ADVERTISEMENT TO THE READER.

THE intention of the Author in publishing this Appendix being only to supply some defects of the former volumes, and to give the reader a general idea of the new system and its application to the chymical part of the foregoing work, and not to write a treatise on the elements of universal chymistry, he has not entered at large into the discussion of the arguments used in support of the different opinions; neither has he described the numerous processes performed to prove the different facts mentioned, or the instruments and machines employed in performing these processes; and therefore must refer those who wish to be particularly informed of these circumstances, to the elaborate works of the Hon. H. Cavendish, Dr. Priestley, Mr. Kirwan, M. Lavoisier, M. Fourcroy, M. Morveau, M. Metherie, and of other
able

I N T R O D U C T I O N.

AFTER the Author's Treatise on Medical and Pharmaceutical Chymistry had been printed in the year 1787, the French Nomenclature, containing a plan of a new system of chymistry, arrived in this country. At first, most of the ingenious men, conversant in pneumatical chymistry, who had long supported the doctrine of phlogiston, suspected that mistakes had been committed, in performing many of the experiments brought in support of the new doctrine, and that false conclusions had been drawn from others; and therefore the Author, in his Preface, took no further notice of this French work, than in mentioning, that it promised to add great improvements to chymistry; thinking that it would not be

right in him to enter into the description of a system, the principles of which were not established, and were even suspected by many ingenious and able men to be erroneous ; particularly as at that time it had not been carried so far, as to point out to us any new or better method of preparing chymical medicines, than those already recommended, or to add one new remedy to those now in use.

But since that period, many discoveries have been made by the authors of the new system, which should seem to establish it on a firmer basis, to enable us to make a more accurate analysis of bodies than formerly, and to lead to the discovery of many chymical preparations, which may prove efficacious remedies in the cure of diseases ; for these reasons the Author thinks it now right to add to his former work such a sketch of the new system, as may give a general idea of it, and enable those who wish to prosecute the study of medical chymistry, to read with more ease and pleasure the elaborate works of our more modern chymists ; and, likewise, to

add a table, in which the changes produced by chymical operations on some of the principal substances, which are the objects of the foregoing work, are to be accounted for by the new theory.

The new doctrine is certainly beautiful, and at present appears in many points to be just; but whether the whole system laid down by Monsieur Lavoisier and his associates, will stand the test of experiment, in its full extent, is as yet uncertain; for the objects of fire, light, aërial fluids, &c. are so very subtile, that many of them cannot be confined in vessels; so that it is not at all improbable but that many mistakes may have been committed, and false conclusions been drawn from the result of some of the experiments which have been made: time however will correct these errors, if the new doctrine is well founded; and if otherwise, it will sap its foundation.

The operations performed for establishing this new system have already led to the discovery of a number of preparations, particularly of the saline class, which have

properties different from those before known ; thus the same acid has different properties, according as its acidifiable basis is more or less impregnated with the basis of pure air, called oxigene, by our modern French chymists ; and the neutral salts, made with the same acids and alkaline substances, differ likewise from one another, if the degree of oxigenation be different in the acids employed : thus the neutral salt, made with the vegetable alkali and the common muriatic acid, differs very much from that made with the same alkali in a caustic state, and the muriatic acid highly oxigenated, *i. e.* impregnated with pure air : the taste of this last salt differs from that of the former, and it detonates when laid on the red hot coal, more strongly than nitre, which the other does not. However, as the salts, and other preparations, made by the inventors of the new theory, have not hitherto been used as medicines, so as to ascertain their particular virtues, properties, and doses, they cannot properly be considered as substances belonging to the materia medica, and

and therefore no further notice will be taken of them at present.

It having been suggested lately to the Author, that some of the experiments made by Mr. Eller (the account of which he had quoted from the Berlin Memoirs for the year 1750), relative to the generation of heat during the time of the solution of Glauber's and other salts in water, were suspected to be erroneous, he repeated some of them; and found that Glauber's and Epfom salts, if dissolved in their crystallized state, generate cold instead of heat; but if they be first reduced to a powder, and then dried, so as to free them from the water of their crystallization, in the manner recommended by Mr. Eller, that they then generate heat, and raise the quicksilver of the thermometer in the time of their solution in water. By mistake, the words dried and powdered had been forgot to be put before some of the salts mentioned in page 185 and beginning of page 186 of vol. i. of the foregoing work.

In repeating these experiments of Mr. Eller's a very particular circumstance oc-

curred, which the Author was at first at a loss how to account for.—Having caused an ounce of true Glauber's salt, and as much green vitriol, to be well dried, separately, and freed of all the water of their crystallization, he put three ounces of New River water, which had passed through a filtering stone, into a large tea-cup; and having placed in it a pocket thermometer, graduated according to Fahrenheit's scale, he observed to what height the quicksilver rose; after which he added by degrees the green vitriol, dried to whiteness and powdered, while he kept stirring about the water, and a heat was immediately generated, which raised the quicksilver of the thermometer above seven degrees. Having let the thermometer remain in the water for ten minutes, to see if the quicksilver would rise higher, which it did not, he, at the end of that period, attempted to remove it, but found it firmly fixed in the cup, which surprised him; and, on pouring out the water to know the cause, he found the ball of the thermometer fixed firmly in a brownish coloured saline cake, which had

had formed in the bottom of the tea-cup, in the same manner as a piece of stick would have been, which had been put into water, and the water afterwards allowed to freeze, by setting it in the open air, in the time of a hard frost.

The same thing happened when the dried Glauber's salt was treated in the same manner; heat was generated on being mixed with water, and a saline cake was formed in the bottom of the tea-cup. In both these cases, the quantity of water was more than would have dissolved the ounce of each of these salts in their crystallized form. Dried Glauber's salts, during its solution, raised the thermometer 6 degrees; dried green vitriol 7 degrees; dried Epsom salt 14; and part of all of them coagulated, and sunk to the bottom of the cup, without dissolving.

This is a circumstance which I have not observed to have been taken notice of by chymical authors, but deserves to be attended to, and experiments to be made to ascertain the reason why these salts, when dried, should generate heat when mixed

with water, and why part of these dried salts should coagulate and not be dissolved in the water, in the same manner as they are when they are in a crystalline state.—The cause of their becoming solid may probably be the same as that assigned by Monsieur Adet, in the *Annales de Chymie*, tom. i. p. 17, for the muriate of tin becoming so, on its being mixed with water; which, he says, is in consequence of that law which forces all bodies to condense; when, during their combinations, they are robbed of the matter of heat (*du calorique*) which holds them in a certain state of dilatation.

Crude sal ammoniac in powder, which had been deprived of most of its water, by being first reduced to a fine powder, and then kept stirring in an earthen pan over the fire, on being mixed with a cup full of New River water, in which I had placed a pocket thermometer, dissolved readily, without forming any cake; and generated such a degree of cold as lowered the quicksilver of the thermometer above sixteen degrees.—In the *Philosophical*

phical Transact. vol. lxxvii. for the year 1787, art. 26, p. 202, Mr. Walker of Oxford tells us, that he found, as Boerhaave had done before him, that sal ammoniac, as well as nitre, well dried in a crucible, and reduced to a fine powder, will produce a greater degree of cold, than if they had not received this treatment.—Do not these experiments confirm M. Adet's doctrine? For when no heat is generated, that is, where the salt to be dissolved does not part with its latent heat, it does not become solid, but dissolves readily. Hitherto we do not know why some salts generate cold, and some heat, during the time of their solution; nay, that the same salts, under different circumstances, should at one time generate heat, and at another cold: in the one case the water should seem to attract the heat from the salt; in the other, the salt should seem to attract it from the water; however, this is only mere conjecture. These phenomena concerning salts are objects which well deserve the attention of chymical philosophers, and ought to be prosecuted with care.

The

The few experiments I have made incline me to believe, that Mr. Eller's experiments, which I have quoted in vol. i. p. 185, from the Memoirs of the Academy of Berlin for the year 1750, will be found to be accurate, if performed in the manner recommended by him.

OF THE
DOCTRINE OF PHLOGISTON,
AND OF THE
NEW THEORY OF CHYMISTRY.

P A R T I.

(This first part should have followed the accounts of Elective Attractions and Solution, between pages 14 and 15 of vol. i. had the account of the New Theory been published before it was printed.)

HAVING mentioned these few things relative to elective attractions and solution, it may seem necessary to say something concerning the nature of fire and of light, and of their different modifications; and likewise to take notice of air and other aëriform

aëriform fluids, which have of late so much engaged the attention of chymists.

The analysis of bodies, made by very modern chymists, begins where that of former times used to end ; for, till within these very few years, an analysis was thought to be completed, when, by distillation and other processes, a body was divided into water, salts, oils, and earth, which were supposed to be its constituent parts ; and little regard was, at that time, paid to those particles which separated in form of vapour or of air : but the industry of the present times has shewn, that many material parts of bodies had escaped in these forms ; and that the other products obtained were themselves compounds, which, by means of certain processes, could be still further divided into different aërial fluids, which could be separated from each other, so as to examine their particular natures, and to form a better judgment of the primitive or elementary principles of the body analyzed.

Of FIRE.

IT is very difficult to define exactly what fire is, though it is one of the most common objects which presents itself to our senses, and its operations are amongst the most curious and extensive of any in nature.—It is so very subtile as to penetrate through the pores of every terrestrial object we are acquainted with.

When certain substances are subjected to its influence in close vessels, which prevent any communication with the external air, it disjoins their component particles, and renders many of them volatile, but without exciting flame, or consuming them to ashes. But when it is united to the same bodies, so situated as to be exposed to a current of atmospheric air, it moves with velocity, excites flame, and acts with such force as to destroy, in a short time, the union of all their constituent parts, and to dissipate them in the air, in form of smoak or vapour; leaving nothing behind, but a pittance of an earthy and saline matter, called the ashes. The
vulgar

vulgar commonly believe, that, during this operation, the fire consumes and annihilates all the other parts of bodies except the ashes ; but the burning of combustible matters under vessels fitted to receive the vapour or steam that comes from them, during the time of their conflagration, shews that the force of fire only renders them volatile, and disperses through the atmosphere, in various forms, those particles which were supposed by the generality of mankind to be consumed and annihilated.

Every one acknowledges that matter to be fire, which, when united to combustible matters, renders them red hot, emits heat, flame and light, and dissipates or seems to consume such matters in the open air. It exists more or less in every known body, and in every climate ; for a flint, struck with force against a plate of steel, instantly throws out fire, which melts the abraded particles of the flint and steel into glass ; and if the spark of fire, thus thrown out, be received upon tinder, or any other very combustible matter placed upon a
large

large quantity of dried wood, a prodigious quantity of fire will soon be collected, and seemingly consume the wood with the greatest violence, even in the coldest regions under the Pole, particularly if it be exposed to a current of air.

It is of so volatile and subtile a nature, that no person hitherto has been able to confine and to collect it in vessels, so as to ascertain its intimate nature; and therefore we are obliged to content ourselves with the examination of the effects it produces.

Chymists have long been divided in their opinions concerning the nature of fire and of heat; some supposing them to be the same; others, that heat is only the effect of fire. And they have been likewise divided in their opinions, whether light be a distinct body, or only a modification of fire.

Hitherto we are certainly ignorant of the particular nature of fire, heat, and light; from what we daily see, we are fully convinced, that they are the principal instruments which nature employs in carrying on most of her operations, and that
they

they are the great efficient causes of the production of all animated and inanimated bodies, and of the various changes which they daily undergo, although we are ignorant of the particular manner in which they are brought about.

From an attentive observation of the effects produced on bodies, subjected to the influence of fire, chymists are convinced that it is the great agent by which most chymical operations are carried on, and they have supposed that *rarefaction*, and *light*, are only effects of it.

1. *Heat* is either fire itself, or is an effect produced by the immediate application of fire; and it is always more or less intense in proportion as the matter of fire, actuated by air, is more or less concentrated, and the body subjected to its influence is more or less dense.—And from observation it appears that the quantity of fire, or matter of heat combined with bodies, determines the form or state in which they exist, for the time being; whether in that of a solid, or of a fluid, or of an air or vapour; for in a *solid state*, bodies contain

less heat than in a *fluid*, and in a fluid less than in an aërial form. Thus, for example, ice is colder than water in its natural state*, and water than its steam or vapour: and the same holds true with respect to oils, bitumens, sulphur, metals, and all other bodies; though it requires different degrees of heat to keep different bodies in these different states. Hogs-lard melts easily, and is kept in a fluid state with a

* I have said in a natural state, because Dr. Black, the Honourable Mr. Cavendish, and lately Dr. Blagden, have shewn that, by means of art, water under different circumstances may be cooled without congealing, even to ten or eleven degrees below what is commonly looked upon as the freezing point. In vol. lxxviii. of the *Philos. Transf.* for the year 1778, p. 125, art. 1c. Dr. Blagden has given an account of a number of ingenious experiments which he made relative to this subject, by setting a glass tumbler, with water variously impregnated, in a frigorific mixture made with snow or ice, and common salt. Amongst other experiments, he mentions that pure water, which had been boiled, sunk the thermometer to twenty-one before it congealed, but that muddy water congealed at thirty-two. The Doctor very candidly says, that he had not been able to account for the phenomena which occurred, and that the subject still remains in great obscurity.

very gentle heat ; though it requires the heat of a reverberatory furnace to melt iron, and to keep it in that state.

As heat is one of the great instruments employed in performing chymical experiments, and the great agent in forwarding fermentation, vegetation, and many other operations of nature ; and as different degrees of it are required for answering these various purposes ; chymists have been assiduous in finding out means for ascertaining the exact degree of it, in any given body or place. In general they measure the degrees of heat, under that of boiling water, by means of thermometers ; and the degrees above that, by certain appearances produced on particular substances by certain degrees of heat applied to them.

There are at present two thermometers which are most commonly used ; the one invented by *Fahrenheit*, the other by *Monf. Reaumur*. 1. That of *Fahrenheit*, where the freezing point is placed at 32°. 2. And that of *Reaumur*, where the freezing point is placed at 0 ; and one degree is equal to $2\frac{1}{4}$ of that of *Fahrenheit's* : in both you
begin

begin to count the degrees, upwards and downwards, from these points; though in common, when you reckon upwards by Fahrenheit's scale, the 32 degrees below the freezing point are included; and hence, when you reduce the degrees of Monsieur Reaumur's thermometer to those of Fahrenheit, you must multiply them by $2\frac{1}{4}$, and add the 32° which are below the freezing point in Fahrenheit's.

M. Fourcroy mentions five degrees of heat, or stations on the scale of the thermometer, below that of boiling water, and five above it; which are necessary to be attended to, in performing chymical operations. These are:

To the Heat of boiling Water.

1. The first degree raises the quicksilver in Reaumur's thermometer from 5 to 8, in Fahrenheit's from $42\frac{1}{4}$ to 50. This degree, he says, favours putrefaction, vegetation, and slow evaporation.

2. The second degree is at 15 in Reaumur's, and at $66\frac{1}{2}$ in Fahrenheit's. This

F 2

keeps

keeps up putrefaction, and excites the vinous fermentation in saccharine liquors.

3. The third degree extends from 25 to 30 in Reaumur's, or from $86\frac{1}{2}$ to $99\frac{1}{2}$ in Fahrenheit's. This, he says, establishes the acetous fermentation, and favours the drying and flowering of plants.

4. The fourth degree raises the quicksilver in Reaumur's to 45, in Fahrenheit's to 133. This disorganizes animal substances, volatilizes essential oils, &c.

5. The fifth degree, which is that of boiling water, he says, may be marked from 80 to 85 in Reaumur's, or in Fahrenheit's from 212 to $223\frac{1}{4}$.

Above the Heat of boiling Water.

1st Degree reddens glass, burns organized bodies, and melts sulphur.

2d Degree melts soft metals, such as lead, tin, bismuth, and fusible glass.

3d Degree melts metals of a middle hardness, such as zinc, regulus of antimony, silver, and gold.

4th Degree bakes porcelain or china ware;

ware; melts refractory metals, such as cobalt, brass, and iron.

5th Degree, which is the strongest of all, is the burning glass, that calcines, burns, and vitrifies in an instant all the bodies which are susceptible of those changes.

2. *Rarefaction.* The second modification or effect of fire which I mentioned, was that of rarefaction; or that effect of heat by which the component particles of bodies, subjected to its influence, are separated from each other, and the bulk or size of the bodies is increased. M. Lavoisier observes, that although some substances may seem to contract; yet that, upon an accurate examination of the particular circumstances in which they are placed, it will be found that rarefaction has taken place, for that is a general and a constant rule of nature.

3. *Light* is so connected with fire, that most chymists formerly looked upon it as one of its attributes; but the late M. Macquer and others have considered it as a distinct matter, and have accounted for a number of phenomena, from its effects

upon other bodies : but as it is too subtile a matter to be confined in vessels, and to try chymical experiments with, nothing certain has hitherto been, or probably ever will be, determined relative to its particular nature.

*Of the Doctrin of PHLOGISTON, or Matter
of FIRE.*

TOWARDS the end of the last century, Dr. Becher, physician to the Electors of Mentz and Bavaria, a most ingenious man, and one of the best chymists of his age, on examining into the nature of inflammable bodies, concluded, that the matter of fire, which he called *phlogiston*, was a particular sort of earth, that subsisted more or less in every body ; and was the cause of many of the changes which they underwent. In the year 1723, Dr. Stahl, one of his disciples, published at Nuremberg a book called *Fundamenta Chemiæ*, in which he illustrates the doctrine

trine of his master. He says that, while phlogiston (or the matter of heat) remains at rest in the bodies to which it is united, it does not excite light or heat, nor produce any visible or remarkable change in their properties, further than in rendering them susceptible of being acted upon, and set in motion, on fire being applied to them; that it is the cause of material cohesion, nutrition, colour, smell, volatility, ductility, malleability, and other properties of bodies; for that all these qualities perish when phlogiston is taken away, and return when it is restored: and that most of the changes which bodies undergo, when subjected to certain chymical processes, are brought about by a quantity of phlogiston being added to, or subtracted from them; which has been termed the *phlogisticating* and the *dephlogisticating* of bodies. Thus he supposed sulphur to be a body compounded of an *acid* and *phlogiston*; and says that, when it is burnt in an open vessel, these two principles rise in form of vapour or phlegm, and separate from each other; and if a proper vessel for col-

lecting and condensing this vapour be put over the sulphur while burning, a fluid acid, called the sulphureous or vitriolic, will be collected; while the other principle, called phlogiston, which is of so subtile a nature as not to be confined in vessels, will make its escape; and that this acid may be again restored to the state of sulphur, by uniting with it a fresh quantity of phlogiston, either by distilling, or subjecting to the action of the fire in a crucible, the acid itself, or substances containing it, along with charcoal, or other bodies containing phlogiston. In like manner if metals, which he alleges are made up of a certain earth and phlogiston, be deprived of their phlogistic matter, either by the force of fire, or by being corroded with acids, they are reduced to the state of calces; but if the phlogiston be restored to these calces, by mixing them in a red-hot crucible with charcoal, or other fluxes containing it, and keeping them there for some time, they resume the form and properties of metals.

This doctrine of Stahl, as it accounted
for

for many things which before were looked upon as inexplicable, was soon universally received, and continued to be supported till within these few years ; for, so late as the year 1779, Sir T. Bergman, in treating of the use of the blow-pipe, says that the whole theory of inflammation depends upon that subtle principle which goes by the name of phlogiston ; but this, so far as is yet known, can never be collected pure and alone, but always requires a suitable basis, to which it must be united, in order to become manageable. Scarce any body exists entirely destitute of it, but a certain accumulation is necessary for inflammation ; this accumulation takes place in vinous spirits, oils, sulphur, zinc, arsenic, and in all inflammable bodies. And in the year 1782 Mr. Kirwan, in vol. lxxii. of the Philosophical Transactions, alleges, that phlogiston, like fixed air, exists in two states : 1. In a solid form, when joined to other bodies : 2. And in an elastic aëriform state, when disjoined from them : that in its first state it is called *phlogiston* ; in its second, *inflammable air* :

air: and he has made an estimate of the quantity of it which is contained in several different bodies.

Of the Doctrine of AIR.

THIS doctrine of phlogiston remained uncontroverted for many years, and seemed to gain ground daily, till chymists began to observe more accurately the changes which bodies underwent, when subjected to the influence of fire; and, finding that they could not, from it, account for the increased weight which most bodies acquired by being calcined, nor for other appearances which occurred, they began to search for other causes; and at last Monsieur Lavoisier and others, on observing with care the circumstances of combustion, and examining the changes which it produced on different bodies, concluded that the matter which brought about those changes was the basis of pure air, and not phlogiston, as had been formerly imagined; for that combustion is no more than a decomposition of oxygenous gas, effected by a com-

combustible body ; and that, during the time in which this is brought about, the basis of pure air is absorbed, and the matter of heat (the calorique) and light are disengaged and set at liberty : however, in order to effectuate this, the pure air must have more affinity with the combustible matter than it has with the matter of heat, the whole must be set in motion by some heated body, and the temperature must be of a certain degree, which is different in almost every combustible substance.

The following are the principal observations and experiments on which they found their opinion.

1. That no body or substance can burn without air ; and that combustion is always more or less rapid, in proportion to the purity and quantity of the air, and the velocity with which it moves,

2. That during the time of combustion there is an absorption of air; and that many bodies acquire an addition of weight by being subjected to this operation.

3. That by calcining metals, in close vessels, in a given quantity of pure air, they

they become heavier; and the additional weight which they acquire is always equal to the weight which the air, employed in their calcination, has lost, during the time of their combustion.

4. That if metallic substances, thus reduced to the state of calces, be put into a close vessel, along with proper fluxes or substances containing inflammable matter, and be exposed to a great heat, the inflammable matter of these fluxes attracts the air which the metallic substances had absorbed; by which means they lose their additional weight, and return to the state of metals.

5. That similar effects follow, when sulphur is burnt in a stream of air; for, during the time of its combustion, it absorbs a quantity of pure air, and thereby acquires additional weight, and becomes vitriolic acid; and that if the vitriolic acid, thus formed, be exposed to a strong heat in proper vessels, along with charcoal, or other combustible matters, which absorb its air, it returns to the state of sulphur.

6. That air in which substances of any
kind

kind have been burnt, always loses of its weight; and what remains of it suffocates animals, is no longer capable of feeding flame, and in short becomes impure or mephitic.

7. That the residua of bodies which have been completely burnt, have been found to be fully saturated with air; and therefore are no longer capable of absorbing it, or of feeding flame, but enter into the state of incombustibles.

From these and a variety of other facts, M. Lavoisier has endeavoured to prove that it is pure air, and not phlogiston, which produces many changes that bodies undergo, when subjected to certain chymical processes.

Many chymists have adopted this new theory entirely, others only in part; while some continue still to support the old doctrine of phlogiston.

Monsieur Fourcroy, who is one of the great supporters of the new doctrine, in his third edition of his *Leçons Chimiques*, says that, notwithstanding the vast researches, of late years, into the phenomena

mena of combustion, the opinion which admits the existence of fire as a principle fixed in bodies, has not yet been overthrown; and its name of *phlogiston* has been changed to that of *calorique*, or *combined heat*: but that it is not to this matter that the property of combustibility is attributed; nor is its presence, in inflammable bodies, that which determines the inflammability.

Late Arguments in favour of PHLOGISTON, and of Doctor PRIESTLEY's new Doctrines.

M. FOURCROY, in his *Leçons Chimiques*, tells us, that the late M. Macquer thought we ought to combine the new and the old doctrines together; for that metals could not lose their phlogiston, and be calcined, without the pure air of the atmosphere being precipitated, and uniting itself to the metals themselves; and that the metals, when reduced to calces, could not be brought back again to their pure metallic state, until the phlogiston, added by heat, disengaged the pure air from them;

them; so that these two matters, *pure air* and *phlogiston*, were mutual precipitants of each other.

The Hon. H. Cavendish, in vol. lxxiv. of the Philosophical Transactions, p. 152, published in the year 1784, after having considered several memoirs of M. Lavoisier, published in the Memoirs of the Royal Academy of Sciences at Paris, in which he entirely discards phlogiston, and explains those phenomena which have been usually attributed to the loss or attraction of that substance, by the absorption of pure or vital air, tells us that he has adhered to the doctrine of phlogiston, because it explains all phenomena, at least, as well as Lavoisier's new theory.

