperas.*

Stains and *spots* may be taken out of mahogany furniture with a little *aquafortis* or *oxalic acid* and *water,* by rubbing the part with the liquid, by means of a cork, till the colour is restored; observing afterwards to well wash the wood with *water,* and to dry it and polish it as before.

MAIZE. Syn. *Indian Corn, Turkey do.; Zea, Triticum Turcicum,*—Lat. The seeds of *zea mays* (Linn.) Like the other corn plants, it is a species of grass (*gramineæ*), the albumen of which is sufficiently large and farinaceous to be ground into flour.

Maize is extremely nutritious, and although it is poorer in proteine matter than wheat, it is, of all the cereal grains, the richest in fatty oil, of which it contains about 9%. (MM. Dumas and Payen.) It is remarkable for its fattening quality on animals, but is apt to excite slight diarrhœa in those unaccustomed to its use. Its *meal* is the "*polenta*" of the shops. The *fine flour* is used by the biscuit-bakers. The *young ears* are also roasted and boiled for food.

MALAGMA. A poultice or emollient

application; recently applied by certain quacks to a notorious advertised plaster.

MALAMIC ACID. See *Aspartic Acid.*

MALAMIDE. Same as *Asparagin.*

MALEIC ACID. Syn. *Malæic Acid.* A peculiar acid obtained by distilling malic acid by a quick fire. A solution of *maleic acid* passes over into the receiver, from which crystals may be obtained by evaporation. It is soluble in water, alcohol, and ether, and possesses a sour taste. Heat resolves it into water and *anhydrous maleic acid.* If kept long fused at a low temperature, it passes into a crystalline mass of *fumaric* acid. It forms salts with the bases termed *maleates,* which are mostly insoluble.

MALIC ACID. Syn. *Acidum Malicum,*—Lat. This acid exists in the juice of many fruits and plants, either alone, or associated with other acids, or with potassa or lime.

Prep. 1. (Everitt.) The *stalks* of *common garden rhubarb* are peeled, and ground or grated to a pulp, which is subjected to pressure; the juice is heated to the boiling point, neutralized with *carbonate of potassa,* mixed with *acetate of lime,* and the insoluble oxalate of lime which falls is removed by filtration; to the clear and nearly colourless liquid, *solution of acetate of lead* is next added as long as a precipitate (*malate of lead*) continues to form; this is collected on a filter, washed, diffused through water, and decomposed by *sulphuric acid,* avoiding excess, the last portion of lead being thrown down by a *stream* of *sulphuretted hydrogen;* the filtered liquid is, lastly, carefully evaporated to the consistence of syrup, and left in a dry atmosphere until it becomes converted into a solid and somewhat crystalline mass of malic acid. If *perfectly pure malic acid* is required, the *malate of lead* must be crystallized before decomposing it with sulphuretted hydrogen. *Prod.* 20,000 gr. of the *peeled stalks* yield 12,500 gr. of *juice,* of which one imperial gallon contains 11,139¾ gr. of dry malic acid.

2. (Liebig.) The *impure solution of the acid,* as it exists in vegetable juices after clarification, is converted into *acid malate of ammonia,* by neutralizing one-half of it, and mixing it with the other half unneutralized. This salt forms larger crystals than the neutral malate, and is easily decoloured by any of the ordinary processes.

3. (Winckler.) The *juice of the mountain ash* (sorbus aucuparia,—*Linn.*), immediately after the fruit has turned red, but still unripe, is heated to the boiling point, skimmed, filtered, nearly neutralized with *ammonia,* and precipitated with a solution of 1 *part* of *acetate of lead* to every 72 *parts* of *juice;* the filtered liquid is again precipitated with *nitrate of lead;* the whole is next allowed to stand until it forms a mass of crystals, which are washed, dried, powdered, suspended in water, and decomposed by a *current of sulphuretted hydrogen;* the liquid is again filtered, neutralized with *ammonia,* decoloured with *animal charcoal,* a second time precipitated with *nitrate of lead,* and the resulting *malate of lead* decomposed by *sulphuretted hydrogen,* as before; the solution is, lastly, filtered, evaporated, and crystallized. *Prod.* Fully $\frac{2}{3}$ of the weight of juice employed, in *crystallized malic acid.*

Prop., &c. Malic acid is slightly deliquescent, very soluble in water, soluble in alcohol, and has a pleasant acidulous taste. The aqueous infusion soon gets mouldy by keeping. When kept fused for some time at a low heat, it is converted into *paramaleic,* or *fumaric acid;* and when quickly distilled, it yields *maleic acid,* while *fumaric acid* is left in the retort. With the bases malic acid forms salts called *malates.* Of these the *acid malate of ammonia* is in large beautiful crystals; *malate of lead* is insoluble in cold water, but dissolves in warm dilute acid, from which it separates on cooling in brilliant silvery crystals; *acid malate of lime* also forms very beautiful crystals, freely soluble in water; *neutral malate of lime* is only sparingly soluble in water; the first is obtained by dissolving the latter in hot dilute nitric acid, and allowing the solution to cool very slowly.

Malic acid may be obtained from the juice of apples and several other sorts of fruit, by processes similar to the above.

MALLEABILITY. The peculiar property of metals which renders them capable of extension under the hammer. See *Metals.*

MALMSEY. See *Wines.*

MALT. Syn. *Bina, Byne, Brasium, Maltum,*—Lat. Corn which has become sweet, from the conversion of a portion of its starch into sugar, in consequence of incipient germination. Barley is the grain usually employed for this purpose.

Proc. The *grain* is steeped in *water* contained in large wooden or stone cisterns, for a period of from 40 to 60 hours, depending on the temperature of the weather, or until it becomes sufficiently swollen and soft enough to be easily pierced with a needle, or crushed between the thumb and finger without yielding a milky juice. The

water is then drawn off, and the *swollen barley* is laid upon the stone floor of a suitable apartment called the *couch*, to the depth of 12 to 16 inches, where it is allowed to remain till the *acrospire* or rudiments of the *plumula* shoot forth. During this period the grain is at first turned every 24 hours, and afterwards 2 or 3 times a day, and at each turning the layer is spread out more and more, until it is reduced to the depth of about 3 or 4 inches. The sprouted grain is next removed to the malt kiln, and dried in a thin layer, until quite hard. By the process of drying the vitality of the seed is destroyed, and it may then be preserved without suffering further change. *Product.* Good barley yields about 80% by weight, and 109% by measure, of dried and sifted malt. Of the loss by weight, 12% must be referred to water existing in the raw grain.

Var. Independently of variations of quality, or of the grain from which it is formed, malt is distinguished into varieties depending on the heat of the kiln employed for its desiccation. When dried at a temperature ranging between 90 and 100° Fahr., it constitutes "*pale malt;*" when all the moisture has exhaled, and the heat is raised to from 120 to 125°, "*yellow,*" or "*pale amber malt,*" is formed; when the heat ranges between 135 and 140°, the product receives the name of "*amber malt;*" at 145 to 165°, "*amber-brown,*" or "*pale brown malt,*" is obtained. When the grain is dried at a still higher temperature, it forms "*brown malt;*" and when the heat is sufficient to blacken or discolour it, it is known as "*patent malt.*" In the preparation of the last variety the heat is sometimes pushed as high as even 430 to 435° Fahr.

Qual. Good malt has an agreeable smell, and a sweet taste; it is round and full in the grain, and is moderately brittle between the teeth. The admixture of *unmalted* with *malted* grain may be discovered by throwing a little into water,—*malt* floats on water, but *raw barley* sinks in it. The only certain method, however, of determining the value of malt, is to ascertain the amount of *soluble matter* which it contains, by direct experiment. This varies from 62 to 70%, and for good malt is never *less* than 66 to 67%. If we assume the quarter of malt at 324 *lb.*, and the average quantity of soluble matter at 66%, then the total weight of soluble matter will be fully 213¾ *lb.* per quarter; but as this "in taking on the form of gum and sugar" during the process of mashing, "chemically combines with the elements of water, so the extract, if evaporated to dryness, would reach very nearly 231 *lb.;* and this reduced to the basis of a barrel of 36 gallons, becomes, in the language of the brewer, 87 *lb.* per barrel, which, however, merely means, that the wort from a quarter of malt, if evaporated down to the bulk of a barrel or 36 gallons, would weigh 87 *lb.* more than a barrel of water." (Ure.)

Assay. 1. A small quantity of the sample being ground in a coffee or pepper mill, 100 gr. are accurately weighed, and dried by exposure for about 1 hour at the temperature of boiling water. The *loss in weight*, in grains, indicates the quantity of MOISTURE *per cent.* This, in good malt, should not exceed 6½ gr.

2. A *second* 100 gr. is taken and stirred up with about ½ pint of *cold* water; the mixture is then exposed to the heat of boiling water for about 40 minutes; after which it is thrown on a *weighed* filter, and the undissolved portion washed with a little hot water; the undissolved portion with the filter is then dried at 212° Fahr., and weighed. The *loss in weight*, less the per centage of moisture last found, taken in grains, gives the *per centage* of SOLUBLE MATTER. This should not be less than 66 gr. The same result will be arrived at by evaporating the filtered liquid and "washings" to dryness, and weighing the residuum.

3. A *third* 100 gr. is taken and mashed with about ½ pint of water at 160° Fahr., for 2 or 3 hours; the liquid is then drained off, the residue gently squeezed, and the strained liquid, evaporated to dryness, as before, and weighed. This gives the *per centage* of SACCHARINE, and should not be less than about 71 gr., taking the above average of malt as the standard of calculation.

Uses, &c. Malt is chiefly employed in the arts of brewing and distillation. Both *brown* and *patent malt* are merely used to colour the worts produced from *pale malt.* 1 *lb.* of *patent malt*, mashed with 79 *lb.* of *pale malt*, imparts to the liquor the colour and flavour of *porter.* The paler varieties of malt contain the largest quantity of saccharine matter. After the malt has been kiln-dried, the acrospire and roots may be removed by means of a sieve. Before malt is mashed for beer, it is ground in a mill. It has also been proposed to employ malt, instead of raw-grain, far fattening domestic animals, and as food for their young and those in a sickly state. Independently of dextrine and sugar, good malt contains

about $\frac{1}{300}$th part of diastase, "which seems closely to resemble," in its catalytic agency, "the animal principle *pepsine*, to the influence of which the action of the gastric juice is now almost universally assigned by chemists." According to Dr. Ure, the failures of experiments in this direction have arisen from the ignorance of the experimentalists of the "most important elements involved in the investigation;" viz., that "diastase cannot exert its peculiar power, except under the influence of water at a somewhat high temperature" (165° to 170° Fahr.) Without availing ourselves of these facts, malt is, of course, less economical as food than raw barley; since a small portion of its carbon is lost in the process of germination. Infusion of malt (*sweet wort*, *malt tea*) is laxative, and has been recommended as an antiscorbutic and tonic. It has been given with great advantage in scurvy; but for this purpose good well-hopped mild beer is equally serviceable and more agreeable. See *Brewing*, *Distillation*, *Fermentation*, *&c.*

MALT LIQUORS. The *qualities* of *ale*, *beer*, and *porter*, as *beverages*, the *detection* of their *adulteration*, and the *methods* of *preparing them*, are described under their respective names and "*brewing;*" the present article will, therefore, be confined to a short notice of the *cellar management*, and the *diseases* of *malt liquors* generally.

Age. The appearance and flavour to which this term is applied, can, of course, be only given to the liquor by properly "storing" it for a sufficient time. Fraudulent brewers and publicans, however, frequently add a little *oil of vitriol* (diluted with water) to *new beer*, by which it assumes the character of an inferior liquor of the class 1 or 2 years old. *Copperas*, *alum*, *sliced lemons*, *Seville oranges*, and *cucumbers*, are also frequently employed by brewers for the same purpose.

Bottling. Clean, sweet, and dry bottles, and sound and good corks should be had in readiness. The liquor to be bottled should be perfectly clear; and if it be not so, it must be submitted to the operation of "*fining.*" When quite fine, and in good condition, the bung of the cask should be left out all night, and the next day the liquor should be put into bottles, which, after remaining 12 or 24 hours, covered with sheets of paper to keep out flies and dust, must be securely corked down. *Porter* is generally wired over. The wire for this purpose should be "annealed" and *not* resilient. If the liquor is intended for exportation to a hot climate, the bottles should remain filled for 2 or 3 days, or more, before corking them. The *stock* of *bottled liquor* should be stored in a cool situation; and a *small quantity* to meet present *demands* only, should be set on their sides in a warmer place to ripen. *October beer* should not be bottled before Midsummer, nor *March beer* till Christmas.

Cloudiness. Add a handful of *hops* boiled in a gallon of the *beer*, and in a fortnight fine it down.

Fining. See *Clarification*, and *Brewing* (*p.* 169).

Flatness. When the liquor is new, or has still much undecomposed sugar left in it, a sufficient remedy is to remove it into a warmer situation for a few days. When this is not the case, 2 or 3 pounds of *moist sugar* (foots), may be "rummaged" into each hogshead. In this way a second fermentation is set up, and in a few days the liquor becomes brisk, and carries a head. This is the plan commonly adopted by publicans. On the *small scale*, the addition of a few grains of *carbonate of soda* or of *prepared chalk*, to each glass, is commonly made for the same purpose; but in this case, the liquor must be drunk within a few minutes, else it becomes again flat and insipid. This may be adopted for home-brewed beer which has become sour and vapid.

Foxing or *bucking.* The spontaneous souring of worts or beer during their fermentation or ripening, to which this name is applied, may generally be remedied by adding to the liquor some *fresh hops* (scalded), along with some *black mustard seed* (bruised). Some persons use a little *made mustard*, or a *solution of alum* or of *catechu*, or a *little diluted sulphuric acid;* and in a week or 10 days afterwards further add some *bean-flour*, *treacle*, or *moist sugar.*

Frosted beer is recovered by change of situation; by the addition of some *hops boiled in a little sweet wort;* or, by adding a little *moist sugar* or *treacle* to induce a fresh fermentation.

Heading. This is added to thin and vapid beer to make it bear a frothy head. The most innocent, pleasant, and effective addition of this sort, is a mixture of *pure ammonia-citrate of iron* and *salt of tartar*, about equal parts, in the proportion of only a few grains to a quart. The composition commonly used by the publicans for this purpose is noticed at *p.* 561.

Improving. This is the trade synonym of "*adulteration*" and "*doctoring.*" Never-

theless there are cases in which "improvement" may be made without affecting the wholesome character of the liquor. Of this kind is the addition of hops, spices, &c., during the maturation of beer that exhibits a tendency to deteriorate. For this purpose some persons cut a *half-quartern loaf* into slices, and after toasting them very high, place them in a coarse linen bag along with ½ *lb.* of *hops*, and 2 *oz.* each of *bruised ginger*, *cloves*, and *mustard seed*, and suspend the bag by means of a string a few inches below the surface of the beer (a hogshead), which is then bunged close. The addition of a *little ground capsicum* in the same way is also a real improvement to beer, when judiciously made.

Mustiness. To each hogshead, racked into clean casks, add 1 *lb.* of *new hops* boiled in a gallon of the liquor, along with 7 *lb.* of *newly-burnt charcoal* (coarsely bruised and the fine dust sifted off), and a 4-lb. *loaf of bread* cut into thin slices and toasted rather black; "rouse up" well every day for a week, then stir in of *moist sugar*, 3 or 4 *lb.*, and bung down for a fortnight.

Recovering. This is said of unsaleable beer when rendered saleable, by giving it "*head*" or removing its "*tartness.*"

Ripening. This technicality in its application to the regular maturation of beer is noticed under "*storage.*" It is also used to express that condition by which liquors already mature, are rendered brisk, sparkling, or fit and agreeable for immediate use. In the language of the cellar, malt liquors are said to be "*up*," when they are well charged with gaseous matter and bear a frothy head. These qualities depend on the undecomposed sugar undergoing fermentation, which when active, can only be of comparatively short duration, and should, therefore, be repressed rather than excited in beers not required for immediate consumption. When we desire to give "*briskness*" to these liquors, whether in cask or bottle, it is only necessary to expose them for a few days to a slight elevation of temperature, by removing them, for instance, to a warmer apartment. This is the plan successfully adopted by "bottlers." The addition of a small lump of *white sugar* to *each bottle of ale* or *beer*, or a tea-spoonful of *moist sugar* to *each bottle* of *porter*, just before corking it, will render it fit for drinking in a few days in ordinary weather, and in 2 or 3 days in the heat of summer. A *raisin* or a *lump of sugar candy* is often added to each bottle with a like intention. The Parisians bottle their beer one day, and sell it the next. For this purpose, in addition to the sugar as above, they add 2 or 3 drops of *yeast.* Such bottled liquor must, however, be drunk *within* a week, or else stored in a very cold place; as it will otherwise burst the bottles, or blow out the corks. (See *p.* 169.)

Ropiness. A little *infusion of catechu* or of *oak bark*, and some *fresh hops*, may be added to the beer, which in a fortnight should be rummaged well, and the next day "fined" down.

Sourness. Powdered chalk, *carbonate of soda*, *salt of tartar*, or *pearlash*, is commonly added by the publicans to the beer, until the acidity is nearly removed, when 4 or 5 *lb.* of *moist sugar* or *foots* per hogshead are "rummaged" in, together with sufficient *water* to disburse double the amount of the outlay and trouble. Such beer must be soon put on draught, as it is very apt to get flat by keeping. *Oyster shells* and *egg shells* are also frequently used by brewers for the same purpose. To remove the acidity of beer, on the *small scale*, a few grains of *carbonate of soda* per glass may be added just before drinking it.

Storing. The situation of the *beer-cellar* should be such as to maintain its contents at a *permanently uniform temperature* ranging between 44° and 50° Fahr., a condition which can only be ensured by choosing for its locality an underground apartment, or one in the centre of the basement portion of a large building. See *Brewing*, *Fermentation*, and *Wines.*

Vamping. Half fill casks with the old liquor, fill them up with some newly brewed, and bung close for 3 weeks or a month.

MANDELIC ACID. Formobenzoilic or formobenzoic acid. (See *p.* 486.)

MANGANESE. Syn. *Manganesium*, *Manganium*, *Manganum*,—Lat. A hard, brittle, grayish-white metal, discovered by Gahn in the black oxide of manganese of commerce.

Prep. Reduce *oxide of manganese* (or preferably the *calcined carbonate*) to fine powder, make it into a paste with *oil*, adding about 1-10th of its weight of *calcined borax*, place the mixture in a Hessian crucible lined with *charcoal*, lute on the cover, and expose it to the strongest heat of a smith's forge for 2 hours; when cold, break the crucible and preserve the metallic button in *naphtha.*

Prop., &c. Very oxidable; fuses with great difficulty; unaffected by cold water; dilute sulphuric acid dissolves it with great energy, and the evolution of hydrogen.

Sp. gr. 8·013. In an oxidized state manganese is abundant in the mineral kingdom, and traces of it have been found in the ashes of plants, and in mineral waters.

The salts of manganese may be easily prepared in a state of purity by dissolving the precipitated carbonate in the acids. Most of them are soluble and several are crystallizable.

Tests. The salts of protoxide of manganese are distinguished as follows:—1. Caustic potassa, soda, and ammonia give white precipitates, insoluble in excess, and quickly becoming brown, and finally, nearly black, on exposure to the air. The presence of sal ammoniac interferes with the operation of these tests.—2. Ferrocyanide of potassium gives a white precipitate.—3. Sulphuretted hydrogen fails to precipitate acid solutions, and precipitates neutral solutions only imperfectly; but in alkaline solutions it gives a bright flesh-coloured insoluble precipitate, which becomes dark brown on exposure to the air.—4. Hydrosulphuret of ammonia, in neutral solutions, also yields a similar precipitate, which is very characteristic.—5. A compound of manganese fused with borax in the outer flame of the blowpipe, gives a bead, which appears of a violet-red colour whilst hot, and upon cooling acquires an amethystine tint; this colour is lost by fusion in the inner flame.—6. Heated upon platinum foil with a little carbonate of soda, in the outer flame, it yields a green mass whilst hot, which becomes bluish green when cold.

MANGANESE (Acetate of). Syn. *Acetate of Protoxide of Manganese; Manganii Acetas, Manganum Aceticum*,—Lat. *Prep.* 1. By neutralizing *concentrated acetic acid* with *carbonate of manganese*, and evaporating the solution so that crystals may form. Pure.

2. By mixing a *solution of sulphate of manganese* with a *solution of acetate of lime.*

Prop., &c. The crystals, when pure, are of a pale-red colour; permanent in the air; soluble in alcohol, and in 3½ parts of water; and possess an astringent and metallic taste. *Dose.* 5 to 10 gr., as an alterative, hæmatinic, &c.

MANGANESE (Carbonate of). Syn. *Carbonate of Protoxide of Manganese; Manganesii Carbonas*,—Lat. *Prep.* (Liebig.) Reduce the *black oxide of manganese* of commerce, to fine powder, and after washing it in *water acidulated with hydrochloric acid*, dissolve it in *strong hydrochloric acid*, and evaporate the resulting solution to dryness; dissolve the residuum in *water*, and add to the solution sufficient *carbonate of soda* to precipitate all the iron present; digest the mixed precipitate in the remainder of the liquid, filter, add *hydrosulphuret of ammonia* until it begins to produce a flesh-coloured precipitate, then filter, and add *solution* of *carbonate of soda* as long as a precipitate falls; lastly, well wash the newly formed *carbonate* in water, and dry it by a gentle heat.

2. By directly precipitating a *solution of the chloride* with *carbonate of soda*, and washing and drying the powder, as before.

Prop., &c. A pale buff or cream-coloured powder; insoluble in water; freely soluble in acids; exposed to a strong heat it loses its carbonic acid, absorbs oxygen, and is converted into the *red oxide.* It is chiefly employed in the preparation of the other salts of manganese. (See *below.*)

MANGANESE (Chloride of). Syn. *Protochloride of Manganese, Hydrochlorate of do., Muriate of do.; Manganesii Chloridum, M. Hydrochloras, Maganum Chloratum*,—Lat. *Prep.* 1. By saturating *hydrochloric acid* with *carbonate of manganese;* the solution is gently concentrated by evaporation, when crystals may be obtained, or it is at once evaporated to dryness; in either case the product must be placed in warm, dry, stoppered bottles, and preserved from the air.

2. From the *dark brown residual liquid* of the process of obtaining *chlorine* from binoxide of manganese and hydrochloric acid; this liquid is evaporated to dryness and then slowly heated to dull redness in an earthen vessel, with constant stirring, and kept at that temperature for a short time; the grayish-looking powder thus obtained is treated with *water*, and the solution separated from sesquioxide of iron and other insoluble matter by filtration; if any iron still remains, a little *carbonate of manganese* is added, and the whole boiled for a few minutes; the filtered solution is then treated as before. This is the least expensive and convenient source of this salt, as also of the *carbonate.*

Prop., &c. Rose-coloured tabular crystals; inodorous; very soluble both in water and alcohol; very deliquescent; when gradually heated to fusion, the whole of the water is expelled and *anhydrous chloride of manganese* remains; at a red heat it slowly suffers decomposition. Astringent, tonic, hæmatinic, and alterative. *Dose.* 3 to 10 gr.; in scorbutic, syphilitic, and certain chronic cutaneous affections; anæmia, chlorosis, &c.

Obs. The red solution formed when

sesquioxide of manganese is digested in *dilute hydrochloric acid*, in the cold, is regarded as SESQUICHLORIDE OF MANGANESE. It is decomposed by heat. PERCHLORIDE is obtained by mixing *permanganic acid* and *hydrochloric acid*, and conducting the evolved gas through a tube cooled to —4° Fahr. It is gaseous at a higher temperature, and is decomposed by moisture.

MANGANESE (Fluoride of). This has been formed by Dumas and Wöhler, but possesses no practical interest.

MANGANESE (Iodide of). Syn. *Manganesii Iodidum*,—Lat. *Prep.* By dissolving the *carbonate* in *hydriodic acid*, and evaporating the filtered liquid in vacuo or out of contact with air. *Dose.* 1 to 3 gr.; in anæmia, chlorosis, &c., occurring in scrofulous subjects.

MANGANESE (Oxides of). Manganese forms seven distinct compounds with oxygen,—5 *oxides* and 2 *acids*. The *protoxide*, or *green oxide of manganese* (Mn + O), is formed when either of the other oxides of manganese is mixed with charcoal, and exposed in a covered crucible to a white heat for some time. It rapidly oxidizes by exposure to the air, possesses strong basic properties, and readily dissolves in the liquid acids, forming the ordinary salts of manganese, many of which have a beautiful pink colour. On the addition of alkalies to these compounds *hydrated protoxide of manganese* (*manganesii oxydum hydratum*) falls as a white powder, which speedily absorbs oxygen and becomes brown unless *entirely* excluded from the air.—*Sesquioxide of manganese* ($Mn_2 + O_3$) is brown or brownish-black, and is found, ready formed, in the mineral kingdom. It is the residuum left in the retort when the black oxide is heated to moderate redness in the process of making oxygen gas.—*Binoxide of manganese* (Mn + O_2) is the well-known *black oxide* or *peroxide* of commerce, and is also found in the mineral kingdom. (See *below*.)—The *red*, or *fourth oxide of manganese* (*oxidum manganoso-manganicum*, $Mn_3 + O_4$), is another native compound. It may be prepared artificially by exposing the binoxide or sesquioxide to a white heat. It has a reddish-brown colour, and is incapable of forming salts. — *Varvacite* ($Mn_4 + O_7$) is another oxide which occurs as a mineral production. The remaining two oxygen compounds of manganese are *manganeseous acid* and *manganesic acid*.

MANGANESE (Binoxide of). Syn. *Black Oxide of Manganese, Peroxide of do.; Manganesii Binoxydum*,—Ph. L. *M. Oxydum*,—Ph. E. *Manganese, Tritoxide of do., Black Magnesia, Magnesia Nigra, M. Vitriariorum*,—Obs. This is the only oxide of manganese that is directly employed in the arts. It is a very plentiful mineral production, and is found in great abundance in some parts of the West of England. The manganese of the shops is prepared by washing, to remove the earthy matter, and grinding in mills. The blackest samples are esteemed the best. It is chiefly used to supply oxygen gas, and in the manufacture of glass and chlorine; in dyeing, and to form the salts of manganese. It has been occasionally employed in medicine, chiefly externally, in itch and porrigo, made into an ointment with lard. It has recently been highly recommended by Dr. Erigeler in scrofula. Others have employed it as an alterative and tonic with variable success. When slowly introduced into the system during a lengthened period, it is said to produce paralysis of the motor nerves. (Dr. Coupar.) *Dose.* 3 to 12 gr., or more, thrice daily, made into pills.

Pur. Native binoxide of manganese (*pyrolusite*) is usually contaminated with variable proportions of argillaceous matter, carbonate of lime, oxide of iron, silica, and sulphate of baryta, all of which lower its value as a source of oxygen, and for the preparation of chlorine. The richness of this ore, can, therefore, be only determined by an assay for its principal ingredient. (See *below*.) "It is soluble in hydrochloric acid, evolving chlorine." (Ph. L.) "Muriatic acid by the aid of heat dissolves it almost entirely, disengaging chlorine; heat disengages oxygen." (Ph. E.)

Assay. There are several methods adopted for this purpose, among which the following recommend themselves as being the most accurate and convenient:—

1. A *portion of the mineral* being reduced to very fine powder, 50 gr. of it are put into the little apparatus employed for the *analysis of carbonates* described at *page* 203, together with about ½ fl. oz. of *cold water*, and 100 gr. of *strong hydrochloric acid*, the latter contained in the little tube (*b*); 50 gr. of *crystallized oxalic acid* are then added, the cork carrying the chloride of calcium tube fitted in, and the whole quickly and accurately weighed or counterpoised; the apparatus is next inclined so that the acid contained in the small tube may be mixed with the other contents of the flask, and the reaction of the ingredients is promoted by the application of a gentle heat; the disengaged chlorine resulting from the mutual decomposition of

the hydrochloric acid and the binoxide of manganese, converts the oxalic acid into carbonic acid gas, which is dried in its passage through the chloride of calcium tube before it escapes into the air. As soon as the reaction is complete, and the residual gas has been driven off by a *momentary* ebullition, the apparatus is allowed to cool, when it is again *carefully* and *accurately* weighed. The *loss of weight* in grains, if doubled, at once indicates the *per centage* richness of the mineral examined in PURE BINOXIDE OF MANGANESE; or more correctly, every grain of carbonic acid gas evolved represents 1·982 gr. of the *binoxide*. (See *below*.)

2. (Fresenius & Will.) The apparatus employed is the *alkalimeter* figured at *page* 19, and described at *page* 42. The operation is similar to that adopted for the assay of alkalies by the same parties, and is a modification of the oxalic acid and sulphuric acid test for manganese, originally devised by M. Berthier. The standard weight of binoxide of manganese recommended to be taken by Messrs. Fresenius & Will is 2·98 grammes, along with 6·5 to 7 grammes of neutral oxalate of potassa. The process, with the quantities altered to adapt it for employment in the laboratories of these countries, is as follows:—*Binoxide of manganese* (in very fine powder), 50 gr.; *neutral oxalate of potassa* (in powder), 120 gr.; these are put into the flask *A* (see *Engr., p.* 19) along with sufficient *water* to about 1-4th fill it; the flasks *A* and *B* (the latter containing the *sulphuric acid*) are then corked *air-tight*, and thus connected into one apparatus, the whole is *accurately weighed*. The opening of the tube *b*, being then closed by a small lump of *wax*, a little *sulphuric acid* is sucked over from the flask *B* into the flask *A*; the disengagement of oxygen from the manganese immediately commences, and this reacting upon the *oxalic acid* present, converts it into *carbonic acid gas*, which passing through the concentrated sulphuric acid in the flask *B*, which robs it of moisture, finally escapes from the apparatus through the tube *d*. As soon as the disengagement of carbonic acid ceases, the operator sucks over a fresh portion of *sulphuric acid*, and this is repeated at short intervals, until bubbles of gas are no longer disengaged. The little wax stopper is now removed, and suction is applied at *h* until all the carbonic acid in the apparatus is replaced by common air. When the whole has become cold, it is again *weighed*. The *loss of weight*, doubled, indicates the amount of pure *binoxide of manganese* in the sample as before. (See *below*.)

3. (Prof. Otto.) 50 gr. of the *sample*, reduced to very fine powder, are mixed in a glass flask, with *hydrochloric acid*, 1½ fl. oz., diluted with ½ oz. of *cold water*, and portions of *pure protosulphate of iron* from a weighed sample, *immediately* added; at *first* in excess, and *afterwards*, in smaller doses, until the liquid ceases to give a blue precipitate with red prussiate of potash, or to evolve the odour of chlorine; heat being employed towards the end of the process. The *quantity of protosulphate* consumed is now ascertained by again weighing the sample. If the binoxide examined was pure, the loss of weight will be 317 gr.; but if otherwise, the per centage of pure oxide may be obtained by the rule of three. Thus; suppose only 298 gr. of the *sulphate* were consumed, then

317 : 100 : : 298 : 94,

and the richness of the sample would be 94%. The per centage value of the oxide for evolving chlorine may be obtained by multiplying the weight of the consumed sulphate of iron by 0·2588, which, in the above case, would give 76% of chlorine. For this purpose as well as for *chlorimetry* the sulphate of iron is best prepared by precipitating it from its *aqueous solution* with *alcohol*, and drying it out of contact with air until it loses its alcoholic odour.

Obs. Before applying the above processes, it is absolutely necessary that we ascertain whether the binoxide examined contains any *carbonates*, as the presence of these would vitiate the results. This is readily determined by treating it with a little *dilute nitric acid*;—if effervescence ensues one or more carbonates are present, and the sample, after being weighed, must be digested for *some time* in *dilute nitric acid* in excess, and then carefully collected on a filter, washed, and dried. It may then be assayed as before. The *loss of weight* indicates the *quantity* of *carbonates* present, with sufficient accuracy for technical purposes. The determination of this point is the more important, as these contaminations not merely lessen the richness of the mineral in pure binoxide of manganese, but also cause a considerable waste of acid when it is employed in the manufacture of chlorine.

MANGANESE (Phosphate of). Syn. *Phosphate of Protoxide of Manganese; Manganesii Phosphas*,—Lat. *Prep.* By precipitating a *solution of sulphate of manganese* with a *solution of phosphate of soda*. It must be preserved from the air. *Dose.* 3 to 12 gr.; in anæmia, rickets, &c.

MANGANESE (Sulphate of). Syn. *Sulphate of Protoxide of Manganese; Manganesii Sulphas, Manganum Sulphuricum,* —Lat. *Prep.* 1. By dissolving *carbonate of manganese* in *dilute sulphuric acid,* and evaporating the filtered solution so that crystals may form, or at once gently evaporating it to dryness. Pure.

2. (*Commercial.*) By igniting *binoxide of manganese* (pyrolusite) mixed with about 1-10th of its weight of *powdered coal* in an iron crucible or gas-retort, and digesting the residuum of the calcination in *sulphuric acid,* with the addition after a time of a little *hydrochloric acid;* the solution of *sulphate of manganese* thus obtained, after defecation, is evaporated to dryness, and heated to redness as before; the mass, after ignition, is crushed small, and treated with *water;* the solution is nearly pure, the whole of the iron having been reduced into the state of insoluble peroxide. *Used* by the calico-printers. Cloth steeped in the solution and afterwards passed through a solution of chloride of lime is dyed of a permanent brown.

Prop., &c. Pale rose-coloured crystals, furnishing a solution of a rich amethystine colour. With sulphate of potassa it forms a double salt (*manganese alum*). *Dose.* As an alterative and tonic, 5 to 10 gr.; as a cholagogue cathartic, 1 to 2 dr., dissolved in water, either alone or combined with infusion of senna. According to Mr. Ure, its action is prompt and soon over; 1 dr. of it occasions, after the lapse of an hour or so, one or more liquid bilious stools. In *large doses* it occasions vomiting, and in *excessive doses* it destroys life by its caustic action on the stomach. (Dr. G. C. Mitscherlich.) It has been administered with manifest advantage in torpor of the liver, gout, jaundice, syphilis, and certain skin diseases; and, combined with iron, in anæmia, chlorosis, rickets, &c.

MANGANESE (Sulphuret of). Syn. *Manganesii Sulphuretum,*—Lat. This is a natural mineral production; but may also be procured by igniting a mixture of 1 part of *sulphate of manganese* and 1 part of *charcoal.*

MANGANESE (Tartrate of). Syn. *Manganesii Tartras,*—Lat. *Prep.* By saturating a *solution of tartaric* with *moist carbonate of manganese.* Alterative and tonic. *Dose.* 4 to 12 gr.

MANGANESEOUS ACID. Syn. *Manganic Acid.* This acid ($Mn + O_3$) is formed whenever an *alkali,* or an *alkaline salt* capable of suffering decomposition by heat, is heated to redness along with an *oxide of manganese.* The addition of *nitre* or *chlorate of potassa* facilitates this change. The deep green saline mass thus obtained is a salt of this acid, and its solution in water, when concentrated *in vacuo,* yields small green crystals. When the crude salt is put into a large quantity of water, *hydrated binoxide of manganese* subsides, and a deep purple solution *of manganesic acid* (MINERAL CHAMELEON) is formed. (See *below.*)

MANGANESIC ACID. Syn. *Permanganic Acid.* This compound ($Mn_2 + O_7$) is best obtained as follows:—Mix *binoxide of manganese,* 8 parts, with *chlorate of potassa,* 7 parts (both in fine powder); add of *hydrate of potassa,* 10 parts (dissolved in a little water); evaporate to dryness, and expose the residuum (reduced to powder), to a *low* red heat, in a platinum crucible; dissolve the calcined mass (*manganate* or *manganeseate of potassa*) in a large quantity of water; decant the clear solution, evaporate until crystals begin to form on the surface, and set the whole aside to cool. The crystals thus obtained are *permanganate* or *manganesate of potassa,* from which the acid may be separated by converting them into *permanganate of baryta,* and by carefully decomposing this salt by *dilute sulphuric acid.* (Gregory.) Both the acid and its salts possess a fine red or purple colour, and bleaching properties, and are rapidly decomposed by organic matter.

MANGE. An animalcular eruptive disease, corresponding to the itch in man, common to several domestic animals, more especially the dog and horse. Like the itch it is contagious. The *causes* are confinement, diet, and bad living. The *treatment* should consist in the immediate removal of the cause, the frequent use of *soft soap and water* followed by frictions with *sulphur ointment* or by *solution of chloride of lime,* the administration of purgatives, and a change to a restorative diet.

MANGEL WURZEL. Syn. *Hybrid Beet, Root of Scarcity.* The *beta hybrida,* a variety of *beta vulgaris* (Linn.) or *common beet.* The *root* abounds in sugar, and has been used in Germany as a substitute for bread in times of scarcity. In these countries it is chiefly cultivated as food for cattle. The *young leaves* are eaten as spinach.

MANHEIM GOLD. See *Dutch Gold.*

MANIA. See *Insanity.*

MANIPULATION. See *Analysis, Laboratory, Testing, &c.*

MANNA. Syn. *Manna,*—Lat. "The

juice flowing from the incised bark" of "*fraxinus rotundifolia*, and *f. ornus* (?), hardened by the air." (Ph. L.) The finest variety of this drug is known as *flake manna* (manna canellata, m. cannulata) and occurs in pieces varying from 1 to 6 inches long, 1 or 2 inches wide, and ½ to 1 inch thick. It has a yellowish-white or cream colour; an odour somewhat resembling honey, but less pleasant; a sweet, mawkish taste; and is light, porous, and friable. It is laxative in *doses* of 1 to 2 oz.

A *factitious manna*, made of a mixture of *sugar*, *starch*, and *honey*, with a *very small* quantity of *scammony* to give it odour and flavour, and to render it purgative, has been lately very extensively offered in trade, and met with a ready sale.

MANNACROUP. A granular preparation of *wheat* deprived of bran, *used* as an article of food for children and invalids. (Brande.)

MANNA RESIN. A peculiar substance found in manna, and on which its disagreeable odour and flavour, and laxative quality are supposed to depend.

MANNITE. Syn. *Grenadine*, *Manna Sugar*, *Mushroom do.*; *Mannita*,—Lat. A sweet, crystallizable substance, found in manna and in several other vegetable productions. It may be formed artificially by exciting the viscous fermentation in a solution of common sugar.

Prep. 1. Digest *manna* in *boiling rectified spirit*, and filter or decant the solution whilst hot; the *mannite* crystallizes as the liquid cools in tufts of slender, colourless needles.

2. (Ruspini.) *Manna*, 6 *lb.*; *cold water* (in which the white of an egg has been beaten), 3 *lb.*; mix, boil for a few minutes, and strain the syrup through linen whilst hot; the strained liquid will form a semi-crystalline mass on cooling; submit this to strong pressure in a cloth, mix the cake with its own weight of *cold water*, and again press it; dissolve the cake thus obtained in *boiling water*, add a little *animal charcoal*, and filter the mixture into a porcelain dish set over the fire; lastly, evaporate the filtrate to a pellicle, and set the syrup aside to crystallize. Large quadrangular prisms; perfectly white and transparent.

Prop., &c. Mannite has a powerfully sweet and agreeable taste; dissolves in 5 parts of cold water, and about half that quantity of boiling water; freely soluble in hot, and slightly so in cold alcohol; fuses by heat without loss of weight; with sulphuric acid it combines to form a new acid-compound. It is *distinguished* from the true *sugars* by its aqueous solution not being susceptible of the vinous fermentation, and not possessing the property of rotary polarization. When pure it is perfectly destitute of purgative properties. It is now extensively imported from Italy, and is chiefly used to cover the taste of nauseous medicines, and as a sweetmeat.

MANURES. Substances added to soils to increase their fertility. The *food of vegetables*, as far as their organic structure is concerned, consists entirely of inorganic compounds; and no organized body can serve for the nutrition of vegetables, until it has been, by the process of decay, resolved into certain inorganic substances. These are *carbonic acid*, *water*, and *ammonia*, which are well known to be the final products of putrefaction. But, even when these are supplied to vegetables, their growth will not proceed unless certain mineral substances are likewise furnished in small quantities, either by the soil, or the water used to moisten it. Almost every plant, when burned, leaves ashes, which commonly contain *silica*, *potassa*, and *phosphate of lime*; often, also, *magnesia*, *soda*, *sulphates*, and *oxide of iron*. These mineral bodies appear to be essential to the existence of the vegetable tissues; so that plants will not grow in soils destitute of them, however abundantly supplied with carbonic acid, ammonia, and water. According to Liebig, the *carbon* of plants is *wholly* derived from carbonic acid, which is either absorbed from the *atmosphere*, and from *rain water*, by the *leaves*, or from the *moisture* and *air* in the soil, by the *roots*. Its carbon is retained and assimilated with the body of the plant, while its oxygen is given out in the gaseous form; this decomposition being always effected under the influence of light at ordinary temperatures. The *hydrogen* and *oxygen* of vegetables, which, when combined with carbon, constitute the ligneous, starchy, gummy, saccharine, oily, and resinous matters of plants, are derived from water chiefly absorbed by the roots from the soil. The *nitrogen* of vegetables is derived chiefly, if not exclusively, from ammonia, which is supplied to them in rain, and in manures, and which remains in the soil till absorbed by the roots. *Ordinary manures* may be regarded the more *valuable* according to the quantity of azotized matter which they contain; and also in proportion as the decomposition of quaternary substances acts gradually, and agrees in its action with the progress of vegetation. It is the azote *in combination* contained in

manures which is the more especially useful; and the proportion of this, when ascertained, indicates the richness of such substances as fertilizing agents. In reference to the mineral constituents of soils, it appears that a soil is fertile or barren for any given plant according as it contains those mineral substances that enter into its composition. Thus, "the *ashes of wheat-straw* contain much *silica* and *potassa*, whilst the *ashes of the seeds* contain *phosphate of ammonia and magnesia* (ammonio-phosphate of lime). Hence, if a soil is deficient in any one of these, it will not yield wheat. On the other hand, a good crop of wheat will exhaust the soil of these substances, and it will not yield a second crop till they have been restored, either by manure or by the gradual action of the weather in disintegrating the subsoil. Hence the benefit derived from fallows and from the rotation of crops.

"When, by an extraordinary supply of any one mineral ingredient, or of ammonia, a large crop has been obtained, it is not to be expected that a repetition of the same individual manure next year will produce the same effect. It must be remembered, that the unusual crop has exhausted the soil probably of all the other mineral ingredients, and that they also must be restored before a second crop can be obtained.

"The salt most essential to the growth of the potato is the double phosphate of ammonia and magnesia; that chiefly required for hay is phosphate of lime; while for almost all plants potash and ammonia are highly beneficial."

From these principles we "may deduce a few valuable conclusions in regard to the chemistry of agriculture. *First*, by examining the *ashes of a thriving plant*, we discover the mineral ingredients which must exist in a soil to render it *fertile* for that plant. *Secondly*, by examining a soil, we can say at once whether it is *fertile* in regard to any plants the ashes of which have been examined. *Thirdly*, when we know the defects of a soil, the deficient matters may be easily obtained and added to it, unmixed with such as are not required. *Fourthly*, the *straw*, *leaves*, *&c.*, of any plant, are the *best manure for that plant*, since every vegetable extracts from the soil such matters alone as are essential to it. This important principle has been amply verified by the success attending the use of wheat-straw, or its ashes, as manure for wheat, and of the clippings of the vines as a manure for the vineyard. When these are used (in the proper quantity) no other manure is required. *Fifthly*, in the *rotation of crops*, those should be made to follow which require different materials; or a *crop* which *extracts little or no mineral matter*, such as *peas*, should come after one which *exhausts the soil* of its *phosphates* and *potassa*."

Of the chemical manures now so much used, BONE-DUST supplies the *phosphates* which have been extracted by successive *crops of grass* and *corn*, the whole of the bones of the cattle fed on these crops having been derived from the soil; its gelatin also yields ammonia by putrefaction. BRAN is a very valuable manure, especially for *potatoes*, as it contains much of the ammoniaco-magnesian phosphate. GUANO acts as a source of *ammonia*, containing much oxalate and urate of ammonia, with some *phosphates*. NIGHTSOIL and URINE, especially the latter, are most valuable for the *ammonia* they yield, as well as for *phosphates* and *potassa;* but are very much neglected in this country, although their importance is fully appreciated in Belgium, France, and China. NITRATE OF SODA probably acts by its alkali replacing potassa. It is also possible that its acid may yield nitrogen to plants, although we possess at present no evidence of this, and, indeed, no evidence that plants can derive their nitrogen from any other source than from ammonia.

All *organic substances* may be employed as manures; preference being, however, given to those abounding in *nitrogen*, and which readily decay when mixed with the soil.

