PREFACE TO THE FIRST EDITION.

IT is necessary to inform the reader that the following Lectures were not originally intended for publication, but were delivered, from very brief notes, before the Society of Arts—the subject having been selected by the Council of the Society. Finding, however, that the lectures have unexpectedly received a large share of attention, and have been printed *verbatim* in several English and American Journals, and that American and French editions of them were in course of publication, I have been induced to revise them more carefully, and to place them in an amended form before the public. All the tables, therefore, have been re-calculated, in order that the numbers might be in accordance with the most approved analytical data.

In dealing, however, with so large a subject as the economy of food, it was difficult, on the one hand, to

select points of interest, and, on the other, to treat them with sufficient clearness within the narrow limits of a short course of four lectures; and therefore, after due consideration, I thought it best to give a brief popular account of the different varieties of human food, and their dietetical values; and to point out the relation which exists between food and labour; and to explain the principles involved in the proper construction of dietaries. Relying upon the experimental data of Dr. Frankland and others respecting the thermotic power of different kinds of food, and the equivalent of that power in mechanical work, as ascertained by the investigations of Mayer and of Joule (*a*), I have endeavoured to express the labour value of most of the commoner articles of diet. Looking also at the actual amount of work performed by an ordinary individual, with a certain fixed diet, it has been easy to determine the *opus vitale* or internal work of the human body in performing the physiological functions of respiration, circulation, nutrition, &c.

In the construction of dietaries I have depended largely upon the enquiries of Dr. Edward Smith, and of Dr. Lyon Playfair—the former having directed his attention to the dietaries of the low-fed operatives of this kingdom, and the latter to the dietaries of well-fed artisans and

(*a*) According to Joule, the heat necessary to raise 1 lb. of water 1 deg. of F., is capable of lifting 772 lbs. one foot high.

others. From these data I have been able to construct standard proportions of food for idleness, and for labour. The importance of this part of the subject cannot be over-rated; for it not only concerns the dietetical wants of the community, but it also affects the dietetical treatment of our paupers and criminals. At present, the dietaries of the prison and the workhouse, are constructed upon the most capricious principles, and hence there is often either a wasteful excess of food, or a serious deficiency of it. As a rule the criminals of this country are over-fed, and it is a very grave question—how much of the turbulence of the jail is referable to the unemployed and even explosive force of a too liberal diet. On the other hand the pauper is frequently under-fed; and the consequences of it are a lowering of the vital powers, and a general debility of the muscular system. These are important social questions, and must ere long receive the attention they deserve.

The functions of the several constituents of food have been examined from new points of view; and the opinions of Liebig, as to the special force-producing or motive power of nitrogenous food have been carefully considered. This has become necessary from the circumstance that they have been recently tested by actual experiment, and it has been found that the muscular energies of the body may be sustained, and considerable labour performed with a purely non-nitrogenous diet.

It is even probable that the thermotic power of food is at all times the true exponent of its mechanical or motive power; and that this is quite independent of its nitrogenous or non-nitrogenous nature; although it is evident from chemical considerations that the carbohydrates, as fat, sugar, and farinaceous matters, are far more sustaining, in a thermotic sense, than nitrogenous foods, whose functions are perhaps chiefly to repair the waste of tissues. It must be admitted, however, that this part of the subject is still incomplete, and requires much experimental investigation before it can be satisfactorily determined.

As regards the culinary and other treatment of food, as well as the preservation of it, I have endeavoured not only to discuss the general principles of the matter, but also to give, especially under the last head, very copious illustrations of practice. I have likewise described the circumstances which render food unwholesome, and have briefly adverted to its principal adulterations. In all cases, however, the numerous subjects have been so treated as to condense the facts as closely as possible, in order that they might be brought within the limited space of a very short [course of lectures; and I submit this to the reader, not merely as a claim upon his indulgence, but as an excuse for many evident imperfections and shortcomings.

PREFACE TO THE SECOND EDITION.

THE rapid sale, within a few months, of a large impression of the first edition of this work has been a sufficient inducement—to use the words of Mr. Accum—for the publication of a second edition; and the delay in responding to the call of the public for a reprint of the work has been occasioned by the difficulty in finding time, amidst continued professional engagements, for a careful examination of the pages of the former edition, with a view to corrections and additions, in order that the work might be even more acceptable to the public.

This, the author has performed to the best of his ability, although, from repeated interruptions in the course of his work, he is conscious of the difficulty of careful supervision, and for this he still asks the reader for his kind indulgence.

CONTENTS.

PREFACE TO THE FIRST EDITION	PAGE v.
PREFACE TO THE SECOND EDITION	„ ix.

LECTURE I.

VARIETIES OF FOOD—THEIR CHEMICAL COMPOSITION AND NUTRITIVE VALUE.

Nutritive Standards, as determined by the Amount of Nitrogenous Matter required daily, and by the Amount of it in Human Milk. Proportions of each of the Nutritive Elements in Different Kinds of Food. Amounts of Carbon and Nitrogen required daily, and the Quantities of each in a Pound of Different Descriptions of Food, together with their Money Values. *Varieties of Food*.—Wheat and Wheaten Flour; Barley-Meal, Scotch and Pearl Barley; Oatmeal, Grits, and Flummery; Rye-Meal and Rye-Bread; Maize, or Indian Corn, Corn Lob, and Corn Flour; Rice; Millets; Quinoa; Pulses—as Beans, Peas, Revalenta, &c.; Manioc and Lotsa Meal; Arrowroots—as Bermuda, Jamaica, East Indian, Brazilian, Tahiti, Portland, English, &c.; Potatoes and other Esculent Vegetables—as Turnips, Carrots, Parsnips, Artichokes, Onions, Leeks, Cauliflower, Cabbage, &c.; Banana and Bread Fruit; Batata, or Sweet Potato; Ripe Fruits—as Apples, Pears, Peaches, &c.; Marine Algæ—as the Lavers, Carrageen Moss, &c.; Fungi and Mushrooms; Sugar and Treacle; Milk, Cream, Skim-milk, Butter-milk, &c.; Cheese; Meat; Horse-flesh; Venison and the Flesh of Wild Animals; Bacon; Poultry; Rabbits; Fish; Shell-fish; Reptiles; Eggs; Butter, Lard, Suet, Saline matter, &c.; Quantities of each Description of Food supplied daily to the Metropolis

	PAGE I
--	--------

LECTURE II.

COMPARATIVE DIGESTIBILITY OF FOODS. FUNCTIONS OF DIFFERENT FOODS.

Phenomena of Digestion.—Proportions of the Different Digestive Secretions. *Saliva* and its Functions; Artificial Substitutes for Saliva. *Gastric Juice* and its Functions; Preparation of Pepsin. *Pancreatic Fluid* and its Functions; Preparation of Pancreatin and Pancreatized Fat. *Bile* and its Functions. *Intestinal Secretions.*—Proportions of Food which Escape Digestion. Relative *Digestibility* of Different Foods, and of the Individual Constituents of Food—as Albuminous Matters, Fibrinous Substances, Gelatine, Tendon, Fat, Starch, Cellulose, Gum, and Saline Compounds. *Functions of Food*—as of Water, Albuminous Matters, Fat, Sugar, Starchy Substances, Saline Compounds, &c. Hypothesis of Liebig, as to the Force Function of Nitrogenous Matter. Experiments of Fick and Wislicenus on a Non-nitrogenous Diet. Amount of Labour Performed and Nitrogen Excreted as Urea, &c. Parke's Experiments in the like manner on Two Soldiers. Smith's Experiments on the Carbonic Acid Exhaled from the Lungs when the Body is at Rest and when at Work. Functions of Fat. Functions of Starchy and Saccharine Matters. Thermotic and Motive Powers of Fat, Sugar, and Starch. Functions of Saline Compounds—as of Salt, Alkaline and Earthy Phosphates, &c. Functions of Tea, Coffee, Cocoa, &c. Functions of Alcohol, and of the Various Condiments as Pepper, Mustard, Spices, &c. Actual and Potential Energy of a Given Quantity of Different Foods, when Consumed in the Body, and when Burnt in Oxygen. Mechanical Power of a Subsistence Diet and a Working Diet. Amount of Work Performed Daily by Different Individuals. Amount of Internal Work, as of Circulation and Respiration. Relative Cost of Human Labour, Horse Labour, and the Work of a Steam Engine; Weight and Cost of Different Articles of Food to Perform the same Amount of Work. *Fattening Functions of Food.*—Proportions of the several Constituents of Food Appropriated by Different Animals during the Process of Fattening PAGE 46

LECTURE III.

CONSTRUCTION OF DIETARIES—PREPARATION AND CULINARY TREATMENT OF FOODS.

Considerations involved in the *Construction of Dietaries.*—Actual Dietetical Wants of the Body, as Determined from the Dietaries of Farm

Labourers and others, and from the Amounts of Carbon and Nitrogen Excreted. Amounts of Food yielding the Plastic Matter Necessary for a Man's Daily Diet. Dietaries of Low-fed Operatives, and of Well-fed Operatives. Dietaries of Hospitals, Prisons, Workhouses, and Lunatic Asylums. Model Dietaries for the Poorer Classes. Dietaries of Children. Dietaries for the Development of Muscular Tissue, as in Training, and for the Production of Fat, as well as for the Suppression of it. Mr. Banting's Dietary. Modes of Associating Different Foods so as to Secure the Proper Proportions of the Chief Constituents. Times for Taking Food. Habits of the Romans, and of the English, in the Middle Ages. A Modern Dinner. A Dinner of Horse-flesh. Proportions of Food at Breakfast, Dinner, and Supper. Diseases arising from Over-feeding, and from Under-feeding, and from an Improper Association of Foods. *Treatment of Foods*, as in the Preparation of Farinaceous Foods—Arrow-root, Semola, Semolina, Maccaroni, Vermicelli, Bread, &c. Different Kinds of Bread—Fermented and Unfermented. Farinaceous Foods for Infants—Liebig's Preparations of Malt, Milk, and Wheaten Flour. Fermented Vegetable Substances, as Sauer-Kraut. Pickles. Preparation of Tea, Coffee, Cocoa, Chocolate, &c. The Coffee and Chocolate Houses of London. Treatment of Animal Foods, as in Boiling, Baking, Roasting, and Frying—Relative Advantages and Economy of these Processes. Preparation of Soup. Liebig's Extract of Meat. Economy of the Kitchen. Cook-shops PAGE 104

LECTURE IV.

PRESERVATION OF FOOD—UNWHOLESOME AND ADULTERATED FOOD.

Preservation of Meat. History of the Process and General Principles of it. Preservation of Food by Drying. Charqui or South American Beef, Pemmican, Preserved Eggs, Preserved Milk, Dried Vegetables—the Patents of Edwards, Grillett, Masson, Devaux, Chollett, and others. Preservation of Food by Excluding Atmospheric Air, as in the Patents of Plowden, De Heine, Appert, Goldner, Warrington, Redwood, and others. Preservation of Food by Cold, and by Chemical Agents, as Vinegar, Salt, Spirit, Syrup, &c. *Unsound and Diseased Meat.* Custom of the Jews in Searching for Disease in Slaughtered Animals. Overseers of the Markets of Ancient Rome. Regulations respecting the Sale of Meat on the Continent. Inspection of Meat in the City Markets. Quantity Seized and Condemned Annually. Signs of Good and of Bad Meat. Effects of Diseased Meat on the Human System. Effects of Meat Infected with Parasites,

as Measles, Trichina, &c. Meat Rendered Unwholesome by the Food of the Animal. Poisonous Fishes. Effects of Putrid Meat and Mouldy Meat, as German Sausages and Musty Cheese. Poisonous Grain, as Ergotised Grain, Darnel, Mouldy Flour, Bread, &c. *Adulterations of Food.* Accum's Treatise thereon. Various Classes of Adulterations, as when it is Practised to Increase the Bulk or Weight of the Article, to Improve its Appearance, and to Give it a False Strength. Examples of each of these Kinds of Adulteration. Conclusion PAGE 182

ON FOOD.

LECTURE I.

VARIETIES OF FOOD—THEIR CHEMICAL COMPOSITION AND NUTRITIVE VALUE.

THE economy of food, in its fullest signification, is a matter of national importance; for the political influence of a nation is as much dependent upon the muscular strength of the people as upon their intelligence and commercial industry; and this strength is wholly referable to a right use and proper distribution of food.

We perceive this not merely in the calamities of actual want, as in the fevers of famine, but also in the less prominent, but equally significant, decline of health in times of only partial distress, when the vigour and energy of the poorer part of the population are so reduced as to render them an easy prey to disease. In fact, the experience of our public hospitals too often elicits the fact that the wasted power of the patient has been the advent of incurable disorder. Nor is this all; for as Mr. Simon observes—"Long before insufficiency of diet is a matter of hygienic concern, long before the physiologist would think of counting the grains of nitrogen and carbon which intervene between life and starvation, the house

hold will have been utterly destitute of material comfort ; clothing and fuel will have been scantier than food ; against inclemencies of weather there will have been no adequate protection ; dwelling-space will have been stinted to the degree in which over-crowding produces or increases disease ; the home will be where shelter can be cheapest bought, where sanitary appliances are least considered, and where cleanliness is almost impossible." And all this distress falls heaviest upon those who are least able to bear it—the mother and her children ; for the father, to be able to work, even lightly, must eat, and thus the others are the largest sufferers. Bad, however, as the immediate consequences are, they are nothing in comparison to the remote—the sickly race that comes of want.

In examining, therefore, this question of the economy of food, we must not only look at the nutritive value of different articles of diet, but we must also consider how food can be best distributed and utilised.

To-day we will investigate the principal varieties of food, and ascertain their peculiar qualities and dietetical values. For this purpose it would be a great advantage to have some simple standard of comparison, but this is avowedly a difficult matter, for if we compare foods according to the proportions of their principal constituents, as the albuminous, starchy, saccharine, and saline, we shall find that the relative quantities vary to such a degree as to make the comparison almost useless ; and if we fix our attention on one of these constituents—the nitrogenous, for example—and make it the exponent of nutritive value, we get into the difficulty of either overloading the equivalent with a large amount of carbonaceous material, or having it deficient therein. If, for instance, we desire to know the quantities of different foods which would furnish the 1220 grains of nitrogenous matter required by a man in his daily diet, we should find that the following are the proportions :—

TABLE I.

Proportions of Different Foods Required to Yield 1220 Grains of Nitrogenous Matter.

	Grains.	Pounds.
Skim cheese	2,723	0·4
Lean meat	2,421	0·9
White fish	6,740	1·0
Fat meat	8,971	1·3
Fat bacon	12,449	1·8
Bread	15,062	2·1
Rice	19,365	2·8
New milk	29,756	4·2
Potatoes	58,095	8·3
Parsnips or turnips .	111,000	15·9
Beer or porter . . .	1,110,000	158·6

In this manner tables have been constructed of the nutritive values of food, and I show you one of them.

TABLE II.

Nutritive equivalents—calculated according to the amounts of Nitrogen in the Dry Substances; Human milk being 100:—

VEGETABLE.

Rice	81	Oats	138
Potatoes	84	White bread . .	142
Maize	100	Black bread . .	166
Rye	106	Peas	239
Radish	106	Lentils	276
Wheat	119	Haricots. . . .	283
Barley	125	Beans	320

ANIMAL.

Human milk	100	Cheese	331
Cow's milk	237	Eel	434
Yolk of egg	305	Mussel	528
Oysters	305	Ox-liver. . . .	570

Pigeon	756	Veal	873
Mutton	773	Beef	880
Salmon	776	Pork	893
Lamb	833	Turbot	898
White of egg .	845	Ham	910
Lobster	859	Herring	914
Skate	859		

From which it would seem that ham and red herring in the dry state are more than nine times as nutritious as the dry matter of human milk. I hardly need say that comparisons of this description are of little practical value, for they furnish no indication of the digestive labour required to utilise the products; besides which, we are far from being assured, at the present time, that the nitrogenous elements of our foods are the most important.

In framing, therefore, a table of alimentary equivalents, regard must be paid to all the constituents, and this I have endeavoured to do in Table No. 3, wherein I have shown the percentage proportions of nitrogenous and carbonaceous matters; but here again the actual value of the several carbonaceous compounds is very different; for, although the fattening and respiratory powers of starch, gum, sugar, and pectin are perhaps nearly the same, yet the power of fat, is about 2.5 times as great as that of sugar; and this must be considered irrespective of other functions of fat in estimating the value of carbonaceous food. I have therefore given the proportions of carbonaceous matters when calculated as starch.

Another method of determining the values of food, is by estimating the proportions of nitrogen and carbon in them, and comparing them with the proportions required in a standard diet.

Judging from the minimum quantities of food which an ordinary individual is capable of existing on, without

* The available carbon consists of all the carbon of the carbonaceous constituents of the food, and of the carbon of the nitrogenous stuffs.

suffering in health, it would seem that about 3,888 grains of carbon and 181 grains of nitrogen are required in his daily diet. These proportions have been determined from a large number of observations, as by those of Dr. Lyon Playfair, in his inquiries into the dietaries of hospitals, prisons, and workhouses, and by those of Dr. Edward Smith, in his examination of the amounts of food which the Lancashire operatives were capable of living on during the cotton famine, and also by his inquiries into the dietaries of in-door labourers. The proportions which Dr. Smith gives as a famine or barely sustaining diet, are as follows:—

	Carbon (grains).	Nitrogen (grains).
Adult woman	3900	180
Adult man	4300	200
	4100	190

These proportions are contained in 2lbs., and in 2lbs. 4ozs. of bread; and they closely accord with another set of facts, derived from an examination of the amounts of carbon and nitrogen exhaled and secreted from the body during health and idleness.

Taking these numbers, therefore, as the exponents of the nutritive values of food, we are able to construct the following table:—

TABLE IV.—*Nutritive Values of Food.*

	GRS. PER POUND.			GRS. FOR ONE WEEKLY COST OF

And now we proceed to examine in detail the general properties and the nutritive qualities of different foods.

Primarily, all our foods are derived from the vegetable kingdom, for no animal has the physiological power of associating mineral elements and forming them into food. What we may yet do by means of chemical agencies in the laboratory is another question; but within our own bodies there is no faculty for such conversion. As I shall hereafter explain to you, our functions are of an opposite kind. We are destructive

creatures, not constructive. It is our province to pull down what the vegetable has built up, and to let loose the affinities which the plant has brought into bondage, and thus to restore to inanimate Nature the matter and cosmical force which the growing plant had taken from her.

VEGETABLE FOODS.

Foremost, therefore, of our foods are those which come at once from the vegetable kingdom; and of these the *cereals* are the most important, as wheat, barley, oats, rye, maize, or Indian corn, rice, millet or durra, and Guinea corn.

WHEAT.—Different species of this grain are cultivated, but the most common in this country is *Triticum vulgare*, of which there is a summer and winter variety.

The grain varies a good deal in composition according to season, climate, and soil; but, as a rule, the wheat of southern climates, and warm seasons, is richer in gluten, and harder of texture than that of colder climes. The grains are then called stronger, although the wheat from colder climates, from its being softer and kinder, gives a larger proportion of flour. Some of the hardest varieties of wheat, as *rivets*, are used to strengthen the flour of new grain, which is always unmanageable, and to improve that of bad seasons and of damaged quality.

The structure of the grain is like that of all the cereals; there is an outer siliceous and woody covering, which is altogether valueless as food; then there is a layer of rich nitrogenous matter, containing a digestive body called *cerealine*, and within that is the flour, which forms the great bulk of the seed.

When ground whole, it forms *brown meal*, which is rarely used in England at the present time, although it was the common food of our forefathers, and even now is much employed in Westphalia to make the dark-coloured bread called *pumper-nickel*. It contains from 5 to 12 per cent. of indigestible matter, in the form of

bran, the removal of which, according to Liebig, is only a refinement of luxury; but, as we shall hereafter see, opinions differ on this important subject.

The practice at the present time is to bolt or sift the ground meal through sieves, or silks of different degrees of fineness, and thus to remove the coarser bran. The products have different names in different places, and have also different values; but generally a hundred pounds of wheat will yield from 78 to 80 parts of good serviceable flour, besides about 2 parts of *specks*, or *tails*, or *tippings*; from 2 to 3 parts of *sharps*; about 3 of *fine pollard*; from 3.5 to 6 of *coarse pollard*; and from 4 to 10 of *bran*. The relative wholesale values of these are about as follows:—

Vegetable Foods.	lbs. per bushel.	Price per bushel.		Price per 20 lbs.	
		s.	d.	s.	d.
Fine flour	56	10	0	3	7
Seconds flour . . .	56	7	9	2	9
Sharps	26	2	0	1	6
Fine pollards . . .	18	1	0	1	1
Coarse pollards . .	14	0	10	1	2
Bran	12	0	9	1	3

The coarser descriptions are used for feeding pigs, and as a condiment for horses.

Seconds flour is practically the best for domestic use; and of this there should be at least 80 per cent. obtained from the grain. Attempts have often been made to increase the produce; for as the bran contains a good deal of nitrogenous matter, and is, moreover, rich in fat and saline substances, it has been thought wasteful to remove it; but the experimental researches of Poggiale, the learned professor at Val-de-Grace, have shown that at least 50 per cent. of the bran is perfectly indigestible, and may be passed successively through the bodies of four or five animals without undergoing change. It, moreover, acts as an irritant; and, by hurrying the food through the alimentary canal, is very likely to cause

waste. Those who labour hard, as railway navigators, invariably choose the whitest bread for food, believing that it is not only more digestible, but is really stronger, and will enable them to do more work. Without doubt, however, there is room for improvement in the treatment of flour, and in the complete utilisation of its several constituents. M. Mège Mouries has invented a process whereby the outer skin only of the wheat may be removed, and from 86 to 88 per cent. of flour realised. The process was examined in 1857, and reported very favourably of by Dumas, Pelouze, Payen, Peligot, and Chevreul. It will be fully described hereafter.

M. Mège Mouries also directed attention to the fact that the bran contains a portion of very soluble nitrogenous matter, *cerealine*, which is of the nature of diastase, and has the property of dissolving starch. If it were not that it gave a dark colour and a soft consistence to bread, it might be utilised by treating the bran with warm water, and using the water in the preparation of the dough for bread.

The nutritive value of wheat is shown in Tables No. 3 and No. 4; and although the average amount of gluten is there set down at about 11 per cent., it ranges from 8 to 15 per cent.—the largest quantity being found in the wheaten flour of India, Egypt, South America, and the South of Europe. The flour of Genesee, New York, and of Canada, contains about 9.8 per cent.; Ohio, Maryland, and Richmond (Virginia), from 11.3 to 11.8 per cent.; George Town (South Carolina), and New Orleans, from 13.4 to 13.7 per cent.; Dantzic, Hamburg, and the North of Europe, from 8.9 to 13.3 per cent.; Spain, Portugal, and the Black Sea, from 10 to 15; and English from 10.4 to 10.8 per cent.

It appears, too, that the quantity of gluten, as represented by nitrogen, increases with the coarseness of the flour, and so, also, does the amount of mineral matter, of which phosphoric acid is the chief constituent.

TABLE V.

Per-centage amounts of Nitrogen and Mineral Matter in the different Products of the Mill:—

	Nitrogen.	Mineral matter.
Fine flour	1·70	0·71
Tails	1·86	0·99
Fine sharps	2·21	1·89
Coarse sharps	2·58	3·80
Fine pollard	2·44	5·50
Coarse pollard	2·42	6·50
Bran	2·39	7·00
	<hr/>	<hr/>
Average in whole grain	1·82	1·62

The starch and sugar amount to about 70·5 per cent. and the fat to 2·0; so that the carbonaceous matters (as starch) are to the nitrogenous as 7 to 1, which are good proportions. Other facts relating to its nutritive value are shown in Table No. 4.

Wheaten bread is preferred to all other varieties of bread, because of its sweetness, and because it may be eaten alone. The nutritive constituents of it are in the same proportion as in wheat—namely, as 1 to 7, and a little more than two pounds of bread will supply the requirements of the system; although, as I shall hereafter explain, it cannot be used alone without loss of health and strength.

BARLEY MEAL is the chief food of a large number of people in the North of Europe and in the South of England, where the labourer is partly paid his wages in meal or grain. It is also used in Wales and Scotland, especially in winter time, when wheaten bread is dear; and to some extent in Ireland. It is employed by about ninety per cent. of the out-door labouring population of England. At the time of Charles I. (1626), according to M'Culloch, it was the usual food of the ordinary sort of people; and as late as the middle of the last century,

hardly any wheat was used in the northern counties of England. In Cumberland the principal families used only a small quantity of wheaten bread about Christmas-time. The crust of the everlasting goose-pie, which adorned the table of every country family, was invariably made of barley meal.

The grain is almost always ground whole, and the farina has much resemblance to wheaten flour, but the amount of gluten is very different; in fact, the nitrogenous matter, which amounts to about six per cent., is chiefly in the form of albumen, hence the bread is heavy and compact, for albumen will not vesiculate or sponge like gluten. The common way of making it into bread is by mixing it with an equal proportion of wheaten flour; and sometimes it is mixed with oatmeal and rye-meal, and baked into cakes. But the best way of using it is in the form of thick gruel, or stirabout, which is made by stirring the meal into boiling water.

PEARL BARLEY and SCOTCH BARLEY are the grain deprived of its husk, and rounded by attrition. The former is more carefully prepared than the latter, but both are used to give consistence to broth.

The nutritive value of barley meal is somewhat inferior to that of wheaten flour, but as the meal is cheaper than flour it is more economical to use it; in fact, it is almost the cheapest article of diet, as may be seen by reference to Table No. 4.

OATMEAL and RYE BREAD were once the chief diet of the servants of the wealthy, and even now the former is used by 90 per cent. of the agricultural labourers of England, and by a still larger proportion of the Scotch. The grain is very rich in gluten and fat, and it contains a good quantity of sugar and starch, the microscopic form of which is remarkable. The Scotch meal is always preferable to the English, on account of its higher nutritive power. It is prepared by grinding the kiln-dried grains, previously deprived of their skins. The Scotch

grind it rather coarsely as compared with the practice in England.

Oatmeal is not nearly so white as wheaten flour, and its taste is peculiar, being at first sweet, then rough and bitter. Like barley meal, it cannot be vesiculated into bread, but it makes good cakes, and these may be either leavened, as is the custom in Yorkshire, or unleavened, as in Scotland. The finer variety of oatmeal is baked thin, but the coarser kind is made into thick cakes, called *bannocks*. Cakes of this description were the common food of the natives of Lancashire and Yorkshire: in fact, so lately as the commencement of the Peninsular War, a regiment was raised in East Lancashire under the name of "the Haver cake lads," from the circumstance that the recruiting sergeant carried an oat-cake on the point of his sword, as a badge of its nationality. In Norway the common food of the peasantry is a thin cake called *flad brod*, which is made of ground oats (husk and all) mixed with potatoes, and baked on a griddle or frying-pan. A very palatable and rather savoury dish is made in some parts of Scotland by toasting oatmeal before a bright fire, then mixing it with a little beef or mutton fat, and after seasoning it with pepper, salt, and onions chopped small, again toasting it.

The common method of cooking it, however, is by stirring it with boiling water until it has the consistence of hasty pudding, and in this manner Scotch *brose* is made; but if more diluted and boiled for a short time it makes *porridge*. In Ireland it is mixed with Indian meal, and then stirred into boiling water, thus making the mixture called *stirabout*. Whey and milk are often used instead of water, and the mixture should be well boiled, as otherwise it is apt to produce pyrosis and flatulence.

The decorticated grain constitutes *grits* or *groats*, and when these are crushed or bruised they go by the name

of *Emden groats*. The sole use of them is for making gruel, a drink that seems to have been a favourite with our forefathers; for in the *London Gazette*, for Friday, August 13, 1695, there is an advertisement to the effect that water-gruel was always ready at the Marine Coffee-house, in Birchin-lane, Cornhill, every morning from six to eleven o'clock, where as much as from four to five gallons of it were consumed daily.

The husks of the grains are sold in Scotland under the name of *seeds*, and these, when steeped in water for a few days, until they become a little sour, like stale brewers' grains, and then squeezed out, produce a liquid which, when boiled down to the consistence of gruel, or thickened with a little oatmeal, makes the food called *flummery* or *sowans* in Scotland, and *sucan* in South Wales, which is generally eaten with milk. If it be boiled still more, until it becomes as thick as jelly, it forms *budrum*, or *brwchan*, as it is named in Wales. Oatmeal is, no doubt, rather hard of digestion, and causes irritation of the bowels, especially if not sufficiently cooked. There is a notion also that it produces heat and irritation of the skin; and formerly, when sufficient care was not taken to remove the husk from the grain before it was ground, it was not an uncommon occurrence to find calculi or concretions of phosphate of lime, mixed with the silky bristles of the grain, in the alimentary canal. Somewhat similar concretions are found at the present time in the bowels of horses that feed too freely on bran or grains. The nutritive value of oatmeal is shown in Tables No. 3 and No. 4, and it will be noticed that although it is, weight for weight, more nutritive than wheaten flour, yet, considering its price, it is not so economical.

RYE MEAL is the chief food of northern nations, and was once a common article of diet with ourselves. It forms the dark-coloured and sour-tasting bread of the North of Europe, and throughout Germany and Holland,

where it is the ordinary food of the lower classes. Sometimes it is placed in thin slices between white bread and butter, forming the *black bread sandwiches* of the rich. In this country it is rarely eaten alone, but is mixed with about twice its bulk of wheaten flour, forming what in many places is called *maslin*, and is then made into bread. The nutritive power of rye-meal is a little less than that of flour, and the proportion of the nitrogenous to the carbonaceous constituents is as 1 to 9·8.

MAIZE or INDIAN CORN is one of the most extensively used grains in the world. It enters largely into the food of the inhabitants of America, Natal, Italy, Corsica, Spain, the South of France, and the Danubian Principalities. In Mexico and Natal it is literally the staff of life, hardly any other food being used. The ration for a Kafir servant is three pints of Indian corn meal per day, and, although he rarely gets anything else to eat, he manages to keep in good health. The plant was originally obtained from Mexico, where it grows wild, but it has been introduced into Europe, Asia, and Africa, and is largely cultivated in the South of Europe, on the African coast of the Mediterranean, in Turkey, Egypt, India, China, and the islands of the Indian Archipelago. Since the potato famine of 1846 it has been more or less used in Ireland, but its flavour is somewhat harsh, and, therefore, it is not liked when more agreeable food can be obtained.

The meal is called *hominy*, or *cominy*, and its farina has a remarkable form and structure, by which it is easily recognised under the microscope.

Although the meal is rich in nitrogenous matter and fat (see Table III.), yet it does not make good bread, and therefore it is cooked by either baking it into cakes or by stirring it into boiling water or boiling milk, as in the case of oatmeal, whereby a sort of hasty pudding or thick porridge is obtained. This is the common method of using it in Ireland, and it is flavoured with salt, or

butter, or treacle. The favourite mess called *corn-lob* by the creoles of British Honduras is prepared with hominy or cominy and milk in the same way, and the favourite *polenta* of the Italian peasantry is a like preparation, mixed with vegetables and flavoured with bacon.

Throughout Mexico, where maize is the staple article of food, it is cooked by baking it into cakes—*Tortillas*. The ripe grain is taken from the cob and boiled with water and a little lye of wood ashes until it is perfectly soft to the core. It is then allowed to cool, and is taken from the pot in small portions at a time, and crushed into a paste between stones—one of the stones being flat (*metaté*), and the other round, like a rolling-pin (*metlapilé*). In this condition it is kneaded into flat cakes, about six inches in diameter and a third of an inch in thickness. These are immediately baked or toasted upon a thin stone or tile placed over a wood fire, and are served hot. Thinner cakes or biscuits, called *totoposté* or *totoporté*, are made for keeping, and for soldiers' rations on the march.

Indian meal mixed with maple sugar, and baked into cakes, formed, at one time, the chief article of diet of the now almost extinct Delaware Indians.

There is a sweet and tender variety of Indian corn called *sugar corn*, the cob or spike of which is cooked entire while in a young green state, and is either thus served to table as *corn in the cob*, or the grains are separated and served like green peas. This is an American luxury of great delicacy.

When deprived of its gluten and harsh flavour by means of a weak solution of caustic soda, and then dried, it forms the expensive food called *Oswego*, *Maizena*, or *corn flour*, which is now largely used for puddings.