Dr. Priestley, who in vol. lxxiii. of Philosophical Transactions, art. 22, gave an account of a number of experiments and observations made in order to support the doctrine of phlogiston, after having examined the new theory and the facts which have been brought in its favour, and made many experiments relative to these subjects, seems to differ
very

very much from the French academicians, both with respect to the facts themselves, and to the conclusions drawn from them. The academicians have asserted, that the basis of pure air, which they have called oxigene, is a simple substance, and that metals and sulphur are the same: but Dr. Priestley, by a number of experiments which he made, and of which he has given an account in vol. lxxviii. and lxxix. of the Phil. Transf. for the years 1788 and 1789, thinks that he has proved that pure air, and all other airs, are compounds, made up of a large quantity of water, in an aëriform state, united to some particular matter which gives it properties that distinguish it from all other bodies: thus he thinks that inflammable air is a fine aqueous vapour, united to an inflammable matter, which he says may as well be called phlogiston as any thing else; that pure or dephlogisticated air is formed of a fine aqueous vapour, united to the acidifying principle, in the proportion of from 18 or 19 parts of water to one of the acidifying principle; and so forth, with the other airs; water being the proper
basis

basis of them all, without which none of them can subsist. He likewise still asserts that metals and sulphur are compound bodies, formed of certain bases united to phlogiston; and having established these facts, as he imagines, he next accounts for the changes which metals undergo when calcined, and sulphur when burnt, in the following manner: He says, when metals are exposed to a very strong heat, where there is access to air, that they part with phlogiston, and absorb a quantity of that water which formed a constituent part of pure air, and not the pure air itself; and that this reduced them to the state of calces: and that these calces are reduced to the state of metals, if they be exposed to a great heat along with substances containing phlogiston; for under such circumstances they absorb a quantity of phlogiston equal to what they had lost, and let go the water which they had taken up. Dr. Priestley, who made these experiments with iron, acknowledges that there is a great difficulty in explaining the reasons why iron should absorb water on parting

with its phlogiston; and why it should again part with it, and imbibe phlogiston, in circumstances of heat so nearly similar to those he has described. To this he only says, that the whole doctrine of affinities, so far as it is true, is founded on facts, and these are clearly such as he has represented; and that a difference of circumstances, which is not apparent at present, may become so, when we have given sufficient attention to them. He says that the reduction of finery cynder, and other calces of iron, to a metallic state in inflammable air, is a certain proof that it is the absorption of this air, containing phlogiston, which produces this effect; and when the absorption of this air takes place, and the iron is reduced back to its metallic state, that nothing but water is expelled from it: which shews that it was water taken up originally by the iron, during the time of its calcination, which had reduced it to the state of a calx; for the quantity of water obtained was much greater than the inflammable air, employed, was supposed to contain.

Of

Of WATER being a Compound Substance.

ACCORDING to the new system, water, which has ever been looked upon as an elementary body, is said to be a compound, made up of *pure* and *inflammable* airs; and that in the performance of many experiments it was formed, and in that of others it was decomposed: and from hence many appearances have been accounted for, which formerly were looked upon as inexplicable. The Hon. Henry Cavendish first broached this doctrine, from appearances he had observed in performing experiments in the years 1781, 82, and 83; and on the 15th of January 1784 he gave in to the Royal Society a particular account of these experiments, and of the observations he had made, which was published in the volume for that year.

M. Lavoisier, in the year 1784, published two papers, the one dated in April 1784, the other later, in the Memoirs of the Royal Academy of Sciences at Paris for the year 1781, but which were not printed till late in the year 1784; and since

that period, he, and other academicians have made a number of curious experiments relative to this subject; from whence they conclude, that a hundred parts of water contain eighty-five of *pure air*, and fifteen of *inflammable air*; and tell us that they had repeatedly decomposed water, and always found that it yielded the above proportions of these two airs; and that, by uniting again these two airs in the above proportions, they had obtained a quantity of water equal in weight to that of the two airs employed. After these experiments, one should think that no doubt could be entertained relative to the truth of these facts. However Dr. Priestley, in his late publications in the *Philosophical Transactions*, has boldly asserted that water is an elementary body, as it always has been believed to be; and that neither Mr. Cavendish, nor M. Lavoisier, nor any other person, has hitherto either composed or decomposed it; and that what water they had obtained in performing the experiments from which they drew their conclusions, was the water
which

which made up the greater part of the pure and inflammable airs they made use of, let loose by the processes employed for the supposed formation of water.

A series of accurate experiments, performed by able chymists, is the only way in which this controversy can be determined.

Of the General Principles of the NEW THEORY OF CHYMISTRY, substituted in room of PHLOGISTON.

FOR these seven or eight years past, many of the French academicians have published, from time to time, Memoirs relative to the subjects of their new theory; and at last, in the year 1787, four very able and ingenious French chymists, Messieurs Morveau, Lavoisier, Bertholet, and Fourcroy, favoured the world with a new nomenclature of chymical substances, in which they have adopted principles entirely new, changed the names of almost every body which is the object of chymistry, and arranged them in a particular

order, adapted to the new system; and since then many treatises have been published by different authors on the same subjects.

These gentlemen begin with mentioning those substances which they had not been able either to decompose, or to form by any combinations which they have attempted. These they have called *simple* or *elementary*, though they say that it is not at all improbable but that hereafter many of them may be discovered to be compounds; but, till then, that they ought to be looked upon as *simple bodies*: and these they have divided into five classes.

C L A S S I.

UNDER this first class they comprehend those *simple substances* or *principles*, which, without shewing the least analogy to each other, have however something in common, that makes them approach to the state of simplicity, and resist all analysis; at the same time that it renders them active in combination: the five following

following they have brought under this head, *viz.*

- | | | |
|--------------------|--|----------------------------------|
| 1. Light. | | 3. Pure or dephlogisticated Air. |
| 2. Matter of Heat. | | 4. Impure or phlogisticated Air. |
| | | 5. Inflammable Air. |

These they look upon as the true active elementary bodies, from whose various combinations with one another, and with other simple substances, they suppose all the different changes which they undergo, by natural or artificial processes, are brought about. In order to understand their nature, I shall consider each of them separately; but as I have already taken notice of *light* and *fire*, I shall at present only mention them very superficially.

I. Of LIGHT—*Lumiere.*

LIGHT, as I have already observed, is a subtile fluid, the great fountain of which is the sun; and it comes from thence to our earth with a velocity of which it is difficult for us to have any conception; for, by a mathematical calculation, it moves at the rate of 240,000 miles

in a second of time. It is so connected with fire, that it is doubtful whether it be a distinct matter of itself, or only a modification, or attribute of it. It is too subtile a matter to be confined in vessels, and to be subjected to chymical experiments: it is only from a few observations made on the effects it produces on terrestrial substances; from the manner in which it affects the nerves of our eyes, by which we see the objects around us; and from some few experiments made relative to the refraction and reflection of its rays coming from the sun, and their producing different colours, that we conjecture any thing about its nature and properties.

M. Fourcroy observes, that it seems to obey, as other bodies do, the laws of affinity of composition; and M. Lavoisier says that, with regard to light, we know but very little about its combinations, and manner of acting upon bodies; but, from the experiments of M. Bertholet, it should seem to have a great affinity with pure air, and is susceptible of combining with
it,

it, and with the matter of heat, to contribute to its transformation into gas.

Experiments made on vegetation seem to give reason for believing, that it combines itself with some parts of plants; and that it is this combination which is the cause of the green colour of their leaves, and of the different colours of their flowers; and that it contributes to their vigour and their health; for that plants raised in houses where the light is excluded, become languid, and their leaves and flowers have little or no colour: and the want of it is likewise observed to affect the health of man.

II. *Of the MATTER OF HEAT, called CALORIQUE by the Academicians.*

THE French academicians, in their new Nomenclature, make use of the word *calorique* to signify the matter of heat, and to distinguish it from *chaleur*, heat, which they employ to express the effects produced by it.

I have already mentioned that fire was
fo

so subtile and so volatile a matter, that no person had hitherto been able to confine and collect it in vessels, to examine its particular nature, and that therefore we were obliged to content ourselves with the examination of the effects it produces—that it seems to be one of the great causes of the changes which bodies undergo in passing from a solid to a fluid state, and of their being rendered volatile, and assuming the form of a vapour or of a gas ; and that it is one of the great instruments of vegetation, of the increase, growth, and decay of all the animal and vegetable creation, and probably likewise of the mineral.

Chymists have given such varieties of names to fire, the matter of heat, the combustible principle, and their different properties and modifications, that it is not always easy to understand their meaning when they speak of them, or of the manner in which they suppose them to produce their effects.

Monfieur Lavoisier thinks that burning, or combustion, is nothing but the decom-

decomposition of oxigenous gas, affected by a combustibile body in the following manner :

Every body capable of combustion, or burning, is such as strongly attracts the basis of pure air (or oxigene); and when such a degree of heat is applied to it as destroys the equilibrium of its constituent parts, while it is so placed as to be exposed to a current of air, it attracts powerfully the pure air, till it is fully saturated with it; and during that time, the matter of heat (or calorique) and light, which are disengaged and set at liberty, fly off, and form that appearance called flame; and the remaining part of the burnt body, which has been fully saturated with air, is now no longer capable of absorbing more, or of burning longer, being reduced to the state of an incombustible substance.

Of the AIR of the ATMOSPHERE.

BEFORE considering the *pure* or dephlogisticated, and the *impure* or phlogisticated airs, as they are called, it is necessary to mention a few things relative to

the air of the atmosphere, which is the great magazine of these two airs, being made up principally of them.

Its specific weight to that of water has been commonly estimated as 850 to 1, but by Mr. Kirwan's account as 816 to 1. It has been said by some authors to contain 2, and by others 3 parts of *impure* air to 1 of *pure*: but by M. Lavoisier's experiments the proportions are a little different; for he says that 100 cubic inches of atmospheric air yielded him 73 of *impure*, and 27 of *pure* air.

Besides these two airs, the atmosphere contains a vast variety of other matters, and is the great magazine of those particles of bodies which are daily rendered volatile by heat, fermentation, putrefaction, and many other operations of nature, and are capable of remaining in an aërial form in the temperature in which we live; and it is not impossible but that particles of every sort, even of metallic substances, may be found floating in it: hence we should naturally be led to suppose that, in analysing the air of the atmosphere, such matters
would

would often be met with in it. But in general this is not the case; for the quantity of these matters being small in proportion to the great body of the air of the atmosphere, they are presently dispersed through this immense unbounded space: part of them is decomposed, and mixed with the general mass; part of them falls down again insensibly to the ground; part of them is attracted by the water of the clouds, and precipitated with rain and dew; part of them goes to form those masses of inflammable matter in the clouds, which detonates in the air, and forms thunder and lightning, and so forth; so that, in analysing the air of the atmosphere, little else is commonly got but the *pure* and *impure* airs, which we shall next consider; though at times, and in particular places, it is found mixed with various foreign matter.

III. Of PURE AIR—*Oxigene*.

THIS air is called by a vast variety of names. It has been called *pure* and *vital*, from its purity and fitness for respiration; *dephlogisticated*, from its being supposed to
be

be freed of phlogiston; and lately it has been called by the French *oxigene*, from its being believed to be proved to be the true *acidifying principle*, which, with different bases, forms the different sorts of acids; the word *oxigene* being a compound of the two Greek words, $\acute{o}\xi\upsilon\varsigma$ *acid*, and $\gamma\epsilon\iota\nu\omicron\mu\omicron\iota$ *to engender*.

This air is got pure, or disjoined from all other matters, in several ways; but principally by separating it from other bodies to which it has been combined by art. Dr. Priestley, who first took particular notice of it, obtained it by distilling nitre in an earthen retort glazed both within and without; for, when the retort was made red hot, the nitre was decomposed, and the *pure air* was set at liberty, and came over into the receiver: and it may be procured by throwing the focus of a burning glass upon calcined metallic substances, such as calcined mercury, minium, calcined manganese, &c. placed under glass receivers of an air pump, which disengages the pure air from these calces.

The general properties of this sort of air are as follow :

I. By Mr. Kirwan's account, 100 cubic inches of pure air weigh 34 grains ; but, by Monsieur Lavoisier's calculation, 100 cubic inches in the state of gas, with Fahrenheit's thermometer at $54\frac{1}{2}$, and the barometer at 28, weigh 50 grains.

II. It is the only air that is fit for respiration, and for the support of animal life ; and it corrects the bad qualities of the impure air with which it is combined, in forming the atmosphere in which we live.

III. It favours combustion, and no substance will burn without being in contact with it ; and if combustible matters are set on fire in a confined vessel or chamber, which contains atmospheric air, the fire will go out or be extinguished so soon as all the pure air is absorbed or consumed ; and the briskness with which the fire burns will always be in proportion to the quantity of pure air which comes in contact with the combustible substances, and the velocity with which it moves.

IV. It

IV. It forms different sorts of acids by being combined with different substances, to which the French have given the name of acidifiable bases.

1. With sulphur it forms the *sulphureous* or *vitriolic* acid. It takes about 143 parts of pure air to saturate 100 of sulphur; the exact quantity not fully ascertained.

M. Bertholet made two experiments to ascertain the proportion of pure air to sulphur in the vitriolic acid.—By the first, 69 parts of burning sulphur attracted 31 parts of pure air, and afforded 100 parts of sulphureous acid. By the second, 72 parts of sulphur only attracted 28 of pure air.

2. With impure air, called by the French *azote*, it forms the *nitrous acid*. It takes 1 part of the impure to 3 of the pure air. Dr. Priestley says that he obtained this acid by decomposing pure and inflammable air with the electric spark.

3. With an unknown basis, it is supposed to form the *muriatic acid*; though hitherto chymists have not been able to
prove

prove its existence in this acid, nor to ascertain the nature of the basis with which it is connected; it is only from analogy that it is conjectured that this acid is thus formed.

4. With charcoal it forms *ærial acid*. It takes, by M. Lavoisier's account, 28 parts of charcoal to 72 of pure air. Dr. Priestley, in Phil. Transf. vol. lxxix. alleges that he got this acid by decomposing pure and inflammable airs by means of the electric spark.

5. With phosphorus it forms *phosphoric acid*. It takes 154 parts of pure air to 100 of phosphorus.

6. With a basis, the nature of which is not hitherto ascertained, it forms *boracic acid*, commonly called sedative salt.

7. With a basis, the nature of which has not as yet been ascertained, it forms *acid of amber*, commonly called salt of amber.

8. With a basis, the nature of which has not been ascertained, it forms a kind of acid, called *fluoric*, or *spathic acid*.

H

9. With

9. With a basis, compounded of *inflammable air* and *charcoal*, and sometimes with the addition of *phosphorus*, it forms the *different vegetable acids*; and the difference of the proportion of these component materials, and of the pure air, constitutes the difference between the acids themselves.

10. With a basis, compounded of four simple substances, viz, *inflammable air*, *charcoal*, *phosphorus*, and *impure air*, it forms the different acids of the animal kingdom.

11. With the three following metallic substances, viz. *arsenic*, *molybdene*, and *tungstene*, it forms three particular sorts of acids; *acid of arsenic*, *acid of molybdene*, and *acid of tungstene*.

12. With iron, by a particular encheirsis, it forms a blue matter, which by some people has been called *Prussian acid*; though many have doubted whether it ought to be accounted an acid.

V. By uniting with certain vegetable, mineral, and other substances, a quantity
of

of pure air, not enough to convert them into acids, but sufficient to make them approach to their nature, we form those substances which the French academicians now call *oxides*, and which in English we have, as yet, no proper name for: the vegetable kingdom furnishes some native substances of this kind, such as *sugar, gum*, and some other vegetable juices; those of the mineral kingdom, to which the academicians have given that name, are mostly formed by the force of fire: for when certain metallic substances or earths are calcined in the open air, or in chambers containing this air, a quantity of it is absorbed, and the metals or earths are reduced to the state of calces, or what the academicians now term *oxides*.

VI. By adding a quantity of this air to certain substances, reduced to the state of oxides, they are converted into acids: thus the addition of pure air to wine converts it into vinegar.

VII. By uniting this with inflammable air in the proportion of 85 parts of this, to 15 of the inflammable air, it forms

H 2 water;

water; though Dr. Priestley of late doubts of this fact.

IV. *Of IMPURE AIR, called by the French* AZOTE.

THIS air has been called by a variety of names, such as *impure, mephitic, phlogificated, &c.* and the French academicians have of late given it the name of *azote*, from the two Greek words *α* without, and *ζωη* life; because it is not fit for respiration, but suffocates animals who breathe in it.

By the accounts of some authors, the air of the atmosphere contains two parts of this and one of pure air; but by M. Lavoisier's experiments, 100 ounces of atmospheric air contains 73 of this, and 27 of pure air. The different qualities of the air of the atmosphere, in the places where the observations were made, may perhaps have occasioned this difference in the proportional quantities of those two airs which constituted its component parts.

This air may be obtained separate, by
placing

placing vessels containing hepar sulphuris and lime-water under an exhausted receiver of an air pump, and then filling the receiver with atmospheric air, and letting it stand for a fortnight, in which time the hepar sulphuris, or lime-water, will absorb all the *pure* from the atmospheric air; and the impure air may be drawn off into vessels proper for receiving it. Or it may be got by dissolving animal substances in weak nitrous acid, almost cold, in an exhausted receiver, which will set the impure air free, so that it may be extracted from thence by means of a pneumatic apparatus.

The principal properties of this sort of air are these :

1. A cubic inch of it does not weigh quite half a grain : M. Lavoisier says that it weighs $\frac{1}{2}\frac{1}{5}\frac{1}{8}$ of a grain ; M. Kirwan, that 100 cubic inches weigh 30 gr. $\frac{5}{1000}$.

2. It is one of the essential principles which constitutes animal matter.

3. United to the matter of heat of our atmosphere, it remains in a state of gas.

4. It is the basis of the acid of nitre ;

H 3

for

for 1 part of it united to 3 of *pure air*, forms the nitrous acid*.

5. It promotes wonderfully the process of putrefaction.

6. By being joined to inflammable air, it forms the volatile alkali, of which it is a constituent part; for no substances which

* From experiments made by the Hon. H. Cavendish, an account of which is given in vols. lxxv. and lxxviii. of the Philosophical Transactions, it appears that what was called the nitrous air is the same as this. Dr. Priestley, in vol. lxii. of Philosophical Transactions for the year 1772, says, that one of the most conspicuous properties of the nitrous air is, the great diminution of any quantity of common air with which it is mixed, attended with a turbid red and deep orange colour, and a considerable heat: but it is amazing that a quantity of this kind of air should, as it were, devour a quantity of another kind of air half as large as itself, and yet be so far from gaining any addition to its bulk, that it is diminished by it. It does not effervesce with, or diminish the bulk of *fixed* or of *inflammable*, or of any other sort of air, except common air, or air fit for respiration: and the Dr. tells us, that, so far as he can judge, the diminution of bulk is in proportion to its fitness for respiration; hence he has established this diminution of bulk as a test for distinguishing wholesome air from that which is not so, and for knowing the degree of its purity.

do not contain impure air, will yield volatile alkali; and the product of the volatile alkali is, always, in proportion to the quantity which the bodies employed for its production contain of this air.

By Monsieur Bertholet's experiments, the volatile alkali is formed of 807 parts of azote (or impure air), and 193 of inflammable air.

7. Mixed in the proportion of 73 parts to 27 of pure air, it forms atmospheric air; or, according to others, in the proportion of 3 to 1.

8. It enters into the composition of Prussian blue.

N. B. Notwithstanding the French academicians have ranked this air among the simple substances, M. Metheric alleges that it is a compound body, formed by the union of pure and inflammable airs; and Mr. Cavendish, in vol. lxxv. of Philosophical Transactions affirm that it is mostly formed of pure air and phlogiston.

V. Of INFLAMMABLE AIR—called by the
French HYDROGENE.

INFLAMMABLE air, or gas, is an æriform fluid which has the appearance of air, but is 10 or 12 times lighter than it. The French have called it hydrogene, from believing it to be one of the component principles of water; this name being derived from the Greek words *ὕδωρ* water, *γεννησις* to engender.

This ærial fluid has long been known, for it often collects in quantity in mines, and proves destructive to miners, by its catching fire, and exploding when a lighted candle is unwarily brought into the chambers in which it is lodged; and it rises through the water of some wells in form of a vapour, which catches flame on the approach of a lighted torch.

Its general properties are these:

1. It is much lighter than the air of the atmosphere, and readily unites with the matter of heat. M. Kirwan says that 100 cubic inches of this air weigh 2 gr. $\frac{613}{1000}$, and that its weight is to that of common or atmospheric

mospheric air, as $84 \frac{3}{10}$ to 1000; and M. Lavoisier asserts, that in the state of gas it is 13 times lighter than atmospheric air. Dr. Metheric tells us that this air, as it is first got, is seldom pure, for it generally carries with it a portion of the substances from which it is obtained; and hence different parcels of it commonly differ in their smell, weight, and other properties: that separated from corrupted animal and vegetable substances, it is commonly the heaviest, and only 4 or 5 times lighter than common air; that got from iron, by means of the vitriolic acid, from 8 to 9 times; that from zinc is still lighter; and that from a red hot iron by means of water, the lightest of all. Hence chymists for some time were in doubt whether there was only one, or many sorts of inflammable air; but M. Fourcroy and other chymists assure us, that the inflammable air got from different substances, iron, zinc, water, the marshes, putrid vegetable and animal substances, is all of the same kind, when freed entirely of foreign matter.

2. It is noxious to animals, who draw
it

it up into their lungs, and immediately suffocates them; but it enters into the composition of both vegetable and animal substances.

3. Iron and zinc both contain a large quantity of this air, which may be separated from them by dissolving them in the vitriolic acid, diluted with water, under a large glass bell, fitted with a pneumatic apparatus; for this air or gas is let loose as the metals dissolve, and floats in the cavity of the bell, from which it may be extracted by means of an air pump. Or it may be obtained by putting one of these metals into a tubulated retort placed on a sand heat, and fitted with a tubulated receiver and proper apparatus; then pour the diluted vitriolic acid upon the metal, and distilling with a very gentle heat, not exceeding that which will raise the quicksilver in Fahrenheit's thermometer to 120 degrees.

The Honourable H. Cavendish, in vol. lvi. of Philosophical Transactions, tells us that zinc dissolves with great rapidity; and, unless the acid be very much diluted, it generates a considerable heat; that an
ounce

ounce of zinc produced 356 measures of inflammable air, and an ounce of iron wire 412. He says that tin likewise produces this air; but an ounce of tin foil only yielded 202 ounce measures.

4. United to pure air, in the proportion of 15 parts to 85 of the pure air, it forms, or is supposed to form, water; and may be separated again from it, by adding some substance which has a greater affinity with the pure air than with it. Iron made red hot, and put into water under the receiver of an air pump, attracts the pure air, and is converted into a calx or oxide, whilst the inflammable air, being let loose, unites with the matter of heat, forms itself into a gas, and floats in the receiver above the water, from whence it may be extracted by means of an air pump. Dr. Priestley, who now denies that water can be decomposed, thinks that the inflammable air, thus procured, comes from the iron, and not from decomposed water.

5. United with charcoal, but without being in the state of gas, it forms, or is supposed to form, *oil*; which is always
more

more or less fixed or volatile, according to the proportion of inflammable air or charcoal it contains. The fixed oils expressed from vegetables contain an excess of charcoal, which separates when they are heated to above the heat of boiling water. The volatile or essential oils are formed of a more just proportion of charcoal and inflammable air, and are not decomposed at the degree of heat immediately above that of boiling water; but they, in their united form, combine with the matter of heat, form a gas, and in that state come over when distilled.

6. In the form of gas it dissolves charcoal, phosphorus, sulphur, and several metals; and, united to sulphur, it forms hepatic air, which is the impregnating matter of most of those waters called sulphureous.

7. It is one of the most combustible substances in nature; it observes the same laws during the time of its burning, as other combustible matters do, and will not burn without the contact of pure air. By itself it burns slowly, but if united with
common

common air, the burning is brisk: if mixed with double its own quantity of atmospheric air, it burns instantly with an explosion; but if it be mixed with double its own weight of pure air, the explosion is much greater. When the inflammable air is perfectly pure, it burns with a flame more or less red; but when it is mixed with foreign matter, it is sometimes blue or yellow.

Such are the five substances which the supporters of the new chymical theory call active elementary principles, from whose various combinations with one another, and with the other substances, which they likewise at present reckon to be simple, they suppose all compound bodies to be formed.

Having taken notice of these three airs, the *pure*, the *impure*, and *inflammable*, which the academicians reckon to be simple or primitive bodies, I shall, before leaving this subject of airs, just name the principal of those which have engaged the attention of modern chymists.

At present chymists call all substances
reduced

reduced to the state of permanent aëri-form fluids or vapour by the name of airs; and it is suspected that there is no body whatever that may not be reduced to this state by means of heat; though the means of effecting this change with some has not as yet been discovered. The diamond, which was long reckoned to be the hardest and most compact body known, on which heat was supposed to make no impression, has at last, by the application of the focus of the burning glass, been found to be one of the most volatile, subtile substances in nature, capable of being resolved into an invisible vapour, which penetrates through glass and porcelain, and leaves not a remnant behind.

The French at present generally confine the name of air, either to that of the atmosphere, or to the *pure* and *impure airs*, of which it is formed, and call by the name of gases all other aërial fluids. The English often call by the name of air every aërial fluid or vapour.

Many believe, and I think not without reason, that there is but one primitive air; which

which is that commonly called pure or dephlogisticated; and that all the other aëriform fluids are this air combined with foreign matter: but this is only mere conjecture unsupported by experiment.

The following are the airs principally taken notice of, which are alleged to be compounded as here mentioned:

1. *Atmospheric air*, compounded of pure and impure airs.

2. *Pure air*, called likewise *vital* and *dephlogisticated*; and by the French, *oxigene*.

3. *Impure air*, called likewise *phlogisticated* and *mephitic*; and by the French, *azote*.

4. *Inflammable air*, called by the French *hydrogene*.

5. *Aërial acid*, called likewise *fixed air* and *acid air*, formed of charcoal and pure air.

6. *Hepatic air*, a solution of sulphur in inflammable air, in the state of gas.

7. *Acid vitriolic air*, commonly called *volatile vitriolic acid*, which by Monsieur Lavoisier's account is sulphur, with too

small a proportion of pure air, to form it into vitriolic or sulphureous acid.