The *analysis* of *manures*, *soils*, and the *ashes of plants*, for the purpose of ascertaining their composition and comparative value, is not easily performed by inexperienced parties; but a rough approximation to their contents, *sufficiently accurate for all practical purposes*, may be generally made by such persons with proper care and attention. See *Agriculture*, *Guano*, *Soils*, *Testing*, *&c.*

MANURES (Artificial). Various formulæ belonging to this head will be found dispersed, under their respective names, throughout this work. The following are additional ones:—

1. (Dr. Anderson.) *Sulphate of ammonia*, *common salt*, and *oil of vitriol*, of each, 10 parts; *chloride of potassium*, 15 parts; *gypsum* and *sulphate of potassa*, of each, 17 parts; *saltpetre*, 20 parts; *crude Epsom salt*, 25 parts; *sulphate of soda*, 33 parts. For clover.

2. (Huxtable.) *Crude potash*, 28 *lb.*;

common salt, 1 cwt.; *bone dust* and *gypsum*, of each, 2 cwt.; *wood ashes*, 15 bushels. For either corn, turnips, or grass.

3. (Prof. Johnstone.) *Sulphate of soda* (dry), 11 *lb.*; *wood ashes*, 28 *lb.*; *common salt*, ¾ cwt.; *crude sulphate of ammonia*, 1 cwt.; *bone dust*, 7 bushels. As a substitute for guano.

4. (Law's *Superphosphate.*) See *Coprolite.*

5. (*Fertilizing Powder.*) A mixture of *very fine bone dust*, 18 parts; *calcined gypsum* and *sulphate of ammonia*, of each, 1 part. The seed is ordered to be steeped in the "drainings" from a dunghill, and after being drained, but whilst still wet, to be sprinkled with the powder, and then dried.

6. (*Liquid Guano.*) See *Flowers.*

7. (*Sulphated Bones.*) See *Superphosphate of Lime.*

MANUS CHRISTI. *Prep.* 1. (*Manus Christi perlatæ.*) Drops, or pastilles, made of pearls, sugar, and rose water.—2. (*Manus Christi simplices.*) Rose drops, or pastilles, made into flat cakes.

MANUS DEI. The name of an old resolvent plaster compounded of *ammoniacum*, *galbanum*, *mastic*, *myrrh*, *oil*, *olibanum*, *wax*, and some other substances.

MANUSCRIPTS (Restoration of). See *Writing.*

MAPLE ACID. See *Aceric Acid.*

MAPS. These, as well as *architect's* and *engineer's designs, plans, sections, drawings, &c.*, may be *tinted* with any of the simple liquid colours, mentioned under the heads—*stains*, *velvet colours*, and *water colours*; preference being given to the first, on account of their transparency not interfering with the lines beneath them. To *prevent* the *colours* from *sinking* and *spreading*, which they usually do on common paper, the latter should be wetted 2 or 3 times with a sponge dipped in *alum water* (3 or 4 *oz.* to the pint), or with a *solution of white size*; observing to dry it carefully after each coat. This tends to give lustre and beauty to the colours. The colours for this purpose should also be thickened with a little *gum water*. Before *varnishing maps* after colouring them, 2 or 3 coats of clean size should be applied with a soft brush, —the *first* one to the back.

MARASCHINO. Syn. *Marasquin*,—Fr. A delicate liqueur spirit distilled from a peculiar cherry growing in Dalmatia, and afterwards sweetened with sugar. The best is from Zara, and is obtained from the *marasca cherry* only. An *inferior quality* is distilled from a mixture of cherries and the juice of liquorice root.

MARASMUS. Emaciation with corresponding debility. A gradual wasting away of the flesh, accompanied by diminished health and vital energy, without any other apparent disease. It is more especially applied to the "decline" of infancy, childhood, and early youth. See *Atrophy*, *Anæmia*, *&c.*

MARASQUIN DE GROSEILLES. *Prep.* From *ripe gooseberries*, 1 cwt.; *black-cherry leaves*, 14 *lb.*; bruise, ferment, distil, and rectify the spirit; to each quart of the product, add of *white sugar*, 1 *lb.*; dissolved in *water*, 1½ pint. A pleasant liqueur. See *Liqueurs.*

MARATHRITES. Wine strongly flavoured with fennel, formerly used in medicine.

MARBLE. Syn. *Limestone*, *Hard Carbonate of Lime*; *Marmor*, *Carbonas Calcis Durus*,—Ph. L. 1836. *M. Album*,—Ph. E. & D. Marbles are merely purer and more compact varieties of limestone, which admit of being sawn into slabs, and are susceptible of a fine polish. White marble is employed for the preparation of carbonic acid, and some of the salts of lime. It contains about 65% of lime. Sp. gr. 2·70 to 2·85. The *tests* of its *purity* are the same as those already noticed under *Chalk.*

Marble is best *cleaned* with a little *soap-and-water*, to which some *ox-gall* may be added. *Acids* should be avoided. *Oil* and *grease* may be generally removed by spreading a paste made of *soft soap*, *caustic potash lye*, and *fuller's earth*, over the part, and allowing it to remain there for a few days; after which it must be washed off with clean water. Any defect of polish may be brought up with *tripoli*, followed by *putty powder*; both being used along with *water.*

Marble is *mended* with one or other of the compounds noticed under *Cements.*

Marble may be *stained* or *dyed* of various colours by applying coloured solutions or tinctures to the stone made sufficiently hot to make the liquid just simmer on the surface. The following are the substances usually employed for this purpose:—

Blue. Tincture or solution of litmus, or an alkaline solution of indigo.

Brown. Tincture of logwood.

Crimson. A solution of alkanet root in oil of turpentine.

Flesh colour. Wax tinged with alkanet root, and applied to the marble hot enough to melt it freely.

Gold colour. A mixture of equal parts of

white vitriol, sal ammoniac, and verdigris, each in fine powder, and carefully applied.

Green. An alkaline solution or tincture of sap green; or wax strongly coloured with verdigris; or the stone is first stained blue, and then the materials for yellow stain are applied.

Red. Tincture of dragon's blood, alkanet root, or cochineal.

Yellow. Tincture of gamboge, turmeric, or saffron; or wax coloured with annotta. Success in the application of these colours requires considerable experience. By their skilful use, however, a very pleasing effect, both of colour and grain, may be produced.

MARBLING (of Books, &c.) The *edges* and covers of *books* are *marbled* by laying the colour on them with a brush, or by means of a wooden trough containing mucilage, as follows:—Provide a *wooden trough*, 2 inches deep, 6 inches wide, and the length of a super-royal sheet; boil in a brass or copper pan any quantity of *linseed* and *water* until a thick mucilage is formed; strain this into the trough, and let it cool; then grind on a marble slab any of the following colours in *table beer*. For—BLUE, *Prussian blue* or *indigo*;—RED, *rose-pink*, *vermilion*, or *drop lake*;—YELLOW, *king's yellow*, *yellow ochre*, &c.;—WHITE, *flake white*;—BLACK, *ivory black*, or *burnt lamp-black*;—BROWN, *umber*, *burnt do.*, *terra di sienna*, *burnt do.*; black, mixed with yellow or red, also makes brown;—GREEN, *blue* and *yellow* mixed;—ORANGE, *red* and *yellow* mixed;—PURPLE, *red* and *blue* mixed. For each colour provide *two cups*,—one for the *ground colours*; the other to mix them with the *ox-gall*, which must be used to thin them at discretion. If *too much* gall is used, the colours spread: when they keep their place on the surface of the trough, on being moved with a quill, they are fit for use. All things being in readiness the *prepared colours* are successively sprinkled on the surface of the mucilage in the trough with a brush, and are waved or drawn about with a quill or stick, according to taste. When the design is thus formed, the book, tied tightly between cutting boards of the same size, is lightly pressed with its edge on the surface of the liquid pattern, and then withdrawn and dried. The *covers* may be *marbled* in the same way, only the liquid colours must be allowed to run over them. The film of colour in the trough may be as thin as possible; and, if any remains after the marbling, it may be taken off by applying paper to it before you prepare for marbling again. This process has been called "*French marbling.*"

To *diversify* the *effect*, a little *sweet oil* is often mixed with the colours before sprinkling them on, by which means a light halo or circle appears round each spot. In like manner, *spirit of turpentine*, sprinkled on the surface of the trough, produces WHITE SPOTS. By *staining* the *covers* with any of the liquid dyes, and then dropping on them, or running over them, drops of the ordinary *liquid mordants*, a very pleasing effect may be produced. *Vinegar black*, or a *solution of green copperas*, thus applied to common leather, produces BLACK SPOTS OR STREAKS, and gives a similar effect with most of the light dyes. A *solution of alum* or of *tin* in like manner produces BRIGHT SPOTS OR STREAKS, and *soda* or *potash water*, DARK ONES. This style has been called *Egyptian marble*.—*Soap marbling* is done by throwing on the colours, ground with a little *white soap* to a proper consistence, by means of a brush. It is much used for book-edges, stationery, sheets of paper, ladies' fancy work, &c.—*Thread marble* is given by first covering the edge uniformly of one colour, then laying pieces of *thick thread* irregularly on different parts of it, and giving it a fine dark sprinkle. When well managed, the effect is very pleasing.—*Rice marble* is given in a similar way to the last by using *rice*.—*Tree marble* is done on leather book-covers, &c., by bending the board a little in the centre, and running the marbling liquid over it in the form of vegetation. The knots are given by rubbing the end of a *candle* on those parts of the cover.—*Wax marble* is given in a similar way to thread marble, but using *melted wax*, which is removed after the book is sprinkled and dried; or a sponge charged with *blue*, *green*, or *red*, may be passed over. This, also, is much used for stationery work; especially for folios and quartos. The "*vinegar black*" of the bookbinders is merely a solution of *acetate of iron*, made by steeping a few *rusty nails* or some *iron filings* in *vinegar*. All the ordinary liquid colours that do not contain strong acids or alkalies, may be used, either alone or thickened with a little gum, for marbling or sprinkling books.

Sprinkling is performed by simply dipping a stiff-haired painter's brush into the colour, and suddenly striking it against a small stick held in the left hand over the work. By this means the colour is evenly scattered without producing "*blurs*" or "*blots*."

Paper, *pasteboard*, &c., in sheets, are

marbled and sprinkled in a similar manner to that above described, but in this case the *gum trough* must, of course, be longer. See *Stains, Sprinkles, &c.*

MARGARIC ACID. Syn. *Magarulic Acid.* A fatty acid obtained by the saponification of oils, so named by Lecanu, on account of the pearly appearance of its crystals.

Prep. 1. Dissolve *olive oil soap* in *water*, and precipitate the solution with a *solution of neutral acetate of lead;* filter, wash, and dry the precipitate (*margarate of lead*), digest it in *ether*, and decompose the residuum by *boiling-hot hydrochloric acid;* lastly, wash the *precipitated acid*, and dissolve it in *boiling alcohol;* the solution furnishes crystals on cooling.

2. Heat *hydrated stearic acid* with its own weight of *nitric acid* for some minutes; press the fatty acid which separates between folds of paper, and purify it by repeated crystallizations from *boiling alcohol.*

3. (*Commercial.*) By the distillation of *crude stearic acid.* "The humidity at the beginning of the process must be expelled by a smart heat, otherwise explosive ebullitions are apt to occur. Whenever the ebullition becomes uniform, the fire is to be moderated." (Ure.)

Prop., &c. Margaric acid forms pearly scales, soluble in cold ether and alcohol; the solution reddens litmus; it is volatile at a high temperature, and boils before being volatilized; assisted by heat it decomposes the alkaline carbonates. It fuses at 140° Fahr. With the bases it forms salts called *margarates.*

MARGARINE. Syn. *Margarate of Oxide of Glyceryle.* The solid fatty matter of certain vegetable oils, and the principal ingredient of human and goose fat.

Prep. A *hot alcoholic solution* of either of the *above fats*, or of the *concrete portion of olive oil*, deposits, as it cools, a mixture of *margarate* and *oleate of glyceryle;* it is purified by compression between the folds of bibulous paper, and solution in *hot ether.*

Prop., &c. It greatly resembles stearine, but is more fusible and pearly looking; it melts at 116° Fahr.; dissolves in cold ether, and in alcohol; and by saponification yields glycerine and *margaric acid.*

MARGARITIC ACID. Obtained, along with *elaiodic acid* and *ricinic acid*, by the saponification of castor oil. It melts at 166° Fahr., and forms soapy salts with the alkalies (*margaritates*); the other acids are oily liquids at ordinary temperatures.

MARGARITINE. Syn. *Ricino-stearine.* The solid, white, crystalline fat, which separates from *castor oil* during cold weather. By saponification it yields glycerine and *margaritic acid.*

MARGARONE. A peculiar fatty substance, obtained by distilling a *mixture* of *quicklime* and *margaric acid.* It forms pearly crystalline scales, and is incapable of saponification.

MARINE ACID. See *Hydrochloric Acid.*

MARKETING. *Directions* for the *choice* of the principal articles of food purchased in this manner, are given under their respective names, or that of the class to which they belong; the periods at which they are in *season* will be found in "*Bills of Fare.*"

MARL. A compound of *clay* and *chalk*, with sand. It is characterized by effervescing with acids. According to the predominance of one or other of its component parts, it is called *argillaceous, calcareous*, or *sandy marl.* It is very generally employed as a *manure* for *sandy soils*, more particularly in Norfolk. See *Soils.*

MARMALADE. Originally, a conserve made of quinces and sugar; now commonly applied to the conserves of other fruit, more especially to those of oranges and lemons.

Prep. Marmalades are made either by pounding the *pulped fruit* in a mortar with an *equal* or a rather larger quantity of *powdered white sugar;* or by mixing them together by heat, passing them through a hair sieve whilst hot, and then putting them into *pots* or *glasses.* The *fruit pulps* are *obtained* by rubbing the fruit through a fine hair sieve, either at once, or after it has been softened by simmering it for a short time along with a *little water.* When heat is employed in mixing the ingredients, the evaporation should be continued until the marmalade "jellies" on cooling. See *Conserves, Confections, Electuaries, Jams, Jellies*, and *below.*

Apricot marmalade; from equal parts of pulp and sugar.

Barbary marmalade; as the last.

Citron marmalade; as orange do.

Marmalade of hips; from the pulp of hips and sugar, in the same way as *confection of hips.*

Mixed marmalade; from plums, pears, and apples, variously flavoured to palate.

Orange marmalade.—1. From oranges (either Seville or St. Michael's, or a mixture of the two), by boiling the peels in syrup until soft, then pulping them through a sieve, adding as much white sugar, and boiling them with the former syrup and the juice of the fruit to a proper consistence.

2. A still *finer marmalade* is made by melting the confection of orange peel (Ph. L.), either with, or without the addition of some orange or lemon juice, and then passing it through a sieve.

Candied orange marmalade; from candied orange peel, boiled in an equal weight each of sugar and water, and then passed through a sieve.

Quince marmalade, Diacydonium; from quince flesh or pulp, and sugar, equal parts; or from the juice (*miva cydoniorum, gelatina do.*), by boiling it to ½, adding an equal quantity of white wine, and ⅔rds of its weight of sugar, and gently evaporating the mixture.

Scotch marmalade.—1. Seville orange juice, 1 quart; yellow peel of the fruit, grated; honey, 2 *lb.;* boil to a proper consistence.

2. Seville oranges, 8 *lb.;* peel them as thinly as possible, then squeeze out the juice, boil it on the yellow peels for ¼ hour, strain, add white sugar, 7 *lb.;* and boil to a proper consistence.

Marmalade of sloes. Conserve of sloes. Astringent.

Transparent marmalade. Orange marmalade, well strained or clarified while hot.

Tomato marmalade. Like apricot marmalade, adding a few slices of onions and a little parsley.

Wood sorrel marmalade; Conserva foliorum lujelæ. Wood sorrel leaves, 1 *lb.;* powdered white sugar, 3 *lb.;* beat together in a mortar. Pleasant, cooling, and acidulous; has a fine red colour.

MARMORATUM. *Finely powdered marble* and *quicklime*, well beaten together; *used* as a cement or mortar. See *Mineral Marmoratum.*

MARQUETRY. Inlaid cabinet-work. See *Ivory, Pearl, Varnishes, Japanning, &c.*

MARRIAGE. Dr. Casper, of Berlin, has calculated, that the mortality among *bachelors*, from the age of 30 to 45 years, is 27 per cent.; whilst among *married men* of the same age, it is only 18 per cent. For forty-one *bachelors* who attain the age of 40 years, there are seventy-eight *married men* who attain the same age. The *advantage* in favour of married life is still more striking in persons of advanced age. At 60 years there remain but twenty-two *bachelors* for forty-eight *married men;* at 70 years, eleven *bachelors* for twenty-seven *married;* and at 80 years, only three *bachelors* against nine *married men.* (Journ. de Chim. Med.) The duration of life is also indicative of the state of the physical health enjoyed by the parties referred to; whilst the statistical returns of the number of lunatics, point still more strongly in the same direction, in reference to the superior mental condition of the benedict over the bachelor. Similar evidence exists in reference to the gentler sex. Thus, it appears indisputable, that the *married* not only *live longer*, but also *better* than those who remain the victims of "single blessedness."

MARROW (Beef). This is extensively employed by the *perfumers* in the preparation of various pommades and other cosmetics, on account of its furnishing an exceedingly bland fat, which is not so much disposed to rancidity as the other fats. It is *prepared* for *use* by soaking and working it for some time in *lukewarm water*, and afterwards, melting it in a water bath, and straining it through a piece of muslin whilst hot. When scented, it is esteemed equal to *bear's grease* for promoting the growth of the hair.

MARRUBINE. Syn. *Marrubina,*—Lat. A vegetable principle obtained from the *marrubium vulgare* (Linn.) or *white horehound.* It is said to be bitter, tonic, febrifuge, and cholagogue. *Dose.* 4 to 21 gr.; in ague, hepatic affections, &c.

MARSH GAS. See *Carburetted Hydrogen.*

MARSH'S TEST. See *Arsenious Acid* and *Tests.*

MARSH-MALLOW. Syn. *Althæa,*—Ph. L. & E. The *root* (leaves and root,—Ph. E.) of *althæa officinalis*, Linn., or *common marsh-mallow.* (Ph. L.) It is emollient and demulcent; the *decoction* is useful in irritation of the respiratory and urinary organs, and of the alimentary canal. The *flowers* as well as the *root* are reputed pectoral.

MARTIN'S POWDER. A mixture of *white arsenic* and the *powdered stems of orobanche virginiana* (Linn.), a plant common in Virginia. An American quack remedy for cancer.

MASHES. See *Veterinary Medicine.*

MASHING. See *Brewing.*

MASS. Syn. *Massa,*—Lat. This term is commonly applied in pharmacy and veterinary medicine to certain preparations which are not "made up" into their ultimate form. Thus, we have *ball masses, pill masses, &c.;* of which, for convenience, large quantities are prepared at a time, and are kept in pots or jars, ready to be divided into *balls* or *pills*, as the demands of business may require.

MASSICOT. Syn. *Masticot, Yellow*

Protoxide of Lead; Plumbi Oxydum Flavum, Cerussa Citrina, Ochra Plumbaria Factitia,—Lat. var. The dross that forms on melted lead exposed to a current of air, roasted until it acquires a uniform yellow colour. Artists often apply the same name to white lead, roasted until it turns yellow. *Used* as a pigment.

MASTIC. Syn. *Mastich, Gum do.; Mastiche*,—Lat. The "resin flowing from the incised bark of *pistacia lentiscus*, var. *chia*" (Linn.), or *lentisk tree*. (Ph. L.) It occurs in pale yellowish, transparent, rounded tears, which soften between the teeth when chewed, and giving out a bitter, aromatic taste. Sp. gr. 1·07. It is soluble in both rectified spirit and oil of turpentine, forming varnishes. It is chiefly used as a *masticatory*, to strengthen and preserve the teeth, and perfume the breath.

MASTIC. Fine mortar or cement used for plastering walls, in which the ingredients, in a pulverulent state, are mixed up, either entirely, or with a considerable portion of linseed oil. It sets very hard, and is ready to receive paint in a few days. See *Cements*.

MASTICATION. The act of chewing food, by which it not only becomes comminuted, but mixed with the saliva, and reduced to a form fit for deglutition. It has been justly regarded by the highest authorities as the first process of digestion, and one, without which, the powers of the stomach are overtasked, and often performed with difficulty. Hence the prevalence of dyspepsia and bowelly complaints among persons with bad teeth, or who "bolt" their food without chewing it. Public attention has been recently called in one of the medical journals to the position which is there assumed as a fact, that such persons furnished a greater per centage of victims to the cholera, during the late visitation of that disease, than other members of the same classes. See *Teeth, &c.*

MASTICATORIES. Syn. *Masticatoria, Pilæ Masticatoriæ*,—Lat. Substances taken by chewing them. They are employed as intoxicants, cosmetics, and medicinals; generally with the first intention. The principal masticatory used in this country is *tobacco*. In *Turkey* and several other Eastern nations, *opium* is taken in a similar manner. In *India*, a mixture of *areca nut*, *betel leaf*, and *lime*, performs the same duties; whilst in some other parts of the world, preparations of the cacao are employed. As COSMETICS, *orris root*, *cassia*, *cinnamon*, and *sandal wood*, are frequently chewed to scent the breath. Among MEDICINALS, *mastic* and *myrrh* are frequently chewed to strengthen the teeth and gums; *pellitory*, to relieve the toothache; and *rhubarb*, *ginger*, and *gentian*, to relieve dyspepsia, and promote the appetite.

Prep. 1. (Augustin.) *Mastic*, *pellitory*, (both in powder), and *white wax*, of each, 1 dr.; mixed by heat and divided in 6 balls. In toothache, loose teeth, &c.

2. (W. Cooley.) *Mastic*, *myrrh*, and *white wax*, of each, 1 part; *rhubarb*, *ginger*, and *extract of gentian*, of each, 2 parts; beaten up with *tincture of tolu*, q. s.; and divided into boluses or lozenges of 10 gr. each. One or two to be chewed an hour before dinner; in dyspepsia, defective appetite, &c.

3. (Quincy.) *Mastic*, 3 oz.; *pellitory* and *stavesacre seed*, of each, 2 dr.; *cubebs* and *nutmegs*, of each, 1 dr.; *angelica root*, ½ dr.; *melted wax*, q. s. to make it into small balls. As a stimulant to the gums, and in toothache.

4. *Opium*, *ginger*, *rhubarb*, *mastic*, *pellitory of Spain*, and *orris root*, of each, 1 dr.; *musk* and *ambergris*, of each, 1 gr.; *melted spermaceti*, q. s. to mix; for 6-gr. pills. As the last, and in toothache and painful gums.

MASTICHIC ACID. Syn. *Soluble Mastic Resin*. The portion of mastic soluble in alcohol. It forms about 90% of the resin. According to Johnstone it is capable of forming salts with the acids.

MASTICINE. Syn. *Neutral Mastic Resin*. The portion of mastic which is insoluble in alcohol, and which gives that substance its peculiar toughness. It is soluble in the alcoholic solution of mastichic acid.

MASTICOT. See *Massicot*.

MATCHES (Cooper's). Syn. *Sweetening Matches*. These are made by dipping strips of *coarse linen* or *canvas* into *melted brimstone*. For *use*, the brimstone on one of them is set on fire, and the match is then at once suspended in the cask, and the bung loosely set in its place. After the lapse of 2 or 3 hours, the match is removed, and the cask filled with liquor. Some persons pour a gallon or two of the liquor into the cask before "matching" it. The object is to allay excessive fermentation. The operation is commonly adopted in the Western Counties for cyder intended for shipment, or other long exposure during transport. It is also occasionally employed for inferior and "doctored" wines. See *Antiferment, Fermentation, &c.*

MATCHES (Instantaneous Light). Of these there are several varieties, of which the one best known, and most extensively used,

is the common "*congreve.*" The following formulæ include all of those which have been employed during the present century, arranged under their common names :—

Chemical Matches, Chlorate Matches.— 1. Take of *chlorate of potassa*, 6 parts; *sulphur* and *powdered lump sugar*, of each, 2 parts; *powdered gum arabic*, 1 part; *vermilion*, q. s. to colour. The ingredients separately reduced to fine powder, are made into a paste with a *little water*, and the tips of the matches are then dipped into the mixture.

2. (Without Sulphur.) *Chlorate of potassa*, 3 *dr.*; *wheaten flour*, 1 *dr.*; *vermilion* and *lycopodium*, of each, ½ *dr.*; make them into a paste with a little *thin mucilage*, and dip the matches into the mixture, as before. The "slips" of wood for this purpose should have been previously dipped into *melted sulphur*, or, preferably, into a solution of *Venice turpentine*, 1 *oz.*, and *camphor*, ½ *oz.*, in *oil of turpentine*, ¼ pint.

Obs. Chlorate matches are inflamed by dipping them into a little *oil of vitriol;* or by *smart* friction. The risk of spilling the acid is avoided by placing a little asbestos in the bottle, and pouring on it as much only of that liquid as the asbestos will absorb. These matches once occupied the same place that lucifers did a few years since, and that congreves do now. The *acid bottle* and *matches* were commonly sold in a case together. That man was far in advance of his neighbours who had moral courage sufficient to induce him to discard the "tinder box" and its "noisy concomitants" for the *instantaneous-light apparatus.*

Congreves, Congreve Matches, Congreve Lights. These are the prevailing matches of the present day, and are characterized by containing phosphorus in a state of minute division.

Prep. 1. (Dr. R. Boettger.) Dissolve *gum arabic*, 16 parts, in the *least possible quantity of water*, add of *phosphorus* (in powder), 9 parts, and mix by trituration; then add of *nitre*, 14 parts; *vermilion* or *binoxide of manganese*, 16 parts, and form the whole into a paste; into this the matches are to be dipped, and then exposed to dry. As soon as the matches are quite dry, they are to be dipped into very dilute copal varnish or lac varnish, and again exposed to dry, by which means they are rendered waterproof, or at least less likely to suffer from exposure in damp weather.

2. (Dr. R. Boettger.) *Glue*, 6 parts, is soaked in a little *cold water* for 24 hours, after which it is liquefied by trituration in a heated mortar; *phosphorus*, 4 parts, is now added, and rubbed down at a heat not exceeding 150° Fahr.; *nitre* (in fine powder), 10 parts, is next mixed in, and afterwards, *red lead*, 5 parts, and *smalts*, 2 parts, are further added, and the whole formed into a uniform paste, into which the matches are dipped, as before. Cheaper than the last.

3. (M. Diesel.) *Phosphorus*, 17 parts; *glue*, 21 parts; *red lead*, 24 parts; *nitre*, 38 parts. This is said to be the composition of the best *German congreves.*

4. (M. Joblonouski.) *Gum arabic* (made into mucilage), 7 parts; *phosphorus* (in powder), 4 parts; mix, add of *gelatine*, 2 parts; *chlorate of potassa* (in powder), 2 parts; make a paste, and proceed as before.

5. (M. Joblonouski.) Put *phosphorus*, 4 parts, into a wide-mouthed phial, with enough *oil of turpentine* to cover it, add of *flowers of sulphur*, 1 part, and put the phial into hot water (using great caution) until the phosphorus is melted; then cork close, and agitate well until cold, when any supernatant spirits of turpentine must be poured off. Into this *pulpy mass* the extremities of the matches are to be dipped, and when they have become *rather dry*, they are to be again dipped into the following mixture :—*Gum arabic*, 3 parts (dissolved in a little water); *chlorate of potassa*, 2 parts; *soot*, *lamp black*, or *vermilion* (rubbed up with a few drops of alcohol), 1 part; mix, and dip the tips of the matches in the paste, as before, and dry them *cautiously* in a warm apartment.

Obs. All the above inflame, *without fulmination*, when rubbed against a rough surface, and are hence termed "*noiseless congreves*" by the makers. The *products* of the first three formulæ commend themselves for their economy and safety. Those containing *chlorate of potassa* explode more readily than those without it, but are regarded as *less* safe; whilst the extreme inflammability of those containing both *sulphur* and *phosphorus* as well as the chlorate, has now led to their disuse. The matches *formerly* sold under the name of "congreves" exploded with a cracking noise, and frequently threw out small sparks of fire, which rendered them dangerous. This arose from their containing too much chlorate of potassa, and from the quantity of the igniting ingredients applied to each match being unnecessarily large. At the present time economy in the use of the igniting composition, is the chief aim of the manufacturer.

To render the small pieces of wood or pasteboard capable of being readily ignited by the combustion of the composition with which they are "tipped," they are submitted to a preliminary process. The ends of the bundles of those formed of *wood*, after being *slightly* charred by rubbing them against a red-hot iron plate, are dipped, for a moment, into as much *white wax*, melted in a suitable vessel, as will stand the $\frac{1}{10}$th or $\frac{1}{8}$th of an inch in depth, after which, being instantly well shaken and allowed to cool, they are ready for the "phosphorus composition." Sometimes they are dipped in *camphorated spirit*, or into the solution noticed under "*chlorate matches*;" to which a little *gum benzoin* and *cascarilla* are occasionally added, by way of perfume. The *common matches* are simply dipped into melted sulphur. The manufacture of *wooden splints* for matches is now almost entirely performed by machinery. *Cigar fusees* are prepared by soaking them in *water* holding some *saltpetre*, *bichromate of potash*, or *acetate of lead* in solution, preference being usually given to the first of these articles; after which they are commonly moistened with a rough *tincture of benzoin* or *cascarilla*, by which they diffuse an agreeable odour whilst burning.

Different *colouring substances* are employed to *tinge* the composition, according to the fancy of the manufacturer, as *smalts*, *red lead*, *vermilion*, *black oxide of manganese*, *soot*, &c.

The *phosphorus* is *reduced* to *powder* by melting it in a phial containing some *fresh urine*, by the heat of *hot water*, and agitating the whole until cold. A *solution of pure urea* employed in the same way is still more effective, but is more expensive. *Rectified spirit* is also sometimes employed for the same purpose.

The manufacture and sale of matches, containing sulphur and phosphorus, have been forbidden in Paris.

Lucifers, Lucifer Matches. These were the forerunners of the "*congreve.*" The two are, however, commonly confounded together, although quite distinct from each other. The *igniting composition* of the "*lucifer*" consists of a *mixture* of *sulphuret of antimony* and *chlorate of potassa*, (both in very fine powder,) made into a paste with a weak *solution of gum*. The body of the match is formed of *pasteboard;* and the composition is inflamed by drawing it smartly through a piece of *emery*, *glass*, or *sand paper*, folded in the middle. The ignition is attended with a sharp noise, like that of the common varieties of congreves.

Locofocos. The popular name in America for congreve matches; from *loco foci*, instead of a fire.

Prometheans. These matches were invented and brought out, some years since, by Mr. Jones, of the once celebrated "Light House," Strand.

Prep. Take of *chlorate of potassa*, and *loaf sugar*, equal parts; *vermilion*, q. s. to colour; powder each separately, mix, make a stiff paste with a *weak solution of gum arabic*, and divide it into small pieces. A number of minute oval glass beads are now made from a small thin glass tube by means of a candle and blowpipe, one end of which is closed while soft. These tubes are dipped whilst still hot into *sulphuric acid*, and the open end is then closed by the flame and blowpipe. A *slip of paper* (1 × 2 inches) is next taken, and one of the corners cut off. A little *mucilage* is then applied, and the paper is rolled into a small cylinder, leaving a hollow at the gummed end. Into this hollow, one of the glass beads surrounded with a little of the red mixture, is now gently squeezed with the fingers, and finished off by smoothing the external surface with the finger moistened with gum water. The whole is, lastly, dried. To inflame them, the bead containing the oil of vitriol at the loaded end is broken by a smart blow, and the acid coming into contact with the chlorate mixture, causes it to burst into flame. The bead and red paste together should not be larger than a barleycorn.

MATERIA HERMAPHRODITA (of Boerhaave). The "*materia saponica*" of Scheele, and the "*extractive*" of modern chemists.

MATERIA MEDICA. A collective name of the various substances, natural and artificial, employed as medicines, or in the cure of disease. In its more extended sense, it includes the science which treats of their properties, classification, and applications. The *materia medica* of the pharmacopœia is a mere list, with occasional notes, "embracing the animal, vegetable, and chemical substances, whether existing naturally, prepared in officinal chemical preparations, or sold in wholesale trade, which we (the college) direct to be used either in curing diseases, or in preparing medicines." (Ph. L.)

MATERIA PERLATA. The white precipitate which forms in the *water used to wash diaphoretic antimony* on the addition of an *acid.*

MATICO. Syn. *Soldier's Herb; Matecó, Matica, Herba Maticæ*,—Lat. The leaves of a Peruvian plant, generally believed to be the *artanthe elongata* (Miquel.), one of the *piperaceæ*. The leaves have been em-

ployed with considerable success as a mechanical external styptic; applied to leech-bites, slight cuts and other wounds, &c., and pressed on with the fingers, they seldom fail to arrest the bleeding. Matico has also been much lauded as an internal astringent and styptic, in hæmorrhages from the lungs, stomach, bowels, uterus, &c.; but as it is nearly destitute of astringent properties, its virtues in these cases must have been inferred from its external action. As an aromatic, bitter stimulant, closely resembling the peppers, it has been proposed as a substitute for cubebs and black pepper, in the treatment of diseases of the mucous membranes, piles, &c. *Dose.* ½ to 2 dr.; in powder; or under the form of infusion, tincture, or boluses.

MATURATION. Growing ripe. Amongst *surgeons*, this term is applied to the process of *suppuration*, or that which succeeds inflammation, and by which pus or matter is collected in an abscess. Warmth, irritation, and a liberal diet promote this change; cold, sedatives, and depletion, retard it. The *maturation* of *fermented liquor* is noticed under *Malt Liquors*, *Wines*, *Brewing*, *&c.*

MAYDEW. Syn. *Ros Majalis*,—Lat. Collected by sponges off the grass. *Used* as a cosmetic.

MEAD. Syn. *Mellina*,—Lat. An old English liquor, made from the *combs* from which the *honey* has been drained, by boiling them in water, and fermenting the saccharine solution thus obtained. It is commonly confounded with *metheglin*. Some persons add 1 *oz.* of *hops* to each gallon; and, after fermentation, a little brandy. It is then called *sack mead*. See *Metheglin*.

MEAL. The substance of edible grain ground to powder, without being bolted or sifted. *Barley meal* and *oat meal* are the common substances of this class in England. In North America the term is commonly applied to ground Indian corn, whether bolted or not. (Goodrich.) The *four resolvent meals* of old pharmacy (*quatuor farinæ resolventes*) are those of *barley*, *beans*, *linseed*, and *rye*.

MEALS. The "periods of taking food, usually adopted, in conformity with convenience and the recurrence of hunger, are those which are best adapted to the purposes of health; namely, the *morning meal*, the *mid-day meal*, and the *evening meal*." "That these are the proper periods for meals, is evident from the fact of their maintaining their place amid the changes which fashion is constantly introducing." "If we look at these periods in another point of view, we shall find an interval of 4 hours left between them for the act of digestion and subsequent rest of the stomach. Digestion will claim between two and three hours of the interval; the remaining hour is all that the stomach gets of rest, enough, perhaps, but not too much, nor to be justly infringed. We here see a rule of diet vividly suggested, namely, to let that '*patient drudge*,' the stomach, alone during its three hours of labour and one of rest; to put nothing more into it, while the mill is at work, nor when it is in repose gathering its strength for another grind. Tease it not, fret it not, if you would keep it in good humour; and without *its* good humour, alas for *yours!* Another inference: — the maxim '*little and often*' is obviously unsound; *moderate* and *seldom*, would be more to the purpose." (Eras. Wilson.)

MEASLES. Syn. *Rubeola*, *Morbilli*,—Lat. This very common disease is characterized by feverishness, chilliness, shivering, head-pains, swelling and inflammation of the eyes, defluxion of sharp tears, with painful sensibility to light, oppressive cough, difficulty of breathing, and sometimes vomiting or diarrhœa. These are followed about the fourth day by a crimson rash upon the skin, in irregular crescents or circles, and by small red points or spots, which are perceptible to the touch, and which, after 4 or 5 days, go off with desquamation of the cuticle. The fever, cough, &c., often continue for some time; and unless there have been some considerable evacuations, either by perspiration or vomiting, they frequently return with increased violence, and occasion great distress and danger.

Treat. When there are no urgent local symptoms, *mild aperients*, *antimonial diaphoretics*, and *diluents*, should be had recourse to; but when the inflammatory symptoms are emergent, and the lungs are weak, especially in plethoric habits, blood may be taken. The *cough* may be relieved by *expectorants*, *demulcents*, and small doses of *opium;* and the *diarrhœa* by the administration of the *compound powder of chalk and opium;* the looseness of the bowels, however, had better not be interfered with, unless it be extreme.

Measles are most prevalent in the middle of winter, and though common to individuals of all ages, are most frequent amongst children. The plethoric, and those of a scrofulous habit, or one which has a syphilitic taint, suffer most from them.

Like the smallpox, the measles are con-

tagious, and seldom attack the same person more than once during life. See *Rashes.*

MEASURE. Syn. *Mensura*—Lat. The unit or standard by which we estimate extension, whether of length, superficies, or volume.

1. *English Measures:*—

TABLE I. *English Lineal Measures.*

Inches.	Feet.	Yards.	Poles.	Furlongs.	Miles.

			512·	256·	64·	32·	8·	1·	—	640

*** The *standard unit* of the above table is the *gallon*, which is declared, by statute, to be capable of "containing *ten pounds* avoidupois weight of *distilled water*, weighed in the air at the temperature of 62° Fahr., the barometer being at 30 inches." The pound avoirdupois contains 7000 grains, and it is declared that a *cubic inch* of *distilled water*, under the above conditions, weighs 252·458 grains; hence the capacity of the *imperial gallon* and its divisions are as follows:—

Imperial gallon = 277·274 cubic inches.
„ quart = 69·3185 „
„ pint = 34·65925 „
Fluid ounce = 1·73296 „
„ drachm = ·21662 „

†‡† The *imperial gallon* is 1-5th *larger* than the *old wine-gallon*,—1-60th *smaller* than the *old beer-gallon*, and — 1-32nd *larger* than the *old dry-measure gallon*.

2. *French Measures* :—

TABLE IV. *French Metrical or Decimal Measures of Length.*

Names.	Eq. in Mètres.	Equivalents in English Inches, at 32° Fahr.	Equivalents in English Long Measure, at 62° Fahr.			
			Miles.	Fur.	Yds.	Feet.	Inch.
Millimètre . . .	·001	. . ·03937					
Centimètre . . .	·01	. . ·39371

Decamètre . . .	10·	. . 393·70790			10	2	9·7
Hectomètre . .	100·	. . 3937·07900			109	1	1·078
Kilomètre . . .	1000.	. . 39370·79300		4	213	1	10·3
Myriamètre . .	10000·	. 393707·90000	6	1	156	0	9·17

*** The *standard unit* of the above table is the mètre, which has been determined to be 39·37079 inches, at 32° Fahr. (Capt. Kater); the English foot is taken at 62° Fahr. The *true length* of the *mètre*, reduced to the latter temperature, is 39·370091 English inches; a number which varies from that in the table only at the fourth decimal figure. It will be perceived that the principle of nomenclature adopted in applying the names, was to prefix the *Greek* numerals to the *decimal multiples*, and the *Latin* numerals to the *decimal subdivisions*.

Barleycorn	= $\frac{1}{3}$ „
Hand	= 4 „
Chain	= 4 Poles or 22 Yards.

MEAT BISCUITS. *Prep.* 1. The *flour* is mixed up with a rich *fluid extract of meat*, and the dough is cut into pieces and baked in the usual manner.

2. *Wheaten flour* (or preferably the whole meal), 3 parts; *fresh lean beef* or other *flesh* (minced and pulped), 2 parts; thoroughly incorporate the two by hand-kneading or machinery, and bake the pieces in a moderately heated oven. Both the above are very nutritious; the last, more especially so. 1 *oz.* makes a pint of good soup.

MEAT (Extracts of). Some preparations of this nature have been already noticed under the heads *Essences* and *Extracts;* the following are additional and highly valuable formulæ :—

Prep. 1. (Dr. Breslau.) *Young ox-flesh* (free from fat) is minced small, and well beaten in a marble mortar, at *first* alone, and afterwards with a little *cold* or *lukewarm water;* the whole is then submitted to the action of a press, and the solid residuum is treated in the same manner, with a little more *cold water;* the juice (reddish in colour) is now heated to coagulate the albumen, strained, and finally evaporated in a water bath to the consistence of an extract. As ordinary flesh contains only 1% of kreatine, while that of the heart, according to Dr. Gregory, contains from 1·37% to 1·41%, this is the part employed by Dr. Breslau. The *product* possesses an agreeable odour and taste; and is easily soluble in water.

2. (Prof. Falkland.) *Fresh lean beef* (or other flesh) recently killed, is minced very fine, and digested, with agitation, in *cold water*, 1 pint, to which *hydrochloric acid*, 6 drops, and *common salt*, 1 *dr.*, have been added; after about an hour, the whole is thrown upon a fine hair sieve, and the liquid portion allowed to drain off without pressure, the first portions that pass through being returned until the fluid, at first turbid, becomes quite clear and transparent; when all the liquid has passed through, *cold water*, ¼ pint, is gently poured on, in small portions at a time, and allowed to drain through into that previously collected. The *product* is about ¾ pint of *cold extract of flesh*, having a red colour, and a pleasant, soup-like taste. It is administered *cold* to the invalid—a tea-cupful at a time, and must on no account be warmed, as the application of even a very slight heat causes its decomposition and the separation of a solid mass of coagulated albumen. This cold extract of flesh is not only much more nutritious than ordinary beef-tea, but also contains a certain quantity of the *red colouring matter* of blood, in which there is a much larger proportion of the iron requisite for the formation of blood particles. The hydrochloric acid also greatly facilitates the process of digestion. This formula is a modification of the one recently recommended by Liebig for the preparation of a highly nutritive and restorative food for invalids.

3. (*Extractum sanguinis bovis*,—Dr. Mauthner.) Pass *fresh blood* (caught from the slaughtered animal) through a sieve, evaporate it to dryness in a water bath, and when *cold*, rub it to powder. *Dose.* 10 to 20 gr., or more, per diem, in a little water.

Obs. The above preparations are intended to supersede the inefficient compounds—beef tea, meat soups, &c., during sickness and convalescence. MM. Breslau and Mauthner describe their extracts of flesh and blood as being peculiarly advantageous in scrofulous exhaustion, exhaustion from anæmia, diarrhœa, &c. The extract of Falkland or Liebig is represented as having been employed both in the hospitals and in private practice at Munich, with the most extraordinary success. It is said to be capable of assimilation with the least possible expenditure of the vital force.

MEATS (Preserved). See *Putrefaction.*

MECHLOIC ACID. This name has been given by Couerbe to the crystalline

mass obtained by passing *chlorine gas* over *fused meconine*. It is purified by removing the chlorine by *oxide of silver*. Before being purified, it is blood red; when pure, it forms white crystals, which are strongly acid.

MECONIC ACID. Syn. *Acidum Meconicum*, — Lat. A peculiar acid, first obtained by Sertuerner from opium, in 1804.

Prep. (Gregory.) *Meconate of lime* or of *potassa*, 1 part, is dissolved in a mixture of *water*, 21 parts, and *hydrochloric acid*, 3 parts, at a temperature a little below 212° Fahr.; *acid meconate of potassa* or *lime* is deposited as the solution cools, which, on being treated a second time in the same way, yields nearly pure *meconic acid*. Its purity is ascertained by its leaving no residue when heated in a platinum or glass capsule.

Prop. Meconic acid forms beautiful pearly scales; possesses a sour astringent taste; is soluble in 4 parts of hot water, and in cold water, and in alcohol. Its solution is decomposed at a boiling heat, and also by animal charcoal. At 248° Fahr. it is decomposed, and *pyromeconic acid* formed along with other products. With the acids it forms salts called *meconates*, most of which are crystallizable. *Meconate of lime* is obtained by heating a solution of chloride of calcium with an infusion of opium made with cold water, and collecting the precipitate. *Meconate of potassa* is prepared by direct solution of the base in the impure acid obtained from meconate of lime till the liquor turns green, heat being applied, when the salt crystallizes out as the liquid cools; it may be purified by pressure, and recrystallization.

Tests. Meconic acid is *characterized* by —1. Precipitating the sesquisalts of iron *red*, and the red colour *not* being destroyed by the action of corrosive sublimate.—2. Precipitating a weak solution of ammonio-sulphate of copper *green*. — 3. With acetate of lead, nitrate of silver, and chloride of barium, it gives white precipitates, which are soluble in nitric acid.—4. It is not reddened by chloride of gold. The above precipitates are all *meconates* of the given bases.