Lastly, it is often mixed with wheaten flour and baked into bread, but its harsh taste is never completely covered.

The grain is said to cause disease when eaten for a

long time, and without other meal—the symptoms being a scaly eruption upon the hands, great prostration of the vital powers, and death after a year or so, with extreme emaciation. These effects have been frequently observed among the peasants of Italy, who use the meal as their chief food; and the sallow, wheezen look of the natives of the Northern States of America is thought to be due to the indigestible preparations of Indian corn, called *mush*, *hominy*, or *Johnny*, which constitute the chief portion of their daily meals; but I am not aware of any such effects having been seen in Ireland, where it is often the only article of diet for many months together.

The nutritive power of Indian meal is very high, and, considering its price, it is almost, if not altogether, the cheapest food for the poor. Calculated according to the physiological wants of the system, a week's diet for an adult will only cost about 11d., and excepting split-peas, which are of difficult digestibility, there is nothing approaching it for economy.

RICE is the principal food of eastern and southern nations, and is probably coeval with the human race. It is called *oruz* by the Arab, *orusa* by the Greek, *oryza* by the Roman, *riz* by the French, and *reis* by the German. It is extensively cultivated in India, China, Arabia, South America, and the southern countries of Europe, and it gives nourishment to not less than a hundred millions of persons. In this country, however, it is rarely employed, except as an adjunct to other foods. Now and then, in times of scarcity, it is used in the place of potatoes. Perhaps 50 per cent. of our labouring classes use it in this manner. It is imported into this country in a decorticated or cleaned condition, but when it has the husk upon it, it is called *paddy*. The kinds which are most esteemed in this country are Carolina and Patna; but, according to Dr. Watson, there are many Indian varieties which are nearly equal

to the American. The proportion of gluten in it is only about 6·3 per cent., and it rarely exceeds 7. It is, in fact, one of the least nitrogenous of all the cereals, and cannot be made into bread unless it is mixed with wheaten flour, as is the custom in Paris in making the best white bread. The proportion of nitrogenous to carbonaceous matter is as 1 to 12·8, this being about twice the amount of the respiratory constituents of wheat. Rice, therefore, is a good adjunct to highly plastic foods, as ox-liver, poultry, veal, fish, and even beans and lentils; with all of which it goes well, especially in the savoury form of *curry*. Boiled with milk also, and dressed with egg, as *rice pudding*, it forms a substantial meal; but in no country is it eaten alone.

The MILLETS, called also *Dhurra* or *Dhoora*, are another kind of grain, and are derived from many species of plants, as *sorghum*, *penicellaria*, *paniscum*, &c. Like rice, they are extensively cultivated in India, Egypt, Algeria, and the interior of Africa, where they are important articles of diet. They are a little more nutritious than rice, for they contain, on an average, about 9 per cent. of nitrogenous matter, with 74 of starch and sugar, 2·6 of fat, and 2·3 of mineral matter. We have no experience of their nutritive properties in this country, except in feeding birds; but in India the grains are ground whole and made into bread. The favourite food of the Kaffir in South Africa is crushed millet toasted into the form of brown sawdust. The name by which he knows it is "*Amabele*," and it is served in a small pot, from which the guests take pinches at a time. A species of millet, called Kaffir corn, is also used in South Africa, and when mixed with maize and fermented it forms a thick, gruel-like drink, named "*tchualla*," or Kaffir beer.

The last of the grains of any importance is QUINOA, a species of *chenopodium*. It is hardly known in this country, although it is extensively cultivated and con-

sumed on the high table-lands of Chili and Peru. Mr. Johnston has described it, and he says there are two varieties of it—the sweet and bitter—both of which grow at an elevation of 13,000 feet above the level of the sea, where barley and rye refuse to ripen. It is very nutritious, and approaches oatmeal in its chemical composition, the amount of gluten being about 19 per cent., the starch and sugar 60 per cent., and the fat 5.

The next class of farinaceous foods are the PULSES, as *peas*, *beans*, and *lentils* of this country, and the *dholls* and *grams* of India. They are grown and eaten in all parts of the world, and are everywhere regarded as very nutritious when they can be digested. Nothing, however, but the most prolonged cooking will serve to help in this particular. As will be seen by reference to the tables, where the composition of peas, the type of all of them, is given, they are rich in nitrogenous matter, for peas and beans contain about 23 per cent. of it, and lentils about 25; but the carbonaceous constituents amount to only 59 per cent., or 1 to 2·7. They are, therefore, when eaten, invariably associated with fat. In India, the favourite pea (*cajanus Indicus*) is rubbed with oil before it is cooked. In Yucatan, and throughout the whole of Central America, where black beans, called *frijoles*, are extensively used as food, they are well boiled in water, and eaten with pepper, salt, and fat pork. Egyptian horse-beans boiled in water and flavoured with ghee and pepper, are much used by the Arabs, especially when they are occupied in laborious work; and the Hindoo adds lentils to his rice and ghee when he has to work hard, as in rowing on the Ganges. *Peas bannocks*, or cakes made from the meal, are a favourite food, with fat and milk, in the south-east of Scotland; and in this country, butter with peas, and fat bacon with beans, are inseparable companions, and have been for centuries. In the time of Elizabeth, according to Fuller, peas were brought from Holland, and were “fit dainties for ladies,

they came so far and cost so dear." They were, therefore, a great luxury. We read, in fact, that on the 19th of May, 1554, when the Princess Elizabeth was released from the Tower, she went to perform her devotions at the church of Allhallows, Staining, and thence she proceeded to a neighbouring tavern, the King's Head, in Fenchurch Street, where she dined off pork and peas. A commemorative dinner of the same kind was, until recently, given annually at the same tavern, which still exists; and on these occasions, the common metal dish and cover used by Elizabeth, were shown to the guests. Nearly two centuries later, in 1698, when the French traveller, Sorbriere, visited the Metropolis, he says the common people feed much upon grey peas, and they delight in them most at supper, for every night there goes a woman crying grey peas and bacon, "though I take it," he says, "that peas be too windy for supper meat." *Revalenta* or *ground lentils* with cocoa, which contains over 50 per cent. of fat, are mixed in a well-known fancy preparation. The nitrogenous matter of the pulses is not of the nature of gluten, but is more like casein, or the cheesy matter of milk, and it is named by Braconnot, its discoverer, *Legumine*. It is very prone to decay, and hence the sourness and irritating effect of pea soup, when it has been kept a little while. During the Franco-Prussian war, a Berlin cook named Grünberg discovered a process for preserving a preparation of peas without becoming sour, and he obtained a reward of £5,555 from the Prussian Government for the secret. They also established a manufactory at Berlin for making sausages with this preparation mixed with bacon, onions, &c.; and as many as 75,000 of them, weighing a pound each, were daily made and forwarded to the troops in France—a single sausage being the daily ration of a soldier—and it was easily cooked by boiling it for a short time in water.

Other farinaceous foods, of little importance to us, are

the meal of the *edible chestnut*, which is largely used by the peasants of Lombardy; the *Manioc* and *Lotsa merl*, which Dr. Livingstone says are the chief vegetable foods of the natives in some parts of South Africa; perhaps, also, the *horse-chestnut* and the *acorn* might be added to the list, for there is hope of their being easily freed from the bitter principle which now renders them useless.

And last of this class of foods are the STARCHES and ARROWROOTS, which are largely imported or prepared in this country. They are *Bermuda*, *Jamaica*, or *West Indian arrow-roots*, from *maranta arundinacea*; *East Indian arrowroot*, from various species of *curcuma*; *Tous-les-mois* from *canna*; *Brazilian arrowroot* from *Fatropa manihot*, which, when dried and partially cooked on hot plates, makes *tapioca*; and which, when baked in its whole condition, forms *cassava* bread; *sago* and *sago-meal*, from the fruit of various species of *sagus*; *Tahiti arrowroot*, from a *tacca*; *Portland arrowroot*, from the tubers of an *arum*; and *English arrowroot* from *potatoes*. All these are obtained in the same way—namely, by crushing, or bruising, or rasping the root or other substance containing them, and after diffusing through water and fermenting, the starch or fæculoid matter deposits, and is collected on a cloth and dried. In this country, starches are obtained by soaking the grain in an alkaline liquor, which dissolves the gluten; then crushing between mills, straining to keep back the husk and cellulose, and finally washing with water, and allowing the starch to subside. By this method of manufacture a quantity of gluten is obtained, which can be set free from the alkali by an acid, and collected for food.

All the starches and arrowroots are known by their microscopic characters; and although they have the same chemical composition and nutritive value, yet they are very different in their digestibility, for the

true arrow-roots of the West Indies, as Bermuda and Jamaica, will often remain on the stomach of an invalid when the others will be rejected.

They contain no nitrogen, or but a trace of it, and therefore have no nitrogenous value, but they are useful for their carbonaceous properties; and they are best cooked by stirring them into boiling water or boiling milk, and then simmering for a minute or so.

The next class of vegetable foods are those which contain much water, and which may be called SUCCULENT VEGETABLE FOODS, of which the *potato* is the most important.

The POTATO was brought to us from America, in the sixteenth century, as a rarity, by Sir Walter Raleigh, who planted it in his garden at Youghall, in the county of Cork, in Ireland, on his return from the unfortunate colonial enterprise in Virginia, in 1586; and it appears that he was so disappointed with the result, for he mistook the fruit, or apples, as they are called, for the potato which he had eaten with so much relish in Virginia, that he ordered his gardener to dig up the plants and throw them away, when he unexpectedly discovered that the real crop was attached to the roots in the ground. It does not seem, however, that this experiment of Raleigh's commanded much attention, for Gerarde, who wrote his "Herbal" in 1597, merely mentions the potato as a rarity, and not fit for common food. In the reign of James the First (1603 to 1625) it was so scarce and so great a delicacy that in the list of articles provided for the household of the Queen it is mentioned as costing two shillings a pound, in money of that day. Even as late as the year 1663 its merits were not generally appreciated, for in that year Mr. Buckland drew the attention of the Royal Society to the value of the tuber as an article of food, and he recommended the cultivation of the plant as a safeguard against famine. Accordingly the members of the Society

who had gardens were invited to try experiments with it, and Mr. Evelyn was requested to mention the subject in his "Sylva." It is evident, however, that he thought very little of it, for he said nothing about it for more than thirty years, when he spoke of the fecundity of the potato in his *Kalendarum Plantarum*. In 1687 Mr. Woolridge described the potato as having been planted in various places in this country with good advantage; but he adds, "I do not hear that it has yet been essayed whether they may not be propagated in great quantities for the use of swine and other cattle." The celebrated Ray, who began to publish his "Historia Plantarum" in 1868, merely alludes to the potato as a thing that may be dressed in the same manner as Spanish batatas (the sweet potato); and in Mortimer's *Gardeners' Kalendar* for 1708 it is stated that "the root is very near the nature of the Jerusalem artichoke, although not so good and wholesome; but it may prove good for swine." More than ten years afterwards Bradley, a great authority in horticulture at that time, said of them that "they are of less note than horse-radish, radish, scorzovera, beets, and skirret; but as they are not without admirers, I will not pass them by in silence." Necessity, however, gradually overcame all prejudice, and at last, chiefly by the agency of the poor themselves, whose little plots of ground were fortunately the means of trying the question, the potato has become an almost universal article of diet; for its advantages are so numerous that it could not fail to be a favourite food. It is, for example, easily cultivated, easily kept, easily cooked, and easily digested; besides which it requires but little flavouring matter, and never wearies the palate. It is therefore used in times of plenty by all classes of persons, and is often eaten in quantities that approach very nearly to the rice allowance of a hungry Hindoo. "In Ireland," says Dr. Edward Smith, "when the season arrives and the potatoes are plentiful, as much as $3\frac{1}{2}$ lbs. are consumed three times

in a day by an adult. This, indeed, is the regular allowance of an Irishman, who finds no difficulty in consuming his rations of $10\frac{1}{2}$ lbs. of potatoes daily." In England the farm labourer consumes, on an average, hardly as much in a week. In Anglesea, however, potatoes are eaten twice a day, and the consumption is about $16\frac{1}{2}$ lbs. per adult weekly; and in Scotland the average allowance is 15 lbs. per head weekly.

The nutritive value of the potato is not great, for, in the first place, it contains only about 25 per cent. of solid matter, and of this hardly 2·1 is nitrogenous: in many descriptions of potato the amount of glutenous matter ranges between 0·8 and 1·9 per cent., and the starch does not exceed 9 per cent. Potatoes are also deficient of fat, and therefore they require admixture with nourishing materials. They go well with meat and fish, and are considerably helped with a little dripping or butter; but the great adjunct is milk. In Ireland potatoes and buttermilk are the principal diet, even in times of plenty; and in Holland, when boiled in fat with other vegetables, they form the ordinary repast of the working classes, who rarely taste meat except on Sundays.

Considering the cheapness of potatoes, they are a most economical food. At the price of a halfpenny a pound, as set down in Table No. 4, it costs but two shillings and sixpence a week to provide the carbon and nitrogen required by an adult; but when potatoes are cultivated upon cottage ground, by the labourer's wife and children, as is the practice almost everywhere, as much as seven pounds can be easily obtained for a penny, and then the cost of the weekly diet would be rather less than eightpence. At this price no vegetable food can compete with it.

Potatoes are best cooked in their skins, for the waste is then only 3 per cent., or half an ounce in a pound; whereas if they are peeled first, it is not less than 14 per cent., or from two to three ounces in the pound.

The mealy varieties are more digestible than the close and waxy : in fact, when they are in this state, as is the case with new potatoes, and potatoes late in the season, which have begun to grow, they are best cooked by stewing them. When in good condition, however, they should always be cooked so as to swell out to the fullest extent the starch granules which form the bulk of the tuber ; by this means the cells are burst, and the potato acquires a mealy appearance. If this is not attended to (and great art is required in the matter) the tuber is sodden, waxy, and disagreeable. Most probably this circumstance had something to do with the early prejudice against the potato as an article of diet ; for it is said that the first specimens, which were cultivated in the county of Forfar, about the year 1730, were so badly cooked that when they were eaten they stuck to the teeth like glue, and had a very disagreeable flavour. It was fortunate that a gentleman who was present had tasted the potato properly cooked in Lancashire, and therefore, suspecting the cause of the failure, he ordered them to be returned to the turf ashes, and kept there until they were thoroughly done. By this means the reputation of the plant was established, when it was nearly lost.

All succulent vegetables are endowed with anti-scorbutic powers, but potatoes are especially renowned for this property. As far back as the year 1781 Sir Gilbert Blane, in his work on the "Diseases of the Fleet," alluded to the beneficial action of the potato in scurvy, and from that time to the present its salutary powers have been repeatedly observed. The late Dr. Baly remarked, in his inquiries into the diseases of prisoners, that wherever potatoes were used scurvy was unknown ; and it is the almost universal practice now to carry potatoes, fresh or preserved, in all ocean-going vessels, with the view of preventing scurvy.

Other succulent vegetables in common use, as *turnips*,

parsnips, carrots, artichokes, onions, leeks, asparagus, cauliflower, cabbages, and greens, have, among themselves, nearly the same nutritive value, but they are all much less nutritious than the potato, as will be seen by reference to the Table No. 3; in fact, they do not contain more than from 9 to 17 per cent. of solid matter, and of this only about 1·2 is nitrogenous. They are chiefly valuable for their anti-scorbutic properties, and for their quality of flavouring insipid food, and diluting strong ones. We have a host of such vegetables in the leaves and young shoots of the wild plants of this country, as the *nettles* (*Urtica dioica*, and *Lamium album*), the *sea beet* (*Beta laritima*), the *good King Henry* (*Chenopodium Bonus Henricus*), the *sharlock* (*Sinapis arvensis*), the leaves of *chicory* (*Cichorium Intybus*), of *dandyion* (*Taraxacum officinale*), of *salsify* (*Fragapoga porrifolium*), of the *wild hop* (*Humulus lupulus*), and the young shoots of *Ornithogalum pyrenaicum*, which are collected in spring time in the midland and western counties, and sold as French asparagus.

BANANA and BREAD-FRUIT are also valuable esculent foods, and are largely used in the tropics. The former contains about 27 per cent. of solid matter, of nearly the same nutritive value as rice. About 6½ lbs. of the fresh fruit, or 2 lbs. of the dry meal, with a quarter of a pound of salt meat or fish, is a common allowance for a labourer. The *bread-fruit* is largely eaten by the natives of the Indian Archipelago, of Central America, and of the Islands of the South Sea. There are several varieties of it which come into season at different times. It is very juicy, containing about 80 per cent. of water, and is generally gathered before it is ripe, when the starch is in a mealy condition, and has not undergone change into sugar. The fresh food is cooked, by peeling it, wrapping it in leaves, and baking it between hot stones. It then tastes like sweet bread; but much of the ripe fruit is preserved by peeling it, cutting it into

slices, and packing it very closely in pits in the ground, made water-tight, and lined with banana leaves. After a while it undergoes a sort of fermentation, or, as we should call it from the smell, putrefaction, and the fruit settles into a mass, of the consistence of soft cheese. When it is required for use, it is well kneaded, wrapped in leaves, and baked, like the fresh fruit, between hot stones.

The Spanish BATATA or SWEET POTATO (*Convolvulus Batatas*) is largely used for food in Central America; and attempts were made as early as the middle of the 16th century to cultivate it in England, but it would not bear the cold of our winters. It was introduced here by Sir Francis Drake and Sir John Hawkins, who had tasted it in tropical America, and a good crop of it was grown at Formby, in Lancashire. The tubers contain about 32 per cent. of solid matter—of which 16 are starch, 10 sugar, 1.5 albumen, 1.1 gum, 0.3 fat, and 2.9 mineral matter. The root of the YUCCA (*Manihot Utileissima*), when well boiled, is also a good substitute for potato, and is more succulent and digestible than the YAM (*Dioscorea alata*). *Cassava bread* is made from the root of the Manihot, by first expressing the juice, then grinding into a coarse meal, and baking in the form of cakes upon thin iron plates. When steeped in oil, and flavoured with cayenne, and lightly broiled upon a gridiron, they are not unpalatable.

RIPE FRUITS, as apples, pears, peaches, pine-apples, oranges, &c., are not of much nutritive value, for they rarely contain above 13 per cent. of solid matter, and this is of no more value than so much rice, but they have agreeable flavours, and serve the purpose of anti-scorbutic drinks. Fruits which contain much sugar, as *dates*, *figs*, and *grapes* or *raisins*, are very nutritious, especially when they are dried. In tropical countries they are largely used for food: the date, for example, is next to bread the staple food of the Arab. New dates (called

ruteb) lasts him for two months in the summer, and during the rest of the year he uses the hard pressed fruit (called *adjone*), of which there are many varieties.

MARINE ALGÆ.—Everywhere along our coasts there is abundance of comparatively nutritious food, which may, by a little management, be made palatable. I allude to our *sea-weeds*; and this Society has distinguished itself by its efforts to utilise this stock of now almost profitless food. Judging from the analyses of Dr. Davy and Dr. Apjohn, of Dublin, it would seem that sea-weeds, in a moderately dry condition, contain from 18 to 26 per cent. of water; and that the nitrogenous constituents amount to from $9\frac{1}{2}$ to 15 per cent., while the starchy matter and sugar average about 66 per cent. These results place sea-weeds among the most nutritious of vegetable substances; in fact they are richer in nitrogenous matter than oatmeal or Indian corn.

The varieties of sea-weed at present used are the following:—

Porphyra laciniata and *vulgaris*, called *laver* in England, *stoke* in Ireland, and *slouk* in Scotland.

Clondrus crispus, called *carrageen* or *Irish-moss*, and also *pearl-moss* and *sea-moss*.

Laminaria digitata, known as *sea girdle* in England, *tangle* in Scotland, and *red ware* in the Orkneys; and *laminaria saccharina*, *alaria esculenta* or *bladder-lock*, called also *hen-ware* and *honey-ware* by the Scotch.

Ulva latissima or *green laver*.—*Rhodomenia palmata*, or *dulse* of Scotland.—These, with many others, are eaten by the coast inhabitants of this country and the Continent. In some parts of Scotland and Ireland they form a considerable portion of the diet of the poor.

To prepare them for food, they should first be steeped in water to remove saline matter; and in some cases a little carbonate of soda added to the water will remove the bitterness. They are then stewed in water or milk until they are tender and mucilaginous; and they are

best flavoured with pepper and vinegar. Under the name of *marine sauce*, the lavers were once a luxury in London.

Several LICHENS are used as food in Arctic regions, where, during the greater part of the year no other food is procurable. *Iceland Moss* (*Cetraria Islandica*) and *Rein-deer Moss*, (*Cladonia rangiferina*) are examples of this. The former contains as much as from 27 to 31 per cent. of starchy matter, and the latter about 5 per cent. Two species of lichen—the *Gyrophora proboscidea* and *Gyrophora crosa* furnished the *Tripe de Roche* of our Arctic navigators, which was their chief food in time of scarcity. Professor Stanberg, of Sweden, has recently devoted much attention to the nutritive properties of Lichens, and has shown, that when they are deprived of their bitter principles, by soaking in an alkaline lye, and then in cold water, they may be made to yield a palatable food. This is especially so with Iceland moss, which in conjunction with rye-meal, forms good and nutritious bread.

As to the last of the vegetable foods—namely, the FUNGI or MUSHROOMS—I have but little to say; for although the edible varieties are highly nutritious, yet they can never become an important article of diet. Most of them are employed at the present time as flavouring agents; and among these are the *common mushroom* for ketchup, the *morel* for gravies, and the *truffle* for turkeys and the livers of geese (*Pâté de foie gras*).

SUGAR and TREACLE.—Both of these are very generally consumed on account of their flavouring and fattening qualities. Dr. Edward Smith found that 98 per cent. of indoor operatives partook of sugar, to the extent of $7\frac{1}{2}$ ozs. per adult weekly. 96 per cent. of Scotch labourers use it, and 80 per cent. of Irish. In Wales, also, it is commonly used to an average extent of 6 ozs. per adult weekly; but there is a marked difference in the rate of consumption in the northern and southern portions of the country. In North Wales, for example, the average

amount per head is $11\frac{1}{4}$ ozs.; whereas, in South Wales, it is only 3 ozs., and the principal use of it is to sweeten tea. Statistical inquiries have shown, that about 1,142,000 tons of sugar are annually consumed by the Anglo-Saxon populations of England and America—averaging 41·4 lbs. per head; and that the Latin race, including the inhabitants of France, Italy, Spain, Belgium, Portugal, and Switzerland, consume about 506,000 tons per annum, or 12·34 lbs. per head; whilst the Teutonic race of the Zollverein, Austria, Holland, the Hanse towns, and Denmark, consume about 262,000 tons per annum, or 7·3 lbs. per head. Lastly, the poor of Russia, Poland, Turkey, and Greece, consume only about 125,000 tons a year, or only 3·3 lbs. per head.

TREACLE has more flavour than sugar, and it is also cheaper. It is, therefore, more largely employed; and that description of it properly called *molasses*, which is the draining from the raw or unrefined sugar—treacle being the drainings from refined sugar—is preferred on account of its stronger flavour, and is most usually sold for treacle. They go well with all descriptions of farinaceous food, as porridge, pudding, dumpling, and bread.

Sugar contains from 4 to 10 per cent. of moisture, and treacle about 23. The rest is carbonaceous matter, without nitrogen. They are, therefore, heat-producing and fattening agents, and their power, in these respects, is about the same as with starch. Whether they can produce disease when used in excess is a matter of doubt; but Dr. Richardson has asserted that they cause blindness by creating opacity of the lens (*cataract*).

ANIMAL FOODS.

First on the list of these is MILK, a liquid which contains all the elements of food required by the very young, and is therefore regarded as the type or standard of food.

In some countries, as in Switzerland, it is the chief diet of the peasantry, and everywhere, if easily obtained, it

is largely consumed. 76 per cent. of the labouring classes of England make use of it; 83 per cent. take it as buttermilk; and 53 per cent. as skimmed milk. In Wales, the average consumption of it by farm labourers is $4\frac{1}{4}$ pints per adult weekly—South Wales averaging only 3 pints, while in North Wales it is $7\frac{1}{2}$. In Scotland the consumption among the labouring classes is still larger, for it amounts to $6\frac{1}{4}$ pints per head weekly, and in Ireland it reaches $6\frac{3}{4}$ pints. Those who take least of it are the poor in-door operatives of London, as the weavers of Spitalfields, who use only about 7·6 ozs. per head weekly, while those of Bethnal Green take only a fraction above $1\frac{1}{2}$ ozs. per head. In Sweden and Denmark, sheep's milk is used; in Switzerland, goat's milk; in Lapland, reindeer's milk; and in Tartary, mare's milk.

When examined under the microscope, milk is found to consist of myriads of little globules of butter floating in a clear liquid. On standing for a few hours the oily particles rise to the surface and form cream, the proportion of which is the test of quality, in cow's milk it should average about 12 per cent. by volume. Cows' milk is heavier than water in the proportion of from 1030 or 1032 to 1,000. Asses' milk is the lightest, for its gravity is only about 1019; then comes human milk, 1020; and lastly, goats' and ewes' milk, which is the heaviest of all, from 1035 to 1042. The average composition of the milk of different animals is, according to M.M. Henri and Chevalier, as follows.

TABLE VI.—*Composition of Milk of different Animals.*

	Asses Milk.	Woman's Milk.	Cows' Milk.	Goats' Milk.	Ewes' Milk.
Caseine	1·82	1·52	4·48	4·02	4·50
Butter	1·11	3·55	3·13	3·32	4·20
Sugar of Milk	6·08	6·50	4·77	5·28	5·00
Various salts	0·34	0·45	0·60	0·58	0·68
Total Solids	9·35	12·02	12·98	13·20	14·38
Water	90·65	87·98	87·02	86·80	85·62
Total	100·00	100·00	100·00	100·00	100·00

The quality of milk varies with the breed of the animal, the nature of its food, and the time of milking, for, in the case of cows' milk, afternoon milk is always richer than morning, and the last drawn than the first. taking, however, the average of a large number of samples, it may be said that cows' milk contains about 12.7 per cent. of solid matter, 3.6 of which are casein, 4.7 sugar, 3.6 butter, and 0.8 saline matter. The relation of nitrogenous to carbonaceous is 1 to 2.3; but as fat is $2\frac{1}{2}$ times more powerful than starch, the relation may be said to be as 1 to 3.8.

When milk is heated to the boiling temperature, the casein is coagulated to some extent; and if the milk has stood before it is heated, so that the cream may rise, the coagulum includes it, and makes the so-called *clotted cream* of Devonshire and Cornwall.

Acids also coagulate the casein, and produce a *curd*, as when milk becomes sour, and in the making of cheese, and *curds and whey*. In some countries milk is allowed to curdle before it is drunk. This is the practice in Central Africa, the natives of which never make use of new milk without causing it to become sour by putting it into vessels charged with the remains of former operations. They call the drink *Amasi*, and they consider it to be far more wholesome than fresh milk.

CREAM is rich in butter, as will be seen by reference to Table No. 3. It contains 34 per cent. of solid matter, 26.7 of which are butter, and its gravity is about 1,013. A quart of good cream will generally yield from 13 oz. to 15 oz. of commercial butter. In good seasons, when the cows are fed on rich pasture land, a quart of cream will often yield about 16 oz. of butter, and if they are fed on oil cake, as much as from 22 oz. to 24 oz. are obtained.

SKIM-MILK is the milk from which the cream has been removed. It contains only about half as much butter as new milk, or even less, and its gravity is about 1037. In all other respects it is similar to new milk.

BUTTER-MILK is the residue of the milk or cream from which the butter has been removed by churning. It is still poorer in fat than skim-milk, containing, in fact, only about half as much. Unless it is very fresh, it is generally a little acid, and frequently the acidity has gone so far as to set the milk into a kind of jelly.

The WHEY of milk is the opalescent liquor from which the curd has been removed in making cheese. Although not highly nutritious, it still holds a little casein in solution, as well as the sugar and saline matter of the milk. It is rarely used as food even by the poor, but it is given to pigs. In Switzerland, however, it is considered to have medicinal virtues, especially for the cure of chronic disorders of the abdominal organs, and the treatment, which is somewhat fashionable, goes by the name of *cure de petit lait*. There is a popular notion, that the whey of milk is sudorific, and hence we have our *wine whey*, *cream of tartar whey*, *alum whey*, *tamarind whey*, &c., when the milk has been curdled by these several substances.

CHEESE is the coagulated product of milk, obtained by the addition of rennet or a little vinegar, and its richness depends upon the quality of the milk, and the proportion of cream or butter contained therein; when, for example, the cream itself is coagulated it makes *cream cheese*, which will hardly bear keeping, but must be eaten fresh. It contains about half its weight of butter, and a fifth of its weight only of curd.

When cream is added to new milk, and the mixture is curdled, it forms very rich cheese, as *Double Gloucester* and *Stilton*.

When new milk alone is used the cheese is less rich, but still of high quality, as *Cheddar*.

When an eighth or a tenth of the cream has been taken off, it produces the quality of cheese which is most sought after, as *Single Gloucester*, *Chester*, *American*, &c.

And when all the cream has been removed, and the skim-milk is curdled, it forms the poor cheese of *Holland, Friesland, Suffolk, Somersetshire, and South Wales.*

At first every variety of cheese is soft and comparatively tasteless, but by keeping they undergo change, and develop their flavours when they are said to be ripe. The change is dependant upon the growth of fungi, and the formation of pungent fatty acids.

Analyses of two of the most important of them are shown on Table No. 3, and it will be noticed that they contain from 56 to 64 per cent. of solid matter, about half of which is curd. In skim-milk cheese the curd amounts to 44·8 per cent., and the fat to only 6·3; whereas, in Cheddar, the curd is only 28·4 per cent., and the fat, 31·1. In nutritive power, therefore, especially in nitrogenous matter, cheese ranks high, and is a valuable article of diet; but there is a limit to its digestibility, and hence it cannot be taken in large quantity. Considering its price, also, it is hardly so profitable as many other foods; although, where good skim-milk cheese can be purchased at from 2½d. to 3d. a pound, it forms, in small quantities at a time, a good adjunct to bread.

MEAT.—There is hardly a class of individuals, however poor, who do not make a strong effort to obtain meat. It would seem, therefore, to be a necessary article of diet. In this metropolis the indoor operatives eat it to the extent of 14·8 ozs. per adult weekly; 70 per cent. of English farm labourers consume it to the extent of 16 ozs. per man weekly; 60 per cent. of the Scotch; 30 of the Welsh; and 20 of the Irish also eat it. The Scotch, probably, have a larger allowance than the English, considering that braxy-mutton is the perquisite of the Scotch labourer; but the Welsh have only an average amount of 2½ ozs. per adult weekly; and the Irish allowance is still less.

It is difficult to obtain accurate returns of the quantity

of meat consumed in London; but if the computation of Dr. Wynter is correct, it is not less than $30\frac{3}{4}$ ozs. per head, weekly, or about $4\frac{1}{2}$ ozs. per day for every man, woman, and child. In Paris, according to M. Armand Husson, who had carefully collected the *octroi* returns, it is rather more than 49 ozs. per head, weekly, or just 7 ozs. a day. It would seem from this we are not such large meat eaters as the French; although there are physiological reasons for believing that we consume more animal food than any other European nation. Looking at the relative proportions of urea in the secretions of Frenchmen, Germans, and Englishmen, Lehmann declares that they are not to be accounted for but by differences in diet—the Frenchman using least nitrogenous matter, and the Englishman most. He says, indeed, that any given number of Londoners, eat six times as much animal food as an equal number of Parisians, and this, he says, is proved by statistics.

About 4 per cent. of the meat consumed in England is imported, but not less than 20 per cent. of that made use of in London comes from abroad, and the quantity is annually increasing.