8. *Nitrous air*, which forms the basis of the nitrous acid, nearly, if not entirely, the same as *impure air*.

9. *Acid nitrous air*, which is the nitrous acid in form of a gas or vapour.

10. *Acid marine air*, which is the marine acid in a state of vapour or gas.

11. *Acid marine air, with an excess of pure air*, which is the marine acid in a state of vapour furcharged with pure air, by being distilled along with manganese, or other substances abounding with pure air.

12. *Acid vegetable air*, the vegetable raised into the state of vapour by heat.

13. *Acid animal air*, animal acid in a state of vapour.

14. *Phosphoric air*, phosphorus dissolved in inflammable gas.

15. *Volatile alkaline air*, the volatile alkali in an aëriform state.

Besides these, a vast variety of other bodies reduced to the state of vapour, have been called by the name of airs.

Mr.

Mr. Kirwan has given the following table of the specific gravities of a number of these airs. He says that the specific gravity of the air of the atmosphere to water, which has commonly been reckoned as 1 to 850, is as 1 to 816.

And that 100 cubic inches of each weighs as follows :

100 cub. inches	Grains.	Propor. to com. air.	
Of common air	31 - - - -	1000	
Of pure air	34 - - - -	1103	
Of impure air	30.535 - - -	985	
Of nitrous air	37 - - - -	1197	
Of vitriolic	} weighs {	70.215 - - -	2265
Of fixed		46.5 - - - -	1500
Of hepatic		34.286 - - -	1106
Of alkaline		18.16 - - - -	600
Of inflammable		2.613 - - - -	84.3

C L A S S II.

THE next class of substances, which the French academicians consider in their new Nomenclature, are what they call the *acidifiable bases*, and also *radicals*, or radical principles of acids: under it they comprehend all such bodies as, when joined

I with

with *pure air* (the true acidifying principle), form an acid.

These are many in number, some of which are known, others hitherto unknown.

M. Lavoisier, in his table of simple or elementary bodies, sets down 6 of them, 3 of which are known, 3 unknown, under the description of bodies which are not metallic oxidables and acidifiable. These are,

Three known.

1. Charcoal.
2. Sulphur.
3. Phosphorus.

Three unknown.

- | | |
|----|------------------------|
| 1. | Base of muriatic acid, |
| 2. | —of fluor. |
| 3. | —of borax. |

Besides these, there are probably in nature a great many simple acidifiable bases, of which hitherto we have no knowledge.

To these perhaps might be added all metallic substances which can be reduced to the state of calces or oxides; but chymists as yet have only been able to bring three of them to the state of acids, viz. *arsenic*, *molybdene*, and *tungstene*; therefore they have put the metallic substances into a class by themselves.

The

The acidifiable bases of the vegetable and animal kingdoms are all compounds, and therefore are omitted here, but shall be considered in their proper place.

The authors of the new Nomenclature observe, that these radicals, or acidifiable bases, as they call them, when managed differently, take up different quantities of the oxigene or pure air, by which means the acid produced has different qualities; and the neutral salts, formed with them and other substances, differ from each other likewise: thus they tell us that the acid produced from sulphur, when fully saturated with pure air, is the common *acid of sulphur*, called oil of vitriol, and vitriolic acid.

That the acid produced when the sulphur is not fully saturated, is what is commonly called the *volatile vitriolic acid*.

That the neutral salts produced from these two acids, differently saturated with *pure air*, differ from each other.

And that the same holds good with respect to the acid of nitre and several other acids.

In order to distinguish these acids from each other in different states of oxygenation, and the salts produced from each of them, the academicians propose, for the sake of regularity and brevity, to add a different termination to the names which they have given to these acids and salts.

Thus they propose naming the acid which now goes by the name of vitriolic or sulphureous acid, *acide sulfurique*, or *sulphuric acid*.

And the volatile vitriolic acid, or acid not completely saturated with pure air, *acide sulfureux*, or *sulphureous acid*.

And that every neutral salt made with the *acide sulfurique*, should be called a *sulfate*.

And every one made with the *acide sulfureux*, a *sulfite*.

And every other combination of sulphur with other bodies, and not carried to the state of an acid, should go by the name of a *sulfure*, or a sulphur.

Thus the table of sulphur and its preparations may run thus :

S U L P H U R,

Completely oxigenated, or faturated with pure air—*acide sulfurique, sulphuric acid.*

Salts prepared with this acid, called *sulfates.*

Sulfate or *sulphate* of vegetable alkali — Tartarus vitriolatus.
————— of fossil alkali — Glauber salt.
————— of volatile alkali — Vitriolic ammoniac.

Salts with the *acide sulfureux*, or sulphureous acid, called *sulfites.*

Sulfite or *sulphite* of vegetable alkali } known by no distinct
————— of fossil alkali } names.
————— of volatile alkali }

The combinations of sulphur with other substances, they express thus :

Sulphur of antimony—to express antimony combined with sulphur or common antimony.

Alkaline sulphur—liver of sulphur, commonly called hepar sulphuris.

Ammoniacal sulphur—liver of sulphur prepared with volatile alkali.

Sulphur of copper—to express pyrites of Scopper

Sulphur of iron—pyrites of iron, &c. &c.

In this manner they have laid down tables of the different acidifiable bases or radicals ; of the different degrees of their saturation with pure air ; and of their combinations with other bodies, in their Dictionary for the new Nomenclature, inserted in their *Methode de Nomenclature Chimique* ; and in the tables added to M. Fourcroy's third edition of his *Leçons Chimiques*.

C L A S S III.

THE authors of the new Nomenclature make this class to contain all metallic substances. We know but little of their analysis or component parts ; and therefore M. Lavoisier, and the other academicians, rank them amongst the simple bodies ; excepting gold, and sometimes silver, they are seldom found in a metallic state in the bowels of the earth, but commonly more or less saturated with pure air, or combined with sulphur, arsenic, or some acid, from which they are separated by art.

The

The number of metallic substances known amounts to seventeen; though it is not at all improbable but that many more exist in nature, which hereafter may be discovered.

The metallic substances known are,

1. Gold.	7. Iron.	13. Molybdene.
2. Platina.	8. Antimony.	14. Nickel.
3. Silver.	9. Arsenic.	15. Quicksilver.
4. Copper.	10. Bismuth.	16. Tungstene.
5. Lead.	11. Cobalt.	17. Zinc.
6. Tin.	12. Manganefe.	

All these metallic substances may be made to unite with pure air, but they do not all produce acids. Three only can be reduced to this state, *viz.* 1. Arsenic, 2. Molybdene, 3. And Tungstene: all the rest only absorb a certain quantity of pure air (or oxigene), which deprives them of their metallic properties, and reduces them to the state of calces, or of *oxides*, as the French academicians now call them; by which they mean to signify a body impregnated with a certain quantity of the oxigene, but not sufficient to bring it to the state of acid.

M. Lavoisier lays it down as a rule, that no metallic substance can be dissolved in an acid, till it be brought to the state of an oxide, by being united somehow or other with *pure air* (the oxigene), whether that come from the decomposition of the acid, or of the water employed.

That all solutions of pure metals are accompanied with an effervescence, which is occasioned by a separation of gas, either from the decomposition of water, or of an acid. When the solution is brought about by the *nitric acid*, the gas is of the nitrous kind; when by the *sulphuric acid*, the gas is either volatile sulphureous acid (sulphureous acid), or inflammable gas, according as it may be separated from the acid or the water.

That if a metallic substance, which is intended to be dissolved, has been previously reduced to the state of an oxide, by having been calcined, or precipitated from a metallic solution, it dissolves without occasioning any effervescence.

That all metallic substances, soluble in oxygenated muriatic acid, dissolve in it
without

without effervescence; the metal in that case taking up the superfluous pure air, by which means a metallic oxide and a common muriatic acid are formed at the same time; and the gas, which would have been separated from the oxygenated muriatic acid, finds more water than is necessary to keep it in a liquid form, and to prevent its appearing in the form of gas.

That metals which have little affinity with *pure air*, and do not act with sufficient force to decompose either the acid or the water, are absolutely insoluble in that state; and it is for this reason that *silver*, *quicksilver*, and *lead* are not soluble in the muriatic acid, in their metallic form; but if they be previously reduced to the state of an oxide, they are easily soluble, and dissolve without effervescence.

From these circumstances he concludes that *pure air* is the means of union between metals and acids, and that probably all substances, which have a great affinity with acids, contain pure air.

C L A S S IV.

THIS class comprehends the different sorts of earth, which are reckoned to be five in number :

1. The vitrescible, such as flint, &c.
2. Earth of alum.
3. Heavy earth or base of ponderous spath.
4. Calcareous earth in a state of lime.
5. Magnesia.

None of those have hitherto been decomposed, and therefore they have been ranked amongst the simple bodies. Four of them, viz. *aluminous earth*, *heavy earth*, *chalk*, and *magnesia*, are soluble in acids, and therefore are adopted into the class of acidifiable bases. The vitrescible earths are used for making glafs, and in other manufactures, but not as medicines.

C L A S S V.

THE authors of the new Nomenclature have made a separate class of the three alkalies; though M. Lavoisier, from know-
ing

ing that the volatile alkali had already been composed and decomposed, and from suspecting that the two first alkalies were likewise compounds, has omitted them in the list of bodies which he calls *simple*.

The academicians, in their new Nomenclature, have, and I think very improperly, changed the names of these salts; which for above these thirty years past have been known by the names

1. *Of vegetable alkali.*
2. — *fossil alkali.*
3. — *volatile alkali.*

Which very clearly pointed out the nature of these substances, and the classes to which they belonged. The reason which they give is, that the names were too long, and that chymists had still increased the length of the names, by adding the word *purum* to each of them, and the word *fixum* to the vegetable and the fossil: but these epithets are certainly superfluous; for where the properties of any salt are treated of, the salt used is always supposed to be pure; and the term *volatile* affixed to the volatile alkali, makes the distinction between it
and

and the two fixed so clear, that it was quite superfluous to add the word *fixum* to the other two.

The names which they have chosen have no reference to the substances themselves: they have called the vegetable alkali, *potassinum*; the fossil, *natrum*; and the volatile, *ammoniacum*.

Potassinum is a barbarous Latin word, invented by themselves, or rather an English or German word, to which they have affixed a Latin termination, and which signifies the ashes of vegetables which have been burnt in an iron pot: these ashes are commonly sold in London under the name of pot-ashes, and are often what their name implies, the ashes of the plants, and not the pure salts separated from them.

The *fossil alkali* they term *natrum*, and at the same time let us know that they mean by it the salt got from the ashes of the kali plant, which grows in Spain near to Alicant (*les crystaux de soude*): but this is not the *natrum* or *natron* of the ancients; for that was the fossil alkali, found either on the surface or in the bowels
of

of the earth, in Egypt, in Tripoli*, and other countries; which is unmixed with the vegetable alkali, as the ashes of the kali plant always are, which renders them more deliquescent, and gives them other properties different from those of the pure fossil alkali; chymists hitherto not having been able to separate these salts from each other.

The *volatile alkali* they have called *ammoniacum*, a term which is likely to create

* In vol. lxi. of the Philosophical Transactions, art. 52, page 567, for the year 1771, I have given a short sketch of the history of the natron, or native fossil alkali, and described a particular pure crystallised species of it, which is found in the country of Tripoli in Barbary, and goes there by the name of trona. It is the purest salt of this kind which I have ever seen, and has no mixture of the vegetable alkali in it. Most of the neutral salts which I made with it, and different vegetable acids, of which I have given an account in vol. lvii. of Philosophical Transactions for the year 1767, still remain entire, without running per deliquium, though kept in open cups in a drawer. It is certainly the purest and best fossil alkali yet known, and the fittest for chymical experiments, where a pure salt of this kind is wanted.

confusion;

confusion ; the word ammoniacum having been originally applied to the crude *sal ammoniacum*, and to the *gummi ammoniacum*. And after all, what does this word ammoniacum signify, and from whence does it derive its origin ? In the desarts of Lybia, west of the north part of Egypt, is a district, formerly called Ammonia, in which stood a temple dedicated to Jupiter, called, from its situation, the Temple of Jupiter Ammon, or Hammon : from this country both the *sal ammoniac*, and the gum ammoniac were brought to Europe ; so that ammoniacum is the salt, either of the country of Ammonia, or of the temple of Jupiter Ammon, where some authors have alleged it was prepared by the priests : hence, if the word ammoniacum was to have been used at all, it ought to have been given to the crude *sal ammoniac*, and not to the volatile.

After considering the different names which modern chymists, for the sake of novelty, have given to the three alkaline salts, I cannot help thinking that none of
them

them are so proper as those which have been lately in common use; as they express clearly the nature of each of these salts, and distinguish them more scientifically from each other, than any other names which have hitherto been adopted*.

* If it be absolutely necessary, as the academicians have hinted, to design each of these salts by one word, in order to avoid confusion, the abbreviations proposed by a young gentleman, Mr. Christie, may be adopted, after having given their names at full length, and having observed that the terms used were abbreviations of these names.

The abbreviations which he proposes are these:

For vegetable alkali	}	to write	{	Ve-kali.
For fossil alkali				Fos-kali.
For volatile alkali				Vol-kali.

Which are shorter than either the words potassinum or ammoniacum, adopted by the academicians; and their propriety appears evident by the following table of neutral salts.

TABLE of NEUTRAL SALTS.

Ve-kali {
 Vitriolatum.
 Nitratum.
 Muriatum, &c.

Fos-kali {
 Vitriolatum.
 Nitratum.
 Muriatum, &c.

Vol-kali {
 Vitriolatum.
 Nitratum.
 Muriatum, &c.

P A R T II.

*Of the Analysis of Vegetable and Animal
Substances.*

HAVING considered these things, I come next to take a view of the substances belonging to the vegetable and animal kingdoms; but as all of them are compound bodies, I think it right, before treating of each of them separately, to make a few general remarks relative to their component parts, and the changes they undergo by being subjected to chymical operations; in doing which, I shall pursue the following plan:

1st, I shall mention the different gross matters which these bodies yield in their natural state, or when subjected to such

K

processes

processes as are not likely to form new combinations, or remarkable changes, in their constituent parts.

2dly, I shall next take notice of the different changes which these bodies undergo, and the different gross matters which they yield, when subjected to the force of fire in close vessels, or when they are burnt in the open air.

3dly, I shall then mention the particular subtile principles which modern chymists suppose these substances to be composed of, and the different changes and combinations which they suppose to take place, in distilling and burning vegetable and animal substances.

4thly, I shall consider the different changes which are produced on them by putrefaction.

5thly, And lastly, I shall take notice of the vinous and acetous fermentations, and of the changes which such of these bodies undergo, as are proper subjects of these operations.

S E C T. I.

OF THE CONSTITUENT PARTS OF
VEGETABLE SUBSTANCES.

I. WE know, from observation and experiment, that vegetable substances contain, 1. fine volatile particles and particular juices, which give the peculiar taste and smell to each vegetable; 2. water; 3. mucilage; 4. fæcule; 5. saccharine juice; 6. salts; 7. oils, unctuous and essential; 8. balsams and resins; 9. earth; 10. and iron.

1. *Spiritus Rectior.*

NEITHER the nature of the fine volatile particles which affect the nostrils, nor of those which give the taste peculiar to each vegetable, has as yet been ascertained with certainty; they are of too subtile a nature to come under the obser-

vation of our senses: Boerhaave and many other chymists have given them the name of spiritus rector; they are extremely volatile, and would fly off immediately, were they not retained by being mixed with the fine essential oils or other matters. They evaporate in a great part when vegetables are dried, or exposed to the open air, though some retain them longer.

In delicate flowers, this spiritus rector is often very volatile, and evaporates soon; in odoriferous woods it should seem to be in great quantity, and to be more fixed, for many of them retain their smell long after they have been dried. Macquer suspected, with Boerhaave, that in general it was composed of an inflammable substance joined to some saline matter; that in some plants it participated more of a saline nature, in others of an oily; and that in some cases he suspected it to be a gas of a particular nature.

2. *Water.*

ALL vegetables contain more or less water, it being the vehicle of all their nourishment,

rishment, and one of the principal constituent parts of all their juices. When vegetable substances are exposed to the open air, a great part of the water evaporates; but still a quantity remains united to the other component parts, which cannot be separated without the assistance of such a degree of heat as decomposes the vegetable itself, and, according to the new doctrine, generates a fresh quantity of water, by combining the pure and inflammable airs which are set loose.

3. *Mucilage and Gum.*

THE mucilaginous or gummous part of vegetables may be obtained in several ways; by evaporating the juices of some plants, by bruising or grinding others, and then mixing them with, or boiling them in water, straining the liquor and evaporating it to a proper consistence. The gums, such as the gum arabic, the gum of the cherry-tree, &c. are the mucilaginous parts dried by the heat of the

fun, as is proved by evaporating with a gentle heat the infusions or slight decoctions of mucilaginous plants.

4. *Fæcule.*

THE juices of most vegetables contain a farinaceous matter, which serves for the nourishment of their organic parts, and is lodged in their leaves, their branches, their trunks, their seeds, and their roots; and some of these particular parts seem to be mostly formed of it; such as the seeds of many of the farinaceous and leguminous tribe, and the tuberoſe roots of others.

This farinaceous part is called the fæcule, and is got from these substances in different manners: by mashing succulent plants, expressing and straining their juices, and then letting the liquor stand to allow the fæcule to precipitate; by bruising dry substances, or reducing them to a flower, steeping or infusing them in a sufficient quantity of water, straining the liquor, then allowing the fæcule to drop
to

to the bottom, and afterwards separating it by decanting off the clear water, and throwing the remainder into a filtre, to allow the rest of the water to drain away. M. Beccarius, and since him M. Fourcroy, has observed, that a fæcule may be got from most vegetables, by treating them in some of these ways; but that some substances yield more, others less. The fæcules which are most commonly prepared are those from *wheat, potatoes, sago, salep, cassavi*, and from some of the *tuberosè roots*.

Some substances yield a mucilage, a fæcule, and a saccharine matter, by being treated somewhat in this manner, of which the wheat is a remarkable instance. In order to obtain these different substances from wheat, M. Fourcroy advises to take some fine flower of wheat, to make it up into a paste with water; to put the paste into a colander, placed upon a large earthen pan or vessel, which will receive any liquor which shall pass through the colander; then to set above the colander a cask or barrel filled with pure water, and

fitted with a cock, so that the water, passing through it, shall fall on the paste; to turn the cock so that only a very small stream of water may pass through it, and to let the water continue to run, while it comes off milky from the paste; but to stop it from running, by turning the cock, so soon as the water is observed to come off clear.

On examining the water in the pan placed below the colander, M. Fourcroy says that the wheat-flour will be found to have separated into three different substances:

1. An elastic, tough, glutinous matter, which may be taken up by the hand, and extended to a great length; when boiled in water it becomes hard, and when dried it becomes transparent and brittle: it has many of the properties of animal substances; it becomes putrid when exposed to moisture in the open air, sends out an empyreumatic smell when burnt, and yields a volatile alkali when distilled in close vessels. It has been called the *glutinous* or *vegeto-animal* part of wheat.

2. At

2. At the bottom of the water is found a whitish grey powder called *starch*, which makes up the greater part of the wheat flour: if the starch be allowed to remain in the watery liquor, the liquor ferments and becomes sour, and whitens the starch. M. Fourcroy says that the starch, considered chymically, is a true mucilage of a particular nature, and, when distilled, yields the same principles as vegetable mucilages: when it is burnt, a fixt vegetable alkali is got from its ashes.

3. A sweetish mucilage, which, on being distilled, yields the same principles as sugar, and remains dissolved in the water from which the *gluten* and *starch* have been separated; and may be obtained by evaporating the water: it is but in small quantity, though it seems to be the fermenting principle in this grain.

Such are the component parts into which the flour of wheat may be separated; but if, before being subjected to the treatment here mentioned, it be mixed with a little salt, and then fermented by the addition of yeast, or of any other ferment,

ment, and this fermentation, when raised, be checked by the heat of an oven, its three component parts, the *gluten*, the *starch*, and the *mucilage*, unite so intimately, that they cannot afterwards be separated by any means we as yet know; and they form a wholesome good bread, which is soluble by our juices, and very proper for our food.

5. Sugar.

MOST vegetables contain that sweet matter called sugar, which modern chymists look upon as a sweet essential salt. It is in such small quantity in most plants as scarce to be perceived; though in some it abounds so much, as to be immediately distinguished by the taste. It is now generally looked upon as the principle of fermentation; and all plants, whose juices or decoctions ferment, are supposed to contain it. All that is used in this country is got from the sugar cane; in Canada a small quantity is prepared from the juice of the great pape tree, called by Linnæus the *acer platanoidea*. The juices
which

which contain sugar contain likewise mucilage and oleaginous parts, from which it is separated by repeated boiling, whilst the scum, which rises to its surface, is taken off, and the liquor clarified by the addition of lime-water; after which it is boiled down to a proper consistence, and is further purified by the means mentioned in treating of sugar.

6. *Salts.*

THE salts got from vegetables are commonly divided into two sorts: 1. Those obtained either from the juices of plants, or from their infusions in water, without any process having been made use of which was likely to generate such salts by forming new combinations. These are supposed to have existed naturally in the plant, and have been called by the name of essential. 2. Those which are found in the ashes of plants which have been burnt in the open air, are commonly believed to have been generated by the force of fire uniting the principles fit for forming

ing

ing them, which existed in the original plant.

Salts are obtained from the juices of plants, and from their infusions in water, by purifying the juices or infusions, by filtering them through paper, and by the other means recommended, in treating of vegetable acids; and then by evaporating the liquors to a proper consistence, and allowing them afterwards to remain in a cool place till the salts crystallize.

It has not hitherto been determined what are the salts which vegetables contain in their natural state: formerly those only were called essential salts, in which an acid was prevalent, and which were got from acescent and acid vegetable substances, by purifying and evaporating their juices to the consistence of a thick syrup, and setting them in a cool place for some time, to allow the salts to crystallize. These salts generally contain a portion of earth, or of an alkali, and may be considered as neutral salts with a superabundance of acid. These are esteemed to be the essential salts proper to vegetables; the
other

other salts (now called likewise essential) they have in common with substances belonging to the other kingdoms.

The following salts are alleged to have been got from different vegetables :

1. and 2. The *mild vegetable* and the *mild fossil alkalies*, which were formerly, and still are by many, believed to be the creatures of the fire. M. Metheric, in the second edition of his *Essais sur Differens Airs*, tom. ii. p. 308, tells us, that Monf. Lorgna had got the fossil alkali, by simply infusing the kali plant, after it had been bruised, in boiling water ; and M. Fourcroy, in his *Leçons Élémentaires*, tom. ii. p. 431, says, that both M. Marggraf and M. Rouelle, jun. had got both the vegetable and fossil alkalies by infusing plants in vinegar ; however, notwithstanding this evidence, some chymists of eminence still doubt the truth of these facts. Future experience must determine this question.

M. Fourcroy says that

3. *Tartarus vitriolatus* has been got from milfoil, old borage, &c. ; 4. *Glauber salt* from tamarisk ; 5. *Nitre* from
borage,

borage, turnsole, tobacco, &c. ; 6. *Digestive salt* from submarine plants ; 7. *Sea salt* from wormwood, dwarf elder, and marine plants ; 8. *Selenites* from rhubarb.

Boerhaave and Macquer have both asserted that some of the alkalescent plants contained a volatile alkali in their natural state ; but Cartheuser, Vogel, and some late chymists have denied this fact.

When vegetables are burnt in the open air till reduced to a white ash, the ashes afford, on being lixiviated, salts of different kinds, principally the *fixt alkalies* : the generality of plants yield only the vegetable alkali, the marine plants both the fossil and vegetable ; but they are often found mixed with neutral salts of different kinds, with *tartarus vitriolatus*, *Glauber salt*, *sal digestivus Sylvii*, *sea salt*, and *selenites*.

As so many salts have been procured from vegetables, and from their ashes, it has been doubted whether these salts were generated by the vegetative process, or whether they were absorbed from the ground by the vessels of the plants, along

with the water which assists in the formation of their juices; and chymists are at present much divided in their opinions on this head. M. Fourcroy thinks that this question might be determined by impregnating fields with different kinds of salts, planting each of them with different sorts of vegetables; and afterwards analysing the plants, when they had come to their maturity, to know what salts they contained.

7. *Oils, unctuous and essential.*

MOST plants contain more or less oil, either unctuous or essential, or both. The unctuous oils are commonly got by expression from the seeds, nuts, roots, or other parts of vegetables which abound with them; the essential by distillation, as shall hereafter be mentioned, when these oils come to be considered.

8. *Balsams and Resins.*

A NUMBER of plants, particularly in the warm climates, yield, by bleeding them,
a thick

thick fluid matter, called a balsam, which is collected in vessels set below the wounded part, to receive it; these balsams should seem only to be inspissated essential oils. The resins are inspissated balsams, which acquire consistence by being exposed to the open air, after they have been separated from the plants; or they are the thicker parts of balsams which remain in the retorts when the fine oils have been drawn from them by distillation; or the balsams inspissated by the heat of the sun in the substance, or on the surface, of the plants which afford them.