MECONINE. A white crystalline, odourless, neutral substance, discovered by Couerbe in opium. It remains in solution when an *aqueous infusion of opium* is precipitated by *ammonia*. It may be obtained by evaporating the *residual liquor*, and purifying the solid matter thus obtained by alternate solution in *alcohol*, *water*, and *ether*. It forms white prisms, and is *distinguished* from *codeia* and *morphia* by the absence of alkaline properties, and also from the latter by its fusibility, its greater solubility in water, and in not being turned blue by the sesquisalts of iron. Chlorine gas passed over fused meconine turns it blood red. Neither meconine nor meconic acid appears to exercise any important physiological action on the human frame, and are of comparatively small importance both in pharmacy and chemistry.

MECONIUM. See *Opium*.

MEDALS, *coins*, and similar objects, may be conveniently and accurately *copied* by means of electricity, but more quickly, by one or other of the following methods :—

1. (G. Osann.) Reduce *recently precipitated* and *well-washed oxide of copper* by means of *hydrogen* passed over it at a gentle heat; the operation being conducted in a glass tube, the one end is left partially open to permit of the escape of the newly formed water; as soon as the powder assumes a fine copper-red colour, it must be immediately removed, and kept in a well-stoppered bottle. For *use*, the medal is placed on a layer of smooth sand, at the bottom of a small cylinder of white iron, and the sifted copper powder is poured on to the depth of about 10 or 12 lines, and then gently compressed with a massive iron cylinder, after which the whole must be placed on an anvil, and struck with a heavy hammer till the powder is no farther compressible. The newly formed cast is then removed from the cylinder with due care, and heated to a red-white heat in a small copper-box, well luted with clay to exclude the air; after which the whole is left to cool. A solid copper medal is thus very quickly obtained. The recently reduced oxides of other metals (*silver*, *gold*, *lead*, &c.) may be substituted for oxide of copper.

2. (Shaw.) Melt a little *isinglass glue* with *brandy* (or *proof spirit*), and pour it thinly over the medal, so as to cover its whole surface; let it remain on for a day or two, or until it has become thoroughly dry and hard, when it will be fine, clear, and as hard as a piece of Muscovy glass, and will have a very elegant impression of the coin. It has also the property of resisting the effects of damp air, which occasions all other kinds of glue to soften and bend, if not prepared in this way. If the wrong side of the isinglass is breathed on, and gold-leaf immediately applied, the latter will adhere, and be seen on the other side, producing a very pleasing effect.

Obs. Medals may also be copied by sur-

rounding them with a hoop of paper, and pouring on them *plaster of Paris* (mixed with water to the consistence of cream) to the depth of about ½ an inch. *Melted wax, stearine, fusible metal, sulphur, amorphous sulphur*, and several other similar materials, are used in the same way. See *Moulds, Sulphur, Wax, Voltatype, &c.*

MEDALLIONS. See *Medals, Bronzing, &c.*

MEDECINE NOIR. A celebrated French nostrum, consisting of a mixture of *tamarinds, manna, glauber salts*, and *senna.*

MEDICINE. However skilful the medical practitioner may be, and however judicious his treatment, both are interfered with, and their value more or less neutralized, if the remedies he orders are not administered precisely according to his instructions. "It is the duty of the attendant on the sick to follow implicitly the directions of the physician, as well in exactly complying with his orders, as in doing nothing that she has not been ordered to do. At the same time, there are exceptions to this rule, in which a suspension of the remedy, or a deviation from the order of the physician, is not only allowable, but is absolutely required. Thus, from idiosyncrasy or some other cause, the remedy in the doses ordered may have no effect, or may produce one widely different from that intended or expected. In such cases, it is evident that a strict adherence to the directions of the physician would be productive of evil; but he should be immediately apprised of the circumstance." The common practice of neglecting to administer the *doses* of medicine at the prescribed time, or after prescribed intervals, and then, to compensate for the omission, giving the medicine more frequently or in larger doses, cannot be too severely censured, as destructive to the welfare of the patient, and injurious to the credit of the physician.

For the purpose of *disguising* the *taste of medicines*, or lessening their nauseating properties, Dr. Pollio has recently recommended a means founded on the physiological fact that a *strong impression on the nerves* (whether of vision, hearing, or taste) renders that which follows less perceptible than under the usual circumstances. Instead, therefore, of applying to the mouth agreeable substances after swallowing nauseous medicines, we should prepare it beforehand, in order that the taste of the medicine may not be perceived. *Aromatic substances*, as *orange* or *lemon peel, &c.*, chewed just before taking medicine, effectually prevent *castor oil, &c.*, being tasted. In preparing the mouth for *bitters*, liquorice is the only sweet that should be used, the others creating a peculiarly disagreeable compound taste. (*Revue Médicale.*) At *page* 285, we have noticed the effect of *oil of orange peel* in correcting the nauseating qualities of copaiba. We have since been able still further to test its efficacy. See *Doses, Posology*, and *Prescribing.*

MEDULLINE. The name given by Dr. John to the *porous pith of the sun-flower.* It is soluble in nitric acid. It is a pure form of lignine.

MEERSCHAUM. Syn. *Ecume de Mer*, —Fr. A silicated carbonate of magnesia. It has a sp. gr. ranging between 2·6 to 3·4; is readily acted on by acids, and fuses before a powerful blowpipe into a white enamel. The finest qualities are found in Greece and Turkey. It is used by the Tartars for washing linen. Its principal consumption is, however, in the manufacture of *tobacco-pipes.* The Germans *prepare* their pipes *for sale* by soaking them in *tallow*, then in *white wax*, and finally, by polishing them with *shavegrass.* Genuine *meerschaum pipes* are distinguished from *mock* ones by the beautiful brown colour which they assume after being smoked for some time. Recently, some of the pipemakers have produced a composition clay pipe, which closely resembles meerschaum in appearance, and is "warranted to colour well." This composition, which is comparatively valueless, is made up into pipes of suitable patterns, which are frequently sold to the ignorant for "meerschaums."

MEGRIM. Syn. *Hemicrania*,—Lat. A pain affecting one side of the head only, often periodic like an ague, and generally of a nervous, hysterical, or bilious character. It is *clavus* when there is a strong pulsation, conveying the sensation of a nail piercing the part. See *Headache.*

MELAM. A curious insoluble powder, discovered by Liebig. It is *prepared* by fusing *sulphocyanide of ammonium* at a pretty high temperature; or, preferably, from a *mixture* of *sulphocyanide of potassium* (perfectly dry), 1 part, and *sal ammoniac*, 2 parts, treated in the same manner. The residuum in the retort, after being washed with water, is *melam.* It is a pale buff-coloured, amorphous substance, which is insoluble in water, but soluble in oil of vitriol, with partial decomposition.

MELAMINE. A basic substance discovered by Liebig. It is *prepared* by dissolving *melam* in a *mixture* of *hydrate of potassa*, 1 part, and *water*, 20 parts, evaporating the liquid until crystalline scales begin to form, and then allowing it slowly

to cool. The resulting crystals are purified by re-solution and recrystallization. It forms very pale-yellow transparent crystals, which are soluble in hot water, fusible by heat, and may be volatilized with only trifling decomposition. It combines with the acids, and forms crystallizable acidulous salts.

MELAMPYRINE. A tasteless, neutral, crystallizable substance, extracted by Hünefeldt from the *melampyrum nemorosum*.

MELANCHOLY. See *Hypochondriasis* and *Insanity*.

MELANIC ACID. A black powder discovered by Piria, and formed when *salicylide of potassium* is exposed to the air until it turns black. In this state the mass consists of the *acetic* and *melanic acids*. Dr. Marcet applied the same name to an acid principle found by him in *black urine*.

MELANILINE. The action of *dry chloride of cyanogen* upon *anhydrous aniline* gives rise to the formation of a resinous substance, which is the *chlorine-compound of melaniline*. This substance, dissolved in *water* and mixed with *potassa*, furnishes *melaniline* under the form of an oily liquid, which rapidly solidifies to a beautiful crystalline mass.

MELANOCHINE. The name given by Brandes and Leber to a peculiar product resulting from the decomposition of quinine.

MELANOGALLIC ACID. See *Metagallic Acid*.

MELANOTANNIC ACID. A black substance formed by the action of *potassa*, in excess, on *tannin* or *gallic acid*.

MELASSES. See *Treacle*.

MELASSIC ACID. The acid principle existing in *melasses* or *treacle*. It appears to be acetic acid disguised by empyreumatic and extractive matter.

MELASSIC ACID. Syn. *Melasinic Acid*. A product of the decomposition of grape sugar.

Prep. Pour a hot saturated solution of *baryta* or of *caustic potassa* or *soda* on *melted grape sugar*, dissolve, and continue the heat until the mixture turns of a deep brown, then precipitate the liquid with an excess of *hydrochloric acid*, and wash the resulting black powder, first with *dilute hydrochloric acid*, and next with water.

MELINUM. See *Cadmium*.

MELISSIC ALCOHOL. A substance obtained by Brodie from *bees' wax*. By oxidation it yields "*melissic acid*."

MELLAGO. The old name for a medicine having the consistence of honey, with a somewhat sweetish taste. *Mellago taraxaci* is fluid extract of dandelion.

MELLITES. See *Honeys* (Medicated).

MELLITIC ACID. A substance discovered by Klaproth in mellite or honey stone.

Prep. From *mellite* or *honey stone*, reduced to powder, and boiled in about 70 times its weight of *water*; the resulting solution being subsequently filtered, evaporated, and crystallized.

Prop., &c. Small colourless needles; permanent in the air; soluble in both water and alcohol, and in boiling oil of vitriol; reaction, strongly acid. It forms salts, which are called *mellitates* with the bases. Those of the *alkalies* are soluble and crystallizable; those of the *earths*, amorphous and insoluble.

MELLON. A compound of carbon and nitrogen, discovered by Liebig. It remains at the bottom of the retort, under the form of a yellow powder, when *bisulphocyanide of mercury* is exposed to heat. It may in like manner be obtained by exposing *melam*, *ammeline*, *ammelide*, or *dry sulphocyanogen*, to a red heat. It is insoluble in alcohol, water, and dilute acids, and is decomposed by concentrated acids, alkalies, and a strong red heat.

MELTING BAGS. See *Sacculi*.

MELTING POINT. The temperature at which solids assume the liquid form.

MEMORY. We have been assured by an eminent medical man now deceased, that the *long-continued* topical application of *iodine* to the scalp tends to weaken the memory; and if the application be accompanied by seclusion and darkness, to ultimately destroy it. This, he accounted for, by the statement that the memory is localized in the cineritious matter of the brain, which, like the mammæ and testes, according to Reichenau and others, is liable to absorption or emaciation from the long employment of iodine. This use of iodine has, we believe, been proposed in certain forms of madness. See *Aberration* (of mind), *Insanity*, *Iodine*, *&c.*

MENISPERMIC ACID. Boullay has applied this name to a crystalline substance found in *cocculus indicus*. It may be obtained from the *cold infusion* or *decoction* of the seeds, in a similar way to that directed under *absinthic acid*. By repeated solutions and recrystallizations from alcohol it loses its bitter taste, and becomes colourless.

MENISPERMINE. Syn. *Menispermia*, *Menispermina*. A neutral basic substance discovered by Pelletier and Couerbe in cocculus indicus. It may be obtained by the action of *alcohol* on the *powdered seed*.

It is freely soluble in alcohol and ether; insoluble in water; fuses at 248° Fahr.; and forms crystallizable salts with the acids. Hot nitric acid turns it into a yellow resin-like mass. *Paramenispermine* is another similar substance, but differs from the preceding by *not* forming salts with the acids. The above exercise no marked physiological action when swallowed, and possess little interest.

MENSTRUATION. Syn. *Menstruatio*, —Lat. In this country the *menses* or *catamenia* usually make their appearance in the female between the 14th and 18th year; the precise time being greatly influenced by the state of the health, and the worldly condition of the patient. The changes which then occur need not be more than referred to here. The preceding indiposition is in some cases more or less severe, and occurs at each successive period until the discharge becomes habitual and regular. In general, the whole amount lost does not exceed five or six ounces, and the period of the indisposition varies from 2 to 4 days. In a state of perfect health, except during pregnancy or lactation, the monthly recurrence of the discharge falls with great regularity, often precisely to a day, until the fortieth, forty-fifth, or even the forty-eighth year, after which it ceases altogether. Any deviation from this necessary and natural course of things, leads to a corresponding loss of health and physical comfort; and if it is extensive, the most painful and calamitous consequences ensue. To *prevent* such occurrences, care should be taken to maintain the general bodily health at the proper standard. Down beds, hot rooms, late hours, luxurious living, excessive clothing, and the like, should be avoided; but on the other hand, the opposite extreme should not be run into, and above all, anxiety, excessive exertion, and exposure to cold, should be particularly avoided both during and a few days previous to the monthly period.

The principal *diseases* connected with the *menstrual function* are—

Amenorrhœa, or *suppression of the menses*, consists of—1. Their *retention* or non-appearance at the proper period of life, by which the *symptoms* noticed under "*chlorosis*" (see *p.* 247) are induced with greater or less severity. This variety requires the same *treatment* as that disease. —2. *Suppression* arising from *accidental causes* operating at the particular period; as *exposure to cold*, *strong mental emotion*, *excessive grief*, *local constriction*, &c. In these cases, a *hot foot-bath* or *hip-bath*, with a dose of *diaphoretic medicine*, or "*something warm*" on retiring to rest, will in many cases bring on the menses in a few hours. If there is much fever, and this method is not successful, a saline purgative, or, in very severe cases, venesection may be had recourse to. — 3. In *suppression* arising from the *existence* of *other diseases* the primary affection should be at once attended to.

Menorrhagia, *flooding*, or *excessive flow of the menses*, is an affection exactly the reverse of the preceding. The common *causes* are violent exertion, sudden surprises or frights, violent passion, plethora, profuse evacuations, and external injuries, as blows, bruises, &c. The *treatment*, in mild or passive cases, should include rest in the horizontal position, a light, nutritious, but non-exciting diet, the use of weak acidulous drinks, and the local application of cold, with cooling saline laxatives as occasion may require. In robust habits depletion is often necessary. In *severe cases*, a more active line of treatment must be adopted, and powerful internal astringents, as *acetate of lead* and *opium*, may be taken; remedies which should, however, be only had recourse to under proper medical advice.

MENSTRUUM. A solvent or dissolvent. The principal *menstrua* employed in chemistry and pharmacy to extract the active principles of bodies by digestion, decoction, infusion, or maceration, are *water*, *alcohol*, *oils*, and *solutions of the acids* and *alkalies*.

MENTHENE. A colourless, ethereal oil, obtained by distilling a *mixture* of *peppermint-oil camphor* and *anhydrous phosphoric acid*.

MENYANTHINE. See *Inuline*.

MEPHITIC ACID. See *Carbonic Acid*.

MEPHITIC AIR. See *Nitrogen*.

MERCAPTAN. Syn. *Hydrosulphuret of Sulphuret of Ethyle*. An ethereal liquid, discovered by Zeise.

Prep. A *solution of caustic of potassa* (sp. gr. 1·28) is saturated with *sulphuretted hydrogen*, then mixed with an equal volume of a *solution*, of the same density, of *sulphovinate of lime*, and next submitted to distillation in a chloride of sodium bath, the retort being connected with a receiver surrounded with *ice*; the distillate consists of *mercaptan* floating on some water; the former is separated, and after digestion on a little *chloride of calcium*, is agitated and rectified along with a little *red oxide of mercury*.

Prop., &c. Limpid, colourless, ethereal; sp. gr. 0·842; very slightly soluble in water; freely soluble in alcohol; boils at

97° Fahr.; very inflammable; colour of flame, blue. Its most remarkable properties are its intense odour of garlic (which adheres to the clothes and person of the operator with extraordinary obstinacy), and its violet action on *red oxide of mercury*, even in the cold. The product of their reaction may be obtained from the alcoholic solution in a crystalline form. Similar compounds are formed with the oxides of *copper*, *gold*, *lead*, and *silver*, when their solutions are added to an *alcoholic solution of mercaptan*.

MERCAPTAN (Methyle). This closely resembles the last, and is obtained by simply employing *sulphomethylate of potassa* instead of sulphovinate of potassa. It boils at 68° Fahr. *Amyl-mercaptan* has also been formed.

MERCURIAL BALSAM. See *Ointment of Nitrate of Mercury*.

MERCURIAL DISEASE. Syn. *Morbus Mercurialis*, *Hydrargyriasis*, — Lat. This results from the injudicious or excessive use of mercury, or exposure to the fumes of this metal. The common and leading *symptoms* are a disagreeable coppery taste; excessive salivation; sponginess, tumefaction, and ulceration of the gums; swollen tongue; loosening of the teeth; exfoliation of the jaws; remarkably offensive breath; debility; emaciation; ending (when not arrested) in death from exhaustion. Fever, cachexia, violent purging and griping, a species of eczema (*eczema mercuriale*, *lepra mercurialis*), and other forms of skin disease, are also phases of the same affection; the first of which occasionally proves fatal under the influence of sudden and violent physical exertion.

The *treatment*, in ordinary cases, may consist in free exposure to the open air, avoiding either heat or cold; the administration of saline aperients, as *Epsom salt*, *phosphate of soda*, &c.; the free use of *lemon juice and water* as a common drink; with weak *gargles* or *washes* of *chloride of soda* or *chloride of lime* to the gums, mouth, and throat. Severe cases often resist every variety of treatment, and instances are recorded in the medical journals in which the use of even small doses of mercurials, administered by the faculty, have, owing to the peculiar idiosyncracy of the patients, been followed by the most horrible sufferings, terminating in death.

MERCURY. Syn. *Quicksilver; Hydrargyrum*,—Ph. L. E. & D. *Aqua Argentea*, *A. Metallorum*, *Argentum Vivum*, *Hydrargyrus*, *Mercurius*,—Obs. Lat. The principal sources of this metal are the mines of Idria, in Carniola, and Almaden, in New Castile, where it exists under the form of *cinnabar*. From this ore the pure metal is obtained by distilling it with *lime* or *iron filings*, in iron retorts, by which the sulphur it contains is seized and retained, while the mercury rises in the state of vapour, and is condensed in suitable receivers. Quicksilver is commonly imported in cylindrical iron bottles, containing from ½ cwt. to 1 cwt. each. It is also imported in small quantities from China, contained in bamboo bottles holding about 20 *lb.* each.

Prep. Mercury, as imported, is usually sufficiently pure for medicinal purposes without any further preparation. Mere mechanical impurities, as floating dust, dirt, &c., may be got rid of by squeezing the metal through chamois leather or flannel, or by filtering it through a small hole in the apex of an inverted cone of paper. It now forms *strained mercury* (*hydrargyrum*,—Ph. L.) The Dublin College orders "*hydrargyrum purum*" to be prepared for medical purposes by putting 6 parts of *mercury* into a retort, and distilling off four parts. The whole of the mercury may, however, be safely drawn over. The product is ordered to be agitated and boiled with *hydrochloric acid*, 2 fl. dr., and *water*, 1 fl. oz., for each *lb.* of the metal, and after being well washed with water, to be dried by heat. A strong earthenware or iron retort, with a low neck or tube dipping into a basin of water, may be used for this purpose. One of the *quickest* and *best means* of *purifying mercury* is to well agitate it with a *concentrated solution of nitrate of mercury*, at the temperature of about 112° Fahr., after which it may be washed with distilled water, and dried by passing it several times through clean dry chamois leather.

Prop., &c. Mercury, at all common temperatures, is a heavy liquid, possessing a nearly silver-white colour, and a brilliant metallic lustre; solidifies (*freezes*) at —39° Fahr., and is then ductile, malleable, and tenacious; boils at 662° Fahr. (656°, —Ure), and escapes in colourless transparent vapour, of great density; it also volatilizes slowly at the ordinary temperature of the atmosphere, and when mixed with water at from 140° to 160° Fahr., it is volatilized in considerable quantities. (Stromeyer.) The presence of minute quantities of lead and zinc greatly retard its evaporation at its boiling heat. It unites with oxygen, chlorine, iodine, &c., forming numerous compounds. With the metals it unites to form *amalgams*. The only acids

which act on metallic mercury, are the sulphuric and nitric; but for this purpose the former must be heated and concentrated. Nitric acid, however, even when dilute and in the cold, dissolves it freely. Pure mercury is unalterable in the air at ordinary temperatures. Sp. gr. 13·59 at 60° Fahr.; 15·00 when in the solid state. (Ure.)

Pur. "It is *totally* dissipated by heat, and is *entirely* dissolved by diluted nitric acid; but is insoluble in boiling hydrochloric acid. The acid poured off, and allowed to cool, is neither coloured, nor yields a precipitate with sulphuretted hydrogen" (Ph. L. 1836.) "Its sp. gr. is 13·5." (Ph. L. 1851.) "A globule moved about on a sheet of paper yields no trail; pure sulphuric acid agitated with it (in the cold) evaporates when heated, without leaving any residuum." (Ph. E.)

Tests. 1. *Metallic mercury* is detected by its volatility; and, when in a finely divided or pulverulent state, by the microscope, or by staining a piece of copper white when rubbed on it, or when heated beneath it.

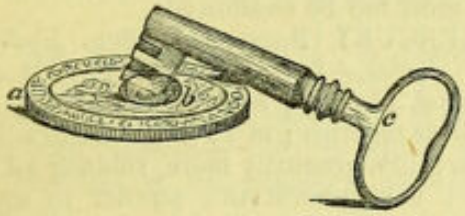
2. The *salts of mercury* are recognized as follows:—

a. They are all volatilized or decomposed by ignition.

b. When intimately mixed with anhydrous carbonate of soda, and heated in a small test tube, under a layer of the carbonate, decomposition ensues, and a crust of gray sublimate forms on the cooler portion of the tube. When examined by a lens, this crust is seen to consist of minute metallic globules. By friction with a bright glass or iron rod, these are united into globules which are visible to the naked eye.

c. Protochloride of tin, added in excess to a solution containing mercury, gives a grayish precipitate of metallic mercury, which may be united into globules by heat and agitation, or more readily, by boiling with hydrochloric acid.

d. A perfectly clean and bright piece of copper immersed in a slightly acid solution of mercury, becomes in a short time covered with a gray or whitish stain, which assumes a silvery lustre when gently rubbed with a piece of soft cork or leather, and is removed by the subsequent application of heat. A *single drop* of liquid may be tested on a *bright copper coin* in this way.



e. The plate of copper with the deposit of mercury, obtained as above, after being washed with a weak solution of ammonia, and in distilled water, and dried by pressure between the folds of bibulous paper, may be cut into small pieces, and heated in a test-tube, in order to obtain metallic globules. When the suspected solution contains organic matter, bright copper filings may be employed, and the process modified so as to nearly resemble Rensch's test for arsenious acid. According to Orfila "scraped copper plate" is capable of detecting the presence of $\frac{1}{80000}$th part of corrosive sublimate in a solution. MM. Trousseau and Reveil state that a plate of yellow copper (brass) is even more susceptible than one of red copper.

f. (Smithson's Galvanic Pile.) This consists of a polished wire or plate of gold or copper round which a strip or thread of zinc or tin is wound in a spiral direction. The suspected liquid is acidulated with a few drops of hydrochloric acid, and after immersion for a longer or shorter period (as half an hour to an hour or two), the gold will have become white if any mercury is present. The coil of zinc or tin is then removed from the gold, and the latter, after being washed, and dried between the folds of bibulous paper, is heated in a test-tube, to obtain metallic globules, as before. *Susc.* $\frac{1}{90000}$ of corrosive sublimate.

g. (MM. Danger & Flandin.) The apparatus of these eminent chemists depends upon the same principle as the preceding. It consists of a vessel tapering at its lower part into a tube with an opening almost capillary, so that the fluid may flow out of it at the rate of about 1 drop in 5 seconds, and then be caught in a capsule for further experiment. The liquid to be tested is placed in this vessel, and a gold wire attached to the electro-positive pole of a Bunsen's battery is placed in it (observing that it passes down into the contracted part), and *another* gold wire attached to the negative pole is introduced into the opening at the lower end of the contracted part. The battery being excited in the ordinary way, a current is established which causes the precipitation of the mercury upon the gold wire attached to the negative pole, and however small may be the quantity of the mercurial compound, it is manifested by this process; and on heating the gold, or treating it by nitric acid, the mercury is removed, and may be examined in any other manner. A false, or tin stain, may be distinguished from a mercurial one by its solubility when the whitened gold is put into concentrated hydrochloric acid. *Susc.* Fully $\frac{1}{100000}$th part of corrosive sublimate, or $\frac{1}{140000}$th part of metallic mercury.

h. An ingenious extemporaneous application of the galvanic test may be made as follows:—Place a drop or two of the

suspected liquid on a clean and bright gold or copper coin, and apply a *bright* key, so that it may at once touch the edge of the coin and the solution. (See *engr.*) A hydro-electric current will then be established as before, and a white spot of reduced mercury will appear on the surface of the metal, which may be recognized in the manner already explained.

a, A gold or copper coin.
b, Drop of suspected solution.
c, A bright key.

3. The *protosalts of mercury* are distinguished by the following reactions :—

a. Sulphuretted hydrogen and hydrosulphuret of ammonia give black precipitates, which are insoluble in dilute acids, hydrosulphuret of ammonia, cyanide of potassium, and hot nitric acid; but are readily dissolved with decomposition by aqua regia.

b. Potassa and ammonia give dark gray or black precipitates, which are insoluble in excess of the precipitant.

c. Hydrochloric acid and the soluble metallic chlorides occasion a precipitate, which assumes the form of a very fine powder of dazzling whiteness, insoluble in excess, but soluble in aqua regia and liquid chlorine. Caustic potassa and ammonia turn it dark gray or black.

d. Iodide of potassium gives a greenish-yellow precipitate, soluble in ether, and subliming in red crystals when heated.

4. The *salts of peroxide of mercury* are known as follows :—

a. Sulphuretted hydrogen and hydrosulphuret of ammonia, added in very small quantities, produce on agitation a perfectly white precipitate, which acquires successively a yellow, orange, and brownish-red colour, as more of the test is added; and, ultimately, when the test is added in considerable excess, an intensely black colour. This precipitate is insoluble in excess of the precipitant, potassa, cyanide of potassium, hydrochloric acid, or nitric acid, even when boiling; but it dissolves readily and completely in sulphuret of potassium, and in aqua regia with decomposition. These reactions are characteristic.

b. Ammonia gives a white precipitate.

c. Potassa gives a reddish precipitate, turning yellow, when the test is added in excess. The presence of ammonia causes the precipitate to be white, and when the solution contains much acid, both reactions are imperfect.

d. Alkaline carbonates give a brick-red precipitate.

e. Iodide of potassium gives a scarlet precipitate, which is soluble in excess, and in alcohol, and solution of chloride of sodium.

f. The alkaline bicarbonates either do not disturb the solution, or only cause a slight degree of opalescence.

5. *Solid* bodies, supposed to contain mercury, may be treated with nitric acid, the solution evaporated to dryness, and the solid residuum dissolved in water, when the filtered solution may be submitted to the usual tests. See *Bichloride of Mercury*.

Uses, &c. Mercury is applied to various purposes in the arts; as the amalgamation of gold and silver, wash gilding, the silvering of looking glasses, the manufacture of barometers and thermometers, and the preparation of several valuable medicines. In its metallic state it appears to be inert when swallowed, unless it meets with much acidity in the alimentary canal, or is in a state of minute division; its compounds are, however, all of them more or less poisonous.

Mercury has been employed in one or other of its forms in almost *all* diseases; but each of its numerous preparations is supposed to have some peculiarity of action of its own, combined with that common to all the compounds of this metal. The mercurials form, indeed, one of the most important classes of the materia medica. See *Mercurial Disease* (and *below*).

MERCURY (Acetate of). Syn. *Protacetate of Mercury; Hydrargyri Acetas, H. Acetis*,—Lat. *Prep.* 1. (Ph. D. 1826.) *Mercury*, 9 parts; *diluted nitric acid* (Ph. D.), 11 parts; dissolve, add it to a boiling solution of *acetate of potassa*, 9 parts, dissolved in *water*, 100 parts, and acidulated with *distilled vinegar*; filter the liquid whilst hot, let it cool, wash the crystals that are deposited with *cold water*, and dry them by a very gentle heat.

2. (Ph. L. 1788.) Dissolve *protoxide of mercury* in *strong acetic acid*, and concentrate the solution so that crystals may form as it cools.

3. (P. Cod.) Dissolve *protonitrate of mercury*, 1 part, in *water* (slightly acidulated with nitric acid), 4 parts, and precipitate the liquid with a solution of *acetate of soda*, gradually added, until in slight

excess; carefully wash the precipitate with *cold water*, and dry it in the shade.

Prop., &c. Small white, micaceous, flexible scales; insoluble in alcohol; soluble in about 300 parts of water; blackened by light; and carbonized by a strong heat. It has been said to be one of the mildest of the mercurials; but this cannot be the case, as it occasionally acts with great violence on both the stomach and bowels, producing much pain and prostration. *Dose.* ¼ to 1 gr., night and morning, gradually increased. The *peracetate* (*acetate of peroxide of mercury*), a similar preparation to the above, is made by dissolving red oxide of mercury in strong acetic acid. According to Robiquet, this is the basis of *Keyser's antivenereal pills*, which do not contain protacetate of mercury, as some parties have asserted.

MERCURY (Ammonio-chloride of). Syn. *White Precipitate, Lemery's do., Cosmetic Mercury, Amido-chloride of Mercury, Chloramide of do., Chloro-amidide of do., Ammoniacal Oxychloruret of do., White Oxide of do., Chloride of Ammonium and Mercury; Hydrargyri Ammonio-chloridum*,—Ph. L. *Hydrargyrum Præcipitatum Album*,—Ph. L. 1824, & Ph. E. *Hydrargyri Submurias Ammoniatum*,—Ph. D. 1826. *Calx Hydrargyri Alba*,—Ph. L. 1788. *Mercurius Præcipitatus Albus*,—Ph. L. 1745. This compound originated with Raymond Lully in the thirteenth century.

Prep. 1. (Ph. L.) *Bichloride of mercury*, 6 oz.; *distilled water*, 3 quarts; dissolve, with heat, and when the solution has cooled, add of *liquor of ammonia*, 8 fl. oz., frequently shaking it; lastly, wash the precipitate with *water*, and dry it. The formulæ of the Ph. E. & D. are nearly similar.

2. (Ph. D. 1826.) Add to the *liquor poured off from precipitated calomel* as much *solution of caustic ammonia* as may be required to throw down the metallic salt; which is then to be washed with *cold water*, and dried on bibulous paper.

3. *Corrosive sublimate* and *sal ammoniac*, of each, ½ *lb.*; *water*, 3 quarts, dissolve, and precipitate with *liquor of potassa*, q. s. Some use only 5 *oz.* of sal ammoniac.

Prop., &c. A white, inodorous, light mass, or powder; insoluble in alcohol, partially soluble in boiling water, and wholly dissolved by sulphuric, nitric, and hydrochloric acids, without effervescence. It is "totally dissipated by heat. Digested with acetic acid, it yields no yellow or blue precipitate with iodide of potassium. Its powder, triturated with lime water, does not become black. When heated with solution of potash it exhales ammonia, and assumes a yellow colour." (Ph. L. 1836.) *Used* to make an ointment, which is employed in herpes, porrigo, itch, and other skin diseases, &c.; and by the lower orders, as a dusting powder to destroy pediculi, an application which, from its liberal employment, is not always a safe one. It is *highly poisonous*, and must not be swallowed.

MERCURY (Borate of). Syn. *Hydrargyri Boras*,—Lat. *Prep.* (Van Mons.) *Calomel*, 11 parts; *borate of soda*, 13 parts; triturate together; in 15 minutes add a little *water*, then gradually more, rubbing all the time; next permit the powder to settle, collect it on a filter, wash it, and dry it.

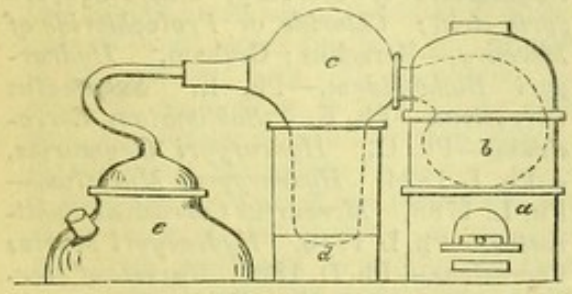
Prop., &c. A white, insoluble powder. *Dose.* 1 to 3 gr.; in similar cases to those in which calomel is given.

MERCURY (Bromide of). Syn. *Protobromide of Mercury; Hydrargyrum Bromidum*,—Lat. *Prep.* (Magendie.) By precipitating a *solution of protonitrate of mercury* by another of *bromide of potassium*. It closely resembles calomel in both its appearance and properties. *Dose.* 1 to 5 gr.

MERCURY (Bibromide of). Syn. *Perbromide of Mercury; Hydrargyri Bibromidum*,—Lat. *Prep.* 1. Formed by dissolving *precipitated peroxide of mercury* in *hydrobromic acid*.—2. (Magendie.) *Bromine* and *mercury*, equal parts; mix, and sublime. Soluble. It resembles the biniodide in its action. *Dose.* $\frac{1}{20}$ to $\frac{1}{8}$ gr.

MERCURY (Chloride of). Syn. *Protochloride of Mercury, Calomel; Hydrargyri Chloridum*,—Ph. L. *Hyd. Chlor. Mite*,—Ph. U. S. *Hyd. Submurias*,—Ph. L. 1824. *Calomelas*,—Ph. E. & D.; & Ph. L. 1788. *Dichloride of Mercury, Subchloride of do.*,—Berzelius, Graham, and others. *Submuriate of Mercury, Sweet Mercury, S. Precipitate of do., S. Sublimate of do., Aquila Alba, Drago Mitigatus, Hydrargyrum Muriaticum Mite, Manna Metallorum, Mercurius Dulcis, Panchymagogum Minerale*,—Obs. var. This substance is one of the best known, and probably the most valuable of all the mercurials; but is, unfortunately, burdened with a long list of synonyms, which those who have endeavoured to introduce the nomenclature of modern chemistry into pharmacy, have in no small degree contributed to confuse.

Prep. 1. (Ph. L.) Mercury, 2 lb; *sulphuric acid*, 21½ fl. oz. (3 lb, — Ph. L. 1836); mix, boil to dryness (in a cast-iron vessel), and when the resulting *bi-*



persulphate has cooled, add of *mercury*, 2 lb, and triturate the ingredients in an earthenware mortar until they are well mixed; then add of *chloride of sodium*, 1½ lb, and again triturate until the globules are no longer visible; next sublime the mixture, reduce the sublimate to the finest possible powder, diligently wash it with *boiling distilled water*, and dry it. *Prod.* 117 to 118% of the weight of mercury employed.

2. (Ph. E.) *Mercury*, 4 oz., is dissolved in a mixture of *oil of vitriol*, 2 fl. oz. 3 fl. dr., and *nitric acid*, ½ fl. oz., by the aid of heat; when cold, *mercury*, 4 oz., is added, and the remainder of the process is conducted as before.

3. (*Calomelas Sublimatum*, — Ph. D.) *Persulphate of mercury*, 10 parts; *mercury*, 7 parts; *dry chloride of sodium*, 5 parts; triturate, &c., as before, and afterwards resublime it into a large chamber or receiver.

4. (*Apothecaries' Hall, London.*) *Quicksilver*, 50 *lb.*, and *oil of vitriol*, 70 *lb.*, are boiled to dryness in a cast-iron vessel; of the *dry salt*, 62 *lb.* are triturated with *quicksilver*, 40½ *lb.*, until the globules are extinguished, when *common salt*, 34 *lb.*, is added, and after thorough admixture, the whole is sublimed, &c., as before. *Prod.* 96 to 100 *lb.*

5. (*Jewel's patent process.*) The receiver, which is capacious, is filled with *steam* so that the calomel vapour is condensed in it in a state of extremely minute division. The *engr.* represents the apparatus now usually employed when this plan is adopted. The *product* is extremely white, and of the finest quality. It is sometimes called "*hydrosublimed calomel*" and "*hydrosublimate of mercury.*" The "*flowers of calomel,*" of old pharmacy, were prepared in a nearly similar manner.

a, Furnace.
b, An earthenware retort, having a short and wide neck, containing the ingredients for making calomel.
c, An earthen receiver having 3 tubulatures.
d, A vessel containing water.
e, A steam boiler.

6. (Soubeiran.) The crude *calomel mixture* is heated in an *earthern tube* in a furnace, and a *current of air* is directed uninterruptedly into the tube by means of a small ventilator. This sweeps away, as it were, the vapours of calomel, and in a straight tube will carry them a distance of 60 feet, to avoid which the end of the recipient is immersed in water, by which means the calomel is moistened and falls down. (Compt. Rend. 1842, 665.) This plan, slightly modified, is now extensively adopted in this country.

7. (*Precipitated Calomel; Calomelas Præcipitatum.*) Digest *pure quicksilver*, 9 parts, in *nitric acid* (sp. gr. 1·20 to 1·25), 8 parts, until *no more metal will dissolve*, applying heat as the effervescence ceases; then mix the hot liquid *quickly* with a *boiling solution* of *common salt*, 8 parts, dissolved in *water* (slightly acidulated with hydrochloric acid), 64 parts; lastly, well wash the precipitate in *boiling distilled water*, and dry it. The *product*, when the process is skilfully managed, is perfectly white and pure. The formula of the Ph. D. 1826, is essentially similar.

Prop. A heavy, white, tasteless powder; insoluble in water, alcohol, and cold dilute nitric acid; volatilizes at a temperature below redness, and yields a white or yellowish-white sublimate; hot nitric acid oxidizes and dissolves it; alkalies and their carbonates, and lime water, decompose it, with the production of the black oxide; caustic ammonia converts it into a dark slate-gray coloured powder (*black precipitate*, — Kane). Sp. gr. 7·14 (Boullay; 7·156,—Pelouze & Fremy; 7·176,—Ure).

Pur. Calomel is frequently contaminated with small quantities of the bichloride or subnitrate of mercury. The *first* may be detected by digesting a little of it in alcohol, decanting the clear portion, and testing it with a drop or two of liquor of potassa, when a reddish precipitate will be formed, if any bichloride be present. The *subnitrate* may be detected by digestion in dilute nitric acid, and the addition of a little liquor of potassa, as before, when a similar precipitate will fall down if it be contaminated with this salt. "It is pulverulent, whitish, and sublimes (entirely) by heat. It becomes black on the addition of potassa, then heat being applied, it runs into globules of mercury. Neither nitrate of silver, lime water, nor sulphuretted hydrogen being added to the water in which it has been washed or boiled, throws down anything." (Ph. L.) "Ether agitated with it, filtered, and then evaporated to dryness, leaves no crystalline residuum, and what

may be left is not turned yellow with liquor of potassa." (Ph. E.)

Tests. See *Mercury.*

Uses. Calomel is one of the milder mercurials, and in this respect, takes its position immediately after *blue pill, quicksilver with chalk*, and the *gray oxide;* but it probably ranks before all the other salts of mercury. Universal experience appears to show it to be a most valuable *alterative*, when judiciously administered. With this intention it is given in *doses* of ¼ to 1 gr., generally combined with antimonials, as in Plummer's pill, and repeated every night, or every other night, for some time, followed by a mild saline aperient in the morning. As a *purgative*, 2 to 5 gr., either combined with or followed by other purgatives, as jalap, rhubarb, senna, colocynth, Epsom salt, &c. As a *vermifuge*, 2 to 5 gr. overnight, followed by a sufficient dose of castor oil next morning. *Combined with opium*, it is frequently used in various complaints to produce salivation, or bring the system under the influence of mercury. It is also employed as a *sedative* and *errhine*, and in a vast number of other indications. It is, indeed, more *frequently* used, and in a *greater variety* of complaints, than probably any other medicine.

Obs. Of the two methods of preparing calomel, that by *precipitation* is not only the best, but the most economical. That by *sublimation*, is, however, the one generally adopted in England. Mr. Brande states that "a small portion of chloride of sodium is *apt* to remain combined with it, which *might* affect its medical uses." Such a contamination is not found in carefully prepared "precipitated calomel," although we doubt whether the quantity of it which exists in any of the samples we have met with, (being merely a trace,) would at all interfere with its therapeutical action; more especially when it is recollected that alkaline chlorides are present in, not merely the primæ viæ, but also in every part of the animal body. The late Mr. Fownes, a chemist who was unsurpassed in the accuracy of his researches, and the caution and delicacy with which he expressed his opinions, once assured us that calomel was more easily and cheaply prepared of the best quality by precipitation than by sublimation; and that if from careless manipulation it occasionally contained a minute quantity of common salt, this was of much less importance than the contamination of corrosive sublimate which was frequently present in samples of sublimed calomel.

To produce a superior article of calomel in the *dry way* is a somewhat difficult task, and the process frequently fails in the hands of inexperienced operators. The solution of the quicksilver is best made in an iron vessel, and the sublimation should be conducted (*preferably*) in an earthenware retort with a *short* but *very wide* neck, and fitted to a spacious receiver, having a large flat bottom, also of earthenware, and containing a little *cold water.* On the *small scale*, the heat may be applied by means of a sand-bath. The form above given for *calomel, by precipitation*, produces a large product, perfectly free from corrosive sublimate and subnitrate of mercury, and is consequently free from the objections frequently raised against that mode of preparing it.

"The form in which calomel sublimes depends much upon the dimensions and temperature of the subliming vessels. In small vessels it generally condenses in a crystalline cake, the interior surface of which is often covered with beautiful quadrangular prismatic crystals, transparent, and of a texture somewhat elastic or horny. In this state it acquires, by the necessary rubbing into powder, a decidedly yellow or buff colour, more or less deep, according to the degree of trituration it has undergone. If, on the contrary, the calomel be sublimed into a very capacious and cold receiver, it falls in an impalpable and perfectly white powder, which requires only one elutriation to fit it for use; it then remains perfectly colourless." (Brande.)

The long-continued action of steam on calomel in a state of minute division, is attended by the formation of a small quantity of corrosive sublimate. (Righini.) Boiling water, hot air, and light, also produce a like effect.

MERCURY (Bichloride of). Syn. *Perchloride of Mercury, Corrosive Sublimate, Oxymuriate of Mercury, Chloro-hydrargyric Acid; Chloride* or *Protochloride of Mercury*,—Berzelius; Graham. *Hydrargyri Bichloridum*,—Ph. L. *Sublimatus Corrosivus*,—Ph. E. *Sublimatum Corrosivum*,—Ph. D. *Hydrargyri Oxymurias*,—Ph. L. 1824. *Hydrargyrus Muriatus*,—Ph. L. 1788. *Mercurius Corrosivus Sublimatus*,—Ph. L. 1746. *Hydrargyri Murias Corrosivus*,—Ph. D. 1826. *Muriate of Mercury, Corrosive do. do., White Mercury*,—Obs. var. This is the "corrosive sublimate" of the shops.

Prep. 1. (Ph. L.) *Mercury*, 2 lb; *sulphuric acid*, 21½ fl. oz. (3 lb,—Ph. L. 1836); boil to dryness, and rub the residuum of *bipersulphate of mercury*, when cold, with *chloride*

of sodium, 1½ lb, in an earthenware mortar; lastly, sublime by a gradually increased heat.

2. (Ph. E.) *Quicksilver*, 4 oz.; *sulphuric acid*, 2 fl. oz. 3 fl. dr.; *pure nitric acid*, ½ fl. oz.; dissolve, add of *chloride of sodium*, 3 oz., and sublime, as before.

3. (Ph. D.) *Persulphate of mercury*, 2 parts; *dried chloride of sodium*, 1 part; triturate, &c., as before.

Prop. The corrosive sublimate of commerce occurs in white, semi-transparent, crystalline masses, of considerable density; it possesses an intense coppery taste; is soluble in about 19 parts of cold, and in 3 parts of boiling water ("in its own weight,"—Ure); the boiling solution deposits its excess of salt in long white prisms as it cools; soluble in 7 parts of cold alcohol (2¼ parts,—Ure), and in 3½ parts of boiling alcohol; very soluble in ether, which has even the property of withdrawing it from its aqueous solutions; the addition of hydrochloric acid, sal ammoniac, or camphor, increases its solubility in all these menstrua. It is decomposed by contact with nearly all metallic bodies, and in solution, by various organic substances, and by exposure to light. Sp. gr. 5·2 (5·14,—Ure; 5·14 to 5·42,—Liebig). It melts at about 509° Fahr., and boils and volatilizes at a higher temperature.

Pur. "Crystalline, liquefies by heat, and quickly (and entirely) sublimes. It is (entirely) soluble in water, rectified spirit, and ether. What is precipitated from the watery solution, on the addition of potassa, soda, or lime-water, is reddish; but when these are added more abundantly it is yellowish. This (yellow substance), when heated, evolves oxygen, and runs into globules of mercury." (Ph. L.)