BUTCHERS' MEAT differs very much in nutritive value according to the proportions of fat and lean; and there is a strong prejudice in favour of beef as the strongest kind of meat. In reality, however, the lean of all meat is of nearly the same nutritive power, provided it is digested; but in this respect there are large differences. The flavour also varies with the nature of the animal, and with its mode of feeding. Pampas-pig, and indeed most wild swine, are horribly rank, but by proper feeding they become delicious. In store animals the proportion of lean is always greater than the fat, and the solid matter does not amount to more than 28 or 29 per cent.; not so, however, in fat animals, for in them the fat is largely in excess of the lean, and the solid matters make up about half the total weight. The tendency

TABLE VII.—Percentage Proportions and Nutritive Value of the Carcass and Offal.

in fact, of the fattening process is to substitute fat for water in the carcass ; and the quality of the meat depends on the intimate intermixture of fat with the muscular tissue. All animals are not alike in their method of depositing fat, for some put it upon the surface of the body, and others accumulate it among the viscera. The art of breeding and feeding stock is to overcome both of these tendencies, and, at the same time, to produce a fat which will not melt or boil away in cooking. Oily foods have always a tendency to make soft fat, which which will not bear cooking.

The average proportions of fat and lean in the offal and carcasses of animals are shown in Table No. 7 ; and Table No. 3 exhibits the proportion of the principal nutritive constituents in different kinds of meat. Under the head of albumen, &c., is included the gelatinous tissues, which are always more abundant in young animals than in old. In veal, for example, it amounts to about 7.5 per cent., and in beef and mutton to about 6 per cent. Lean meat is evidently deficient of carbonaceous matter, and this is best supplied in bread or potato ; but in fat meat, considering that the nutritive power of fat is twice and a half as great as that of starch or sugar, the carbonaceous matter is often in excess of the right proportion ; it is remarkably so in pork, which will bear dilution with the flesh of rabbit, poultry, and veal.

The amount of bone in meat varies : it is rarely less than 8 per cent. In the neck and brisket of beef it is about 10 per cent., and in shins and legs of beef it amounts to one-third, or even half the total weight. The most economical parts are the round and thick flank, then the brisket and sticking-piece, and lastly the leg. In the case of mutton and pork the leg is most profitable, and then the shoulder.

HORSE-FLESH is hardly known in this country, except as canine food ; but on the continent, and especially in Germany, Belgium, and Switzerland, it is regularly sold

in the public markets, and is considered by many persons superior to beef. Possibly we have often eaten it on the Continent without knowing it. A *Châteaubriand*, or double beef-steak of Paris, is said to be best of horse-flesh; and no doubt the frequenters of the *restaurants* of Paris have unwittingly acquired a fondness for it, and have relished it as good beef. A story is told by a writer in the *Saturday Review* of a Frenchman who blandly remonstrated with an Englishman for his scorn of French beef. "I have," he said, "been two times in England, but I navère find the bif supérieur to ours. I find it vary conveenient that they bring it you on little pieces of stick for one penny, but I do not find the bif supérieur," "Good heavens!" cried the Englishman, red with astonishment, "you have been eating cat's meat." To be serious, however, I do not see why the flesh of healthy horses should not be used as human food. It has, indeed, many powerful advocates, among whom is the great naturalist, Geoffroy St. Hilaire; and attempts have been made in this country to naturalize it, as it were, through the instrumentality of French cookery, but in vain, for our prejudices are strongly against it. In times of scarcity, however, horse-flesh has often been found a very acceptable food. During the siege of Paris, for example, in 1870, it was eagerly purchased, and it soon became an important article of diet. At first its price was about 6½d. per lb. for the best parts, but as it became scarcer it rose to nearly 5s. a lb. Under ordinary circumstances as many as 3,000 horses are slaughtered annually in France for human food; but during the four autumn months of 1870 there were not less than 30,000 horses consumed in Paris. Mules and asses were in like manner pressed into the public service, and at last the scarcity of animal food was so great that dogs, cats, and even rats were made use of. A writer in the *Food Journal* for December, 1870, says that cats were publicly sold at six francs each, and that dogs were

quoted at four francs the half animal. At the house of a *gourmet* the bill of fare on one occasion was *filet de cheval roti, escaloppes d'anon, plum-pudding, au graisse de bœuf*. But why should this be so marvellous when we know that in China certain breeds of cats, dogs, and rats are regularly fattened for the public markets, and are the choice food of the epicure. According to Hippocrates, puppies, as well as the flesh of the horse and ass, were eaten by the Greeks; and the Arabs and the Patagonians eat the horse, ass, and camel.

VENISON and the dark flesh of other wild animals differs from butchers' meat in the circumstance that it is leaner, and that it contains more blood; but its nutritive power, when properly cooked, is not inferior to that of beef or mutton, and it is always more digestible.

THE OFFAL OF MEAT constitutes about one-third of the entire weight of the slaughtered animal. (See Table 7.) It consists of the *blood*, the *head* and its contents (the *tongue* and *brain*), the *heart* and *lungs*, the *abdominal viscera*—as the *diaphragm*, the *liver*, *spleen*, *pancreas*, *stomach*, *intestines* and *reproductive organs*, the *feet*, *tail*, and *skin*. In the case of the pig, the skin and head are parts of the carcass.

Nearly all these, when properly treated, are good for food. The *blood* of the pig is mixed with groats and fat, and converted into *black pudding*, which contains about 11 per cent. of nitrogenous matter. The *stomach* of the bullock is cleaned and boiled for *tripe*, which contains 13 per cent. of albumen and 16 of fat. The *heart*, *lungs*, and *pancreas*, which constitute about 7 per cent. of the live weight of animals, are as nutritious as lean meat. The *head*, especially of the ox, makes good soup; but it requires long boiling to extract the nutriment. Boiled for eight or nine hours it will yield one-fourth of its weight of gelatine; besides which an ox-cheek will furnish about four pounds of good meat. *Bones* also contain much fat and nitrogenous matter, which they give up when broken

small and boiled for many hours. Six pounds of bones are equal to one of meat for nitrogen, and to nearly two pounds of meat for carbon.

BACON differs from fresh meat in the relatively large amount of fat and small proportion of water. It is an almost universal article of diet among the labouring classes. 74 per cent. of farm-servants use it to the extent of from $\frac{1}{4}$ lb. to 2 lbs. per adult weekly. 69 per cent. of the Scotch use it, and 40 per cent. of the Irish. It is preferred to butchers' meat for many reasons—as that it goes further, especially with children, who do not generally like fat; it has more relish; it is easily cooked, and suffers less waste in cooking; besides which it is easily kept, and is always handy. Preference is nearly always given to English bacon, notwithstanding that it is double the price of American, for the flavour is better, and it does not boil away in cooking. No doubt the inferiority of American bacon is due to the method of feeding the pigs, for they run wild and eat large quantities of acorns and oily nuts. Good bacon should not lose more than from 10 to 15 per cent. in cooking.

The nutritive values of both green and dried bacon are shown in Table No. 3 and Table No. 4. Their peculiarity is the large amount of carbonaceous matter they contain as compared with nitrogenous. Calculated as starch, it is as 21 or 24 to 1. Hence it is that it improves the value of substances which are rich in nitrogen, as eggs, veal, poultry, beans and peas.

POULTRY and the WHITE MEAT OF RABBITS are not of themselves very nourishing. They contain too much nitrogenous matter and too little fat. In the case of aquatic birds, as the *goose* and *duck*, the fat is more abundant; but it contains certain flavouring matters which are not easy of digestion. The darker flesh of game is also somewhat indigestible, and requires management in its culinary treatment.

FISH is not a favourite article of diet with the labour-

ing classes, unless it is salted or smoked, and then it is chiefly used for its flavouring qualities. There is a prejudice that it has no nutritive strength, and it arises, perhaps, from the circumstance that it does not easily satisfy hunger, and is quickly digested, but the inhabitants of our coasts use it largely as food. In Holland, Sweden, and Russia, where the poor rarely taste meat, the staple article of diet, with coarse bread, is dry, salted fish, and it is found to be sufficiently nutritious.

The quantity of fish supplied to Billingsgate Market during the year is considerable, amounting to about 95,373 tons annually, and of this about 38,000 tons come by rail, and 57,000 tons by water. About 800 tons of live eels are brought from Holland, and 2,300 tons of mackerel, and 1,500 tons of herrings from Norway. Beside all these there is a very large delivery of fish to Columbia Market.

The nutritive values of the white varieties of fish, as *whiting*, *cod*, *haddock*, *sole*, *plaice*, *flounder*, and *turbot*, are shown in the Tables No. 3 and 4, and it will be remarked that they contain only about 22 per cent. of solid matter—18 of which is nitrogenous. They want butter, therefore, to increase their nutritive value.

Mackerel, *eels*, *salmon*, and *trout*, are, however, richer in fat, for the former contains about 7 per cent., and the latter 6, while the oily matter of eels amounts to nearly 14 per cent. The same is the case with the *sprat*, the *herring*, and the *pilchard*, and with most of our fresh-water fish, especially the *lamprey*, which, at one time, was considered a great luxury. Every one has heard of the fatal surfeit of Henry the First of England, who, when at Rouen, in December, 1135, on his way home, "desired gretely after a day's hunting to ete a lampray; for that mete," says Capgrave, who described his illness, "loved he well, and evir it did him harme." According to Pennant it was so much prized, that annually it had been an old custom at Gloucester

to present His Majesty with a lamprèy pie; and yet, although these fish are caught in great abundance in the Thames and the Severn from October to March, yet they are rarely eaten, but are sent to Holland as bait for cod and turbot.

All fish are in their best condition at the time of the ripening of the milt and roe, for not only are they fatter at that time, but when cooked they have a better flavour, and the flesh is solid and opaque. On the other hand, when they are out of condition the flesh is semi-gelatinous and watery. Most of our fresh-water fish, in fact, are very deficient of flavour, and are more or less woolly in their texture. They, therefore, require good treatment by the cook to render them palatable. In olden times it was the custom to boil them in wine, and to serve them with savoury sauces; but to our fancy they are best broiled directly they are taken from the water. The flesh of the *sturgeon* and of the *pike*, is firmer than that of other fish, and approaches veal in consistence.

SHELL-FISH of all descriptions have nearly the same nutritive values. They contain about thirteen parts of solid matter in the hundred, and this has the composition of white fish. The digestibility varies—*mussels*, *limpets*, and *whelks* being rather hard of digestion, while *scallops*, *cockles*, *periwinkles*, *lobsters*, and *crabs* are, perhaps, a little more easily digested, and *oysters* still more so. None of them, however, are suited for delicate stomachs, although the poorer inhabitants on the coast eat them freely. *Vineyard snails* on the Continent, and even *slugs* in China, have a reputation for delicacy and nutritive power.

REPTILES furnish but few examples of articles that are used as food. The *green turtle* of the West Indian Islands and the Southern Coast of America, and the *edible frog* of France and Austria, are the best illustrations; but besides these the *land tortoise* is eaten by the

inhabitants of Italy and the Levant, and the *iguana* by the natives of tropical America. The flesh of all of them is delicate and full of gelatinous matter.

EGGS contain about 26 per cent. of solid matter, 14 of which is nitrogenous, and $10\frac{1}{2}$ carbonaceous or fatty. The *yolk* is the part which contains the fat, for it there amounts to 31 per cent., while the *white* of the egg, which is entirely free from fat, is the richest in nitrogen—the albumen amounting to 20·4 per cent. Altogether, however, eggs are very deficient of carbonaceous matter. For, calculated as starch, it is only in the proportion of 1·75 to 1 of nitrogenous. Hence it is that eggs consort well with oil in salads, with fat bacon, and with all kinds of farinaceous matters in puddings.

FAT of some description, as *butter*, *lard*, *suet*, or *dripping*, is universally consumed. In many cases it exists in sufficient quantity in the food, as in bacon and fat meat, but when this is not the case, it is invariably supplied from some other source. 99 per cent. of farm labourers use fat of some sort—butter or dripping, to the extent of $5\frac{1}{2}$ ozs. weekly per adult. It is difficult to say how much is really required by the human system, but looking at the proportion in milk, which we may regard as model food, it would seem to be not less than 28 per cent. of the dry, solid matter of food. The fats in common use contain about 80 per cent. of real fatty matter, the rest being water and salt, and although butter is the fat ordinarily purchased, yet dripping is equally valuable, and so are other fats of even a commoner quality. During the siege of Paris, when it became necessary to utilise every available article of food, the fat of horses was largely employed instead of butter, and, according to Payen, it was superior in all respects to the fat of oxen, as it never had the objectionable tallow-like smell which the latter acquires whenever it has once been heated above the temperature of boiling water; its odour, in fact, was rather agreeable than otherwise for it was like ripe apples; besides

which the fat of the soft tissues was more solid than that of beef, requiring a temperature of 61° to set, whereas the latter is fluid at 40° of Fahrenheit. The fat of bones, however, is always very soft. The researches of Dubrunfaut have shown that the bad odour of all fats may be removed by passing steam through them, and then they may be utilized for food. - The vegetable fats of the tropics are also good dietetical agents. *Cocoa* and *chocolate* owe their chief value as foods to the fat they contain. Cocoa is composed of 50 per cent. of solid fat, called *cocoa butter*, and chocolate is a sweet preparation of it.

Of liquid articles of diet, *beer* and *porter* stand first in nutritive value. They contain about 9 per cent. of solid matter, $8\frac{3}{4}$ of which are sugar and gum. Their nutritive power is not, therefore, great; and yet, according to Liebig, whenever beer and porter are not used in a household, there is always a larger consumption of bread.

The nutritive functions of *tea* and *coffee* are not at all understood; for although they are largely used, and, as it were, from an instinctive craving, yet their actual nourishing power is insignificant. I shall, however, deal with this subject hereafter, when I come to the functions of food.

The last constituent of food we have to consider is SALINE MATTER. Broadly, it may be stated that we require *phosphates* and *sulphates* of *potash*, *lime*, and *magnesia*, and that we also want a still larger proportion of *common salt*. In most cases the phosphates and sulphates are in sufficient quantity in ordinary foods; in fact, Mr. Lawes found in his experiments on the fattening of animals that for every single part of saline matter retained in the system of the pig, there were from 14 to 15 parts in the food; not that the whole of this was lost, for probably it performed important functions in the process of assimilation and secretion. Com-

mon salt, however, is not present in the food to any large extent, and therefore it must be added to it.

And now, before leaving this part of the subject, let us pause to consider the vast machinery which is in operation for the supply of food to this metropolis. At the present time over three millions of people have to be fed daily; and yet so regular is the supply, that no one considers even the possibility of its failing. On the other hand, there is no redundancy; and not only does this supply regularly reach the metropolis, but it is distributed to our very doors. About 300 tons of fish; over 4,000 sheep; nearly 700 oxen; about 90 calves; 4,000 pigs, including bacon, and hams; not less than 5,000 fowls, and other kinds of poultry; besides a million or so of oysters; and eggs innumerable, with flour enough to make nearly a million quartern loaves; and vegetables, butter, and beer in proportion, are daily brought to this city. "Imagine," as Archbishop Whately says, "a Head Commissioner entrusted with the office of furnishing all these things regularly to the people. How would he succeed?" And yet all this goes on with the regularity and precision of a machine—without Government or even municipal interference, but simply through the magical power and unfettered action of free-trade.

Note.—Taking one year with another the consumption of wheat and wheat flour in the United Kingdom is assumed to be at the rate of $5\frac{1}{2}$ bushels per head, and of this quantity two-thirds are produced at home, and one-third is imported. In the case of meat, about four per cent. is supplied from abroad, and the quantity is fast increasing. During the year 1866 only about £320 worth of preserved meat was imported from Australia, whereas in 1870, it amounted to £204,000, and in 1871, it exceeded half a million sterling.

LECTURE II.

COMPARATIVE DIGESTIBILITY OF FOODS—FUNCTIONS OF DIFFERENT FOODS.

DIGESTION.

THE phenomena of digestion are altogether of a physical and chemical nature; there is nothing whatever of a vital quality about them; for the comminuted food is brought successively under the influence of special solvents furnished by the saliva, the gastric juice, the pancreatic fluid, the biliary secretion, and the intestinal mucus; all of which are associated with a large volume of water. Digestion, indeed, as Berzelius remarked, is a true process of rinsing—the amount of fluid secreted into the alimentary canal, and again absorbed from it, being, according to the researches of Bernard, Bidder, and Schmidt, not less than three gallons in the twenty-four hours. The following, in fact, are the daily proportions of the several secretions and their solid constituents:—

TABLE VIII.

Amounts of Digestive Fluids Secreted Daily, and the Proportions of their chief Constituents.

	lbs.	Solid Matter. grs.	Active Principles. grs.
Saliva	3.54	231	107 of ptyalin.
Gastric Juice	14.11	2690	316 of pepsin.
Pancreatic fluid	8.82	6172	773 of pancreatin.
Bile	3.54	1233	1073 { of organic ferment.
Intestinal mucus	0.47	46	28 { of organic ferment.

Total	30.48	10,372	2297 } of special solvents.

All of which, by their special solutive actions on the several constituents of food, rob it of its nutritive principles, and carry them into circulation.

Each of the fluids so largely secreted into the alimentary canal, has its special functions.

The SALIVA, which is a secretion from many glands opening into the mouth, is a thin, glairy liquid, of slight alkaline reaction, except while fasting; and containing about 1 per cent. of solid matter—half of which is a peculiar organic body, called *ptyalin*, and the rest is composed of chloride and phosphate of sodium, with a little carbonate and sulphocyanide. Ptyalin is a nitrogenous substance, of the nature of diastase—the ferment which in the vegetable converts starch into sugar, and hence it has been called *animal diastase* by Mialhe, who attaches great importance to it as the principal agent concerned in the digestion of starchy foods—one part of ptyalin, according to him, being capable of converting 8,000 parts of insoluble starch into soluble glucose. Saliva has

no chemical action on fat, or fibrin, or albuminous bodies—its real functions being to lubricate the food for deglutition, to carry oxygen into the stomach, and, above all, to furnish a solvent for starch and tender cellulose. Those animals, therefore, which feed chiefly on woody matters, as the beaver, and most of the rodents, have large salivary glands, and provision is also made for prolonged contact of the secretion with the vegetable tissue, so as to ensure its transformation.

An artificial saliva, may be obtained from seeds which have sprouted or fermented, and in which the diastase is abundant. *Liebig's extract of meat* is an example of this; and Mr. Morson has taken advantage of the discovery of M. Mege Mouries, that the inner layer of bran contains a nitrogenous digestive principle called *cerealin*, of the nature of diastase, and has extracted it, and consolidated it with sugar, in a preparation which he has named *saccharated wheat phosphates*. Both of these are aids to the digestion of farinaceous matters, and when properly applied are useful in the treatment of infants' food, as will be hereafter described.

GASTRIC JUICE is a secretion from the entire surface of the stomach. It is a transparent liquid, of a pale, yellow colour, and of a saline and acid taste. It is much heavier than water, (sp. gr. about 1020), and it contains from 2 to 3 per cent. of solid matter—about 1·7 of which is a remarkable nitrogenous organic body, called by Schwann, its discoverer, *pepsin*. Its peculiarity is that, in the presence of an acid, it converts almost every description of albuminous and fibrinous matter into a soluble form of albumen, called by Lehmann *peptone*, and by Mialhe *albuminose*, which differs from common albumen in many particulars—it is, for example, more liquid; it is not coagulated by heat, nor by weak spirits, nor by acids, nor by most mineral salts; it is not very prone to decomposition; and it is capable of *dialysis*, that is, of transudation through animal membrane, and,

therefore, of absorption, which albumen is not. The digestive power of pepsin is very great, for Wasmann found that an acid liquid containing only one part of it in 60,000 of the solution—that is, about a grain in a gallon, was capable of dissolving meat; and Lehmann ascertained that 100 parts of the gastric juice of a dog would digest 5 parts of coagulated albumen.

The nature of the free acid in gastric juice is somewhat doubtful; Lehmann, who has frequently examined it, says it is lactic acid, but Schwann asserts that he has often found free hydrochloric acid. It is very possible that the chlorides contained in the stomach are partially decomposed by lactic acid, during the process of analysis, and thus the hydrochloric acid may, to some extent, be accounted for, but the evidence is strongly in support of the opinion that this acid, as well as lactic, butyric, and phosphoric, or acid phosphates, are present in the fresh gastric juice. It so happens, however, that when the acids are in too large excess, the digestive action is abnormal, and the same is the case when they are deficient; Lehmann states that the best proportion is when 100 parts of the gastric juice is just neutralized with 1·27 of potash.

Considering the importance of pepsin as a digestive agent, the preparation of it for dietetical purposes is largely practised. In France it is obtained from the stomach of the pig by carefully washing it, and scraping off the soft mucous membrane, then rubbing it down with a little water, filtering, precipitating the foreign matters, with acetate of lead, again filtering, and finally precipitating the excess of lead with sulphuretted hydrogen, after which it is allowed to stand, or it is warmed, to get rid of excess of sulphuretted hydrogen; it is then filtered once more, and after carefully evaporating to the consistence of syrup, it is consolidated with dry starch. In this country it is prepared from the stomach of the sheep as well as of the pig, and we have our

pepsina ovis and *pepsina porci*; besides which, the use of lead and sulphuretted hydrogen is avoided by precipitating the foreign matter with alcohol—pepsin being soluble in weak spirit. The process recommended by Dr. Lionel Beale, in 1858, was to press the mucous from the glands of the pig's stomach, and then to dry it upon glass; after which it is to be powdered, and preserved in stoppered bottles. It keeps well for years, and is always ready for use—a grain of it being sufficient to dissolve 800 grains of coagulated white of egg. Distilled water dissolves it, and, when filtered, yields a clear, colourless solution. On the lecture table are specimens of Boudault's pepsin as well as those of Mr. Morson, of London, Messrs. Turner and Co., and Mr. Claridge, of Warwick, all of which are in operation, showing their relative digestive powers on animal fibrin.

The pepsin preparations on the table contain varying proportions of starch, as from 20 to 50 per cent.; but the digestive power of any specimen may be easily tested by putting a dose of the preparation into a small bottle with half an ounce of water, acidulating with 20 drops of hydrochloric acid, and then adding half a drachm of hard-boiled egg chopped small, or the same weight of lean meat, or 120 grains of the fibrin of blood. On standing in a warm place at a temperature of from 100° to 110° of Fahrenheit the digestion should be complete in two hours. Tried in this manner, Dr. Pavy found, some time ago, that nearly all the preparations in common use were inert; not so, however, at the present time, for, as you will notice, digestion is proceeding rapidly.

I am told that the strongest pepsin is obtained from young healthy pigs kept hungry, and excited by savoury food which they are not allowed to eat; and then while the influence of the expected meal is strong upon them, and the secretions of the stomach are being poured out in large quantity, the animals are killed.

Pepsin, like diastase, is rendered inert by a temperature of from 120° to 130° F.; and, therefore, very hot drinks after a meal are hurtful.

PANCREATIC FLUID is a secretion from the pancreas or sweet-bread. Until recently its true digestive functions were not well determined. It is a colourless fluid of a gravity of 1008 or 1009. Like the saliva, it is generally a little alkaline, and it contains about 1·3 per cent. of solid matter, one-eighth of which is a nitrogenous organic substance of the nature of ptyalin or diastase, and is called *pancreatin*.

More than twenty years ago, Bernard proved what Valentin had long before suspected, that the pancreatic fluid was concerned in the digestion of fatty matters; but he fell into error in supposing that its action was to saponify the fat and to set glycerin free. Here is a specimen of glycerin and of lead-soap obtained from fat upon which the pancreatic fluid had previously acted showing that saponification had not been effected. The true action of the pancreatic secretion is evidently to break up the large granules, crystals, and globules of oil and fat, into myriads of minute particles of from 1-3,000 to 1-15,000 of an inch in diameter. In this way the fat is emulsified and converted into a milky liquid, which mixes freely with water, and passes through the tissues of the intestines into the lacteals. We are indebted for this knowledge to Dr. Dobell, who had long been of opinion that the secretions of the pancreas were important in certain diseases, and required elucidation. With the assistance of Mr. Julius Schweitzer, of Brighton, the then manager of the laboratory of Messrs. Savory and Moore, he made a large series of investigations into the properties of the pancreatic secretion, and he found that when the fresh pancreas, (and best of the pig) is rubbed down in a mortar with twice its weight of hog's lard, it rapidly emulsifies it; and on adding about four or five times the bulk of water, and straining through muslin, there is

obtained a thick milky liquid, of the consistence of cream, which gradually consolidates. If this be treated with ether, the pancreatised fat dissolves; and when the ether is separated by distillation, there remains the purified pancreatised fat, which is still miscible with water; in fact, when mixed with four or five parts of water it forms the creamy emulsion which is used dietetically and medicinally in doses of a teaspoonful at a time.

The properties of the pancreatic fluid have been well described by Dr. Dobell, in a paper recently read before the Royal Society of London; and it would seem that the fluid has not only the remarkable property of emulsifying oil and fat, and so rendering them capable of absorption, but it has also the power of dissolving starch by converting it into glucose. In this respect its action is like that of saliva, but it is much more energetic; for in its fresh state, one part of the pancreas will dissolve eight parts of starch, and even after it has emulsified fat, it will dissolve two parts of starch. It is, therefore, a powerful agent of digestion, in so far as fat, and starch, and young cellulose are concerned, but it has little or no action on albuminous substances.

I am indebted to Dr. Dobell and to Mr. Morson for the specimens of *pancreatin* and *pancreatised fat* upon the table. The first of these preparations is obtained by treating the fresh pancreas with water, and carefully evaporating the solution to the consistence of syrup, and then consolidating it with the flour of malt. Perhaps the dried pancreas, powdered and mixed with ground malt, would be a stronger preparation.

BILE is a complex liquid, consisting of biliary acids (*taurocholic, glycolic, &c.*) in combination with soda. Its reaction is slightly alkaline, and it contains about 14 per cent. of solid matter, not less than 12 of which are organic.

The true function of the bile is unknown; perhaps it

aids in neutralising the acid peptones from the stomach ; perhaps, also, in emulsifying fat ; and it may be that it helps the digestion of starchy foods, and aids in the transformation of sugar. Lehmann thinks it is a rich residuum from the manufacture of blood globules in the liver, and that it is secreted into the alimentary canal, only to be reabsorbed into the blood. Mr. Lea, also, is of opinion, from his examination of the foetal liver, that it separates a highly nutritious substance from the portal blood, which is elaborated in the intestines. Its functions, however, are manifestly obscure.

Dr. Macvicar is of opinion that it serves to prevent the formation of plant tissue (*plyto-cellulose*) from the vegetable matters of food, and determines the productions of animal tissue (*zoo-cellulose*), the former being a simpler and inferior molecular or morphological change, to which vegetable food is naturally prone. It is therefore, an animalising agent. Further investigations, however, are wanted for the real functions of bile.

Lastly, the **INTESTINAL SECRETION** which is thrown out along the whole course of the small intestines, is, according to the researches of Bidder and Schmidt, a powerful agent of digestion ; for it combines the activity and digestive power of all the other secretions—starch, fat, and albuminous substances being all equally well digested by it.

It will be easily understood therefore, how, when the food comes into contact with these special solvents, and is copiously drenched with fluid, it gives up its nutritive constituents. Admirable, however, as this provision is for the digestion of all kinds of food, yet a considerable portion of useful matter often passes through the bowel unchanged ; for cellulose, starch globules, and muscular fibre are common constituents of sewage. Dr. Lyon Playfair says that in the case of an adult man, with good digestion, 1-12th of the nitrogen of the food passes away

with the excreta, and others have computed it at 1-8th. In a dry state the fæces of man contain about 6·5 per cent. of nitrogen, and in the fresh state, 1·7. In Ranke's experiments, it was ascertained that the nitrogen in the fæces was to that in the urine as 1 to 12·5. Much of this is, doubtless, derived from the secretions which have done the work of digestion, and have thus become effete; indeed, Dr. Marcet is of opinion that the alvine discharges are chiefly composed of the residuum of albuminous substances which have been secreted into the bowel for the purposes of digestion, but they also contain the remains of undigested food. In ordinary individuals they amount to from 4 ozs. to 5·5 ozs. a day—(Wehsurg says 4·6 ozs.; Liebig, 5·5 ozs.; Lawes, 4·2 for a middle-aged adult, and 6·2 for a person over 50—the mean amount for adult males being 5·2 ozs., and for adult females 1·4 ozs.); and when calculated in a dry state they amount to about 1·1 ozs. for male, and 0·4 ozs. for females daily. It would, seem, however, that when indigestible and irritating food is used, the quantity of fæcal matter is increased, as if the food was hurried through the intestines without undergoing digestion. At the Wakefield Prison, for example, it was found that when brown bread, containing bran, was given to the prisoners, the weight of the fæces was 7 ozs. per head daily; and the same fact has been observed at the Coldbath-fields Prison. This is a strong argument against the use of whole meal for bread.

With this general account of the digestive function of the different secretions discharged into the alimentary canal, we are prepared to inquire into the digestibility of different alimentary substances.

DIGESTIBILITY OF FOODS.

NITROGENOUS, PROTEINACEOUS, or ALBUMINOUS SUBSTANCES, constituting the leading articles of diet, are evidently digested by the gastric juice and the intestinal mucus. In the former case they are converted into acid peptones, of which, according to Lehmann, there are several varieties, *albumino-peptones*, *fibrino-peptones*, *caseino-peptones*, *gelatino-peptones*, &c., according as they are derived from albumen, fibrin, casein, gelatin, &c., and of these substances the fluid form of albumen is most easily converted; then coagulated albumen; then fibrin; then casein; and, lastly, the derivatives of albumen, gelatin, chondrin, and cartilage, as the tegumentary forms of albumen, hair, wool, feathers, &c., which are entirely indigestible. Here is an example of the indigestibility of hair; it is a ball of it, obtained from the alimentary canal of a cow, where it has remained perhaps for years, having been originally licked off from a calf. Serpents and other animals that swallow their prey entire, digest the soft tissues and bones, but they disgorge the hair and feathers unchanged.

It is difficult to speak of the comparative digestibility of different nitrogenous foods; for the well-known experiments of Dr. Beaumont on the Canadian with a fistulous opening in the stomach, and even experiments made in bottles with pepsin, do not represent the full and natural conditions of the process: at the same time there can be no doubt that there are great differences in the digestibility of different animal substances. Reverting to Dr. Beaumont's inquiries, he found that soused pigs' feet, and soused tripe were the most digestible of all foods, and that boiled tendon of meat was the least digestible. The following, in fact, are the times given by him for the chymification of different animal foods:—

TABLE IX.

Relative Digestibility of Animal Substances.

Articles of diet.	How cooked.	Time of chymification.	
		H.	M.
Pigs' feet (soused)	Boiled	1	0
Tripe (soused)	Boiled	1	0
Eggs (whipped)	Raw	1	30
Salmon trout	Boiled	1	30
Venison steak	Broiled	1	30
Brains	Boiled	1	45
Ox liver	Broiled	2	0
Codfish (cured dry)	Boiled	2	0
Eggs	Roasted	2	15
Turkey	Boiled	2	25
Gelatine	Boiled	2	30
Goose	Roasted	2	30
Pig (sucking)	Roasted	2	30
Lamb	Broiled	2	30
Chicken	Fricasseed	2	45
Beef	Boiled	2	45
Beef	Roasted	3	0
Mutton	Boiled	3	0
Mutton	Roasted	3	15
Oysters	Stewed	3	30
Cheese	Raw	3	30
Eggs	Hard Boiled	3	30
Eggs	Fried	3	30
Beef	Fried	4	0
Fowls	Boiled	4	0
Fowls	Roasted	4	0
Ducks	Roasted	4	0
Cartilage	Boiled	4	15
Pork	Roasted	5	15
Tendon	Boiled	5	30

Cheese and tendons are perhaps digested only in small

quantity; and it is evident, from these experiments, as I shall hereafter explain, that cooking has considerable influence on the digestibility of food.

It is a curious problem why the stomach does not digest itself, seeing that it belongs to the class of most easily digestible substances, as tripe. Hunter explained it by referring the protective power to the vital force, for when dead the stomach digests itself in common with the food contained in it; but Bernard's and Pavy's experiments have proved that this is not the right explanation, for if the legs of living frogs, or the ears of living rabbits, are introduced into the stomach of a dog through a fistulous opening in the side, they digest like other proteinaceous substances. Liebig supposed that the protective power was in the thick mucus which lined the stomach, but Pavy denuded a part of the inner walls of a dog's stomach, and found that the tissue did not digest, but, on the contrary, quickly healed, and he is of opinion that the protective power is in the alkaline condition of the blood, which circulates so freely through the capillary vessels of the stomach during digestion.