9. *Earth, 10. and Iron.*

WHEN all the salts have been separated from the ashes of plants burnt in the open air, by lixiviating them with water, there remains a quantity of a white insoluble matter, which has been alleged to be an earth of the argillaceous or calcareous kind; though M. Fourcroy has suspected that it may hereafter be found to be a phosphorated calcareous earth, of the same kind

kind as is obtained from the ashes of bones; but he says that hitherto he has made no experiments to support the conjecture. This earthy matter, got from the ashes of vegetables, has been found to be mixed with some particles of iron, which are attracted by the load-stone, and which some naturalists have suspected to be the matter which gives colour to vegetables. M. Metherie, in his *Essais sur differens Airs*, tom. i. p. 434, says that a very small pittance, both of gold and of manganese, has likewise been discovered, mixed with these ashes.

S E C T. II.

OF THE CONSTITUENT PARTS OF ANIMAL SUBSTANCES.

ANIMAL substances are all of vegetable origin; for every animal, we know, either lives on vegetable food, from which it receives all its nourishment, or devours other animals which had fed upon herbs, roots, fruits, or other vegetable substances; hence

L

all

all animal matter may be considered as vegetable, more or less elaborated by the animal process, according to the animal which produced it.

The animal process, when it is fully perfected in a full grown animal, brings all the fluids to a putrescent state; for they putrefy, when exposed to a heat of about 60 degrees of Fahrenheit's thermometer, in a moist place in the open air, instead of fermenting or turning sour; and therefore these juices must have undergone in the animal body such changes, by the animal process, as are analogous to those effected by the two first processes of fermentation, the vinous, and the acetous, and likewise the beginning of the third, the putrescent: however these juices never become putrid in a healthy living animal, owing to the constant supply of fresh liquors, from the food the animal takes down, while in life.

Animals are composed of fluid and of solid parts. The *fluid* are the blood and the liquors separated from it, *viz.* the saliva, the bile, the gastric and pancreatic
I
juices;

juices ; the mucus of the nose, intestines, and joints ; the fine liquors secreted into the cavities, and by the vessels of the skin ; the urine, the wax of the ear, the fat, the marrow, and other oils, &c. The solid parts are, the viscera, the skin, the membranes, the muscles, the bones, &c.

M. Fourcroy mentions three sorts of viscid juices found in animals :

1. The mucilaginous or gelatinous, which is softer, attracts humidity more readily, and is not so easily dried as the mucilages of vegetables : this, he says, is extracted from the white parts, *viz.* the skin, the ligaments, the periosteum, and the cartilages.

2. The albuminous matter, which concretes and becomes opake by the application of heat, and the mixture with acids and with alcohol : of this kind is the whites of eggs, the caseous part of milk, the serum of the blood.

3. And the concrescible fibrous matter, which goes into a kind of membrane by cold ; it is analogous to the gluten of vegetables, but of a much more tenacious

nature, and of it the muscles and organs of motion are composed.

The fixt oils of animal substances differ from those of vegetables, in being almost always found more or less in a concrete state; and in some instances, such as that of the spermaceti, are capable of becoming dry, and assuming somewhat of a crystalline form. Volatile oils are rarely to be met with in the animal kingdom, though a pittance of such oils is to be got from some particular substances, such as from musk, castor, &c.

The saline matters, which animal substances afford, are some of them of the same nature as what are got from vegetables, such as sea salt, &c. and as they contain more impure air than alkalescent vegetables, they yield by distillation a greater quantity of volatile alkali. The urine, evaporated, yields the sal mirabile perlatum, called likewise fusible salt, besides other salts of a particular nature; and the animal, as well as the vegetable, afford acids of a particular kind: of these M. Lavoisier reckons six:

1. The

1. The acid of milk.
2. —————of sugar of milk.
3. —————of the silk worm.
4. —————of ants.
5. —————of fat.
6. The Prussian acid: to which may be added the acid of phosphorus.

The bones, or hard solid parts of animals, on being analysed, afford a gelatinous matter and other animal fluids; and their solid parts have been found to be composed of a particular kind of salt, formed of calcareous earth, and the phosphoric acid.

The blood, from which all the other liquors are separated, is made up of three different parts; a watery serum, a coagulable lymph, and red globules. When it comes from a vein of a living animal, it separates into two parts, a watery, transparent, yellowish liquor, or serum; and a red coagulated part, which is called crassamentum; part of the coagulable lymph remaining dissolved in the serum, and the rest of it serving to form the crassamentum along with the red part of the blood.

Water mixes readily with the blood as it comes from a vein, and prevents, for some time, its separating into serum and crassamentum; and it dissolves all the secreted liquors of the animal body, except those of an oily nature, such as the fat, and the oil and marrow of the bones; and with the assistance of heat extracts most of the juices, the watery, the mucous, the glutinous, the saline, &c. from the solid parts of animal bodies.

Blood left exposed to a heat which raises Fahrenheit's thermometer to between 50 and 60 degrees, dissolves into a thin fetid liquor; first the serous, and then the grumous part; and if suffered to remain long enough, its fluid parts evaporate, leaving behind but a small quantity of residuum: when it is once dissolved by putrefaction, it cannot again be coagulated.

It is dissolved or rendered more fluid, by mixing with it alkaline salts or nitre. It is coagulated by alcohol, and by mineral acids. If thrown into boiling water, the lymph coagulates into a firm substance like
the

the white of an egg, and becomes infoluble in water.

If blood be put into an evaporating glass, and exposed to a degree of heat which raises Fahrenheit's thermometer to about 140 degrees, its fluid parts evaporate, it becomes dry, and is reduced to about one seventh part of its original weight: if this solid part be put in an open fire, it burns, leaving but a small quantity of solid matter behind; which, on examination, has been found to contain a small quantity of earth, a salt composed of sea salt and natron, and some particles of iron, which are attracted by the loadstone, and alleged to give the blood its red colour.

S E C T. III.

OF THE PRINCIPLES OF VEGETABLE AND OF ANIMAL SUBSTANCES.

HAVING mentioned the different matters which vegetable and animal substances produce in their natural state, I shall next take notice of the principles of

which modern chymists allege their component parts are formed.

M. LAVOISIER says that all vegetable substances contain three principles, without which they cannot exist; viz. 1. *pure air*; 2. *inflammable air*; 3. *charcoal*: that some particular plants contain others besides: the cruciform, or those called alkalescent, containing likewise *impure (mephitic) air* and *phosphorus*.

And that animal substances contain *pure, impure and inflammable airs, charcoal, and phosphorus*, the same as the alkalescent vegetables; but they abound more with impure and inflammable airs, and hence afford more oil, and more volatile alkali when distilled.

M. METHERIE alleges that common vegetables contain, besides the principles mentioned by Lavoisier, an *acid air*; and that the alkalescent plants, as well as animal substances, afford an *hepatic air* by putrefaction.

1. The fine volatile principle, called *Spiritus rector*, which gives smell, &c. to aromatic vegetables, has not hitherto been examined,

examined, it being of too subtile a nature to be confined in vessels.

2. *Oils*.—M. Lavoisier alleges that oils are formed of charcoal and inflammable air, without its being reduced to the state of a gas, by means of the matter of heat (calorique); and that the oils thus formed are more or less volatile, according to the proportions of charcoal, and of inflammable air they contain; the *fixt* or *unctuous* oils containing an excess of *charcoal*, which separates when they are exposed to a degree of heat above that of boiling water; the *essential* contain a greater proportion of inflammable air, and not being decomposed by a degree of heat immediately above that of boiling water, rise in form of gas, and coming over into the receiver, along with the aqueous vapour, there again unite in the form of oil. He says that the *fixt* or *unctuous* oils contain about seventy-nine parts of charcoal, and twenty-one of inflammable air; and that those which appear in a solid form, such as the beeswax, probably contain a greater proportion of pure air than the fluid ones of the
same

same class ; and that all of them, when burnt in pure air, are converted into water and aërial acid.

3 and 4. The *balsams* and *resins* were originally essential oils, and contain nearly the same principles : they acquire solidity by absorbing a quantity of pure air, while part of their inflammable air evaporates.

5, 6, and 7. *Sugar, gums, and starch*, M. Lavoisier places in the class of oxides ; and alleges that, in their formation, the inflammable air and charcoal unite to form a basis, which, combined with more or less pure air, forms them into oxides ; and that, by combining an additional quantity of pure air, they may be reduced to the state of vegetable acids. He says they differ only from one another, in the proportion of the different principles which each of them contains.

8. *Salts*.—M. Lavoisier and others have of late published an account of a number of experiments, to prove that pure air was the universal principle of acidity ; and that this, combined with different substances,
which

which they have called the bases, constitutes the different sorts of acids.—Thus

Pure air with *sulphur* forms the *sulphureous* or *vitriolic acid*; with *impure* (mephitic) *air*, *nitrous acid*; with an *unknown basis*, *muriatic acid*; with *charcoal*, *aërial acid*; with *inflammable air* and *charcoal*, and sometimes with the addition of *phosphorus* and *impure air*, it forms the different vegetable acids; with a basis compounded of *inflammable* and *impure airs*, *charcoal* and *phosphorus*, it forms the different acids of the animal kingdom.

The true nature of the fixt alkaline salts is not hitherto known. M. Fourcroy and M. Lavoisier both acknowledge their ignorance of their composition; though M. Metherie asserts that they are made up of *pure* and *impure airs*, *inflammable air*, water and matter of heat, which he calls *causticon*; and that the *volatile alkali* only differs from the *two fixt*, in containing more inflammable air.

The volatile alkali has been proved, by the experiments of Mons. Bertholet and
Dr.

Dr. AUSTIN, to be a compound of impure and inflammable airs.

The neutral salts of course contain the principles of their component acids and alkalies, except such as may be dislodged by their union with one another.

9. and 10. Pure *earth* and *iron* are looked upon as primitive substances, having never hitherto been decomposed.

Animal substances are only the vegetable more elaborated in the vessels of animals by the processes they there underwent. When they have been completely animalised, M. LAVOISIER says they are made up of *pure, impure, and inflammable airs, charcoal and phosphorus*; to these we may add earth, and a pittance of iron, which are got from the ashes remaining after they have been burnt; and a very small quantity of sulphur, for they yield an hepatic air, on being putrefied.

S E C T. V.

OF THE CHYMICAL ANALYSIS OF VEGETABLE AND OF ANIMAL SUBSTANCES.

HAVING premised these few things relative to the component principles of vegetable and animal substances, I shall next take a view of the effects produced by subjecting them to a chymical analysis, as it was formerly called, that is, by distilling them in close vessels; the method which chymists formerly employed for the discovery of their constituent parts; believing that the different matters, obtained in this way, were the same as those which subsisted in the substances which they distilled.

All the principles of which vegetable and animal substances are composed, remain in equilibrium with each other, while they continue in a sound or healthy state, in the degree of heat in which they naturally exist or live; but when these substances are subjected to a degree of heat considerably

considerably above that of the natural temperature of the atmosphere, or are set to ferment, or to putrefy, a decomposition of their component principles takes place; and these unite, two and two together, according to the degree of affinity they have to each other, and to the degree of heat applied.

1. *Analysis of Vegetable Substances.*

WHEN vegetable or animal substances are to be distilled, the retort in which they are put ought to have a tubulated receiver fitted to it, and another receiver or bottle fixed to its tube, to receive and keep the volatile vapours or airs which separate towards the end of the distillation; otherwise these volatile fluids fly off and escape, without our having it in our power to examine them.

Most vegetable substances, except those of the alkalescent kind, when distilled in retorts, yield the following products:

As soon as they begin to be heated, there arises a watery vapour, which has the flavour of the original substance. This vapour
condenses.

condenses into phlegm, which has something of an acid taste, acquires a yellowish colour, and becomes more acid, as the distillation advances. After some time, a yellow-coloured empyreumatic oil begins to come over, along with the watery phlegm, which gradually becomes of a deeper colour, and thicker consistence, while the quantity of water gradually diminishes: at the time when this empyreumatic oil comes over, there arises a quantity of elastic vapour, which formerly was believed to be air; but now, since chymists have been able to preserve it in receivers, or bottles fixed to the tubes of tubulated receivers, and to examine it, it has been found either to be aërial acid, or inflammable gas, or a mixture of both.

At last, after the fire has been raised till it has made the retort red hot, and has been kept up till nothing more comes over into the receiver, upon removing the fire, and suffering the vessels to cool, there is found remaining in the retort a black mass, commonly called the caput mortuum; which, on examination, is found

to

to be made up of charcoal, a little earth, a saline matter, and a pittance of iron; and if the retort has not been kept of a red heat, for some time, before the operation has been finished, the charcoal is sometimes found mixed with a little empyreumatic oil: M. Fourcroy seems to think that it generally contains some inflammable air. If this mass which remains in the retort be burnt in an open fire, the charcoal disappears, and there remains a white ash composed of an earth, a fixt alkaline salt, and some particles of iron, which may be extracted by means of a loadstone, and sometimes a little of some neutral salt.

The changes which happen, in performing this analysis, are accounted for, by the new theory, in the following manner:

Immediately on the application of heat, almost all the fine aromatic particles, which form what is called the spiritus rector, evaporate and fly off, being too subtile to be confined in vessels; at the same time, part of the pure and of the inflammable

air being reduced to the state of gas, and set in motion by the heat, unite, and come over in form of water, along with part of the natural moisture of the plant, and some of its fine aromatic particles which gave it flavour and smell. As the heat increases, it sets more and more of these two principles in motion, and disengages likewise part of the charcoal; the effect of which is, that part of the pure air, uniting with part of the charcoal, comes over in form of aërial acid; while another part of the pure air, uniting with inflammable air, continues to come over in form of water; and at the same time, another part of the inflammable air, uniting with part of the disengaged charcoal, comes over in form of oil. As the heat increases, more and more of the charcoal is disengaged, and a larger proportion of it is united to the inflammable air, so that the oil becomes thicker as the distillation advances. At last, when the heat is raised so much as to make the retort red hot, the remaining part of the pure and inflammable airs, which were most intimately united with the vegetable

substance, and part of the charcoal being set in motion, instead of forming water and oil as before, are forced over into the receiver in form of inflammable gas, and of aërial acid.

The charcoal being the most fixed principle, a great part of it remains behind in the retort, mixed with a little earth, some fixed salt, and a pittance of metallic matter; but if it be burnt in the open air, it attracts a quantity of pure air from the atmosphere, and evaporates in form of aërial acid, leaving behind the earth, and fixed saline and metallic parts.

2. *Alkalescent Vegetables.*

THE changes produced by distillation on those vegetables called alkalescent, which, besides *pure* and *inflammable airs* and *charcoal*, contain a small portion of *impure air* and of *phosphorus*, do not differ a great deal from those observed on analysing other plants; owing, as Mons. Lavoisier observes, to the small quantity of

3

these

these two last principles, which enter into their composition : however, they have their effect ; for, in distilling these plants, it often happens that, soon after the application of heat, a pittance of the *inflammable* and *impure airs* rising in form of gas, unite and form a volatile alkali, which mixes with the watery phlegm, and afterwards, towards the end of the distillation, when the heat is increased, is formed in quantity, comes over with the empyreumatic oil, and adheres to the sides of the receiver. The phosphorus, M. Lavoisier says, continues united with the charcoal, which gives it fixity, so that it does not alter the appearances produced by the distillation.

When the black matter, composed of charcoal, &c. which remains in the retort, is burned in the open air, scarce any fixt alkaline salt is to be procured from the ashes ; the principles, which form it, having gone to the formation of the volatile alkali, during the distillation of the plant.

3. *Analysis of Animal Substances.*

ANIMAL substances contain, M. Lavoisier says, the same principles as the alkalescent plants, but have a much greater proportion of inflammable and impure airs* in their composition, than these plants;

* M. Bertholet, and since him M. Fourcroy, look upon the bases of impure air, which they call *azote*, as one of the most distinguishing principles of animal matter; and that it exists in greater or in less quantity in every species of it. M. Fourcroy seems to think that impure air is the great agent, which, by its fixation, changes vegetable into animal matter. He says that it is easily separated from it by means of the weakest nitrous acid, and a heat which will raise the quicksilver of Fahrenheit's thermometer to 64° ; and that the proportion of the azote, in animal substances, determines the quantity of volatile alkali, which they furnish by the action of the fire: for when they are deprived of all their impure air, they yield no more volatile alkali; and when all the volatile alkali has been separated from them by the force of fire, they yield no more impure air or azote.

M. Fourcroy says that the principles fit for forming the volatile alkali and the Prussian blue, are found more abundantly in the animal than in the vegetable kingdom, and sometimes in such abundance, that these two
compounds

plants; they yield a much greater quantity of empyreumatic oil and volatile alkali on being distilled; and the coal left behind in the retort, on being burned in the open air, leaves no fixed alkali mixed with the ashes which remain.

Of Charcoal, Earth, &c. left in the Retort.

I HAVE mentioned that, when vegetable and animal substances are distilled in close vessels, and the heat has been gradually raised till it made the vessels red hot, and kept in that state till all the parts, which are capable of being volatilised, have come over into the receiver, there remains in the retort a quantity of matter, which, when taken out of the retort, after it is cold, is of a black colour, and, on being examined, is found to be made up of *char-*

compounds have been found ready formed in animal substances some time after death; and in the *Annales de Chimie*, tom. i. p. 65, he mentions the case of a woman of thirty-five years of age, who was a patient in the Hotel Dieu, who was reduced to a very low state, and whose blood tinged linen of a blue colour, and was in a dissolved state.

coal, an *earth*, a *saline matter*, and some few *metallic particles*. The quantity of this black matter is always more or less in proportion to the solidity of the substance which has been distilled, the most solid yielding the largest quantity; in some it amounts to near a third of the weight of the original substance, in others not to a sixth.

M. Lavoisier and some other modern chymists allege that *charcoal* is a primitive substance, at least that it has not hitherto been decomposed; that of itself it is of a fixed nature; but when united, by the force of fire, to pure air, it forms aërial acid; and with inflammable air, oil: that in animal and vegetable substances it assists in forming the solid parts; and that the vegetative and animal processes produce effects somewhat similar to those of heat in the vessels of these organic bodies; and unite part of it, in them, with *pure* and *inflammable airs*, for the formation of acids, and oils in vegetables; and of fat, oil, mucus, and other juices in animals.

On the contrary, M. Metherie, in the
new

new edition of his *Essai Analytique*, published A. D. 1788, and other chymists, assert that charcoal is not a simple, but a compound substance, made up of *pure, impure, inflammable*, and *acid airs*; and affirm that they have extracted these matters from it; and that the charcoal of animal substances contains likewise a quantity of phosphoric acid.

This account of charcoal, given by M. Metherie, is so very different from that given by M. Lavoisier, that it is not easy to know what to think of it; it requires a number of accurate experiments to be made by able artists, to determine which of them is in the right.

The *earth* of bones and other animal substances which is left after the *caput mortuum* has been burned in the open air, is now known to be of the calcareous kind, but so intimately united with the phosphoric acid, that it may be looked upon as a phosphoric selenites; and M. Fourcroy suspects that the earth of plants will be found to be of the same nature.

The fixed and the neutral salts, and like-

wise the metallic matters found in the ashes of the *caput mortuum*, have been already considered; and therefore I shall say no more about them at present.

S E C T. VI.

OF COMBUSTION, OR THE BURNING OF
ANIMAL AND VEGETABLE SUBSTANCES
IN THE OPEN AIR.

I HAVE already observed frequently that the fire and the effects it produces are every day presented to our eyes; and although the ablest philosophers and chymists have in all ages employed their time in investigating its nature, yet they had established nothing certain; that all they had said was only mere conjecture and hypothesis; and that mankind remain as ignorant about its true nature, as they were a thousand years ago: nor is it yet determined what fire is, or what are its real properties; for chymists are even at this day divided in their opinions whether light and heat be only properties of fire, or
distinct

distinct bodies ; and the different divisions they have made of heat, matter of heat, and of light, phlogiston, causticon, and calorique, &c. are only a play of words, to fill up blanks in the different theories and systems they have formed.

From the observation of the effects of fire which daily present themselves to our view, it appears that all animal and vegetable, and likewise many mineral substances contain a quantity of matter which is readily acted upon, and set in motion by that active principle called fire, when subjected to its influence under certain circumstances ; and that even the smallest particle of fire, when once it is set at liberty, is capable of setting in motion all the matter, capable of feeding it, with which it comes in contact, and of spreading its influence all around with the greatest rapidity ; for the smallest spark which comes from a plate of iron struck with a flint, if properly managed, is capable of setting on fire and destroying, in a very short space of time, the largest ships, houses, and towns built of combustible matter.

It

It has long been observed that no body would burn without being in contact with air; and the experiments of late chymists have ascertained that this air must contain *pure air*; and that the combustion is always more or less rapid in proportion to the purity of the air in which the body is placed, and to the quantity of pure air which is supplied during the time of the conflagration: for if a combustible body be placed under the receiver of an air pump, from which the air is extracted, it will not burn on the application of fire; but if the receiver be filled with pure air, it will burn in it, till all the pure air is exhausted, or decomposed, after which it will burn no longer: and if a combustible body be set in a place where it is exposed to a brisk current of pure air, it will burn with the greatest rapidity till all the combustible matter is either destroyed or evaporated, or so decomposed as to be no longer capable of burning.

Hence we see the reason why bodies put into retorts, or other close vessels, to which the air has no access, do not take fire,

fire, or burst out into flame, but are only decomposed when exposed even to a heat, which renders the vessels in which they are contained red hot ; and why the same bodies, on being exposed to a current of pure air, burn briskly, and are reduced to ashes when fire is applied to them.

From all the experiments lately made it appears that pure air is one of the great agents for feeding or keeping up flame.

M. Lavoisier, in his *Traité Élémentaire de Chimie*, p. 478, &c. observes, that combustion is no other thing than the decomposition of oxygenous gas, effected by a combustible body, where the oxygen or pure air which formed the basis of the gas is absorbed ; while the matter of heat (or calorique) and light are disengaged, and set at liberty ; and that, to bring this combustion about, it is necessary that the basis of the oxygenous gas, that is the pure air, have more affinity with the combustible body than it has with the matter of heat, and be absorbed by it ; and that some heated body be brought near to break the equilibrium, and make the first impression

sion

sion, so as to set the whole in motion : for no combustion can take place while every thing remains in equilibrio, in the temperature in which we live ; an additional quantity of heat must be at first applied, though the matter of heat, afterwards let loose, by the decomposition of the oxygenous gas, is sufficient to keep up the combustion till the combustible body is fully saturated, and no longer capable of absorbing pure air or oxigene.

He says that a great part of the appearances observed in distilling vegetable substances in close vessels, are to be met with in burning them in the open air ; but that the presence of atmospheric air introduces three new ingredients into the operation, which are *pure and impure airs*, and the matter of heat (the *calorique*) ; two of which at least occasion considerable changes in the result of this process. He alleges that the inflammable air of the vegetable, or that which comes from the decomposition of water, on being driven off in form of gas by the force of fire, flames immediately on coming in contact with the air,

and forms water again, by uniting with the pure air of the atmosphere, and that the matter of heat (*le calorique*) of the two gases which become free, at least in greater part, produces flame: that when all the inflammable air has been driven off, burned, and reduced to water, the charcoal which remains now burns, but without flame, and escapes under the form of aerial acid, carrying with it a portion of the matter of heat, which had reduced it to the state of a gas. The surplus of the matter of heat (*le calorique*) being set at liberty, escapes, and produces the heat and light which one observes in the burning of charcoal.

Every vegetable, he says, is in this manner reduced to water and aerial acid; and there remains only a small portion of a grey-coloured matter, known by the name of ashes, which contains the only true fixed principles, which enter into the composition of vegetables.

S E C T. VII.

OF THE ANALYSIS OF VEGETABLE AND
ANIMAL SUBSTANCES BY PUTREFACT-
TION.

HAVING mentioned the changes brought about on animal and vegetable substances, by being exposed to the influence of fire, both in close vessels and in the open air; I come next to take a view of those produced by putrefaction.

Putrefaction, which is commonly looked upon as the third stage of fermentation, makes a complete analysis of all vegetable and animal matter; it disengages and dissipates the totality of their constituent principles, leaving nothing behind but their fixed earthy and metallic parts, and a little charcoal.

While plants or animals live and remain in health, the vegetative and animal processes prevent any fermentation or putrefaction from taking place; but when they are dead, and exposed to a certain degree of
heat

heat and of moisture, in a place to which air has access, they begin to ferment, or to putrefy, according to what nature they are of. Vegetable substances generally undergo a kind of fermentation before they putrefy: animal most commonly putrefy immediately; their juices having already undergone such changes in the vessels to which they belonged, as were analogous to the two first stages of fermentation, and to the beginning of the third or the putrid.

When vegetable or animal substances are so placed as to be exposed to a certain degree of heat and moisture, the matter of heat unites with the different sorts of air which form part of their component principles, and reduces them to the state of gases, which, being volatile, separate from the body left to putrefy; but these gases, on coming in contact with each other, and with the charcoal and other component principles of the body, which are now set at liberty, either immediately evaporate, or unite two and two together, according to the degree of affinity which they have
to

to each other, and form new combinations.

I. *Of the Putrefaction of Vegetable Substances.*

M. LAVOISIER says that vegetable substances, formed of the three necessary substances only, *viz.* the *pure* and *inflammable airs* and *charcoal*, ferment with difficulty; and their putrefaction is a long time of being completed; and, when it does take place, that the inflammable air, on separating, escapes in form of inflammable gas; and that the pure air and charcoal, uniting with the matter of heat, evaporate in form of aërial acid, leaving nothing behind but the vegetable earth, mixed with a little charcoal and iron.