Tests. By the tests noticed at *p.* 769, the presence of corrosive sublimate as a *persalt of mercury* is, under most circumstances, readily detected. To show that this persalt exists under the form of *bichloride* we must apply the tests for chlorine or hydrochloric acid. If, on filtering the solution, acidulating it with dilute nitric acid, and testing it with nitrate of silver, a cloudy white precipitate be formed, which is insoluble in excess of the precipitant, and in nitric acid, but soluble in ammonia water, and blackened by lengthened exposure to light, corrosive sublimate is shown to be present in the substance examined. Calomel, the only compound of mercury with chlorine besides corrosive sublimate, is an *insoluble* powder, which could not, therefore, be found in the *filtered* liquid. Calomel or the white precipitate formed by the *protosalts of mercury* with hydrochloric acid and the soluble chlorides, is soluble in excess of chlorine, and is not only insoluble in liquor of ammonia, but is *immediately* blackened by it.

For the purpose of *demonstrating* the *presence of corrosive sublimate* in a *highly coloured liquid* or one *loaded* with *organic matter*, it is necessary to agitate it for some minutes with an equal volume of *ether*. After repose for a short time the ethereal solution is decanted, and allowed to evaporate spontaneously. The residuum (if any) contains the corrosive sublimate, which after being dissolved in *distilled water*, is readily recognized by the above characteristics.

When the substance under examination consists of food, or the contents of the digestive canal, or of animal tissue, it is in general necessary to destroy the organic matter in a nearly similar way to that described under "*testing for arsenious acid.*" The process adopted by M. Devergie for this purpose consists in dissolving the substance in *concentrated hydrochloric acid*, and passing a *stream of chlorine* through the liquid.—M. Flandin first carbonizes the mass with ⅓ or ½ its weight of *concentrated sulphuric acid*, at 212° Fahr., and then saturates the acid in the cold, with *dry chloride of lime*, added in fragments, assisting the action by stirring, and further adding, by degrees, as the matter thickens and becomes white, a sufficient quantity of *distilled water*.—M. Lassaigne boils the suspected mixture for some time with a *solution of chloride of sodium*; a method which, according to Orfila, is not sufficiently delicate to withdraw minute portions of mercury from flesh.—M. Millon agitates organic liquids (more especially *blood*, *milk*, &c.) in large flasks containing *gaseous chlorine*, which is frequently renewed. — M. Orfila either dissolves the matter in *aqua regia*, and passes a *stream of chlorine* through the liquid, or he carbonizes it by means of *concentrated sulphuric acid*, in close vessels.—M. Personne proceeds by a similar method, but avoids raising the temperature of the substances operated on.—M. Reveil employs either the last method or that of M. Millon. In all cases it is advisable to operate in close vessels, on account of the volatility of the bichloride. M. Orfila's apparatus consists of a mattras, provided with a bent tube, the one end of which is plunged into a jar of cold distilled water. The corrosive sublimate is found both in the volatilized matter, and in the carbonized residuum;

and is extracted from the latter by boiling it for 15 or 20 minutes in *aqua regia*.

When the organic matter has been destroyed by any of the above processes, and a colourless and filtered solution in *distilled water* obtained, the usual tests may be at once applied. But in this way, we can only detect the presence of mercury, but are unable to decide in what way it has entered the system, although we may infer it from other circumstances. It is, therefore, *absolutely necessary*, in all medico-legal investigations, to previously employ ether (see *above*), in order that we may be enabled to examine the deleterious matter in its original form, or that in which it was swallowed.

Uses, &c. Bichloride of mercury is employed as an alterative, diaphoretic, and resolvent, in the chronic forms of secondary syphilis, rheumatism, scrofula, cancer, old dropsies, numerous skin diseases, &c.; and *externally*, as a caustic, in cancer, and made into an ointment, lotion, or injection, in a vast number of skin diseases, ulcers, gleet, &c., and as a preventive of contagion. It acts quicker than the other preparations of mercury, and it is less apt to induce salivation; but it has been said that its effects are less permanent. *Dose.* $\frac{1}{16}$ to $\frac{1}{4}$ gr., either made into a pill, or in solution. It is *highly poisonous*, and must be exhibited and handled with the greatest caution. Its use is contra-indicated in cases complicated with pulmonary affections or nervous derangement.

Pois.—1. *Symptoms.* Strong coppery or metallic taste; intense pain in the mouth, pharynx, œsophagus, stomach, and intestines; nausea, vomiting (often bloody), diarrhœa, and (sometimes) violent dysentery (these evacuations are generally more frequent than in poisoning by other metallic compounds). After a certain time, there is generally an abatement of the severity of the symptoms; the circulation becomes slower, the pulse small and thready, the respiration gentle, and the skin cold; syncope then supervenes, and great general insensibility, always commencing at the pelvic extremities; and sometimes convulsions occur; the secretion of urine is generally diminished, sometimes even entirely suppressed; but the patients always urinate if the sublimate has been employed in a very diluted state, and if drinks have been administered. Death often appears to result from the shock to the nervous system, from intense exhaustion, or from mortification or intense inflammation of the primæ viæ. Poisoning by *corrosive sublimate* is distinguished from that by *arsenic*, by "the countenance being flushed, and even swollen; whereas, in poisoning by arsenic, it is usually contracted and ghastly" (Christison); and by "the whitened condition of the epithelium of the mouth." (Pereira.)

2. *Antidotes.*—*White of egg, hydrated persulphuret or protosulphuret of iron*, and *gluten*, are each of them powerful antidotes. White of egg has proved efficacious in numerous cases. (Christison, Thénard, Ure, and others.) It requires the white of one egg to decompose 4 gr. of corrosive sublimate. (Peschier.) The recently precipitated protosulphuret of iron is, however, according to M. Mialhe, the antidote *par excellence*, not only to corrosive sublimate, but to the salts of lead and copper. The *gluten of wheat* has also been recommended (Taddei); or what is equally efficacious, *wheat flour* mixed up with water. When any of the above are not at hand, copious draughts of *milk* may be substituted. *Iron filings* have been occasionally used as an antidote. All these substances should be taken in considerable quantities; the dose should be frequently repeated, and the *general treatment* similar to that in cases of poisoning by arsenic. (See *p.* 93-4.) Vomiting should be, in all cases, immediately induced, to remove, if possible, the poisonous matter from the stomach.

Obs. In preparing corrosive sublimate, as well as calomel, by the common process, the solution of the mercury is usually made in an iron pot, set in a furnace under a chimney, to carry off the fumes; and the sublimation is conducted in an earthen alembic placed in a sand bath; or in an iron pot, covered with a semi-spherical earthen head. Corrosive sublimate may also be made by the direct solution of the *red oxide of mercury* in *hydrochloric acid*, or by bringing its constituents together in the state of vapour. The latter plan was patented by the late Dr. A. T. Thomson. See *Hydrargyro-chlorides*, *Hydrated Sulphuret of Iron*, *Mercury*, *&c.*

MERCURY (Bichloride of,—Albuminated). Syn. *Hydrargyri Bichloridum cum Albumine*,—Lat. *Prep.* From *bichloride of mercury* (in fine powder), 1 dr.; *rectified spirit*, 4 fl. dr.; dissolve, and add, gradually, the *strained white of* 2 *eggs* (previously diluted with an equal volume of *water*), triturating all the time; next place the mortar in *water*, nearly boiling, and continue stirring the mixture until it acquires a sufficient consistence; lastly, spread it on plates, and dry it in warm air. Milder

than corrosive sublimate, but equally effective in double doses.

MERCURY (Bichloride of,—Ioduretted). Syn. *Hydrargyri Bichloridum Ioduretum*,—Lat. *Prep.* (Lassaigne.) Add a *solution of corrosive sublimate* to an *alcoholic solution of iodine* until the colour disappears, then gently evaporate and crystallize. An exceedingly active preparation. *Dose.* $\frac{1}{16}$ to $\frac{1}{8}$ gr. See *Iodo-chloride of Mercury*.

MERCURY (Cyanide of). Syn. *Bicyanide of Mercury, Percyanide of do., Cyanuret of do.; Hydrargyri Bicyanidum*,—Ph. L. 1836. *Hyd. Cyanuretum*,—Ph. D. 1826. *Prussiate of Mercury, Hydrocyanate of do., Cyanodide of do., Prussian Mercury, Hydrargyri Hydrocyanas, Hydrargyrum Borussicum*, &c.,—Obs. var. There is only one compound of cyanogen and mercury, the names of which, as applied by different parties, vary according to their view of the atomic weight of the metal, in a similar way to those of the chlorides, oxides, &c.

Prep. 1. (Ph. L. 1836.) *Percyanide of iron* (pure prussian blue), 8 oz.; *binoxide of mercury*, 10 oz.; *distilled water*, 4 pints; boil for half an hour, filter, evaporate, and crystallize; wash what remains frequently with *boiling distilled water*, and again evaporate that crystals may form. This is Proust's process.

2. (Ph. D. 1826.) *Prussian blue* (pure), 6 parts; *nitric oxide of mercury*, 5 parts; *distilled water*, 40 parts; as the last.

3. (Winckler.) Saturate *dilute hydrocyanic acid* with *binoxide of mercury*; evaporate and crystallize. Pure.

Prop., &c. Heavy, colourless, inodorous, square prisms; tasting strongly metallic; soluble in 8 parts of cold water; slightly soluble in alcohol. Those made by the first two formulæ are of a pale yellow colour. It is "transparent and totally soluble in water. This solution, on the addition of hydrochloric acid, evolves hydrocyanic acid, known by its smell; and a glass moistened with a solution of nitrate of silver, and held over it, gives a deposit soluble in boiling nitric acid. When heated it evolves cyanogen, and runs into globules of metallic mercury." (Ph. L. 1836.) It has been administered in some hepatic and skin diseases, and has been proposed as a substitute for corrosive sublimate. (Parent.) It has been said to act directly on the skin and bones, and to have proved useful in allaying the pain of nodes and in dispersing them. (Mendaga.) It is, however, principally used as a source of cyanogen and hydrocyanic acid. *Dose.* $\frac{1}{16}$ to $\frac{1}{4}$ gr. (beginning with the smaller quantity), made into pills with crum of bread, or in alcoholic solution; as a *gargle* or *lotion*, 10 gr., to water, 1 pint; as an *ointment*, 10 or 12 gr., to lard, 1 oz.

MERCURY (Ferrocyanide of). Syn. *Hydrargyri Ferrocyanidum*,—Lat. A white powder which separates from a *solution of a salt of mercury* on the addition of *ferrocyanide of potassium*. It suffers decomposition almost as soon as precipitated.

MERCURY (Hydrochlorate of). See *Bichloride of Mercury*.

MERCURY (Hydrocyanate of). See *Cyanide of Mercury*.

MERCURY (Iodate of). Syn. *Hydrargyri Iodas*,—Lat. *Prep.* Precipitate a *solution of mercury in nitric acid* with a solution of *iodate of potassa*. A yellow powder resembling Turpeth's mineral.

MERCURY (Iodide of). Syn. *Protiodide of Mercury, Ioduret of do., Green Iodide of do.; Subiodide of do.*,—Berzelius; Graham. *Hydrargyri Iodidum*,—Ph. L. *Hyd. Iod. Viride*,—Ph. D. *Prep.* 1. Precipitate a *solution of protonitrate of mercury* by another of *iodide of potassium*; wash the precipitate, first in a *solution of chloride of sodium*, and then in *pure water*; lastly, dry it in the shade.

2. (Ph. L.) *Mercury*, 1 oz.; *iodine*, 5 dr.; triturate together, gradually adding of *rectified spirit*, q. s. (about 1 to 2 fl. dr.), until globules are no longer seen; dry the powder by a gentle heat, in the shade, as quickly as possible, and preserve it in a well-stopped black-glass vessel. The formula of the Ph. D. is similar.

Prop., &c. A heavy, greenish-yellow powder; insoluble in water, alcohol, and a solution of common salt; soluble in ether, and slightly so in an aqueous solution of iodide of potassium. "Freshly prepared it is yellowish. Heat being cautiously applied it sublimes in red crystals, which quickly turn yellow, and, on access of light, blacken. It is insoluble in a solution of chloride of sodium." (Ph. L.) The process of the Ph. L. does not answer when larger quantities than 4 or 5 *oz.* are prepared at once; owing to the great heat generated by the reaction of the ingredients, and the consequent volatilization of a portion of the iodine, by which the colour of the product suffers. *Dose.* $\frac{1}{8}$ to 1 gr., made into pills; "in syphilis and scrofula, especially where they occur in the same individual." (Pereira.) It is also used *externally*, in the form of ointment. It is *very poisonous*.

MERCURY (Biniodide of). Syn. *Periodide of Mercury, Deutiodide of do., Red Iodide of do.; Iodide* or *Proti-*

tiodide of do.,—Berzelius; Graham. *Prep.* 1. (Ph. L. 1836.) *Mercury*, 1 oz.; *iodine*, 10 dr.; *rectified spirit*, q. s. (2 or 3 fl. dr.); triturate until the globules of mercury disappear, and the mixture assumes a scarlet colour, then dry it in the *shade*, and preserve it in a well-stoppered vessel.

2. (Ph. E.) *Mercury*, 2 oz.; *iodine*, 2½ oz.; *spirit*, q. s.; triturate together as last, dissolve the product, by brisk ebullition, in *concentrated solution of chloride of sodium*, 1 gall., filter whilst boiling hot, wash the crystals that are deposited as the solution cools, and dry them.

3. (Ph. D.) *Bichloride of mercury*, 1 *oz.*; *hot distilled water*, 25 fl. oz.; dissolve; *iodide of potassium*, 1¼ oz.; *water*, 5 fl. oz.; dissolve; when the solutions are cold, mix them, collect the precipitate on a paper filter, drain it, wash it with *distilled water*, 10 fl. oz., and dry it at a heat not above that of boiling water.

Prop., &c. A bright scarlet powder, soluble in alcohol, and in the solutions of several of the iodides and chlorides. It is also soluble in cod-liver oil, and in several other fixed oils. (Pharm. Journ., xiii, 188.) *Dose.* $\frac{1}{16}$ to ¼ gr., dissolved in alcohol or made into a pill; in the same cases as the subiodide, from which it differs chiefly in its greater energy, and *poisonous* qualities.

Obs. The last is the most convenient process; but the Edinburgh formula produces the most sightly preparation. The treatment with a solution of common salt, may, however, be applied to biniodide of mercury prepared by any other process. Not more than 4 or 5 *oz.* can be conveniently prepared at a time by direct admixture of the ingredients, as in the first process, for the reasons already stated. "By heat, cautiously applied, it is (entirely) sublimed in scales, which soon become yellow, and afterwards, when they are cold" (or at once if touched by a hard body), "red. It is partially soluble in boiling rectified spirit, and the solution affords crystals as it cools. It is alternately dissolved and precipitated by iodide of potassium and bichloride of mercury. It is completely soluble in a solution of chloride of sodium." (Ph. L. 1836.) "Entirely soluble in 40 parts of a concentrated solution of muriate of soda at 212°, and is again deposited in fine red crystals on cooling." (Ph. E.)

The bright yellow powder that forms when a mixed solution of *protonitrate* and *pernitrate of mercury* (the latter in excess) is treated with another of *iodide of potassium*, is said to be "*sesquiodide of mercury*." It should be purified by digestion in a concentrated solution of common salt, and then washed and dried.

MERCURY (Iodo-chloride of). Syn. *Iodo-hydrargyrate of Chloride of Mercury; Hydrargyri Iodo-chloridum*,—Lat. *Prep.* (Boutigny.) *Crystals of calomel* are suspended in a stoppered bottle, at the bottom of which is placed some *iodine*; after a time the crystals assume a red colour, and are then removed, and preserved in a well-stoppered bottle.

MERCURY (Iodo-bichloride of). Syn. *Chlor-iodide of Mercury, Iodo-hydrargyrate of Bichloride of do.; Hydrargyri Chloro-iodidum, Hyd. Iodo-bichloridum*,—Lat. *Prep.* 1. (Caventou.) *Biniodide of mercury* is dissolved in *rectified spirit* holding an equal weight of *bichloride of mercury* in solution, and the liquid is either gently concentrated so that crystals may form, or it is at once evaporated to dryness.

Obs. The last two preparations possess considerable remedial power in certain complaints, but their precise action has not yet been determined. They are said to combine the properties of their constituents, but to be more active than either of them. *Dose.* $\frac{1}{20}$ to $\frac{1}{10}$ gr. M. Recamier has recommended the last one as a powerful discutient. It is principally used in the form of ointment.

MERCURY (Iodo-cyanide of). See *Iodo-cyanide of Mercury and Potassium.*

MERCURY (Muriates of). See *Chlorides of Mercury.*

MERCURY (Nitrates of). Nitric acid varies in its action upon mercury, according to the temperature. When *cold* and somewhat diluted, only salts of the protoxide or gray oxide are formed; and these are either neutral or subsalts, just as the acid or the metal happens to be in excess. When, however, the nitric acid is concentrated and hot, the mercury is raised to its highest state of oxidation, and a salt of the binoxide or red oxide is produced. Both classes of salts are apt to be decomposed by a large quantity of water, giving rise to insoluble, or sparingly soluble compounds, containing an excess of base, which are rendered more and more basic as the washing is prolonged, or the temperature of the water raised. No less than six solid compounds of nitric acid and the oxides of mercury are named by chemical writers, of which only two, or at most three, are of practical importance.

MERCURY (Protonitrate of). Syn. *Nitrate of Mercury, Nitrate of Suboxide of Mercury, Neutral do.; Hydrargyri Nitras, Hyd. Protonitras*,—Lat. *Prep.* 1. By

digesting *mercury*, in excess, in *cold dilute nitric acid*, observing to remove the short prismatic crystals within a short time after they are formed; these when drained, and redissolved in *water slightly acidulated with nitric acid*, furnish crystals of pure "*neutral protonitrate of mercury*" by cautious evaporation.

2. (P. Cod.) *Quicksilver* and *nitric acid* (sp. gr. 1·320), equal parts; mix in a wide-bottomed glass matrass, and after digestion for 24 hours in a cool situation, remove the crystals which have formed, wash them with a little *nitric acid*, drain them, and preserve them from the air in a stoppered bottle.

Obs. When the above salt is triturated with an excess of chloride of sodium, and water subsequently added, the whole of the mercury is thrown down as calomel, and the filtered supernatant liquid does not contain corrosive sublimate. If this last salt is detected, the salt examined contained peroxide of mercury; and if any basic nitrate of the protoxide was present, the newly formed calomel has a green or gray colour. *Dose.* $\frac{1}{16}$ to $\frac{1}{8}$ gr. It is seldom used internally. A *solution* is sometimes employed as a mild caustic to ulcers; and, more dilute, as a *lotion* in lepra, porrigo, psoriasis, &c.; or made into an *ointment*, in the same diseases. The "*acid nitrate of mercury*" (*hydrargyri nitratis acidum*) of the P. Cod. is made by dissolving *quicksilver* in twice its weight of *nitric acid* (sp. gr. 1·320), and evaporating the solution to 3-4ths of its original weight. Dr. H. Bennett's preparation under the same name is made with similar proportions, but *strong nitric acid* is used, with heat. It is therefore an *acid pernitrate*. Both are employed as *liquid caustics*.

MERCURY (Pernitrate of). Syn. *Nitrate of Peroxide of Mercury; Hydrargyri Pernitras*,—Lat. *Prep.* 1. (*Neutral.*) This can only be obtained by solution of *red oxide of mercury* in excess of *nitric acid*. The solution evaporated in a bell-jar over sulphuric acid or lime, yields crystals which are neutral. The same compound is obtained as a crystalline powder when the *syrupy liquid* is dropped into *strong nitric acid*.

2 (*Bibasic pernitrate of mercury, Dipernitrate of do.*) By dissolving *quicksilver* in excess of *nitric acid*, with heat, until the solution, when diluted with distilled water, ceases to give a precipitate with common salt. It is now a mixed solution of the neutral and bibasic pernitrates; but by evaporation crystals of the latter salt only are deposited. The *acid solution* (before evaporation) is used as a caustic in cancerous, syphilitic, and other ulcerations; but it frequently produces intense pain, and occasionally, the usual constitutional effects of mercury. It was *formerly* given in similar cases to those in which the bichloride is now employed. *Dose.* (Of the dry salt) $\frac{1}{20}$ to $\frac{1}{12}$ gr. This last is the preparation ordinarily referred to under the name "*pernitrate of mercury*."

MERCURY (Subnitrate of). Syn. *Tribasic Pernitrate of Mercury; Dinitrate of do.? Hydrargyri Subnitras*,—Lat. This compound is prepared by saturating *strong nitric acid* with *mercury*, by heat, throwing the solution into *cold water*, and collecting, and drying the precipitate. It is also formed when the *crystallized pernitrate of mercury* is put into *hot water*.

Obs. This preparation is a heavy, yellow powder, but the shade varies according to the heat of the water employed to effect the precipitation, until, at the boiling temperature, the colour is a dull red. It is extensively employed for the *extemporaneous* preparation of the *ointment of nitrate of mercury*, according to the formula on the following label which accompanies each bottle:—"*Hydrarg. subnitras.*" "*Two scruples, mixed with one ounce of simple cerate, make the ung. hydrarg. nit. of the London Pharmacopœia.*" We need scarcely add that this statement, so unblushingly uttered, is a dangerous falsehood. An ointment so made possesses neither the quantity of mercury nor of nitric acid employed in the pharmacopœia preparation, besides wanting many of its most sensible and valuable properties. (Cooley, Chem., iv, 374.)

MERCURY (Oxides of). Of these compounds there are two, which are, perhaps, more clearly distinguished by names indicative of their colour, than by their more recent synonymes.

MERCURY (Protoxide of). Syn. *Oxide of Mercury, Gray Oxide of do., Black Oxide of do.; Dioxide* or *Suboxide of do.*,—Braude; Graham. *Hydrargyri Oxydum*,—Ph. L. 1836. *Hyd. O. Cinereum*,—Ph. L. 1824. *H. O. Nigrum*, —Ph. D. 1826. *Prep.* 1. (Ph. L. 1836.) *Calomel*, 1 oz.; *lime water*, 1 gall.; mix, agitate well together, decant the clear liquid after subsidence, and well wash the sediment with *distilled water;* lastly, drain and dry it, wrapped in bibulous paper, in the air.

2. (Ph. D. 1826.) *Sublimed calomel*, 1 part; *liquor of potassa* (warm), 4 parts; triturate together, &c., as last.

3. (Donovan; Liebig.) Briskly triturate *calomel* in a mortar with *pure potassa*, in

excess; wash it with *cold* water, and dry it in the shade.

Prop., &c. A very dark gray or black powder, rapidly suffering decomposition by exposure to light and air, becoming olive coloured, from a portion being resolved into metallic mercury and binoxide. "Digested for a short time in dilute hydrochloric acid, it remains undissolved, and the filtered liquid is not affected by liquor of potassa, or by oxalate of ammonia. It is totally soluble in acetic acid, and *entirely* dissipated by heat." (Ph. L. 1836.) *As a medicine*, pure protoxide of mercury is *one* of the mildest of the mercurials, and is used both internally and externally; but chiefly, as a fumigant, or made into an ointment. *Dose.* ½ gr. to 3 gr. twice a day.

Obs. The compound sold for the above in the shops, has usually a dirty gray colour, and contains much undecomposed calomel. The beautiful blue-black, or dark slate-blue powder prepared by decomposing calomel with liquor of ammonia, or a mixture of the liquors of ammonia and potassa, as recommended by Mr. Tyson, is not pure protoxide of mercury, and differs from the old preparation known as "Hahnemann's black oxide of mercury" only in containing variable proportions of the *proto-ammonio-chloride*, and in possessing much more power than the pure protoxide.

MERCURY (Binoxide of). Syn. *Deutoxide of Mercury*, *Peroxide of do.*, *Red Oxide of do.*; *Oxide* or *Protoxide of do.*,— Berzelius; Braude; Graham. There are several methods by which this substance may be prepared. The following are those which have been ordered at different times in the pharmacopœias:—

1. By Precipitation,—*Hydrargyri Binoxydum*, Ph. L. 1836. *Bichloride of mercury*, 4 oz.; *distilled water*, 6 pints; dissolve, and add of *liquor of potassa*, 28 fl. oz.; drain the precipitate, wash it in distilled water, and dry it by a gentle heat.

Obs. A bright orange-red powder. It usually contains a little combined water; hence its readier solubility in acids than the oxide prepared by heat. "When heated sufficiently it yields oxygen, and the mercury either runs into globules, or is totally dissipated. It is *entirely* soluble in hydrochloric acid." (Ph. L. 1836.) The preparation of the shops has frequently a brick-red colour, and contains a little *oxychloride of mercury*, arising from too little alkali being used.

2. By Calcination of Metallic Mercury,— *Red Precipitate per se*, *Calcined Mercury*, *Coagulated do.*; *Hydrargyrus Calcinatus*, Ph. L. 1788. The *mercury* is placed in a glass vessel having a narrow mouth and a broad bottom, and exposed to a heat of about 600° Fahr., until it is converted into red scales.

Obs. This process is very tedious and unsatisfactory, as it requires considerable attention, and generally occupies *several weeks* to complete it. It is now obsolete. The *product* has the form of small brilliant scales of a ruby red-colour.

3. By Calcination of Nitrate of Mercury, —*Nitric Oxide of Mercury*, *Red Precipitate*; *Hydrargyri Nitrico-oxydum*, Ph. L. *Hyd. O. Rubrum*, Ph. E. & D. *Hydrargyrus Nitratus Ruber*, Ph. L. 1788. *Mercury*, 3 *lb.*; *nitric acid*, 18 fl. oz. (1½ *lb.*, Ph. L. 1836); *water*, 2 quarts; dissolve by a gentle heat, evaporate to dryness, powder, and calcine this in a shallow vessel, with a gradually increased heat, until red vapours cease to arise. The processes of the Ph. E. and D. are similar, except that the Dublin College directs the evaporation and calcination to be performed in the same vessel, *without powdering* or *stirring* the mass.

Obs. Bright red crystalline scales, which usually contains a little undecomposed pernitrate of mercury; in other respects it resembles the last two preparations. It is more generally used as an *escharotic* and in *ointments*, than the precipitated oxide. It is volatilized by heat without the evolution of nitrous vapours. "It consists of crystalline, shining, red scales; at an intense heat it sublimes and gives out no acid vapours. It is (entirely) soluble in hydrochloric and in nitric acid." (Ph. L.) "Neither lime water nor sulphuretted hydrogen produce any change in water in which it has been boiled." (Ph. L. 1836.) According to Mr. Brande, it contains about 2½ per cent. of nitric acid. According to Mr. Barker, the process of the Ph. D. yields the finest coloured product; but Mr. Brande states, that "the nitrate requires to be *constantly* stirred during the process, which is usually performed in a cast-iron pot." (Man. of Chem.) On the *large scale* the evaporation is generally conducted in a shallow earthen dish, and as soon as the mass becomes dry, a second dish is inverted over it, and the calcination is continued, without disturbance, until the process is concluded. The heat of a sand bath is employed. 100 *lb.* of *mercury* and 48 *lb.* of *nitric acid* (sp. gr. 1·48) yield 112 *lb.* of *red precipitate*. (Brande.)

Uses, &c. Red oxide of mercury, whether obtained by calcination or precipitation, possesses the same general properties. It

is very slightly soluble in water, but sufficiently so to give that fluid an alkaline reaction and a metallic taste. The test of purity given in the Ph. L. 1836, therefore, requires some qualification. It was formerly employed in *medicine* to induce salivation; but is now chiefly used as an escharotic, either in the form of powder or made into an ointment. *Dose.* ⅛ to 1 gr., combined with opium. It is very *poisonous.*

MERCURY (Oxide of,—Hahnemann's). See *Hahnemann's Soluble Mercury.*

MERCURY (Oxide of,—Nitric). See *Binoxide of Mercury.*

MERCURY (Oxide of,—Sulphuric). See *Subsulphate of Mercury.*

MERCURY (Oxymuriate of). See *Bichloride of Mercury.*

MERCURY (Panacea of). Calomel.

MERCURY (Phosphate of). Syn. *Hydrargyri Phosphas, Hydrargyrum Oxydulatum Phosphoricum,*—Lat. *Prep.* Add a *solution of protonitrate of mercury* (slightly acidulated with nitric acid) to a *solution of phosphate of soda*, and wash and dry the precipitate which forms. In its physical characters it closely resembles calomel, than which it is said to be more appropriate in certain cases, especially in secondary syphilis. Alkalies turn it black. *Dose.* ¼ to 1 gr., made into a pill with sugar and aromatics.

MERCURY (Potassio-tartrate of). Syn. *Pressavin's Vegeto-mercurial Salt; Hydrargyri Potassio-tartras,*—Lat. *Prep.* (Van Mons.) To a *boiling saturated solution of nitrate* (protonitrate) *of mercury* add, drop by drop, a *boiling saturated solution of bitartrate of potassa*, as long as a precipitate forms; wash this in *cold water*, dissolve it in *boiling water*, and set the solution aside to crystallize. *Dose.* ½ to 2 gr. It forms the basis of the once celebrated *liqueur de Pressavin*, but is now seldom used. According to Soubeiran, its composition is variable.

MERCURY (Precipitates of).—*Black Precipitate*, Hahnemann's soluble mercury. —*Green do.* (mercurius præcipitatus viridis, lacerta viridis), from equal parts of *quicksilver* and *copper*, separately dissolved in *nitric acid*, the solutions mixed, evaporated to dryness, and then calcined until red fumes cease to arise. Caustic.— *Red do.*, nitric oxide of mercury.—*White do.*, ammonio-chloride of mercury.

MERCURY (Submuriate of). Calomel.

MERCURY (Submuriate of,—Ammoniated). See *Ammonio-chloride of Mercury.*

MERCURY (Subsulphate of). Syn. *Yellow Subsulphate of Mercury, Subpersulphate of do., Tribasic Persulphate of do., Turpeth Mineral, Turbith do., Queen's Yellow; Hydrargyri Subsulphas, H. S. Flavus, Turpethum Minerale; H. Oxydum Sulphuricum,*—Ph. D. 1826. *Prep.* 1. Dissolve *mercury* in an equal weight of *oil of vitriol* by boiling them to dryness, fling the mass into *hot water*, and wash and dry the resulting yellow powder.

2. (Ph. D. 1826). *Persulphate of mercury*, 1 part; *warm water*, 20 parts; triturate together in an earthen mortar, wash well with *distilled water*, drain, and dry it.

Prop., &c. A heavy, lemon-yellow powder, soluble in 2000 parts of cold, and about 600 parts of boiling water. By long-continued washing with very hot water, it loses all its remaining acid, and is at length converted into red oxide of mercury. *Dose.* As an *alterative*, ⅛ to ½ gr.; as an *emetic*, 3 to 5 gr.; as an *errhine*, 1 gr., mixed up with a pinch of liquorice powder or mild snuff. It is a *powerful poison*, and one of the least useful of the mercurial preparations.

Obs. The temperature of the water employed to decompose the persulphate influences the shade of colour of the resulting subsulphate, in a similar manner to that pointed out under the subnitrate. A *sulphate of the gray oxide* (frequently called subsulphate) falls as a white crystalline powder when sulphuric acid is added to a solution of protonitrate of mercury. It is now superseded as a pigment by chrome yellow and orpiment, which are not only more beautiful, but cheaper preparations.

MERCURY (Persulphate of). Syn. *Bipersulphate of Mercury; Hydrargyri Bipersulphas; Hyd. Persulphas,* — Ph. D. 1826. *Prep.* (Ph. D. 1826.) Dissolve *mercury*, 6 parts, in a mixture of *sulphuric acid*, 6 parts, and *nitric acid*, 1 part, by boiling them in a glass vessel, and continue the heat until the mass becomes perfectly dry and white. *Used* to make calomel.

Obs. When 2 parts of mercury are gently heated in 3 parts of sulphuric acid, *protosulphate* of mercury is formed; but if the solution be effected by a strong heat, and the liquid be evaporated to dryness, a *bisulphate of the peroxide* (bipersulphate) results. When this sulphate is thrown into hot water, decomposition ensues, the yellow *subsulphate of mercury* is precipitated, and a portion of the bisulphate, together with some free sulphuric acid, remains in solution. (Liebig.) The above sulphates should be entirely volatilized by heat.

MERCURY (Sulphurets of). Two sul-

phurets of mercury are used in pharmacy and the arts :—

MERCURY (Protosulphuret of). Syn. *Black Sulphuret of Mercury, Sulphide of do., Subsulphide of do., Amorphous Sulphuret of do.; Hydrargyri Sulphuretum, H. S. Nigrum*,—Lat. This falls as a black precipitate when a *solution of protonitrate of mercury* is treated with *sulphuretted hydrogen* or *hydrosulphuret of ammonia*.

MERCURY (Sulphuret of,—with Sulphur). Syn. *Ethiop's Mineral; Hydrargyri Sulphuretum cum Sulphure*,—Ph. L. 1836. *Hyd. S. Nigrum*,—Ph. L. 1824 & Ph. D. 1826. *Hydrargyrus cum Sulphure*,—Ph. L. 1788. *Æthiops Mineralis*, Ph. L. 1745. *Prep.* (Ph. L. 1836 & Ph. D. 1826.) *Quicksilver* and *sulphur*, equal parts, triturated together (in a stone-ware mortar,—Ph. D.) until globules are no longer visible.

Prop., &c. A heavy, insoluble, black powder. It is frequently met with imperfectly prepared, and sometimes adulterated. It is said to be a mixture of bisulphuret of mercury and sulphur, in variable proportions, depending on the length of the trituration. On the *large scale*, it is generally made by melting the ingredients together, and afterwards reducing the mass to fine powder in a mill or mortar. It is said to be vermifuge and alterative, and has been used in some cutaneous and glandular diseases, but appears to be nearly inert. *Dose.* 5 to 30 gr.

Pur. If it contains *free mercury*, it will stain a piece of bright copper or gold *white* when rubbed on it; if it contains *charcoal, blacklead*, or *bone black*, these will remain behind when it is heated; the presence of *black sulphuret of antimony* may be detected by boiling it in hydrochloric acid, and testing the filtered liquid. The sp. gr. indicates whether it contains the proper quantity of mercury. When pure "it is totally dissipated by heat (without incandescence), no charcoal or phosphate of lime being left." (Ph. L. 1836.)

MERCURY (Bisulphuret of). Syn. *Red Sulphuret of Mercury, Factitious Cinnabar, Vermilion; Sulphide* or *Sulphuret of Mercury*,—Brande; Graham. *Hydrargyri Bisulphuretum*,—Ph. L. *Cinnabaris*,—Ph. E. *Hyd. Sulphuretum Rubrum*,—Ph. L. 1824 & Ph. D. *Cinnabaris Factitia*,—Ph. L. 1746. *Prep.* (Ph. L.) *Quicksilver*, 24 oz.; *sulphur*, 5 oz.; melt together, and continue the heat till the mixture swells up, then cover the vessel, remove it from the heat, and when cold, powder, and sublime it. The formulæ of the other Colleges are similar.

Prop., &c. Bisulphuret of mercury has a dark-red semi-crystalline appearance in the mass, but acquires a brilliant scarlet colour by powdering. It is tasteless, odourless, and insoluble. It is chiefly used as a pigment; but it is occasionally employed in medicine as a diaphoretic and vermifuge, and in some cutaneous diseases, and gout. *Dose.* 10 to 30 gr.; as a *fumigation* about ½ dr. is thrown on a plate of iron heated to *dull* redness. For the last purpose it is inferior to the gray oxide of mercury, owing to the more irritating nature of its vapour.

When pure, "it is totally dissipated by heat; and on potassa being added to it, runs into globules of mercury. It is insoluble in nitric or hydrochloric acid, but dissolves in a mixture of them. Spirit, water, or acetic acid digested on it, acquires no colour, nor is either of these menstrua afterwards affected by iodide of potassium." (Ph. L. 1836.) See *Vermilion*.

MERCURY (Tartrate of). Syn. *Prototartrate of Mercury; Hydrargyri Tartras*,—Lat. *Prep.* 1. (Swediaur.) By boiling *gray oxide of mercury* in a *solution of tartaric acid* until saturated, and then evaporating so that crystals may form as the liquid cools.

2. By adding a *solution of tartrate of potassa* to a *cold solution of protonitrate of mercury in water slightly acidulated with nitric acid*, as long as a precipitate forms. *Dose.* ½ to 2 gr.

MERCURY (Alkalized). See *Mercury and Chalk*.

MERCURY (Ammoniated). See *Ammonio-chloride of Mercury*.

MERCURY BASE. When red oxide of mercury is digested in a large excess of *pure caustic ammonia*, a yellow compound is obtained, possessing powerful basic properties. When heated to 260° Fahr., it becomes brown and anhydrous, and then is capable of forming well-defined compounds with the acids, and absorbing carbonic acid with avidity from the air, like baryta or lime. It is insoluble in water, alcohol, and ammonia, and is unaffected by cold liquor of potassa.

MERCURY (Calcined), See *Binoxide of Mercury*.

MERCURY (Coagulated). See *Binoxide of Mercury*.

MERCURY (Corneous). Native calomel.

MERCURY (Cosmetic). See *Ammonio-chloride of Mercury*.

MERCURY (Hahnemann's Soluble).

Syn. *Black Precipitate of Mercury, Hahnemann's Black Oxide of do.; Hydrargyri Præcipitatum Nigrum, Hydrargyrum Oxydulatum Nigrum, Mercurius Solubilis Hahnemanni,*—Lat. *Prep.* 1. By dropping *weak liquor of ammonia* into a *solution of protonitrate of mercury*, as long as the precipitate formed is of a black colour; the powder is washed, dried in the shade without artificial heat, and then preserved from the light and air.

2. (Ph. Bor. 1847.) *Solution of protonitrate of mercury* (recent; sp. gr. 1·1), 9¼ oz.; *distilled water*, 2 lb; mix, filter, and add to the solution *liquor of ammonia* (sp. gr. 0·960), ½ oz., diluted with *water*, 4 fl. oz.; collect the powder immediately on a filter, wash it with *water*, 5 fl. oz., and dry it, &c., as before. A very black powder. *Dose.* ¼ to 1 gr.

MERCURY OF LIFE. Oxychloride of antimony.

MERCURY (Prussian). See *Cyanide of Mercury.*

MERCURY (Purified). See *page* 768.

MERCURY (Sweet). See *Calomel.*

MERCURY AND AMMONIA (Chloride of). Syn. *Sal Alembroth; Hydrargyri et Ammonii Chloridum,* — Lat. *Prep.* (P. Cod.) From *bichloride of mercury* and *sal ammoniac*, equal parts, triturated together. "The object in adding the sal ammoniac here, is to render the corrosive sublimate more soluble in water. The action of the latter is not otherwise altered." (Redwood.) It is chiefly used for lotions and injections.

MERCURY AND AMMONIA (Nitrate of). Syn. *Ward's Mercurial Salt; Ammonio-nitrate of Mercury; Hydrargyri et Ammoniæ Nitras,*—Lat. *Prep.* To *nitric acid*, 4 parts, contained in a spacious bolt-head or matrass, add, gradually, *sesquicarbonate of ammonia*, 2 parts; afterwards add of *quicksilver*, 1 part, and digest in a gentle heat, until the solution is complete; then gradually increase the heat, and add a little more *quicksilver* at intervals, until no more will dissolve; lastly, evaporate the liquid until a pellicle forms, and set it aside to crystallize. More active than the simple nitrate. It is the basis of Ward's "*white drop.*"

MERCURY AND ANTIMONY (Sulphuret of). Syn. *Hydrargyri et Antimonii Sulphuretum, H. et Stibii S., Hydrargyrum Stibiato-sulphuretum, Æthiops Antimonialis,*—Lat. *Prep.* (Ph. Austr. 1836, *Hamb.* 1845, Saxon. 1837, &c.) *Quicksilver* and *sulphur*, of each, 1 part; *powdered sulphuret of antimony*, 3 parts; triturate in a warm mortar (adding a *little hydrosulphuret of ammonia*) until the globules are extinguished. See *Ethiops of Antimony.*

MERCURY AND POTASSIUM (Iodide of). Syn. *Iodo-hydrargyrate of Potassium, I. of Iodide of Potassium; Hydrargyri et Potassii Iodidum,* — Lat. *Prep.* 1. (M. Boullay.) *Biniodide of mercury, iodide of potassium*, and *water*, equal parts; dissolve by heat, and crystallize by evaporation or refrigeration, or gently evaporate to dryness.

2. (Puche.) From *biniodide of mercury* and *iodide of potassium*, equal parts, triturated together. *Dose.* 1/16 to ⅛ gr., dissolved in water; in the same cases as the biniodide, and in chronic bronchitis, hooping-cough, inflammatory sore-throat, &c.

MERCURY AND POTASSIUM (Iodocyanide of). Syn. *Hydrargyro-iodocyanide of Potassium; Hydrargyri et Potassii Iodocyanidum,*—Lat. *Prep.* To a *concentrated solution of bicyanide of mercury* add a *rather strong solution of iodide of potassium*, and dry the precipitate by a gentle heat.

Prop., &c. Small, white, pearly, crystalline plates or scales. It is chiefly used as a test of the purity of hydrocyanic acid. When put into this liquid it is instantly turned red if any mineral acid is present.

MERCURY AND QUININE (Chloride of). Syn. *Hydrargyri et Quinæ Chloridum,*—Lat. *Prep.* (M'Dermott.) From *bichloride of mercury*, 1 part; *hydrochlorate of quinine*, 3 parts; separately formed into *saturated* solutions with *water*, and then mixed; the crystalline precipitate is collected, and dried by a gentle heat. *Dose.* ⅛ to ½ gr., made into a pill with crum of bread; daily as an alterative in debilitated habits; or combined with opium, thrice daily, to produce salivation.

MERCURY (with Chalk). Syn. *Quicksilver with Chalk, Mercurial Powder; Hydrargyrum cum Cretâ,* — Ph. L. E. & D. *Gray Powder, Alkalized Mercury, Mercurius Alkalisatus, Æthiops Absorbens,*—Lat. var. *Prep.* (Ph. L. & E.) *Quicksilver*, 3 oz.; *prepared chalk*, 5 oz.; triturated together until globules are no longer visible.

2. (Ph. D.) *Quicksilver*, 1 *oz.; prepared chalk*, 2 *oz.;* as last.

3. (Ph. D. 1826.) As *quicksilver and magnesia*, Ph. D. 1826, but using *precipitated chalk.* This is about twice as strong as the *quicksilver and chalk* of the present pharmacopœias.

Prop., &c. A gray powder. "When pure, part is evaporated by heat; what remains is colourless, and totally soluble in

acetic acid with effervescence; this solution is not coloured by sulphuretted hydrogen. These substances can scarcely be so diligently triturated that no globules shall be visible." (Ph. L. 1836.) As commonly met with, this powder contains too little mercury. When properly prepared, it effervesces when digested in *cold dilute acetic acid*, and the dark undissolved portion, when dried, should be equal to $\frac{3}{8}$ths of the weight of the powder employed; this residuum should also be totally dissipated by heat, without incandescence, and readily and entirely soluble in nitric acid; when examined by the microscope it should exhibit minute globules of mercury unmixed with foreign matter.

Uses. Quicksilver with chalk is a very mild mercurial, and also possesses antacid properties. It is much used in the syphilitic affections of infancy, in disordered or deficient action of the liver, clay-coloured stools, purging, &c.; and as an alterative in chronic glandular enlargements, &c. *Dose.* 5 to 20 gr., for an adult; 1 to 3 gr., for children.

Obs. To hasten the extinction of the globules, sufficient water is commonly added to form a portion of the chalk into a pasty mass. Mr. Tyson has proposed the following substitute for the preparation of the Pharmacopœias:—*Calomel*, 4 oz.; *liquor of potassa*, 6 fl. oz., or q. s.; triturate together, add of *liquor of ammonia*, ½ fl. oz., and again triturate; decant the clear liquid, well wash and gently dry the bluish powder, and mix it with twice its weight of *prepared chalk*. See *Protoxide of Mercury*.

MERCURY (with Magnesia). Syn. *Hydrargyrum cum Magnesiâ*,—Ph. D. *Prep.* 1. (Ph. D.) From *mercury*, 1 *oz.*; *carbonate of magnesia*, 2 *oz.*; triturated together until the globules disappear.

2. (Ph. D. 1826.) *Quicksilver* and *manna*, of each, 8 parts; triturate together (adding enough *water* to make a paste) till the globules disappear, then add of *carbonate of magnesia*, 1 part, mix, and further add of *warm water*, 64 parts; again well mix, and after repose, decant the clear; repeat the washing with *fresh water*, a second, and a third time, then add 3 parts more of *carbonate of magnesia*, mix well, and dry the whole on bibulous paper. *Uses* and *dose* the same as those of mercury and chalk.