STARCHY SUBSTANCES and CELLULOSE are digested by the ptyalin of the saliva, and the pancreatin of the pancreatic fluid, as also by the animal diastase of intestinal mucus. The solution is effected by the conversion of the starch and cellulose into a low form of sugar, called *glucose*, which is either freely absorbed into the circulation, or is changed in the stomach into lactic acid, where it serves an important function in the digestion of nitrogenous matter. If, however, by mal-assimilation, through the agency, perhaps, of putrefactive processes, it becomes changed into butyric acid, it hinders digestion, and causes much discomfort. It is on this account that saccharine foods are apt to disagree with the stomach; and it is very probable that this abnormal transformation is due to the presence of those infusorial creatures which swarm in putrifying animal matters. The time

necessary for the digestion of different vegetable substances, as determined by Dr. Beaumont, is as follows:—

TABLE X.

Relative Digestibility of Vegetable Substances,

Articles of Diet.	How prepared.	Time of Chymification.	
		H.	M.
Rice	Boiled	1	0
Apples (sweet and mellow)	Raw	1	30
Sago	Boiled	1	45
Tapioca	Boiled	2	0
Barley	Boiled	2	0
Apples (sour and mellow)	Raw	2	0
Cabbage with vinegar	Raw	2	0
Beans	Boiled	2	30
Sponge cake	Baked	2	30
Parsnips	Boiled	2	30
Potatoes	Roasted	2	30
Potatoes	Baked	2	33
Apple dumpling	Boiled	3	0
Indian corn cake	Baked	3	0
Indian corn bread	Baked	3	15
Carrot	Boiled	3	15
Wheaten bread	Baked	3	30
Potatoes	Boiled	3	30
Turnips	Boiled	3	30
Beets	Boiled	3	45
Cabbage	Boiled	4	0

It would seem from this that the time of digestion is in proportion to the amount of cellulose or woody tissue in the food. No doubt there is a more complete solution of these matters in the small intestines, where the pancreatic secretion and intestinal mucus, aided by the alkaline condition of the fluids, exert the greatest action on them, but it is very doubtful whether hard cellulose and

woody matter are at all digested by man. Even in the case of the pig, whose digestive powers are singularly active, it is thought by Messrs. Lawes and Gilbert, from their experiments on the fattening of animals, that there is little or no digestion of these substances; and, under any circumstances, a very prolonged contact with the secretions is necessary for their digestion. Raw starch will pass a considerable distance along the alimentary canal of man without much change, and it is only towards the end of the small intestines that the starch granules undergo marked disintegration. Those animals which feed entirely on vegetables have always a contrivance for keeping the food a long time in contact with the secretions. It occurs as the paunch in ruminants, the crop in birds, the large cæcum in rabbits and other rodentia, and as the long alimentary canal of all of them; but even then a large portion of the vegetable tissue passes through the bowels unchanged. Cooking, grinding, and otherwise disintegrating the tissue, help considerably in the digestion of it; and so also does the prolonged contact of the starchy matters of food with the natural diastase of the vegetable. An infusion of malt will rapidly sweeten barley, as the brewer knows from daily observation; and the starch of potatoes can readily be converted into glucose by digesting it for a few hours with the parings of the potato. This operation, in fact, is largely practised by German farmers in the preparation of food for fattening pigs.

GUM and PECTIN are probably not digested at all, for as they are unchanged by contact with the secretions, and are incapable of dialysis or absorption, they must pass through the alimentary canal without serving any purpose in nutrition, beyond acting as demulcents.

FATTY MATTERS are digested by the emulsifying action of the pancreatic fluid; and by being thus broken up into extremely minute globules they are freely admitted into the lacteal vessels; in fact the emulsified

globules of fat are seen covering the villi of the intestines, penetrating their tissues, pervading the subjacent cellular bodies, and thus entering the lacteals; and, no doubt, the peristaltic action of the intestines contributes largely to this emulsifying process.

SALINE SUBSTANCES are generally soluble in water, and are therefore easily absorbed, but when this is not the case, as with the earthy phosphates, they are attacked by the acid constituents of the gastric juice.

And, here, in concluding this part of the subject, I may remark that the great aids to digestion are:—

1st. Proper selection of food, according to the taste and digestive power of the individual.

2nd. Proper treatment of it as regards cooking, flavouring, and serving it.

3rd. Proper variations of it, both as to its nature and treatment, so that the appetite may not fail, or be wearied.

4th. Exercise, warmth, and a genial disposition.

5th. Regularity of meals, with a proper interval between them.

FUNCTIONS OF FOOD.

Although much attention has been directed to the important subject of the immediate and remote functions of food, yet it must be admitted that the difficulties of the question have not been surmounted, and that we are hardly able to particularise the phenomena which are incidental to the transformations of food. We can see clearly enough that its ultimate destiny is the manifestation of force—the letting loose of the cosmical agencies which are bound up in it, as when, by undergoing oxidation, it returns more or less completely to its original forms—carbonic acid, water, and ammonia; but how and where these changes occur, and what are the subsidiary phenomena, and concurrent functions, besides those of

common motion and animal heat, are as yet almost unknown to us. Nor are we sufficiently acquainted with the special attributes of the principal constituents of food, as the albuminous, the fatty, the farinaceous, the saccharine, and the saline; for although the well-known opinions of Liebig, with regard to the dynamic or force-producing functions of the nitrogenous or plastic elements of food, and of the thermotic or respiratory powers of the carbonaceous have been generally received, yet there are abundant reasons for believing that both of these classes of food may perform exactly the same functions in respect of the development of force; and, again, it is more than probable that the nitrogenous or plastic constituents of food may, like the carbonaceous, be oxidised and consumed in the living body without ever entering into the composition of tissue. In these respects, therefore, there are great points of divergence from the views of Liebig.

Looking, however, at the proximate elements of food, it may, perhaps, best serve our present purpose if we inquire generally into the several functions of water, albuminoid compounds, fatty substances, farinaceous and saccharine matters, and mineral salts.

1st. WATER is unquestionably of great physiological value, for as much as 75 per cent. of the muscular tissue of the animal frame is composed of it; and of the 20 lbs. of blood which an average-sized adult contains in his body, about $15\frac{1}{2}$ lbs. are water. It is computed, also, that not less than 30 lbs. of fluid (*vide* Table No. 8), ebb and flow daily from the blood and alimentary canal by secretion and absorption. Bidder, indeed, estimates that about 28.6 lbs. of chyle and lymph are carried daily by the thoracic duct alone into the circulation—a quantity of fluid that amounts to nearly one-fifth of the entire weight of the adult human body; and then with regard to the excretions, we find that rather more than a pound of water is exhaled daily by the breath, about a pound and

three-quarters by the skin, and not less than two pounds and three-quarters by the kidneys, making altogether about five pounds and a half per adult daily.

These results indicate the importance of water in the functions of the animal body. It serves indeed to dissolve the food and carry it into the circulation; to effect the distribution of it throughout the system; to dissolve effete matters, as the metamorphosed constituents of worn-out tissues, and so convey them out of the body; to establish the chemical activity which is necessary for nutrition and decay; to combine mechanically with the tissues and lubricate them, so that they may perform their functions easily; and lastly, to evaporate by the air-passages and skin, and thus maintain the proper temperature of the body.

2nd. The second constituents of our food—namely, ALBUMINOUS, NITROGENOUS, or PLASTIC MATTERS, were once, and until very recently, thought to have the sole function of constructing and repairing the muscular parts of the body; and having so entered into the composition of tissues, their oxidation and decay were attended with the manifestations of force which were the working powers of the animal machine. “We see,” says Liebig, “as an immediate effect of the manifestation of mechanical force, that a part of the muscular substance loses its vital properties,—its character of life; that this portion separates from the living part, and loses its capacity for growth and its power of resistance. We find that this change of properties is accompanied by the entrance of a foreign body (oxygen) into the composition of the muscular fibre; and all experience proves that this conversion of living muscular fibre into compounds destitute of vitality, is accelerated or retarded according to the amount of force employed to produce motion. Nay, it may safely be affirmed, that they are mutually proportional; that a rapid transformation of muscular fibre, or, as it may be called, a rapid change

of matter, determines a greater amount of mechanical force; and conversely, that a greater amount of mechanical motion (of mechanical force expended in motion), determines a more rapid change of matter." He further remarks that "the amount of azotised food necessary to restore the equilibrium between waste and supply is directly proportional to the amount of tissue metamorphosed," that "the amount of living matter, which in the body loses the condition of life, is, in equal temperatures, directly proportional to the mechanical effects produced in a given time." That "the amount of tissue metamorphosed in a given time may be measured by the quantity of nitrogen in the urine;" and "that the sum of the mechanical effects produced in two individuals in the same temperature, is proportional to the amount of nitrogen in their urine; whether the mechanical force has been employed in voluntary or involuntary motions; whether it has been consumed by the limbs, or by the heart and other viscera."

These are the generalisations of Liebig and they go to show, not only that the dynamical action of the animal body depends wholly on the transformation of muscular tissue, and may be measured by the quantity of nitrogen excreted as urea; but also that no oxidation of nitrogenous matter can take place until it has passed from the condition of food to tissue, and has thus become organised. According to this view, the mechanical force of the human machine is derived entirely from its own combustion, and not from the oxidation of matters contained in the food.

For some time past there have been suspicions that this view of the case is not correct; and the doubts of physiologists have been strengthened by the circumstance that great labour might be performed for a short period without the use of a nitrogenous diet; and that while there was always a relation between the quantity of nitrogen in the food and that excreted as urea, there

was no such relation between the dynamical actions of the body and the proportions of urea. Moritz Troube, in fact, asserted in 1861, after a careful examination of the subject, that all muscular force was derived from the oxidation of fat and hydrocarbons, and none from the oxidations of tissue. Haidenham, in 1864, arrived at a similar conclusion, and Donders was likewise of opinion that tissue transformation would not account for all the force of the animal body.

The hypothesis of Liebig has been further shaken by the investigation of Dr. Edward Smith, who has shown that the proportion of nitrogen in the urine does not increase with exercise, although the amount of carbonic acid exhaled by the lungs does. But the most convincing proof of the fallacy of the hypothesis was furnished in 1866 by the experiments of Dr. A. Fick, the Professor of Physiology at Zurich, and Dr. J. Wislicenus, the Professor of Chemistry.

On the 29th of August of that year they prepared themselves for an ascent of the Faulhorn, one of the Bernese Alps, which rises 6417·5 feet above the Lake of Brienz. For seventeen hours before the journey, they took nothing in the way of solid food but cakes composed of starch, fat, and sugar; and on the following morning, at half-past five o'clock, they began the ascent, choosing the steepest of the practical paths from the little village of Iseltwald on the Lake of Brienz. At twenty minutes past one in the afternoon their journey was accomplished without fatigue, and from that hour to seven in the evening they remained at rest in the hotel at the top of the mountain. During the whole of that time (a period of thirty-one hours) they took no other food than the non-nitrogenous cakes, but at seven o'clock they had a plentiful meal of meat, &c.

The urine was collected at three intervals, namely:—

Ist. From 6 o'clock p.m. of the 29th to 5 a.m. of the 30th; and this they called the *night urine* (before work).

2nd. From 5 a.m. of the 30th to 1.20 p.m.; and this they called the *work urine*.

3rd. From 1.20 p.m. to 7 p.m.; and this they called the *after-work urine*.

4th. From 7 p.m. on the 30th, to 5.30 of the morning of the 31st; and this they called the *night urine* (after work).

All these were analysed for nitrogen, and the results were as follows:—

	Grains of Nitrogen Excreted by		
	Fick.	Wislicenus.	
1st. Night urine (before work)	106·7	103·2	
2nd. Work urine	51·1	48·3	} 85·6
3rd. After work urine	37·5	37·3	
4th. Night urine (after work)	74·3	82·5	

So that not only were they able to perform the work without a nitrogenous diet, but the quantity of nitrogen excreted was less during the work than before or after. Even calculated at the hourly rate of excretion it stands thus:—

	Grains of Nitrogen Hourly Excreted.	
	Fick.	Wislicenus.
During 1st night	9·70	9·38
During time of work	6·14	5·89
During rest after work	6·63	6·59
During 2nd night after work	7·08	7·86

The work which they had performed was estimated thus:—Fick with clothes and equipments weighed 145·5 lbs. avoirdupois, and Wislicenus 767·5 lbs.; and as they ascended 6417·5 feet, it is clear that Fick had raised 933,746 lbs. one foot high ($145·5 \times 6417·5$), and Wislicenus 1,074,931 lbs. ($167·5 \times 6417·5$); so that for an expenditure of muscular tissue, represented in the one case by 88·6 grains of nitrogen, and in the other by 85·9 grains, the foregoing amounts of work had been done. Now, as one of nitrogen represents 6·49 of dry

muscular tissue, it is evident that Fick had consumed 575 grains of muscle, and Wislicenus 555.5 grains.

At the time of the experiment, the thermotic and mechanical powers of these proportions of flesh were not accurately known, but they have since been determined in a very careful manner by Dr. Frankland, who finds that when pure dry lean of beef, albumen, and urea are completely oxidised in a proper apparatus, they develop the following amounts of heat and mechanical force:—

	Lbs. of water raised 1° Fahr.	Lbs. lifted one foot high.
10 grains of pure dry beef . . .	13.12	10,128
10 grains of pure albumen . . .	12.85	9,920
10 grains of pure urea . . .	5.67	4,400

In considering the mechanical power of muscular tissue, it must be remembered that it is never completely oxidised in the animal body, but is changed into carbonic acid, water, and about one-third of its weight of urea, so that the potential energy of muscle is not so great as in the preceding results. Calculated, indeed, according to the proportions of urea formed, the tissues of Fick and Wislicenus were capable of the following amounts of physiological energy:—

	Fick.	Wislicenus.
Quantity of muscle consumed . . .	575.0 grs.	555.5 grs.
Actual energy if fully burnt . . .	582,360 ft.-lbs.	562,610 ft.-lbs.
Available energy, deducting the urea	498,525 ft.-lbs.	481,618 ft.-lbs.
Work actually done	933,746 ft.-lbs.	1,074,931 ft.-lbs.

So that in the case of Fick 435,221 foot-pounds of work, and, in the other, 593,313 foot-pounds are unac-

counted for. But this is not all, for, besides the mere labour of ascending the mountain, there were the movements of respiration, and the beating of the heart, and other internal motor actions, to be added to the work actually done.

Now each beat of the heart is estimated as equal to a lift of 4.63 lbs. one foot high; and it is considered from Donder's well-known investigations that the work of respiration is nearly the same—namely, 4.56 lbs. a foot high. Fick says that during the ascent his pulse beat at the average rate of 120 a minute and his respirations were 25. The beating of his heart, therefore, during the 5½ hours actually taken in the ascent was equal to 183,348 lbs. lifted a foot high; and the respiration to 37,620 lbs. If the internal labour, or, as it may be called, the *opus vitale* of Wislicenus was in proportion to his bodily weight, as compared with Fick's—that is, as 7 to 6, then the ascertainable work done, was to the power of the muscle consumed as follows:—

	Fick. Ft.-lbs.	Wislicenus. Ft.-lbs.
Work of ascending the } mountain }	933,746	1,074,931
Work of circulation . .	183,348	213,906
Work of respiration . .	37,620	43,890
	<hr/>	<hr/>
Total ascertainable work	1,154,714	1,332,727
Actual energy of the } consumed muscle . . }	498,525	481,618
	<hr/>	<hr/>
Energy unaccounted for	656,189	851,109

From which it appears that taking only the three factors of ascertainable work—namely, external labour, circulation and respiration, and disregarding other unascertainable motor actions of the body, which are estimated by many as greater than all the rest, the work

actually performed exceeds the energy of the oxidised muscle by more than as much again.

It may be said, and truly, that these experiments of Fick and Wislicenus were of too short a duration to afford an opportunity of ascertaining whether the oxidised muscle was not afterwards excreted; but the recent researches of Dr. Parkes on the elimination of nitrogen by two healthy men (soldiers) in the prime of life, during a period of seventeen days, and under different conditions of diet and exercise, have shown that, although the results are not altogether accordant with those of Fick and Wislicenus—yet the conclusions are certainly borne out, that a non-nitrogenous diet will sustain the body during exercise for a short time, and that exercise produces no notable increase in the nitrogen of the urine. On the contrary, the amount of urea is actually less during work than at a period of rest; and he thinks that the muscle, instead of oxidising, and, therefore, losing its substance during labour, actually appropriates nitrogen and grows—its exhaustion being dependent, not so much on its decay, as on the accumulation of the oxidised products of hydro-carbon, as lactic acid, &c., in its tissue, which require rest and time for their removal. That some decay of the muscle takes place there can be no doubt; for, as Dr. Parkes observes, “although it is certain that very severe exercise can be performed on non-nitrogenous diet for a short time, yet it does not follow that nitrogen is unnecessary. The largest experience shows, not only that nitrogen must be supplied, if work is to be done, but that the amount must augment with the work. For a short period the well-fed body possesses sufficient nitrogen to permit muscular exertion to go on for some time without a fresh supply; but the destruction of nitrogenous tissues in these two men is shown by the way in which, when nitrogen was again supplied, a large amount was retained in the body to compensate for previous depriva-

tion." It would seem, too, from the great exhaustion of the men on the second day of a non-nitrogenous diet, that their muscles and nerves were becoming structurally impaired, and that if the experiments had been continued for a third day there would have been a large diminution in the amount of work. The work which they actually performed on a non-nitrogenous diet of starch and butter, in the form of biscuits and arrowroot, was walking exercise of 23.76 miles the first day, and 32.78 the second. The first day's work occupied, with intervals of rest, about ten hours and three-quarters, and it was done without fatigue; but the second day's work took twelve hours, and the last thirteen miles were accomplished with great fatigue. Calculated according to Haughton's formula (that walking upon a level surface is equal to lifting 1-20th of the weight of the body through the distance walked), the labour in the two days was, for—

	S.	T.
	Weighing with clothes 162.4 lbs.	Weighing with clothes 124.2 lbs.
The first day	1,018,676 ft.-lbs.	779,062 ft.-lbs.
The second day	1,405,397 ft.-lbs.	1,074,817 ft.-lbs.
	<hr/>	<hr/>
Total work	2,424,073 ft.-lbs.	1,853,879 ft.-lbs.
	<hr/>	<hr/>
Total nitrogen excreted	529.16 grains.	492.46 grains.
Equal to muscle oxidised	3,434.25 grains.	3,196.07 grains.
The energy of which)		
(minus urea) is }	2,977,495 ft.-lbs.	2,770,993 ft.-lbs.

The amount of nitrogen excreted during the time of actual exercise was only about half the above; and, calculated in this way, it would only account for about two-thirds of the labour-force. The results, therefore, prove that although the basis for the calculations of Fick and Wislicenus was too narrow for accurate deductions, yet the mechanical force of the oxidised muscle is not sufficient to account for external and internal work; and the conclusion is that, in the above experiments, the motive power of the muscles was not derived from their

own oxidation, but from the oxidation of non-nitrogenous matters.

The researches of Dr. Edward Smith have thrown additional light on the subject, for he ascertained that the amount of carbonic acid exhaled by the lungs was in proportion to the actual work performed.

	Grs. per hour.
During sleep it was at the rate of	293
When lying down and approaching sleep . .	355
In a sitting posture	491
When walking two miles an hour	1,088
When walking three miles an hour	1,552
And when working at the treadmill	2,926

It is highly probable, therefore, that the largest amount of muscular force is derived from the hydrocarbons of our food; not that the nitrogenous matters of it may not also be a source of power, as in some cases they must be; but there is no necessity, as Liebig supposes, for their being previously constructed into tissue. The experiments of Mr. Savory with rats, and of Bischoff and Voit with dogs, show that these animals can live and be in health for weeks on a purely nitrogenous diet, and it is nearly certain that under these circumstances the nitrogenous matters are in great part oxidised without entering into the composition of tissue. This, as I have said, is the main point of divergence from the hypothesis of Liebig; and it is further supported by the fact that the amount of nitrogen excreted, as urea, is not in proportion to the work done, but to the quantity of it in the food, and this is observed even when there is no muscular exertion.

That the chief function of nitrogenous matters is to repair tissue there can be no doubt, for animals kept on a purely carbonaceous diet, quickly lose weight, and at last die from disintegration of tissue; but it is equally certain that the nitrogenous constituents of food have other offices to perform. A daily diet of 2 lbs. of bread contains enough nitrogen to supply the mechanica

wants of the system, but it will not maintain life, for an addition of animal food is required. Indeed, the instincts and habits of the human race show, beyond all question, that a comparatively rich nitrogenous diet is necessary for the proper sustenance of life, especially when work is performed. It is very probable that nitrogenous matters assist the assimilation of hydrocarbons; and in this way they may help in the development of force without contributing directly to it. This may serve to explain the fact, that there is always a relation between the amount of nitrogen contained in the food and the labour value of it. Carnivorous animals, for example, are not only stronger and more capable of prolonged exertion than herbivorous, but they are also fiercer in their disposition—as if force were superabundant. The bears of India and America, says Playfair, which feed on acorns, are mild and tractable, while those of the Polar regions, which consume flesh, are savage and untameable; and, to take instances of people, the Peruvians, whom Pizarro found in the country at its conquest, were gentle and inoffensive in their habits, and they subsisted chiefly on vegetable food; whilst their brethren in Mexico, when found by Cortes, were a warlike and fierce race, feeding for the most part on animal diet. The miners of Chili, who work like horses, also feed like them, for Darwin tells us that their common food consists of bread, beans, and roasted grain. Again, the Hindoo navvies, who were employed in making the tunnel of the Bhore Ghat Railway, and who had very laborious work to perform, found it impossible to sustain their health on a vegetable diet; and being left at liberty by their caste to eat as they pleased, they took the common food of the English navigators, and were then able to work as vigorously. According to Liebig, it is the rich nitrogenous diet of Englishmen which is the great source of their indomitable energy, for “it is only necessary,” he says, “to compare the per-

performances of German workmen, who consume bread and potatoes chiefly, with those of English and American workmen, who eat meat, in order to acquire a clear perception of the degree in which the magnitude, energy, and duration of the work done by the latter are augmented by the kind of food they live upon. Again," he says, "compare the English statesman, who, in expounding his views or maintaining a debate in Parliament, delivers a speech lasting five hours or more, who at sixty years of age retains the capability of taking part in field sports, with the German philosopher, who at the same age keeps up with difficulty the remains of his power in order to be capable of work, while he becomes fatigued by a walk of a few hours." Abundant examples of this description—some of which will be further discussed as we proceed, may be cited in proof of the direct relation of plastic food to mechanical work; but there is no proof that this material must first form tissue before its dynamical power can be elicited; that is to say that the nitrogenous matter of food must be converted into muscle before it can develop muscular force, as this force, according to Liebig, is entirely referable to a transformation of the tissue of the moving muscle, oxygen taking part therein, but not directly causing it, and urea being the product of the change. At one time Liebig would not allow that urea had any other origin than this, but he now admits that the experiments of Bischoff and Voit, in Munich, have proved beyond doubt that urea may be derived from the nitrogenous matters of food, as well as from the living muscular tissues, and, therefore, that its proportions in the secretions are not, as he once believed, the measure of the quantity of muscular work performed. He even acknowledges that the error of his former opinions has confused the question of the origin of muscular force; but he still maintains that the force is generated by the transformation of the nitrogenous constituents of the living muscle, in which oxy-

gen takes part, though without causing it, and, therefore, not by combustion. Others, however, are of opinion that this force is due to the combustion of carbo-hydrogens, which may or may not be nitrogenous; and experiments have been made to determine the actual energy of different articles of diet (see Table 13), but of this anon.

It would seem that all forms of nitrogenous food have not the same nutritive value. The glutinous matters of barley and wheat, for example, though almost identical in chemical composition, have very different sustaining powers. It is the same with muscular flesh, and artificially prepared fibrin and gelatine. Majendie found that dogs, fed solely for 120 days on raw meat from sheep's heads, preserved their health and vigour during the whole of the time; but more than three times the amount of isolated fibrin, with the addition of much gelatine and albumen, were insufficient to preserve life.

We may conclude from all this, that although the main functions of nitrogenous matters are to construct and repair tissue, yet they have manifestly other duties to perform of an assimilative, respiratory, and force-producing quality which are far from being understood. What do we know, indeed, of the actual *modus operandi* of the nitrogenous ferments—ptyalin, pepsin, pancreatin, &c., which are secreted so abundantly into the alimentary canal; or of the conjugate nitrogenous compounds which are present in the bile? and how far have we advanced in interpreting the functions of the nitrogenous constituents of tea, coffee, maté, guarana, cocoa, &c., which the instincts of mankind in every part of the globe have evidently chosen for some physiological purpose? The same may be said of the crystalline nitrogenous matters of soup—as creatin, creatinin, inosinic acid, &c., which can hardly be regarded as foods, although they have powerful sustaining properties. But enough of this for the present; and before leaving this part of the subject, I would direct attention to the fact,

that nitrogenous matters, when oxidised in the animal body, never yield up the whole of their potential energy, for, by being converted into urea, which is the chief product of their decay, there is at least a seventh part of their power lost in this secretion. It may be that this is a necessity arising out of the circumstance that if they were completely oxidised in the animal body and converted into carbonic acid, water, and nitrogen, the last-named gas would be unable to quit the system, because of its insolubility in the animal fluids.

3rd. FUNCTIONS of FAT.—The hydrocarbons which go by the name of fat differ from other hydrocarbons, as sugar and starch, in the circumstance that the oxygen is never in sufficient quantity to satisfy the affinity of the hydrogen, and therefore fat is more energetic as a respiratory or heat-producing agent. Its power, indeed, in this respect, is just twice and a-half as great as that of dry starch or sugar; for ten grains of it in a dry state will, by combining with oxygen, develop sufficient heat to raise 23.32 lbs. of water 1 deg. F. ; and according to the deductions of both Joule and Meyer, this is equivalent to the power of raising 18,003 lbs. one foot high. In cold countries, where animal warmth is required, food rich in fat is always preferred; and the fat bacon of the English labourer contributes in no small degree to the production of mechanical force.

But besides this, fat serves important functions in the processes of digestion, assimilation, and nutrition. According to Lehmann, it is one of the most active agents in the metamorphosis of animal matter; and this is seen not merely in the solution of nitrogenous articles of food during digestion, but also in the conversion of nutrient plastic substances into cells and masses of fibre. Elsässer long since observed that during the process of artificial digestion, the solution of nitrogenous foods was considerably accelerated by means of fat; and Lehmann has since determined, by actual experiment on dogs,

that albuminous substances deprived of fat remain longer in the stomach, and require more time for their metamorphosis than the same substances impregnated with fat. It is probable, indeed, that the digestive power of the pancreatic fluid is due, in great measure, to the presence of fat; and that the subsequent chymification of food, and its absorption into the blood, is greatly assisted by it. There is also good reason for believing that it is largely concerned in the formation of bile, and that the biliary acids are conjugated fatty compounds. This may account for the well-known action of fat bacon and other such foods in promoting the secretion of bile.

The digestive power of fat is certainly considerable; and it is no less active in the subsequent conversion of nitrogenous matters into cells and tissues, and perhaps also in effecting their retrograde decay. Colourless blood corpuscles receive, perhaps, the first impulse of their formation from the metamorphosis of fat; and thus it may be an important aid in the genesis of blood. It would appear, too, from the latest investigations of physiologists that it plays an equally important part in every kind of cell development. Acherson showed, as far back as 1840, that albumen always coagulates from its solution around a fat globule, and this is seen in the little fatty particles of milk, which have a covering like a cell-wall of consolidated casein. Hunefield, Nasse, and others, have further shown that the nucleoli of cells invariably consist of fat, and that recently formed plasma always contains more fat than the mature cell. The conclusion, therefore, is that it takes an active part in all the processes by which the nutrient constituents of food are converted into the solid substrata of organs; and so energetic are its powers in this respect, that when the nitrogenous matters of the fluids are not in sufficient quantity to form cells with the fat, it borrows the material from muscular or other tissues, and thus produces a fatty

degeneration of the part. This is observed in the muscular structures of over-fed animals, in the tissues of drunkards, who take a large amount of fat-forming food, and in the livers of geese that are crammed with a farinaceous diet.

And not only is it concerned in the formation of new tissue, but it also pervades, and finally disintegrates, the older structures, especially when the vitality of them is low. In this manner it helps in the solution and subsequent removal from the animal body of decayed and morbid products of the protein type.

Again, its presence in large quantity in the tubules of nerves, and in the ganglionic centres, indicates that it performs some highly important functions in nervous action.

And lastly, the distribution of it in the tissues, and the accumulation of it around certain organs, serve to fill up the vacuities of the body, to give rotundity to the form, to equalise external pressure, to diminish the friction of parts, to give suppleness to the tissues, and by its bad conducting property to retain the animal warmth. Fat, therefore, must enter largely into the composition of our food, for other hydrocarbons, though capable of transformation into fat, cannot entirely take its place.

4th. FUNCTIONS of STARCH, CELLULOSE, and SACCHARINE MATTERS.—These substances are well called hydrates of carbon, for the oxygen and hydrogen contained in them are nearly always in the proportion to form water, the carbon alone being capable of oxidation. According to Liebig, their functions are entirely calorific or respiratory; but, like other heat-producing agents, they must also have an equivalent of mechanical power, for everything that will raise the temperature of a pound of water 1 deg. F. will, by another mode of action, raise 772 lbs. a foot high. The energies, however, of this class of substances are not nearly so great as with fats, for in the last case, as I have said, there is much available

hydrogen, as well as carbon, for oxidation. The diagram which is before you will make this clear.

TABLE XI.

Calorific and Motive Powers of 10 Grains of the Substance in its Natural State.

	Lbs. of water raised 1° F.	Lbs. lifted one foot high.
Grape sugar	8.42	6500
Lump sugar	8.61	6647
Arrowroot	10.06	7766
Butter	18.60	14,421
Beef-fat	20.91	16,142

So that in round numbers the calorific power of fat in its natural state is about twice as great as that of starch and sugar, and when dry it is twice and a-half as great.

But these substances have other duties to perform besides the development of animal heat, which is, in fact, the final result of their oxidation, for after becoming changed into glucose by digestion, they take the form of various acid compounds, as lactic acid, which occurs in the stomach and in the juice of flesh ; butyric, formic, and acetic acids, which are found in the perspiration. The exact functions of these acids are not known to us, although, as I have already explained, the presence of lactic acid in the stomach is essential to the digestion of nitrogenous matters ; and perhaps its occurrence in the juice of flesh is for a similar object—namely, the solution of effete tissues.

Starches and sugars are also concerned in the production of fat. This was once the subject of an animated discussion by Liebig and Dumas, whose views of it were in complete antagonism ; but the experiments of Boussingault, Persoz, Lawes, and others, on the feeding of animals, have proved beyond all question that fat may be derived from the hydrates of carbon, and that

therefore the views of Liebig were correct. Common experience, indeed, has fully taught us that foods which are rich in farinaceous matters and sugar are very capable of producing fat. The dietary system of Mr. Banting, and the opposite system in Turkey, whereby the ladies of the harem are fattened on honey and thick gruel, are examples in point, and so also are the processes used for fattening poultry.

5th. The SALINE or MINERAL constituents of food are largely concerned in the metamorphosis of matter; and, perhaps, this is their principal function, for it is a speciality of these substances to give a soluble form to the plastic constituents of food and of the animal tissues. They are, therefore, concerned in the phenomena of digestion, absorption, sanguification, assimilation, disintegration, and secretion. In truth, they are the chief, if not the only, media for the transference of organic matter from place to place in the animal body—being on one hand the purveyors of nutrient materials into the system, and on the other the carriers of effete substances out of it; besides which, it is very probable that they are the agents whereby liquid colloidal forms of nutriment are changed into solid or pectous, as in the formation of solid tissues from the blood, and conversely the solid into liquid. In the case of digestion and absorption, the plastic elements of our food, as albumen, fibrin, gelatin, &c., are not of themselves capable of dialysis by passing through the walls of the alimentary canal; and, therefore, absorption must be assisted by some physical agent. This agent is the highly diffusive acids and salts which are secreted so freely into the stomach during digestion; and it is very probable that they not only effect a solution of the proteinaceous matter of food, but by converting it into peptones, as Lehmann expresses it, they also change the molecular form of the material, and make it pass from an unabsorbable colloid into a highly diffusive crystalloid. If, indeed, it be, as Mr.