Alkalescent vegetables, such as those of the cruciform and cepaceous tribes, which contain impure (mephitic) air, besides the three necessary principles, putrefy soon; for this air has been found to hasten and to promote putrefaction greatly, and it unites with part of the inflammable gas, and
escapes

escapes with it in form of a volatile alkali, which gives a peculiar penetrating smell to such putrid matter.

Some plants contain also phosphorus, and others sulphur; and when vegetables containing them putrefy, part of the inflammable air unites with the phosphorus, and forms phosphorated inflammable gas, which strikes the nose with a smell of rotten fish; and part unites with the sulphur, and forms inflammable hepatic gas, which has the smell of rotten eggs; hence vegetables, and more particularly animal substances that contain *impure air, phosphorus,* and *sulphur*, when they putrefy, emit a most disagreeable fetid smell, which arises from a mixture of the volatile alkali, and of phosphorated and sulphurated inflammable gases, which separate from these substances during the time of putrefaction.

2. *Of the Putrefaction of Animal Substances.*

ANIMAL substances contain nearly the same principles as the alkalescent vegetables, viz. *pure, impure,* and *inflammable airs,*

N charcoal,

charcoal, phosphorus, and a pittance of sulphur and of iron; but the proportions of impure and inflammable airs, and of phosphorus and of sulphur, is greater in them than in vegetables: hence a greater quantity of volatile alkali, and of phosphorated and sulphurated inflammable gases is formed, and separated from them, and occasions a stronger, more disagreeable, fetid smell, than what arises from vegetables. Hitherto neither vegetable nor animal substances have been so accurately analysed, as to ascertain either the proportions of their component principles, or the quantity of the different products which they yield.

With regard to putrefaction, M. Metherie observes, if vegetables be putrefied, either under water or in heaps, that the inflammable air, or the inflammable hepatic air, if there be any, acts upon the iron, reduces it to the state of a black æthiops, which is attracted by the loadstone, and gives a black colour to the whole mass; hence that all plants or woods which putrefy under water, or in a heap, acquire a black colour: whereas, if the
putrefaction

putrefaction is made in the open air, the iron passes to the state of an ochre, and the putrefied vegetables become of a reddish or ochry colour. That all salts, even tartarus vitriolatus, nitre, sea salt, and fixed alkalies, are decomposed by putrefaction; and, after vegetable or animal substances have been completely putrefied, that not a residue of them is to be found in the matter which remains. He tells us that M. Parmantier dissolved two pounds (thirty-two ounces) of sea salt in a quantity of water, and put into the water some skait and brett fish, which he allowed to stand till they putrefied; and, afterwards, till the putrefaction was entirely over, and they emitted no more putrid smell: for a long time the fetid smell was almost unupportable, and he was obliged to add water from time to time. At last, when the putrefaction was quite completed, he examined the water which remained, and got from it only one ounce of sea salt, without any loose alkali; so that thirty-one ounces of the sea-salt had been decomposed. And he adds, that the same thing takes place in putrefying

vegetable substances with salts, as happened here with the fish.

The excrements, particularly of carnivorous animals, contain a quantity of oily matter, formed by the union of charcoal with part of the inflammable air; and likewise a quantity of hepatic and phosphorated inflammable gases, which give them their fetid smell. M. Metherie tells us, that it has been found by experiment that the green matter, which swims at the top of water that covers human excrement in ditches, which are used as necessaries, is compounded of sulphur and calcareous earth.

M. Lavoisier observes, that the process of putrefaction sometimes produces particular effects under certain circumstances: he tells us that M. Fourcroy and M. Thouret, in examining the progress of putrefaction in bodies which had been buried under ground, where the access of air was prevented, found *the muscular parts often converted into a true animal fat*, which he thinks must have happened from the *impure* (mephitic) air of the animal

mal

mal substance having some how or other made its escape; and from the inflammable air and charcoal, which remained, uniting and forming fat after it was gone. This explanation of the manner in which this change was brought about, seems to be mere conjecture, founded on no certain facts or experiments.

S E C T. VIII.

OF THE VINOUS FERMENTATION.

FERMENTATION, or that process by which certain substances combined with water produce a fermented liquor, containing spirit, or alcohol, has been called the vinous fermentation; and the continuance of it to produce an acid or vinegar, has been called the acetous fermentation. The proper subjects of these fermentations are vegetable juices, which contain a saccharine principle, and a certain quantity of an extractive matter. Sugar refined to its utmost purity will not ferment; it requires the assistance of yeast, or

of some other extractive matter, called a ferment, to excite an intestine motion in the liquor; though brown sugar, or melasses, which contain likewise an extractive matter, ferment readily. When a liquor impregnated with a due proportion of such materials is to be fermented, it must be put into a cask, which is to be filled about nine tenths of its height; then to be slightly covered, and set in a degree of heat capable of raising the quicksilver of Fahrenheit's thermometer to between 60 and 70 degrees; after which the fermentation will soon begin, and must be allowed to go on till the vinous process is finished.

Hitherto chymists are neither agreed as to the nature or number of the principles which compose the bodies which are the subjects of fermentation, nor as to the changes which are produced during the operation, nor as to the principles of which the spirit or matter produced are formed.

If the facts mentioned by M. Lavoisier, in the account he gives of experiments made by himself, relative to the subject, shall be found to agree with those of fu-
ture

ture operators, and no mistake has been committed, it will set this matter in a clear light. His experiments were made with substances whose component principles he had ascertained; to wit, *sugar*, *water*, and *yeast*, in preference to the juice of the grape, or of other vegetables, whose analysis was more complicated, and not so easy to be made with accuracy.

He dissolved 100 pounds of sugar in 400 pounds of water; and added to this solution 10 pounds of yeast from beer, which contained 7 pounds, 3 ounces, 6 drachms, and 44 grains of water, and 2 pounds, 12 ounces, 1 drachm, 28 grains of dried yeast,

The 100 pounds of sugar contained

8 pounds of inflammable air
 28 ——— of charcoal
 64 ——— of pure air

The 407 pounds, 3 ounces, 6 drachms, 44 grains of water, including the water of the yeast, contained

lb.	oun.	dr.	gr.	
61	1	2	71.40	of inflammable air
and 350	2	3	44.60	of pure air

N 4

The

The 2 pounds, 12 ounces, 1 drachm, 28 grains of dried yeast, contained

lb.	oun.	dr.	gr.	
—	12	4	59	of charcoal
—	4	5	9.30	of inflammable air
—	0	5	2.94	of impure air
1	10	2	28.76	of pure air

Hence we see that the whole materials used in this process contained

	lb.	oun.	dr.	gr.
Of inflammable air	69	6	0	8.70
Of pure air - -	411	12	6	1.36
Of impure air - -	0	0	5	2.94
Of charcoal - -	28	12	4	59
	<hr/>			
	510			
	<hr/>			

Having ascertained the quantity and quality of each of the component principles of the liquor to be fermented, he put the whole into a vessel fitted with an apparatus for receiving, and afterwards examining the different gases, which might be separated (a description of which he has given in the third part of his *Traité Élémentaire*), and set this vessel in a place
where

where the heat raised the quicksilver from $65\frac{3}{4}$ to $72\frac{1}{2}$ degrees of Fahrenheit's thermometer.

In an hour or two after, he could perceive the marks of a beginning fermentation; some air bubbles rose to the surface of the liquor, and broke. After some time the air bubbles became very frequent, rose to the surface, and discharged a quantity of aërial acid, accompanied with a froth or scum, which, on examination, proved to be part of the yeast; and the whole liquor seemed to be in a ferment, or to boil.

At the end of some days, according to the degree of heat, the fermentation diminished, but did not cease entirely till after some time.

The weight of aërial acid which had separated in this operation, and which was preserved in a proper receiver, was 35 pounds, 5 ounces, 4 drachms, and 19 grains; and it had carried along with it 13 pounds, 14 ounces, and 5 drachms of water, which had condensed in the receiver.

And M. Lavoisier says that there remained

mained behind in the vessel, where the fermentation had been carried on, a vinous liquor, gently acid, which was at first muddy or turbid, and then clear, after depositing a little yeast, which weighed 397 pounds, 9 ounces, and 29 grains.

There should seem either to have been lost during the time of the operation, or to have remained in the vessel, a lee or dreg weighing 63 pounds, 3 ounces, 6 drachms, and 24 grains, which M. Lavoisier takes no notice of; though he lumps them into the following table which he gives of the products got by fermentation, and of the principles which he obtained from each of these products by analysing them separately.

The products obtained were,

	lib.	oun.	dr.	gr.
1. Of aërial acid - - - -	35	5	4	19
2. Of water - - - -	408	15	5	14
3. Of alcohol - - - -	57	11	1	58
4. Of acetous acid - - - -	2	8	0	0
5. Of sugar which remained undecompos.	4	1	4	3
6. Of yeast undecomposed - -	1	6	0	50
	<hr/>			
	510			
	<hr/>			

The

The principles of which these products were composed were as follow ;

<i>Aerial acid.</i>		lb.oun. dr.gr.
35 lb. 5 oun. 4 dr. 19 gr.	} contained	{ Of pure air - - - 25 7 1 34
		{ Of charcoal - - - 9 14 2 57

<i>Water.</i>		
408 lb. 15 oun. 5 dr. 14 gr.	} contained	{ Of pure air - - - 347 10 0 59
		{ Of inflammable air - 61 5 4 27

57 lb. 11 oun. 1 dr. 58 gr.	} contained	{ Of pure air combined
		with inflammable 31 6 1 64
		{ Of inflammable air com-
		bined with pure air 5 8 5 3
		{ Of inflammable air com-
bined with charcoal 4 0 5 0		
		{ Of charcoal - - - 16 11 5 63

<i>Acetous acid.</i>		
7 lb. 8 ounces	} contained	{ Of inflammable air - 0 2 4 0
		{ Of pure air - - - 1 11 4 0
		{ Of charcoal - - - 0 10 0 0

<i>Sugar remaining undecomposed.</i>		
4 lb. 1 oun. 4 dr. 3 gr.	} contained	{ Of inflammable air - 0 5 1 67
		{ Of pure air - - - 2 9 7 27
		{ Of charcoal - - - 1 2 2 53

<i>Yeast remaining undecomposed.</i>		
1 lb. 6 oun. 50 gr.	} contained	{ Of inflammable air - 0 2 2 41
		{ Of pure air - - - 0 13 1 14
		{ Of charcoal - - - 0 6 2 30
		{ Of impure air - - - 0 0 2 37

In looking over this table, which shews the gross matters which were obtained from

from the five hundred and ten pounds of materials that were employed, and the principles of which each of these products was composed, one observes that 4 pounds, 1 ounce, 4 drachms, and 3 grains of the sugar remained undecomposed; so that only 95 pounds, 14 ounces, 3 drachms, and 69 grains of it were divided into its original principles, which were,

	lb.	oun.	dr.	gr.
Of pure air - -	61	6	0	45
Of inflammable air	7	10	6	6
Of charcoal - -	26	13	5	19
	<hr/>			
	95	14	3	70
	<hr/>			

From whence it appears, that most of the *alkohol*, and of the *aërial and acetous acids*, which were the products of the fermentation, were formed from the principles of the decomposed sugar; for in examining the quantities of the different principles which these products are said to have yielded, we find them to be as follow:

	lb.	oun.	dr.	gr.
Of pure air - -	58	8	7	26
Of inflammable air	9	11	1	3
Of charcoal - -	27	4	0	48
	95	8	1	5

Which comes near to what the sugar produced: the greatest difference is in the quantities of the inflammable air; that in the products being above two pounds more than in the original sugar. This additional quantity was probably supplied from the water and yeast, which were all in some measure acted upon by the fermenting process.

M. Lavoisier alleges, that the effects of fermentation are to separate into two portions the sugar, which is an oxide; to oxygenate one at the expence of the other, to form of it aërial acid; and to disoxygenate the other in favour of the first, to form a combustible substance, which is alkohol; inasmuch that if it was possible to recombine the *aërial acid* and the *alkohol*, one would form again *sugar*. It ought however to be remarked, that the
inflammable

inflammable air and the *charcoal* are not in a state of oil in the alcohol, but are united with a portion of *pure air*, which renders them miscible with water; that these three principles exist in a state of equilibrium in the alcohol; and that, by making them pass through a glass or china tube made red hot, you may recombine them two and two, and form again *water*, *inflammable air*, *aërial acid*, and *charcoal*.

Such is the substance of the account given by M. Lavoisier, of the changes and new combinations which are brought about by the fermenting process; it is the first of the kind which has been published; and such inaccuracies as may have crept into it, may probably be corrected by the author himself, who is still busied in making experiments of the same kind, or by other chymists who are following the same pursuits.

S E C T. IX.

OF THE ACETOUS FERMENTATION.

AFTER the vinous fermentation is over, if the liquor be left in the same temperate degree of heat as before, where the air has free access to it, a fresh fermentation, called the acetous, takes place; which converts the wine into vinegar.

The addition of the lees of wine, or of vinegar, or of tartar reduced to a powder, or of a small quantity of good vinegar, or of the skins and stalks of grapes, cherries, currants, &c. or of yeast or other ferments, promotes the acetous fermentation greatly; and the putting the liquor into wooden casks in which vinegar has been kept, produces the same effects.

M. Fourcroy says that the three conditions necessary for promoting this fermentation are, 1. A degree of heat which raises Fahrenheit's thermometer to between 76 and 84 degrees: 2. A viscous and at the same time an acid body, such as mucilage

cilage and tartar : 3. The contact of air : And he approves much of the method recommended by Dr. Boerhaave, of employing two casks, with a hurdle made of ozier, and covered with twigs and stalks of vine put near the bottom ; and filling the one full, and the other only half full ; and daily filling the one that is only half full, from the other that is full ; and continuing to do so till the vinegar is completely formed, which generally happens in about twelve or fifteen days.

M. LAVOISIER alleges, that the acetous fermentation is no other than the acidifying of wine by the absorption of *pure air* from the atmosphere ; in proof of which he says, 1. That wine cannot be converted into vinegar without the contact of air : 2. That the acetous fermentation is accompanied with a diminution of the volume of air in which it is performed ; and that this diminution is occasioned by an absorption of pure air by the fermenting liquor : 3. That wine may be transformed into vinegar, by impregnating it with pure air in any manner whatever.

Vinegar

Vinegar, he says, is a compound, whose acidifiable basis is made up of *inflammable air* and *charcoal*; but that the proportions of these two ingredients are not yet known; and that this basis is reduced to the state of an acid, by the mixture of pure air: and he thinks this proved by an experiment made by M. Chaptal, professor of chymistry at Montpellier. He took a quantity of aërial acid, disengaged from beer in a state of fermentation, and impregnated it with water to the point of saturation, which was till it had absorbed about a quantity equal to its own bulk: this he put into a cellar, in vessels which allowed access to air; and at the end of some time the whole was converted into vinegar. The aërial acid arising from beer in fermentation in the vat, is not pure; it carries with it a small quantity of alcohol, which it keeps dissolved: there are therefore in water, impregnated with aërial acid, disengaged from vinous liquors in a state of fermentation, all the materials fit for forming an acetous acid. The alcohol furnishes the inflammable air and a portion of charcoal, and the aërial acid supplies the rest

of the charcoal and pure air ; and the air of the atmosphere contributes what is deficient of pure air, to carry the mixture to the state of acetous acid.

From hence, he says, it appears that it is only necessary to add inflammable air to aërial acid, to convert it into vinegar, or, to speak more generally, to transform it into a vegetable acid, for these differ from each other only in the degree of their oxygenation ; and that, on the contrary, it is only necessary to take away the inflammable air from a vegetable acid, to convert it into aërial acid.

When the acetous fermentation has been completed, and the liquor has dropped its feculent part, and become clear and transparent, the clear part of the vinegar is to be drawn off into another cask, which is to be stopped and put in a cool place : if it be allowed to remain on the lees or dreg, the putrid fermentation is apt to take place, and the vinegar to be spoilt.

It has been common to employ the worst wines for making vinegar ; but experience has shewn that the stronger and more spi-

rituous the vinous liquor is, the better and stronger vinegar it yields.

Vinegar does not deposit tartar, as wine does; that salt, M. Fourcroy says, seems to combine with the spirit and water, and to contribute to the taste and other properties of this acid.

S E C T. X.

OBJECTIONS MADE TO THE NEW THEORY OF CHYMISTRY.

SUCH are the outlines of the new chymical system laid down by Messrs. Lavoisier, Morveau, Fourcroy, and Bertholet, which was first made known to the world in a work entitled *The New Chymical Nomenclature*, which was published in the year 1787, and since then by works of the above-named and other ingenious philosophers, who have adopted their theory, and made experiments relative to these subjects. However, since the publication of the *Nomenclature*, other able chymists have raised a number of objections to it, of which the following seem to be amongst the principal:

1st, It has been doubted whether light and heat are real distinct substances, or are only the qualities and properties of other bodies.

2dly, That what is called the *calorique*, or matter of heat, is either the phlogiston of Stahl, or a matter nearly approaching to it, or what has been called *latent heat*; and that it was only a love of novelty which could induce them to give it a new name. M. Gadolin thinks that, according to the plan of the Nomenclature, the academicians ought to have called it *gasogene*, because in melting bodies it reduces them to a state of gas, or elastic fluid; in the same manner as they have expressed themselves by the word *oxigene*, for the matter they suppose generates acid; and *hydrogene*, for the matter which contributes to the formation of water.

3dly, That the composition and decomposition of water, discovered by the Hon. Henry Cavendish, and supported by a number of ingenious experiments made by M. Lavoisier and other French academicians, on which a great deal of the new theory is built, has been denied of late by Dr. Priestley

Priestley and M. Metherie. Future trials, however, can only determine whether Mr. Cavendish and the French academicians, or Dr. Priestley and M. Metherie, have committed mistakes in performing their experiments.

4thly, That the authors of the New Nomenclature have asserted, that the basis of pure air (called by them *oxigene*) is the universal acidifying principle; but they have mentioned no less than twenty-six different kinds of acids, and have demonstrated from experiment (or believed they have done so) that only a few of these acids are thus formed: but they have not hitherto been able to make, or to decompose, any of the others which they mention; nor have they been able to shew the existence of pure air in them, or to ascertain the nature of their acidifiable bases: and therefore, till they can analyse them, or at least part of them, it cannot be admitted as a certain truth, that all acids are formed in this manner. Professor Gadolin, of Abo, says, further, that as we are ignorant of the nature of the basis of pure air, and of the manner in which it combines itself with

bodies, we cannot affirm that it is the principle of acidity; for we do not know whether it gives acidity, or whether, by its combination, it only sets at liberty bodies which already had the properties of acids.

5thly, That Dr. Priestley, M. Metherie, and a number of other late authors, tell us they have performed experiments, which prove that the aërial and other acids have been formed in a different manner from what is mentioned by M. Lavoisier; and that, in repeating many of the experiments mentioned by him, and the other French academicians, in support of their new system, they had turned out differently from what is reported by them. Dr. Priestley, in the *Philosoph. Trans.* vol. lxxix. p. 7, tells us that he never failed, when the experiments were conducted with due attention, to procure some acid, whenever he decomposed dephlogisticated (pure) and inflammable air in close vessels; and concluded from thence that an acid was the necessary result of the union of these two sorts of air. And in vol. lxxviii. p. 319, he says, "I have supposed, with M. Lavoisier and others,
that

that the principle of acidity is in the dephlogisticated (pure) air only; but as the acid is always formed by the union of this air and the inflammable, it may perhaps with equal probability be supposed to be in either of them, or to be a compound of them both."

6thly, That M. Gadolin does not think the denomination of *oxide* agrees to all metals combined with the oxigene; because, if some appear to have acquired some properties of an acid, others seem to have acquired those of earths or of alkalies.

7thly, That they have denied that inflammable air is separated from many metals, during the time of calcination, and when subjected to other particular processes; which seems to be proved by the experiments of the Honourable H. Cavendish, of Dr. Priestley, and others.

8thly, In considering the account given of water being composed of 85 parts of pure air, and 15 parts of inflammable air, as above mentioned, it should seem that, if this was the case, water should be one of the most inflammable sub-

substances known ; for, on the application of fire to inflammable air, placed in a large receiver filled with pure or dephlogistified air, it burns with great violence : may not one suspect that, if water is a compound, some subtile and hitherto unknown matter enters into its composition, which renders it an extinguisher instead of a promoter of flame ? This however is only mere conjecture, thrown out with a view of engaging those very able and accurate philosophers, who are employed at present in chymical researches, to remove all objections to this doctrine, if it be well founded.

From all which it appears that, although the new theory seems to be just in some points, yet that a great deal remains still to be done, before it can be received in its full extent ; and that, although it may be well founded, yet that it will require a length of time, and the labours of many, to establish it on a firm basis, and to correct the many errors and mistakes which may have been committed, in operating on such subtile objects.

P A R T

P A R T III.

OF THE APPLICATION OF THE NEW
THEORY TO THE FORMER PARTS OF
THIS WORK.

IN this third part the Author has endeavoured to point out some of the principal alterations which it may be necessary to make in the theoretical part of the foregoing work, should the new chymical doctrine prove well founded; and has likewise marked some few things, which he thought necessary, that had either been omitted, or have occurred since his work was printed.

S E C T.

S E C T. I.

Of ACIDS.

(See vol. i. chap. ii. p. 41.)

IN the chapter on Acids, the following are the principal things which occurred to the Author, in looking over the very late works of our modern chymists, that had not been taken notice of before.

1. *Of the Sulphureous or Vitriolic Acid.*

(See vol. i. p. 42, &c.)

THE sulphureous or vitriolic acid is now almost always prepared from sulphur, which was believed by Dr. Stahl to be made up of a large quantity of this acid, and a small quantity of phlogiston; and that sulphur, when it was burnt*, was decomposed,

* Of late it has been found, both in England and in France, that sulphur may be burned more easily and at a cheaper rate in chambers, than in any sort of glass or earthen vessels; and therefore chambers, lined every where with lead, have been fitted up for that purpose; and

decomposed, and that the acid rose in form of a fine vapour, which, when received into a proper vessel, condensed in form of a liquor; whilst the phlogiston, which was too subtile to be confined in any sort of vessels, made its escape; and that the condensed liquor, when purified, by distilling off the water which was mixed with it, formed the fixed vitriolic or sulphureous acid; but that when this fixed acid was united to a certain quantity of inflammable matter, as mentioned in vol. i. p. 48, it became volatile, and was called the volatile vitriolic acid. But M. Lavoisier, and his associate academicians, now tell us that sulphur is a simple substance, which, when burned in *atmospheric* or in *pure* air, attracts, during the time of its combustion, such a quantity of the basis of pure air (the oxigene) as converts it into a sulphureous acid; which, they say, may be demonstrated by burning a quantity of sulphur in a close vessel, filled

and the sulphur has been so placed in them, as to be exposed to a current of air; and a sufficient quantity of water has been put in the bottom of the chambers, to facilitate the condensation of the acid vapour.

with

with pure air: for, after the burning is over, it will be found that the sulphur converted into this acid, has gained as much additional weight as the pure air, in which it has been burned, has lost. M. Bertholet, in repeating these experiments, observed, in one experiment, that 69 parts of sulphur attracted 31 parts of the basis of pure air, and with them formed 100 parts of vitriolic acid; and, in another, that 72 parts of sulphur only attracted 28 parts of the pure air, to form the same quantity of acid.

The same academicians allege that sulphur is capable of two degrees of impregnation with the basis of pure air (the oxigene); the first, when it is fully saturated with it, and constitutes the fixed sulphureous or vitriolic acid, which they call *acide sulphurique*: the second, when it is impregnated only with a certain quantity of the oxigene (less than in the former case), and becomes of a volatile nature; in which state it has been called by the English *volatile vitriolic acid*, and by the French academicians *acide sulphureux*.

They tell us, likewise, that this acid, in
these

these two different states, has different properties, for that neutral salts made with them and alkaline salts differ from one another; but hitherto these salts have not been particularly examined.

Notwithstanding what the French academicians have said, Dr. Priestley still continues to support the doctrine of phlogiston, and to assert that sulphur is a compound body made up of vitriolic acid and it; and, amongst other proofs of its being so, he says that he has converted oil of vitriol into sulphur, by evaporating it to dryness, under a receiver filled with inflammable air.

Mr. Kirwan, in the new edition of his *Essay on Phlogiston and the Constitution of Acids*, published in the year 1789, after considering what the French academicians have said on this subject, admits that sulphur enters wholly into the composition of the acid of sulphur, and that air of some sort or other is absorbed, during the conversion of sulphur into an acid; and has given it as his opinion, that this acid consists of a basis or radical principle, which

which, when saturated with phlogiston, constitutes sulphur; when saturated with fixed air, becomes common *fixed vitriolic acid*; and, when combined partly with the one and partly with the other, becomes *volatile vitriolic acid*; so that volatile vitriolic acid is nothing else but common vitriolic acid, holding sulphur in solution.

The French academicians have made a long reply both to Dr. Priestley and Mr. Kirwan; but the matter in dispute still seems to remain undecided.

2. *Nitrous Acid.*

(See vol. i. p. 55, &c.)