MERCURY (with Gum). Syn. *Hydrargyrum cum Acaciâ*,—Lat. *Prep.* (P. Cod.) *Mercury*, 1 part; *gum*, 2 parts; make a mucilage with 1-4th the *gum*, rub the mercury with it till extinguished, add the *remainder of the gum* with *water*, q. s., mix well, dry by a gentle heat, and pulverize. *Dose, &c.* As the last.

MERCURY (with Sugar). Syn. *Mercurius Saccharatus*, *Hydrargyrum Saccharatum*,—Lat. *Prep.* From *quicksilver* and *white sugar*, of each, 1 oz.; *oil of tansey*, ½ fl. dr.; triturate till the globules disappear. *Dose.* ½ to 1 dr.; as a vermifuge. The Ph. E. 1744 orders *oil of juniper* instead of oil of tansey.

MESMERISM. Syn. *Animal Magnetism.* The French government, about 70 years since, appointed a committee to investigate the merits of this agent or influence, among whom were Bailly, Franklin, Lavoisier, and other persons of equally high scientific qualifications and unblemished integrity. An English translation of their report was published in 1785, from which we make the following extract:—"This pretended agent is not magnetism; for, on examining the assumed grand reservoir of the fluid by a needle and electrometer, neither magnetism nor electricity could be detected. We tried it upon ourselves and others without effect; and on blindfolding those who possessed great susceptibility of its influence, all its ordinary effects were produced when *nothing* was done but when they imagined they were magnetized, whilst none of its effects were produced when they were really magnetized but imagined nothing was done." "The effects, therefore, are *purely imaginary*; and although they have wrought some cures, they are *not without danger*, for the convulsions sometimes spread among the feeble of body and mind, and especially among women. And, finally, there are parts of the operations which may readily be turned to vicious purposes; and, in fact, *immoral practices* have already grown out of them." Our personal observations in connection with this subject, extending over a period of many years, have confirmed the truthfulness of the opinions so fairly stated by the committee of Continental philosophers just referred to. Every impartial investigator must, indeed, soon discover the whole of the pretended powers of animal magnetism, electro-biology, or mesmerism, to be a mockery and a delusion, the influence of which, whether for evil or good, entirely depends on the weak or disordered mental organization of its dupes. A short time since we heard one of the oldest and most successful lecturers on this subject, admit the whole to be an imposture; and he explained the way in which the "startling effects" were accomplished.

They all depended on his vigorous power of arresting the attention of the party and leading the imagination in a certain direction; points on which, Love, the polyphonist, and other conjurers and ventriloquists, infinitely excelled him. "Unfortunately, some lamentable attempts have been made, during the last few years, to revive mesmerism in London; not by quacks and impostors, but by regular practitioners, and even by persons who enjoy no inconsiderable share of public respect and favour. They have, however, reaped the bitter fruits of their credulity and folly; and the mania has again subsided, and will now probably remain dormant." The admirable exposures which have, from time to time, appeared in the columns of the '*Lancet*,' have done much to effect this desirable object.

MESITILOLE. An oily liquid obtained by distilling *acetone* along with about half its volume of *Nordhausen* or *fuming sulphuric acid*. It is lighter than water, is very inflammable, and has a feeble garlic odour.

MESITYLE. Syn. *Mesitule*. This name has been applied by Kane to the theoretical organic radical or salt-basyle, of which acetone is presumed to be the hydrated oxide. *Chloride of mesityle* is made by acting on acetone with perchloride of phosphorus; and this compound, by the action of pure potassa water, yields chloride of potassium and *oxide of mesityle*. *Mesitylene* is obtained with other products when acetone is distilled with fuming sulphuric acid. (Kane.)

MESLIN. A mixture of various kinds of grain. (Brande.)

MESOXALIC ACID. A compound formed with other products when a saturated solution of alloxanate of baryta or strontia is heated to the boiling point.

Prep. A *solution of alloxan* is slowly added to a *boiling solution of acetate of lead*, and the heavy granular precipitate is collected, washed, and decomposed by *sulphuretted hydrogen*; the filtered solution yields crystals by evaporation.

Prop., &c. Very acid taste and reaction. Its salts are called *mesoxalates*. Those with baryta and lime are only slightly soluble in water. *Mesoxalate* of silver is insoluble, and suffers decomposition, with effervescence, when gently heated.

METACETONE. Syn. *Propione*. A colourless, ethereal liquid obtained by distilling a mixture of *sugar*, 1 part, and *finely-powdered quicklime*, 8 parts, at a heat of about 285° Fahr., and adding *water* to the product, when the *metacetone* separates. It is insoluble in water, and boils at 212° Fahr.

METACETONIC ACID. Syn. *Propionic Acid*. This compound is obtained along with other products during the distillation of a mixture of *metacetone*, *bichromate of potassa*, and *sulphuric acid*. It closely resembles acetic acid, from which, however, it is distinguished by the high solubility of its soda salt. *Metacetonate of baryta* yields *pure metacetonic acid* by destructive distillation.

METAGALLIC ACID. Syn. *Melangallic Acid*. Obtained by heating *dry gallic acid* or *tannic acid*, by a quick fire, to about 490° Fahr., or until it froths, melts, and becomes black and solid, then dissolving the residuum in an *alkali*, filtering, and precipitating by an *acid*. An insoluble, black powder.

METAL. Syn. *Metallum*,—Lat. See *Metals*.

METALDEHYDE. The colourless, transparent, prismatic crystals that form in *aldehyde* when kept at ordinary temperatures. It is soluble in alcohol and ether, insoluble in water, and sublimes, without fusion, at a temperature a little above 212° Fahr.

METALLICA. Preparations of the metals. One of the divisions of the Ph. L.

METALLIC TRACTORS (Perkins'). These were formed of two small rods of different metals, and resembled, in principle, the galvanic rings of the present time. They were used by simply drawing them over the affected part. They were introduced as a method of curing diseases, by Dr. Perkins, of Norwich, Connecticut, towards the end of the last century, and their employment was called "*Tractoration*" or "*Perkinism*." They have now long sunk into disuse.

METALLIC TREES. See *Vegetation* (Metallic).

METALLIZING (by electricity). See *Voltatype*.

METALLO-CHROMES. A name given by Nobili to extremely thin films of *peroxide of lead* deposited by electrolytic action upon plates of polished steel, so as to produce an iridescent play of colours. The effect is often very beautiful.

METALLOIDS. A name sometimes applied to the *non-metallic inflammable bodies*, as sulphur, phosphorus, &c., and to the metallic bases of the alkalies and earths.

METALLURGY. The art of working in metals, from the state of ore to the manufactured implement or utensil. It is now usually restricted to the separation of metals from their ores or combinations. "This art," says Dr. Ure, "which supplies industry

with the instruments most essential to its wants, is alike dependent upon the sciences of *chemistry* and *mechanics;* upon the *former*, as directing the smelting processes best adapted to disentangle each metal from its mineralizer; upon the *latter*, as furnishing the means of grinding the ores, and separating the light stony parts from the rich metallic matter."

"Notwithstanding the striking analogy which exists between common chemical and metallurgic operations, since both are employed to insulate certain bodies from each other, there are essential differences which should be carefully noted. In the *first* place, the *quantity* of *materials* being *always very great in metallurgy*, requires corresponding adaptations of apparatus, and often produces peculiar phenomena; in the *second* place, the *agents to be employed* for treating great masses, must be selected with a view to economy, as well as chemical action. In *analytical chemistry*, the main object being exactness of result, and purity of product, little attention is bestowed upon the value of the reagents, on account of the small quantity required for any particular process. But in *smelting metals* upon the *great scale*, profit being the sole object, cheap materials and easy operations are *alone* admissible." (Dict. Arts, Man. & Mines, Ed. 4, ii, 146.)

The above admirable remarks from the pen of so distinguished a chemist and mineralogist, at once point out a criterion of the value of all metallurgical operation, and will serve to lead the spirit of enterprise and experiment in the right direction. The limits of this work do not permit of more than a general reference to the leading operations of metallurgy under this head. These are — *digging*, *picking* or *sorting*, *stamping* or *crushing*, and *washing*, included under the general term "*dressing ores;*"— *roasting* or *calcination*, which is either performed with the fuel in contact with the ore, or in reverberatory furnaces; and the *liquation or reduction to the reguline form.* The application of these processes is noticed under the leading metals. Those who desire to study them more minutely are referred to the authority quoted above.

METALS. Syn. *Metalla*,—Lat. Metals are elementary or undecompounded bodies which are distinguished by their weight, lustre, fusibility, power of conducting heat and electricity, &c., and the numerous compounds which they furnish by combination with one another, and with other bodies. When their solutions are electrolysed, the metals always appear at the electro-negative surface, and are hence termed *electro-positive bodies*, or *cations.*

The characteristics and leading chemical properties of the metals are noticed under each of them in its alphabetical place, and a list of them is given in the table of *elements* at *page* 360. The following table exhibits some other useful particulars:—

TABLE *of some of the properties of the Metals.*

Names arranged in the order of their			
Ductility.	Malleability.	Power of conducting Heat.	Power of conducting Electricity.
Gold.	Gold.	Gold.	Copper.
Silver.	Silver.	Platinum.	Gold.
Platinum.	Copper.	Silver.	Silver.
Iron.	Tin.	Copper.	Zinc.
Copper.	Platinum.	Iron.	Platina.
Zinc.	Lead.	Zinc.	Iron.
Tin.	Zinc.	Tin.	Tin.
Lead.	Iron.	Lead.	Lead.
Nickel.	Nickel.		Mercury.
			Potassium.

METAMARGARIC ACID. A compound formed along with *metoleic acid* by the action of *sulphuric acid* on twice its weight of *olive oil*, in the cold. It is a solid substance, which closely resembles ordinary margaric acid.

METAMERIC. Isomeric. See *Isomerism.*

METANTIMONIC ACID. The name given by M. Fremy to that variety of antimonic acid obtained by decomposing *pentachloride of antimony* (See *p.* 71). It differs from common antimonic acid in being *bibasic*, and forming two different classes of salts with the acids. The *acid metantimoniate of potassa* is the only reagent which yields a precipitate with the soda salts, and is therefore of great value in chemical analysis. It is *prepared* by fusing *antimonic acid* with excess of *potassa*, in a silver crucible, dissolving the fused mass in a little *cold water*, and allowing it to crystallize in vacuo. The resulting crystals (*metantimoniate of potassa*) by solution in *pure water*, are resolved into free potassa and the *acid salt*. (Fremy.)

METAPECTIC ACID. See *Pectine.*

METAPECTINE. See *Pectine.*

METAPHOSPHORIC ACID. See *Phosphoric Acid.*

METASTYROL. A peculiar substance into which *styrol* is converted by exposure, in a sealed glass tube, for about half an hour, to a temperature of about 400° Fahr. It is a transparent, glassy, fusible substance, which, by distillation at a high temperature, is again reduced into the form of liquid styrol.

METHEGLIN. Syn. *Hydromeli, H. Vinosum, Mellis Vinum,*—Lat. *Prep.* From *honey*, 1 cwt.; *warm water*, 24 gall.; stir well until dissolved; the next day, add of *yeast*, 1 pint; and *hops*, 1 *lb.*, previously boiled in *water*, 1 gall.; along with *water*, q. s. to make the whole measure 1 barrel; mix well, and ferment the whole with the usual precautions adopted for other liquors. It contains on the average from 7% to 8% of alcohol. *Mead* and *metheglin* are frequently confounded together. (See *p.* 758.)

METHIONATE OF BARYTA. *Prep.* Saturate *ether* with *anhydrous sulphuric acid*, at the ordinary temperature of the atmosphere, dilute with *water*, neutralize with *carbonate of baryta*, and when nearly about to crystallize, add an equal bulk of *alcohol: methionate of baryta* will be precipitated, and may be purified by resolution and crystallization. Resembles chlorate of potassa, and is soluble in water.

METHIONIC ACID. A sour liquid, obtained from *methionate of baryta*, in the same way as ethionic acid is from ethionate of baryta. Its salts have been little studied.

METHYLAL. A peculiar ethereal liquid obtained along with other products by distilling a mixture of *pyroxylic spirit*, *water*, *oil of vitriol*, and *binoxide of manganese.*

METHYLAMINE. Syn. *Methylammonia.* A gaseous substance prepared by distilling *cyanate of methyle* with a *concentrated boiling solution of hydrate of potassa*, and collecting the product in a receiver surrounded with ice; the distillate is saturated with *hydrochloric acid*, and evaporated to dryness; the crystalline residuum (*chloride of methylammonium*) yields pure *gaseous methylamine* by distillation along with *quicklime*, which must be collected over mercury.

Methylamine has a slight fishy odour and is inflammable, by which it is distinguished from ammonia. Its most remarkable property is its extreme solubility in water, which, at 53·5° Fahr., absorbs above 1000 times its own bulk of this gas. It is liquid at —18° Fahr., and has the sp. gr. 1·08. *Bimethylamine* (bimethyl-ammonia), *trimethylamine* (trimethyl-ammonia), *hydrated oxide of tetremethyl-ammonium*, *methylamine urea*, and other compounds similar to those formed by ethylamine, have been obtained.

METHYLE. Syn. *Methule, Methylene.* The hypothetical radical of pyroxylic spirit and the methyl-series. It forms a number of compounds analogous to those of ethyle.

METHYLE (Chloride of). *Prep.* From *pyroxylic spirit*, 1 part; *chloride of sodium*, 2 parts; and *oil of vitriol*, 3 parts; heated together, and the evolved gas collected over water. It has a peculiar odour, and a sweetish taste, and burns with a pale flame fringed with green. Sp. gr. 1·731 to air 1.

METHYLE (Cyanide of). *Prep.* A mixture of *sulphomethylate of baryta* and *cyanide of potassium* (both dry) is heated in a retort connected with a well-cooled receiver; the distillate is rectified *first* from *red oxide of mercury*, to remove hydrocyanic acid, and next from *anhydrous phosphoric acid*, to remove water. It is an ethereal, aromatic liquid, boiling at 170½° Fahr., and decomposed by hot caustic potassa.

METHYLE (Hydruret of). Syn. *Hydride of Methyle.* Marsh gas. See *Carburetted Hydrogen.*

METHYLE (Iodide of). *Prep.* From a *mixture* of *phosphorus*, 1 part; *iodine*, 8 parts; and *pyroxylic spirit*, 13 parts; distilled together. A highly volatile, colourless, heavy liquid, insoluble in water, and boiling at 112° Fahr. Sp. gr. 2·237. Its diluted vapour is said to form an excellent inhalation in pulmonary affections and ulcerated lungs; it has also been recommended as an application to scrofulous ulcers. Iodine may be detected in the

urine and saliva within a few minutes after smelling it. *Bromide*, *fluoride*, and *sulphide of methyle* have also been formed.

METHYLE (Oxide of). Syn. *Wood-spirit Ether*, *Methylic do.*, *Methyl-ether*, *Hydrate of Methylene*. A gaseous substance obtained from a *mixture of pyroxylic spirit* and *oil of vitriol*, equal volumes, heated together in a flask or retort; the evolved gas (*oxide of methyle*) after being passed through a *strong solution of potassa*, is collected over mercury.

Prop., &c. Colourless, inflammable, liquefies at 2·5° Fahr.; it has an agreeable odour, and it imparts it to water, which absorbs about 35 volumes of this gas. It forms several compound ethers, of which the following are the principal:—

Acetate of Oxide of Methyle, *Methylo-acetic Ether*. From *pyroxylic spirit*, 2 parts; *glacial acetic acid* and *oil of vitriol*, of each, 1 part; distilled together. It closely resembles ordinary acetic ether; boils at 136° Fahr.; sp. gr. 0·919. It has lately been highly recommended as a diffusible stimulant, and as having a strong tendency to diminish expectoration in phthisis, &c.

Chloro-carbonate of Oxide of Methyle. By the direct action of the *gaseous acid* on *pyroxylic spirit*.

Formiate of Oxide of Methyle, *Methylo-formic Ether*. A very volatile liquid formed by heating a mixture of equal parts of *sulphate of oxide of methyle* and *dry formiate of soda*.

Nitrate of Oxide of Methyle, *Methylo-nitric Ether*. A mixture of *pyroxylic spirit*, 1 part, and *oil of vitriol*, 2 parts, is poured upon *nitrate of potassa* (in fine powder), 1 part, contained in a tubulated retort connected with a tubulated receiver containing some *ice-and-salt*, and surrounded with the same, and furnished with a tube to carry off the incondensable gases; the distillate is collected and rectified several times from a mixture of *chloride of calcium* and *litharge*, the product not being collected the last time until the boiling point rises to 150° Fahr. A colourless, neutral liquid, feebly odorous, and burning with a yellow flame; its vapour, heated to 300° Fahr., explodes with tremendous violence. Sp. gr. 1·182.

Oxalate of Oxide of Methyle, *Methylo-oxalic Ether*. From a *mixture* of *oxalic acid*, *oil of vitriol*, and *pyroxylic spirit*, distilled together; on the liquid distillate being exposed to the air, part evaporates, and the remainder forms crystalline plates; these, after pressure between the folds of porous paper, are rectified from a little *oxide of lead*. It melts at 124° Fahr., and then resembles ordinary oxalic ether; boils at 322° Fahr. It is soluble in alcohol, ether, and pyroxylic spirit, and in water with decomposition. See *Oxamethylene*.

Sulphate of Oxide of Methyle, *Methylo-sulphuric Ether*. This is obtained by distilling a *mixture* of *pyroxylic spirit*, 1 part, and *oil of vitriol*, 8 parts; the distillate is agitated with *water*, and rectified from *caustic baryta* (in powder). It is an oily liquid, smelling strongly of garlic, and boiling at 370° Fahr.; sp. gr. 1·324. It is decomposed by water, slowly in the cold, but rapidly and with violence at 212°, pyroxylic spirit and *sulphomethylic acid* being formed. The caustic earths and alkalies also decompose it, with the production of *pyroxylic spirit*, and *sulphomethylate* of the base.

METHYLE (Hydrated Oxide of). See *Pyroxylic Spirit*.

METHYLE ETHER. See *Oxyde of Methyle*.

METHYLE (Zinc). This for the most part resembles zinc-ethyle, and is formed in a similar manner.

METHYLENE. See *Methyle*.

METOLEIC ACID. A liquid oily acid resulting from the decomposition of *sulpholeic acid* by *water*.

MEZEREON. Syn. *Garou*; *Mezereum*, —Ph.-L. E. & D. The "bark of the root" of "*daphne mezereum*" (Linn.) or spurge olive. (Ph. L.) It is employed as a sudorific and alterative, in syphilis, rheumatism, scrofula, and chronic cutaneous diseases, usually in conjunction with sarsaparilla. It has also been used as a masticatory, in toothache, paralysis of the tongue, &c. On the Continent it is used as a *vesicant*. For this purpose it is softened by soaking it in *hot vinegar*, and is then bound on the part, and renewed after intervals of some hours, until vesication is produced. See *Decoctions*.

MICE. See *Rats* and *Vermin*.

MICROCOSMIC SALT. Syn. *Phosphate of Soda and Ammonia*, *Tribasic do.* *Prep.* 1. *Phosphates of soda* and *ammonia*, equal parts; *water*, q. s.; dissolve separately, mix the solutions, evaporate, and crystallize. A slight excess of phosphate of ammonia aids the crystallization.

2. (Fownes.) *Phosphate of soda*, 6 parts; *water*, 2 parts; liquefy by heat, and add of *sal ammoniac* (in powder), 1 part; common salt separates, and after its removal the liquid is concentrated so that crystals may form. *Used* as a flux in blow-pipe assays.

MICROSCOPE. The value of the mi-

croscope in chemistry and the collateral sciences, is now so generally acknowledged, that it would be folly to do more than merely to allude to the subject here. Yet the student and busy practitioner who is desirous of possessing himself of one of these useful instruments, is often at a loss where to make his purchase, and after being disgusted with the inferior quality of some, and startled at the high prices of others, sits himself down and abandons the intention altogether. Happily for these parties, Mr. Highley, of 32, Fleet Street, has lately supplied this desideratum, by the production of an instrument under the title "*Hospital Microscope*," which is unique of its kind, and, in the words of its proprietor, "combines economy with simplicity, elegance of form, and excellence of workmanship." It is, indeed, a boon, not only to the professional man, but to every person who feels interested in investigating the forms and structures of that minute, but illimitable world, which lies beyond the reach of unassisted vision. We advise parties who desire to possess a really valuable and useful microscope, to call at Mr. Highley's and judge for themselves.

Under the head "*lens*" we have said a few words on the subject of *simple microscopes*, to which we refer the reader. We may here add, that the *crystalline lens* of the eye of the *common minnow* may be employed instead of the drop of water or Canadian balsam there referred to.

The use of a *brilliant port-fire* has been lately adopted with considerable success as a substitute for the *lime-light* of the oxy-hydrogen microscope. A clear and powerful light is thus produced at very little expense and trouble, adapted to all the more usual applications of the instrument.

MILDEW. Syn. *Rust*, *Blight*. The mouldy appearance on the leaves of plants produced by innumerable microscopic fungi. The hop, wheat, and the choicest garden fruit-trees are those most commonly attacked. The *causes* are said to be excess of moisture, and absence of the free circulation of air and sunshine. On the *small scale*, finely powdered sulphur is occasionally dusted over the parts affected, as a remedy.

MILIARY FEVER. Syn. *Miliaria*,—Lat. Among the other *symptoms* are—anxiety and frequent sighing, the perspiration has a strong and peculiar smell, and there is a sensation of pricking on the neck and breast, followed by an eruption of small red pimples, which in two or three days become white vesicles, dry up, peel off, and are succeeded by others. The moist weather of spring and autumn are the periods in which it is most prevalent; and delicate females, particularly in child-bed, are those most liable to its attacks. Sometimes it assumes a malignant character. The *treatment* of this affection consists chiefly in combating the depression of the system by a supporting diet; but everything that heats or stimulates the skin should be avoided. The apartment should be kept cool and well ventilated, and cooling saline laxatives and bitter tonics, with cooling drinks, should also be had recourse to.

MILK. Syn. *Lac*,—Lat. The value of milk as an article of food is clearly shown by the fact of it being sufficient to support, and to increase the growth of the young of every species of the mammalia; at once supplying materials for the formation of the osseous, fleshy, and liquid portions of the body. "The substances present in milk are wonderfully adapted to its office of providing materials for the rapid growth and development of the animal frame. It contains an azotized matter, *caseine*, nearly identical in composition with muscular flesh, *fatty principles*, and a peculiar *sugar*, and, lastly, various *salts*, among which may be mentioned *phosphate of lime*, held in complete solution in a slightly alkaline liquid.

"The white, and almost opaque, appearance of milk is an optical illusion. Examined by a microscope of even moderate power, it is seen to consist of a perfectly transparent fluid, in which float about numbers of minute transparent globules; these consist of fat surrounded by an albuminous envelope, which can be broken mechanically, as in the churning, or dissolved by the chemical action of caustic potassa, after which, by agitating the milk with ether, the fat can be dissolved." (Fownes.)

Comp. Cow's MILK, of average quality, contains from 10% to 12% of *solid matter* when evaporated to dryness by steam heat, and has the mean sp. gr., 1·030; while that of the *skimmed milk* is about 1·035; and of the *cream*, 1·0244. (Ure.) The average CREAM of *cow's milk* contains 4·5% of *butter*; 3·5% of *curd*, and 92% of *whey*. (Berzelius.) The SKIMMED MILK consists of *water*, 92·9%; *curd*, 2·8%; *sugar of milk*, 3·5%; *lactic acid*, *lactate of potash*, and a trace of *lactate of iron*, 0·6%; *muriate* and *phosphate of potash*, and *earthy phosphates* (lime), 0·2%. (Berzelius.)

The following analysis of *fresh milk* is by M. Haidlen:—

Water	873·00
Butter	30·00
Caseine	48·20
Milk-sugar . . .	43·90
Phosphate of lime . .	2·31
,, magnesia .	·42
,, iron . .	·07
Chloride of potassium .	1·44
,, sodium .	·24
Soda in combination with caseine . . .	·42
	1000·

Prop. These are well known. Perfectly fresh milk is slightly alkaline, but soon becomes acid on exposure to the air, and after a time white coagula of caseum, or *curds*, separate from it. This change is immediately effected by the addition of rennet or an acid. That from the first, when dried and pressed, constitutes *cheese.* When rennet ceases to produce coagula, the addition of some acetic acid causes the separation of a further quantity, which is termed *serai* or *zieger.* (See *Cheese.*)

Pur. The milk of London, until recently, was, perhaps, the very worst, and the most adulterated of any in the world. Now happily, owing to the facility of transport afforded by the numerous railways, good milk is as plentiful and nearly as cheap in the metropolis as in the other large towns of the kingdom. The *common frauds* practised by the milk-dealers, are the *addition of water* and the *subtraction of part of the cream.* Sometimes *potato flour* or *farina* is added to the milk to give it a creamy or rich appearance, and this addition is still more frequently made to cream, to increase its consistence and quantity. The method of detecting the first two of these frauds is noticed under "*Lactometer.*" The presence of *potato starch* may be determined by boiling some of the milk with a little vinegar, and after separating the coagula by a strainer, and allowing the liquid to become cold, testing it with solution or tincture of iodine. If it turns *blue*, starch, flour, or some other amylaceous substance has been used to adulterate it. In most cases it will be sufficient to apply the test to the unprepared suspected milk.

It has frequently been stated that chalk, plaster of Paris, gum, gelatine, sugar, flour, mucilage of hemp-seed, the brains of animals, and other similar substances, are often added to London milk; but there is no reason to suppose there is any truth in these assertions, as some of these articles are too costly to be used, and the presence of others would so alter the flavour or appearance of the milk, or would so soon exhibit themselves by subsidence, as to lead to their detection. The "*farm-yard milk*" hawked about the suburbs of London at 2*d.* per quart, contains more than one-half water, and is generally the production of consumptive cows, which are fed almost exclusively on brewers' grains. The milk employed for baths in some of the Metropolitan hospitals also finds its way into the milk-pails of these itinerant dairymen, who appear to act upon the principal that "nothing should be wasted."

Pres. Milk may be preserved in stout bottles, well-corked, and wired down, by heating them, in this state, to the boiling point in a water-bath, by which means the oxygen of the small quantity of inclosed air becomes decomposed. It must be afterwards stored in a cool situation. By this method, which is also extensively adopted for the preservation of *green gooseberries, green peas, &c.*, milk will retain its properties unaltered for years. A few grains of *carbonate of magnesia*, or still better, of *bicarbonate of potassa* or *soda*, may be advantageously dissolved in each bottle before corking it.

Under *Bethel's patent* the milk or cream is scalded, and when cold, strongly charged with *carbonic acid gas*, by means of a soda-water machine, and the corks are wired down in the usual manner. The bottles should be kept inverted, in a cool place.

An *excellent method* of *preventing milk turning sour*, or *coagulating*, is to add to every pint of it about 10 or 12 gr. of *carbonate* or *bicarbonate of soda.* Milk thus prepared may be kept for eight or ten days in temperate weather. This addition is harmless, and, indeed, is advantageous to dyspeptic patients. According to D'Arcet, $\frac{1}{2000}$th part of the bicarbonate is sufficient for the purpose. An excess of alkali used in this manner may be detected by the milk turning turmeric paper brown, even after it has been kept some hours, and by the ash obtained by evaporating a little to dryness and then heating it to dull redness, effervescing with an acid. (See *below.*)

*** Milk should not be kept in *lead* or *zinc vessels*, as it speedily dissolves a portion of these metals, and becomes poisonous.

Obs. The principal difference between *cows' milk* and *human milk* consists in the former containing more *caseine* (cheese), and less *sugar of milk* than the latter. Prof. Falkland, who has practically investigated the subject, has prepared a *nutritive*

fluid for *infants* from cows' milk, closely resembling that of the healthy adult woman. His process is, however, unnecessarily complicated, and, therefore, unsuited to those who would have to employ it in the nursery. To remove this objection, we have adopted the following formula;—*Sugar of milk*, ½ *oz.*; *hot water*, ¼ pint; dissolve, and when the liquid has become *quite cold*, add it to *fresh cows' milk*, ¾ pint, and stir them together. This quantity, prepared morning and evening, will constitute the proper food for an infant of from 5 to 8 months old. More may be allowed it, if it "craves" it; but there must be no "cramming." At first it will be advisable to remove a *little* of the cream from the milk before adding to it the saccharine solution; but after a few days this will be found to be unnecessary, and, indeed, injurious. One very important particular to be attended to, is the employment of *pure* cows' milk, obtained from a healthy grass-fed animal only. With this precaution, and the use of a *good biberon*, the infant will thrive nearly as well, as on the breast of any human female, excepting its mother's.

Human milk (*lac humanum*), unlike cows' milk, coagulates with difficulty, a fact which has been passed over unnoticed by the majority of writers on the subject. It is sweeter than cow's milk. Some of its properties vary with the food. A drop placed on the nail flows slowly down if it is good.

Asses' milk closely resembles human milk in colour, smell, and consistence, but it contains rather less cream.

Ewes' milk (*lac ovillum*) closely resembles cows' milk, than which, however, it is slightly richer in cream.

Goats' milk, for the most part, resembles cows' milk, but its consistence is much greater, and it contains much more solid matter.

Mares' milk (*lac equinum*), in consistence, is between that of cows' and human milk. Its cream is not converted into butter by agitation. See *Butter*, *Cheese*, *Dairy*, *Lactic Acid*, *&c.*

MILK (Almond). See *Emulsions.*

MILK (Arrow-root). *Prep.* From *arrow-root*, 1 table-spoonful; first wetted and stirred with a little *cold water*, afterwards adding, gradually, of *boiling water*, ¼ pint; and, lastly, of *boiling milk*, ½ pint; with *sugar*, *spice*, *wine*, *&c.*, to palate. Very nutritious, and excellent in chronic diarrhœa. Some persons employ all milk.

MILK (Artificial). *Prep.* 1. *Asses' milk.* See *p.* 99, and *above.*

2. *Goats' Milk.* (A. T. Thomson.) *Fresh mutton suet* (minced), 1 *oz.*; tie it in a muslin bag and boil it in *cows' milk*, 1 quart; lastly, add of *sugar candy*, 2 dr. In scrofulous emaciation, and in the latter stages of phthisis. The proportion of suet in the above may be advantageously increased a little. The *lac cum sero* of Guy's hospital is a similar preparation.

3. *Human Milk.*—*a.* See *above.*

b. (Rosenstein.) *Almonds* (blanched), 2 in number; *white sugar*, 1 dr.; *water*, 4 fl. oz.; make an emulsion, strain, and add of *fresh cows' milk*, 6 fl. oz. As a substitute for the breast in nursing.

MILK (Chalybeated). Syn. *Lac Ferratum*,—Ph. E. 1744. *Cows' milk*, in which a *red-hot iron* has been repeatedly quenched. Tonic; in debility and diarrhœa.

MILK (Chocolate). *Prep.* Dissolve *chocolate* (scraped), 1 *oz.*, in *boiling new milk*, 1 pint. Nutritious; but apt to offend delicate stomachs.

MILK (Coffee). *Prep.* 1. *Coffee*, 1 *oz.*; *boiling water*, ¼ pint; infuse for 10 or 15 minutes in a warm situation, and add the strained liquid to *boiling milk*, ¾ pint.

2. *Coffee*, 1 *oz.*; tie it loosely in a piece of muslin, and simmer it for 15 minutes in *milk*, 1 pint. Both the above have been recommended for persons of spare habits, and for those disposed to affections of the lungs, more especially for the asthmatic.

MILK (Elephant's). Syn. *Urine d'Elephant*,—Fr. *Prep.* From *gum benzoin*, 2 *oz.*; *rectified spirits of wine*, 1 pint; dissolve, add of *boiling water*, 2½ pints, agitate for 5 minutes in a strong corked bottle, and when cold, strain, and add of *lump sugar*, 1½ *lb.*

MILK (Preserved). Syn. *Milk Powder*; *Lactis Pulvis*, *Lac Pulveratum*,—Lat. *Prep.* 1. *Fresh skimmed milk*, 1 gall.; *sesquicarbonate of soda* (in very fine powder), 1½ dr.; mix, evaporate to 1-3rd by the heat of steam or a water-bath, with constant agitation, then add of *powdered white sugar*, 3½ *lb.*, and complete the evaporation at a reduced temperature; reduce the dry mass to powder, add the *cream* (well drained) which was taken from the milk, and after thorough admixture put the whole into well-stoppered bottles or tins, which must be at once hermetically sealed.

2. (Legrip.) *Carbonate of soda*, ½ dr.; *water*, 1 fl. oz.; dissolve, add of *fresh milk*, 1 quart; *sugar*, 1 *lb.*; reduce it by heat to the consistence of a syrup, and finish the evaporation on plates by exposure in an oven.

Obs. About an ounce of the powder

agitated with a pint of water, forms an agreeable and nutritious drink, and a good substitute for milk at sea. It may also be used for tea or coffee in the solid form. This process, which is very old, has been recently *patented*. See *Milk* (above), and *Putrefaction*.

MILK (Sago). Syn. *Lac Sago*,—Lat. *Prep.* (Dr. A. T. Thomson.) *Sago*, 1 *oz.*; *cold water*, 1 pint; macerate ½ an hour, pour off the water, add of *milk*, 1½ pint, and boil slowly until the sago is dissolved. Very nutritious; also in lieu of arrow-root milk.

MILK (Vanilla). Syn. *Lac Vanillæ*,—Lat. *Prep.* 1. *Essence of vanilla*, 12 drops; *lump sugar*, 1 *oz.*; triturate, and add gradually, *new milk*, 1 pint.

2. (Beral.) *Vanilla sugar*, ½ *oz.*; *milk*, 16 oz.; dissolve.

MILK OF ROSES. Syn. *Lac Rosæ*,—Lat. *Prep.* 1. (*English.*)—*a.* *Almonds* (blanched), 1 *oz.*; *oil of almonds*, and *white soft soap*, of each, 1 dr.; *rose water*, 1 pint; make an emulsion.

b. From *liquor of potassa* and *oil of almonds*, of each, 1 fl. oz.; *hot water*, 2 fl. oz.; agitate together until mixed, then add of *rose water* and *distilled* or *filtered soft water*, of each, ¼ pint, and again agitate well.

c. As the last, but using half a teaspoonful of *salt of tartar* for the liquor of potassa.

d. (Redwood.) *Blanched almonds*, 8 *oz.*; *rose water*, 3 pints; make an emulsion, add of *white Windsor soap*, *white wax*, and *oil of almonds*, of each, ½ *oz.*; previously melted together by a gentle heat, triturate until united, and strain; lastly, add a solution of *oil of bergamot*, ½ *oz.*; *oil of lavender*, 1 dr.; and *attar of roses*, ½ dr.; (dissolved in) *rectified spirit*, 12 oz.

2. (*French.*)—*a.* From *rose water*, 1 quart; *tinctures of benzoin* and *styrax*, of each, 1 fl. oz.; *spirit of roses*, ¼ fl. oz.; *rectified spirit*, 2 fl. oz.; mix.

b. (Augustin.) *Tincture of benzoin*, ½ fl. oz.; *liquor of carbonate of potassa*, 2½ fl. dr.; *rose water*, ½ pint; agitate well together. As a lotion in acne.

c. (Giannini.) *Tincture of benzoin*, 1 dr.; *tincture of balsam of Peru*, 20 drops; *rose water*, 1 pint; as the last.

d. (Schubarth.) *Almond paste*, 3 dr.; *rose water*, ½ pint; *tincture of benzoin*, ½ fl. oz. As before. The addition to the last 3 of a little *rectified spirit* is an improvement.

3. (*German.*) From *dilute solution of diacetate of lead* (Goulard water), and *spirit of lavender*, of each, 1 fl. oz.; *rose water*, 6 fl. oz.; *soft water*, 1 pint.

Obs. All the above are used as cosmetic washes, and to remove scurf, pimples, and eruptions, in slight cases.

MILK OF SULPHUR. See *Sulphur* (Precipitated).

MILK BLOTCH. See *Porrigo*.

MILK FEVER. Syn. *Febris Lactea*,—Lat. A febrile condition of the system that sometimes occurs at the time the milk begins to be secreted after parturition. It often assumes a malignant character. See *Puerperal Fever*.

MILK SCALL or *Milk Crust*. See *Porrigo* and *Crusted Tetter*.

MILLEPEDS. Syn. *Millepedes*. Several small insects (*crustaceans*) have been included under this name:—*Armadillo officinalis*, *a. vulgaris*, common or pill millepeds;—*oniscus asellus*, carpenter, or common wood-louse;—*porcellio scaber*, or sclater. These were formerly included in the pharmacopœias, but are now discarded. They were reputed diuretic, anti-icteric, &c. Those still sold in France under the name of *cloportes préparés*, are pill millepeds, which have been killed by tying them loosely in a piece of muslin, and then suspending them over the vapour of boiling spirit. They are afterwards dried.

MILLET. Syn. *Milium*,—Lat. There are several varieties of millet, all of which are imported. That commonly referred to under the name is the produce of *panicum miliaceum* (Linn.) The husked seeds (*milium mundatum*) are used to make gruel, and are ground for flour. *Barbadoes millet* or *Guinea corn*, is produced by *sorghum bicolor* (Willd.);—*Indian* or *Turkey millet* (durra, jooar; milium Indicum) by *sorghum vulgare* (Willd.);—*Yellow Indian millet*, by *sorghum saccharatum* (Willd.) In some parts of the world *millet flour* is used for bread, but it is chiefly cultivated as food for domestic animals.

MIMOTANNIC ACID. Syn. *Tanningenic Acid*. Names given to the astringent matter of *catechu*.

MINCE MEAT. *Prep.* From *stoned raisins*, *currants*, *sugar*, and *suet*, of each, 2 *lb.*: *sultana raisins* and *boiled beef* (lean and tender), of each, 1 *lb.*; *apples*, 4 *lb.*; *juice of* 2 *lemons*; the *rind of* 1 *lemon*, chopped very fine; *mixed spice*, ¼ *lb.*; *candied citron* and *lemon peel*, of each, 2 *oz.*; *brandy*, a glassful or two; the whole chopped very fine. It may be varied by adding other *spice* or *flavouring*, and by the addition of *eggs*, or the substitution of

chopped fowl or *veal* for beef, according to the taste of the cuisinier.

MINDERERUS'S SPIRIT. See *Acetate of Ammonia* and *Solutions.*

MINERAL ALKALI. See *Soda.*

MINERAL CHAMELEON. *Prep.* From a mixture of *binoxide of manganese* and *potash* or *nitre*, equal parts, heated to redness. It must be preserved in a well-corked bottle until required for use.

Prop., &c. When dissolved in water its solution, at first green, passes spontaneously through all the coloured rays to the red, when, if potassa be added, the colour retrogrades until it reaches the original green. The addition of oil of vitriol, or of chlorine, renders the solution colourless. The addition of a weak acid, or even boiling or agitating the liquid, turns it from green to red. See *Manganeseous Acid.*

MINERAL GREEN. See *Green Pigments.*

MINERAL MARMORATUM, *Mineral Metalline, Mineral Succedaneum.* See *Teeth* (Stopping for).

MINERAL WHITE. See *White Pigments.*

MINERAL YELLOW. See *Yellow Pigments.*

MINERALIZERS. Substances which, by association with metallic bodies, deprive them of their usual properties, and impart to them the character of ores. Their removal belongs to metallurgy. The term *mineralized* has been applied to caoutchouc, gutta percha, bitumen, &c., which has been combined with sulphur, silica, or metallic matter. See *Metallurgy, Caoutchouc, &c.*

MINIM. Syn. *Minimum*,—Lat. A measured drop, of which 60 are equal to a fluid drachm. The size of drops vary so greatly with different liquids, and are also so much influenced by the size and shape of the vessels from which they are poured, that they afford no reliable measure of quantity for medicinal purposes. The *poured drop* has, in some cases, only $\frac{1}{3}$rd the volume of the *measured drop* or *minim;* whilst, in others, it is nearly 3 times as large. According to Mr. Durande, "liquids which contain a small proportion of water, afford a small drop; while, on the contrary, liquids containing a large quantity of water, furnish a large drop." "Among liquids containing a large proportion of water, those which are not charged with remedial substances, give a larger and heavier drop than the same liquids when containing extraneous bodies in solution." (Journ. Phil. Col. of Pharm., i, 165.) In *all* cases in which the word *drop* is mentioned in this work a *minim* is intended, and the quantity should be determined by means of a *graduated minim measure.*

MINIUM. See *Red Pigments.*

MINT. Syn. *Spearmint, Green do.; Mentha Viridis*,—Ph. L. "The recent and the dried flowering herb" of *mentha viridis*, (Linn.) It is aromatic and carminative, but its flavour is less agreeable than that of peppermint. It is employed in flatulence, colic, nausea, diarrhœa, &c.; also to make sauce.

MIRRORS. See *Amalgams, Silvering, Speculum Metal, &c.*

MISCARRIAGE. See *Abortion.*

MITES. See *Acarus.*

MITHRIDATE. Syn. *Damocrates's Confection; Mithridatium, Confectio Damocratis*,—Lat. "This composition originally consisted of but few ingredients; viz., 20 *leaves of rue*, 2 *walnuts*, 2 *figs*, and a *little salt.* Of this we are informed that Mithridates took a dose every morning, to guard himself against the effects of poison. It was afterwards altered, and the number of the ingredients increased to sixty-one. In this more complex form it contained opium, and was, in effect, an aromatic opiate, of which the confection of opium of the present day may be considered as a simplification. The *mithridate* is still prepared in some shops, and is occasionally, though very rarely, prescribed." (Med. Lex.) "The above formulæ" (for *confection* or *electuary of catechu*) "may be considered as the representatives, in our modern pharmacopœias, of the once celebrated recipes for *confectio damocratis* and *theriaca andromachi.*" (Redwood.) The formula of the Ph. L. 1746 would more than fill one of our columns. It contained nearly 50 ingredients, with 2 gr. of *opium* in each ounce. *Mithridate* was formerly conceived to be good for nearly every disease, and an antidote for every known poison.

MIXTURE. Syn. *Mistura*,—Lat. A compound liquid medicine, taken in divided doses.

Mixtures are usually extemporaneous preparations, and in prescribing them, care should be taken not to bring together substances that decompose each other, nor to order heavy powders, that speedily separate from the body of the liquid by subsidence. *Emulsions, juleps*, and *mucilages* are now included in the "*misturæ* of the London Pharmacopœia.

Mixtures are usually *dispensed* in flat octagonal 6 or 8-oz. bottles, with long necks; or in regular "octagons," with short necks, having the doses marked on

the glass, to which the strength of the medicine is made to correspond.

The remarks respecting "*draughts*," at *page* 334, equally apply here. By putting the active ingredients of *six* draughts into a 6-oz. mixture bottle, and filling it up with *distilled water*, a mixture will be made of corresponding properties, of which the *dose* will be 2 table-spoonfuls. When the formula for the draughts includes a decoction or infusion as the vehicle instead of water, *four* of them only must be taken, which will then fill the 6-oz. bottle, and the proper *dose* will be 3 table-spoonfuls, or a small wine-glassful.

The following formulæ embrace the whole of the "*misturæ*" of the British pharmacopœias, as well as a few others in general use. These will serve as examples for the like preparations of medicinals which are not included in the list. (See also *Draughts, Emulsions, Juleps, Waters, &c.*)

MIXTURE (Absorbent). See *Antacid Mixture.*

MIXTURE (Acacia). See *Gum Mixture.*

MIXTURE (Acetate of Ammonia). Syn. *Minderus's Mixture; Mistura Ammoniæ Acetatis,*—Lat. *Prep.* From *solution of acetate of ammonia*, 1½ fl. oz.; *nitre*, 40 gr.; *camphor mixture*, 6 fl. oz.; *rose syrup*, ½ fl. oz. *Dose.* 1 to 3 table-spoonfuls, every third or fourth hour, as a diaphoretic in inflammatory fevers, &c.

MIXTURE (Alkaline). See *Antacid Mixture.*

MIXTURE (Almond). Syn. *Emulsion of Almonds, Milk of do., Mistura Amygdalæ,* —Ph. L. E. & D. *M. Amygdalarum,*—Ph. L. 1824, & Ph. E. *Lac Amygdalæ,*—Ph. L. 1788. *Emulsio Communis,*—Ph. L. 1746. *Prep.* 1. (Ph. L.) *Confection of almonds*, 2½ oz.; *distilled water*, 1 pint; gradually add the water to the confection while triturating, until they are mixed; then strain the liquid through linen.

2. (Ph. E.) From *almond confection*, 2 oz., and *water*, 1 quart; as the last. Or, from *sweet almonds* (blanched), 10 dr.; *white sugar*, 5 dr.; *mucilage*, ½ fl. oz. (or *powdered gum*, 3 dr.); made into an emulsion with *water*, 1 quart.

3. (Ph. D.) *Sweet almonds* (blanched), 5 *dr.; refined sugar*, 2 *dr.; powdered gum*, 1 *dr.; distilled water*, 8 *fl. oz.;* as the last.