Graham supposed, that a colloid molecule is but a group of smaller crystalloids, the action of the saline and acid constituents of the gastric juice may be to break up the larger colloid molecule and thus give it the property of diffusion and absorption. An opposite condition of things would occur in the alkaline blood, whereby the colloid molecule would regain its structure, and lose its diffusive tendency; but, coming to the tissues, where an acid condition of the fluids again exists, it once more changes its molecular structure, and quits the blood to serve the purposes of nutrition. The exact nature of the phenomena that occur when the liquid nutrient matter which thus escapes is changed into solid tissue is unknown to us; but there is good reason for believing that it is no more than a molecular movement effected by the agency of saline matter. In the case of certain structures which contain more than a common amount of mineral salts, this is unquestionably so, for it occurs in the consolidation of the spiculæ of sponges, the calcareous tissues of polypes, the hard dermal structures of the radiata, mollusca, crustacea, &c., and in the calcareous deposits of bone, teeth, tegumentary scales, egg-shells, &c., of the vertebrata. In all these instances the secreted matter must first have been crystalloidal, or it could not have been secreted; it then takes the form of a liquid colloid or jelly; and finally, by a further molecular movement, it passes into the condition of a pectous solid—the saline constituents, according to their nature and proportion, determining the degrees of hardness.

Again, the removal of effete matters, and worn-out tissues is undoubtedly effected by the agency of saline substances; for during the process of oxidation, acid compounds are produced, which, by acting chemically on the saline constituents of the animal fluids, give them a solutive power upon plastic matters, and thus enable them to remove the *debris* of worn-out tissue.

As to the special functions of each of the several saline

constituents of food, little can be said; but it is a remarkable fact that the *alkaline or basic phosphate of soda* is invariably found in the blood, while *acid phosphate of potash* is the chief constituent of the juice of flesh. Most likely the former is concerned in preserving the liquid colloidal condition of albumen and fibrin, and so keeping them from being lost by secretion; while the latter is engaged in an opposite duty. The alkalinity of the blood also helps in the oxidation of organic matters; and as the basic phosphate of soda is endowed, like an alkaline carbonate, with the power of absorbing carbonic acid, it is the chief agent whereby this compound is removed from the system. This is a remarkable property, and is one of the chief uses of basic phosphate of soda in the blood. In point of fact, when it is not there in sufficient quantity to perform this function, it is replaced by an alkaline carbonate. We find this to be so in the blood of herbivorous animals, where the proportions of the two salts are the reverse of what they are in man and carnivora. Some notion may be formed of the relative importance of the saline matters of the blood by reference to this Table from Liebig.

TABLE XII.

Percentage Composition of the Mineral Matters of Blood.

	Man.	Pig.	Dog.	Fowl.	Sheep.	Ox.
Phosphoric Acid	31.79	36.50	36.82	47.26	14.80	14.04
Alkalies	55.66	49.80	55.24	48.41	55.79	60.00
Alkaline Earths	3.33	3.80	2.07	2.22	4.87	3.64
Mineral Acids and Oxide of Iron }	9.22	9.90	5.87	2.11	24.54	22.32
Total	100.00	100.00	100.00	100.00	100.00	100.00

And in those cases where the phosphoric acid is deficient, it is replaced by carbonic acid. In man, for example, the quantity of combined carbonic acid, in the ashes of the blood is only 3.78 per cent., whereas in

the calf it is 9.85, and in the sheep 19.47 per cent., so that in all cases the alkalinity of the blood remains the same.

In cow's milk, according to Hardless, the saline matters amount to from 5 to 8 parts in a thousand of milk—the average being 5.83, of which the individual constituents are as follows:—Phosphate of lime, 2.88; phosphate of magnesia, 0.53; phosphate of peroxide of iron, 0.07; chloride of potassium, 1.63; chloride of sodium, 0.29; and free soda, 0.43.

The *salts of potash* in the juice of flesh have, no doubt, an equally important duty to perform, although of an opposite character; for while the alkaline phosphate of soda in the blood prevents the transudation of nutrient matter, the acid phosphate of potash in the muscular fluid promotes it; and thus it is concerned in nutrition and in the solution of worn-out tissues.

Earthy phosphates, especially *phosphate of lime*, are, perhaps, the agents for the consolidation of tissue; for not only are they present in the hard structures of the body, as the bones and teeth, but they also enter into the composition of flesh,

And not less important in the morphological functions of the animal body is the presence of *common salt*. It is a large constituent of every one of the secretions, and forms about half the total weight of the saline matters of the blood. Unlike the phosphates, however, it does not enter into the composition of tissue, but seems to be only a medium of absorption and secretion; and so necessary is it for this purpose, that it is not possible to alter, to any large extent, its proportion in the blood. If we drink water containing but little common salt in solution it does not permanently dilute the blood, but passes off immediately by the kidneys; and if we try to increase the amount in the blood, by drinking solutions of salt, as sea-water, it refuses to be absorbed. This normal proportion of it in the blood is evidently a physiological

necessity, which the conditions for diffusion imperatively demand. It is a curious fact, also that common salt has the faculty of forming crystallisable compounds with most of the unorganised and effete constituents of the body. May it not, therefore, be an important agent of diffusion, and be thus concerned in the phenomena of absorption and secretion; for as colloidal matters—albumen and fibrin—cannot pass through the walls of the intestines or the blood-vessels, it may well be that through the agency of common salt and the free acid of the gastric and muscular juices, they temporarily assume a crystalloidal condition, and are thus absorbed or secreted.

The constant presence of common salt in the secretions, and the necessity for it in due proportion in the blood, indicate the importance of a proper supply of it with the food. We perceive this in the instinct of animals, and in our own craving for it when it does not exist in sufficient quantity in the food. Animals, in fact, will travel long distances, and brave the greatest dangers, to obtain it. Men will barter gold for it; indeed, among the Gallas and on the coast of Sierra Leone, brothers will sell their sisters, husbands their wives, and parents their children, for salt. In the district of Accra, on the Gold Coast of Africa, a handful of salt is the most valuable thing upon earth after gold, and will purchase a slave or two. Mungo Park tells us that with the Mandingoes and Bambaras the use of salt is such a luxury, that to say of a man "he flavours his food with salt" is to imply that he is rich; and children will suck a piece of rock-salt as if it were sugar. No stronger mark of respect or affection can be shown in Muscovy, than the sending of salt from the tables of the rich to their poorer friends. In point of fact, the value of salt in a dietical and sanitary point of view, has been recognised from the earliest time. In the Book of Leviticus, it is expressly commanded as one of the ordinances of

Moses, that every oblation of meat upon the altar shall be seasoned with salt, without lacking; and hence it is called the Salt of the Covenant of God. The Greeks and Romans also used salt in their sacrificial cakes; and it is still used in the services of the Latin Church—the “*parva mica*,” or pinch of salt being, in the ceremony of baptism, put into the child’s mouth, while the priest says, “Receive the salt of wisdom, and may it be a propitiation to thee for eternal life.” Everywhere, and almost always, indeed, it has been regarded as emblematical of wisdom, wit, and immortality. To taste of a man’s salt, was to be bound by the rites of hospitality; and no oath was more solemn than that which was sworn upon bread and salt. To sprinkle the meat with salt was to drive away the devil, for in the quaint language of an old divine, “He loveth no salt on his meat, for that is a sign of immutability,” and to this day, nothing is more unlucky than to spill the salt.

The experiments of Boussingault on animals have shown that, although salt mixed with the fodder does not much affect the quantity of flesh, fat, or milk obtained from them, yet it seriously affects their appearance and general condition; for animals deprived of salt, other than that contained naturally in the food, soon get heavy and dull in their temperament, and have a rough and staring coat. Reulin states that animals which do not find it in their food or drink, become less prolific, and the breed rapidly diminishes in number. This is confirmed by Dr. Le Saine, who says, in his prize-essay on salt, that it increases the fertility of the male and the fecundity of the female, and it doubles the power of nourishing the fœtus. During the period of suckling, also, salt given to the mother renders the milk more abundant and more nutritious. It likewise accelerates growth, and gives a finer condition to the skin; and the flesh of animals fed with it is better flavoured, and more easily digested, than that of animals which do not par-

take of it. In barbarous times, the most horrible of punishments, entailing certain death, was the feeding of culprits on food without salt; and in the experiments of the French Academicians, flesh deprived of its saline constituents by being washed with water, lost its nutritive power, and animals fed on it soon died of starvation. Even after a few days, with such a diet, the instincts of the animals told them it was worthless as food, and they fed on it with reluctance; indeed, for all purposes of nutrition, it was, as Liebig says, no better than the eating of stones, and the utmost torments of hunger were hardly sufficient to induce them to continue the diet. There was plenty of nutritious matter in the food, but there was no medium for its solution and absorption, and hence it was useless.

The *Oxides of iron*, and their homologues, the *oxides of manganese*, are largely concerned in the processes of sanguification and oxidation. They enter into the composition of the globules of the blood—manganese being the chief mineral constituent of the corpuscles of white-blooded animals, and iron of red. In fact, the colouring-matter of the blood discs (*hæmoglobin*), as well as that of the muscles (*myochrome*), is a compound of iron and albumen (*globulin*), which has a remarkable property of absorbing oxygen when exposed to the air, and of giving it out again in the presence of reducing agents. In the one case it acquires an arterial tint, and in the other a venous; and the spectrum informs us that these two conditions of it are easily assumed—one by the presence of atmospheric oxygen, and the other by decaying organic matter. It is hardly to be doubted that these are the conditions of it in blood—the bright red oxidised hæmoglobin being the form of it in arterial blood, and the dark reduced variety of it in venous. The functions, therefore, of both hæmoglobin and myochrome are entirely of a respiratory nature; for in the former case it is the medium whereby oxygen is absorbed from the air in the

lungs, and is carried with the blood-discs throughout the body, and in the latter it is probably the agent of interstitial oxidation.

Lastly, there is a mineral constituent of our food, *silica*, which enters into the composition of all the tegumentary appendages. Its presence is not of so much importance to us as to the lower animals, whose warmth is retained by a natural covering of hair, or wool, or feathers. In the case of birds, indeed, the quantity of silica in the feathers is very considerable, and Gorup-Besanez has described its physiological relations, showing how necessary is the presence of silica in their food.

As to the proportions of mineral substances required in the food, it is difficult to speak. Dr Edward Smith says that an adult man requires daily from 32 to 79 grains of phosphoric acid; from 51 to 175 grains of chlorine (equal to from 85 to 291 grains of common salt); from 27 to 107 grains of potash; from 80 to 171 of soda; from 2.3 to 6.3 of lime; and from 2.5 to 3 of magnesia. According to Mr. Lawes, a very small portion of these salts is retained in the system; for in fattening pigs he found that of every 11 lbs. of mineral matter contained in the food, only 12 ozs were stored up in the body, and this was chiefly the earthy phosphates, all the rest being either unabsorbed, or else used in the work of absorption, assimilation, and secretion. In most cases, therefore, there is sufficient saline matter, excepting common salt, in all ordinary food; but for all this, the presence of it in the water we drink is not an unimportant question. Four-fifths of the earth's surface are composed of calcareous strata, which yield water which is more or less rich in carbonate and sulphate of lime; and it may be that this is a wise provision for the supply of these salts to the animal system. As Mr. Johnson has truly observed in his "Chemistry of Common Life," "The bright sparkling hard waters which gush out in frequent

springs from our chalk and other limestone rocks are relished to drink, not merely because they are grateful to the eye, but because there is something exhilarating in the excess of carbonic acid they contain and give off as they pass through the warm mouth and throat; and because the lime they hold in solution removes acid matters from the stomach, and thus acts as a grateful medicine to the system. To abandon the use of such a water, and to drink daily in its stead one entirely free from mineral matter, so far from improving the health, may injure it;” in fact, the water of a country may determine the diet of its inhabitants. The soft waters of the lakes of Scotland, for example, may have had something to do with the choice of brown meal, which contains so much saline matter; and but for the calcareous waters of Ireland the potato could not have become a national food.

And now, before I leave this part of the subject, it is right that I should say a few words respecting the *FUNCTIONS OF CERTAIN BEVERAGES* (as *TEA, COFFEE, and FERMENTED LIQUORS*), which have been more or less in use in all ages, as if from an untaught physiological instinct. We find, indeed, that vegetable infusions containing the same active principles—namely astringent matter, volatile oil, and a crystallisable body rich in nitrogen, have been resorted to for some undefined purpose by the natives of every country; in fact, to use the words of Mr. Johnson, “the practice has prevailed equally in tropical and in arctic regions. In Central America, the Indian of native blood, and the Creole of mixed European race, indulge alike in their ancient chocolate. In Southern America the tea of Paraguay is an almost universal beverage. The native North American tribes have their Apalachian tea, their Oswega tea, their Labrador tea, and many others. From Virginia to Louisiana, in the United States, and over all the West India Islands, the naturalised European races sip their favourite coffee;

while over the Northern States of the Union, and in the British provinces, the tea of China is in daily and constant use.

“All Europe, too, has chosen its prevailing beverage; Spain and Italy delight in chocolate; France and Germany, and Sweden and Turkey, in coffee; Russia, Holland, and England, in tea; whilst poor Ireland makes its warm drink of the husks of the cocoa,—the refuse of the chocolate-mills of Italy and Spain.

“All Asia feels the same want, and in different ways has long gratified it. Coffee, indigenous in Arabia, or the adjoining countries, has followed the banner of the Prophet, wherever in Asia or Africa his false faith has triumphed. Tea, a native of China, has spread spontaneously over the hill country of the Himalayas, the table lands of Tartary and Thibet, and the Plains of Siberia; has climbed the Altai, overspread all Russia, and is equally despotic in Moscow as in St. Petersburg. In Sumatra, the coffee-leaf yields the favourite tea of the dark-skinned population; while Central Africa boasts of the Abyssinian chaat as the indigenous warm drink of its Ethiopian people. Everywhere, in fact, unintoxicating and non-narcotic beverages are in general use among tribes of every colour, beneath every sun, and in every condition of life. The custom, therefore, must meet some universal want of our nature, some physiological function which science has not yet explained: and considering that these beverages contain essentially the same chemical compound, it is remarkable that they should have been selected from the whole range of the vegetable kingdom.” As Mr. Johnston truly observes, “What constitutional craving common to us all have prompted to such singularly uniform results! Through how vast an amount of unrecorded individual experiences must these results have been arrived at!”

The principal constituents of these vegetable substances are:—

1st. A *volatile oil* on which their aroma depends, and which rarely amounts to one part in 150. 2nd. An *astringent acid*, of the nature of *tannic acid* in tea, and called *caffeic acid* in coffee, which give them their bitter styptic taste; it amounts to from 13 to 18 per cent. in tea, and to about 5 per cent. in coffee; and 3rd. A crystallised nitrogenous substance of an alkaline nature called *theine* or *caffeine*, and *theobromine*. The average amounts of the alkaloid in different vegetable substances, according to Dr. Stenhouse, are here recorded:—

	Theine or Caffeine per cent.
Guarana or Brazilian Cocoa, from <i>Guarana officinalis</i>	5·07
Good Black Tea	2·13
Black Tea from Kemaon, E. I.	1·97
Dried Coffee leaves	1·26
Maté or Paraguay Tea, from <i>Ilex Paraguayensis</i> . .	1·20
Various samples of Coffee beans, from 0·8 to	1·00

These results were obtained at a time when the chemical process of analysis was not so perfect as it now is in the hands of Dr. Stenhouse, and it is probable that the quantities of them are understated; for a good sample of Himalayan green tea has lately yielded 4·94 per cent. of the alkaloid.

The physiological properties of them and of its homologue, theobromine, are not clearly discoverable. Mulder states that they are not the agents concerned in the peculiar action of tea and coffee. Liebig, however, points to the fact that, with the addition of oxygen and the elements of water, they can yield taurine, which is the nitrogenised constituent of bile; and he asks whether they may not be concerned in the production of bile. Theine, he also states, is related to kreatinine—that remarkable compound, produced in the vital process, and occurring in the muscular system of animals; and to glyocol, which we may suppose to exist in gelatine coupled with another compound. In fact, according to him, there are no drinks which in their complexity

and in the nature of certain constituents, have more resemblance to soup than tea and coffee; and it is very probable, he says, that the use of them as a part of food depends on the exciting and vivifying action which they have in common with soup. Reasoning in this way, it may be said that theine or caffeine and theobromine are closely related in their composition to nervous tissue, and that therefore they are suited for the repair and renovation of the exhausted brain. Experiments made by Lehmann, in 1854, with infusion of roasted coffee and caffeine, went to show that their chief influence on the human body was to retard the waste of tissues; that when, for example, an infusion of three-quarters of an ounce of roasted coffee was taken daily for a fortnight, the amount of urea and phosphoric acid excreted by the kidneys was less by one-third than when the same food was taken without the coffee. The empyreumatic oil was found to exert a stimulating action on the nervous system, and when taken in excess caused excitement and wakefulness. It also operated on the skin by producing a gentle perspiration, and it removed the sensation of hunger. The conclusion from both these experiments was, that both tea and coffee exhilarate the nervous system, and by lessening waste, enable the food to go further in its nutritive action; that with a given quantity of food, more work could be performed when these beverages were taken than otherwise; and that in old, infirm persons, where the desire for tea is so strong, the waste and decay of the system was lessened. It operates, in fact, as a sort of lubricant to the animal system, and, as it were, by oiling the machinery, enables it to work easier and longer.

The more recent experiments of Dr. Edward Smith, are not exactly to the same purpose; for, in his opinion tea promotes rather than checks the chemico-vital functions of the body, for directly after it is taken, the quantity of carbonic acid emitted from the lungs, and

the quantity of air inspired are increased, and there is greater depth and freedom of respiration. In this way, he thinks it promotes the transformation of starchy and fatty food; besides which, it increases the action of the skin, and by inducing perspiration lessens the heat of the body. Coffee, he says, has an opposite effect, for it lessens the action of the skin, and promotes that of the bowels; and its influence on the respiratory processes is somewhat less than that of tea.

It is manifest from all this, that we have yet to learn what are the special actions of these beverages; and why it is that they have been used in all times, and in all countries, as a means of supplying some natural want which science is unable to discover—that everywhere the poor and the needy, the aged and the infirm, will make a sacrifice of even nutritious food for some such beverage as tea and coffee—that not less than 500 millions of the human race make use of an infusion of tea; that more than 100 millions drink coffee from the roasted berry, and perhaps 2 millions from the dried leaves; that about 50 millions drink cocoa, or use it as chocolate; and that not less than 10 millions of the inhabitants of Peru, Paraguay, and the Brazils, use an infusion of matê or guarana. But besides this, about 40 millions use chicory, either alone or mixed with coffee; 400 millions eat or smoke opium; 300 millions haschish or Indian hemp; and nearly all the people of the earth smoke or chew tobacco, and drink intoxicating beverages. In this country more than 100 millions of pounds of tea are consumed annually, and perhaps, about half as much of coffee. All this looks like the influence of some deep-seated necessity, which our philosophy is unable to fathom, and which science has yet to explore.

With regard to the use of *fermented liquors*, there is the same universal indication of their serving a profound physiological purpose, and supplying a common

want. It is no argument that because these things have been abused, they serve no purpose in man's economy. On the contrary, the fact of their use in all time, and that no saccharine liquid, or juice of ripe fruit, can be exposed to the air without spontaneous and almost immediate fermentation, are striking evidences of design for some useful purpose. They may not enter into the composition of tissues, but they may stimulate the energies of the living frame, and rouse them into increased activity. It is not merely the brick-work and marble, so to speak, of the human body, nor yet the rough movements of the machine, that have to be sustained, for there are rarer forms of matter, and higher manifestations of force, concerned in man's existence; and his resort to such beverages as these may be for something more than the nourishment of the system, or even the mere raising of his spirit above the common concerns of this work-o'-day world.

That *alcohol* stimulates the action of the nervous system there is no doubt, and it is equally certain that it increases the respiratory changes, but the effect must not be carried too far. Dr. Parkes found, in his experiments, on a young healthy soldier, that small quantities of alcohol increased the appetite, and roused the action of the heart and capillary vessels, accelerating the circulation; but in larger quantities, as when narcotism began, the effects were distressing. The same was the case with good claret (Haut Brion), 10 ounces of which, containing one ounce of pure alcohol, taken in the course of the day, did good, while twice this quantity did harm by making him feverish and uncomfortable, besides which the alcohol began to appear in the urine, showing that it was in excess in the body. Dr. Edward Smith is of opinion that alcohol lessens the action of the muscles which are subject to volition, and increases, in a certain degree, the action of those which are independent of it, as the heart and respiratory muscles. He

finds, too, that it diminishes the functions of the skin, and by thus lessening the waste of animal heat, it has a conservative tendency. The effects of alcohol are, however, much modified by the substances with which it is associated in different alcoholic liquids—*beers* and *ale*, for example, act on the respiratory functions by reason of the saccharine and nitrogenous matters they contain; *wine*, also, as well as *cider* and *perry*, have a similar action, and in proportion to their saccharine and acid constituents; *brandy* and *gin* lessen the respiratory changes, and the latter acts on the kidneys by reason of the volatile oil in it; *whisky* is uncertain in its effect on the lungs; while *rum*, like *beer* and *ale* is a true restorative, as it sustains and increases the vital powers; he says, indeed, that the old-fashioned combination of *rum* and *milk* is the most powerful restorative with which he is acquainted.

Liebig is of opinion that alcohol is burnt or oxidised in the system, and is therefore a calorific agent; but the researches of Lallemand, Perrin, and Duray, as well as those of Dr. Edward Smith, have demonstrated that a large portion of it passes through the system unchanged, and appears in the breath and perspiration, as well as in the urine. They, therefore, conclude that alcohol is not a food, but it is a mere excitor of the nervous centres. On the other hand, Dr. Thudichum, in a rather large experiment on the students of his class (33 in number), found that of the 61,730 grains of alcohol in the 44 bottles of wine which they drank at one sitting, only 154·3 grains appeared in the urine; and assuming that the same quantity was exhaled by the breath and skin, he concluded that only 0·5 per cent. of alcohol escaped unchanged. He therefore believes that alcohol is oxidised in the body, and is a true food.

But besides this, the inquiries of Poiseuille have shown that it is a physical as well as a chemical and physio-

logical agent, for it hinders the flow of liquids in narrow tubes, and may act in the same way on the movements of the blood in the capillary vessels. He found, for example, that when the flow of a certain quantity of water through a small tube occupied 575·8 minutes, and of the serum of blood 1048·5 minutes, the flow of the same quantity of Madeira wine under the same circumstances was 1138 minutes; of sparkling Sillery, 1463; and of Jamaica rum, 1832. May it not be, then, that the increased action of the heart, and the influence of alcohol, is an effort or struggle to overcome the resistance by the capillaries. The functions of alcohol are manifestly of a complicated nature; in fact, the whole subject is remarkably obscure, and requires the light of science to illuminate it. As in the case of tea and its allies, ages of empiricism are waiting for a philosophical interpretation.

7th, and lastly. As to the FUNCTIONS of CONDIMENTS, as PEPPER, MUSTARD, SPICES, &c. They are merely stimulants of the digestive organs, promoting the flow of saliva, the gastric juice, and other intestinal secretions, and increasing the peristaltic movements of the viscera. They thus aid in the processes of digestion, and by giving flavour to the food, they whet the appetite, and so increase the relish for it; indifferent food is thus made palatable, and its digestion accelerated. As an example of this, I may mention the *curry powder* of the East, which gives such a relish to the otherwise insipid rice, and which, for the same reason, we use with the almost flavourless mixtures of rice with chicken, rabbit, or fish. In Ceylon, where it is prepared in perfection, it consists, according to Dr. Balfour, of a piece of green ginger, two fragments of garlic, a few coriander and cummin seeds, six small onions, one dry chili, eight peppercorns, a small piece of turmeric, half a dessert-spoonful of butter, half a cocoanut, and half a lime; but

to have it in perfection it must be made on the same day on which it is cooked.

Pot-herbs are used for the same purpose, and especially for flavouring broth and soup.

THERMOTIC, MECHANICAL, AND FATTENING POWERS OF FOOD.

And now, in conclusion, we may safely inquire, as a supplementary question to the functions of food, what are the probable mechanical and thermotic powers, as well as the fattening capabilities, of various articles of diet?

THERMOTIC POWERS of FOOD.—Dr. Frankland has made some very careful determinations of *the calorific values of different substances used as food*; and remembering that every pound of water raised 1 deg. F. represents a mechanical force of 772 lbs. lifted a foot high, it is easy to calculate the possible working energy of any substance from its thermotic power when burnt in oxygen, or when less perfectly consumed in the animal body. Arranging the results under these two heads, we shall find that the energies of different articles of diet may be expressed as follows:—

TABLE XIII.

Thermotic Power and Mechanical Energy of 10 Grains of the Material, in its Natural Condition, when Completely Burnt in Oxygen, and when Oxidised into Carbonic Acid, Water, and Urea, in the Animal Body.

Name of Food	Per cent. of Water in Material.	Lbs. of Water Raised 1° F.		Lbs. Lifted 1 foot high.	
		When Burnt in Oxygen.	When Oxidised in the Body.	When Burnt in Oxygen.	When Oxidised in the Body.
Butter . . .	15	18·68	18·68	14,421	14,421
Cheshire cheese . . .	24	11·95	11·20	9,225	8,649
Oatmeal . . .	15	10·30	10·10	7,952	7,800
Wheat flour . . .	15	10·12	9·87	7,813	7,623

Name of Food.	Per cent. of Water in Material.	Lbs. of Water Raised 1° F.		Lbs. Lifted 1 foot high.	
		When Burnt in Oxygen.	When Oxidised in the Body.	When Burnt in Oxygen.	When Oxidised in the Body.
Pea-meal . . .	15	10.12	9.57	7,813	7,487
Arrowroot . . .	18	10.06	10.06	7,766	7,766
Ground rice . . .	13	9.80	9.52	7,566	7,454
Yolk of egg . . .	47	8.82	8.50	6,809	6,559
Lump sugar . . .	19	8.61	8.61	6,649	6,649
Grape sugar . . .	20	8.42	8.42	6,510	6,510
Entire egg (boiled)	62	6.13	5.86	4,732	4,526
Bread crumb . . .	44	5.74	5.52	4,431	4,263
Ham (boiled) . . .	54	5.09	4.30	3,929	3,321
Mackerel . . .	71	4.60	4.14	3,551	3,200
Lean beef . . .	71	3.03	3.66	3,111	2,829
Lean veal . . .	71	3.38	3.01	2,609	2,324
Guinness's stout . . .	88	2.77	2.77	2,138	2,138
Potatoes . . .	73	2.60	2.56	2,007	1,987
Whiting . . .	80	2.32	2.03	1,791	1,569
Bass's ale . . .	88	1.99	1.99	1,536	1,536
White of egg . . .	86	1.72	1.48	1,328	1,143
Milk . . .	87	1.70	1.64	1,312	1,246
Carrots . . .	86	1.36	1.33	1,050	1,031
Cabbage . . .	89	1.12	1.08	864	834

It will be understood, of course, that to obtain these results in the animal body the materials must be completely absorbed, and fully oxidised into carbonic acid, urea, &c.

Estimated in this manner, it may be said, that a daily subsistence diet of 2.67 ozs. of dry nitrogenous food, and 17.65 ozs. of dry carbonaceous, calculated as starch; and a daily working diet of 4.48 ozs. of dry nitrogenous matter, and 22.14 ozs. of dry carbonaceous, have the following mechanical energies:—

Kind of Diet.	Lbs. Lifted 1 foot high.	
	When Burnt in Oxygen.	When Oxidised in the Body.
Subsistence diet . . .	8,497,237	8,256,486
Working diet . . .	11,159,904	10,874,136

But the actual working power of the human body does not approach this. In fact, although a man's daily

labour has a very large range, as from 300,000 foot-pounds when lifting dung into a cart, to 1,500,000 foot-pounds when pushing or pulling horizontally; yet, the average is not much above one million foot-pounds, as will be seen from this diagram:—

TABLE XIV.

Actual Daily Work in Pounds Raised 1 Foot High.

Kind of labour.	Amount of work in foot-pounds.	Authority.
Bricklayer's labourer carry- ing bricks }	1,627,200	Mayhew.
Coal whipping	1,774,221	Mayhew.
Ascending Faulhorn	1,074,913	Wislicenus.
Ascending Faulhorn	933,746	Fick.
Treadmill	1,008,000	Mayhew.
Treadmill	865,166	Ed. Smith.
Turning a winch	837,766	Coulomb.
Pedestrians (20 miles a day)	792,000	Haughton.
Paving and pile driving	788,480	Coulomb.
Porters carrying loads	732,480	Coulomb.
Shot-drill punishment	694,400	Haughton.
Average	1,011,670	

And even when we add the calculated internal work of a man's body, as the beating of the heart and the movements of respiration, the total of it does not much exceed a million and a-half foot-pounds a day.

	Foot-pounds.
External work or actual labour	1,011,670
Work of circulation (75 beats a minute)	500,040
Work of respiration (15 a minute)	98,496
Total ascertainable work per day	1,610,206

It is evident, therefore, that a large portion of our food must escape digestion and absorption (although the thermotic power of the food actually consumed daily, as estimated by the carbonic acid exhaled and the urea secreted, is almost sufficient to raise the temperature of 10,000 lbs. of water 1 deg. F. This is equal to a force of 7,720,000 lbs. lifted a foot high.) Consequently it would seem that the ascertainable internal and external work of the food is only about one-sixth of its actual energy, the rest of the power being consumed in molecular movements, which cannot be estimated within the animal body. Helmholtz asserts that the external work should be a fifth part of the mechanical force of the digested food, but labour must be well applied to develop anything like this proportion of its energy.

In the steam-engine, according to Sir William Armstrong, only a tenth part of the actual power of the fuel is realised as work. The human machine is therefore more economical of its force than a steam-engine; in fact, it is assumed by Heidenham and others that not less than half the force applied to the living muscles, as it is developed in their tissue, is utilised. But although the animal machine is so much more economical of force than the steam-engine, yet on account of the costliness of its fuel, &c., it is far more expensive. Taking, for example, a steam-engine of one-horse power (that is, a power of raising 33,000 lbs. a foot high per minute), it will require two horses in reality to do the same work for ten hours a day, or twenty-four men; and the cost, at the utmost, would be only 10d. for the steam-engine, while it would be 8s. 4d. for the two horses, and just £2 sterling for the twenty-four men.

Dr. Frankland has estimated the weight and cost of various articles of food required to be oxidised in the animal body in order to raise 140 lbs. (a rather small man), to the height of 10,000 feet, supposing that as

much as one-fifth of the actual energy of the food is manifested as external work.

TABLE XV.

Weight and Cost of various Articles of Diet required to raise a Man (140 lbs.) to the height of 10,000 feet.

Name of Food.	Price per lb.		Ozs. required.	Cost.	
	s.	d.		s.	d.
Oatmeal	0	2 $\frac{3}{4}$	20·5	0	3 $\frac{1}{2}$
Flour	0	2 $\frac{3}{4}$	21·0	0	3 $\frac{3}{4}$
Pea-meal	0	3 $\frac{1}{4}$	21·4	0	4 $\frac{1}{2}$
Bread	0	2	37·5	0	4 $\frac{3}{4}$
Potatoes	0	1	81·1	0	5 $\frac{1}{4}$
Rice	0	4	21·5	0	5 $\frac{1}{2}$
Beef-fat or Dripping	0	10	8·9	0	5 $\frac{1}{2}$
Cheshire cheese	0	10	18·5	0	11 $\frac{1}{2}$
Cabbage	0	1	192·3	1	0 $\frac{1}{4}$
Butter	1	6	11·1	1	0 $\frac{1}{2}$
Hard-boiled Eggs	0	6 $\frac{1}{2}$	35·3	1	2 $\frac{1}{2}$
Lump sugar	0	6	24·1	1	3
Milk (per quart)	0	5	128·3	1	3 $\frac{1}{2}$
Lean beef	1	0	56·5	3	6 $\frac{1}{2}$
Guinness's Stout	0	10	6 $\frac{3}{4}$ bottles.	5	7 $\frac{1}{2}$
Bass's Pale Ale	0	10	9 bottles.	7	6

The motive power of fatty foods is thus shown to be far higher than that of lean meat or farinaceous substances, and this accords with experience, for the labouring classes have long since discovered that fat bacon is a good material for heavy work. Its efficacy may, in great part, depend on the ease and certainty with which it is digested and utilised in the body.