THE nitrous acid has for some years been known to be made up of two sorts of air, or rather of their bases, to wit, the *impure* (or azote), and the *pure* (or oxigene), in the proportion of one part of the *impure* to three parts of the *pure*. It has been divided into these two sorts of air, and been again formed by uniting them.

Dr. Priestley mentions the nitrous air in vol. lxii. of the Philosophical Transactions

tions for the year 1772 ; and the Hon. H. Cavendish, in vol. lxxv. for the year 1785, gives an account of his having produced nitrous acid, by uniting these two airs by means of the electric spark ; and, in the year 1788, he repeated the same experiment* with the same success ; and the experiments of M. Lavoisier and the other academicians confirm the truth of M. Cavendish's opinion, of the nitrous acid being formed by the intimate union of these two sorts of air. From these accounts it appears that the acid of nitre is made up of the same materials as the common atmospheric air, but in different proportions : this accounts for the artificial formation of nitre, when certain earths, containing alkaline salts and materials capable of fermenting and of putrefying, are exposed

* Mr. Cavendish's experiment was this : he put into a glass tube some soap ley, and with it seven parts of pure air and three parts of impure air ; and, having shut the tube, he made the electric spark pass through it ; after which, by filtering and evaporating the soap ley, he obtained a small quantity of nitre, the acid of which must have been formed by the intimate union of the two airs, brought about by the electric spark.

to the common air for a length of time; for the materials, when thus exposed, attract from the atmosphere a quantity of *pure* and *impure* airs, which are united by the fermenting and putrescent processes, which are perpetually going forward in these heaps of materials, and form nitrous acid; which is immediately attracted by the alkaline salts, with which these materials abound.

M. Lavoisier, and the other academicians, tell us that the nitrous, like the vitriolic acid, is capable of appearing in various forms, which depend upon the different proportions of *pure* and of *impure air* of which it is composed. 1. When there are two parts (in weight) of pure air to one of impure, the product is *nitrous gas*, which is not miscible with water, but has such an affinity with pure air, that it attracts it from the atmosphere when it comes in contact with it. 2. When there are three parts of *pure* to one of *impure air*, the product is a red fuming liquor, called *nitrous acid*: M. Lavoisier says that these two substances, the nitrous gas, and
nitrous

nitrous acid, may be converted into each other; for, by adding pure air to the gas, it becomes nitrous acid; and, by separating some of the pure air from the nitrous acid, by means of heat, it is reduced to the state of gas. 3. When the proportion of *pure air* is to that of the *impure* as four to one, the product is a white acid, without colour, which the French call *acide nitrique*; this Dr. Metheric says is the pure nitrous acid, and is much more active than the fuming spirit of nitre.

3. *Muriatic Acid.*

(See vol. i. page 65, &c.)

THE authors of the new chymical theory have supposed, from analogy, that this, like the sulphureous and nitrous acids, is a compound formed by the union of an acidifiable basis with pure air (the oxygen); but hitherto they have not been able to demonstrate its acidifiable basis, or to prove that it contains pure air. This acid however should seem to be capable both of being composed and decomposed, though

P

hitherto

hitherto we are ignorant of the manner in which this is brought about; for a quantity of sea salt is always got from the mud walls prepared for the generation of nitre: and M. Palmantier, as I before observed, found that 31 ounces of sea salt (out of 32 which he dissolved in water, in which skate and bret fish were allowed to putrefy, and let stand till the putrefaction was entirely over) had been decomposed, and had evaporated during the time that the putrid process had been going forward; without leaving a remnant of either the acid or the alkaline parts behind.

One part of muriatic acid mixed with three of the nitrous, has been called *aqua regia*, from its having the property of dissolving gold, which used to be called the king of metals. For a long time it was supposed that the addition of the pure nitrous acid gave it this property; but it has been discovered lately that it was not the nitrous acid itself, but a quantity of pure air (oxigene), which it imparted to the muriatic acid, which gave it this quality; for if the muriatic acid be impregnated

pregnated with a quantity of the oxigene, by distilling it along with the calces of manganese, or of mercury, or with any other substance abounding with pure air, it acquires the same property of dissolving gold, as when it is mixed with nitrous acid.

This acid, when saturated with pure air, becomes more volatile, and is always in a state of gas; when thus impregnated, it is not absorbed by water in such quantity as before; it dissolves silver, quicksilver, lead, &c. without effervescence: and M. Bertholet mentions that it is capable of uniting with a number of acidifiable bases; and that the salts formed from this union are capable of detonating with charcoal, and with a number of metallic substances; and that, when the basis of the pure air (the oxigene) is in large quantity, the explosions are frequently so violent as to become dangerous. M. Lavoisier says, if this acid be oxygenated beyond a certain degree, that it precipitates to the bottom of the vessel in which it is kept, in a concrete form.

M. Bourdelin, in the Memoirs of the French Royal Academy of Sciences for the year 1742, has endeavoured to prove that the acid of succinum (amber) was the muriatic; but from the experiments I made with this salt in the year 1767, an account of which is given in vol. lvii. of the Philosophical Transactions, p. 509, &c. it is evident that the sal succini is an acid of a particular kind; and the neutral salts made with it and alkaline salts, are very different in figure, taste, and other properties, from those made with the muriatic acid.

4. *Aërial Acid, called Fixed Air.*

(See vol. i. page 93, &c.)

CHYMISTS are not as yet agreed about the composition of this acid. M. Lavoisier calls it *acide carbonique*, and asserts that it is made up of 72 parts of the basis of pure air (the oxigene) and 28 parts of charcoal; and says that it may be prepared by burning charcoal in pure air in form of gas, or by combining powder of charcoal with

with

with a metallic calx (or oxide), in a just proportion. Dr. Metherie seems to doubt of these facts: and Dr. Priestley, in a paper published in vol. lxxviii. art. 2, for the year 1788, tells us that he has procured *fixed air* by uniting *pure* and *inflammable airs* together.

5. *Phosphoric Acid.*

(See vol. i. page 100.)

THE phosphoric acid, according to the new chymical doctrine, is phosphorus, saturated with the basis of pure air (or oxygen).

Phosphorus was discovered about the year 1667, by an alchymist of the name of Brandt. Till within these few years it was believed to exist only in the urine; but of late it has been discovered to be contained in almost all animal substances, and in many vegetable, particularly in those called alkalescent. At present its acid is mostly procured from bones, which contain it in large quantity, so firmly united to a calcareous earth, that it is not dis-

lodged by calcination. The method now generally employed for separating it from bones, is this :

Take a quantity of bones, calcine them to whiteness, reduce them to a very fine powder ; pour on this powder as much diluted sulphureous acid as will dissolve a great part, but not the whole, of the powder ; digest them together for 12 hours, and during that time stir them about frequently with a wooden spatula, by which means the sulphureous acid will dislodge the phosphoric, and form a selenites with the calcareous earth of the bones, which will precipitate to the bottom of the liquor, while the phosphoric acid will remain united to the water ; then decant off and strain through a cloth the watery acid liquor ; wash the selenites with distilled water, and add the water to the diluted phosphoric acid ; after this, boil the liquor, which will drop a quantity of selenites as it evaporates ; and, when it drops no more, separate all that has formed, either by straining the liquor through a fine cloth, or by filtering it through paper ; and then
evaporate

evaporate the liquor till there remains in the evaporating glass a matter of the consistence of honey, or soft extract, and of a brown colour; put this into a crucible, and let it remain over the fire till it emits no more sulphureous and aromatic smell, and till it ceases to boil. In this state it has a half vitreous consistence, an acid taste, and attracts the humidity of the air: if this glass be reduced to a fine powder, and be mixed with a third part of its weight of powdered charcoal, and then thrown into a heated crucible, it forms a good phosphorus.

The acid of phosphorus, procured in the manner above mentioned, is not so pure as that obtained by combustion, or by the nitrous acid, and therefore is not so proper to be used for experiments. M. Lavoisier says that the best method of obtaining it pure, and free of all mixture, is to burn phosphorus under a glass bell, whose inside has been moistened with water; and that during the combustion it absorbs twice and a half its own weight of the basis of pure air, the oxigene. Phospho-

rus may likewise be converted into an acid, by burning it slowly in the following manner:—Place small bits of it, supported by pieces of wood, in the inside of a wide glass funnel, whose nose has been set into the mouth of a crystal bottle; and leave it exposed to the air, when it will absorb by slow degrees such a quantity of the basis of pure air (the oxigene) as will convert it into an acid; and this acid, as it forms, will attract moisture from the open air, and will run per deliquium, and fall down into the bottle in which the nose of the glass funnel had been placed: but the phosphoric acid thus formed will contain less of the oxigene, that is, it will be less acid, than when the phosphorus has been burnt quickly.

Phosphorus may likewise be converted into phosphoric acid, by distilling it when mixed, either with the nitrous acid, or with oxygenated muriatic acid, in the following manner:

Take a retort with a tube rising from the upper side of the wide part of its neck, and let the tube have a glass stopper fitted to it. Place this retort, after it has been half
filled

filled with nitrous acid (or with oxygenated muriatic) in a sand heat, and fit a receiver to it: take out the stopper of the glass tube, and introduce by it, successively, some small pieces of phosphorus, which the nitrous acid will immediately dissolve with an effervescence, and part of the nitrous acid will rise in form of red fumes; continue to add by degrees, after the effervescence raised by each piece of phosphorus is over, till the acid will dissolve no more; then put the stopper into the tube, and apply such a heat to the retort as will force over all the nitrous acid into the receiver, which ought to be a tubulated one; then remove the fire, and allow the retort to cool; when the phosphoric acid will be found in it, partly in a solid, partly in a liquid form. In this process, the nitrous acid, or the oxygenated muriatic, if that has been employed, imparts to the phosphorus such a quantity of the basis of pure air (the oxigene), as to convert it into an acid; and the remainder of the nitrous acid evaporates, or is forced over into the receiver, when the heat is applied to the
retort.

retort. With this acid, and the pure fossil alkali, a neutral salt, called NATRON PHOSPHORATUM, has lately been prepared, and been used as a purgative medicine, in doses from six to ten drams, dissolved in from half a pint to a pint of mutton or veal broth. Dr. Pearson recommends it to be prepared by dissolving two ounces, seven drams, and two grains of pure crystallized natron, or fossil alkali, in four ounces and three drams of distilled water, which has been heated till it raises the quicksilver of Fahrenheit's thermometer to between 140 and 150 degrees; and then to add, by degrees, an ounce and a scruple of pure phosphoric acid; and, after the effervescence is over, to boil the liquor for a few minutes, and then to pour it into a shallow vessel, placed in a temperature of air which will raise Fahrenheit's thermometer to between 80 and 90 degrees, and allow the salts to shoot into crystals of a rhomboidal figure. By repeated evaporations and crystallizations, one gets from this quantity of materials, from three ounces ten grains, to three ounces and a dram, of crystallized salt; and

if the water which remains be evaporated to dryness, it will leave about 150 grains of a saline matter.

6. *Of Vegetable Acids.*

(See vol. i. page 71, &c.)

HITHERTO our modern chymists have not examined vegetable acids with that care and attention which they deserve. Even M. Lavoisier and M. Fourcroy, in their latest works, tell us that only thirteen different kinds of them had been discovered; though, so long ago as the year 1767, I had published, in vol. lvii. of the Philosophical Transactions, an account of twenty-two different kinds of vegetable acids; and had proved, by saturating them with the native fossil alkali of the country of Tripoli in Barbary, and then by crystallizing the neutral salts thereby produced, that each of them differed from the other, and that probably the acid of every vegetable differs in its natural state, in some respects, from that of another.

Monf.

Monf. Lavoifier has faid that all vegetable acids are formed by the union of the oxigene and a bafis made up of inflammable air and charcoal, and fometimes with the addition of phofphorus and of azote (or impure air) ; and that the different proportions of thefe materials, in their compofition, conftituted the difference between them.

The beft method of obtaining vegetable acids for making experiments with, is to purify the acid juice by filtering and by other means, and then to concentrate them by evaporating with a gentle heat, or by expofing them in the open air in the time of a hard froft, which will freeze the watery part, and leave the acid pure behind, M. Georgius of Stockholm, by expofing lemon-juice to a frofty air, in which the quickfilver of Fahrenheit's thermometer flood at about 24 or 25 degrees, reduced it to one eighth part of its bulk.

The common method of obtaining vegetable acids in a concentrated ftate, employed by modern chymifts, has been to form neutral falts with them and the vegetable

getable alkali, or with calcareous earth, or with some metallic substance; and then to put these neutral salts into a retort, and to pour over them some of the strong mineral acids, which sets loose the vegetable acid; so that, on distilling, it comes over into the receiver: however, it ought to be observed that this method is apt to lead into error, if we are not on our guard; for generally some of the lighter parts of the mineral acids rise and come over into the receiver, and mix with the vegetable acids; and if the nitrous or oxygenated muriatic acids be employed, they are apt to impart to the vegetable acids such a quantity of the basis of pure air (the oxigene) as alters their properties; besides, these strong mineral acids may decompose the vegetable; and it may perhaps be owing to some of those causes, that M. Lavoisier and his associates were able to convert the acid of tartar into that of sorrel, or into that of apple, or into the acetous acid. For these reasons, if we make use of the strong mineral acids to separate the vegetable from neutral salts, some method ought to be fallen upon to discover,

discover, and to correct, any mistake which may have been committed; before we draw any conclusion with regard to the nature of these acids in the natural state:

7. *Prussian Blue.*

(See vol. i. page 98.)

IN note to p. 170, 171, of this Appendix, I have mentioned that M. Fourcroy had observed the Prussian blue ready formed in animal substances: since that sheet was printed, a gentleman, who formerly studied physic, came to town to ask my advice, for a pain and uneasiness at his stomach; attended sometimes with sickness and vomiting, which he had laboured under for some months. In giving the history of his case, he mentioned that what he had thrown up, when attacked with sickness and vomiting, was generally mixed with a green or yellow bile; but that, in two of these attacks, what he vomited was of a bright blue colour; exactly resembling a solution of copper in diluted volatile alkali; a circumstance which he said neither he, nor the apothecary who attended him

him in the country, could account for: Might this blue colour have proceeded from Prussian blue generated in the biliary vessels, which coloured the bile that was mixed with the contents of the stomach? Or might the blue colour have been generated in the stomach, the gentleman having taken about that time some bark mixed with a small quantity of sal martis?

S E C T. II.

ALKALINE SALTS.

(See vol. i. page 120.)

HITHERTO chymists have not been able to decompose the fixed alkaline salts, and therefore many of them have ranked these amongst the simple substances; but, notwithstanding, others still support the old opinion of their being compounds. M. Metherie is of this opinion, and says that they only differ from the volatile alkali, which is now known to be a compound, in containing more inflammable air; but he has not hitherto brought any certain proof of its being so. He seems
likewise

likewise to support the opinion of alkaline salts being originally formed in plants, and not generated by the force of fire; and says that the neutral salts got from the juices of many plants, and the nitre and sea salt generated in the earthen banks prepared for the formation of nitre, evidently prove that the vegetable and fossil alkalies are not always the product of combustion; and he quotes M. Lorgna for a fact, which, if true, should seem to put this matter beyond all manner of doubt. In p. 308 of tom. ii. second edition, of his *Essay Sur Differentes Airs*, he says that M. Lorgna, having got a large parcel of the kali plant, burned one half of it, and infused its ashes in boiling water for some hours; and then from the water, which he strained off and evaporated to dryness, he got 436 grains of fossil alkali: that after this he bruised the other half of the kali plant; and, by infusing it in like manner in boiling water, and then evaporating the water after it had been strained through a cloth, he got 473 grains of the same sort of fossil alkaline salt as he had obtained from the other parcel.

1. *Vegetable Alkali.*

(See vol. i. page 125, &c.)

M. FOURCROY tells us, that, by saturating the caustic vegetable alkali with ærial acid, and exposing it to the vapour of fermenting liquors, it will shoot into most beautiful crystals, which taste mild, and undergo no alteration from being exposed to the open air; that they dissolve in four times their own weight of water; and generate cold, in the time of their solution in the water. This should seem to be another instance of what I have mentioned in page 69 of this Appendix, of some salts generating cold in the time of their solution, when in a crystallized state, which generate heat when dried, and deprived of the water of their crystallization.

2. *Fossil Alkali.*

(See vol. i. page 131.)

THE native fossil alkali, the natron of the ancients, can by care be freed of all impurities, and obtained in a state of purity; but the salt got by burning the kali, or other marine plants, is always

Q

mixed

mixed with the vegetable alkali, from which it cannot be separated by any means we hitherto know: it is brought to us from Spain, mixed with ashes and other impurities, in form of large hard black lumps, and goes by the name of *soda* or *barilla*: by breaking these lumps, and reducing them to a fine powder, and then boiling this powder repeatedly in six times its own weight of water, till the water becomes insipid, and then separating all the insoluble matters, one obtains, by evaporating to dryness all the water in which the barilla has been boiled, about 55 pounds of alkaline salt from 100 of the best gross black barilla, according to the account given by Dr. Dejean of Leyden, in his Inaugural Dissertation de Soda Hispanica. The salt, thus obtained, ought afterwards to be purified, in the manner recommended in the New Pharmacopœia of the College of Physicians in London.

In vol. xxxv. of Observations sur la Physique, &c. p. 295, for the year 1789, there is an account given by M. Westrumb of his having precipitated the fossil alkali from sea salt, by means of the vegetable; by which it
appears

appears that from 26 pounds of sea salt dissolved in 60 pounds of water, by the addition of 25 pounds of pure pot-ashes, he obtained by repeated evaporations, crystallizations, &c. 20 pounds of fossil alkali in large crystals, and one pound and a half which was not so pure; besides a large quantity of sal digestivus and some tartarus vitriolatus.

3. *Volatile Alkali.*

(See vol. i. page 158, &c.)

M. BERTHOLET, in the year 1784, proved, by a number of experiments, that the volatile alkali is formed by the union of impure and inflammable airs; which has since been confirmed by other experiments, mentioned in art. 23 of vol. lxxviii. of the Philosophical Transactions, by Dr. Austin; who says, many other similar experiments might be mentioned, but these are sufficient to prove that, if light phlogisticated (*i. e.* impure) and light inflammable airs be presented to each other, at the instant of their separation from solid or liquid substances, and before their particles have receded from each other, they readily combine, and generate volatile alkali.

S E C T. III.

OF NEUTRAL SALTS.

(See vol. i. page 172.)

IN looking over this chapter on Neutral Salts, I see little to be added or subtracted, as I have mentioned all those which are at present used in practice, besides several which are not ; and have given a particular account of the best methods of preparing them, and of their virtues and uses. The salts made with alkaline substances and the mineral acids in their different states ; that is, when, according to the new system, they have been more or less impregnated with the basis of pure air (the oxygen), I have not mentioned ; as hitherto none of them have been used as medicines, or been particularly examined.

The accounts we have of the quantity of water it takes to dissolve the different salts, and of the degrees of cold or of heat which they occasion during the time of their solution in water, differ very much from

from one another, even those related by authors of credit; owing to the different states the salts were in, at the time the experiments were made with them, and to the purity and temperature of the water employed for their solution: circumstances which were formerly little attended to, as being supposed to be of no moment; but have of late been discovered to occasion a great difference in the result of such experiments. Thus Glauber salts, fully impregnated with water, dissolve readily in this fluid, and generate cold during the time of their solution in it; but if the same salt be perfectly dried, and freed of all the water of its crystallization, it becomes much more difficult of solution, and generates heat at that time.

In order to obtain a complete table of the quantity of distilled water it requires to dissolve neutral salts, a quantity of each of them ought to be prepared in the most exact manner, and in a state of perfect crystallization, and experiments be tried with each of them in that state; after which the same experiments ought to be repeated with parcels of

the same sorts of salts, after they have been well dried, and freed of all the water of their crystallization ; and likewise be repeated with parcels of the same sorts of salts, freed of a half, and of two thirds, of their water, to see what difference the different quantities of water will occasion. And all such experiments ought to be made repeatedly, and with distilled water of different degrees of heat, and in a room where the air is kept of the same temperature, during the time the operations are performed.

1. *Magnesia Vitriolata.*

(See vol. i. page 198.)

Epsom Salt.—M. Fourcroy, in a memoir published in the year 1784, says that the pure magnesia vitriolata, made with magnesia and the vitriolic acid, is an efflorescent salt ; and not one that runs perdeliquium, as the common English Epsom salt does, which he alleges is owing to that salt containing about a fifth part of the magnesia muriata.

2. *Borax.*

2. Borax.

(See vol. i. page 231, &c.)

IN my preface to vol. i. I have mentioned that this salt has been found native in the country of Thibet in the East Indies; and of late we have had an account, published by Mr. H. Fr. Hoëfer, apothecary to the Duke of Tuscany, in Italy, of its acid, called *sal sedativus*, having been found dissolved in the water of the lakes of Castel Nuovo, and Monte Rotundo, in that duchy, so pure as to form a true borax, by saturating it with fossil alkali.

S E C T. IV.

O F M E T A L S.

(See vol. i. page 23, &c.)

METALS have for a number of years been looked upon as compound substances, made up of a certain earthy matter united to phlogiston (or matter of heat), which gave them their metallic properties; and

the changes which they underwent, in being calcined, were alleged by Stahl and his disciples to be brought about by the force of fire dissipating their phlogiston; and that, when this phlogiston was restored to them, they again acquired the properties of metals, and became fusible, ductile, &c. But the authors of the new doctrine have ranked metals amongst the simple substances; and allege that they do not contain phlogiston; and that, when they are calcined, they absorb from the atmosphere a quantity of the basis of pure air, the oxigene, during the time of their combustion; which gives them the form, and other properties, of those substances which used to be called *calces*, but which the supporters of the new doctrine name *oxides*; believing them to be impregnated with a certain quantity of the oxigene, the supposed principle of acidity, though not sufficient to convert them into acids; and that, if these metallic calces or oxides be again deprived of their oxigene, or basis of pure air, by being exposed to a very strong heat in crucibles, along with charcoal or other
fluxes,

fluxés, which attract or take up the oxygen (the basis of pure air) which they had absorbed, they return to the state of metals.

When metals are dissolved in acids, and precipitated from them by means of alkaline salts, they are likewise reduced to the state of calces or oxides: and M. LAVOISIER lays it down as a rule, that no metallic substance can be dissolved in an acid, till it be brought to the state of a calx or oxide, by being united some how or other with *pure air*; whether it get this air from the decomposition of water, or of the acid itself: and he says that the following things are to be observed in the solution of metals by acids.

1. That in all solutions of pure metals an effervescence arises, occasioned by a separation of gas (aërial fluid) on the decomposition of either the acid, or of the water employed—That, when the solution is brought about by means of the nitrous acid, the gas is the nitrous; when the vitriolic or sulphureous, the gas is either the volatile sulphureous acid, or inflammable
air,

air, according as it may be separated from the sulphureous acid, or from the water, whose pure air (oxigene) oxidated the metal.

2. That all metals dissolve without effervescence in the aërated (i. e. oxigenated) muriatic acid; the metal in that case taking up the superfluous pure air: by which means a metallic oxide or calx, and common muriatic acid, are formed at the same time; and the gas, which would otherwise have been separated, finds more water than is necessary to keep it in a liquid form, and to prevent its appearing in form of gas or vapour.

3. That, if the metallic substances have been previously reduced to the state of calces (oxides), they dissolve without any effervescence; for, the metal having been already aërated, no decomposition of water or of acid takes place during the time of the solution.

4. That metals which have such a small degree of affinity with the basis of pure air, the oxigene, as not to be capable of attracting it from the acid or from the
water,

water, so as to decompose these bodies, are absolutely insoluble: and it is for these reasons that silver, mercury, and lead are not soluble in the common muriatic acid, in their pure metallic state; though the same acid dissolves them easily when they have been reduced to the state of calces.

Hence M. Lavoisier says it should appear that the basis of pure air, the oxigene, is the means of union between metals and acids; which makes one inclined to believe that all substances which have a strong affinity with acids, contain pure air.

Mr. Kirwan, who acknowledges the decomposition of water, has in the new edition of his *Essay on Phlogiston, and the Constitution of Acids*, published in 1789, p. 167, given it as his opinion, that metals, when calcined, lose their phlogiston, which is nothing else than inflammable air in a concrete state; and that they at the same time unite most commonly to fixed air, formed during the operation; but sometimes some of them unite to water, and other substances, by whose means they are calcined: and that the calces of the
perfect

perfect metals may be reduced or brought back to their metallic state, by the decomposition of fixed air; and those of the imperfect and semi-metals, partly by the decomposition of their fixed air, and partly by its expulsion, and that of the other bodies they had absorbed, and their simultaneous re-union to the inflammable principle. In answer to this, M. Fourcroy has said, that it is only the oxigene, the basis of pure air, which is capable of changing metals to the state of calces or oxides; and that the phenomena are the same in the calcination of all metals: and therefore there is no reason to suspect that the means of bringing about calcination are different in different substances.

I. *Gold.*

(See vol. i. page 244.)

GOLD is of a very fixed nature, and requires the heat of the focus of a burning-glass to reduce it to the state of a calx.