Obs. The last formula produces the article usually employed in dispensing in the shops. The addition of a little more sugar renders it pleasanter; and 2 or 3 *bitter almonds*, as in the formula of the Ph. D., 1826, or 1 or 2 fl. dr. of *rose* or *orange-flower water*, may occasionally be added to diversify the flavour. *Dose.* 2 or 3 table-spoonfuls, ad libitum; as a demulcent and emollient in coughs and colds, or as a vehicle for more active medicines.

MIXTURE (Ammoniacum). Syn. *Emulsion of Ammoniacum, Milk of do., Mistura Ammoniaci,*—Ph. L. & D. *Lac Ammoniaci,* —Ph. L. 1788. *Prep.* 1. (Ph. L.) *Prepared ammoniacum*, 5 dr.; *distilled water*, 1 pint; rub the ammoniacum with the water, gradually added, until they are perfectly mixed.

2. (Ph. D.) *Ammoniacum*, ½ *oz.; water*, 8 *fl. oz.;* as the last, but straining through muslin.

Obs. The last formula produces the best and most effective mixture, owing to the use of the raw instead of the strained drug. *Dose.* 1 to 2 table-spoonfuls, either alone or combined with squills or ipecacuanha; as an expectorant and demulcent in chronic coughs, humoral asthma, &c.

MIXTURE (Anodyne). Syn. *Mistura Anodyna, Julepum Calmans,*—Lat. *Prep.* 1. *Prepared chalk*, 2 dr.; *syrup of poppies*, 1 oz.; *fœtid spirit of ammonia*, 1½ dr.; *oils of dill* and *aniseed*, of each, 3 drops; *water*, 4½ fl. oz. *Dose.* A teaspoonful 3 or 4 times a day, in the diarrhœa and colic of infancy.

2. (P. Cod.) *Syrup of opium*, 2 dr.; *syrup of orange flowers*, 6 dr.; *lettuce water*, 4 fl. oz. To allay pain, induce sleep, &c. *Dose.* 1 table-spoonful.

3. (*Vicat's.*) *Ammoniated alcohol*, ¾ fl. oz.; *powdered opium*, 1 dr.; *powdered camphor*, ½ dr.; *proof spirit*, 1½ fl. oz.; digest, with agitation, for 3 or 4 days, and filter. In toothache arising from caries, and as a lotion to the temples in headache.

MIXTURE (Antiemetic). Syn. *Mistura Anti-emetica,*—Lat. *Prep.* 1. *Creasote*, 12 drops; *acetate of morphia*, 1½ gr.; *camphor*, 10 gr.; *rectified spirit*, ½ fl. oz.; *syrup of orange peel*, 1½ fl. oz.; *distilled vinegar*, 4 fl. oz. In sea-sickness, &c. *Dose.* 1 table-spoonful on the approach of vomiting, and repeated at intervals of ½ an hour until the vomiting ceases.

2. (Dr. Barker.) *Compound tincture of camphor*, 1 fl. dr.; *burnt brandy*, 1 fl. oz.; *sugar*, ½ oz.; *infusion of mint*, 6 fl. oz. *Dose.* ½ to 1 table-spoonful every ¼ hour, until the vomiting ceases.

MIXTURE (Antacid). Syn. *Absorbent Mixture, Alkaline do., Mistura Alkalina, M. Antacida,*—Lat. *Prep.* 1. *Liquor of potassa* and *spirit of nutmeg*, of each, 2 fl. dr.; *tincture of rhubarb*, 3 fl. dr.; *tincture of opium*, 1 fl. dr.; *water*, 5 fl. oz. In dyspepsia, heartburn, &c., accompanied with flatulence.

2. *Spirit of sal volatile* and *orange-flower water*, of each, 1 fl. oz.; *simple syrup*, 1½ fl. oz.; *water*, 2½ fl. oz. In acidity, &c., accompanied with langour and low spirits.

3. *Sesquicarbonate of ammonia*, 2 dr.; *syrup of orange peel* and *tincture of gentian*, of each, 1 fl. oz.; *water*, 4 fl. oz.. In dyspepsia, heartburn, &c., arising from excessive indulgence in spirituous or fermented liquors. It also possesses considerable stimulating properties, and will *partially* remove the fit of drunkenness.

4. (Collier.) *Prepared chalk*, 2 dr.; *tincture of ginger*, 2 fl. dr.; *compound tincture of cardamoms*, 1½ fl. oz.; *pimento water*, 6 fl. oz. In diarrhœa accompanied with acidity.

5. (Collier.) *Chalk mixture*, 5 fl. oz.; *tinctures of catechu* and *cinnamon*, of each, ½ fl. oz. In chronic diarrhœa.

6. (Ryan.) *Liquor of potassa*, 2 fl. dr.; *tincture of opium*, 1 fl. dr.; *calcined magnesia*, 1 dr.; *oil of peppermint*, 5 drops; *lime water*, 8 fl. oz. In dyspepsia accompanied with acidity, flatulence, and constipation.

MIXTURE (Anticroupal). Syn. *Mistura Senegæ*,—Lat. *Prep.* (Jadelot.) *Infusion of senega*, 4 oz.; *syrup of ipecacuanha*, 1 oz.; *oxymel of squills*, 3 dr.; *tartarized antimony*, 1½ gr.; mix. By spoonfuls in croup.

MIXTURE (Antiepileptic). Syn. *Mistura Antiepileptica*,—Lat. *Prep.* (M. Lemoine.) *Liquor of ammonia*, 12 drops; *syrup of orange flowers*, 1 oz.; *distilled water of linden flowers*, 2 oz.; *do. of cherry laurel*, ½ oz.; mix. According to M. Lemoine, this is a specific in epilepsy. *Dose.* 1 table-spoonful, or more.

MIXTURE (Antihysteric). Syn. *Mistura Antihysterica*,—Lat. *Potion Antihysterique*,—Fr. *Prep.* (Dr. Josat.) *Cyanuret of potassium*, 1¾ gr.; *distilled lettuce water*, 4½ fl. oz.; *syrup of orange flowers*, 1½ fl. oz. *Dose.* 1 or 2 tea-spoonfuls every ten minutes when the fit is expected; *during the fit* it may be given in double doses. Dr. Josat declares its efficacy to have been indisputably proved, in upwards of 55 cases.

2. (Magendie.) *Cyanide of potassium*, 2 gr.; *lettuce water* (distilled), 4 oz.; *syrup of marshmallow*, 2 oz. Resembles the last.

3. (Dr. Paris.) *Assafœtida*, 1 dr.; *peppermint water*, 5 fl. oz.; make an emulsion and add of *ammoniated tincture of valerian*, 2 fl. dr.; *tincture of castor*, 3 fl. dr.; *sulphuric ether*, 1½ fl. dr. *Dose.* 1 table-spoonful, 3 or 4 times a day, or oftener.

4. (P. Cod.) *Syrup of wormwood*, 1 oz.; *tincture of castor*, ½ dr.; *valerian water* and *orange-flower water*, of each, 2 oz.; *ether*, 1 dr. As the last.

MIXTURE (Antimonial). See *Contra-stimulant Mixture.*

MIXTURE (Antipertussic). Syn. *Mistura Antipertussiens*,—Lat. *Prep.* 1. *Cochineal* (powdered), 2 dr.; *carbonate of potassa*, 1 dr.; *boiling water*, 8 fl. oz.; infuse for 1 hour, strain, and add of *lump sugar*, 1½ *oz.*

2. (Dr. Bird.) *Extract of hemlock*, 12 gr.; *alum*, 25 gr.; *syrup of red poppies*, 2 fl. dr.; *dill water*, 3 fl. oz.

3. (Dr. Reece.) *Tincture of assafœtida*, 1 fl. dr.; *tincture of opium*, 10 or 12 drops; *powdered ipecacuanha*, 10 gr.; *water*, 2 fl. oz. *Dose.* A tea-spoonful every 3 hours, in hooping cough, for a child 2 or 3 years old, and other ages in proportion.

MIXTURE (Antiscrofulous). Syn. *Mistura Antiscrofulosa*,—Lat. *Prep.* From *tincture of bichloride of gold*, 30 drops; *tincture of iodine*, 40 drops; *tincture of gentian*, 1 fl. dr.; *simple syrup*, 7 fl. dr.; *rose water*, 5 fl. oz. *Dose.* A dessert-spoonful 3 or 4 times daily, in a wine-glassful of water; observing to shake the bottle before pouring out the liquid. The writer of this article has seen repeated instances of the excellent effects of this medicine in scrofula, syphilis, and various glandular diseases, even under all the disadvantages of a salt-meat diet, and confinement on shipboard.

MIXTURE (Antispasmodic). Syn. *Mistura Antispasmodica*,—Lat. *Prep.* 1. *Tincture of castor*, 6 fl. dr.; *sulphuric ether* and *laudanum*, of each, 1 fl. dr.; *syrup of saffron*, 1 fl. oz.; *cinnamon water*, 4 fl. oz.

2. (Dr. Collier.) *Assafœtida* and *camphor mixtures*, of each, 2½ fl. oz.; *tincture of valerian*, 1 fl. oz.

3. (P. Cod.) *Lime* or *linden flower water* and *orange flower water*, of each, 2 oz.; *syrup of orange flowers*, 1 oz.; *ether*, ½ dr. *Dose.* (Of each of the above) 1 to 2 table-spoonfuls.

MIXTURE (Aperient). Syn. *Mistura Aperiens*,—Lat. *Prep.* 1. (Abernethy.) *Sulphate of magnesia*, 1 oz.; *manna*, ½ oz.; *infusion of senna*, 1½ fl. oz.; *tincture of senna*, ½ fl. oz.; *mint water*, 2 fl. oz.; *distilled water*, 4 fl. oz.; mix. This is the true "*Abernethy Black Draught.*"

2. (Dr. Christison.) *Sulphate of magnesia*, 1½ oz.; *water*, 4 fl. oz.; dissolve, and add of *tincture of senna*, 1 fl. oz.; *infusion of roses*, 4 fl. oz. *Dose.* A wine-glassful hourly until it begins to operate.

3. (Dr. Collier.) *Sulphate of iron*, 20 gr.;

Epsom salt, 1 oz.; *pennyroyal water*, 1 pint; dissolve. *Dose.* A wine-glassful twice a day, in atonic amenorrhœa.

MIXTURE (Aromatic). Syn. *Mistura Aromatica*,—Lat. *Prep.* 1. (P. Cod.) *Syrup of clove gillyflowers*, 1 oz.; *spirit of cinnamon*, ½ oz.; *confection of hyacinth*, 2 dr.; *peppermint water* and *orange-flower water*, of each, 2 oz.

2. (Guy's Hosp.) *Aromatic confection* (Ph. L., in powder), 3 dr.; *peppermint water*, 9 fl. oz. Sometimes a little *tincture of calumba* is added.

3. (St. B. Hosp.) *Aromatic confection*, 2½ dr.; *water*, 5 fl. oz.; *pimento water*, 3 fl. oz.; mix. The last two are excellent aromatic absorbents in diarrhœa, heartburn, flatulence, acidity, &c. *Dose.* 1 or 2 table-spoonfuls every 2 or 3 hours, or as required.

MIXTURE (Arsenical). Syn. *Mistura Arsenicalis*,—Lat. *Prep.* From *liquor of arsenite of potassa* (Ph. L.), 2 fl. dr.; *compound tincture of cardamoms*, 4 fl. dr.; *cinnamon water*, 2 fl. oz.; *pure water*, 3 fl. oz.; mix. *Dose.* A small table-spoonful, twice a day, after a full meal; in agues, periodic headaches, lepra, psoriasis, chronic rheumatism, &c. It should be exhibited with caution, and its effects watched; and after 5 or 6 days, the dose should be reduced to half the quantity.

MIXTURE (Assafœtida). Syn. *Emulsion of Assafœtida*, *Milk of do.*; *Mistura Assafœtidæ*,—Ph. L. 1836 & D. 1826. *Lac Assafœtidæ*,—Ph. D. 1807. *Lac Asæ Fœtidæ*,—Ph. L. 1788. *Prep.* 1. (Ph. L. 1836.) *Assafœtida*, 5 dr.; *water*, 1 pint; mix gradually, triturating all the time.

2. (Ph. D. 1826.) *Assafœtida*, 1 dr.; *pennyroyal water*, 8 fl. oz. As the last. Stimulant and antispasmodic. *Dose.* 1 to 3 table-spoonfuls; chiefly in hysteria. It is also used as an enema in flatulent colic, worms, hooping-cough, and the convulsions of children.

MIXTURE (Astringent). Syn. *Mistura Astringens*,—Lat. *Prep.* 1. (Pradel.) *Tannin*, 12 gr.; *tincture of rhatany*, 1 dr.; *simple syrup*, 7 dr.; *mucilage*, 1 oz.; *camphor mixture*, 4 oz.

2. (A. T. Thomson.) *Extract of catechu*, 2 dr. (or *tincture*, 1 oz.); *cinnamon water*, 8 oz.; dissolve. *Dose.* 1 to 3 table-spoonfuls, after every liquid dejection, in diarrhœa and dysentery.

MIXTURE (Atrophic). Syn. *Mistura Atrophica*,—Lat. *Potion Atrophique*,—Fr. *Prep.* (Magendie.) *Iodide of potassium*, 4 dr.; *lettuce water*, 8 oz.; *peppermint water*, 2 dr.; *syrup of marshmallow*, 1 oz. *Dose.* 1 table-spoonful, twice a day; in hypertrophy (enlargement) of the heart. Sometimes 1 to 2 dr. of *tincture of foxglove* is added to the mixture.

MIXTURE (Barley). Syn. *Mistura Hordei*,—Lat. See *Decoctions.*

MIXTURE (Brandy). Syn. *Mixture of Spirit of French Wine*; *Mistura Spiritûs Vini Gallici*,—Ph. L. *Egg-flip*, *Egg-hot*,—Vulgo. *Prep.* (Ph. L.) *Brandy* and *cinnamon water*, of each, 4 fl. oz.; *yelks of 2 eggs*; *white sugar*, ½ oz.; *oil of cinnamon*, 2 drops; mix. A valuable stimulant and restorative, in low fevers, and in extreme exhaustion from hemorrhages, &c.; but scarcely a fitting subject for the labours of the College of Physicians, since almost every cook and housewife could produce a better compound than the product of the college formula.

MIXTURE (Camphor). Syn. *Camphor Julep*, *Camphor Water*; *Mistura Camphoræ*,—Ph. L. & D. *Emulsio Camphoræ*,—Ph. E. *Mistura Camphorata*,—Ph. L. 1788. *Julepum è Camphorâ*,—Ph. L. 1746. *Prep.* 1. (Ph. L.) *Camphor*, ½ dr.; *rectified spirit*, 10 drops; triturate together, gradually adding of *water*, 1 pint; and strain through linen.

2. (Ph. D.) *Tincture of camphor*, 1 fl. oz.; *distilled water*, 3 pints; agitate well together, and after 24 hours, filter through paper.

3. (Ph. E.) See *Emulsions.*

Uses, &c. Camphor julep is chiefly used as a vehicle for other medicines. *Dose.* ½ to 1 wine-glassful.

MIXTURE (Camphor,—with Magnesia). Syn. *Mistura Camphoræ cum Magnesiâ*,—Ph. E. & D. *Aqua Camphoræ*,—Ph. U. S. *Prep.* 1. (Ph. E.) *Camphor*, 10 gr.; *carbonate of magnesia*, 25 gr.; triturate together, then gradually add of *water*, 6 fl. oz.; still continuing the trituration.

2. (Ph. D.) *Camphor*. 12 gr.; *carbonate of magnesia*, ½ dr.; *water*, 6 fl. oz.; as last.

3. (Ph. U. S.) *Camphor*, 2 dr.; *rectified spirit*, 40 drops; triturate, add of *carbonate of magnesia*, 4 dr., and again triturate, adding, gradually, of *water*, 32 fl. oz. Antacid, antispasmodic, and anodyne. *Dose.* 1 to 2 table-spoonfuls. Used *without* straining. It is stronger than the simple mixture.

MIXTURE (Carminative). Syn. *Mistura Carminativa*,—Lat. *Prep.* (Dr. Paris.) *Calcined magnesia*, ½ dr.; *peppermint water*, 2½ fl. dr.; *compound tincture of lavender*, ½ fl. dr.; *spirit of caraway*, 4 fl. dr.; *syrup*

of ginger, 2 fl. dr.; mix. Antacid and carminative. For 1 or 2 doses.

MIXTURE (Cascarilla, — Compound). Syn. *Mistura Cascarillæ Composita*,—Ph. L. 1836. *Prep.* (Ph. L. 1836.) *Infusion of cascarilla*, 17 fl. oz.; *vinegar of squills*, 1 fl. oz.; *compound tincture of camphor*, 2 fl. oz. *Dose.* 1 to 3 table-spoonfuls 2 or 3 times a day; in chronic cough and asthma, and in the catarrh of elderly people.

MIXTURE (Cathartic). See *Aperient Mixture, Senna do., &c.*

MIXTURE (Chalk). Syn. *Cretaceous Mixture; Mistura Creta*,—Ph. L. E. & D. *M. Cretacea*,—Ph. L. 1788. *Julepum è Cretâ*,—Ph. L. 1746. *Prep.* 1. (Ph. L.) *Prepared chalk*, ½ oz.; *sugar*, 3 dr.; *mixture of acacia* (mucilage), 1½ fl. oz.; triturate together, then add of *cinnamon water*, 18 fl. oz.

2. (Ph. E.) *Prepared chalk*, 10 dr.; *white sugar*, 5 dr.; *mucilage*, 3 fl. oz.; *spirit of cinnamon*, 2 fl. oz.; *water*, 1 quart; as the last.

3. (Ph. D.) *Prepared chalk*, 2 dr.; *syrup* and *mucilage*, of each, ½ oz.; *cinnamon water*, 7 fl. oz.

Obs. The above are antacid and absorbent. *Dose.* 1 to 3 table-spoonfuls, either alone or combined with aromatic confection; in heartburn, and in diarrhœa after every liquid motion. In the latter affection, a little *tincture of catechu* or *laudanum* is often added; and when there is vomiting or nausea, either *peppermint* or *spearmint water* is generally substituted for the whole or a part of the simple water ordered in the above formulæ.

MIXTURE (Cinchona). Syn. *Bark Mixture; Mistura Cinchonæ*,—Lat. *Prep.* (Copland.) *Confection of roses*, ½ oz.; *boiling decoction of bark*, 8 fl. oz.; triturate, in 10 minutes strain, and add *diluted sulphuric acid*, 1½ fl. dr.; *spirit of nutmeg*, 4 fl. dr. Febrifuge, tonic, and stomachic. *Dose.* 1 to 3 table-spoonfuls, 2 or 3 times a day.

MIXTURE (Colchicum). Syn. *Gout Mixture; Mistura Antarthritica, M. Colchici*,—Lat. *Prep.* (Sir C. Scudamore.) *Magnesia*, 1½ dr.; *vinegar of colchicum* and *syrup of orange-peel*, of each, 4 fl. dr.; *peppermint water*, 3 fl. oz. A table-spoonful every 3 or 4 hours during the fit of gout.

MIXTURE (Contra-stimulant). Syn. *Mistura Contra-stimulans, Julepum C., M. Antimonii Potassio-tartratis*, — Lat. *Prep.* (Laennec). *Tartar emetic*, 3 gr.; *infusion of orange-leaves*, 8 fl. oz.; *syrup of do.*, 1 fl. oz. *Dose.* A wine-glassful, or more, every 2 hours; in inflammation of the lungs, hooping-cough, &c.

MIXTURE (Cough). Syn. *Mistura Bechica*,—Lat. *Prep.* 1. *Almond mixture*, 4 fl. oz.; *oxymel of squills*, 1 fl. oz.; *ipecacuanha wine* and *syrup of tolu*, of each, ½ fl. oz.

2. *Tincture of tolu*, ½ fl. oz.; *paregoric elixir* and *tincture of squills*, of each, 1 fl. oz.; *syrup of poppies*, 2 fl. oz.; *water*, 3½ fl. oz.

3. *Mixture of ammoniacum*, 4 fl. oz.; *syrup of squills*, 2 fl. oz. In the coughs of old persons.

4. *Antimonial wine*, 3 fl. dr.; *syrup of poppies*, 1½ fl. oz.; *water*, 4 fl. oz. In dry husky coughs. *Dose* (of each of the above), 1 table-spoonful, 2 or 3 times a day, or oftener.

5. (*Dr. Munro's.*) *Paregoric*, ½ fl. oz.; *sulphuric ether* and *tincture of tolu*, of each, ¼ oz. *Dose.* A tea-spoonful, in water, night and morning, or when the cough is troublesome.

6. (*Dr. Radcliff's.*) *Syrup of poppies, syrup of squills*, and *paregoric*, equal parts. *Dose.* As the last. In all cases the bowels should be kept gently moved by some mild aperient.

MIXTURE (Creasote). Syn. *Mistura Creasoti; M. Creazoti*,—Ph. E. *Prep.* (Ph. E.) *Creasote* and *acetic acid*, of each, 16 drops; mix, then add of *compound spirit of juniper* and *syrup*, of each, 1 fl. oz.; *water*, 14 fl. oz.; and agitate well together. *Dose.* ½ to 1 wine-glassful, in nausea and vomiting; especially to prevent or relieve sea-sickness.

MIXTURE (Demulcent). Syn. *Mistura Demulcens*,—Lat. See *Almond Mixture, Gum do., &c.*

MIXTURE (Diaphoretic). Syn. *Mistura Diaphoretica*,—Lat. *Prep.* 1. *Solution of acetate of ammonia*, 3 fl. oz.; *antimonial wine*, 2 fl. dr.; *tincture of henbane*, 1½ fl. dr.; *camphor mixture*, 3 fl. oz. *Dose.* 1 table-spoonful every 3 or 4 hours; in fevers, &c.

2. To the last add of *sweet spirit of nitre*, ½ fl. oz. As above.

MIXTURE (for Diarrhœa). See *Chalk Mixture, &c.*

MIXTURE (Diuretic). Syn. *Mistura Diuretica*,—Lat. *Prep.* 1. *Nitrate of potassa*, 2 dr.; *sweet spirit of nitre*, 3 fl. dr.; *syrup of squills*, 1½ fl. oz.; *peppermint water*, 4 fl. oz.

2. (A. T. Thomson.) *Infusion of foxglove*, 5½ fl. oz.; *tincture of foxglove*, ½ fl. dr.; *acetate of potassa*, 2 dr.; *spirit of juniper*, ½ fl. oz.; *tincture of opium*, ½ fl. dr. In dropsy. *Dose.* 1 to 2 table-spoonfuls,

every 2 or 3 hours. The last must be used with caution.

MIXTURE (Emetic). Syn. *Mistura Emetica*,—Lat. *Prep.* 1. (Copland.) *Sulphate of zinc*, 40 gr.; *ipecacuanha wine* and *tincture of serpentary*, of each, 4 fl. dr.; *tincture of capsicum*, 40 drops; *oil of chamomile*, 12 drops; *peppermint water*, 4½ fl. oz. As an excitant emetic; in cases of poisoning by narcotics, &c.

2. (Magendie.) *Coloured emetine*, 4 gr. (or *white emetine*, 1 gr.); *acetic acid*, 8 drops; mix, and add of *infusion of orange-leaves* or *lime flowers*, 3½ fl. oz.; *syrup of marsh mallows*, 1 fl. oz.

3. (A. T. Thomson.) *Ipecacuanha*, ½ dr.; *tartar emetic*, 1 gr.; *tincture of squills*, 1 fl. dr.; *water*, 6 fl. oz. *Dose.* 1 to 2 table-spoonfuls, followed by half the quantity every 10 or 15 minutes, until vomiting is produced; at the same time assisting the action of the medicine by drinking copiously of warm water.

MIXTURE (Emmenagogue). See *Steel Mixture, &c.*

MIXTURE (Expectorant). Syn. *Mistura Expectorans*,—Lat. (Collier.) *Oxymel of squills* and *mucilage*, of each, 1 oz.; *syrup of marsh-mallows*, 2 oz.; *camphor julep*, 3 fl. oz. *Dose.* 1 to 2 table-spoonfuls 2 or 3 times a day; in coughs, hoarseness, asthma, &c.

2. (A. T. Thomson.) *Almond mixture*, 5 fl. oz.; *ipecacuanha wine* and *tincture of squills*, of each, 1 fl. dr.; *syrup of tolu*, 6 fl. dr. *Dose.* 1 table-spoonful; in humoral asthma, catarrh, &c., when the cough is urgent.

MIXTURE (Febrifuge). Syn. *Mistura Febrifuga*,—Lat. See *Mixture of Acetate of Ammonia, Diaphoretic do., &c.*

MIXTURE (Gentian,—Compound). Syn. *Mistura Gentianæ Composita*,—Lat. *Prep.* (Ph. L. 1836.) *Compound infusion of gentian*, 12 fl. oz.; *compound infusion of senna*, 6 fl. oz.; *compound tincture of cardamoms*, 2 fl. oz. Tonic, stomachic, and aperient. *Dose.* 2 to 3 table-spoonfuls; in dyspepsia accompanied with constipation.

MIXTURE (Gregory's). See *Powders.*

MIXTURE (Griffith's). See *Steel Mixture.*

MIXTURE (Guaiacum). Syn. *Emulsion of Guaiacum, Milk of do.; Mistura Guaiaci*,—Ph. L. & E. *Lac G.*,—Ph. L. 1788. *Prep.* (Ph. L.) *Gum guaiacum*, 3 dr.; *white sugar*, ½ oz.; *gum acacia*, 2 dr.; (all in powder); triturate together, and to these, whilst rubbing, gradually add of *cinnamon water*, 1 pint.

2. (Ph. E.) *Guaiacum*, 3 dr.; *sugar*, ½ oz.; *mucilage*, ½ fl. oz.; *cinnamon water*, 19½ fl. oz.; as before. *Dose.* 1 to 3 table-spoonfuls, 2 or 3 times a day; in chronic rheumatism, gout, &c.

MIXTURE (Gum). Syn. *Mucilage; Mistura Acaciæ*,—Ph. L. *Mucilago*,—Ph. E. *Mucilago Acaciæ*,—Ph. D. *Mucilago Arabici Gummi*,—Ph. L. 1788 and Ph. D. 1826. *Prep.* 1. (Ph. L.) *Gum acacia* (in powder), 10 oz.; *boiling distilled water*, 1 pint; rub the gum with the water, gradually poured in, until solution is complete.

2. (Ph. E.) *Gum*, 9 oz.; *cold water*, 1 pint; macerate, with occasional stirring, until dissolved, then strain through linen or calico.

3. (Ph. D.) *Gum* (coarsely powdered), 4 *oz.*; *water* (cold), 6 fl. oz.; dissolve, and strain through flannel.

Uses, &c. Mucilage of gum acacia is chiefly employed to render oily and resinous substances miscible with water. "*Oils* require about ¾ their weight; *balsams* and *spermaceti*, equal parts; *resins*, 2 parts; and *musk*, 5 times its weight," for this purpose. (Montgomery.) The *Gum Mixture*, Ph. E. will be found under "*Emulsions.*"

MIXTURE (Hydrocyanic). Syn. *Mixture of Prussic Acid; Mistura Acidi Hydrocyanici*,—Lat. *Prep.* From *medicinal prussic acid*, 15 drops; *simple syrup* (pure), 1 fl. oz.; *distilled water*, 5 fl. oz. *Dose.* 1 table-spoonful 2 or 3 times daily. Each dose contains 1¼ drops of medicinal prussic acid. The bottle should be shaken before pouring out the dose. Magendie's formulæ for this mixture are omitted because the acid which he orders is not kept in the shops in England.

MIXTURE (Iron). See *Steel Mixture.*

MIXTURE (Marshmallow). Syn. *Mistura Althææ*,—Ph. E. *Decoctum Althææ*,—Ph. E. 1839. *Prep.* (Ph. E.) *Marshmallow root* (dried), 4 oz.; *stoned raisins*, 2 oz.; *water*, 5 pints; boil to 3 pints, strain through linen, and after the sediment has subsided, decant the clear portion.

2. (Ph. D.) See *Decoctions.* Demulcent. *Dose.* A few spoonfuls ad libitum, so as to take 1 to 3 pints in the 24 hours; in strangury, calculus, coughs, fevers, &c.

MIXTURE (Musk). Syn. *Mistura Moschi*,—Ph. L. 1836. *M. Moschata*,—Ph. L. 1788. *Julepum è Moschâ*,—Ph. L. 1746. *Prep.* (Ph. L. 1836.) *Musk, powdered gum*, and *sugar*, of each, 3 dr.; triturate them well together, then add, gradually, of *rose water*, 1 pint, still continuing the trituration. Each fluid ounce contains 9 grains of musk. In order to produce a good mix-

ture, the quantity of gum should be more than doubled. *Dose.* 2 to 4 table-spoonfuls, as a stimulant, antispasmodic, and anodyne; in hysteria, epilepsy, chorea, tetanus, low fevers, &c. A little ammonia is a common and useful addition.

MIXTURE (Myrrh). Syn. *Emulsion of Myrrh; Mistura Myrrhæ,*—Lat. *Prep.* (Copland.) *Myrrh,* 1½ dr.; add to it gradually, triturating all the time, *decoction of liquorice,* 6 fl. oz.; and strain. *Dose.* 1 to 2 table-spoonfuls, twice or thrice a day, combined with carbonate of soda, dilute hydrochloric acid, or paregoric; in debility, and diseases of the digestive organs.

MIXTURE (Narcotic). Syn. *Mistura Narcotica, M. Febrifuga,*—Lat. *Prep.* 1. *Tincture of henbane,* 2 fl. dr.; *solution of acetate of ammonia,* 3 fl. oz.; *water,* 2¾ fl. oz.; mix. *Dose.* 1 to 2 table-spoonfuls, to relieve pain, procure sleep in fevers, &c.

2. (W. Cooley.) *Laudanam,* 1½ fl. dr.; *syrup of poppies, sulphuric ether,* and *spirit of cinnamon,* of each, 1 oz.; *tincture of henbane,* 2½ fl. dr.; *tincture of capsicum,* 4 fl. dr.; *water,* 2 fl. oz. *Dose.* 1 to 2 table-spoonfuls at the commencement of the hot fit of ague.

MIXTURE (Oleo-balsamic). Syn. *Mistura Oleo-balsamica,*—Lat. *Prep.* (Hamb. Cod.) *Oils of cedrat, cinnamon, cloves, lavender, mace,* and *marjoram,* of each, 20 drops; *oil of rue,* 10 drops; *balsam of Peru,* ½ dr.; *rectified spirit,* 10 oz.; digest and filter.

MIXTURE (Purgative). Syn. *Mistura Cathartica, M. Laxativa, M. Purgans,*—Lat. *Prep.* 1. From any of the *purging salts* (Epsom, glauber, tasteless, &c.), 2 *oz.; infusion of senna,* 5 fl. oz.; *syrup of orange-peel,* 1 fl. oz.; *tincture of ginger,* ½ fl. oz.; *spirit of pimento,* 2 fl. dr.; mix. *Dose.* 1 to 3 table-spoonfuls, early in the morning; as an aperient in stomach complaints, &c.

2. (Dr. Copland.) *Manna,* 1½ oz.; *cream of tartar,* ½ oz.; *whey,* 1 quart. By wine-glassfuls, as an aperient drink, in fevers, &c.

3. (Corvisart.) *Borotartrate of potassa* (soluble tartar), 1 oz.; *tartar emetic,* ½ gr.; *sugar,* 2 oz.; *water,* 1½ pint; dissolve. By wine-glassfuls, until it begins to operate. This has been called "*Napoleon's medicine,*" from its having been frequently taken by that emperor. See *Mixtures of Scammony, Senna, &c.*

MIXTURE (Saline). Syn. *Mistura Salina,*—Lat. See *Draughts* and *Lemonade.*

MIXTURE (Scammony). Syn. *Scammony Milk; Mistura Scammonii,*—Lat. *Prep.* 1. (Ph. E.) *Resin of scammony,* 7 gr.; *unskimmed milk,* 3 fl. oz.; gradually mix, triturating all the time, so as to form an emulsion. Purgative. *Dose.* One-half.

—2. (*Planche's Purgative Potion.*) To the last add of *white sugar,* ¼ oz.; *cherry laurel* (or bitter almond) *water,* 4 or 5 drops. The above are the most tasteless and pleasant purgatives of an active character known.

MIXTURE (Senna,—Compound). Syn. *Black Draught, Abernethy's do., Cathartic Mixture; Mistura Sennæ Composita,*—Lat. *Prep.* 1. *Infusion of senna,* ¾ pint; *tincture of senna,* 1½ fl. oz.; *Epsom salts,* 4 *oz.; carbonate of ammonia,* ½ *dr.; sugar,* 3 *oz.;* agitate until the solids are dissolved.

2. *Senna,* 13 *oz.; boiling water,* 2 quarts; digest for 4 hours in a hot place, then press out the liquor in a tincture press, and add of *compound tincture of senna,* ¾ pint; *Epsom salts,* 1 *lb.*

3. *East India senna,* 2 *lb.; boiling water,* 9 quarts; *tincture of senna* and *Epsom salt,* of each, 3¼ *lb.;* as the last.

4. *Senna,* 8 *lb.; boiling water,* 9 gall.; *Epsom salt,* 16 *lb.; tincture of senna,* 1½ gall.; *treacle* and *colouring,* of each, 1 quart.

5. (Guy's Hosp.) *Senna* and *mint,* of each, 1¼ oz., (say, 1½ *oz.*); *boiling water,* 1 quart; *Epsom salt,* 7½ oz., (say, ½ *lb.*)

6. (Redwood.) *Infusion of senna,* 18 oz.; *tincture of senna,* 3 oz.; *sulphate of magnesia,* 6 oz.; *extract of liquorice* and *spirit of sal volatile,* of each, ¾ oz.; *oil of cloves,* 6 drops.

Obs. As the above mixture contains very little spirit, and from its great consumption, being made in large quantities at a time, it frequently spoils before the whole is sold, especially in hot weather. To avoid this, 1½ dr. of *cloves* and 3 dr. of *mustard seed,* both bruised, may be added to every gall. of the strained liquor at the same time with the salts, spirit, and colouring, after which it must be shaken up repeatedly for a few days, and then allowed to repose for a few days more, when it will become quite clear. It may be filtered through a flannel bag, but there is much loss and delay, owing to the consistence of the liquid. It is *purgative* in *doses* of 1 to 1½ fl. oz.

It is a singular circumstance, that although an enormous quantity of this preparation is consumed in these countries, there is no standard formula for it in the British pharmacopœias. See *Aperient Mixture, &c.*

MIXTURE (Steel). Syn. *Mistura Chalybeata,*—Lat. Two compounds of this class are officinal:—

1. *Griffith's Mixture, Compound Iron do.; Mistura Ferri, M. F. Protoxydi; M. F. Composita,*—Ph. L. E. & D. *Prep.*—*a.*

(Ph. L. & E.) *Carbonate of potassa*, 1 dr.; *powdered myrrh*, 2 dr.; *spirit of nutmeg*, 1 fl. oz.; triturate together, and whilst rubbing, add gradually, of *sugar*, 2 dr.; *rose water*, 18 fl. oz.; mix well; then add of *sulphate of iron* (powdered), 50 gr., and place it at once in a bottle, which must be kept closely corked.

b. (Ph. D.) *Powdered myrrh* and *sugar*, of each, 1 *dr.*; *carbonate of potassa*, ½ *dr.*; *essence of nutmeg*, 1 fl. dr.; *rose water*, 7 fl. oz.; *sulphate of iron*, ½ *dr.*; (dissolved in) *rose water*, 1 fl. oz. *Dose.* 1 to 2 oz., 3 or 4 times a day, as a mild and genial chalybeate tonic and stimulant; in amenorrhœa, chlorosis, debility, &c., when there is no determination of blood to the head.

2. *Heberden's Mixture, H. Ink; Atramentum Heberdii; Mistura Ferri Aromatica*,—Ph. D. *Prep.* (Ph. D.) *Pale cinchona bark*, 1 *oz.*; *calumba root*, 3 *dr.*; (both in coarse powder;) *cloves* (bruised), 2 *dr.*; *iron filings*, ½ *oz.*; *peppermint water*, 16 fl. oz.; digest in a close vessel for 3 days, agitating frequently, then strain, and add of *tincture of cardamoms* (comp.), 3 fl. oz.; *tincture of orange-peel*, 3 fl. dr. Bitter, stomachic, and aromatic. *Dose.* 1 or 2 table-spoonfuls, or more, 3 or 4 times a day. It is very slightly chalybeated.

MIXTURE (Tonic). Syn. *Strengthening Mixture; Mistura Tonica*,—Lat. *Prep.* 1. *Infusion of cascarilla*, 5 fl. oz.; *tincture of orange-peel*, 7 fl. dr.; *aromatic sulphuric acid*, 2 fl. dr.

2. (Collier.) *Decoction of bark*, 5½ fl. oz.; *tincture of do*, 3 fl. dr.; *aromatic confection*, 20 gr.; *aromatic spirit of ammonia*, 1 fl. dr.

3. (Thomson.) *Infusion of calumba*, 5½ fl. oz.; *compound tincture of cinnamon* and *syrup of orange-peel*, of each, 2 fl. dr. *Dose.* 1 to 3 table-spoonfuls, 2 or 3 times a day; in debility of the digestive organs, loss of appetite, to check nausea and vomiting, &c.

MIXTURE (for Worms). Syn. *Mistura Anthelmintica, M. Vermifuga*,—Lat. *Prep.* 1. (Collier.) *Sulphate of iron*, 20 gr.; *infusion of quassia*, 8 fl. oz. *Dose.* Two table-spoonfuls every morning fasting.

2. (Copland.) *Valerian*, 2 dr.; *worm-seed*, 4 dr.; *boiling water*, 8 fl. oz.; macerate 1 hour, strain, and add of *assafœtida*, 1 dr., previously triturated with the *yelk of one egg*. As the last.

3. (Richard.) *Root of male fern*, 1 oz.; *water*, 9 fl. oz.; boil to 6 fl. oz., strain, and add of *sulphuric ether*, 1 dr.; *syrup of tansy*, 1 fl. oz. In tape worm; as above.

MIXTURE (Zinc). Syn. *Mistura Zinci, M. Z. Sulphatis*,—Lat. *Prep.* (Collier.) *Sulphate of zinc*, 5 gr.; *sulphate of quinine*, 10 gr.; *compound infusion of roses*, 2 fl. oz. Tonic. *Dose.* A tea-spoonful 2 or 3 times a day in a glass of water. "I have found this mixture very efficacious in the cure of *barking* (gastric?) coughs manifestly of a spasmodic character." (*Trans. Ph. L.*, p. 178.)

MIXTURES (Arithmetic of). The constantly recurring necessity in business and chemical manipulations of determining the value of mixtures, and of producing articles and preparations of different strengths or prices to those already in stock, has rendered a ready means of making such calculations an indispensable qualification in almost every department of trade and industrial art. As we address ourselves to the intelligent operative and busy tradesman, as well as to those more blessed by education and leisure, we feel we are bestowing a boon on many of our readers, in giving a short, but sufficient outline of this useful branch of commercial arithmetic, which is most intimately connected with the objects of the present work.

1. To determine the price of a mixture from the value and quantity of each ingredient of which it is composed.—Rule. *Divide the "gross value" by the "gross saleable" or "useful quantity;"* the quotient is the value or cost per gallon, pound, &c., as the case may be.—*Example.* Required the *value per gallon* of a hogshead of wine containing—

			s.	*d.*		£.	*s.*	*d.*
30	Gallons	@	10	6	. .	15	15	0
20	„	@	12	6	. .	12	10	0
13	„	@	14	6	. .	9	8	6
63					)	37	13	6
	Cost per gallon . . .					0	11	11½

2. To determine the proportions of substances or articles of different values or strengths which must be taken to prepare a mixture of any other value or strength.—Rule. *Arrange the "prices" or "strengths of the ingredients" in a column, and link them together in pairs; each of those* above *the required price being always connected with another* below *it. Then set the difference between the required price and these numbers, alternately* against those they are *linked to;* when they will indicate the quantities to be taken, as in the following *examples*:—*a.* Required the proportions of tea at 3*s.*, 4*s.*, 6*s.*, and 7*s.*, that

must be taken to produce a mixture at 5*s.* the pound. Here —

5	3	1, or 1 *lb.*	@ 3*s.*
	4	2, „ 2 „	„ 4*s.*
	6	2, „ 2 „	„ 6*s.*
	7	1, „ 1 „	„ 7*s.*

b. (When the number of the ingredients or prices is odd.) Required the proportions of teas at 3*s.*, 5*s.*, and 6*s.* the pound, to sell at 4*s.* Here the odd number must be taken a second time :—

4	3	1 + 2, or 3 *lb.*	@ 3*s.*
	5	1, „ 1 „	„ 5*s.*
	6	1, „ 1 „	„ 6*s.*

c. (When the number of the ingredients is not merely odd, but the prices are unequally distributed either above or below the required price.) A dealer having wines of the same name at 7*s.*, 9*s.*, 11*s.*, 12*s.*, and 14*s.* per gallon, wishes to produce a mixture of them worth 10*s.* per gallon :—

10	7	1+4, or 5 gall.	@ 7*s.*
	9	2, „ 2 „	„ 9*s.*
	11	3, „ 3 „	„ 11*s.*
	12	1, „ 1 „	„ 12*s.*
	14	3, „ 3 „	„ 14*s.*

It will be seen that by varying the manner of linking the numbers, different answers may often be obtained to the same question. It also often happens that the dealer or operator desires to use a *given quantity* of *one particular article*, or to produce a *certain quantity only of the mixture* instead of those indicated by the above calculations. In these instances he has simply to apply the common rule of "*practice*" or the "*rule of three*," as the particular case may demand.

In the above manner the *proportions* of the *constituents of a compound* may be determined from their *specific gravity*, when no change of volume has arisen from their admixture ; but when this is the case, as in alloys, alcoholic mixtures, &c., it is either quite inapplicable, or the results obtained are mere approximations to the truth. It may, however, be conveniently employed for calculations connected with the "mixing" and "reduction" of spirits and other liquids, by substituting their per centage value in "proof gallons" or other corresponding denomination, for the prices in the above examples ; water, when introduced be reckoned = 0. Thus :—A spirit merchant having *two puncheons of rum* of the strengths of 17 and 21 o. p., wishes to know what *proportions* of *each* and of *water* he must take to form a spirit 10 u. p. The proof values 100 gallons of these spirits are respectively equal to 121, 117, 90, and 0 (water). Therefore—

90	0	27 + 31, or 58 gallons of *water*.	
	117	90, „ 90 „	*rum* @ 117 o. p.
	121	90, „ 90 „	*rum* „ 121 o. p.

Suppose the dealer required to use different proportions of the spirits referred to, instead of equal measures, he has only to take such aliquot parts of the quantities thus found referring to the smaller proportion ; or such multiples of those referring to the larger one, as he wishes them to bear to each in the new mixture. Numerous other applications of this rule will occur to the ingenious reader.

Questions in "*alligation*," as the department of arithmetic above referred to is called, are very easily resolved by the "*method of indeterminate analysis*," even by persons but slightly conversant with rudimentary algebra ; of which, indeed, they form a simple class of problems, often admitting of an almost indefinite number of solutions.

MOCHLIQUE (Des Frères de la Charité). *Prep.* From *glass of antimony* (in fine powder), 1 *oz.* ; *white sugar*, 2 *oz.* ; triturated together. *Dose.* 20 to 30 gr. Said to be a specific in lead colic.

MODELING CLAY. By using *glycerine* instead of water to knead the *clay* with, a mass is obtained which continues moist and plastic for a considerable length of time, thus removing one of the greatest inconveniences suffered by the modeler. (Barreswil, *Journ. de Pharm.*, 1852.)

MOHAIR. The hair of a goat indigenous in Asia Minor. It is *dyed* and *manufactured* by similar materials and in a similar manner to wool.

MOIL. See *Cider* (p. 257).

MOIREE METALLIQUE. Syn. *Crystallized Tin.* This is *tin plate* which has been submitted for a few seconds, whilst gently heated, to the action of *dilute aqua regia*, by which it acquires a variegated primrose appearance. It is afterwards washed in *hot water*, dried, and lacquered. The degree of heat and dilution of the acid modifies the beauty and character of the surface. The effect is also varied by employing *dilute sulphuric acid*, either alone, or mixed with a portion of *nitric* or *hydrochloric acid* ; or by using a solution of *citric acid* or *caustic potassa*. According

to Herberger, the best metal for the purpose is *plate iron* which has been coated by dipping it into a tin-bath composed of *pure tin*, 200 parts; *copper*, 3 parts; *arsenic*, 1 part. The *varnish* should consist of *copal* in *highly rectified spirit*. *Moirée metallique* is in much less demand now than formerly.