The fattening and flesh forming powers of food are liable to great variation, not merely from the quality of the food itself, but from the peculiarity of the individual consuming it. This is a matter of common observation, and is well-known to the breeders of stock. Messrs. Lawes and Gilbert found in their experiments on the feeding of bullocks, sheep, and pigs, that very different quantities of food were required to produce the same increase of weight. Oxen and sheep, for example, feeding on the same diet, namely oil-cake, hay, and turnips,

consume, in one case (that of oxen), 1,109 lbs. of dry substance for every 100 lbs of increase in the live weight, while in the other, the sheep consume only 912 lbs.; and pigs fed on barley-meal, will fatten to the same extent on 420 lbs. of the dry material. Pigs, therefore, store up about one-fourth of their food, reckoned in this way, sheep about one-ninth, and oxen only one-eleventh.

The proportions of the several constituents of the food are also very differently used by these animals; for in every 100 parts of the dry food eaten, the several amounts of nitrogenous, carbonaceous, and mineral matters are thus disposed of:—

TABLE XVI.

Proportions of the several Constituents of Food appropriated and used by different Animals.

Constituents of the Dry Food.		Proportions in Dry Food.	Proportions Stored in Animal.	Proportions in Manure.	Proportions lost in Respiration
Oxen	{ Nitrogenous	19.66	0.8	29.1	57.3
	{ Carbonaceous	72.86	5.2		
	{ Mineral	7.48	0.2	7.4	—
		100.00	6.2	36.5	57.3
Sheep	{ Nitrogenous	19.41	0.8	25.1	60.1
	{ Carbonaceous	73.57	7.0		
	{ Mineral	7.02	0.2	6.8	—
		100.00	8.0	31.9	60.1
Pigs	{ Nitrogenous	12.38	1.7	14.3	65.7
	{ Carbonaceous	85.00	15.7		
	{ Mineral	2.62	0.2	2.4	—
		100.00	17.6	16.7	65.5

So that the power of appropriation is greatest with pigs and least with oxen; in fact, of every 100 lbs. of the several constituents of the food, the following are the proportions stored up in the three classes of animals:—

	Pigs.	Sheep.	Oxen.
Of 100 Nitrogenous . . .	13.5	4.2	4.1
Of 100 Carbonaceous . . .	18.5	9.4	7.2
Of 100 Mineral	7.3	3.1	1.9

It will be noticed, too, that the proportions lost in respiration are very different in the three cases; for it is greatest in the pig—amounting to 66 per cent. of all the food eaten, and least in the ox—57.3 per cent. These proportions represent the vital work of the body during the processes of growth and repair, it being evident that where the growth is fastest, as in pigs, the vital work, as represented by the food lost in respiration, is most energetic.

The time also that is occupied in producing fat and muscular tissue is different with these animals, for the pig increases from 6 to 6.5 per cent. of its weight per week; the sheep not more than 1.75 per cent.; and the ox only 1 per cent. Some of this difference is doubtless due to the quality of the food made use of, for the pigs were fed on a nutritious and easily digestible diet—oat-meal; while the sheep and oxen made use of food with a large quantity of cellular tissue and woody fibre; and here, I may remark, that the power of utilising the inferior varieties of food is very different with different classes of animals. Man, as I have already explained, is unable to digest woody fibre, or even the harder kinds of cellulose; it is doubtful, indeed, whether he can digest cellulose at all. The pig also has but a limited capacity for this kind of work; whereas oxen and sheep, and the herbivora generally, can eat woody tissues with advantage, and convert them into flesh and fat. In eating meat, therefore, we are utilising the digestive powers of other animals; and are, in fact, economising force by employing their stomachs to do for us that which we could not do for ourselves without a large expenditure of vital energy. This, as Mr. Lawes says, is proved, not

merely by the testimony of common experience, but also by certain anatomical facts relating to the structure and comparative size of the stomach in different animals. In oxen, for example, the stomach weighs 51 ozs. for every 100 lbs. of live weight; in sheep it weighs 39 ozs.; in pigs 14 ozs.; and in man only 6 ozs. It is manifest, therefore, that the food of man should be more concentrated than that of the lower animal; and that he acts wisely in eating flesh and fat, which are the very essence of food, for he thereby economises labour, and employs the assimilative powers of other creatures to bring the crudest materials into a nutritious and highly digestible form. It is true that man, in common with other animals, is able to convert starch and sugar into fat, and the lower qualities of vegetable albumen into flesh, but by so doing he expends force, for in the case of fat he locks up in it twice and a half the potential power of sugar and starch; and in that of flesh, he concentrates to an unknown extent the energies of albumen in the several constituents of muscle and its juice.

Looking, therefore, broadly at the functions of food, it is evident that, however intricate are the various processes of chemical and other molecular changes to which food is subject within the living animal body, yet the ultimate destiny of it is the development of heat and other modes of motion, which constitute the physiological phenomena of animal life. It is obvious, in fact, that the animal machine is a contrivance for the manifestation of these phenomena through the latent energies of food—energies which were locked up in it by the plant during the processes of reduction or deoxidation to which it was subject in the course of its formation; and which the animal lets loose in reversing the operations of the vegetable by processes of oxidation or combustion. In most cases, it is thought, that these processes occur in the blood, where the constituents of food

are dissolved ; but it is still a question whether, under some circumstances, as in the generation of muscular force, the changes may not occur in the muscular tissues themselves. In the former case, it is supposed that the constituents of food are oxidised while circulating with the blood, and, therefore, without entering into the composition of the animal structures ; but in the latter, it is maintained that the nitrogenous elements of food must become muscular tissue before they can undergo the transformations which are the source of muscular power. Liebig and his followers are of this opinion, for they argue that muscular force is always generated by transformation of the nitrogenous constituents of muscle, in which oxygen takes part, though without directly causing it ; while others contend that all manifestations of force within the living animal body are referable to the combustion of matters dissolved in the blood, and that these matters are generally of a non-nitrogenous nature. A portion of tissue, they say, no doubt decays in the transference of its energies to other forms of action, and, therefore, requires repair ; but the decay is not, as Liebig supposes, the cause of muscular motion, but the effect of it. "In man," says Dr. Frankland, "the chief materials for muscular power are non-nitrogenous ; but nitrogenous matter can also be employed for the same purpose, and hence the greatly increased evolution of nitrogen under the influence of a flesh diet, even with no increase of muscular exertion. The non-nitrogenous matters, also, which find their way into the blood, yield up all their *potential* energy as *actual* energy ; whereas the nitrogenous, in leaving the body as urea, carry with them a portion (at least one-seventh) of their potential energy unexpended. The transference of potential energy into muscular power is necessarily accompanied by the production of heat within the body, even when the muscular power is exerted externally. This is, doubtless, the

chief, and probably the only source of animal heat." All, however, are agreed that the functions of food are the development of force; the manifestations of which are motion—muscular and molecular. Further investigations must determine whether, under any circumstances, food must, as a physiological necessity, enter into the construction of the animal body before it can generate force, or whether all the force of the living animal is the result of transformations and oxydations of the dietetical matters dissolved in the blood.

LECTURE III.

CONSTRUCTION OF DIETARIES—TIMES OF MEALS—PREPARATION AND CULINARY TREATMENT OF FOODS.

CONSTRUCTION OF DIETARIES.

THE construction of dietaries involves a variety of considerations, as—1st. The determination of the real wants of the body under different circumstances of age, sex, constitution, labour, and climate; 2nd. A proper selection of food, as regards quality, nutritive power, appetising property, digestibility, and price; 3rd. The association of foods in such wise as not to offend the appetite or burden the digestive powers; 4th. A right treatment of them by cooking, &c., so as to render them most useful to the system; and 5th. A just distribution of the daily diet in appropriate meals.

As regards the first question—namely, THE DETERMINATION OF THE ACTUAL DIETETICAL WANTS OF THE BODY—it may be answered from two sets of facts, as those which pertain to the minimum quantities of food capable of being used without loss of health or bodily vigour, and those which relate to the amounts of carbon and nitrogen exhaled from the body during different conditions of labour.

In a general way it may be said that a healthy vigorous man consumes from 700 to 750 lbs. of solid food (dry) in a year. This amounts to about 2 lbs. of

dry solid matter daily; and the quantity of water (free and combined) is about $5\frac{1}{2}$ lbs. daily.

Pursuing the inquiry a little farther, we find that a man cannot live on a punishment prison diet of 1 lb. of bread a day with water, for in three days he will lose about 3 lbs. in weight, and will show signs of commencing starvation. This diet contains 1.3 ozs. of nitrogenous matter and 8.8 of carbonaceous (= 1,975 grains of carbon and 88 of nitrogen). Even the poor needlewomen of London can only just exist, in a state of feeble vitality, with an average diet of $1\frac{1}{2}$ lbs. of bread a day, with about 1 oz. of dripping. This contains nearly 2 ozs. of nitrogenous matter, and 14.7 of carbonaceous, calculated as starch (= 3,366 grains of carbon and 132 of nitrogen). And in military prisons, where as much as 3.8 ozs. of nitrogenous food, and 22.2 ozs. of carbonaceous (= 5,090 grains of carbon and 256 of nitrogen), are supplied daily to prisoners for short terms of confinement, they frequently lose weight and give evidence of decay; so that for longer periods of imprisonment it is found necessary to increase the diet to 4.7 ozs. of plastic matter, and 27.8 of respiratory (= 6,362 grains of carbon and 317 of nitrogen); in fact, according to Dr. Christison, the men confined in the prison at Perth cannot even do the work of pumping the water for the prison on a daily diet of 6 ozs. of plastic matter, and 25 of respiratory (= 6,082 grains of carbon, and 404 of nitrogen).

During the siege of Paris, when provisions were almost exhausted, it is said that the daily rations were reduced to 300 grammes (4,629 grains of bread, and 30 grammes (463 grains) of meat per head daily—the bread being composed of 30 parts wheat, 30 rice, 20 rye, and 20 oats. This is in the proportion of only 1.44 ozs. of dry nitrogenous matter (= 94 grains of nitrogen) and 10.01 ozs. of dry carbonaceous matter, calculated as starch (= 2,234 grains of carbon) daily. It is not possible, however, to maintain life on such a diet. Earlier in the

siege, when the French Government became anxious about the food supply, they consulted the leading physicians of Paris on the subject, and Dr. Sée was instructed to lecture on it at the School of Medicine. He said that the daily diet of an adult might be made up as follows:—100 grammes (= 1,543·2 grains) of beef, 20 grammes (= 308·6 grains) of salt-fish, 750 grammes (= 11,574·3 grains) of bread, 50 grammes (= 771·6 grains) of bacon, and 50 grammes of vegetables. These contain 3·14 ozs. of dry nitrogenous matter (= 235 grains of nitrogen) and 18·53 ozs. of carbonaceous, calculated as starch (= 4,241 grains of carbon); but these proportions are barely sufficient to maintain life, even when the body is performing no work beyond its own physiological movements.

Dr. Edward Smith found in his inquiries into the dietaries of adult male operatives of Lancashire and Cheshire, during the cotton famine, and also into those of the low-fed operatives of England, that the daily amount of food, only barely sufficient for existence, must contain 2·84 ozs. of nitrogenous matter, and 19·25 of carbonaceous (= 4,321 grains of carbon and 191 of nitrogen). These are contained in 2 lbs. 4 ozs. of bread, which is regarded as a famine diet. The farm labourers of England consume daily an average of 3·18 ozs. of plastic matter and 26·01 of respiratory. In Scotland, Wales, and Ireland, the amounts are somewhat larger, as will be apparent from this diagram:—

TABLE XVII.

Average Daily Diet of Farm-Labourers in the United Kingdom.

	Dry Nitrogenous Matter. ozs.	Dry Carbonaceous Matter as Starch. oz.	Containing	
			Carbon. grs.	Nitrogen. grs.
In England . . .	3·18	29·32	5,705	214
In Wales . . .	4·12	35·51	6,909	277
In Scotland . . .	4·76	36·30	7,063	321
In Ireland . . .	4·94	34·26	6,665	333
Average of all . . .	4·25	33·85	6,585	286

These are the results of inquiries into the dietaries of many hundreds of families, the proportions being computed as for adults; but it is very probable, as Dr. Smith remarks, that the nourishment obtained by the labourer himself is somewhat above the average. This, in fact, is confirmed by the more extensive investigations of Dr. Lyon Playfair, who concludes, from a large series of observations, that the following may be regarded as the average proportions of the several constituents of food in the daily dietary of an adult man under different circumstances of existence:—

TABLE XVIII.

Daily Diet according to Work Done.

Daily Diets for	Flesh-former. ozs.	Fat. ozs.	Starch and Sugar. ozs.	Nitro- genous. ozs.	Carbonaceous. Calculated as Starch. ozs.
Subsistence only	2.0	0.5	12.0	= 2.0	+ 13.3
Quietude . . .	2.5	1.0	12.0	= 2.5	+ 14.5
Moderate exercise	4.2	1.8	18.7	= 4.2	+ 23.2
Active labour . .	5.5	2.5	20.0	= 5.5	+ 26.3
Hard work . . .	6.5	2.5	20.0	= 6.5	+ 26.3

These conclusions accord pretty well with the determinations of Pettenkofer and Voit, who say that an adult requires daily, when at work, 5.22 ozs. of nitrogenous matter and 22.38 of carbonaceous (calculated as starch). A Bavarian wood-cutter, according to Liebig, receives from his employer, when he goes after breakfast on a Monday into the forest, 3.4 lbs. of dripping, and 7.8 lbs. of meal, and 4.5 lbs. of bread. He comes home on Saturday evening to supper. This quantity of food is therefore, sufficient for five days; and it represents a daily supply of 4.31 ozs. of dry nitrogenous matter (=290 grains of nitrogen), and 49.91 ozs. of carbonaceous, calculated as starch (=9704 grains of carbon). A Russian peasant, whose yearly rations are accurately apportioned, has an average daily ration con-

taining 5.67 ozs. of dry nitrogenous matter (= 381 grains of nitrogen), and 42.41 ozs. of carbonaceous, calculated as starch (= 8,246 grains of carbon); and a Chinese labourer, receives as food from his employer, an average daily dietary containing 4.66 ozs. of dry nitrogenous matter (= 313 grains of nitrogen), and 36.32 ozs. of carbonaceous matter calculated as starch (= 70.62 grains of carbon).

Taking, therefore, the mean of all these researches, it may be said that a man requires daily in his food, the following amounts at least, of carbonaceous and nitrogenous matters for idleness, for ordinary labour, and for active labour:—

Daily Diets for	Nitrogenous. ozs.	Carbonaceous. ozs.	Carbon. grs.	Nitrogen. grs.	
Idleness	2.67	19.61	} = {	180	
Ordinary labour	4.56	29.24		5,688	307
Active labour	5.81	34.97		6,823	391

By pursuing the second method of inquiry and estimating the wants of the body from the amounts of carbon and nitrogen exhaled and secreted, it is found that the proportion of carbon evolved as carbonic acid from the lungs of a man in health varies from 6 ozs. to 13½ ozs. daily, the difference being dependent on temperature, exercise, &c. Dr. Edward Smith says that it amounts to—

7.85 ozs. daily while the body is quiet;
9.11 ozs. daily with moderate exercise;
12.9 ozs. daily with considerable labour.

And he considers that a healthy man of average weight (150 lbs.) emits 8.57 ozs. of carbon from his lungs daily. This, added to the quantity discharged from the skin and bowels, is not less than 9.6 ozs. daily (= 4,200 grains) or just 28 grains per lb. of the man's weight. During light labour, he says it ranges from 9.6 ozs. to 10.5, and during hard work from 12.5 to 14 ozs. These are in the

proportions of 21·6 ozs. of dry carbonaceous matter, calculated as starch for idleness; 23·63 ozs. for moderate exercise; and 31·5 ozs. for hard labour; but these proportions do not include the carbon excreted by the kidneys, which would bring them up to the quantities before mentioned.

The amount of nitrogen excreted as urea, &c., in the urine is also subject to great variation, according to diet and exercise. Dr. Parkes found in his experiments on two soldiers, that with an ordinary diet and no exercise, it amounted to 2·03 grains per lb. weight of the body (= 304 grains per 150 lbs.); and that with a non-nitrogenous diet, and no exercise, it was 0·95 grains per lb. weight (= 142 grains per 150 lbs.); and with the same diet and active exercise it was 2·42 grains per lb. weight (= 364 grains per 150 lbs.)

Professors Fick and Wislicenus observed that the nitrogen secreted during an ordinary diet, and no exercise, was at the rate of 1·53 grains per lb. weight (= 203 grains per 150 lbs.); and that it fell to a little less than one grain per lb. weight with a non-nitrogenous diet during the labour of ascending the Faulhorn.

The researches of the Rev. Dr. Haughton, of Dublin, have led him to conclude that an average-size man performing routine work, secretes 187 grains of nitrogen as urea daily (= 1·25 grains per lb. weight); and Dr. Edward Smith has estimated it at from 0·93 to 1·4 grains per lb. weight—a fair average being 1·15 (= 173 grains per 150 lbs.).

The more extensive inquiries of Playfair, Ranke, Beigel, Moos, Vogel, and others, give a daily average of 171 grains of nitrogen as urea for a healthy man at rest, and 252 grains for ordinary labour.

It may therefore be safely concluded that with an ordinary diet, an average-size man excretes daily as urea 175 grains of nitrogen; and during labour of a moderate description it amounts to about 250 grains. Adding to

these the proportions of nitrogen excreted in other forms in the urine, and the quantities passed from the bowels, the total amounts are probably about 190 grains while at rest, and 300 grains when at routine work; the difference, perhaps, being more dependent on the food than on the metamorphosed tissues of the body.

It thus appears that the proportions of carbon and nitrogen excreted correspond very closely with those contained in the diets which experience has proved to be necessary for man's sustenance; for when the results are put into a tabular form they stand thus:—

TABLE XIX.

Daily Requirements of the Body.

		Nitro- genous Food. ozs.	Carbon- aceous Food. ozs.		Carbon. grs.	Nitrogen. grs.
During idleness as determined	{ By dietaries . . .	2·67	19·61	=	3,816	180
	{ By excretions . . .	2·78	21·60	=	4,199	187
Average . . .		2·73	20·60	=	4,005	184
Routine work as determined	{ By dietaries . . .	4·56	29·24	=	5,688	307
	{ By excretions . . .	4·39	23·63	=	4,694	296
Average . . .		4·48	26·44	=	5,191	302

The first of these averages is represented by 2 lbs. 2 oz. of bread, and the second by about 3½ lbs.

It appears also that the relation of the nitrogenous to the carbonaceous constituents of food should be about as 1 to 6 or 6½. These, in fact, are the proportions which Messrs. Lawes and Gilbert found to be best suited for fattening pigs. In milk the proportions are as 1 to 3·6 (the butter being calculated as starch); and no doubt these are the right proportions for the dietaries of children, who have to build up their structures, and therefore require a large proportion of nitrogenous matter. Again, it will be observed, that the relation of nitrogen to carbon is nearly as 1 to 19; whereas in milk

it is about as 1 to 13. Referring to Table No. 3, it will be noticed that the proportions in bread are as 1 to 23, and in meat as 1 to 10, showing that the former requires the addition of plastic matter, and the latter of respiratory.

In preparing dietaries, however, it will be best to take a rather liberal view of the question, and, therefore, I shall adopt the conclusions of Dr. Edward Smith—that even in periods of idleness a man's daily food should contain not less than 4,300 grains of carbon, with 200 of nitrogen; and a woman's at least 3,900 grains of carbon, with 180 of nitrogen—these bring the proportions which, in his opinion, are necessary to avert starvation diseases; and they are represented in the case of a man's diet by 22 oz. of carbonaceous food, with 2.97 of nitrogenous. The diagram before you exhibits the amounts of different articles of diet capable of furnishing this quantity of nitrogenous matter, and it also shows the proportions of carbonaceous matter (calculated as starch) associated with it:—

TABLE XX.

Amounts of Food Yielding 200 Grains of Nitrogen or 2.97 ozs. of Plastic Matter necessary for a Man's Daily Diet.

Description of Food	ozs.	Carbonaceous Matter in it as Starch. ozs.	Carbon in it. grs.	
Skim-cheese	6.6	0.89	778	Carbon deficient.
White fish	16.4	1.19	836	
Lean meat	15.6	1.78	951	
Skim milk	74.2	7.43	2,049	
Peas	11.2	8.02	2,164	
New milk	72.4	10.69	2,683	
Oatmeal	23.6	18.41	4,184	Carbon in excess.
Baker's bread	36.7	20.20	4,532	
Wheat flour	27.5	26.79	4,647	
Indian meal	26.8	22.84	5,046	
Rye meal	37.1	29.11	6,265	
Barley meal	47.1	38.02	7,997	
Rice	47.1	38.31	8,053	
Bacon	33.7	61.78	12,617	

So that, whilst the first seven of these substances are deficient of carbonaceous matter (22 ozs. being required), the last seven contain it in excess. It is, therefore, not difficult to construct a dietary from the several Tables which I have placed before you; but perhaps it would interest you to know exactly what are the actual dietaries in use among different classes of persons; and first I will direct your attention to what Dr. Edward Smith found to be the average weekly dietaries of the low-fed operatives of England, Wales, Scotland, and Ireland. (See Table XXI. on next page).

You will see from this table that the poor needle-women of London are the worst fed of all the operatives in the three kingdoms, for they subsist on a weekly allowance of 117·71 ozs. of carbonaceous food, calculated as dry starch with 14·10 ozs. of nitrogenous (=16·82 ozs. carbonaceous, with 2·01 ozs. nitrogenous daily), while the farm labourers of Ireland are, as regards the real nutritive value of their food, the best fed of the lower operative classes. But it will also be noticed that the cost of the weekly dietary of the Irish labourer is only 1s. 9 $\frac{3}{4}$ d. per week, while that of the needle-woman is 2s. 7d.—the latter feeding chiefly on bread, bacon, and tea, which are expensive foods, while the former consumes potatoes, milk, and Indian meal—foods which yield more nutriment for their money value than the more expensive foods of the English, Welsh, and Scotch labourers.

I have already described the diet of the Bavarian wood-cutter—consisting for five days of 3·4 lbs. of dripping, 7·8 lbs. of meal, and 4·5 lbs. of bread, with a little fruit which he finds for himself. This yields him 4·31 ozs. of dry nitrogenous matter, and 49·91 ozs. of carbonaceous daily, and he sustains himself well upon them. According to Mr. Yapp, the monthly allowance to a Chinese weaver, is 60 lbs. of rice, costing 4s.; 13·3 lbs. of fish, costing 2s. 6d.; 10·6 lbs. of pork, costing 9s. 8d.; 2 fowls, costing 3s. 6d.; and 2s. 6d. worth of vegetables.

Average per day ...	26.3	11.1	1.4	0.6	1.5	6.1	0.4	0.1	4,881	214	0 4 $\frac{1}{2}$

This, with a little tea and tobacco, costs the employer a little more than 10d. a day; and it yields 4.66 ozs. of dry nitrogenous matter, and 36.32 ozs. of carbonaceous. The yearly dietary of a Russian peasant consists of 451 lbs. of rye flour, worth 19s. English money; 421 lbs. of wheat flour, worth £1 6s. 7d.; $5\frac{3}{4}$ bushels of grits, buckwheat, &c., worth 4s. 9½d.; $30\frac{3}{4}$ lbs. of peas, worth 1s. 1¼d.; $17\frac{1}{2}$ lbs. of oil and butter, worth 4s. 6d.; $32\frac{1}{2}$ lbs. of salt, worth 1s. 4¾d.; 117 lbs. of meat, worth 13s. 2d.; and fish and cabbage costing 9½d.; so that a Russian peasant, when most favourably situated, will get 12 ozs. of meat, principally in soup, on 155 days in the year, and 2 lbs. 6 ozs. of bread and flour, besides buckwheat, peas, &c., at a cost of 2⅓d. per diem; and this amounts, on an average of the whole year, to 5.67 ozs. of dry nitrogenous matter, and 42.41 ozs. of carbonaceous, calculated as starch, daily.

And now we will contrast the dietaries of the poorer classes of operatives with those of better-fed persons, as soldiers, sailors, navigators, &c.; and for this purpose I shall avail myself of the accurate returns obtained and published by Dr. Lyon Playfair:—(Table XXII.)

In all these cases the carbonaceous matters of the food are estimated as starch; and I may state that the soldiers' dietary, when at peace, is calculated from the rations of the English, French, Prussian, and Austrian service; and when at war, it is derived from the actual dietaries of European and American soldiers during recent wars. When our volunteers were in camp in September, 1871, the daily ration per man consisted of $1\frac{1}{2}$ lb. of bread, or 1 lb. of biscuit; $\frac{3}{4}$ lb. of fresh meat, or 1 lb. of salt meat, or $\frac{1}{2}$ lb. of preserved meat; one-sixth of an oz. of tea; one-third of an oz. of coffee; 2 ozs. of sugar; 1 oz. of salt; and a very small quantity of pepper, the charge per man being 6d. This, exclusive of the tea and coffee, contains 270 grains of nitrogen,

and 4721 of carbon, which are equal to only 24·27 ozs. of dry carbonaceous matter, calculated as starch, and 4 ozs. of nitrogenous—quantities which are barely sufficient for active duty, and which were no doubt supplemented by other food at the cost of the volunteers.

TABLE XXII.

Daily Diaries of Well-fed Operatives (Playfair).

Mean of low-fed operatives . . .	3·04	0·64	21·18	22·78	3·04	4881	214

It would be interesting, if time permitted, to compare these diaries with the diaries of hospitals, prisons, workhouses, and lunatic asylums; for we should then perceive not merely how greatly they vary in their nutritive value, but also how little attention is paid to the principles which ought to guide our public authorities in the construction of public diaries. In the prisons of England, Scotland, and Ireland, the several diaries

for short terms of imprisonment, as well as for longer periods, and for hard labour, vary respectively to so great an extent as to furnish an inducement for the commission of crime in certain districts rather than in others, because of the richness of the prison rations; and in all cases the dietaries of prisons are so greatly in excess of the union, that in times of distress they offer encouragement for misdemeanour, in order that the prison may be reached in preference to the workhouse; in short, while the day's ration of an unfortunate inmate of a union contains only about 17 ozs. of dry, nutritious matter, that of a destitute debtor contains 19·4 ozs., and that of a convict 22 ozs.; moreover, a prisoner confined for more than a month, without hard labour, in the jails of England, Scotland, and Ireland, would have 18·8 ozs., 22·4, and 23·9 of dry nutriment respectively; the average rations for hard work containing about 21·7 ozs., 31·5, and 25·6 in the prisons of the three countries.

Dr. Edward Smith has drawn attention to the serious want of uniformity in the dietaries of the unions of his district, and has urged the workhouse authorities to improve them. He also submitted to the Privy Council tables of dietaries, which are well suited to meet the requirements of the body at the lowest money cost. Here are a few of them, which may, perhaps, prove useful to those who are engaged in the benevolent work of supplying food to the poor in times of distress; and you will perceive that at various sums, from about 2s. to 3s. a week per adult, very substantial rations may be provided. (See Table XXIII. on next page.)

The dietaries of women should be about one-tenth less than those of men in the case of indoor operatives, but they ought to be from one-third to one-fourth less than the larger dietaries of men engaged in out-door labour.

As regards the dietaries of children, it may be stated

generally that the chief part of their food should be milk. Up to the age of nine or ten months it should, if possible, be the milk of woman, which is richer in sugar than cow's milk, and much less rich in caseine; failing this, however, ass's milk is a good substitute, as it contains nearly the same amount of sugar and caseine as human milk. I have already given the table from MM. O. Henri and Chevalier, of the proportions of the several constituents in 100 parts of the milk of different animals (Table VI., page 31), from which it will be seen that the solid constituents of the milk of different animals range from 9.35 per cent. in ass's milk to 14.38 in ewe's. Very recent inquiries by my lecture colleague, Dr. Tidy, have shown that the composition of woman's milk varies to the following extent:—

TABLE XXVI.

Maximum, Minimum, and Average Composition of Woman's Milk, compared with the Average Composition of Cow's Milk.

	Woman's Milk.			Cow's Milk.
	Max.	Min.	Average.	Average.
Caseine	4.36	2.97	3.52	3.64
Butter	5.18	4.45	4.02	3.55
Sugar of milk	4.43	3.29	4.27	4.70
Various salts	0.23	0.38	0.28	0.81
Total solids	14.20	11.09	12.09	12.70
Water	85.80	88.91	87.91	87.30
Total	100.00	100.00	100.00	100.00

According to Sourdats the milk of the right breast is generally much richer in butter and caseine than that of the left.

Attempts have been made to produce an artificial milk, but they are not very successful. Dr. C. A. Condereau, for example, recommends a mixture of 8 eggs with 2 ozs. of sugar, and enough water to make a pint

and a half of liquid, to which he adds a little lime water and a small quantity of sulphate of potash and chloride of sodium. Dubrunfaut states that a good substitute for milk may be made by emulsifying about 900 grains of olive oil, or other comestible fatty matter, with from 600 to 870 grains of sugar (milk-sugar, cane-sugar, or glucose), from 300 to 460 grains of dried albumen (the dried white of egg, as met with in Paris), and from 15 to 30 grains of crystals of carbonate of soda, dissolved in a pint of water. The liquid thus prepared has the appearance of cream, and requires to be mixed with twice its volume of water to produce a liquid like milk. But experience has shown that although these substitutes may serve the purposes of milk under some circumstances, as when they are used by adults, yet they cannot be safely used in the nourishment of children, for, as Dumas suggests, it is very probable that there are minute quantities of other substances than albumen, fat, sugar, and salts in milk, which are necessary for the nutrition of infants. Even cow's milk does not always agree with them, the curd being very different from that of woman's milk, and it always requires to be diluted with about one-third of its bulk of water, and to be sweetened with sugar before it is given to children.

Up to six or seven months no other food but milk should be administered, for infants have not the power of digesting farinaceous or fibrinous substances; and a child may take from two to three pints of milk thus diluted daily. After seven months, and to about twenty months, farinaceous matters may be mixed in gradually increasing quantities with the milk; but they should be well cooked by first baking them and then thoroughly dissolving them by boiling. After this age, and up to the third year, the quantity of well-cooked farinaceous matters may be still further increased, and given as puddings with a little egg. Bread and butter may also

be eaten, and towards the end of the time, the child will digest well-boiled potato, with a little gravy of meat. From the third to the fifth year a little meat may also be given, and at the end of the ninth year it may partake of the usual food of the family; but all along it should make use of a large proportion of milk, in the various forms of bread and milk, or milk puddings, with eggs. About the tenth year a child will require about half as much food as a woman; and at the fourteenth year it will eat quite as much as a woman; in fact, the proportion of food required by the child is much greater per pound weight of the body than by adults, because it has to form its tissues and build up its several structures. Dr. Edward Smith calculates that the proportions of carbon and nitrogen in the daily food at different ages should be about as follows:—

TABLE XXV.

Daily Proportions of Carbon and Nitrogen in the Food at Different Ages, per Pound Weight of the Body.

	Carbon. grs.	Nitrogen. grs.
In infancy	69	6·78
At ten years of age	48	2·81
At sixteen years of age	30	2·16
At adult life	23	1·04
In middle age	25	1·13

So that for its weight the infant requires three times as much carbonaceous food and six times as much nitrogenous as an adult.