Formerly

Formerly the only menstruum capable of dissolving it (when in a metallic state), that was known, was a mixture of the nitrous and muriatic acids, which went by the name of *aqua regia*. But it has been lately discovered, as I before observed, in treating of the muriatic acid, that the nitrous acid did not contribute further to the solution of this metal, than in furnishing the muriatic with a quantity of the basis of pure air (or oxigene); for that, if the muriatic acid was impregnated with the same quantity of oxigene by other means, it produced the same effects. But although this metal is not soluble by other acids, in its metallic state; yet, after it has been precipitated in form of a calx, or oxide, from *aqua regia*, by means of fixed alkaline salts, it becomes soluble in the sulphureous and nitrous acids.

2. *Silver.*

(See vol. i. page 247.)

SILVER is one of the most unchangeable metals we know: for although heat
makes

makes it boil, and even volatilizes it, it does not change its nature; for M. Fourcroy says that its vapours, condensed in chimneys or in retorts, are found to be pure silver unchanged. Junker however reduced it to the state of a calx, by keeping it long in a reverberatory furnace; and M. Macquer, by exposing it to the focus of a burning-glass.

3. *Copper.*

(See vol. i. page 249.)

COPPER, exposed to the air, contracts a rust on its surface, which does not penetrate into its substance, but seems to serve as a cover to preserve it, and to prevent its being destroyed or corroded by other bodies. It should seem to be owing to this rust, that many antique medals and statues have been so long preserved entire. The Italian antiquarians call it *patina*.

4. *Iron.*

4. *Iron.*

(See vol. i. page 259.)

THE first class of the preparations of iron which I have mentioned, comprehends, 1. the filings; 2. the æthiops; 3. the safron or crocus; 4. and the rust of iron.

If the new chymical doctrine be true, the three last are calces or oxides of iron.

Æthiops Martialis.

(See vol. i. page 262.)

THIS preparation is commonly called Dr. Lemery's *Æthiops Martialis*, and is prepared thus:

Put filings of iron into an unglazed earthen vessel; pour pure water over them, till it rises four inches above the filings; stir them well about every day, and supply them with more water, as that in the vessel evaporates, so that the filings remain always covered with some inches of water; continue this operation for some weeks, till the filings fall down into an impalpable black powder, which separate and dry. In

this process it should seem as if the iron had attracted the pure air of the water, and was thereby converted into a calx or oxide. A black powder of the same kind may be procured by burning some very fine thin laminæ of iron in pure air, under the receiver of an air pump, in the manner recommended by M. Lavoisier in his *Traité Élémentaire*, page 45, &c. ; and then reducing them to a fine powder, which is easily done, as they are extremely brittle and friable. When the operation has succeeded well, 100 grains of iron yield 135 or 136 of æthiops.

Rubigo Ferri.

(See vol. i. page 262.)

The filings of iron exposed to the air, and moistened frequently with water, imbibe a quantity of the basis of pure air (the oxigene); and are converted to the state of a calx or oxide, in form of a brown powder, called *rust*. M. Lavoisier says that 100 grs. of the filings of iron, when reduced to the state of rust, weigh from 140 to 150 grains:

hence the difference, between the *rust* (rubigo) and the *æthiops*, seems to be in the one taking up a greater quantity of the oxigene than the other; and, as a further confirmation of this, M. Lavoisier says, if 100 grains of the *æthiops martialis* be exposed to the open air, it will be converted into a rust, which, on being weighed, will be found to have increased from 5 to 14 or 15 grains in weight.

Crocus Martis.

(See vol. i. page 262.)

THE *crocus martis* is a preparation of the same nature, being iron reduced to the state of a calx by the force of fire, while it is exposed to the open air.

Sal Martis, or Green Vitriol.

(See vol. i. page 263.)

THIS salt, called in the London Pharmacopœia *ferrum vitriolatum*, is seldom prepared by dissolving iron in the vitriolic acid: M. Fourcroy says that it is

R commonly

commonly extracted from the pyrites stone; for, by exposing it to the air, it becomes covered with a white effervescence: that is the sal martis; which, on being separated, dissolved in boiling water, and evaporated, forms itself into beautiful green crystals.

Ferrum Ammoniacale.

(See vol. i. page 266.)

THIS preparation, which used formerly to go by the name of *flores martiales*, is commonly made by sublimation; but it may be prepared by solution in the following manner:

Dissolve a pound of crude sal ammoniac in as small a quantity of boiling water as possible, and filter it through paper whilst quite hot; then immediately add to it a clear solution of half an ounce of filings of iron in the muriatic acid, and set it in a cool place to crystallize. This preparation has the advantage of that prepared by sublimation, in so far as it lets us know the exact proportion of iron that is contained in
any

any given quantity of it, which cannot be known when the medicine is prepared by subliming the materials.

It may be given in doses from five grains to a scruple.

Of Iron being absorbed by the Lacteal and Lymphatic Vessels.

(See vol. i. page 260.)

IT has long been doubted by physicians, whether iron, given as a medicine, is taken up into the blood by the absorbent vessels, or whether it only acts as a tonic on the nerves of the stomach and bowels.

Of late it is generally believed that it is absorbed, and acts on the general system; and that the blood owes its red colour to the effects of this metal. In analysing animal substances, particles of iron are found amongst the products: and the account given by M. Menghini, in the *Commentaria Academiae Bononiensis*, of the blood of persons using chalybeate medicines becoming of a deeper colour, and containing more iron than the natural quan-

tity ; joined to the observations mentioned by Dr. Lory in M. Fourcroy's *Leçons de Chimie*, of the urine of people who were taking preparations of iron striking a red colour with galls—put it beyond all doubt that this metal enters the blood, and acts upon the general habit.

5. *Lead.*

(See vol. i. page 273, &c.)

I HAVE mentioned that the saccharum saturni, called cerussa acetata, was formerly given freely in many diseases ; but that now its use was confined to some particular cases of violent or obstinate hæmorrhages, where other remedies had failed. In complaints which arise from manufacturing lead in any form, or from swallowing any of its preparations, M. Navier recommends a solution of hepar sulphuris in water, or repeated doses of five or six grains of it made up into pills with mild substances, as a good remedy for removing them ; as likewise for removing
I those

those occasioned by arsenic, or corrosive sublimate.

6. *Quicksilver.*

(See vol . i. page 292.)

IT is commonly believed that all those people who work in the quicksilver mines are unhealthy: but M. Jussieu, when he was at the quicksilver mines at Almaden in Spain, had observed that none of the miners, except the slaves who worked in the inner chambers, where there were fires, were so; and says that he believes that their bad health was owing to the fires volatilizing a portion of mercury, so that they lived perpetually in a mercurial vapour.

I have already observed that quicksilver is commonly found combined to sulphur, in form of cinnabar, in the bowels of the earth. M. Fourcroy mentions its being found in form of prismatic crystals, in a mine of earthy iron, at Muschel Landsberg, in the duchy of Deux-ponts, in Germany; and that M. Lefage looked upon these crystals as a sweet mercury (*mercurius dulcis*) formed of quicksilver and the muriatic acid.

Æthiops Mineral,

(See vol. i. page 314, &c.)

NOW called *hydrargyrus cum sulphure*, has sometimes raised a salivation : might not this have happened from its having been prepared with unwashed flowers of sulphur, which had a quantity of loose vitriolic acid adhering to them, which united during the trituration to some of the particles of the quicksilver, and in that way formed an active medicine ?

Mercurius Calcinatus,

(See vol. i. page 317, &c.)

NOW called *hydrargyrus calcinatus*, is a calx or oxide, formed by quicksilver absorbing a quantity of the basis of pure air (the oxigenæ), by being kept long exposed to a heat capable of raising Fahrenheit's thermometer to 600 degrees.

Quicksilver,

Quicksilver, with the Muriatic Acid.

(See vol. i. page 328.)

QUICKSILVER, in its metallic state, does not dissolve in the common muriatic acid; though it unites readily with it, when reduced to the state of a calx, either by the force of fire, or by being precipitated from other acids: and this acid acts remarkably upon it, when it comes in contact with it in a divided state; as may be seen by dropping it into a solution of quicksilver in the nitrous acid; when each drop of it lays hold of some of the dissolved quicksilver, and precipitates with it in form of a white powder.

Mercurius, or Hydrargyrus acetatus.

(See vol. i. page 345.)

M. FOURCROY observes that a salt of this kind may be presently formed by mixing a solution of quicksilver in the nitrous acid, with a solution of the diuretic salt (the alkali vegetabile acetatum), in

R 4 water;

water; for, immediately on mixture, the nitrous acid lays hold of the vegetable alkali, and remains dissolved in the liquor; and the acetous acid unites with the quicksilver, and precipitates in form of brilliant spangles, which may be separated by throwing the whole into a coffin of spongy paper, and filtrating off the liquor.

7. *Antimony.*

(See vol. i. page 347.)

CRUDE antimony, as I formerly observed, is a half purified ore, which on examination has been found commonly to consist of about ten parts of regulus (that is, pure metal) and six parts of sulphur; though the proportion of metal to sulphur frequently varies in different parcels of this substance.

Of the Grey Calx, the Glass (Vitrum), the Saffron (Crocus), the Regulus, and the Argentine Flowers of Antimony.

(See vol. i. page 358, &c.)

BY reducing crude antimony to a powder, and calcining it with a flow fire, while it is perpetually stirred about till no more sulphureous vapours arise, it will be found to be converted to the state of a *grey calx*; and to have absorbed, during the time of the evaporation of the sulphur, a quantity of the oxigene, or basis of pure air.

If this grey calx or oxide be exposed to a great heat, it absorbs more of the basis of pure air, and melts into a reddish vitreous matter, called *glass of antimony*, which is more or less fusible, and more or less transparent, according as it has been more or less calcined, or contains more or less sulphur. If it contains little sulphur, the glass is transparent, is not easily fused, and is what is called the *true glass of antimony*; but if it contains more sulphur,
and

and approaches more to the state of a metal, and is more fusible and opaque, it is then called the *saffron* or *crocus* of antimony, on account of its colour*.

If

* The crocus or saffron of antimony, prepared by deflagrating crude antimony in powder, mixed with an equal quantity of powdered nitre, is a preparation entirely of the same nature as the crocus here mentioned. From what has been said above, it appears that the principal difference between the crocus and the glass of antimony consists in the crocus containing a much larger proportion of sulphur than the glass does. For a number of years past, great complaints have been made, that the emetic tartar was not always of the same strength; for that at one time it was a very strong active medicine, and a grain or two operated powerfully; while at another it required two or three times that quantity to produce the same effect. This should seem in part to have been owing to the crocus having been used for making this preparation, instead of the preparations more free of the sulphur; for, as we have no criterion to judge of the proportion there is of sulphur to the regulus in the crocus, the quantity of regulus is much greater in the crocus used at one time than at another: besides, in preparing the emetic tartar with crocus, if the operator is not very careful, a quantity of undissolved regulus precipitates along with the sulphur, and is separated along with it; by which means the emetic tartar is rendered too weak: for these reasons, the
glass

If the grey calx, or the glass, or the saffron, be mixed with an equal weight of the black flux, and a little black soap or oil, and be then exposed to a strong heat in a crucible, these substances absorb the basis of pure air (the oxigene) which they had imbibed during the time of their calcination; and they return back to their metallic state, that is, to regulus of antimony.

If the pure regulus of antimony be melted with a strong fire in an iron or an earthen vessel, into which there is free access of air, it calcines readily, that is, it absorbs a quantity of the oxigene (or, according to Dr. Priestley, of water); and it rises in form of a thick white smoke, which either falls back on the surface of the melted metal, or attaches itself to the cover of the crucible, where it forms a number

glass of antimony is preferable to the crocus; and the calx precipitated from the antimonium muriatum, by throwing it into a watery solution of the vegetable alkali, is preferable to either, and more likely to form an emetic tartar which will at all times be of the same strength,

of

of small white spiculæ, called by the name of *the snow, or argentine flowers, of the regulus of antimony*; which, on examination, are found to be a pure calx, or oxide, as the academicians call it.

Of the Preparations of Antimony, by deflagrating it with Nitre.

(See vol. i. from page 270 to page 272.)

NITRE abounds with the basis of pure air (the oxigene); and, when deflagrated with crude antimony, it carries off a quantity of sulphur, at the same time that it imparts to the regulus, or metallic part of the antimony, a quantity of the oxigene; and, in proportion to the quantity of nitre employed, the antimony is more or less freed of its sulphur, and reduced to the state of a calx.

8. *Arsenic.*

(See vol. i. page 408, &c.)

SINCE the printing of the first volume of this work, I have perused a treatise on the Effects of Arsenic, written by Dr. Thomas Fowler of Stafford; accompanied with two letters, one from Dr. Arnold of Leicester,
and

and another from Dr. Withering of Birmingham, on the same subject; in which it is mentioned, that a medicine sold under the title of *Tasteless Ague and Fever Drops* (or the Patent Ague Drops) has been largely circulated through the kingdom as a specific for agues; which, on trial, has been found to be a preparation of white arsenic, and probably is the same I have mentioned in vol. i. page 410 of this work, to have been sold by an itinerant quack in Lincolnshire, about thirty years ago. Dr. Fowler says that he administered the following preparation of arsenic with success in aguish complaints: he dissolved sixty-four grains of white arsenic, and as much fixed vegetable alkali, by boiling them in half a pint of distilled water, in a Florence flask; and then, after filtering the liquor, and adding half an ounce of compound spirit of lavender, he mixed with it as much more distilled water as made the whole to weigh exactly sixteen ounces; by which means each ounce contained four grains of arsenic: and this medicine he administered in the following manner:

To

To patients		Drops.	
From 2 to 4	} years of age, he gave from	} 3 to 5 5 to 7 7 to 10 10 to 12 12	} twice of thrice a day, at the dif- tance of 8 or 12 hours
— 5 to 7			
— 8 to 12			
— 13 to 18			
— 18 & upwards			

Dr. Arnold and Dr. Withering both made a solution of eight grains of white arsenic in eight ounces of distilled water, without the addition of any alkaline salt; though Dr. Withering added nitre, to prevent the arsenic from precipitating, which Dr. Fowler alleges neutralized the arsenic, by its having a greater affinity with the alkaline basis of the nitre than the nitrous acid; and these practitioners administered their medicines in doses from 15 to 30 or 40 drops.

These three physicians all assert that they have cured a great many agues by the preparations of arsenic mentioned; they acknowledge that, in some instances, the medicines produced a nausea and vomiting, and sometimes a purging, and sometimes both; and that, in other cases, they occasioned swellings, particularly of the face,

and of the eye-lids ; and which sometimes were pretty general, affecting the limbs and other parts. They say that these symptoms were not attended with danger, but generally went off by suspending the use of the medicine ; and by giving a puke, or a dose of rhubarb, or a few drops of laudanum.

Notwithstanding what these physicians have said, I cannot help having doubts whether this mineral, which is of such a deleterious nature, may not have produced bad effects on the constitutions of many of those who have taken it : and I should not now have mentioned it, had I not known that it is at this time administered freely in many parts of this kingdom ; and that I wished that enquiries should be made by practitioners, gentlemen, and magistrates, in the counties where it is used, concerning the healths of those people who have taken it, and to have it ascertained whether or not any people have fallen sacrifices to its use.

S E C T. V.

Of E A R T H S.

(See vol. i. page 417.)

EARTHS, according to the new chymical system, are ranked amongst the simple substances. Macquer had alleged that there were only three sorts of primitive earths, *viz.* 1. the calcareous; 2. the argillaceous; 3. and the vitrescible. Since then Sir Torbern Bergman has mentioned five different kinds, which he says are distinct, and have not been transmuted into each other by any menstruum or process which has hitherto been tried; and these are, 1. lime or calcareous earth; 2. magnesia; 3. clay (*argilla*); 4. heavy earth (*terra ponderosa*); 5. and vitrescible earth, such as flint, &c.

Alum.

(See vol. i. page 442.)

SINCE the first volume of this work was published, a surgeon of character informed

formed me that he had removed small steatomatous tumors from the face, by applying to them the coagulum aluminosum mixed with conserve of roses, and renewing the application daily for some time.

S E C T. VI.

Of WATER.

(See vol. ii. page 1, &c.)

I HAVE already mentioned that the Hon. H. Cavendish had, from a number of experiments made in the years 1781, 1782, and 1783, concluded that water was a compound body, made up of *pure* and *inflammable airs*; and that this seemed to be confirmed by other experiments since made by M. Lavoisier and other French academicians; but that of late Dr. Priestley had asserted that water was not a compound, but an elementary body, as it had always been believed to be; and that what water these gentlemen had obtained was separated from the pure and inflammable airs, of

S

which

which it made a considerable part. Since then MM. Faets, Van Troostfwyk, and Deiman, have published a letter in vol. xxxv. of the *Observations sur la Physique, sur l'Histoire Naturelle, & les Arts*, for the last six months of the year 1789, in which they give an account of experiments they made by passing the electric spark through water; by which they think they have proved, both by analysis and synthesis, that water is a compound body, as the Hon. Mr. Cavendish had asserted it to be.

They tell us that they were opposers of the new chymical theory, till on making experiments lately, along with Mr. Cuthbertson, on different bodies, with the electric spark, they agreed to try what effects it would have on water; and for that purpose took a glass tube, the diameter of which was the eighth part of an inch, and its length twelve inches: they sealed up one end of it hermetically, after having fixed in it a gold thread (or wire), which went down about an inch and a half into the tube; and then filled it with water, and introduced by the open end a long gold thread
(or

(or wire), till its end came to within five eighths of an inch of the lower end of the short thread fixed in the sealed end of the tube; and, after putting the open end of the tube and the end of the long thread in a vessel filled with water, they placed the tube, with its apparatus, in a proper electric machine; by working of which they conveyed the electric fire to the gold wires (or threads), and soon observed, as they worked the machine, that the electric fire came out in a stream from the ends of the gold wires which were near each other; and at the same time saw a number of air bubbles, separated from the water, ascend to the top of the glass tube, which was hermetically sealed; and there form an apparent vacuity, by forcing down the water till it sunk below the lower end of the short gold wire, from which there issued a stream of electric fire; and so soon as this fire touched the air which formed the seeming vacuum, an explosion took place, in the same manner as happens when fire is applied to inflammable air, mixed with a quantity of pure air: imme-

diately after the explosion, the water in the tube rose, and filled up most of the vacuity which had been made by the airs that had separated from the water.

By repeating these experiments for a number of times, these gentlemen concluded that the pure and inflammable airs (or rather their bases, the oxigene and hydrogene) were separated from the water, of which they made a part; and that, when the electric spark from the lower end of the short tube pervaded the column which these airs formed, they exploded, and returned to the state of water.

They likewise mention a number of experiments which they made, which they think prove that the airs separated came from the water itself, and not from any atmospheric air which had been mixed with it; and that the electric spark did not contribute in any manner to their formation. They also mention that, from the experiments they made, they think that the acid obtained by Dr. Priestley and others, on mixing pure and inflammable airs together, was accidental, and was formed

formed by some *impure air*, which had some how or other been mixed with the pure or inflammable airs employed, and united with some of the pure air, and formed nitrous acid; though they do not seem to have proved this last fact. The particular account of these experiments, which is inserted in the above-mentioned work, deserves to be perused by all those who are employed in making experiments of this kind; and the force of the arguments used to prove that water is a compound body, ought to be well considered.

S E C T. VII.

OF MINERAL WATERS.

(See vol ii. page 14, &c.)

1. *Of Hepatic Air.*

THE principal discovery made with regard to mineral waters since the printing of vol. ii. of this work, is that of the nature of hepatic air, with which most natural fulphureous waters are impregnated.

Sir Tobern Bergman, as I have mentioned in vol. ii. page 60, had alleged that sulphur had been resolved into the form of vapour, by means of phlogiston and the matter of heat in the sulphureous mineral waters; and that the sulphur might be precipitated from these waters by the addition of the strong nitrous acid, which attracted the phlogiston that was united to the matter of heat: but M. LAVOISIER has since then, in the Memoirs of the Academy of Sciences, proved that hepatic air, which gives the smell, taste, and other sulphureous qualities, to mineral waters, is nothing but sulphur, dissolved and suspended in inflammable air. This hepatic air may be got by adding sulphureous acid to hepar sulphuris, or to sulphur united to iron; and it is produced in most processes where substances containing inflammable air and sulphur are employed. This hepatic air may be decomposed by the addition of pure air, or of any other body which has a greater affinity with inflammable air, than inflammable air has with sulphur; and hence most mineral sulphu-

reous waters let drop their sulphur on being exposed to the open air, or when nitrous acid, or aërated muriatic acid, is added to them, as they are taken up from their springs.

1. *Tilbury Water.*

(See vol. ii. page 70.)

IN the account of the analysis of this water published by Dr. Higgins in the year 1780, the Doctor, amongst other products, says that he got 49 grains of true nitre from a Winchester gallon of this water. If no mistake has been committed in performing the analysis, this is the only water situated at a distance from large cities, in this country, in which a true nitre has been found. It is to be wished that this water was repeatedly evaporated, to ascertain the true nature of its salts.

2. *Cheltenham Water.*

(See vol. ii. page 134.)

IN a late account of this water, published by Dr. Fothergill, of Bath, 2d edition, a wine gallon of these waters contain the following principles :

Of Solid Contents.

1. *Purging salt*, partly Glauber, partly Epsom, an ounce, or 480 grains. 2. *Of marine salt*, 5 grains. 3. *Of iron*, combined with fixed air, nearly 5 grains. 4. *Magnesia*, combined partly with marine acid, partly with fixed air, 25 grains. 5. *Calcareous earth*, combined with vitriolic acid in form of selenites, 40 grains.

Of Aërial Fluids.

1. Fixed air combined with water, 24 ounce measures. 2. Phlogisticated air, with a portion of hepatic air, also loosely combined with the water, 8 ounce measures.

3. *German*

3. German Spa Waters.

(See vol. ii. p. 128.)

In the year 1788, Dr. John Ash published an account of five of these waters, and gives the following table of their contents :

Fountain.	Quantity of water.	Solid contents.	Aerated lime.	Magnesia aerated.	Aerated min. alkali.	Aerated iron.	Selenite.	Aerated veg. alkali.	Gas, ounce measure.
Pohoun	33 ounces	16 $\frac{1}{4}$ grains	2 $\frac{3}{4}$ grains	9 $\frac{1}{2}$ grains	2 $\frac{1}{4}$ grains	1 $\frac{1}{4}$ grains			35 $\frac{3}{4}$
Geronstere	32 $\frac{3}{4}$	5 $\frac{1}{2}$	2 $\frac{1}{2}$		1 $\frac{3}{4}$	$\frac{3}{4}$	$\frac{1}{2}$ grain		24 $\frac{3}{4}$
Sauviniere	32 $\frac{1}{2}$	3 $\frac{3}{4}$	1 $\frac{1}{2}$		2 $\frac{3}{4}$	$\frac{1}{2}$		1 grain	33 $\frac{1}{2}$
Groisbech	32 $\frac{1}{4}$	5 $\frac{1}{4}$	1 $\frac{1}{2}$		1	$\frac{3}{4}$		2 grains	35 $\frac{1}{2}$
Tonnelet	32	2	$\frac{1}{4}$		$\frac{3}{4}$	3			40 $\frac{3}{4}$

S E C T. VIII.

Of Vinous Liquors, Fermentation, &c.

(See vol. ii. page 202, &c.)

NOTHING at present seems necessary to be added to what has been said on Fermentation and Vinous Liquors, in vol. ii. and in part ii. of this Appendix.

1. *Of the Mixture of Spirit with Vitriolic Acid.*

(See vol. ii. page 220.)

HAVING mentioned the most approved methods of obtaining the *dulcified spirit*, the *oil of wine*, and the *vitriolic æther*, from the mixture of spirit with this acid, I shall only now observe that chymists have differed very much with regard to the proportion of spirit to the acid which they have used: some have ordered six parts of spirit to one of the acid, while others have ordered an equal weight of each; and of late that has been the proportion adopted in most of the new Pharmacopœias; and the

the oil of wine has been ordered to be drawn off, as I have mentioned, from the materials which remain in the retort, after the distillation of the dulcified spirit, which contains the æther. Some have lately directed the oleum vini to be prepared by a distinct process, in which double the weight of vitriolic acid to that of the spirit is employed; but on enquiring at Apothecary's Hall, and of Mr. Godfrey and other chymists who had performed this process, I was informed that the product of oil of wine obtained by this process is so small as to render it a much dearer medicine, than that got by distilling from the materials which remain after the distillation of the dulcified spirit, and that it is not better in quality.

2. *Æther Vitriolicus.*

(See vol. ii. page 233.)

M. LAVOISIER, in his *Traité Élémentaire*, p. 14, observes that, as a heat equal to that of the blood is capable of raising æther into aërial vapour, it must be converted

verted into that state in the first passages when swallowed as a medicine ; and that probably many of its virtues depend on this mechanical effect, if one may term it so.

S E C T. IX.

S U L P H U R.

(See vol. ii. page 248.)

I HAVE already mentioned that the authors of the new theory of chymistry have alleged that sulphur is a simple substance, which, by the addition of the basis of pure air, is converted into the sulphurous or vitriolic acid ; and that the supporters of the doctrine of phlogiston still imagine it to be a compound formed of the same acid and phlogiston.

Of late it has been discovered to be soluble in inflammable air ; and, when dissolved in this menstruum, forms what is called hepatic air, which is the matter which commonly gives the sulphureous properties to the sulphureous mineral waters.

Hepar

Hepar Sulphuris, or Sulphur Alkalifatum.

(See vol. ii. page 261, &c.)