MOLASSES. See *Treacle*.

MOLES. The small soft excrescences and discolorations of the skin which are popularly known under this name, may, when slight, be removed by touching them every day with a little *concentrated acetic acid*, by means of a hair pencil, observing due care to prevent the application from spreading to the surrounding parts. This does not discolour the skin. The application of *lunar caustic* is also very effective, but it turns the spot temporarily black. In the pure mole there is always a considerable production of hair. When other means fail, they may be easily and safely removed by surgical means. The operation is trifling; and, when judiciously performed, no trace of such a proceeding is left behind.

MOLUCCA BALM. See *Liqueurs*.

MOLYBDATE. See *Molybdic Acid*.

MOLYBDENUM. Syn. *Molybdena; Molybdenum*,—Lat. A very rare metal, having a white colour, discovered by Hielm, in 1782.

Prep. By exposing *molybdic acid*, mixed with *charcoal* and placed in a covered crucible, to the strongest heat of a smith's forge.

Prop., &c. It is brittle, and very infusible; when heated in contact with the air, it is converted into *molybdic acid*. Sp. gr. about 8·625. With oxygen it forms a *protoxide* and *binoxide*, and *molybdic acid*. With chlorine it forms a *protochloride* and *bichloride*. With sulphur it unites to forms 2 or more *sulphurets*. The only one of the above compounds that possesses any practical interest is molybdic acid. (See *below*.)

MOLYBDENUM (Protoxide of). Syn. *Molybdeni Protoxydum*,—Lat. *Prep.* A *solution of molybdate of potassa* is treated with *hydrochloric acid* in sufficient excess to redissolve the precipitate (*molybdic acid*) at first thrown down; *metallic zinc* is then immersed in the acid solution, and after a time an excess of *caustic potassa* is added, when *hydrated protoxide of molybdenum* is precipitated. In this state it is soluble in acids and in solution of carbonate of ammonia. By exposure to heat in the air it is converted into *binoxide of molybdenum*.

MOLYBDENUM (Binoxide of). Syn. *Molybdeni Binoxydum*,—Lat. *Prep.* 1. By digesting *metallic copper* in a *hydrochloric solution of molybdic acid* until the liquid turns red, and then adding *ammonia* in considerable excess. Hydrated; soluble in acids yielding red solutions; nitric acid converts it into *molybdic acid*.

MOLYBDIC ACID. Syn. *Molybdenic Acid, Peroxide of Molybdenum; Acidum Molybdicum*,—Lat. *Prep.* 1. *Sulphuret of molybdenum ore* (in fine powder) is digested in *aqua regia* until completely decomposed; the residuum is then briskly heated. A white heavy powder.

2. *Native sulphuret of molybdenum*, after being well roasted, is reduced to fine powder, dissolved in *liquor of ammonia*, and the solution precipitated with *nitric acid*. Small white scales.

Prop., &c. Soluble in 570 parts of water; the solution reddens litmus paper; dissolves in the alkalies forming *alkaline molybdates*, from which it is again precipitated by strong acids. It is used in the preparation of *molybdenum blue*, and in *calico-printing*, but its scarcity precludes its extensive employment in the arts. *Molybdate of ammonia* is the salt principally used in dyeing. *Silks* and *cottons* passed through a solution of this salt, then through a bath soured with *hydrochloric acid*, and, lastly (without washing), through another of *protochloride of tin*, are dyed of a rich and permanent blue colour. A *molybdous acid*, mentioned by old writers, does not exist.

MOMORDICINE. See *Elaterine*.

MONESIA. Syn. *Monesia Bark, Buranheim do.; Cortex Monesiæ*,—Lat. The bark of *chrysophyllum buranheim*, a tree growing in the Brazils. The rough imported extract of this drug also commonly passes under the name of *monesia*. It is astringent, and possesses no advantage over rhatany or catechu. *Dose.* (Of the latter.) 15 to 30 gr.

MONESINE. A peculiar acrid principle, analogous to saponine, found in *monesia bark*, to the extent of 4·7%. (Journ. de Pharm.)

MONOMANIA. See *Insanity*.

MONTANINE. The bitter principle of *St. Lucia bark* or *quinquina piton*.

MORDANT. *Prep.* 1. *Water* or *beer* rendered adhesive by the addition of a little *gum*, *sugar*, or *honey*, and tinged with a little *gamboge* or *carmine*, to mark the parts to which it is applied. *Used* to attach gold leaf to *paper*, *taffety*, *vellum*, *&c.*

2. (*Mixtion.*) From *asphaltum*, 1 part; *mastic*, 4 parts; *amber*, 12 parts; fused together, and then mixed with *hot boiled*

oil, 1 pint. *Used* for *gilding wood*, &c. See *Gold Size.*

MORDANTS are substances employed to fix the colouring matter of dye-stuffs in the fibres of organic bodies, and to give it brilliancy and permanency. This they effect either by serving as a bond of union between the two, owing to their mutual attraction for each of them; or they act by uniting with the colouring particles in the minute pores of the fibres, and rendering them insoluble in the alkaline, soapy, and other liquids, to the action of which they will subsequently be exposed. When an infusion of some dye-stuff, as *cochineal* or *madder*, for example, is mixed with *alum* or *acetate of alumina*, and a little *alkali*, a precipitate immediately forms, consisting of alumina in combination with colouring matter, constituting a *lake*. It is by a similar reaction occurring within the fibres that the permanent dyeing of the cloth is effected. Here the colouring matter of the dyeing materials not only passes from the soluble to the insoluble form, but it enters into chemical combination with other substances, and in the new compounds it assumes greater brilliancy and permanency than it previously possessed. *Annotta* and *safflower* afford instances of the second mode of action above referred to, by which substances operate as mordants. The colouring matter of these dye-stuffs is soluble in *alkaline lyes*, and into a solution of this kind the cloth is dipped. It has now received an extremely fugitive colour only; but by passing it through *acidulated water* the alkaline solvent is abstracted, and the tinctorial matter is precipitated in an insoluble and minutely divided state within its pores, and it becomes permanently dyed. A similar reaction takes place in dyeing with the *indigo vat*, in which atmospheric oxygen performs the part of a mordant. It is believed that even in these cases the colouring principle, during its transition from the liquid to the solid form, enters into combination with the fibres of the organic substance, and that, in proportion to the affinity existing between the two, is the integrity and excellence of the dye. In *wool* and *silk*, the affinity between their filaments and the tinctorial particles of the dye-bath is, in general, so considerable, that a permanent stain is very easily communicated to them; but with *cotton* and *flax*, the materials of which calicoes and linen goods are made, the reverse is the case, and the intervention of a third material, in the shape of a mordant, is absolutely necessary to dye them of a permanent colour.

"Experience has proved, that of all the bases, those which succeed best as mordants are *alumina*, *tin*, and *oxide of iron*; the first two of which, being naturally white, are the only ones which can be employed for preserving to the colour its original tint, at least without much variation. But whenever the mordant itself is coloured, it will cause the dye to take a compound colour quite different from its own. If, as is usually said, the mordant enters into a real chemical union with the stuff to be dyed, the application of the mordant should obviously be made in such circumstances as are known to be most favorable to the combination taking place; and this is the principle of every day's practice in the dye-house."

"In order that a combination may result between two bodies, they must not only be in contact, but they must be reduced to their ultimate molecules. The mordants to be united with stuffs are, as we have seen, insoluble in themselves, for which reason their particles must be divided by solution in an appropriate vehicle. Now this solvent or menstruum will exert in its own favour an affinity for the mordant, which will prove to that extent an obstacle to its attraction for the stuff. Hence we must select such solvents as have a weaker affinity for the mordants than the mordants have for the stuffs. Of all acids which can be employed to dissolve *alumina*, for example, *vinegar* is the one which will retain it with the least energy, for which reason the *acetate of alumina* is now generally substituted for *alum*, because the acetic acid gives up the alumina with such readiness, that mere elevation of temperature is sufficient to effect the separation of these two substances. Before the substitution of the acetate, alum alone was employed; but without knowing the true reason, all the French dyers preferred the alum of Rome, simply regarding it to be the purest; it is only within these few years that they have understood the real grounds of this preference."

"The two principal conditions, namely, extreme tenuity of particles, and liberty of action, being found in a mordant, its operation is certain. But as the combination to be effected is merely the result of the play of affinity between the solvent and the stuff to be dyed, a sort of partition must take place, proportioned to the mass of the solvent, as well as to its attractive force. Hence the stuff will retain more of the mordant when its solution is more concentrated, that is, when the base diffused

through it is not so much protected by a large mass of menstruum ; a fact applied to very valuable uses by the practical man. On impregnating, in calico printing, for example, different spots of the same web with the same mordant in different degrees of concentration, there is obtained in the dye-bath a depth of colour upon these spots intense in proportion to the strength of their various mordants. Thus, with *solution* of *acetate of alumina* in different grades of density, and with madder, every shade can be produced from the *fullest red* to the *lightest pink;* and with *acetate of iron* and *madder*, every shade from *black* to *pale violet.*" (Ure.)

In the *employment* of *mordants* in the ordinary processes of *dyeing*, the goods are passed through the solution for a period varying, under different circumstances, according to the object in view. The cloth is subsequently aired, dried, and well rinsed before immersing it in the colouring bath. In *calico printing* the mordant is applied partially or topically to the cloth by means of wooden blocks, or some similar contrivance, or certain parts of the cloth are stopped out by a suitable preparation or "*resist*," by which means a pattern is produced, as the colouring matter of the dye-bath is removed from the other portions by the washing or scouring to which it is subsequently subjected. The *substances* used to *thicken* the *mordants* by the calico printers, to prevent them spreading, are *starch* and *British gum*. The first is preferred for neutral solutions; the last, for acidulous ones. The *removal* of the *undecomposed particles of the mordant*, so as to preserve the other portion of the cloth from their action, is effected by adding *cow-dung* to the scouring-bath, by which means the aluminous and ferruginous salts are absorbed, or converted into an inert or insoluble form.

The *process* of *galling* or *rooting*, commonly employed as a preparation of *cotton* and *linen* for fast dyes, consists in working the stuff for some time, at a good hand heat, in a *decoction of galls* or an *infusion of sumach*. In this case the astringent matter plays the part of a mordant. About 2½ *oz.* of *galls*, or 5 *oz.* of *sumach*, and 3 or 4 pints of *water*, are commonly taken for every *lb.* of *cotton*. See *Calico Printing*, *Dyeing*, and the *respective dye-stuffs* and *mordants*.

MORESQUE. See *Arabesque*.

MORINE. The colouring principle of the wood of *morus tinctoria* or *old fustic*.

MOROCCO LEATHER. See *Tanning*.

MOROXYLIC ACID. A sour principle obtained by Klaproth from the bark of the *morus alba*, or *white mulberry*. It is found under the form of *moroxylate of lime*.

MORPHIA. Syn. *Morphine; Morphia, Morphina, Morphium*,—Lat. The hypnotic principle of opium. Morphia was discovered by Ludwig in 1688, but it was first obtained pure, and its precise nature pointed out by Sertuerner, in 1804. It is peculiar to the papaveraceæ, or poppy tribe.

Prep. 1. (Ph. D.) *Turkey opium* (cut into thin slices), 1 *lb.*, is macerated for 24 hours in *water*, 1 quart, and the liquid portion decanted ; the residuum is macerated for 12 hours with a *second* quart of *water*, and the process is repeated with a *third* quart of *water*, after which the insoluble portion is subjected to strong pressure ; the mixed liquids are evaporated by a water or steam heat to a pint, and filtered through calico ; to the filtrate is added a solution formed of *chloride of calcium*, 6 *dr.*, dissolved in *distilled water*, 4 fl. oz., and the liquid is further evaporated until it is so far concentrated that nearly the whole of it becomes solid on cooling; this is enveloped in a couple of folds of *strong calico*, and subjected to powerful pressure, the dark liquid which exudes being preserved for subsequent use; the squeezed cake is next treated with about ½ pint of *boiling water*, and the undissolved portion is washed on a paper filter; the filtered solution is again evaporated, and the solid portion thus obtained submitted to pressure, as before; if the product is not quite white, this process is repeated a third time; the squeezed cake is now dissolved in *boiling water*, 6 fl. oz., and the solution filtered through *animal charcoal* (if necessary); to the clear solution is added *liquor of ammonia*, in slight excess; the crystalline precipitate which forms as the liquid cools, is collected on a paper filter, washed with *cold distilled water*, and, lastly, the filter is transferred to a porous brick, in order that the morphia which it contains may become dry. (From the liquids reserved from the expressions more morphia may be obtained by dilution with *water*, precipitation with *ammonia*, resolution in *boiling water*, and treatment with a little *animal charcoal*, *&c.*, as before.)

2. (Ph. L. 1836.) *Hydrochlorate of morphia*, 1 oz., is dissolved in *distilled water*, 1 pint, and *liquor of ammonia*, 5 fl. dr. (or q. s.), previously diluted with *water*, 1 fl. oz., is added with agitation ; the precipitate is well washed in *distilled water*, and dried by a gentle heat. By a

similar process morphia may be obtained from its other salts.

2. (Merck.) A *cold aqueous infusion of opium* is precipitated with *carbonate of soda*, in excess, the precipitate washed, first with *cold water* and then with *cold alcohol* of sp. gr. 0·85; the residuum is dissolved in *weak acetic acid*, the solution filtered through *animal charcoal*, and precipitated with *ammonia;* the precipitate is again washed with *cold water*, dissolved in *alcohol*, and crystallized. A good process where spirit is cheap.

4. (Mohr.) *Opium*, 4 parts, is made into a *strong infusion* with *water*, q. s.; *lime*, 1 part, reduced to the state of milk with *water*, is then added; the mixture is next heated to boiling, at *once* filtered through linen, and treated whilst still hot, with *sal ammoniac*, in fine powder, in slight excess (about 1 *oz.* to each *lb.* of opium); the *morphia* is deposited as the liquid cools, and may be purified by a second solution in *lime* and precipitation by *sal ammoniac*. This process is remarkably simple, and in many points is preferable to any other, either on the *small* or *large scale*.

Prop. The morphia of *commerce* is a white crystalline powder; but when crystallized in alcohol, it forms brilliant prismatic crystals of adamantine lustre. It exerts an alkaline re-action on test paper; imparts a perceptible bitter taste to water; requires 1160 parts of cold water, and 94 parts of boiling water for its solution; insoluble in ether; dissolves in 90 parts of cold, and about 30 parts of boiling alcohol; it also dissolves in the fixed and volatile oils, and in solutions of the alkalies; heated in close vessels it forms a yellow liquid like melted sulphur, which becomes white and crystalline on cooling; heated in the air it melts, inflames like a resin, and leaves a small quantity of charcoal behind. With the acids it forms salts, which are mostly soluble and crystallizable. These may all be made by the direct solution of the alkaloid in the dilute acid. The only ones of importance are the acetate, hydrochlorate, and sulphate.

Pur. Commercial morphia and its preparations are often contaminated with codeia, narcotine, and colouring matter. The proportion of the first two may be estimated by the loss of weight which the sample suffers when digested in ether; or by dissolving out the morphia by digestion in weak liquor of potassa. Pure morphia "is scarcely soluble in cold water, sparingly so in boiling water, and readily so in alcohol. This solution is alkaline to test paper, and by evaporation leaves crystals, which are wholly dissipated by heat. It is soluble in pure potassa." (Ph. L. 1836.)

Tests. 1. Potassa and ammonia precipitate morphia from solutions of its salts under the form of a white crystalline powder, which is very soluble in excess of potassa, and, with somewhat more difficulty, in excess of ammonia. The solution formed by excess of the first is precipitated on the addition of bicarbonate of potassa. The precipitate in either case is soluble in a solution of hydrochlorate of ammonia, and in dilute acetic acid, and is insoluble in ether. A careful inspection of the precipitate through a lens of small power shows it to consist of minute acicular crystals; and seen through a glass which magnifies 100 times, these crystals present the form of right rhombic prisms.—2. The carbonates of potassa and soda produce the same precipitate as potassa, and which is insoluble in excess of the precipitant.—3. The bicarbonates of potassa and soda also give similar precipitates from neutral solutions, insoluble in excess. In each of the above cases stirring with a glass rod and friction on the sides of the vessel promote the separation of the precipitate.—4. If to a mixture of morphia and oil of vitriol a minute fragment of bichromate of potassa be added, oxide of chrome is set free, and a fine green colour developed. 5. A drop or two of solution of terchloride of gold added to a weak solution of morphia, gives a yellow precipitate which is mostly redissolved on agitating the liquid, which then assumes various hues (green, blue, violet, purple) on the addition of a drop of liquor of potassa.—6. A minute fragment of terchloride of gold and of hydrate of potassa very gently dropped into the liquid, occasion purple clouds or streaks in dilute solutions, followed by a precipitate, which is violet, purple, or blue-black, according to the strength of the liquid.

The above are the most reliable precipitates for morphia; the first two may, indeed, be regarded as characteristic, and the remainder as almost so. The following are often referred to by medical writers, but are less exclusive and trustworthy:—Morphia and its salts are,—7. *Reddened* by nitric acid, and form orange-red solutions, darkened by ammonia in excess, and ultimately turning yellow, with the production of oxalic acid.—8. They are turned *blue* by sesquichloride of iron, either at once, or on the addition of an alkali, and this colour is destroyed by water, and by alkalies, or acids in excess.—9. Iodic acid added to their

solutions, turns them yellowish brown, by setting iodine free, and the liquid forms a blue compound with starch.

Uses. Morphia and its salts are exhibited either in substance, made into pills, or in solution, generally the latter; or *externally*, in fine powder, applied to the dermis denuded of the cuticle. They are principally employed as anodynes and hypnotics in cases in which opium is inadmissible, and are justly regarded as the most valuable medicines of their class. "In cases wherein both opium and the morphia salts are equally admissible, I prefer the former, its effects being better known and regulated: moreover, opium is to be preferred as a stimulant and sudorific, and for suppressing excessive mucous discharges." (Pereira.) *Dose.* Of pure morphia, $\frac{1}{12}$ to $\frac{1}{6}$ gr.; of its salts, $\frac{1}{8}$ to $\frac{1}{4}$ gr.; *externally*, $\frac{1}{2}$ to $1\frac{1}{2}$ gr. Morphia is chiefly used for the preparation of the acetate, and some of its other salts.

Good opium yields from 10% to 13% of *morphia*. See *Morphiometry*.

MORPHIA (Acetate of). Syn. *Morphiæ Acetas*,—Ph. L. E. & D. *Prep.* 1. (Ph. L. 1836.) *Morphia*, 6 dr.; *acetic acid* (Ph. L.), 3 fl. dr.; *distilled water*, 4 fl. oz.; dissolve, gently evaporate, and crystallize.

2. (Ph. E.) *Hydrochlorate of morphia*, 1 part, is dissolved in *warm water*, 14 parts; and the solution, when cold, is precipitated with *liquor of ammonia*, in slight excess; the precipitate is washed in *cold water*, and dissolved, by means of *pyroligneous acid* (acetic acid, Ph. E.) in excess, in *warm water*, 12 parts; from the solution crystals are obtained as before.

3. (Ph. D.) *Morphia* (in fine powder), 1 *oz.*; rectified spirit, 8 fl. oz.; mix, apply a gentle heat, and add of *acetic acid* (sp. gr. 1·044), $4\frac{1}{2}$ fl. dr., or q. s., until a neutral or slightly acid solution is obtained; evaporate this to the consistence of a syrup by steam or water heat, and set aside the residuum for a few days until it solidifies.

Pur. "Soluble in water and rectified spirit" (less so in the last than the other), "and when the spirit is distilled from the solution, it yields crystals which are totally destroyed by heat." (Ph. L.) "100 measures of a solution of 10 gr. in $\frac{1}{2}$ fl. oz. of water, and 5 minims of acetic acid, heated to 212° and decomposed by a very slight excess of ammonia, yield by agitation a precipitate which, in 24 hours, occupies $15\frac{1}{2}$ measures of the liquid." (Ph. E.)

Obs. The acetate of morphia of commerce is usually in the form of a whitish powder, and is prepared by the mere evaporation of the solution to dryness by a gentle heat. During the process a portion of the acetic acid is dissipated, and hence this preparation is seldom perfectly soluble in water, unless it has been slightly acidulated with acetic acid. In the Ph. L. 1851 this salt (in crystals) is included in the materia medica. See *Morphia*.

MORPHIA (Citrate of). See *Morphia* and *Liquor of Opium*.

MORPHIA (Hydriodate of). Syn. *Morphiæ Hydriodas*,—Lat. *Prep.* (A. T. Thomson.) *Hydrochlorate of morphia*, 2 parts; *iodide of potassium*, 1 part; dissolve each separately in a *little water*, mix the solutions, wash the precipitate in a *little very cold water*, press it in bibulous paper, redissolve it in *hot water*, and crystallize.

MORPHIA (Hydriodate of,—Iodureted). Syn. *Hydriodate of Morphia with Iodine; Morphiæ Hydriodas cum Iodinio*,—Lat. *Iodure d'Iodohydrate de Morphine*,—Fr. *Prep.* (Bouchardat.) Dissolve *sulphate of morphia* in *water acidulated with sulphuric acid*, mix the solution with a *solution of ioduretted iodide of potassium*, and after keeping the mixed liquid at the temperature of about 140° Fahr. for an hour, collect the crystalline scales, wash them, and dry them by a gentle heat. The solutions should be rather concentrated. *Dose.* $\frac{1}{4}$ to $\frac{3}{4}$ gr., at bedtime. In phthisis, hemicrania, neuralgia, &c.

MORPHIA (Hydrochlorate of). Syn. *Muriate of Morphia; Morphiæ Hydrochloras*,—Ph. L. *Morphiæ Murias*,—Ph. E. D. & U. S. *Prep.* 1. (Ph. L. 1836.) Macerate *sliced opium*, 1 ℔, in *water*, 4 pints, for 30 hours; then bruise it, digest it for 20 hours more, and press it; macerate what remains a *second*, and a *third* time in water until exhausted, and as often bruise and press it; mix the liquors, and evaporate at 140° Fahr. to the consistence of a syrup; add of *water*, 3 pints, and after defecation decant the clear portion; gradually add to this liquid, *crystallized chloride of lead*, 2 oz. (or q. s.), dissolved in *boiling water*, 4 pints, until it ceases to produce a precipitate; decant the clear liquid, wash the residuum with water, and evaporate the mixed liquids, as before, that crystals may form; press these in a cloth, then dissolve them in *distilled water*, 1 pint, add *freshly burnt animal charcoal*, $1\frac{1}{2}$ oz., digest at 120°, and filter; finally, the charcoal being washed, cautiously evaporate the mixed liquors, that *pure crystals* of *hydrochlorate of morphia* may form. To the *decanted liquor from which the crystals were first separated*, add of *water*, 1 pint, and drop in *liquor of ammonia*, frequently shaking, until all the morphia is precipitated;

wash this precipitate with *cold distilled water*, saturate it with *hydrochloric acid*, digest with *animal charcoal*, 2 oz., filter, wash the filter as before, and evaporate the mixed liquors, cautiously, as above, that *pure crystals* may be obtained.

2. (Ph. E.) *Opium*, 20 oz., is exhausted with *water*, 1 gall., in the quantity of a quart at a time, and the mixed liquors are evaporated to a pint; *chloride of calcium*, 1 oz., dissolved in *water*, 4 fl. oz., is added, and, after agitation, the liquid is placed aside to settle; the clear decanted liquid, and the washings of the sediment, are next evaporated, so that they may solidify on cooling; the cooled mass, after very strong pressure in a cloth, is redissolved in *warm water*, a *little powdered white marble* added, and the whole filtered; the filtrate is acidulated with *hydrochloric acid*, the solution again concentrated for crystallization, and the crystals submitted to powerful pressure, as before; the process of solution, clarification with *powdered marble* and *hydrochloric acid*, and crystallization, is repeated until a snow-white mass is obtained. The above is the process of Gregory and Robertson, and is one of the easiest and most productive on the large scale. To procure the salt quite white, 2 to 4 crystallizations are required, according to the power of the press employed. The Edinburgh College recommends, on the *small scale*, the solution, after two crystallizations, to be decoloured by means of *animal charcoal;* but, on the *large scale*, to purify the salt by repeated crystallizations alone.

3. (Mohr.) By dissolving the *precipitate of morphia* (see 4, *p.* 803) in *dilute hydrochloric acid*, and by crystallization, as before.

Pur., &c. It "is completely soluble in rectified spirit, and in water. What is precipitated from the aqueous solution by nitrate of silver is not entirely dissolved either by ammonia, unless added in excess, or by hydrochloric or nitric acid." (Ph. L.) "Snowy white; entirely soluble; solution colourless; loss of weight at 212° Fahr. not above 13⅜; 100 measures of a solution of 10 gr., in water, ½ fl. oz., heated to 212°, and decomposed with agitation by a *faint* excess of ammonia, yield a precipitate which, in 24 hours, occupies 12½ measures of the liquid." (Ph. E.) It takes 20 parts of cold, and about its own weight of boiling water to dissolve it. The hydrochlorate of morphia of the shops is usually, like the acetate, under the form of a white crystalline powder.

Obs. Of all the salts of morphia, this one appears to be that most suitable for medical purposes, from its free solubility, and from its solution not being liable to spontaneous decomposition, at least under ordinary circumstances. "The opium which yields the largest quantity of precipitate by carbonate of soda, yields muriate of morphia, not only in the greatest proportion, but also with the fewest crystallizations." (Ph. E.) Smyrna opium contains the most morphia.

MORPHIA (Meconates of). *Prep.* 1. (*Neutral Meconate of Morphia; Morphiæ Meconas*,—Lat.) By saturating an aqueous solution of *meconic acid* with *morphia*, and evaporating the solution by a gentle heat, so that crystals may be obtained.

2. (*Bimeconate of Morphia; Morphiæ Bimeconas*,—Lat.) *Meconic acid*, 11 parts; *morphia*, 14 parts; dissolve each separately, in *hot water*, q. s.; mix the solutions, and either gently evaporate and crystallize, or at once evaporate to dryness.

Obs. Morphia exists in opium under the form of *bimeconate*, and hence this preparation of that drug has been preferred by some practitioners. A solution of this salt for medical purposes, may be directly prepared from *opium*, by treating its infusion in *cold water* with a little *animal charcoal*, filtering, gently evaporating to dryness, redissolving the residuum in *cold water*, filtering, and repeating the treatment with *animal charcoal*. The dose of the dry bimeconate is ¼ gr., or more; and of the meconate rather less. "A powder is also sold, called '*bimeconate of morphia*,' which is of the same strength as *powdered opium*, and is given in similar doses. It is obviously incorrect to apply this name to a powder which consists principally of foreign matter. It is to be hoped that physicians will not prescribe this powder under the above name, as such a practice might lead to fatal results, if the prescription should be prepared with the substance which the name strictly indicates." (Prof. Redwood.)

MORPHIA (Muriate of). See *Hydrochlorate of Morphia*.

MORPHIA (Nitrate of). Syn. *Morphiæ Nitras*,—Lat. *Prep.* By saturating *very dilute nitric acid* with *morphia* (in slight excess), concentrating the solution by a gentle heat, and setting it aside to crystallize.

MORPHIA (Phosphate of). Syn. *Morphiæ Phosphas*,—Lat. As the last.

MORPHIA (Sulphate of). Syn. *Morphiæ Sulphas*,—Lat. *Prep.* Saturate *very dilute sulphuric acid* with *morphia*, evaporate to one half, add a little animal charcoal, continue the evaporation for a short time longer at a gentle heat, filter whilst hot, and abandon it to spontaneous evaporation. It

is decomposed by driving off the water of crystallization. *Sulphate of morphia* is included in the Ph. U. S. According to Magendie this salt sometimes agrees with patients who cannot bear the acetate.

MORPHIA (Tartrate of). Syn. *Morphiæ Tartras.*—Lat. *Prep.* As the last.

MORPHIA AND CODEIA (Hydrochlorate of). Syn. *Gregory's Salt; Morphiæ et Codiæ Hydrochloras,*—Lat. *Sel de Gregory,*—Fr. This is commercial *hydrochlorate of morphia* prepared according to Dr. Gregory's process.

MORPHIA AND ZINC (Hydriodate of,—Ioduretted.) Syn. *Morphiæ et Zinci Hydriodas cum Iodinio.*—Lat. *Prep.* (Bouchardat.) *Ioduretted hydriodate of morphia*, 1 part; *pure zinc*, 10 parts; *water*, 50 parts; boil together, after some hours filter the boiling liquid, and collect the crystals which are deposited as it cools. *Dose.* ½ to 1½ gr., made into a pill; in various painful affections of the stomach, &c.

MORPHIOMETRY. A name given to the process of determining the richness of opium in morphia. See *Opium.*

MORISON'S PILLS. See *Patent Medicines.*

MORSULI. An old name applied to lozenges and masticatories. It is still retained in some foreign pharmacopœias.

MORTAR is the well-known cement, made of *lime*, *sand*, and *water*, employed to bind bricks and stones together in the construction of walls, buildings, &c.

In the composition of mortar, *stone lime* is preferred to that obtained from chalk, and *river sand* to pit or road sand. *Sea sand* is unfitted for mortar until it has been well soaked and washed in fresh water. Sifted *coal ashes* are frequently substituted for the whole or a part of the sand.

Hydraulic mortars or *cements* are those which, like *Roman cement*, are employed for works which are either constantly submerged, or are frequently exposed to the action of water. The poorer sorts of limestone are chosen for this purpose, or those which contain from 8% to 25% of alumina, magnesia, and silica. Such limestones, "though calcined, do not slake when moistened; but if pulverized they absorb water without swelling up or heating, like *fat lime*, and affords a paste which hardens in a few days under water, but in the air they never acquire much solidity."

"The essential constituents of every good hydraulic mortar are *caustic lime* and *silica;* and the hardening of this composition under water consists mainly in a chemical combination of these two ingredients through the agency of the water, producing a hydrated silicate of lime. But such mortars may contain other ingredients besides lime, as for example, clay and magnesia, when double silicates of great solidity are formed; on which account *dolomite* is a good ingredient in these mortars. But the silica must be in a peculiar state for these purposes; namely, capable of affording a gelatinous paste with acids; and if not so already, it must be brought into this condition, by calcining it along with an *alkali* or an *alkaline earth*, at a bright red heat, when it will dissolve and gelatinize in acids. *Quartzose sand*, however fine its powder may be, will form no water mortar with lime; but if the powder be *ignited* with the lime, it then becomes fit for hydraulic cement. *Ground felspar* or *clay* forms with slaked lime no water cement; but when they are previously calcined along with the lime, the mixture becomes capable of hardening under water."

"*All sorts of lime* are made *hydraulic*, in the *humid way*, by mixing the slaked lime with solutions of common alum or sulphate of alumina; but the best method consists in employing a solution of the silicate of potash, called *liquor of flints* or *soluble glass*, to mix in with the *slaked lime* or *lime and clay*. An hydraulic cement may also be made which will serve for the manufacture of *architectural ornaments*, by making a paste of *pulverized chalk*, with a *solution* of the *silicate of potash*. The said liquor of flints likewise gives chalk and plaster a stony hardness, by merely soaking them in it after they are cut or moulded to a proper shape. On exposure to the air, they get progressively indurated. *Superficial hardness* may be readily procured by washing over the *surface* of *chalk*, *&c.*, with *liquor of flints*, by means of a brush. This method affords an easy and elegant method of giving a *stony crust* to the *plastered walls* and *ceilings of apartments;* as also to *statues* and *busts*, cast in gypsum mixed with chalk."

Under *Prof. Kuhlman's patent*, dated April, 1841, "instead of calcining the limestone with clay and sand alone, as has been hitherto commonly practised, this inventor introduces a small quantity of *soda*, or, preferably, *potash*, in the state of *sulphate*, *carbonate*, or *muriate;* salts susceptible of forming silicates when the earthy mixture is calcined. The *alkaline salt*, equal in weight to about 1-5th that of the *lime*, is introduced in solution among the earths." (Ure, *Dict. of A. M. & M.*, Edn. 4.)

The hardening of the common mortars and cements is in a great measure due to the gradual absorption of carbonic acid; but even after a very great length of time, this conversion into carbonate is not complete. Good mortar, under favorable circumstances, acquires extreme hardness by age.

Attempts have been made at various times to introduce the use of bituminous cements into this country, and thus to restore both to land and submarine architecture a valuable material which has now lain neglected for a period of fully 30 centuries; but unfortunately, owing to the interest of our great building and engineering firms lying in another direction, these attempts have been hitherto unsuccessful. See *Asphaltum, Cements, Lime, &c.*

MORTIFICATION. Syn. *Gangrene; Gangrena, Mortificatio,*—Lat. Local death; the loss of vitality in one part of the animal body, whilst the rest continues living. "The terms gangrene and mortification are often used synonymously; but *gangrene* properly signifies the state which immediately precedes mortification, while the complete mortification, or absolute death of a part, is called *sphacelus.* A part which has passed into the state of sphacelus is called a *slough.* When a part becomes gangrenous, it loses its natural heat and sensibility, it becomes livid, and vesications appear on its surface. Although this state generally leads to that of complete mortification, a certain degree of vitality remains, and, in some rare instances, the circulation is re-established, and the part restored to health. When *sphacelus* has taken place, the part becomes black and putrid, it is entirely dead and disorganized, and the living system must either cast it off, or sink from the effects of the absorption of putrid matter." (*Med. Lex.*)

The *common causes* of *mortification* are—inflammation (especially the erysipelatous); interrupted circulation; severe mechanical injury; exposure to intense cold (*gelatio*); the use of poisonous food, &c.; specific contagion; action of chemical agents, (heat, escharotics, &c.)

The *common symptoms* of *mortification* supervening on inflammation are—loss of pain, and sudden and overwhelming depression of the vital powers; diminution of the fever; small, sinking pulse; hiccough, delirium, cold sweat, and fainting, which precedes death.

The *treatment*, in the *early* or inflammatory stage of this disease, when the pulse is strong and quick, is antiphlogistic or depletive, more especially in young and vigorous subjects; in the *second* stage, when the symptomatic fever has given way to debility, and the pulse is sunk and feeble, stimulants and tonics, with strong soups, wine, &c., are to be had recourse to. "*Bark, port wine*, and *opium*, have been the constitutional remedies most generally employed in the cure of mortification; but the whole class of stimulants may be occasionally resorted to with more or less advantage," after once the inflammatory symptoms have subsided. During the *first* stage, emollient poultices mixed with *yeast* or *freshly burnt charcoal* should be applied hot, and renewed every 3 or 4 hours; and between the applications the parts should be well bathed with hot fomentations of *poppies, henbane*, or *opium.* In the *second* stage, stimulating liniments, as those of *camphorated spirit, vinegar, turpentine, &c.*, are used. In gangrene of the extremities, amputation is often necessary. See *Hospital Gangrene, &c.*

MOSAIC GOLD. See *Brass, Gold, &c.*

MOSSES. Syn. *Musci,*—Lat. Several vegetables of the natural orders, *algæ, fungi, lichenes*, and *muscoideæ*, commonly pass under this name with the vulgar. Of these the following are the principal:—

Australian Moss. For the most part resembles *Irish moss.*

Bog Moss (*Sphagnum palustre*). Very retentive of moisture. *Used* to pack up plants for exportation.

Ceylon Moss (*Plocaria candida,*—Nees.) Very nutritive; made into a decoction or jelly, which is highly esteemed as an article of diet for invalids and children, more especially for those suffering under affections of the mucous membranes or phthisis. See *Decoctions.*

Club Moss (*Lycopodium clavatum,*—Linn.) See *Lycopodium.*

Corsican Moss, C. Worm do. (*Plocaria helminthocorton,*—Endl.) *Dose.* ½ to 2 dr., in powder, mixed up with sugar; as a vermifuge. See *Decoctions.*

Cup Moss, C. Lichen (*Lichen pyxidatus,*—Linn.) Astringent and febrifuge. A cupful of the decoction taken warm generally proves gently emetic. *Used* in hooping cough, &c.

Fir Club-moss (*Lycopodium selago,*—Linn.) Violently emetic and purgative. It is also irritant and narcotic.

Hairy Tree-moss (*Lichen plicatus,*—Linn.) *Used* occasionally as an astringent.

Iceland Moss, Liverwort; Muscus Islandicus; Cetraria,—Ph. L. (*Cetraria islandica,*—Achar. *Lichen islandicus,*—Linn.) Highly nutritious and easy of digestion. The decoction is a favorite alimentary sub-

stance in affections of the lungs and digestive organs. In Iceland, after the bitter has been removed by soaking it in hot water, it is made into jelly, or dried, ground to flour, and made into bread. See *Decoctions.*

Irish Moss, Pearl do., Carrageen do. (*Chondrus crispus,*—Grev. *Fucus crispus,* —Linn.) Very nutritious. The *decoction* or *jelly* is a useful and popular demulcent and emollient in pulmonary affections, dysentery, scrofula, rickets, &c. It is often employed by cooks and confectioners instead of isinglass; and by painters to make their size.

Rein-deer Moss (*Lichen rangiferinus,*— Linn.) Esculent, very nutritious. *Used* for making *Cyprus powder* and *French scent bags* or *sachets.*

Rock Moss, Orchill, Canary Archil, Herb do., Dyer's Rocella, Dyer's Fucus (*Rocella tinctoria,*—D. C. *Lichen rocella,* —Linn. This is the most celebrated and valuable of the tinctorial lichens. The *decoction* is used to allay tickling phthisical coughs, &c. See *Archil, Cudbear,* and *Litmus.*

Tartareous Moss (*Lichen tartareus,*— Linn.) See *Cudbear.*

MOTHER OF PEARL. See *Pearl.*

MOTHER'S MARKS. See *Skin.*

MOTHER WATER. See *Crystallization.*

MOULDS. Numerous materials and compositions are employed for the purpose of taking moulds, among which are the following:—

1. (*Compo'*) — *a.* From *spermaceti, stearine* or *hard tallow,* and *white wax,* equal parts, melted together. For fine work, as medals, small casts, &c.

b. From *black rosin,* ¾ *lb.; hard tallow,* ½ *lb.; bees' wax,* 6 oz.; as the last. For coarse work, as architectural ornaments, &c. The above are poured on the objects to be copied (previously oiled) whilst in the melted state. Articles in *plaster of Paris* are first soaked in water, observing that none of it remains on the surface so as to interfere with the design.

2. (*Elastic.*)—*a.* Flexible or elastic moulds may be made of *gutta percha* softened in *boiling water,* and after being freed from moisture, pressed strongly against the object to be copied, by means of a screw press. A ring or support should be employed to prevent undue lateral spreading.

b. By the use of *gelatine* or *glue,* elastic moulds are formed capable of reproducing, with accuracy, and in a single piece, the most elaborately sculptured objects, of exquisite finish and delicacy. Casts from these are now common in the streets. The credit of the application of this substance to the purpose is due to Mons. H. Vincent. The process of casting consists in simply dissolving a certain quantity of *gelatine* in *hot water* until it is reduced to the state of liquid paste, when it is run over the object, previously oiled, intended to be reproduced. As it cools the gelatine assumes a consistency offering a considerable degree of resistance, and is highly elastic, which latter quality enables it to be easily detached from the work on which it has been fitted. In the hollow formed by the gelatine, the *finest plaster* mixed to a thick cream with *water,* is next run; and when the plaster has acquired the requisite hardness, the gelatine mould is detached in the same manner as from the original. From this apparently fragile mould as many as six copies may be taken, all reproducing the original with unerring fidelity.

3. (*Metallic.*)—*a.* From *fusible metal.*

b. (*Clichée moulds.*) From a fusible alloy formed of *bismuth,* 8 parts; *lead,* 5 parts; *tin,* 4 parts; *antimony,* 1 part; repeatedly melted together. The above are poured out in the melted state on a plate or slab, and after being stirred until in a pasty state, the object to be copied is strongly pressed on the alloy at the moment it begins to solidify. They are chiefly used for medals and other like objects.

c. (*M. Chameroy's patent.*) By melting together one part of some *easily fusible metal* in a crucible, and then mixing with it four parts of a *metal far less readily fusible, steeped in ammonia and reduced to powder.* Such a compound is stated to be of great solidity, hardness, facility of soldering, melts at a low temperature, and has great tractability in moulding to any form; and in casting takes the sharpest impressions, whilst in its nature it is peculiarly unchangeable. See *Voltatype, &c.*

MOUSE. This pretty and agile little animal which so commonly infests our dwelling houses and granaries, is the *mus musculus* (Linn.), one of the smaller *rodentia.* Its *flesh* was formerly much esteemed in certain diseases. Its *fat* and *excrement* are included among the simples of the Ph. L. 1618.

MOUTH COSMETICS. See *Breath, Teeth, Lozenges, Pastes, Powders, Washes, &c.*

MOXAS. Substances burnt upon the body, for the purpose of acting as counter-irritants, and allaying deep-seated pains, and inflammation. They have been used in

gout, rheumatism, &c. The small cone constituting the moxa, is placed upon the part, lighted, and allowed to burn to its base. The *Chinese moxas* are made of the downy portion of the leaves of a species of wormwood (*artemisia sinensis*); but various other substances, as the *pith of the sunflower*, *cotton*, or *paper*, soaked in a *weak solution of nitrate*, *chlorate*, or *chromate of potassa*, answer as well. The actual cautery is said to be preferable to any of them.

MUCIC ACID. Syn. *Mucous Acid*, *Saccholactic Acid*. A compound discovered by Scheele, and by him named saccholactic acid. It is obtained in a state of purity by digesting 1 part of *sugar of milk*, in 4 parts of *nitric acid* (sp. gr. 1·42), diluted with 1 part of *water*, and applying heat till the effervescence ceases; on cooling, the acid is deposited. *Gum* may be substituted for sugar of milk, but yields a less pure acid.

Prop., &c. Mucic acid is a white, crystalline powder; soluble in 66 parts of boiling water, and in oil of vitriol, to which it imparts a crimson colour. By dry distillation it yields *pyromucic acid*, and other products; with the bases it forms salts called *mucates*. The *alkaline mucates* are soluble; the *earthy* and *metallic mucates*, insoluble.

MUCILAGE. Syn. *Mucilago*, — Lat. An aqueous solution of *gum*, or other like substance that gives a considerable consistency to water. See *Decoctions*, *Mixtures*, *&c.*

MUCILAGE (Tragacanth). Syn. *Mucilago Tragacanthæ*,—Ph. E., & Ph. D. 1826. *Prep.* (Ph. E. & D.) *Tragacanth*, 2 dr.; *boiling water*, 9 fl. oz. (8 fl. oz.,—Ph. D.); macerate for 24 hours, triturate, and press through linen. *Used* to make up pills, to suspend heavy powders in liquids, as an application to burns, &c.

MUCILAGINOUS FERMENTATION. See *Viscous Fermentation*.

MUDARINE. Syn. *Madarine*. A peculiar substance possessing powerful emetic properties, extracted from the *root-bark* of *calotropis mudarii* or *gigantea* (*madar*, *mudar*, or *yercund*), in which it exists to the extent of 11%. (Duncan.) It is soluble in water and in alcohol, and its aqueous solution, unlike that of most other substances, gelatinizes by heat, and becomes fluid again on cooling.

MUFFINS. *Prep.* Take of *fine flour*, ¼ peck; *warm milk-and-water*, 1 quart; *yeast*, a wine-glassful; *salt*, 2 *oz.*; mix for 15 minutes, then further add of *flour*, ¼ peck, make a dough, let it rise 1 hour, roll it up, pull it into pieces, make them into balls, put them in a warm place, and when the whole dough is made into balls, shape them into muffins, and bake them on tins; turn them when half done, dip them into *warm milk*, and bake them to a pale brown.

MUFFLE. See *Assaying*.

MULBERRY. Syn. *Morum*, — Lat. Mulberries (*mora*, *mori baccæ*) are the *fruit* of *morus nigra* (Linn.) or *black mulberry tree*. They are cooling and laxative; but when eaten too freely are apt to disorder the stomach and bowels. *Mulberry juice* (*mori succus*) is officinal in the Ph. L. A syrup (*syrupus mori*) is made of it. It is also, occasionally, made in wine.

MULLED. Sweetened and enriched with spices or aromatics. See *Wines*.

MULLET. Syn. *Red Mullet*; *Mullus*, —Lat. The *mullus barbatus*, a species of spiny-finned fishes (*acanthopterigians*). It is esteemed a delicacy; but is said to be rather indigestible. The Romans held it in such repute, that prodigious sums of money were given for it. The *striped mullet* or *striped surmullet* (mullus sarmuletus) is little inferior to the last. The *silvery gray mullet*, another esteemed table-fish, is the *mugil cephalus*, a genus of soft-finned abdominal fishes (*malacopterigii abdominales*.) The red mullet was formerly believed to be "good in colic. Applied fresh, they help the bitings of scorpions, spiders, &c." (!)