The construction of dietaries for particular purposes, as for training, for developing muscular tissue, for producing fat, or for reducing it, is beyond the scope of these lectures; but it may generally be said that, as in training the object is to form muscular tissue, with great endurance of action, and, at the same time, to reduce the weight of the body, it is accomplished by the use of nitrogenous food, with but little fat or farinaceous

matter, and as little fluid as possible—so that muscular tissue may take the place of fat and water; and by constant exercise, the endurance and strength of the muscular tissue is increased, and the proportion of water in the tissues is diminished. King, in training, is said to have taken for his breakfast two lean mutton-chops, somewhat under-done, with dry toast or stale bread, and a single cup of tea, without sugar; for dinner, 1 lb. or $1\frac{1}{4}$ lb. of beef or mutton, with toast or stale bread, and very little potato or other vegetable, and half-a-pint of old ale, or a glass or two of sherry; for tea, a single cup of unsweetened tea, with an egg and some dry toast; and for supper, half-a-pint of oatmeal-porridge or half-a-pint of old ale. The action of this is to produce only a short-lived state of effectiveness, for, carried a little beyond the appointed time, it leads to disease; and even after such training, there is often, as in the case of Heenan, terrible prostration of the system, and a necessity for returning immediately to an ordinary diet.

Foremost among the foods for developing fatty tissue are fats, as fat of meat, butter, milk, cream, &c.; next to these are sugar and all sweet substances, as honey, saccharine fruits, parsnips, &c.; and after these are farinaceous matters, as arrowroot, bread, potato, pastry, farinaceous puddings, &c. Fermented liquors, as beer and porter, have also a high reputation for their fat-producing properties, and for their capability of forming milk when drunk by nursing women. Malt liquors, in fact, contain so much nutriment that tiplers, like Boniface, may be said to eat and drink their ale. Aristotle and Xenophon have spoken of the invigorating properties of barley wine, and the poor labourer who often experiences the sustaining power of a glass of beer, will, as Dr. Pereira observes, by no means admit the truth of Dr. Franklin's assertion, that a penny loaf and a pint of water yield more nourishment than a pint of beer.

Even Hogarth, in his illustration of the drunkards of *Beer alley* and *Gin lane*, has made a striking difference between the plump condition of the one, and the emaciated appearance of the other. In cases of obesity, therefore, all these foods, but especially fat and sugar, should be avoided, or used but sparingly: they are, however, well suited for the lean and hungry constitution. The ancient physicians were well aware of this, and have left us many excellent rules for the dietetical treatment of those who are corpulent or thin. Four hundred years before Christ, Hippocrates of Cos, who is called the Father of Physic, wrote the most precise instructions concerning it; in fact, the writings of all the older physicians abound with illustrations of the effects of different kinds of food on the body. Cornelius Celsus, for example, who lived at the time of our Saviour, and Claudius Galen, who practised medicine in the second century—both having been keen observers of the luxurious habits of the Romans—have given very circumstantial accounts of the way in which the human system is to be dietetically treated in health and disease—the three books of Galen, "*De Alimentorum Facultatibus*," being devoted not only to the properties of different kinds of food, but also to a description of a fat and lean mode of life. Later still, in the 17th century, the specific effects of food on the weight of the body were accurately determined by Sanctorius, the celebrated medical professor of Padua; and he tells us in one of his aphorisms, that "the body will be rendered heavier by 4 ozs. of very nourishing food, as *pork, eels*, and all *fat meats*, than by 6 ozs. of a slender nourishment, as *fish, chickens*, small *birds*, and others of the like kind." But the most striking illustrations of the fat-producing power of farinaceous foods were furnished by Liebig in his experiments on the fattening of geese; for he found that a lean goose, weighing only 4 lbs., gained 5 lbs. in weight in 36 days,

by feeding it on maize alone; and of these 5lbs., $3\frac{1}{2}$ lbs. were fat—thus proving that farinaceous matters are capable of quickly forming fat; and a like conclusion was derived from his experiments on sugar. In Turkey, and throughout the East, where the beau-ideal of female beauty is a fat and well-rounded figure, the women are sometimes fattened in much the same manner; for Mrs. Walker tells us, in her work on “Female Beauty,” that in the Bey’s seraglio at Tripoli, the women are fattened against a certain day by means of a diet of Turkish flour mixed with honey—the operation being assisted by enemata of rich soups, and frequent bathing. In fifteen days the operation is complete—the beauty being then as plump as an ortolan. Very recently the effect of such food on persons disposed to be corpulent has been graphically described by Mr. Banting, whose gross obesity had become a positive torture to him. In vain he strove to reduce it by physic, by baths, by violent exercise, and by all the depletive artillery of scientific medicine; but nothing touched it until he practised the ancient rules of Hippocrates, and avoided fat and farinaceous foods. He then found, by the test of Sanctorius, that he rapidly decreased in bulk—falling in the course of twelve months from a weight of 202 lbs., or about $14\frac{1}{2}$ stone, to 150 lbs., or rather less than 11 stone. It may interest you to know exactly what was his daily diet. “For breakfast,” he says, “at 9 a.m., I take 5 or 6 ozs. of either beef, mutton, kidneys, broiled fish, or cold meat of any kind excepting pork or veal; a large cup of tea or coffee, without milk or sugar; a little biscuit, or one ounce of dry toast; making together six ounces of solid and nine of liquid. For dinner, at two p.m., five or six ounces of any fish except salmon, herrings, or eels; any meat except pork or veal; any vegetable except potato, parsnip, beet-root, turnip, or carrot; one ounce of dry toast, fruit out of a pudding, not sweetened; any kind of poultry or game, and two or three glasses of

good claret, sherry, or Madeira—champagne, port, and beer forbidden; making together ten or twelve ounces solid, and ten liquid. For tea, at six p.m., two or three ounces of cooked fruit, a rusk or two, and a cup of tea without milk or sugar; making together two to four ounces solid, and nine liquid. For supper, at nine p.m., three or four ounces of meat or fish, similar to dinner, with a glass or two of claret or sherry and water, making together four ounces solid, and seven liquid. For night-cap, if required, a tumbler of grog (gin, whisky, brandy, without sugar), or a glass or two of claret or sherry; and “this plan,” he says, “leads to an excellent night’s rest, with from six to eight hours’ sound sleep.” It is difficult to estimate the carbonaceous constituents of the 43 ozs. of liquid made use of, but the 24 ozs. of solid contain about 3·21 ozs. of nitrogenous matter, and 4·06 carbonaceous—the proportions for ordinary routine work being, as I have already explained, 4·48 ozs. of nitrogenous and 22·14 carbonaceous. There is, therefore, a large deficiency of the latter; nevertheless, it appears that the diet is quite capable of sustaining health; for having pursued it for nearly seven years, Mr. Banting finds that he keeps very closely to his standard weight of eleven stone, never varying so much as three pounds on either side of the scale, except when he is making experiments on himself, as when he takes sugar or farinaceous food. Sugar, he says, is the most active of all fat-forming foods; for he has repeatedly observed that five ounces of sugar distributed over seven days (less than an ounce a day) will augment his weight nearly one pound by the end of that time. Other forbidden substances are not so marked in their results; but his rule is to avoid all roots or vegetables grown underground, all fat, and all farinaceous matters—taking bread only when it has been well toasted.

HOW TO ASSOCIATE DIFFERENT ARTICLES OF DIET.

In associating different articles of diet, so as to secure the right proportions of the several constituents of food—fat, sugar, or starch, and nitrogenous matter—we find that we may not only rely on the sound indications of science, but may also trust, and trust safely, to the unerring guidance of our instincts, provided they have not been vitiated by fashion or perverted by evil habits. Science teaches us that the best proportions for the common wants of the animal system are about 9 of fat, 22 of flesh-forming substances, and 69 of starch and sugar; and experience also shows that these are the very proportions which we are constantly striving to maintain in our daily dietaries. Borrowing largely from the graphic illustrations of Liebig and Johnston, I may state that, whenever one kind of food is wanting in any particular constituent, we invariably associate it with another that contains an excess of it. Certain meats, for example, which are deficient of fat are always eaten with substances that are rich in it—bacon is associated with veal, with liver, and with fowl, or we capon the latter, and thus increase its natural fat. We use melted butter with most kinds of fish, or we fry them in oil; while the herring, the salmon, and the eel are usually fat enough in themselves, and are dressed and eaten alone. It is with a view to similar adjustment that we mix eggs and butter with sago, tapioca, and rice; that we add oil and the yolk of an egg to salad; that we boil rice with milk, and eat cheese with maccaroni. The same instinct has determined the use of vegetables with meat, and butter with bread. Bacon and greens, or beans and bacon, like pork and peas-pudding, is a conjunction of viands which does not owe its popularity to old habit or the mere taste of the epicure; and so with a dish, common in Ireland, under the name of Kol-cannon—the potato, which is poor in gluten, and the cab-

bage, which is usually rich in this ingredient, are mixed together, and thus they approach the composition of wheaten bread, but both of these substances are deficient in fat ; add, therefore, a little bacon or fat pork to the mixture, and you have a Kol-cannon which has all the good qualities of the best Scotch oatmeal, and to many it is more savoury and palatable. Again, the mixture so usual in Ireland and Alsace, of butter-milk or curdled milk and potatoes, and the combinations of rice and fat, which make the diet of eastern nations ; even the little dab of butter upon the poor man's potato, and the bit of cheese that he eats with his dinner, are matters not of luxury but of necessity, and they show how, by long experience, we have at last learned to adjust the proximate constituents of food so as best to maintain the health and vigour of the body.

NUMBER, VARIETY, AND DISTRIBUTION OF MEALS.

And then, again, the times for taking food and the proper distribution of it in appropriate meals, are questions of considerable importance, notwithstanding that they have ever been influenced by the caprices of fashion and the artificial habits of society. How much they have had to do with the modification of the human species and even with the extinction of whole races of men, is an etiological problem of much interest.

Man in his savage condition feeds with great irregularity, for when he finds that food is plentiful he eats, from morning to night, and knows no other pleasure than that of eating and drinking and sleeping ; but when it is more scarce he is content with a single meal a day. In both cases, however, the quantity of food consumed is excessive. We are told by travellers that the Hottentots, the Bushmen, and the inhabitants of South Africa, who feed in this manner, are enormous gluttons. " Ten

of them," says Barrow, "ate, in his presence, an ox, all but the hind legs, in three days; and the three Bosjesmen that accompanied his waggon, devoured a sheep on one occasion in less than twenty-four hours." Parry, Ross, and others have also given the most astonishing accounts of the dietetical capabilities of the Esquimaux. Captain Parry once tried the capacity of a young lad scarcely full-grown, and in twenty-four hours he had eaten 4 lbs. 4 ozs. of the raw, hard-frozen flesh of a sea-horse, the same quantity of it boiled, 1 lb. 12 ozs. of bread and bread-dust, besides a pint and a quarter of rich gravy-soup, a tumbler of strong grog, three wine-glasses of raw spirits, and nine pints of water. According to Sir John Ross, the daily rations of an Esquimaux are 20 lbs. of flesh and blubber. But the most marvellous example of gluttony is given by Captain Cochrane, on the authority of the Russian Admiral Saritcheff, who was told that one of the Yakuti had consumed the hind quarter of a large ox in twenty-four hours, together with 20 lbs. of fat, and a proportionable quantity of melted butter. To test the truth of this, he gave him a thick porridge of rice boiled down with 3 lbs. of butter, weighing together 28 lbs.: although the glutton had already breakfasted, yet he sat down to the meal with great eagerness, and consumed the whole without stirring from the spot; and, except that his stomach betrayed more than ordinary fulness, he showed no signs of inconvenience. Captain Cochrane further adds, that a good calf, weighing 200 lbs., will just serve for a meal for four or five Yakuti; and that he has himself seen three of them consume a reindeer at a meal. Liebig accounts for this by saying that a nation of hunters, especially when they go naked and are exposed to great losses of temperature, must consume large quantities of respiratory food; and if it so happens that the food is in its least effective form, as lean flesh, the quantity disposed of is enormous.

Among civilized nations, and until comparatively

recent times, there were but two meals a-day—namely, dinner and supper. These were the meals of the Romans—the *prandium* or dinner, being for the most part a light refreshment, eaten while standing, at about nine o'clock in the morning; and it generally consisted of the cold remains of yesterday's supper. It was commonly taken without wine, and, in fact, there was so little ceremony about it that Plautus, in his comedies, has facetiously called it *caninum prandium*. The great meal of the day was the supper, or *cæna*, which was taken about three or four o'clock in the afternoon, and to which friends were invited. This was the ceremonious meal for which the wealthy and high families of Rome exhausted the resources of luxury and art. It always consisted of three parts—the *gustus*, or antepast, which was intended as a mere smack or relish to whet the appetite. Then came the main part of the feast—consisting of many courses, with a chief dish or *caput cænæ*, and when in thrifty families it was the only dish which went the round of the frugal board, it was aptly termed the *cæna ambulans*. After this there came the second course, or *mensa secunda*, composed of fruits and pastry, like a modern dessert.

The sums of money expended by the wealthy Romans on this meal were often ruinous. Vitellius is said to have spent as much as 400 *sestertia* (about £3,228 of our money) on his daily supper; and the celebrated feast to which he invited his brother Lucius cost no less than 5,000 *sestertia*, or £40,350 sterling. It consisted, according to Suetonius, of 2,000 different dishes of fish and 7,000 of fowls, with other equally numerous meats. His daily food, says our classical writers, was of the most rare and exquisite nature, the deserts of Libya, the shores of Spain, the waters of the Carpathian Sea, and even the coasts and forests of Britain, were diligently searched for dainties to supply his table; and had he reigned long he would, says Josephus, have exhausted

the great opulence of the Roman Empire. *Ælius Verus* another of those worthies, was hardly less profuse in the extravagance of his suppers; for it is said that a single entertainment, to which only about a dozen guests were invited, cost above six million sesterces (6,000 *sestertia*, or nearly £48,500); and we are told by historians that his whole life was wasted in eating and drinking—being spent in the voluptuous retreats of *Daphne*, or else at the luxurious banquets of *Antioch*. So profuse, indeed, was the extravagance of those times, that to entertain an emperor at a feast was to encounter almost certain financial ruin—one dish alone at the table of *Heliogabalus* has been known to cost about £4,000 of our money; no wonder, therefore, that these imperial feasts were lengthened out for hours together, and that every artifice, often revolting in the extreme, was used to prolong the pleasure of eating, or that *Philoxenus* should have wished that he had the throat of a crane with a delicate palate all the way down.

Hardly less extravagant were the dining propensities of our own forefathers, who in every way copied too closely the luxurious habits of their Roman conquerors. In fact, no circumstance, as *Mr. Wright* observes, is more remarkable in ancient history than the readiness with which the people who came under the sway and influence of Rome, abandoned their nationality, and followed the luxurious habits of their rulers. Even so late as the time of *Holinshed*, the famous chronicler of the 16th century, the manners of the English were the subject of severe comment; for he tells us that “in number of dishes and changes of meat, the nobility of England, (whose cooks are, for the most part, musical-headed Frenchmen and foreigners), do most exceed; sith there is no day in manner that passeth over their heads wherein they have not only beef, mutton, veal, lamb, kid, pork, cony, capon, pig, or so many of them as the season yieldeth, but also some portion of the red and fallow deer, beside great

variety of fish and wild fowl, and thereto sundry other delicacies, wherein the sweet hand of the seafaring Portingale is not wanting; so that for a man to dine with one of them, and to taste of every dish that standeth before him, is rather to yield unto a conspiracy with a great deal of meat for the speedy suppression of natural health, than the use of a necessary meal to satisfy himself with a competent repast to sustain his body withal." He adds, too, "that gentlemen and merchants keep much about the same rate; and when they make their ordinary or voluntary feasts, it is a world to see what great provision is made of all manner of delicate meats from all parts of the country, wherein, beside that, they are often comparable herein to the nobility of the land; so that they will seldom regard anything that the butcher usually killeth, but reject the same as not worthy to come in place. In such cases, also, *geliffes* of all colours, mixed with a variety in the representation of sundry flowers, herbs, trees, forms of beasts, fish, fowls, and fruits; and thereunto *marchpane*, wrought with no small curiosity; tarts of divers hues and sundry denominations; conserves of old fruits, foreign and home-bred; suckets, codiniacs, marmalades, sugarbread, gingerbread, florentines, wild fowl, venison of all sorts, and sundry outlandish confections, altogether seasoned with sugar, besides infinite devices, not possible for me to remember."

The learned Caius, also, in his "Counsell against the Sweat," of the same century (1552), comments, in severe terms, on the gluttony of his time, saying that the reason why the disease attacks the English more than others is that they have "so moche sweating stuffe, so many euille humoures laid up in store, fro this displeasante, feareful, and pestilent disease, cause of their euille diet, which destroy more meates and drynckes withoute al ordre, conveniet time, reason, or necessite, the either Scotlande, or al other countries under the sunne."

Gradually, too, as the dinner got to be later in the day,

and reached noontime, there was necessity for a light, early meal, or *breakefaste*, as it was called; and as the dinner became later and later still, a fourth meal was added—the *lunch* or *luncheon*, which literally meant a slice of bread. In process of time, also, with the introduction of tea and coffee into England, there came a fifth meal; but all along, the dinner was the great feast of the day; and the rule in using it was pretty much as Dr. Kitchener, in his time, advised—namely, to eat until there was a sense of satiety, the stimulus of every fresh dish being but as a whip to the appetite, so that the sense of satiety might come and go a dozen times. “It is produced in us,” says Christopher North, “by three platefuls of hotch-potch; and to the eyes of an ordinary observer our dinner would seem to be at an end: but no; strictly speaking, it is just going to begin. About an hour ago did we, standing on the very beautiful bridge of Perth, see that identical salmon, with his back-fin just visible above the translucent tide, arrowing up the Tay, bold as a bridegroom, and nothing doubting that he should spend his honeymoon among the gravel-beds of Kinnaird or Moulenearn, or the rocky sofas of the Tummel, or the green marble couches of the Tilt. What has now become of the sense of satiety? John—the castors!—mustard—vinegar—cayenne—catsup—peas and potatoes, with a very little butter—the biscuit called ‘rusk;’ and the memory of the hotch-potch is as that of Babylon the Great.” Sense of satiety, indeed!—“We have seen it for a moment existing on the disappearance of the hotch-potch—dying on the appearance of the Tay salmon—once more noticeable as the last plate of the noble fish melted away—extinguished suddenly by the vision of the venison—again felt for an instant, and but for an instant, for a brace and a half of as fine grouse as ever expanded their voluptuous bosoms to be devoured by hungry love.”

We smile at the accounts given of the gormandising

powers of the natives of Arctic regions, and the savages of Southern Africa, but our own habits in eating and drinking are scarcely less preposterous. Look at a modern dinner; beginning with soup, and perhaps a glass of cold punch; to be followed by a piece of turbot or a slice of salmon with lobster-sauce: and while the *caput cœnæ*, the venison or South Down, is getting ready, we toy with an oyster paté or a bit of sweetbread, and mellow it with a bumper of Madeira. No sooner is the venison or mutton disposed of, with its never-failing accompaniments of jelly and vegetables, than we set the whole of it in a ferment with champagne, and drown it with hock or sauterne. These are quickly followed by the wing and breast of a partridge, or a bit of pheasant or wild duck; and when the stomach is all on fire with excitement, we cool it for an instant with a piece of iced pudding, and then immediately lash it into a fever with undiluted alcohol, in the form of cognac, or a strong liqueur; after which there comes a spoonful or so of jelly as an emollient, a morsel of ripe stilton or paté de foie-gras as a digestant, a piquante salad to whet the appetite for wine, and a glass of old port to persuade the stomach, if it can, into quietness. All these are more leisurely succeeded by the *mensa secunda*, or dessert, with its ices, its preserves, its bakemeats, its fruits, its geliffes, codiniacs, and suckets, as Holinshed would call them, and its strong drinks; to be afterwards muddled with coffee, and complicated into a rare mixture with tea, floating with the richest of cream.

As a modest example of this sort of thing, and an indication, moreover, of the kind of novelties yet in store for us, let me read to you the *menu* of a late dinner at the Langham, where horse-flesh was the principal *viande*. It is very appropriately prefaced with a little bit of French philosophy—*Les préjugés sont des maladies de l'esprit humain.*"

"Potages—Consommé de cheval. Purée de destrier.
Amontillado.

“*Poissons*—Saumon à la sauce arabe. Filets de soles à l’huile hippophagique. *Vin du Rhin*.

“*Hors-d’œuvres*—Terrines de foie maigre chevalines. Saucissons de cheval aux pistaches syriaques. *Xérès*.

“*Relevés*—Filet de Pégase rôti aux pommes de terre à la crème. Dinde aux châtaignes. Aloyau de cheval farci à la centaure, et aux choux de Bruxelles. Culotte de cheval braisée aux chevaux-de-frise. *Champagne sec*.

“*Entrées*—Petits pâtés à la moëlle Bucéphale. Kromeskys à la Gladiateur. Poulets garnis à l’hippogriffe. Langues de cheval à la Troyenne. *Chateau Perayne*.

“SECOND SERVICE.

“*Rôts*—Canards sauvages. Pluviers. *Volney*. Mayonnaises de homard à l’huile de Rossinante. Petits pois à la française. Choux-fleurs au parmesan.

“*Entremets*—Gelée de pieds de cheval au marasquin. Zéphirs sautés à l’huile chevaleresque. Gâteau vétérinaire à la Ducroix. Feuillantines aux pommes des Hespérides. *Saint-Peray*.

“*Glaces*—Creme aux truffes. Sorbets contre-préjugés. *Liqueurs*.

“*Dessert*—Vins fins de Bordeaux. Madère. Café.

“*Buffet*—Collared horse-head. Baron of horse. Boiled withers.”

Even put into plain English all this would sound remarkable; and taken, as it is said to have been, without shying or gibbing, although, perhaps with a little bolting, it must have puzzled the stomach; and, like all our modern dinners, must also have severely taxed its powers, in selecting from the complicated mess the right proportions of fat and flesh and farinaceous matter required for the sustenance of the body.

During the siege of Paris, in December, 1870, the resources of the epicure were severely taxed, and the following is said to have been the *menu* of a *dîner de siège*, given by the Paris Jockey Club. It

was entrusted to the famous epicure, the Baron Brisse, and consisted of the following items:—

Hors-d'œuvre—Radishes, herring *mariné*, onions *à la Provençale*, slightly salt butter, gherkins, and olives.

First course—Soup of slightly salted horse, with vegetables; ass-flesh cutlets, with carrots; mule's liver *sauté aux champignons*; horse's lights, with white sauce; *carpe à la matelotte*; fried gudgeons; celery heads, with seasoning.

Second course—Quarter of dog braised; leg of dog roasted; rats, cooked upon the ashes; rat pie, with mushrooms; *Eel à la broche*; salad of celery and small salad.

Dessert—Dutch cheese, apples, pears, marmalade *au Kirsch*, *gateau d'Italie au fromage de Chester*.

The banquet, which was served in one of the principal establishments of the *Chaussée d'Antin*, is stated to have been a complete success.

Mr. Cochran has given an account of a Mandarin's dinner, which was served with great ceremony. The dinner began with hot wine, made from rice, and sweet biscuits of buckwheat. Then followed the first course of custards, preserved rice, fruits, salted earth-worms, smoked fish and ham, Japan leather, and pigeons' eggs, having the shells softened by vinegar: all of which were cold. After this came shark's fins, birds' nests, deer sinews, and other dishes of an appetising and dainty character. These were succeeded by more solid foods, as rice and curry, chopped bears' paws, mutton and beef cut into small cubes and floating in gravy; pork in various forms; the flesh of puppies and cats boiled in buffalos' milk; shantung or white cabbage, and sweet potatoes; fowls split open, flattened, and grilled, their livers floating in hot oil; and cooked eggs of various descriptions, containing embryo birds. "But the surprise of the entertainment was to come. On the removal of some of the flower vases, a large covered flat

dish was placed in the centre of the table, and at a signal the cover was removed. The hospitable board immediately swarmed with juvenile crabs, which made their exodus from the vessel with surprising agility ;” for the crablets had been thrown into vinegar just as the guests sat down, and this made them sprightly in their movements ; but fast as they ran, they were quickly seized by the nearest guests, who thrust them into their mouths, and crushed them without ceremony, swallowing the strange gelatinous morsel with evident gusto. After this, *soi* was handed round, which is a liquor made from a Japan bean, and is intended to revive the jaded palates. Various kinds of shell and fresh fish followed, succeeded by several thin broths, and it was concluded by the costly birds'-nest soup. The dessert being a variety of scorched seeds and nuts, with sundry hot wines, and tea.

In America the elaborateness of the *menu* for breakfast, dinner, and supper is very striking—the breakfast in the large hotels being from eight to eleven, luncheon from one to three, dinner from six to eight, tea from eight to nine, and supper from ten to twelve ; making ten hours a day for the disposal of most elaborate meals.

On the other hand it is hardly right to content ourselves, like savages, with a single meal a day, as was the custom of Dr. Fordyce, the celebrated professor of chemistry of the last century, who, by studying the habits of carnivorous animals, and reflecting on the principles of chemistry and physiology, came to the conclusion that man requires but one meal a-day for all his physiological wants ; and for more than twenty years his daily mode of dining was generally as follows :—At four o'clock of the afternoon, he would present himself at “ Dolly's chop-house,” and take his seat at the table reserved for him. Immediately on his arrival, the cook would place a pound and a half of rump-steak upon the gridiron, and while it was cooking the doctor would

amuse himself with some such trifle as half a boiled capon, or a plate of fish, and a glass or two of brandy—his regular allowance being a quarter of a pint. Then came the steak with a full accompaniment of bread and potato, and it was always served with a quart tankard of strong ale. This was followed by a bottle of old port; and when the dinner was finished, as it invariably was in an hour and a half, he walked leisurely to his rooms in Essex Street, in the Strand, where he met his class and gave his lecture on chemistry.

But these are not the habits of the great bulk of mankind, and although they may be practised for a while with impunity, yet they serve not as illustrations of what ought to be done in the way of eating, but rather as examples of the wonderfully accommodating power of the stomach under the most disadvantageous circumstances; for experience teaches us that three meals a day of the simplest quality, are best suited for our wants—breakfast to supply the place of long fasting, and to restore the waste of secretion during the night; dinner in the middle of the day to support the system during the fatigue of ordinary labour; and a light meal at night, in the form of tea, or an early supper to carry on the functions of repair and secretion during the night. According to Dr. Edward Smith, the daily distribution of the food, supposing a physiological diet of 43,000 grains carbon, with 200 grains of nitrogen to be taken, should be somewhat in this manner:—

TABLE XXVI.

Relative Proportions of Food at Different Meals.

	Carbon.	Nitrogen	Equal to	
			Carbon-aceous	Nitrogenous.
	grs.	grs.	ozs.	ozs.
For breakfast	1,500	70	6·62	1·04
For dinner	1,800	90	7·85	1·34
For supper	1,000	40	4·52	0·59
Total in the day	4,310	200	18·99	2·97

So that about one part should be eaten for supper, one and a half for breakfast, and about two parts for dinner.

It is hardly necessary to say that, in constructing dietaries, *the foods should be associated in such a way as not to offend the appetite or burden the digestive powers*; and that they should also be varied from time to time, not merely in their kind, but also in their treatment, and in the manner of cooking and flavouring them; for the best descriptions of food will, if eaten in the same fashion day after day, occasion disgust, and be wasted. This is often the case in the badly arranged dietaries of work-houses, and on ship-board. It was once so with the dietaries of the English army, when the same daily rations of boiled meat were provokingly served out to the men, while they listened to the tune of "Oh the roast-beef of old England." All this is easily provided for, and it is true economy to do it, as by varying the food, the mode of cooking it, the manner of flavouring it, and by serving it, in the case of dinner, with different kinds of vegetables. In constructing dietaries, therefore, the main considerations are the due proportions of nitrogenous and carbonaceous matters; for when these are not adjusted in a proper manner, the health is endangered, and the constitution may be slowly undermined. To use the words of Liebig—"There is a law of nature which regulates these things, and it is the elevated mission of science to bring this home to our minds; it is her duty to show why man and animals require such admixture in the constituents of their food for the support of the vital functions, and what the influences are which determine, in accordance with the natural law, changes in the admixture."

"The knowledge of the law elevates man, in regard to an important function which he possesses in common with the lower animals, above the level of those beings which are destitute of reason, and supplies him, in the regulation of those bodily wants which are essential to

his existence and prosperity, with the protection which the lower animals do not require, because in them the commands of the instinctive law are not opposed or overpowered by the allurements of sense, or by a perverted and resisting will."

The recognition of this law, and the practical application of it to the dietaries of a community, are obviously of great advantage, for not only would they tend to increase the health and strength of the population, but they would also effect a great economy in the general use of food. That there are difficulties in the way of such an application cannot be doubted; in fact, the natural peculiarities of individuals, to say nothing of the differences of occupation, and the ever-varying quality of the food itself, are enough to create a doubt as to the possibility of its general application until the progress of science has gone far beyond its present position. Nevertheless, there are certain well-acknowledged facts at our disposal which may safely serve as a guide to practice; and these I have endeavoured to explain.

DISEASES ARISING FROM IMPROPER FOOD.

The diseases which are incidental to an abuse of the law can hardly be discussed in this place, but it may be said, in general terms, that too much or too little of either of the main constituents of food will soon be followed by marked derangement of the animal body. *An excess of respiratory food* not only promotes the growth of fat, but actually interferes with the nourishment of muscular tissue. Those who feed largely on rice, potatoes, or other farinaceous foods, or who indulge too freely in malt liquors, have commonly a bloated appearance, and have no faculty for sustained exertion. The brewer's drayman, for example, is a bad subject for the ward of an hospital; for although he generally looks strong and muscular, yet in reality his vital power is feeble, and his

tissues are fatty rather than muscular. The same is often the case with animals in the Zoological Gardens, when too large a quantity of respiratory food has been eaten, and their flesh has undergone a kind of fatty degeneration.

On the other hand, *when the plastic elements of the food are in excess*, the system becomes excited; too much blood is formed, and diseases of a plethoric character are induced. Medical travellers say that savages who feed almost entirely on animal food are subject to itch, scurvy, leprosy, malignant ulcers, and putrid fevers; but besides this, according to Liebig and his followers, an excess of force is developed, which manifests itself in irritability of temper, and in a savage disposition. How far this may be concerned in the frequently ungovernable conduct of our over-fed convicts may be deserving of consideration. A nation of animal feeders, says Liebig, is always a nation of hunters, for the use of a rich nitrogenous diet demands an expenditure of power, and a large amount of physical exertion, as is seen in the restless disposition of all the carnivora of our menageries.

A deficiency of food, however, is quickly followed by a general breaking up of the animal frame. Plague, pestilence, and famine are always associated in the public mind; and the records of every country show how closely they are related. The medical history of Ireland is remarkable for illustrations of how much mischief may be occasioned by a general deficiency of food. Always the habitat of fever, it every now and then becomes the very hot-bed of its development. Let there be but a small failure in the usual imperfect supply of food, and the lurking seeds of pestilence burst into frightful activity. The famines of the present century, and notably those of 1817 and 1847, are forcible illustrations of this, for they produced epidemics which have not been surpassed by the most appalling of

the middle age. The principal form of the scourge was known as the contagious famine fever (relapsing fever), and it spread, not merely from end to end of the country in which it had originated, but, breaking through all boundaries, it crossed the broad ocean, and made itself painfully manifest in localities where it was previously unknown. Thousands fell under the virulence of its action, for wheresoever it came it struck down a seventh of the people; and when it was largely associated with typhus, the mortality was frightful. Even those who escaped the fatal influence of it were left the miserable victims of scurvy and low fever. Another example, not less striking, of the terrible consequences of what may be truly called famine, was the condition of our troops during the early part of their sojourn in the Crimea. With only just enough of food to maintain the integrity of the system at a time of repose, and at ordinary temperatures, they were called upon to make large muscular exertions, and to sustain the warmth of the system in the midst of severe cold. What, therefore, could be expected but that the scourges which wait upon famine, as fever, diarrhœa, dysentery, and scurvy, should make their appearance in great force, and that the soldiers should suffer severely. With an average strength of 24,000 men, the deaths from sickness alone, in the course of seven months, were at the rate of thirty-nine per cent., and, in some cases, it amounted to seventy-three. "Never before," says Colonel Tulloch, "is there record of a British army having sustained so frightful a loss in so short a time." During the Peninsula War, though the troops occasionally suffered much from sickness, the loss from that cause did not average above twelve per cent. for a whole year. Even in the ill-fated expedition to Walcheren, which threw the nation into mourning, the deaths amounted to only about 10·3 per cent. for the half-year; and here, in this great city, with all the aggra-

vating circumstances of want, vice, infancy, old age, and disease, it did not reach two per cent. during the time that our strong men were dying by thousands. "Armies have perished by the sword, and have been overwhelmed by the elements, but never, perhaps," says Colonel Tulloch, "since the hand of the Lord smote the host of the Assyrians, and they perished in a night, has such a loss from disease been recorded as on this occasion." May the lesson of so great a calamity be wisely applied in the future.