DR. NAVIER, a physician at Chalons in France, who has made it his study to discover the medicines which counteract the effects of mineral poisons, has recommended the *hepar sulphuris* as one of the best remedies for preventing the bad effects of *arsenic* and of *corrosive sublimated mercury*, when taken down into the stomach, and to remove complaints arising from the effects of lead. He orders, in such cases, to dissolve a dram of *hepar sulphuris* in a French pint (near an English quart) of water, and to give frequent repeated glassfulls of this solution to people who have swallowed any of the above-mentioned corrosive substances; or to make them take five, six, or more grains of the *hepar sulphuris* made up into pills with some mild body, in frequent repeated doses, and to drink a glass-full of warm water after each dose. In cases of *arsenic* he says that the addition of iron improves the virtues of
this

this remedy ; for the hepar unites with the arsenic to form orpiment, at the same time that it combines with the iron.

S E C T. X.

Fossil Oils.

(See vol. ii. page 261, &c.)

M. MACQUER had alleged that these oils are of vegetable origin : M. Fourcroy and Parmantier think that some of them have been so ; but that others were originally animal oily matter, particularly of shell and other sea fish ; as they are often found in the earth at places where there are layers of shells, and other traces which shew that they had been formerly covered with the sea.

S E C T. XI.

Animal Oils.

(See vol ii. page)

M. FOURCROY, in his *Leçons de Chimie*, observes that the fat of man and of quadrupeds

quadrupeds has consistence, and is white or yellow; that of carnivorous animals is more or less fluid; that of animals which live on fruits or herbs is firm and solid; that of birds is more fine, soft, and unctuous; that of fishes is almost fluid; and that the fat of all animals is softer and more fluid in the living than in the dead subject.

I have already observed that all oils contain an acid, and that the firmer consistence they have, the more acid in general they yield; and in page 99 of vol. i. I mentioned that probably the acid of our food and drink was united with the oily particles of our fluids by the animal process, and formed the fat; and, since the publication of this work, I was happy to see that so ingenious a physician as Dr. Cullen, in the second volume of his *Materia Medica*, page 338, published in the year 1789, had adopted this doctrine. The effects of fixed alkaline salts (which are of an opposite nature to acids) on the human body, seem in some measure to confirm this conjecture; for I have observed that most people, who have put themselves on
a course

a course of the soap ley, with an intention of dissolving the stone in the bladder, and continued this course for some time, have been emaciated thereby.

S E C T. XII.

Oil of Camphor.

(See vol. ii. page 326, &c.)

A YELLOW, clear, transparent liquor, smelling strong of camphor, which goes by the name of its oil, is often brought home from the East-Indies, where it is much esteemed as a powerful remedy for removing rheumatic and other pains, by being rubbed on the parts affected. Whether it is got by distillation from the camphor tree (the *laurus camphora*), or from any other substance; or whether it be a solution of camphor in any particular liquor, or a preparation made by distilling camphor along with other things, I know not, having never been able to procure any authentic account of it. I have had several specimens of it given me by gentlemen who brought

brought it home from the East-Indies, but none of them could give me any information of its origin.

S E C T. XIII.

Mucous Gums, Starch, and Sugar.

(See vol. ii. pages 434 and 443, &c.)

M. LAVOISIER, in his *Traité Élémentaire*, chap. xi. ranks *mucous gums, starch,* and *sugar*, amongst the vegetable oxides: he says they contain inflammable air united to charcoal, so as to form in a manner one basis, which is brought into the state of an oxide by a portion of the basis of pure air (the oxigene); that they do not differ from one another, but in the proportion of the principles which compose them; and that they may be made to pass to the state of acids, by combining with them an additional quantity of the basis of pure air, the oxigene. The acid which Sir Tobern Bergman got from *sugar*, by pouring nitrous acid over it, and distilling, should seem to have been formed

in this manner; that is, the nitrous acid which abounds with the oxigene, should seem to have imparted to the sugar such a quantity of it, as to convert its acidifiable parts into an acid.

S E C T. XIV.

Cantharides (Spanish Flies).

(See vol. iii. page 39, &c.)

M. FOURCROY, in his *Leçons Élémentaires*, tells us that M. Thouvenel analysed the cantharides, and found that one half of the dried insect consisted of the viscera (un Parenchyma) which he did not examine; that an ounce of the other part yielded three drams of an extractive yellow reddish matter, which afforded an acid by distillation, twelve grains of a yellow waxy matter, that gives colour to the flies, and sixty grains of a green oily matter, analogous to wax, which smells of the cantharides, and has a sharp taste; and, if distilled, yields a sharp acid, and a concrete oil like wax.

Water

Water dissolves the yellow extractive matter, the yellow oil, and even part of the green; but æther only dissolves this last, and may be employed to separate, from the other matters, this green waxy oil, in which the virtues of the cantharides reside. In order to obtain a tincture which shall contain the extractive matter, as well as the green and yellow waxy part, one must employ a liquor composed of equal parts of alcohol and water, which if distilled affords a spirit that smells strong of the cantharides. M. Thouvenel tells us that he tried the effects of the green waxy matter, in which the virtue of the cantharides resides, on himself; and found that nine grains of it applied to the skin raised a blister full of serum; and that the tincture above-mentioned, when applied externally, in the quantity from two drams to two ounces and a half, produced good effects in rheumatic pains, the sciatica, and wandering gout; that it warms the parts, accelerates the circulation, and excites an evacuation by sweat, by urine, or by stool,

according to the parts to which it is applied.

*Cinchonæ Species, quæ Insulâ Sanctæ Lucie
innascitur.*

IN the year 1783, Mr. Davidson, one of the surgeons to the troops then at the island of St. Lucia in the West-Indies, sent to Mr. George Wilson, apothecary in Henrietta-Street, Covent-Garden, a quantity of bark got from a species of the cinchona, or Peruvian bark tree, which had been discovered growing in that island by a Mr. Alex. Anderson; accompanied with an account of its effects in curing intermittent disorders in that island.

In the year 1784, an account of this bark was published in vol. lxxiv. art. 34, page 452, of the Philosophical Transactions. This bark breaks more woody, is more nauseous than the true Peruvian bark, and has an emetic and purgative quality. Its decoction is of a dull Burgundy colour, and its extract resembles more the bitter of gentian, than of the true cinchona. Sir Joseph

Joseph Banks, who examined the specimens of the tree sent home, says that the tree is undoubtedly a cinchona, but not the *cinchona officinalis* of Linnæus.

The bark, which was first used at the island of St. Lucia, not having been sufficiently dried, had a strong emetic and purgative quality, which soon brought it into disrepute; but afterwards Mr. Davidson having procured some which had been kept long, and was perfectly dry, he again administered it; and it fully answered his wish, and cured a number of soldiers who laboured under intermitting complaints.— He generally used the cold infusion of it, either prepared in lime-water or in simple water, in the proportion of one ounce to three pints of the water. He says, “I have likewise given it in substance from 20 to 30 grains, but never exceeded the last quantity: in general the stomach would not retain more than 20 grains.” This bark, mixed with *canella alba*, yields an agreeable and elegant tincture with spirit. A tincture made with the seeds has an infinitely stronger taste than the bark itself.

This bark has been tried in the London hospitals; but it was found still to retain its emetic and purgative qualities.

In remitting and intermitting complaints, particularly of the warm climates, where the first passages are loaded with bile, it may probably be found to be a very useful remedy to clear off the bile, before the true bark is administered; and if its emetic and purgative qualities can be corrected by the addition of cordials and opium, it may prove a good substitute for the true bark, where that cannot be had.

Duke of Portland's Gout Powder.

BETWEEN forty and fifty years ago a powder composed of equal parts of the roots of *birthwort* and *gentian*, and of the leaves and tops of the *germander*, *ground pine*, and *lesser centaury*, was recommended as a cure for the gout. It was ordered to be taken in doses of a drachm every morning fasting, in a tea-cupful of wine and water, broth, or tea, for three months; and then three fourths of this quantity for three months longer; and
afterwards

afterwards half, for six months; and, when the year was out, to take half a drachm every other day for a year longer. It was called lately the Duke of Portland's Powder, from the late Duke having been believed to have received benefit from its use.

Medicines of this kind were used many hundred years ago by the Greek physicians, as we see by the account given of them by the late Dr. Clephane, in art. 14 of vol. i. of London Medical Observations and Enquiries. He says many of the ancient physicians bestow great encomiums on the use of medicines of this kind, in that sort of gout which they call pituitous; though in the other species of gout, which they term sanguineous and bilious, they deemed them prejudicial; and Aëtius says they are extremely hurtful in the hot and bilious habits, and are only proper in cold and phlegmatic constitutions.

The ancients recommend the use of these remedies principally in recent cases; and seem to think that their use is unsafe, if the gouty person has already laboured

under the disorder for five years, or at farthest for seven years.

Several people in England have been thought to have hurt their health by the use of this powder; and the death of others has been supposed to have been hastened by the same means: and Dr. Cullen, in his *Materia Medica*, published last year, mentions that some people of rank in Scotland, who took these powders for above a year, in the manner recommended, seemed at first to receive benefit, but afterwards died of complaints which were supposed to have been occasioned by the effects of this powder; which has brought it into disrepute in that country.

Fumaria. H.

Fumaria Officinalis—*Fumitory, the herb.*—

This plant has long been esteemed to be a most useful bitter; and formerly was much used to strengthen the tone of the viscera. It loosens the belly, and promotes the urinary and other secretions; and it has been greatly recommended for its effi-

cacy in removing many cutaneous disorders. Simon Pauli asserts that he has removed the most inveterate scabies by an infusion of this herb in whey of cow's milk, and by decoctions of it in beer: Hoffman and many other authors extol its virtues greatly; and Dr. Cullen, in his *Materia Medica*, vol. ii. page 77, says that he has experienced its good effects in many instances of cutaneous disorders, which he would have called the lepra.

Its expressed juice is given the length of two ounces, two or three times in the day; and an extract is ordered to be made from it, in many of the foreign dispensatories, which is administered for the same purposes as the herb itself.

The dried plant retains the flavour and taste of the fresh, and is used in infusion and decoction when the fresh plant cannot be procured.

Maredant's Drops.

THIS medicine, which sometimes of late goes by the name of Norton's Drops, has
been

been sold in large quantity for the cure of eruptive disorders. By the receipt of it given in to the Patent Office, and by its frequently having brought on a salivation, it should appear to be only a solution of the corrosive sublimate mercury.

The original proprietor should seem to have been guilty of an evasion, when he gave in the receipt to the Patent Office; for he only mentions the ingredients, which he tells us are *corrosive sublimate, gentian and ginger roots, and cochineal*; but takes no notice of the proportions used of any of them, or of the menstruum in which the tincture is prepared. It is given in doses which are measured by the number of drops.

Nux Moschata.

THE nutmeg is said by Bontius, in his treatise *De Medicina Indorum*, to have a soporific quality. Dr. Cullen, in vol. ii. page 204 of his *Materia Medica*, mentions his having seen an instance of this:—A
 person

person swallowed in the forenoon above two drachms of nutmeg in powder : he felt no uneasiness for an hour ; but at the end of that period he was seized with a drowsiness, succeeded with a complete stupor. Being put to bed, he continued in a deep sleep for some hours, waking from time to time in a state of delirium ; and soon after dropt again asleep. He continued in this manner for above six hours, when he awoke perfectly returned to his senses ; though he still complained of a head-ach and drowsiness all the remainder of that day. But going to bed late in the evening, he fell into a profound sleep, and awoke next morning in good health.

Of the Tables of Affinities or Elective Attractions.

OF late M. Lavoisier * and his associate academicians have raised a number of

* See M. Lavoisier's notes on Mr. Kirwan's criticisms on his Table of Affinity of the Oxigene, in page 46, &c. of the French translation of Mr. Kirwan's Essay on Phlogiston and Acids.

objections

objections to all the tables of affinities, or of elective attractions, which have hitherto been offered to the public; the principal of which are,

1st. That they only represent the results of simple affinities; whereas there only exist in nature, so far as has been observed, cases of double affinity, often triple, and others perhaps still more complicated.

2dly. That they take no account of the effects of the attractions of water, and perhaps its decomposition in its combinations in the humid way: it is considered as an agent simply passive, though it acts with a real and disturbing force, which ought to be brought into consideration in the results.

3dly. That there are certain substances which, when combined with others, have two or three evident degrees, or periods, of saturation: and there are others in which a greater number obtain; as is the case with the basis of pure air, called oxygen, and acidifiable bases.

4thly. That different degrees of heat, applied to the same substances, produce different

ferent effects on them: thus mercury, or quicksilver, exposed for a long time to a certain degree of heat, in a place to which there is access to air, attracts the oxigene, and is converted into an oxide or calx: but if this calx be exposed to a still greater heat, which is capable of softening glass, the oxigene, which had been absorbed, is disengaged, and the mercury is revived, or returns to the state of quicksilver.

For these reasons neither M. Lavoisier, in his *Elementary Treatise*, nor M. Fourcroy, in his third edition of his *Elements of Natural History and Chymistry*, has given us any general tables of affinities.

But although the objections raised are certainly just, and the tables we have are for these reasons defective in many points; yet we know that they have been the instruments which have led to many of the most important discoveries of modern times; and therefore they ought not to be laid aside, till others, in which their defects have been supplied, are constructed.

Lunar Caustic, or Nitrated Silver.

IN vol. iii. page 307 of the *Annales de Chimie*, published by MM. Morveau, Lavoisier, &c. we are informed that M. Hahnemann has proved that lunar caustic (the *argentum nitratum Pharm. Lond.*), which is silver dissolved in the nitrous acid and evaporated to dryness, is one of the most powerful antiseptic substances known; for if one part of it be dissolved in 500 parts of pure water, the water thus impregnated will preserve a piece of meat (animal flesh) for ever from putrefaction.

And if a stronger solution be used, and the meat be kept in it for 15 days, and be then exposed to heat, it dries without putrefying, and hardens so that no worms will affect it.

If one part of the lunar caustic be dissolved in 1000 parts of pure water, it will preserve it sweet in every degree of heat, provided it be not exposed to the sun. If people are afraid to drink the water in this state, which certainly cannot be attended with any sort of danger, they may, before
using

using it, dissolve in it a little common sea salt, which will precipitate some of the silver in form of a black powder, when exposed to the heat of a fire, or to the sun.

M. Hahnemann has employed with success a solution of one part of lunar caustic in 1000 parts of pure water, for the cure of old sores, particularly of those of the mouth, occasioned by the use of mercury; and he has found astonishing good effects from the use of this water, as a drying and strengthening remedy.

Repeated trials ought certainly to be made of the effects of this solution of silver in the nitrous acid, to ascertain whether it may be used in quantity with safety; as it may be of the greatest service in preserving meat as well as water in long sea voyages, should it be found not to injure the health of those who use it.—And trials ought likewise to be made with the pure nitrous acid, to ascertain whether the effects produced depend on the solution of silver, or upon the acid independent of the silver.

Acer Major, & Periclymenum rectum foliis laurinis.

BEFORE concluding this treatise, I think it is right to observe, that there are two substances mentioned in it, both growing in cold climates, which particularly deserve the attention of the public; which are—1st, the acer major, or great maple tree, which grows in Canada, whose juice yields a sugar that is used by the inhabitants of the country.—2^d. The other the periclymenum rectum, foliis laurinis, or tree which affords the warm aromatic bark, called after Capt. Winter, Winter's bark. Both these trees would probably grow in this climate; and the sugar and warm bark which they afford, would be of the greatest service to the poorer sort of people, particularly to the inhabitants of the mountainous parts of this island. *

* The seeds or young plants or shoots of the great maple tree, may be easily imported by the ships which come yearly from Canada; and those of the winter bark tree, which grows on the shore of the Streights of Magellan, in South America, by the vessels employed in the southern whale fishery.

GENERAL INDEX

TO THE

THREE VOLUMES AND THE APPENDIX,

The LONDON PHARMACOPOEIA excepted, which has a copious Index annexed to itself.

N. B. The names in this Index are all in English, as the Latin Names are mostly used in the Tables of Contents of each Volume; and in the Table to Vol. III. the Latin Names of entire Animal and Vegetable Substances are ranged alphabetically with the English Names after each; so that a Latin Index was not necessary.

A.

ACIDS, the distinguishing marks of, v. i. p. 41. ap. p. 2.

———— the medical virtues and properties of, v. i. p. 102.

———— the different sorts of, formed by the union of the basis of pure air (the oxigene) and acidifiable bodies, ap. p. 102.

———— aerial or fixed air, v. i. p. 93, and ap. 103, and 216.

———— muriatic or marine, v. i. p. 65. ap. p. 213.

———— nitrous, v. i. p. 55, ap. p. 210.

———— sulphureous or vitriolic, v. i. p. 42. ap. p. 206.

———— vegetable native, different sorts of, v. i. p. 72 and 82, and ap. p. 223.

———— distilled, v. i. p. 74.

———— fermented, v. i. p. 75.

Acids of amber, v. i. p. 96.

———— of ants, v. i. p. 97.

———— of arsenic, v. i. p. 96.

———— of blood, v. i. p. 96.

———— of dew, v. i. p. 95.

———— of fat, v. i. p. 98.

———— of fluor or spath, v. i. p. 96.

———— of heavy earth, v. i. p. 96.

———— of molybdene, v. i. p. 97.

———— of phosphorus, v. i. p. 100, ap. p. 217.

———— of tartar, v. i. p. 81, ap. p. 4.

———— of tungstene, v. i. p. 96.

———— of urine, v. i. p. 100.

———— of vinegar, v. i. p. 76.

Acidifiable bases, ap. p. 119.

Acidifying principles, the basis of pure air, oxigene, ap. p. 100.

Affinities, or elective attractions, v. i. p. i. ap. p. 289.

Æther, muriatic, v. ii. p. 243.

———— nitrous, v. ii. p. 234.

———— vitriolic, v. ii. p. 220, ap. p. 273.

- Æther, vegetable, or acetous, v. ii. p. 246.
 Agaric, v. iii. p. 8.
 Air, ap. p. 97.
 — of the atmosphere, ap. p. 97.
 — pure or vital, or dephlogisticated, ap. p. 99.
 — impure or mephitic, or phlogisticated, ap. p. 106.
 — inflammable, or hydrogene, ap. p. 110.
 — hepatic, ap. p. 114, 117.
 — different sorts of fluids so called, ap. p. 117.
 — doctrine of, ap. p. 80.
 Alkaline salts, v. i. p. 120, ap. p. 9, 128.
 — fossil, v. i. p. 131, 140, ap. p. 231.
 — vegetable, v. i. p. 125, 140— aerated, its use in calculous disorders, ap. p. 9, 229.
 — volatile, v. i. p. 158, ap. p. 231.
 Alkohol, v. ii. p. 209; its composition, ap. p. 191.
 — with acetous acid, v. ii. p. 246.
 — with muriatic acid, v. ii. p. 243.
 — with nitrous acid, v. ii. p. 234.
 — with sulphureous or vitriolic acid, v. ii. p. 220.
 Almonds, v. iii. p. 12.
 Aloes, v. ii. p. 419.
 Alum, v. i. p. 442, ap. p. 262.
 Amber, v. ii. p. 274.
 — liquid, v. ii. p. 358.
 Ambergrite, v. ii. p. 272.
 Ammoniac salt, v. i. p. 219.
 — gum, v. ii. p. 380.
 Analysis of animal and vegetable substances, v. i. p. 17, ap. p. 135, &c.
 Angelica, v. iii. p. 16.
 Angeline tree, v. iii. p. 18.
 Anise, v. iii. p. 19.
 Antimony, v. i. p. 347, ap. p. 254.
 Antimony, argentine flowers of ap. p. 255.
 — calx, with hartshorn, v. i. p. 364.
 — ditto with nitre, v. i. p. 372.
 — calx muriated, called algarott, v. i. p. 383.
 — cinnabar of, v. p. 376.
 — glass of, v. i. p. 360, ap. p. 255.
 — ditto cerated, v. i. p. 361.
 — James's powder, v. i. p. 366.
 — Kermes mineral, v. i. p. 375.
 — liver or saffron, v. i. p. 371, ap. p. 255.
 — mild emetic, v. i. p. 372.
 — muriated or caustic, v. i. p. 380.
 — nitrated, v. i. p. 380.
 — regulus of, v. i. p. 359.
 — regulus medicinalis, v. i. p. 370.
 — sulphur precipitated of, v. i. p. 373.
 — with soluble tartar, v. i. p. 394.
 — tartarified or emetic tartar, v. i. p. 387.
 — wine of, v. i. p. 384.
 Arsenic, v. i. p. 408, ap. p. 258.
 Artichoke, v. iii. p. 67.
 Asafœtida, v. ii. p. 377.
 Asarabacca, v. iii. p. 25.
 Ash-coloured ground liverwort, v. iii. p. 157.
 Ashes of vegetables, v. i. p. 126.
- B.
- BALM, v. 3. p. 168.
 Balsams, v. ii. p. 335.
 — of Canada, v. ii. p. 340.
 — of Copaiva, v. ii. p. 341.
 — of Mecca, v. ii. p. 342.
 — of Peru, v. ii. p. 344.
 Balsam

- Balsam of Tolu, v. ii. p. 345.
 ——— of turpentine, v. ii. p. 348.
 Barbadoes tar, v. ii. p. 267.
 Barley, v. iii. p. 134.
 Barilla, or soda, v. i. p. 135, ap. p. 232.
 Bdellium, v. ii. p. 382.
 Bearfoot, v. iii. p. 128.
 Bear's whortle-berry, v. iii. p. 287.
 Benzoin, v. ii. p. 367.
 Birthwort, v. iii. p. 24.
 Bismuth, p. i. p. 406.
 Bistort, v. iii. p. 33.
 Bittersweet, v. iii. p. 102.
 Bitumen, v. ii. p. 271.
 Butumen Judaicum, v. ii. p. 273.
 Blessed thistle, v. iii. p. 47.
 Blood-stone, v. i. p. 416.
 Blue cardinal flower, v. iii. p. 160.
 Blue wolfs-bane, v. iii. p. 7.
 Boles, v. i. p. 441.
 Borax, v. i. p. 231. ap. p. 237.
 Borage, v. iii. p. 33.
 Box wood, v. iii. p. 35.
 Brimstone of sulphur, v. ii. p. 248.
 Brooklime, v. iii. p. 30.
 Broom, v. iii. p. 115.
 Bryony, *white*, v. iii. p. 34.
 Buckthorn, v. iii. p. 275.
 Burning or combustion, ap. p. 67, 96, 174.
- C.
- CALAMINE, or lapis calami-
 naris, v. i. p. 397.
 Calomel, or mercurius sublim.
 dulc. v. i. p. 337.
 Calx of antimony, v. i. p. 372.
 ——— of mercury or quicksilver,
 v. i. p. 317.
 ——— of tin, called aurum mu-
 sivum, v. i. p. 290.
 Camphor, v. ii. p. 326; its oil,
 ap. p. 278.
 Canella alba, v. iii. p. 37.
 Cantharides or Spanish flies, v.
 iii. p. 39, ap. p. 280.
 Carpo-balsamum, v. iii. p. 49.
 Carraway, v. iii. p. 50.
 Carrot, *common*, v. iii. p. 87.
 Ditto of Crete, v. iii. p. 87.
 Ditto wild, v. iii. p. 89.
 Cascarella, v. iii. p. 105.
 Cassia cinnamon, v. iii. p. 51.
 Ditto fistularis, Pharm. v. iii.
 p. 310, 330.
 Cassumanar, v. iii. p. 50.
 Castor, v. iii. p. 52.
 Catechu, or terra Japonica, v. ii.
 p. 399.
 Cautic, alkaline, v. i. p. 142.
 ——— antimonial, v. i. p. 380.
 ——— lunar, v. i. p. 247, ap.
 p. 292.
 Cerusse, v. i. p. 276.
 Chalk, v. i. p. 420.
 Chalybeate wine, v. i. p. 371.
 Camomile, v. iii. p. 58.
 Chervill, v. iii. p. 55.
 China-root, ap. p. 19.
 Cinnabar, factitious, v. i. p. 315.
 ——— native, v. i. p. 315.
 ——— of antimony, v. i. p.
 376.
 Cinnamon, v. iii. p. 68.
 Cinquefoil, v. iii. p. 199.
 Civet, v. iii. p. 291.
 Cloves, v. iii. p. 47.
 Clove July-flower, v. iii. p. 48.
 Cochineal, v. iii. p. 70.
 Colomba, v. iii. p. 76.
 Coloquintida, v. iii. p. 72.
 Coltsfoot, ap. p. 24.
 Combustion, ap. p. 67, 96, 174.
 Conessi, v. iii. p. 78.
 Constituent parts of animal sub-
 stances, ap. p. 151.
 Constituent parts of vegetable
 substances, ap. p. 137.
 Copper and preparations, v. i.
 p. 249, ap. p. 244.
 ——— ammoniated, v. i. p. 251.
 ——— blue vitriol, v. i. p. 254.
 ——— verdigrise, v. i. p. 250.

Coral, v. i. p. 424.
 Coriander, v. iii. p. 79.
 Cowhage, v. iii. p. 98.
 Crabs claws, v. i. p. 424.
 Cream, or crystals of tartar, v. i.
 p. 81.
 Cubebs, v. iii. p. 83.
 Cuckowpint, v. iii. p. 19.