MULTUM. A *mixture* of *extract of quassia* and *liquorice*, used by fraudulent brewers instead of malt and hops.

MUM. A beverage prepared from *wheat malt*, in a similar way to ordinary beer from barley malt. A little *oat* and *bean meal* is frequently added. It was formerly much drunk in England; but its use at the present day is chiefly confined to Germany, and to Brunswick more particularly.

MUMMY. Syn. *Mumia*,—Lat. The mixed resinous mass with which the Egyptian corpses have been preserved, reduced to powder. *Used* by artists; a good glazing colour, but dries slowly. *Burnt Prussian blue*, or a *mixture of asphaltum and burnt sienna* melted together, are said to be good substitutes. Pure *asphaltum* (mumia mineralis) is superior to all the above for "glazings."

At one time a perfect rage existed for *Egyptian mummies* in Europe, the physicians having pronounced them to possess the most extraordinary virtues. The consequence was that "*mummy*" and its *preparations* "went up" in the market, and certain ingenious Jews commenced the manufacture of "*factitious mummy*." This

traffic lasted for a long time, until an ungrateful slave of Damietta, who entertained a serious objection to personally constituting pills, potions, and powders for Christian Europe, exposed the whole transaction to the Pacha. A serious persecution of the manufacturers of factitious mummy followed; the fastidious sick of Western Europe suddenly discovered that their doses of medicine lacked the peculiar palate of the ashes of the Pharoahs and Cleopatras, the doctors felt they had been outwitted, Avicenna fell into disgrace, and mummy went rapidly out of fashion.

MUMPS. Syn. *Parotitis*,—Lat. Inflammation of the parotid gland, which is situated under the ear, between the mamillary process of the temple-bone and the angle of the lower jaw. There is little constitutional derangement, but the cheeks become swollen and painful, and there is some difficulty in opening the mouth, and in swallowing. The *treatment* consists in simply keeping the part warm with flannel, and the use of warm fomentations, at the same time that the bowels are kept freely open with some mild laxative.

The *mumps* are said to be contagious, as when the affection appears in a school, it generally goes through every member of it. Low, damp situations are those most favorable to it. Occasionally, it is suddenly translated from the throat to the mammæ or testes, when it assumes a slightly more serious character, and a low diet, active purgation, and even local bleeding, should be had recourse to.

MUREXAN. Syn. *Purpuric Acid*,—Prout. *Prep.* (Liebig.) *Murexide* is dissolved in a *solution of caustic potassa*, heat is applied until the blue colour disappears, and *dilute sulphuric acid* is added in excess; silky crystalline scales of *murexan* or *purpuric acid* are deposited, and after being washed with a little *cold distilled water*, are, lastly, dried.

Prop., &c. It is only very slightly soluble in cold water; freely soluble in solutions of ammonia and the fixed alkalies; the first by exposure to the air becomes purple, and deposits brilliant crystals of *murexide*. These compounds are the *purpurates* of Dr. Prout.

MUREXIDE. Syn. *Purpurate of Ammonia*,—Prout. A highly interesting compound so named on account of its rich colour.

Prep. (Gregory.) *Hydrated alloxan*, 7 gr.; *alloxantine*, 4 gr.; *boiling water*, 240 gr.; dissolve, and add the solution to 80 gr.-measure of a *cold* and *strong solution of carbonate of ammonia*; crystals of murexide will separate as the liquid cools.

Prop., &c. It forms iridescent crystals, having a metallic lustre, of a magnificent green colour by reflected light, and an equally beautiful reddish-purple by transmitted light. It is soluble in boiling water, only very slightly soluble in cold water, and insoluble in alcohol and ether. An analogous substance, formed as above, by treating amalic acid with ammonia, is called "*caffein-murexide*."

MURIATE. See *Hydrochlorate*.

MURIATIC ACID. See *Hydrochloric Acid*.

MURIDE. The name originally given to *bromine*, by M. Balard.

MURRAIN. A disease affecting neat cattle, more especially young cows, in the seasons of spring and autumn. The *common symptoms* are tumefaction and discoloration of one of the hind quarters of the animal, with consequent lameness and inability to move; a peculiar emphysema or intumescence of various parts of the body, particularly over the region of the spine; and all the common features of putrid fever. In severe cases, gangrene soon follows, and death frequently ensues in from 12 to 24 hours.

The rapid progress of this disease admits of little being done in the way of medication or attempted cure. Extensive scarifications of the affected side, hot yeast or charcoal poultices, or hot fomentations, and active purgatives, appear to constitute the only useful treatment. The following *drenches* have been recommended for this affection:—

1. (Blaine.) *Sweet spirit of nitre*, ½ fl. oz.; *powdered cascarilla*, 2 oz.; *liquor of acetate of ammonia*, 4 fl. oz.; *yeast*, 8 fl. oz.; one every 3 or 4 hours.

2. (Clater.) *Laudanum* and *sweet spirit of nitre*, of each, ½ fl. oz.; *solution of chloride of lime*, ¼ fl. oz.; *prepared chalk*, 1 oz.; *warm gruel*, 1 pint. As the last.

The apparent incurability of this disease renders it of the utmost importance to the farmer to adopt *preventive measures*. These should consist of the supply of wholesome food and pure water, the adoption of extreme cleanliness, and the free access of pure air to all the stalls, barns, stables, and other buildings in which the cattle may be sheltered. As the disease is generally regarded as contagious, it is only prudent to separate, as speedily as possible, the healthy animals from those affected. The free use of chloride of lime as a disinfectant, is also advisable.

MUSHROOMS. Edible fungi. The

species commonly eaten in England are the *agaricus campestris* (Linn.), or *common field* or *garden mushroom*, used to make ketchup, and eaten either raw, stewed, or broiled;—the *morchella esculenta* (Linn.), or *common morel*, used to flavour soups and gravies;—and the *tuber cibarium* (Sibth; *lycoperdon tuber*,—Linn.), or *common truffle*, also used as a seasoning.

Several species of agarici, which to the inexperienced closely resemble the common edible mushroom, possess poisonous narcotic properties, and their use has not unfrequently been productive of serious, and, in some cases, fatal results. Unfortunately, no simple test exists by which the edible and poisonous varieties can be distinguished from each other. So strongly was the late Prof. L. C. Richards, the eminent botanist, impressed with this feeling, that though "none was better acquainted with the distinctions of fungi than he was, yet he would never eat any except such as had been raised in gardens, in mushroom beds." Certainly all mushrooms may be regarded as suspicious which are either not so raised, or not collected from a known pasture or meadow by a competent party. The following are a few of the published tests of the wholesomeness of mushrooms:—

1. Sprinkle a *little salt* on the spongy part or gills of the sample to be tried: if they turn *yellow*, they are *poisonous;* if *black*, they are *wholesome*.—2. *False mushrooms* have a *warty cap*, or else the fragments of membrane adhering to the upper surface, are heavy, and emerge from a vulva or bag; they grow in *tufts* or *clusters* in *woods*, on the stumps of trees, &c., whereas, the *true mushrooms* grow in *pastures*.—3. *False mushrooms* have an *astringent, styptic,* and *disagreeable taste*.—4. When cut they turn *blue*.—5. They are moist on the surface, and are generally of a *rose* or *orange* colour.—6. The *gills* of the *true mushroom* are of a *pinky red*, changing to a liver colour.—7. The flesh is white.—8. The stem is white, solid, and cylindrical.—9. "Introduce a silver spoon, or a new shilling or sixpence, or an onion, into a vessel in which mushrooms are seething; if, on taking either of them out, they assume a dark discoloured appearance, the circumstance denotes the presence of poison existing amongst them; if, on the other hand, the metal or onion on being withdrawn from the liquor wears its natural appearance, the fruit may be regarded as genuine, and of the right sort." (*Times*, Aug. 10, 1841.)

In cases of *poisoning* by *fungi*, vomiting should be immediately induced by an emetic and tickling the fauces with the finger or a feather; after which a purgative clyster or a strong cathartic should be administered, with ½ to 1 fl. dr. of *ether* in a glassful of water or weak brandy. As an antidote, a solution of *tannin*, ½ dr., in *water*, 1½ pint, or a *decoction* of ½ *oz.* of *powdered galls*, or of 1 *oz.* of *powdered cinchona bark* in a like quantity of *water*, has been strongly recommended by M. Chansarel.

Alexis Soyer is eloquent on the exquisite flavour and bouquet of mushrooms gathered in September or October, and baked under a glass or basin on toast, along with *scalded* or *clotted cream*, or a little *melted butter*, with *one clove*, and *salt, pepper, &c.*, to taste. They take about ¼ of an hour in a gentle oven or before the fire. "When it is taken up, do not remove the glass for a few minutes, by which time the vapour will have become condensed and gone into the bread; but when it is, the aroma, which is the essence of the mushroom, is so powerful as to pervade the whole apartment." "The sight, when the glass is removed, is most inviting,—its whiteness rivals the everlasting snows of Mont Blanc, and the taste is worthy of Lucullus. Vitellius would never have dined without it; Apicius would never have gone to Greece to seek for crawfish; and had he only half the fortune left when he committed suicide, he would have preferred to have left proud Rome and retire to some villa or cottage to enjoy such an enticing dish." (Soyer.)

MUSK. Syn. *Moschus*,—Ph. L. E. & D. "A secretion deposited in a follicle of the prepuce" of "*moschus moschiferus*, Linn." (Ph. L.) an animal inhabiting the mountains of Eastern Asia. It is imported from Bengal, China, and Russia; and, latterly, from the United States of America. That known as *Tonquin musk* is the most esteemed for its odour; but that from Russia is the only kind which reaches us in perfect bags, or which has not been tampered with. *Pod Musk* (*moschus in vesicis*) is the bag in its natural state, containing the musk. *Grain musk* (*moschus in granis, m. ex vesicis*) is the matter contained in the pods, and which constitutes true musk. The *average weight* of one of the *pods* is about 6 dr.; that of the *grain musk* which it contains, about 2½ dr.

Pur., &c. The musk of the shops is generally adulterated. *Dried bullock's blood* or *chocolate* is commonly employed for this purpose, along with a little *bone black*. The extent of these additions varies from 25% to

75% of the gross weight of the mixture. The blood is dried by the heat of steam or a water bath, then reduced to *coarse* powder, and triturated with the genuine musk in a mortar along with a few drops of *liquor of ammonia*. It is then either replaced in the empty pods, or it is put into bottles, and sold as grain musk. The writer of this article has seen a large quantity of dried blood thus employed, and sold for musk, and therefore speaks, not from mere hearsay, but from personal observation. There are only three certain ways of detecting this *fraud*, viz.—by the *inferiority of the odour*, by an assay for the iron contained in the blood, or—by the microscope. Genuine musk often becomes nearly inodorous by keeping, but recovers its smell on being exposed to the *fumes of ammonia*, or by being moistened with *ammonia water*. The perfumers sometimes expose it to the fœtid ammoniacal effluvia of privies for the same purpose.

Pure musk, by trituration or digestion with boiling water, loses about 75% of its weight, and the boiling solution, after precipitation with nitric acid, is nearly colourless. A solution of acetate of lead, and a cold decoction of galls, also precipitate the solution; but one of corrosive sublimate does not disturb it. The ashes left after the incineration of pure musk, are neither red nor yellow, but *gray*, and should not exceed 5 to 6%. The Chinese appear to be the most skilful and successful adulterators of musk.

Uses, &c. Musk is chiefly employed for its odour. As a *medicine*, it is a powerful stimulant and antispasmodic, and is a valuable remedy in various diseases of a spasmodic or hysterical character, or attended with low fever. *Dose.* 3 to 15 gr., made into an emulsion.

MUSK (Factitious). Syn. *Resin of Amber, Resina Succini, Moschus Artificialis. M. Factitius*,—Lat. *Prep.* 1. *Oil of amber*, 1 fl. dr.; *nitric acid*, 3½ fl. dr.; digest in a cold tumbler, and after 24 hours, wash in *cold water* the orange-yellow resinous matter which has formed, and carefully dry it.

2. (Elsner.) From *oil of amber*, 1 part; *fuming nitric acid*, 3 parts; as the last, but employing artificial cold to prevent any portion of the oil being carbonized.

Obs. Resin of amber smells strongly of musk, and is said to be antispasmodic and nervine. A tincture (*tinctura resinæ succini*) is made by dissolving 1 dr. of it in *rectified spirit*, 10 fl. dr., of which the *dose* is 1 fl. dr.; in hooping-cough, low fevers, &c.

Dr. Collier mentions an artificial musk, prepared by digesting for 10 days *nitric acid*, ½ oz., on "*fœtid animal oil*, obtained by distillation, 1 oz.; then adding of *rectified spirit*, 1 pint, and digesting the whole for a month." (Collier's *Pharm.* p. 184.)

MUSK SEED. Syn. *Grains d'Ambrette.* The seed of *hibiscus abelmoschus* (*Linn.*), or *musk mallow.* They are chiefly *used* for their odour, in perfumery, hair powder, coffee, &c.

MUSLIN, *Blonde, Lace*, and other like textile fabrics of a delicate description, are commonly cleaned by gently washing them with *white soap* and *water*, and after well rinsing them in *clean water*, they are either *clear-starched* or stretched on a frame to dry. Narrow blondes, lace, &c., are usually folded several times, and then loosely "tacked" together before putting them into the water. See *Clear-Starching.*

MUSQUITOS. See *Gnats.*

MUSSEL. See *Shell-fish.*

MUST. Syn. *Mustum*,—Lat. The *expressed juice* of *ripe grapes*, before fermentation. When boiled to 2-3rds, it is called *carenum;* when boiled to ½, it is called *sapa.* On further concentration, it yields a species of granular sugar (*grape sugar*).

MUST (Factitious). Syn. *Mustum Factitium*,—Lat. *Prep.* Dissolve *cream of tartar*, ¾ *oz.;* in *boiling water*, 7 pints; when cold, add of *lump sugar*, 2½ *lb.;* *raisins* (chopped small), ½ *lb.;* digest for 3 or 4 hours, strain through flannel as quickly as possible, and add of *lemon juice*, ½ pint.

MUSTARD. Syn. *Sinapis*,—Lat. "The seed" of "*sinapis nigra* and *s. alba.*" (Ph. L.) "Flour of the seeds of *sinapis nigra*, generally mixed with those of *sinapis alba*, and deprived of fixed oil by expression." (Ph. E.) "The flour of the seeds." (Ph. D.) That of the shops is very frequently *adulterated* with *wheat flour.* When this is the case, it does not readily make a *smooth paste* with water, but exhibits considerable toughness, and somewhat of a stringy appearance, especially when *little* water and *much* heat is employed. The common proportions taken by some grocers are,—*dried common salt, wheat flour*, and *superfine mustard*, equal parts; with *turmeric*, to colour, and *cayenne*, q. s. to give it piquancy and fire.

Uses, &c. Pure flour of mustard is used in medicine, to make stimulating poultices, pediluvia, &c. As a condiment it is useful in torpor and coldness of the digestive organs. A few years since the use of mustard seed, by spoonfuls, ad libitum, was a

common and fashionable remedy in torpor or atony of the digestive organs. The practice was a revival of that recommended by Dr. Cullen; but it has now again sunk into disuse. Sir Jno. Sinclair also approved of the use of mustard seed in this way, especially for the preservation of the health of the aged. (*Lancet*, Jan. 1834.) See *Poultices*, &c.

MUSTARD (for the Table). The common practice of preparing mustard for the table with *vinegar*, or, still more, with *boiling water*, materially checks the development of those peculiar principles on which its pungency or strength almost entirely depends. To economise this substance, we should use *luke-warm water* only; and when "flavouring matter" is to be added to it, this is better deferred until after the paste is made. The following forms for "*made mustard*" are much esteemed for their flavour:

Prep. 1. *Mustard* (ground), 3½ *lb.*; *water*, q. s. to form a *stiff* paste; in ½ hour, add of *common salt* (rubbed very fine), 1 *lb.*; with *vinegar*, *grape juice*, *lemon juice*, or *white wine*, q. s. to reduce it to a proper consistence.

2. To the last add a *little soluble cayenne pepper*, or *essence of cayenne*.

3. (M. Lenormand.) *Best flour of mustard*, 2 *lb.*; *fresh parsley*, *chervil*, *celery*, and *tarragon*, of each, ½ *oz.*; *garlic*, 1 clove; 12 *salt anchovies*; (all well chopped;) grind well together, add of *salt*, 1 *oz.*; *grape juice* or *sugar*, q. s. to sweeten; with sufficient *water* to form the mass into a thinnish paste by trituration in a mortar. When put into pots a red-hot poker is to be thrust into each, and a *little vinegar* afterwards poured upon the surface.

4. (*Moutarde à l'estragon.*) From *black mustard seed* (gently dried until friable, and then finely powdered), 1 *lb.*; *salt*, 2 *oz.*; *tarragon vinegar*, q. s. to mix. In a similar way the French prepare several other "*mustards*," by employing *vinegars* flavoured with the respective substances, or *walnut* or *mushroom ketchup*, or the liquors of the richer pickles.

5. (*Moutarde superbe.*) *Salt*, 1½ *lb.*; *scraped horseradish*, 1 *lb.*; *garlic*, 2 cloves; *boiling vinegar*, 2 gall.; macerate in a covered vessel for 24 hours, strain, and add of *flour of mustard*, q. s.

6. (*Patent.*) *Black ginger* (bruised), 12 *lb.*; *common salt*, 18 *lb.*; *water*, 15 gall.; boil, strain, and add to each gallon, *flour of mustard*, 5 *lb.*

7. (M. Soyés.) Steep *mustard seed* in twice its bulk of *distilled vinegar* for 8 days, then grind the whole to a paste in a mill; put it into pots, and thrust a red hot poker into each of them. (*Patented.*)

MUSTINESS. See *Malt Liquors* and *Wines*.

MUTAGE. The term applied to the "matching" of *grape must* to arrest the progress of fermentation. See *Antiferments*, *Matches*, &c.

MUTTON (*Choice of.*) That of the *first quality* is "between *four* and *five* years old; but at present it is rarely got above three, and often under two. The flesh ought to be of a darkish, clear, red colour, the fat firm and white, the meat short and tender when pinched, and it ought not to be too fat." (Soyer.) The flesh of the "*South-down wether*" is esteemed the finest flavoured. *Mutton* is one of the most wholesome of the "red meats," and in commercial importance is second only to beef.

MYKOMELINIC ACID. A new acid discovered by Wöhler and Liebig, and obtained by heating to 212° a *solution of alloxan* with *ammonia* in excess, adding *dilute sulphuric acid*, also in excess, and boiling for a few minutes. The new acid falls as a yellow gelatinous precipitate, which dries to a yellow porous powder. It is only slightly soluble in water, but is freely soluble in alkaline solutions.

MYRICINE. The portion of *bees' wax* which is insoluble in alcohol, and saponified with difficulty.

MYRISTIC ACID. A monobasic fatty acid, obtained by the saponification of *myristine*. It melts at 120° Fahr.

MYRISTICINE. The *stéaroptène* deposited by *oil of nutmegs* by keeping.

MYRISTINE. Syn. *Sericine*. The white, solid portion of the *expressed oil of nutmegs* which is insoluble in cold alcohol. See *Myristic Acid*.

MYROLES. The *myrolés* of French pharmacy, are solutions of oleaginous or resinous substances in the volatile oils.

MYRONIC ACID. Bussy has given this name to an inodorous, bitter, non-crystallizable acid found by him in black mustard. It is soluble in water and alcohol.

MYROSINE. Syn. *Emulsine of Black Mustard*. A name given by Bussy to a peculiar substance soluble in water, and which possesses the power of converting *myronic acid*, in the presence of *water*, into the *volatile oil of mustard-seed*.

MYROSPERMINE. The name given by Richter to the portion of the *oil of balsam of Peru* which is soluble in alcohol.

MYROXILINE. The name given by

Richter to the portion of the *oil of balsam of Peru* which is insoluble in alcohol. By oxygenation it forms *myroxilic acid.*

MYRRH. Syn. *Myrrha*,—Ph. L. E. & D. "Gum resin exuded from the bark" of "*balsamodendron myrrha*, Nees." (Ph. L.)

Pur.—1. Triturate a small quantity of the *powder* of the *suspected myrrh* with an equal amount of *hydrochlorate of ammonia*, adding *water*, gradually; if the whole is *readily* dissolved, the myrrh is genuine; otherwise it is *sophisticated* with some inferior substance. (Giovanni Righini.)—2. When incinerated it should not leave more than 3½ to 4% of ashes.

Uses, &c. Myrrh is a stimulating aromatic bitter and tonic, and is given in several diseases accompanied by relaxation and debility; especially in excessive secretions from the mucous membranes, and in disorders of the digestive organs. *Externally*, as an ingredient in dentifrices and rashes, in caries of the teeth, spongy and ulcerated gums, &c. *Dose.* 10 to 30 gr.; either alone or combined with aloes or chalybeates.

MYRRHIC ACID. The hard resinous portion of myrrh. It is soluble in the caustic alkalies, forming *alkaline myrrhates.*

NAILS (The) should be kept clean by the daily use of the *nail brush* and *soap-and-water.* After wiping the hands, but whilst they are still soft from the action of the water, the skin, which is apt to grow over the nails, should be *gently* loosened and pressed back, which will not only preserve them neatly rounded, but will prevent the skin cracking around their roots (*agnails, nail-springs*), and becoming sore. The free ends or points of the nails should be pared about once a week; and biting them should be particularly avoided, as being at once destructive to their beauty and usefulness. "The (free) edge of the scarf-skin *should never be pared*, the surface of the nail *never scraped*, or the nails cleaned with *any instrument whatever* saving the nail brush." (Eras. Wilson.)

The consequences of wearing a shoe that is obviously too short for the foot are thus described by the above authority. "In this case, Nature gives us warning, by means of her agent, *pain*, that such a proceeding is contrary to her laws. We stop our ears, and get accustomed to the pain, which, perhaps, is not severe, and soon goes off; the shoes get a scolding for their malice, and we forget all about it for a time. But does Nature check her course to suit the convenience of thoughtless man? No, no. In a short time we find that the nail, intercepted in its *forward* course, has become *unusually thick* and *hard*, and has *spread* out so much upon the sides, that it is now growing into the flesh, and so makes a case for the doctor. Or, perhaps, the continuance of pressure may have inflamed the sensitive skin at the root, and caused a *sore* and *painful place* there. And instances are by no means infrequent in which the power of production of the nail at the root becomes entirely abrogated, and then it *grows* in *thickness only.*"

When the *nails* are *stained* or *discoloured*, a little *lemon juice*, or *vinegar-and-water* is the best application. Occasionally a little *pumice stone*, in impalpable powder, or a little "*putty powder*," may be used along with *water* and a piece of *soft leather* or *flannel* for the same purpose. The frequent employment of these substances is, however, injurious to the healthy growth of the nail.

Dr. Beau, a French writer quoted by Mr. Wilson, estimates the growth of the nails of the *hand* at 1 millimetre, or ⅔ths line a week; and the same length in 4 weeks for those of the *feet.* According to him, the portion of nail formed during the progress of disease is thinner than that produced during health, and may be distinguished on the surface as a transverse groove. If the disease has been sudden, the outer boundary of the groove is abrupt, and *vice versâ.* And if the disease is one in which the nutritive functions are seriously affected, the depth of the groove maintains an exact correspondence. From the changes thus produced on the surface of the nail, Dr. Beau suggests the possibility of *determining the period* of *occurrence* and also the *period of duration* of a *disease*, provided the time does not exceed that required for the entire growth of the nail. "For example:—a *groove*, or rather *ledge*, situated at the distance of eight millimetres from the edge of the root of the *thumb-nail*, or five from the free margin of the skin, is indicative of an attack of disease which commenced eight weeks previously; while the breadth of the groove being two millimetres would prove the disease to have continued for the space of two weeks. *After five months*, the *thumb-nail* ceases to be a tell-tale, on account of its entire growth in length being accomplished, and the vestige of disease consequently obliterated. The *great toe-nail* is now to be appealed to. At five months, the groove indicative of the above disease has advanced only five millimetres from the root, and is

only just becoming apparent beyond the free margin of the skin, the breadth of the groove being only half a millimetre. In making these observations, M. Beau selects the thumb-nail and corresponding nail in the foot, because in them only he finds the appearances regularly present."

NANCEIC ACID. See *Zumic Acid*.

NANKEEN. The coloured cotton cloth which bears this name was originally brought from Nankin, the ancient capital of China, and was prepared from a native cotton, of a brownish-yellow hue. It is now successfully imitated in England, and at the present time the English manufacturers supply the Canton market. In this country the colour is generally given to the cloth by successive baths of *sulphate of iron* and *crude carbonate of soda* or *lime water*.

NANKEEN DYE. The liquid sold under this name in the shops, is the *annatto dye*, noticed at *p.* 69. It is employed to dye white calicoes of a nankeen colour; but, chiefly to restore the colour of faded nankeen clothing.

NAPHTHA. Syn. *Mineral Naphtha; Naphtha*,—Lat. A name given to the limpid and purer varieties of *liquid bitumen* or *rock oil*, which exudes from the surface of the earth in various parts of the world.

Prop. Naphtha possesses a penetrating odour and a yellow colour, but may be rendered colourless by distillation; its boiling point varies from about 160° to 201° Fahr., according to its purity; it is very inflammable; it does not mix with water, but imparts to that fluid its peculiar taste and smell; mixes with alcohol, and oils, and dissolves sulphur, phosphorus, camphor, iodine, most of the resins, wax, fats, and spermaceti; and forms with caoutchouc a gelatinous varnish, which dries with very great difficulty. Sp. gr., 0·753 to 0·780. The liquid distilled from the coal oil of the gas works, and commonly vended under the name of *naphtha*, or *coal-tar naphtha*, differs from true mineral naphtha in possessing a highly offensive odour and a different chemical constitution, although in many points, as in solvent power, &c., the two substances resemble each other. Coal naphtha has the sp. gr. 0·857, and does not boil at a lower temperature than 316° Fahr., unless when highly rectified.

Pur. Mineral naphtha is very frequently adulterated with oil of turpentine, a fraud which may be detected by—1. The addition of some oil of vitriol, which will, in that case, thicken and darken it.—2. Hydrochloric acid gas passed through the liquid for an hour will occasion the formation of hydrochlorate of camphine, either at once, or after a few hours' repose, even if only $5\frac{0}{0}$ of oil of turpentine is present. (Dr. Bolley.)—3. If a few grains of iodide of potassium and a little water are rubbed with the suspected sample, the colour of the water should continue unchanged; the presence of $\frac{1}{300}$th part of oil of turpentine will cause it to assume a red or orange colour. (Saladin.)

Uses. Naphtha is chiefly employed for the purposes of illumination, as a solvent for Indian rubber, and in the preparation of a very superior black pigment. It has been highly spoken of as a remedy for cholera, by Dr. Andreosky, a Russian physician; and, recently, a *naphthalized* or *petrolized soap* has been prepared, which is highly spoken of, both for the purposes of the toilet and as a remedial agent in several skin diseases. *Coal-tar naphtha* is principally employed in the preparation of certain coarse paints and varnishes, and as a solvent of Indian rubber. See *Pyroxylic Spirit*.

NAPHTHA (Acetic). See *Acetic Ether*.

NAPHTHA (Black). See *Petroleum*.

NAPHTHA (Coal-tar). See *above*.

NAPHTHA (Vitriolic). See *Ether*.

NAPHTHA (Wood). See *Pyroxylic Spirit*.

NAPHTHALAMIDE. A compound obtained by the distillation of *naphthalate of ammonia*.

NAPHTHALIC ACID. A crystalline substance resembling benzoic acid, obtained by Laurent from naphthaline.

NAPHTHALIDINE. A substance obtained by Zinin, by the action of *sulphide of ammonium* upon an *alcoholic solution of nitro-naphthalase*. It forms colourless, silky needles; is neutral; fusible; volatile without decomposition; soluble in alcohol and ether, but scarcely so in water; has a powerful odour; a hot taste; and forms crystallizable compounds with the acids.

NAPHTHALINE. A white, crystallizable, odorous, volatile substance, obtained by redistilling coal-tar.

Prep. The last portion of the *volatile oily product* is collected separately, and allowed to repose, when crude naphthaline separates. By pushing the distillation until the residuum in the still begins to char, a further portion of dark-coloured naphthaline may be obtained in the solid state. It is purified by resublimation a second, or even a third time.

Prop., &c. Soluble in alcohol and ether; slightly soluble in boiling water; melts at 178° Fahr.; boils at 413°; highly inflammable, burning with a red and smoky flame; with sulphuric acid it unites to

form *sulphonaphthalic acid.* It has lately been extensively employed as a stimulating expectorant. *Dose.* 5 to 20 gr.; or, preferably, ½ gr., frequently. *Externally*, made into an ointment, in dry tetters, psoriasis, &c.

NAPLES YELLOW. See *Yellow Pigments.*

NARCEINE. Syn. *Narceina, Narceia.* A peculiar substance discovered by Pelletier in opium. It is *obtained* from the *aqueous solution of opium*, after it has been freed from morphia and narcotine by ammonia, by adding to it *hydrate of lime*, or, preferably, *baryta.* On boiling the filtered solution to expel the ammonia, and evaporating the liquid, *crystals of narceine* are gradually deposited. It may be purified by solution in *hot alcohol* and recrystallization.

Prop., &c. White, silky, acicular prisms; neutral; inodorous; bitter; pungent; soluble in 375 parts of water at 60°, and in 230 parts at 212° Fahr.; insoluble in ether; does not neutralize the acids, and is destitute of basic properties. It is *distinguished* from *morphia* by its easier fusibility (198°), and by forming a blue liquid with the dilute mineral acids, which on gradual dilution changes to violet, and rose red, and ultimately becomes colourless. It does not strike a blue colour with sesquichloride of iron, like morphia, but forms a blue compound with starch. It appears to be inert, and has not been applied to any useful purpose.

NARCOGENINE. A basic substance, of little importance, resulting from the oxidation of *narcotine* by *bichloride of platinum.*

NARCOTICS. Syn. *Stupefacients; Narcotica, Stupefacientia,* — Lat. Medicines which produce drowsiness, sleep, and stupor. In *small doses*, narcotics mostly act as stimulants, but in *larger ones* they produce calmness of mind, drowsiness, and torpor; and in *poisonous doses*, delirium, coma, and death. The general objects in the administration of these agents, are the production of sleep, and the alleviation of pain. Their action is modified to a greater degree by idiosyncracy and habit, than that of, perhaps, any other class of medicines. Hence the care necessary in their administration. *Alcohol, camphor, chloroform, ether, foxglove, hemlock, henbane, morphia, opium,* and *tobacco*, are *narcotics.*

NARCOTINE. Syn. *Narcotina,*—Lat. *Sel d'Opium, Matière de Derosne,*—Fr. A peculiar crystalline substance found by Derosne in opium, and on which its stimulant property was at first supposed to depend.

Prep. 1. From *opium exhausted of soluble matter by cold water*, by treating it with *water acidulated with acetic* or *hydrochloric acid*, filtering, neutralizing with *ammonia*, and dissolving the washed precipitate in *boiling alcohol;* the *narcotine* is deposited as the liquid cools, and may be purified by solution in ether.

2. By acting on *opium* (previously exhausted by *cold* water) with *ether.*

Prop., &c. White, inodorous, fluted or striated prisms; neutral to test paper; insoluble in cold water; sparingly soluble in boiling water; freely soluble in boiling alcohol, and in ether. It is only feebly basic.

Narcotine is *distinguished* from *morphia* by its insipidity, solubility in ether, insolubility in alkalies, giving an orange tint to nitric acid, and a greasy stain to paper when heated on it over a candle. *Another test* for narcotine, said by Orfila to be characteristic, is to add to a little of the suspected substance a drop or two of oil of vitriol, and then to add a *very small fragment of nitrate of potassa;* the liquid speedily acquires a deep blood-red colour if narcotine is present. Morphia treated in the same way strikes a brown or olive-green colour.

Obs. The physiological action of narcotine is differently stated by different authorities. 1 gr. of it dissolved in *olive oil*, killed a dog in 24 hours; but 24 gr. dissolved in *acetic acid* were given with impunity. (Magendie.) In the solid state it is inert; 129 gr. at a dose scarcely produce any obvious effects. (Bally.) Scruple doses have been given without injury. (Dr. Roots.) It has been recently proposed as a substitute for quinine in the cure of agues. For this purpose the *sulphate* or *hydrochlorate* is preferable. 200 cases of intermittent and remittent fevers have been thus successfully treated in India. (Dr. O'Shaughnessy.) *Dose.* 3 to 10 gr., as an antiperiodic, sedative, &c.

Turkey opium contains about 1%, and East Indian opium about 3% of narcotine.

NATRIUM. See *Sodium.*

NATRON. Native sesquicarbonate of soda.

NAUSEA. See *Sickness.*

NAUSEANTS. Syn. *Nauseantia,*—Lat. Substances which induce an inclination to vomit, without effecting it. See *Emetics.*

NECKLACES (Anodyne). These are formed of the *roots of henbane*, of *Job's tears, allspice steeped in brandy, jumble*

beads, elk's hoof, &c., cut and strung on ribbon or strings, according to the fancy of the quacks who prescribe them. Formerly, commonly used to promote easy dentition, sleep in fevers, &c.; and still occasionally employed by the ignorant and superstitious for the same purposes.

NECTAR. The fabled drink of the mythological deities. The name was formerly given to *wine dulcified with honey;* it is now occasionally applied to other sweet and pleasant beverages of a stimulating character. The following *liqueurs* are so called:—

Prep. 1. *Chopped raisins*, 2*lb.; loaf sugar*, 4*lb.; boiling water*, 2 gall.; mix, and stir frequently until cold, then add 2 *lemons*, sliced; *proof spirit* (brandy or rum), 3 pints; macerate in a covered vessel for 6 or 7 days, occasionally shaking, next strain with pressure, and let the strained liquid stand in a cold place for a week to clear; lastly, decant the clear portion, and bottle it.

2. *Red ratifia*, 3 gall.; *oils of cassia* and *caraway*, of each, 25 drops; (dissolved in) *brandy*, ½ pint; *orange wine*, 1 gall.; *sliced oranges*, 6 in no.; *lump sugar*, 2 *lb.;* macerate for a week, decant and bottle. See *Arrack* (Factitious).

NEGUS. A well-known beverage, so named after its originator and patron, Colonel Negus. It is made of either *port* or *sherry wine*, mixed with about twice its bulk of *hot water*, sweetened with *lump sugar*, and flavoured with a little *lemon juice* and *grated nutmeg*, and a *small fragment* only of the *yellow peel of the lemon*. The addition of about 1 drop of *essence of ambergris*, or 8 or 10 drops of *essence of vanilla*, distributed between about a dozen glasses, improves it.

NEPENTHES. The "*Homeri nepenthes*," that Helen cast into the wine, is now a sealed mystery. A composition containing *ambergris, crocus solis, lignum aloes, opium*, and *saffron*, was so called by the old writers; afterwards christened *laudanum*, by Paracelsus. The "*nepenthe*" of Messrs. Ferris and Score, of Bristol, in all essential points resembles Battley's *liquor opii sedativus*.

NERVINES. Syn. *Neurotics; Neurotica*,—Lat. Substances or agents which relieve disorders of the nerves. The *antispasmodics, chalybeates*, and *vegetable tonics*, belong to this class.

NERVOUS FEVER. Syn. *Febris Nervosa*,—Lat. A low continued fever, of a typhoid character (*typhus mitior*) in which nervous derangement or sensorial debility are leading symptoms. The *treatment* consists in allaying nervous irritation, and supporting the strength of the patient. See *Typhus*.

NERVOUSNESS. The indescribable derangement of health, and the complication of disagreeable sensations which are popularly described under this name, quite as much deserve the serious attention of both patient and physician as any other affection to which the human frame is liable. Although, in itself, not a definite disease, it is indicative of the vital system being out of order, that its energies are failing or overtasked, and that the functions of some of its members or organs are languidly or imperfectly performed. This condition, if not removed, will gradually increase into active disorganization and disease, if it be not prematurely cut short by the advent of some more serious malady, to which its existence has rendered the body peculiarly susceptible.

The *treatment* of nervousness consists mainly in restoring the healthy action of the stomach and bowels, and in the use of proper *exercise*, especially in the open air. The stomach should not be overloaded with indigestible food, and the bowels should be occasionally relieved by the use of some mild aperient. Mental, as well as bodily relaxation, should be sought, and the pleasures, without the vices of society, should be indulged in as discretion and inclination may direct. Abernethy's injunction to a nervous and dyspeptic lady, "*Dismiss your servants, madam, and make your own beds*," should be recollected by all, and may be taken as a proof of the importance that eminent surgeon attached to EXERCISE. See *Exercise, Flatulence, Hypochondriasis, Hysterics, Indigestion, &c.*

NETTLE RASH. See *Rashes*.

NEURALGIA. Literally, pain in a nerve. "Various parts of the body are liable to be affected with excruciating pain, which is quite independent of any inflammation of the part, and which may often be traced in the course of the nerves." These affections constitute *neuralgia*. One of the most distressing forms of this disease is *facial neuralgia* or *tic douloureux* (neuralgia facialis), which, when it assumes a marked intermittent character, is popularly known as *face ague*. Sometimes it attacks the nerves of the female breast; or those of the hand, feet, hip, or loins, in which cases it is often confounded with acute rheumatism of those parts.

The *treatment*, when neuralgia is *symptomatic* of any other affection, must be directed to the primary disease. When it is idiopathic, or an independent affection, powerful tonic medicines, and powerful local counter-irritation are generally found the most successful remedies. Of *tonics*,

carbonate of iron and bark (both in very large doses) are generally preferred; the last, more particularly when the affection is of an intermittent kind. As a counter-irritant, caustic ammonia has been much relied on. When all other means fail, a current of mild streaming electricity through the part will often give immediate and permanent relief.

NEUTRALIZATION. The admixture of an *alkali* or *base* with an *acid* in such proportions that neither shall predominate. A neutral compound neither turns turmeric paper *brown*, nor litmus paper *red*.

NICARAGUA WOOD. An inferior variety of *Brazil wood*. With a *mordant of tin* it dyes a bright but fugitive red.

NICKEL. Syn. *Nickelium*,—Lat. A metal obtained from speiss or kupfernickel, a native arseniuret of nickel found in Westphalia.

Prep. The *powdered ore* is roasted first by itself, and next with *charcoal powder*, until all the arsenic is expelled, and a garlic odour ceases to be evolved; the residuum is mixed with *sulphur*, 3 parts, and *potassa*, 1 part, and the compound is melted in a crucible with a gentle heat; the fused mass, when cold, is reduced to powder, edulcorated with *water*, dissolved in *sulphuric acid mixed with a little nitric acid*, and precipitated with *carbonate of potassa*; the precipitate (*carbonate of nickel*) is washed, dried, mixed with *powdered charcoal*, and, lastly, reduced by the heat of a powerful furnace.

When nickel predominates in the ore, after the arsenic, iron, and copper have been separated, *ammonia* is digested in the *mixed oxides of cobalt and nickel*, and the resulting blue solution, after dilution with *boiled pure water*, is treated with *caustic potassa* until the colour disappears, when the whole is put into an air-tight vessel, and set it aside for some time. The powder (*hydrated oxide of nickel*) which subsides, after edulcoration, is mixed with *charcoal*, and reduced by fusion in a crucible containing some *crown glass*.

On the *small scale*, for chemical purposes, *pure nickel* is best obtained by moderately heating *oxalate of nickel* in a covered crucible lined with *charcoal*.

Prop. White; hard; malleable; magnetic; capable of receiving the lustre of silver: sp. gr., when hammered, about 8·82; fusibility between that of manganese and iron; it is not oxidized in the air; and is little attacked by dilute acids unless when nitric acid is present; this last acid dissolves it freely. With the acids, &c., it forms numerous compounds, most of which may be prepared by the direct solution of the carbonate.

Tests. The *salts of nickel* in the *anhydrous* state are for the most part yellow; when *hydrated*, green,—and furnish solutions possessing a pale-green colour. Solutions of its salts exhibit the following reactions:—1. Caustic alkalies give a pale apple-green precipitate, insoluble in excess, but soluble in a solution of carbonate of ammonia yielding a greenish-blue liquid.—2. Ammonia gives a similar precipitate, soluble in excess, yielding a deep purplish-blue solution. The presence of ammonia or free acids interferes with this reaction.—3. Cyanide of potassium produces a green precipitate, soluble in excess, forming an amber-coloured liquid which is reprecipitated by hydrochloric acid. This last precipitate is scarcely soluble in excess of the acid in the cold, but readily so upon boiling the liquid.—4. Ferrocyanide of potassium gives a greenish-white precipitate.—5. Sulphuretted hydrogen occasions no change in solutions of nickel containing free mineral acid; but in alkaline solutions gives a black precipitate.—6. Hydrosulphuret of ammonia in neutral solutions gives a black precipitate, soluble with difficulty in hydrochloric acid; but freely soluble in aqua regia.

Estim. Nickel may be thrown down from its ores in the form of either carbonate or hydrated oxide (see *above* and *Carbonate of Nickel*), and after ignition, may be weighed as oxide, each grain of which is equal to $\frac{7}{8}$ gr. of PURE NICKEL; or more accurately, 0·7871 gr.

According to H. Rose, *nickel* may be separated from *cobalt* as follows:—The mixed metals are dissolved in considerable excess of *hydrochloric acid*, and the solution is diluted with a very large quantity of *water*; a current of *chlorine* is then passed through the liquor for several hours, and the upper part of the flask is left filled with the gas after the current has ceased; *carbonate of baryta* is next added, in excess, the whole digested together with frequent agitation for 15 or 18 hours, and then thrown on a filter. The *filtrate* yields pure OXIDE OF NICKEL by precipitation with caustic potassa; whilst the residuum on the filter, after being washed in water, dissolved in hot hydrochloric acid, and the baryta precipitated with sulphuric acid, furnishes, with hydrate of potassa, a precipitate of *hydrated oxide of cobalt*, free from nickel, which when washed and dried, is reduced in a platinum or porcelain crucible, by hydrogen gas. See *German Silver*.

Uses. Nickel is chiefly employed in the manufacture of German silver. Some of its salts have been recently introduced into medical practice, and appear likely to prove most valuable additions to the materia medica. (See *below.*)

NICKEL (Acetate of). Syn. *Nickelii Acetas,* — Lat. *Prep.* By neutralizing *acetic acid* with *carbonate* or *oxide of nickel,* and gently concentrating by evaporation so that crystals may form. Small green crystals, soluble in 6 parts of water.

NICKEL (Carbonate of). Syn. *Nickelii Carbonas,*—Lat. This salt may be obtained in the manner described at *p.* 818, or by simply adding *carbonate of soda* to a *solution of chloride* or *sulphate of nickel,* but in this state some *hydrate of nickel* is precipitated along with it. The following is another formula which produces a nearly pure carbonate, but one which may still contain a little cobalt, the *entire* separation of which is a matter of extreme difficulty, and can only be effected in the manner described above.

Prep. The *mineral* (crude speiss or kupfernickel) is broken into small fragments, mixed with from one fourth to one half its weight of *iron filings,* and the whole dissolved in *aqua regia;* the solution is gently evaporated to dryness, the residue treated with *boiling water,* and the insoluble *arseniate of iron* removed by filtration; the liquid is next acidulated with *hydrochloric acid,* treated with *sulphuretted hydrogen,* in excess, to precipitate the copper, and, after filtration, is boiled with a little *nitric acid,* to bring back the iron to the state of sesquioxide; to the *cold* and *largely diluted* liquid a *solution of bicarbonate of soda* is gradually added, and the *sesquioxide of iron* separated by filtration; lastly, the filtered solution is boiled with *carbonate of soda,* in excess, and the pale-green precipitate of *carbonate of nickel* collected, washed, and dried.

Uses, &c. It is freely soluble in the acids, and is chiefly employed to prepare the salts and other compounds of nickel.

NICKEL (Chloride of). Syn. *Muriate of Nickel; Nickelii Chloridum*—Lat. *Prep.* From *carbonate* or *oxide of nickel* and *hydrochloric acid,* as the *acetate.* Small green crystals, which are rendered yellow and anhydrous by heat, unless they contain cobalt, when the salt retains a tint of green.

NICKEL (Oxalate of). Syn. *Nickelii Oxalas,*—Lat. *Prep.* By adding a *strong solution of oxalic acid* to a like solution of *sulphate of nickel,* and collecting the pale bluish-green precipitate which forms after a time. *Used* to prepare both *metallic nickel* and its *oxide.*

NICKEL (Oxides of). *Prep.* 1. (*Oxide of Nickel, Protoxide of do.*)—*a.* By heating the *nitrate, carbonate,* or *oxalate* to redness in open vessels. Anhydrous.