The brain and nervous system also become impaired or deranged by low diet. Madness, for example, is not uncommon with ship-wrecked sailors, after long and severe privation, and the hallucinations of the mind after Lent are clearly referable to the same cause. The great witchcraft epidemic of the 16th century, which broke out among the nuns of a convent at Hoorn, in Flanders, appeared at the close of Lent, when the sisters had been living very sparingly on a coarse, vegetable diet.

The connection of scurvy with improper or insufficient food is a matter of medical history, and its prevention by the use of fresh vegetables, especially potatoes, is so well known that it has often been the subject of legislation. Rarely appearing in the cabin, where the dietary is good, it is a frequent visitor to the fore-castle; so that half of the men of our sea-going vessels are found to be suffering from the disease when they return to port. As many, indeed, as 70 per cent. of a ship's crew are not unfrequently disabled by it; and there is no saying how many of the disasters at sea are caused by the inability of the men to work the vessel in times of severe weather. The legal supplementary allowance in emigrant vessels is 8 ozs. of preserved potato, 3 ozs. of other preserved vegetables (carrots, turnips, onions, celery, and mint), besides pickles, and 3 ozs. of lemon juice for each person weekly; and this is found to be a perfect

prophylactic of the disease, so that the one essential cause of it is evidently a privation of vegetable food.

And not less important are the morbid results of *too much or too little saline matter in the food*. I have already spoken of the salutary effect of certain calcareous salts in the water we drink; but according to Dr. Grange, the presence of magnesian salts in the water of a district may have something to do with the development of those remarkable forms of disease which are known as goitre and cretinism. In France, Germany, England, Sardinia, and elsewhere, among all classes of people, of all habits, and in every variety of climate, these diseases are endemic where the soil is composed of magnesian rock, and the water is charged with magnesian salts. How far the connection extends is a chemico-physiological problem that has yet to be determined.

TREATMENT OF FOODS.

In the *treatment of vegetable foods* it is important to remember, that all corky and woody tissues, as the skins of fruits, tubers, and cereals, are quite indigestible, and that, in consequence of their irritating action, they hurry food through the alimentary canal, and so occasion waste. (See p. 9.) It is necessary, therefore, that all such tissues should be removed as completely as possible, or be disintegrated and softened by cooking or other culinary treatment.

When it is required to obtain the *starchy farinaceous matters of vegetables*, one or other of the following processes is followed.

(a). The material is pulped or crushed, and diffused through a considerable volume of cold water. It is then strained and allowed to stand until the farina or starch subsides.

(b). Or it is allowed to pass into a state of putrefactive decomposition, whereby the albuminous matter, as the gluten, &c., decay, and leave the starch untouched.

(c). Or it is subjected to the action of a weak alkaline solution, generally of caustic soda, which dissolves the gluten, and allows the starch to subside. The gluten thus dissolved may be again recovered by neutralising the alkaline solution with acid, and collecting the precipitated gluten, as in the processes of Durand and others.

I have already explained (page 9) that in the treatment of the ground meal of wheat and other grain, the bran and coarser kinds of flour are separated by sieves of different degrees of fineness, and that in this manner about eight or nine varieties of product are obtained, as *biscuit flour, best or fine households, seconds, tails, fine sharps or middlings, coarse sharps, fine pollard, coarse pollard, and long bran*, the proportions of which from ordinary brown meal will vary according to circumstances; but processes have been invented by M. Mège-Mouries, M. D'Arblay, and others, whereby the yield of fine flour is increased to 86 or even 88 per cent. of the grain, and by which the quantity of gluten is also regulated. The process of M. Mège-Mouries is as follows:—The corn is moistened with from 2 to 5 per cent. of water saturated with sea salt, and at the end of some hours the exterior covering only became moist and tender. The grain is then thrown between nearly-closed millstones, and 70 per cent of flour is obtained without cerealine; besides which there is from 10 to 14 per cent. of meal, which is subsequently bruised between light stones, and separated by winnowing from the greater part of the husk remnants. The process is used extensively at the Scipion Works, Paris, where large quantities of bread are made for the public charities, and for the workmen of Paris.

When the flour is rich in gluten, as is the case with the hard wheat of Sicily, Russia, Sardinia, Algeria, and Egypt, or when it is strengthened with gluten obtained from flour in the process of starch making, it is well

suited for the manufacture of certain granular powders and dried pastes, which are known as *Semola*, *Semolina*, *Soujee*, *Mannacroup*, *Maccaroni*, *Vermicelli*, and *Cagliari paste*. The last three are generally imported from Naples or Genoa, where they are made from a highly glutinous wheaten flour, by kneading it into a thin dough or tenacious paste, and then forcing it through holes or slits in a metallic plate. In this way the several varieties of *pipe*, *celery*, and *ribbon maccaroni*, are obtained; and the fancy forms of it, called *Cagliari paste*, which are in the shape of stars, rings, Maltese crosses, &c., are produced by stamps. All these varieties of raw wheaten paste are cooked by boiling or baking, and are associated with soup or beef tea, or milk, or are mixed with eggs, cheese, &c.

The best variety of flour for bread is that which contains less gluten than the preceding, as from 8 to 10 per cent. of it instead of from 12 to 14 or 15. Dantzic flour and soft Spanish, as well as the American called Genessee, are the best examples of it, and are highly esteemed by bakers on account of the fine quality of bread which is procurable from them, the richer varieties of hard glutenous wheat being used only to impart strength to weak and inferior descriptions of flour.

The tests for good flour are its sweetness and freedom from acidity or musty flavour; and its nutritive value, as far as gluten is concerned, is estimated by the process of Beccaria, who discovered gluten in wheat more than a century ago. A given weight of flour (say 500 grains) is made into rather stiff dough, and is carefully washed by tender manipulation under a small stream of water. The gluten remains, and when it is baked it expands into a clean-looking ball, which should weigh, when thoroughly dried, about 54 grains. Bad flour makes a thin ropy-looking gluten which is very difficult to deal with, and which has a dirty brown colour when baked.

BREAD, which is the most important preparation of flour, owes its value as an article of diet to a good and equable vesiculation of the dough, the vesiculation being effected by the diffusion of small bubbles of carbonic acid gas throughout its substance; and, as this vesiculation can only take place in a proper manner when the gluten of the flour is in sufficient quantity, and of good quality, it is, to some extent, a test of the goodness of the meal; for those flours which contain too little gluten, or gluten which is deficient in strength, cannot be vesiculated into bread. This is the case with almost every description of flour, excepting that of wheat and rye.

The most common, and also the most ancient method of vesiculating bread is by fermentation; and the process is not very different in the present day from what it was in the earliest time, for yeast of some sort, as brewers' yeast; or patent yeast, prepared from infusion of malt and hops; or German yeast, which is the solid residue of the yeast produced by the fermentation of rye for making Hollands; or baker's yeast, which is made from potatoes and flour; or leaven, which is old dough in a state of fermentation, is mixed with the flour or dough; and this soon begins to ferment by the action of the yeast fungus (*micoderma cerevisiæ*) on the sugar of the flour, whereby carbonic acid is produced, which being diffused through the substance of the dough vesiculates it, and causes it to rise or swell.

In olden time, the ferment was a small portion of dough from a former operation—it having been found, to use the language of the proverb, that “a little leaven leaveneth the whole lump.” The yeast of the Romans was made by steeping bran or the waste of the mill in Levant wine for three days; then rolling into balls, and drying in the sun. When required for use, a ball was set fermenting with a small quantity of flour and water, and this was mixed with more flour to make the dough.

Vienna yeast is obtained from malted barley, maize, and rye, ground together and infused in water for a few hours at a temperature of from 150° to 170° Fahrenheit. The clear liquor, when cold, is fermented with a little yeast, and the scum which forms in abundance, is removed as fast as it is produced; and having been drained upon cloths, it is pressed into cakes, and sent into commerce as Vienna yeast. But the most usual practice with the baker is somewhat as follows:—A special ferment is prepared from mealy potatoes (technically called *fruit*) by boiling them in water, mashing them, and allowing them to cool to a temperature of about 80° of Fahrenheit. Yeast is then added to them, together with a little flour to hasten the fermentation. In three or four hours, at a proper temperature (as from 80° to 90° Fahr.), the whole mass is generally in a state of active fermentation, with a sort of cauliflower-head. It is then diluted with water and strained, and is mixed with sufficient flour to make a rather thin dough, which in about five hours rises to a fine *sponge*. This is again diluted with water containing salt, and is worked with the necessary quantity of flour into dough; and after standing for two or three hours, it rises, and is in a fit condition to be baked into loaves.

It can hardly be said that the potatoes are an adulteration in this case, for they do not ever amount to more than 6 lbs. to a sack of flour, which makes about 380 lbs. of bread, or 95 four-lb. loaves. The salt is added to the extent of about 4 lbs. or a little more to a sack of flour, the proportions being regulated according to circumstances, for the object of it is to improve the quality of the loaf as regards whiteness, firmness, and flavour.

There is, no doubt, a slight loss of nutritive matters by this mode of vesiculation, for a small portion of the sugar of the flour is converted into alcohol and carbonic acid; but the quantity is so inconsiderable as to be undeserving of notice. The advantage of the process, how-

ever, is that it is an excellent test of the quality of the flour; for weak flour, or flour that has been injured by germination, or by keeping, will not stand the action of yeast, but will be either ropy, or sticky, or heavy when baked into bread.

If whole meal is used in making bread, the cerealine of the husk or bran sets up a peculiar kind of fermentation, whereby lactic acid, glucose, dextrine, and colouring matters are produced. These give to the bread the sweetish-sour taste, the soft consistence, and the dark colour which are so noticeable in brown bread. To avoid this, M. Mège-Mouries recommends that the 10 or 14 per cent. of meal which is obtained by his process (see page 43) should be kept apart from the 70 per cent. of white flour, and should not be added to the dough made from the latter, until it is well fermented and is ready to be baked. In this manner he realises from 80 to 82 per cent. of the farinaceous matter of wheat, and produces a white loaf. As I have already said, the process is employed with great advantage at the Scipion works at Paris, where about 5,500 lbs. of bread are made daily. A modification of this process has been proposed by Dr. Sézille, who recommends that the decorticated grain should be soaked in water and then ground into a paste for bread.

Another method of vesiculation is to generate carbonic acid in the dough by the action of an acid on bicarbonate of soda. *Dr. Whiting's process*, which was patented in 1836, was to mix the carbonate of soda with the flour, and then to act upon it with a proper proportion of muriatic acid in the water. He used from 350 to 500 grains of carbonate of soda to 7 lbs. of flour, and to this he added $2\frac{3}{4}$ pints of water charged with from 420 to 560 grains of muriatic acid. Other proportions are used by bakers who make unfermented bread; but in all cases the proportions should be such as to form common salt (which is the product of the action of muriatic acid upon

carbonate of soda)—the carbonic acid being liberated in the substance of the dough. Care should be taken that the muriatic acid is pure, for that of commerce is generally highly charged with arsenic.

In 1845, another acid was patented instead of muriatic—namely, tartaric; and the various preparations called *baking-powders*, *custard-powders*, *egg-powders*, &c., are, for the most part, mixtures of tartaric acid and carbonate of soda, with a little farinaceous matter, the common proportions being 1 part of tartaric acid, $1\frac{1}{2}$ of carbonate of soda, and 4 of potato-flour or other dry starch, with a little turmeric powder to impart a rich yellow tint. When these are mixed with flour and wetted, they effervesce, as in the case of a common seidlitz powder, and so diffuse carbonic acid through the dough.

Very lately, Mr. McDougall has proposed the use of phosphoric acid, as a more natural constituent of food than the preceding, and this, with an alkaline carbonate, forms the preparation which is known as *phosphatic yeast*. Other mixtures for the same purpose consist of bisulphate of potash, or alum, and carbonate of soda.

A third process, which is now extensively used in the vesiculation of bread, is that of Dr. Dauglish, by which the bread called *aerated bread* is obtained. The dough is made by adding a solution of carbonic acid in water to flour under pressure in a closed air-tight vessel, in which the dough is well kneaded by machinery; and directly the outlet of the vessel is opened, and the pressure is thus removed, the gas escapes from the water, as in the case of an uncorked bottle of soda-water, and expands into little bubbles within the substance of the dough. By its expansion, also, it forces the dough out of the mixing-chamber in the form of a spongy mass.

In all cases, however, where carbonic acid is generated within the dough by other processes than fermentation, the dough must be baked immediately or it will soon fall, and produce a heavy loaf.

Various contrivances have been suggested for helping the process of kneading, which is laborious, and sometimes not altogether cleanly. Mr. Stevens's hand-machine appears to accomplish this very well. It is in use in the Holborn Union, where about 5,633 lbs. of bread are made every week by one man and two boys; and they contrive to make ninety-six 4-lb. loaves out of every sack of flour (280 lbs.). The materials used on the average of a whole year being as follows:—

Proportions per Week.

Flour	4,129 lbs.	} Which produce 5,632 lbs. of bread, or 1,408 four-pound quartern loaves.
Cones	140 lbs.	
Potatoes	168 lbs.	
Salt	68 lbs.	
Malt	13 lbs.	
Hops	1½ lbs.	

The potatoes, the malt, and the hops are for the purpose of making the yeast or ferment for the bread.

But, by whatever process bread is made, it is necessary to observe certain precautions to ensure the production of a good loaf.

1st. The flour should be from sound grain, sufficiently rich in good gluten, as from 8 to 10 per cent.

2nd. The yeast should be sweet, and should show a lively action in the sponge.

3rd. The dough should be well kneaded to insure the thorough diffusion of the gas, and to promote toughness of the gluten.

4th. The salt should be used in such proportion as to regulate the fermentation, so that the gluten may be firm, the bread white, and of good flavour.

5th. The baking should be so managed as to insure the thorough heating of the loaf to the temperature of at least 212 deg. of Fahrenheit, in order that the insoluble starch may be changed by the heat into soluble dextrine; and the crust should be light-coloured and thin. This is best effected when loaves are baked

singly, as on the Continent, and not in batches, as with us; for in the last case the top and bottom crusts are thick and hard, and are frequently scorched, while the interior of the loaf is doughy and under-done. In most cases, however, a large portion of the starch remains unaltered by the action of the heat, and may be washed out of the bread by kneading it in water, and straining through coarse muslin, when the starch subsides as a fine white powder. Collected in this way it is found that nearly 75 per cent. of the starch is unaltered.

In practice 100 lbs. of flour will make from 133 to 137 lbs. of bread, a good average being 136 lbs.; so that a sack of flour of 280 lbs. should yield 95 four-pound loaves; but the art of the baker is exercised to increase this quantity, and he accomplishes it by hardening the gluten through the agency of a little alum or sulphate of copper, or by means of a gummy mixture of boiled rice—three or four pounds of which, when boiled for two or three hours in as many gallons of water, will make a sack of flour yield 100 four-pound loaves. Such bread, however, is always dropsical, and gets soft and sodden at the base, where it stands, and quickly becomes mouldy. A good loaf should have the following characters:—

Kindness of structure—that is, it should not be chaffy or flaky, or crummy, or sodden; and *sweetness* to the palate and to the smell.

Bread is most digestible the day after it is baked, for new bread is gummy in its nature, and is difficult of mastication. The change which takes place in the act of becoming stale is entirely molecular, for the properties of new bread may be restored to the loaf by heating it for a short time in a closed vessel.

Several varieties of bread have always been in use. The Romans had six or seven varieties, from the coarse brown bread (*panis ater, cibarius, autopuros*) of the common household to the whitest kind (*panis candidus*,

primarius) of the wealthy; and these were generally marked with four deep cuts, like our hot cross-buns, for the convenience of breaking into pieces or *quadra* at the table. Juvenal applies the phrase "*alienâ vivere quadrâ*" to the man who frequently dines out. In England, in the 13th century, there were three qualities of bread, regulated by law as *Wastel* bread (fine wheaten), *cocket bread* (seconds), and *bread of tourte* (brown bread). The instructions in *Liber albus*, as regards the assize of bread in the City of London, refer to many varieties of bread, as *white bread*, *wastel bread*, *demeine bread*, *French bread*, light bread called *puffe* or *pouf*, and *tourte*, or brown bread, each of which was the subject of legal regulations, which were not abolished until 1815.

Specimens of the different kinds of bread at present in use are upon the table; and you will notice the dark colour of the *rye-bread* of the Continent. I am indebted for these illustrations to the kindness of Mr. Twining, who has liberally placed the valuable collection of foods in his museum at our disposal. Here, also, is a sample of rye-bread supplied by Mr. William Ray Smee, who, in the interest of the poor, has had it made according to the formula of the Board of Agriculture in France of 1795. It consists of one part of rice and four parts of rye ground together, and sifted in the usual manner. The meal is then made into dough with yeast; and after it has fermented it is baked in these long rolls. The bread is very dark, like all rye-bread, and has a close texture, but it is agreeable to the palate, and is very nutritious. The great recommendation of it is its cheapness, for it can be made at less than a penny a pound, and is therefore a very suitable bread for the poor.

Those meals or flours which do not contain sufficient gluten of the proper quality for fermentation or vesiculation, as barley-meal, oat-meal, Indian-meal, cassava-meal, and the flour of peas and lentils, are best cooked by baking them in the form of cakes or

biscuits—a practice which is as ancient as the time of the Patriarchs, when, during the Passover, they were commanded to eat unleavened bread. The chief food of the common people of Rome was a heavy kind of unleavened bread (*panis azymus*), like the present *polenta* of the Italians, which is a mixture of Indian meal and cheese. As in former time, biscuits and unfermented cakes are made from meal or flour mixed with water and baked; but the texture of the substance is close, and it is not easy of digestion unless it is thoroughly disintegrated. When biscuits are lightened by means of egg and sugar, with a little butter, they are much more digestible; and they are still more so when they are vesiculated and puffed up by means of a small quantity of carbonate of ammonia, as in the case of *cracknells* and *Victoria biscuits*.

The so-called FARINACEOUS FOODS FOR INFANTS are only baked flour, sometimes sweetened with sugar. The flour must be baked until it acquires a light brown colour, the temperature being about 400 or 450 deg. of F. The granules of starch are thus disintegrated, and converted into a soluble substance, named *dextrin*, which by a further process of cooking or boiling, as in making pap, forms, when properly sweetened, a very excellent food for children. *Tops* and *bottoms* owe their value to the same circumstances—namely, that the farinaceous matter, which is so indigestible with infants, is broken up by baking into soluble dextrin.

All varieties of MEALS AND ARROWROOTS are easily cooked by stirring them into boiling water, or boiling milk, until they have the consistence of gruel or hasty pudding, and then boiling for a few minutes. In the case of Indian-meal, rice, split-peas, lentils, and haricots, the boiling should be continued for a considerable time, and the whole grain should be previously steeped in water for many hours; for the starch and cellulose of these vegetables are not digestible unless they are

thoroughly disintegrated by cooking. It may be said, indeed, that all vegetables with dense tissues require prolonged boiling to cook them, in order that the cellulose and soft woody tissue be completely broken up by the action of heat, for even starch is likely to pass through the alimentary canal unchanged, if it be not rendered soluble by fermentation or cooking. It is an important question, therefore, whether in utilising starchy foods, it may not be advantageous to help their transformation by allowing the grain to germinate to some extent, as in the process of malting, when the starch becomes changed into sugar. Mr. Lawes has examined this question, and has concluded, from his experiments on stock, that in the case of pigs and bullocks the fattening effect of the grain is not increased; but it may be very different with the human stomach, where the transformation power is not nearly so active as with lower animals. Here, in fact, is an example of it:—

The food which Liebig recommends for infants is a mixture of malt with wheaten flour and milk, to which a little bicarbonate of potash has been added; and the reputation of it in Germany, as an article of diet for children, is considerable. The preparation is made by mixing one ounce of wheaten flour with ten ounces of milk, and boiling for three or four minutes; then removing it from the fire, and allowing it to cool to about 90 deg. One ounce of malt powder previously mixed with 15 grains of bicarbonate of potash, and two ounces of water are then stirred into it, and the vessel being covered, is allowed to stand for an hour and a half, at a temperature of about 100 deg. of F. It is then put once more upon the fire, and gently boiled for a few minutes. Lastly, it is carefully strained, to remove any particles of husk, and then it is fit for the child's food. The composition of the food, according to Dr. Liebig, is as follows:—

	Plastic matter.	Carbonaceous matter.
10 ozs. milk	0·40 oz.	1·00 oz.
1 oz. wheat flour	0·14 „	0·74 „
1 oz. malt flour	0·07 „	0·58 „
	<hr/>	<hr/>
	0·61 „	2·32 „

The relation of the plastic to the carbonaceous being as 1 to 3·8, which is the right proportion for the food of children.

The effect of the malt flour is to transform the starch into glucose, and thus the mixture gets thinner and sweeter as it stands; and the bicarbonate of potash is added to facilitate the change, and to neutralise the acid constituents of the flour and malt.

Liebig's extract of malt is another such preparation for a quick assimilation of starchy matters.

VEGETABLE SUBSTANCES ARE OCCASIONALLY FERMENTED, either for the purpose of increasing the relative amount of glutinous matter, or for the purpose of rendering them acid. Potatoes, for example, as well as barley, wheat, and rye, leave a residuum after fermentation, which contains proportionately more gluten than the original substance, because of the transformation of sugar and starch into alcohol; and although the residuum is coarse, and is hardly suited for human consumption, yet it is an excellent food for cattle; in fact, in Germany it is often eaten by the poor.

When the process is carried still further, and the mass acquires an acid property in consequence of the formation of acetic, butyric, and lactic acids, various sour preparations are obtained, which are no doubt useful in assisting the digestion of other foods. The ancient Romans had many such fermented substances which were not unlike the *sauer kraut* of the Germans. This, as you know, is made from the leaves of cabbages, gathered generally in autumn, and from which the stem and mid-rib are removed. They are cut up into thin slices, and are placed

in a tub or vat, alternately with a layer of salt, until the vessel is full. It is then subjected to pressure, and allowed to stand for five or six weeks (according to the temperature); the lactic fermentation is thus set up, and the mass becomes sour. It is cooked by stewing it in its own liquor with bacon, pork, or other fat meat; and certain condiments, as dill or carraway, are added to improve its flavour. In Prussia, and in many parts of Germany, there is a similar preparation of fermented beans; and in Holland and the South of Europe, cucumbers are fermented. We also have our pickled vegetables, in which acetic acid takes the place of lactic acid. All these preparations are no doubt aids to digestion, especially when the fibre of meat is tough, and contains tendon, or hardened cellular tissue. This is especially so with salted meat, and, therefore, a little pickle is always a good and palatable addition to cold boiled beef.

Vegetable substances, as TEA, COFFEE, MATE, COCOA, &c., the infusions of which are used as beverages, are prepared for commerce in nearly the same manner. When taken from the tree, and while in a fresh condition, they are allowed to undergo a moderate kind of fermentation, and they are then dried and roasted. In the case of tea, the roasting operation is performed during the process of drying and curling, by heating the leaves upon wire-sieves held over a charcoal fire; but cocoa and coffee are roasted in metallic cylinders, which are kept revolving over a clear fire—coffee being roasted until it is nearly charred, and has lost from 14 to 20 per cent. in weight. By this means the aroma, or volatile oil, is in each case produced; and there is also an empyreumatic change in the astringent acids, the sugar, the gum, and the starch, whereby extractive matters varying in amount and quality, according to the degree of heat, are formed. Shrader has examined the subject in respect of coffee,

and has ascertained that the following are the proportions of the several constituents in raw and roasted coffee:—

	Raw Coffee.	Roasted Coffee.
Peculiar coffee principles	17.58	12.50
Gum and mucilage	3.64	10.42
Fatty matter and resin	0.93	2.08

Infusions of tea and coffee should be made with boiling water, but they should never afterwards be boiled, for the aromatic principle is very volatile, and would be thus lost; besides which, a decoction of tea or coffee is disagreeably bitter, on account of the solution of the coarse forms of extractive matter. Soft water also extracts these matters, and therefore appears to give a stronger infusion than moderately hard water, but it is always at a sacrifice of delicate flavour. Excellent tea is made in London with water of 14 or 15 degrees of original hardness, and of about 5 degrees when boiled. This was a subject of investigation by the Government Chemical Commission (Professors Graham, Miller, and Hofmann), who were appointed in 1851 to inquire into the chemical quality of the water supply of London; and they reported that in their experiments they found that tea made from the boiled London water of 5 degrees of hardness could not generally be distinguished from tea made with the water of only $2\frac{1}{2}$ degrees, although a delicate palate would recognize a slightly increased bitterness in the latter, without any enhancement of flavour. It would seem, indeed, that moderately hard water always makes the best flavoured tea, provided it is allowed to stand upon the tea sufficiently long. At Greenwich Hospital, the tea is made for the pensioners from water of

24 degrees of hardness before boiling, and 18·6 degrees after ; but the infusion is prolonged for half an hour, by surrounding the vessel with a steam case ; and thus an excellent flavoured tea is obtained. In fact, the Commissioners remark, that “ where any great loss of strength of tea infusion has been observed in passing from a soft water to a harder, it may be probably referred to the circumstance that the mode of infusing it has not been properly adapted to the hard water ; and then there is doubtless some waste of tea.” Lake waters have been a good deal extolled on account of their softness and supposed fitness for making tea, solely because they happen to produce a deep-coloured solution, which conveys a false notion of strength ; for, in reality, there is no increase of physiological or dietetical property. The Chinese, who are very good authorities on this subject, never use either very soft or very hard waters, for their rule is to take the water of a running stream—“ best from the hill side, and next from a river.” We may conclude, therefore, that water of from four to seven degrees of hardness after being boiled, is best suited for infusions of tea and coffee ; for such water dissolves the aromatic and physiological constituents, without extracting the disagreeable bitter principles. In the case of coffee, in fact, a little acid, as a portion of lemon juice, improves the flavour, notwithstanding that it adds to the hardness of the infusion. Experimentally it is found that infusions of tea and coffee are strong enough when the former contains 0·3 per cent. of extracted matter and the latter 2 per cent., so that a moderate sized cup (5 ozs.) should contain about 6·6 grains of the extract of tea, or 43·7 grains of coffee. These proportions will be obtained when 263 grains of tea (about 5 teaspoonfuls), or 4 ozs. of freshly roasted coffee are infused in a quart of boiling water ; and the amounts of the several constituents dissolved are about as follows :—

Constituents.	Tea. grs.	Coffee. grs.
Nitrogenous matters	17·2	88·0
Fatty matter	—	6·0
Gum, sugar, and extractive	31·7	206·4
Mineral matters	9·1	45·6
Total extracted	58·0	346·0

So that tea yields to boiling water about 22 per cent. of its weight, and coffee about 20 per cent. Lehmann found that only $15\frac{1}{2}$ per cent. of tea was dissolved by water; whereas, Sir Humphry Davy estimated it at $33\frac{1}{2}$ per cent. No doubt the quality of the water as well as that of the tea affects the results, for cold distilled water will extract from 30 to 40 per cent. of black tea, and nearly 50 per cent. of green; but for all this, about 22 per cent. is a good average with ordinary boiling water.

Tea is generally measured into the tea-pot by the spoonful, and Dr. Edward Smith has made a curious inquiry into the average weights of a spoonful of different kinds of tea. The results are here shown:—

WEIGHT OF A SPOONFUL OF TEA.

<i>Black Teas.</i>		<i>Green Teas.</i>	
	grs.		grs.
Oolong	39	Hyson	66
Congou (inferior)	52	Twankay	70
Flowry Pekoe	62	Fine Imperial	90
Souchong	70	Scented Caper	103
Congou (fine)	87	Fine Gunpowder	123

From which it would seem that from three to seven tea-spoonfuls of black tea, or from two to four of green, are required for a quart of infusion of the strength already given.

In China, the practice among the wealthy is to infuse the tea at once in the tea-pot, using an elegant porcelain cup, with a cover of the same material, and having a little disc of filagree silver to keep the leaves from floating; but in Japan the leaves are ground to powder, and after infusing it in the tea-cup, the mixture is beaten

up into a frothy state with a split bamboo, and drank—powder and all.

Coffee, which is the favourite beverage of Eastern nations, is often drank in great excess. In some parts of Arabia, as in the Hedjaz, according to Burckhardt, it is not uncommon for well-to-do persons to drink twenty or thirty cups a day. Even the neediest labourer never takes less than three or four cups a day; and if from poverty he is unable to get the berry itself, he makes an infusion of the roasted skins of it, which he calls "*Keshree*," and which he drinks in great profusion.

COCOA is best made by boiling the mixture for a little while, for it nearly always contains a large proportion of starchy matter, which has been added to dilute the rich fat of the cocoa. Indeed, cocoa contains so much butter or solid fat (from 48 to 50 per cent.), that it is necessary to reduce it with some easily digestible substance, as starch, lentil powder, carageen moss, Iceland moss, sugar, &c.; hence the various preparations of it called *granulated cocoa*, *soluble cocoa*, *chocolate*, &c., the processes for making which I will briefly describe. When the berry is roasted and is cold, it is passed through a machine called a "kibbling-mill," which deprives it of its husk, and of the thin skin which surrounds the kernel or nib. If the nibs thus cleaned are ground in proper mills, they form the variety of cocoa called *flaked cocoa*, but if other preparations are to be made, the nibs are ground between heated rollers or otherwise, until they form a smooth paste, when the diluting substances are mixed with it and are thoroughly incorporated. If *soluble cocoa* is to be made, the diluting material is sugar with some kind of arrowroot, as *tous-les-mois*, *maranta*, *curcuma*, &c. If *chocolate* is required, the diluting material is sugar only, with some flavouring agent, as *vanilla*; and if fancy preparations, as *carageen moss cocoa*, *Iceland moss cocoa*, *lentil cocoa*, &c., are required, then these several substances are incorporated. *Granu-*

lated cocoa is a preparation of cocoa, with sugar and starch, so ground as to form a coarse powder, in which the particles of broken cocoa are covered with a layer of sugar and starch. It is obvious that whenever the mixture consists of starch or other farinaceous substance, the solution of the cocoa preparation must be boiled; but when sugar has been used, as in chocolate, which is the most ancient preparation of it, the combination is such as to require no culinary treatment, or, at most, the action of boiling water or boiling milk. A pint of cocoa made with an ounce of ground nibs will contain the following proportions of nutritious matters:

	Grains.
Nitrogenous matters	96·2
Fatty matter	218·8
Gum, sugar, and extractive	65·6
Mineral matter	17·5
	<hr/>
Total extracted	398·1

It is remarkable that, although cocoa is much less used than either tea or coffee, yet it was known in Europe a century before either of the others. As early, indeed, as 1520, it was brought from Mexico by Columbus, who there found it the common beverage of the people; and when Cortes was entertained at the court of the Aztec Emperor, Montezuma, he was treated to a sweet preparation of cocoa, called *chocollatl*, flavoured with vanilla and other aromatic spices, and served to him in a golden vessel. The Spaniards thus acquired a knowledge of the berry and of its chief preparation, which they kept secret for many years, selling it very profitably as *chocollat* to the wealthy and luxurious classes of Europe; but it was an expensive preparation, and did not come into general use until long after the public coffee-houses of London were established. The earliest notice of it, according to Hewitt, is in Needham's *Mercurius Politicus*, for June, 1659, wherein it is stated that "chocolate, an excellent West-India drink,

is sold in Queen's Head Alley, in Bishopsgate street, by a Frenchman, who did formerly sell it in Gracechurch street and Clement's Churchyard, being the first man who did sell it in England; and its virtues are highly extolled." This was about five years after the London coffee-houses had been established, for the first of them is said to have been opened in 1650, by a Levantine named Pascal Rossee, in St. Michael's Alley, Cornhill and a year after they were opened in Paris and in Holland. In 1660 they were so much frequented, and coffee was so largely drank, that they were made a source of revenue, a tax of 4d. a gallon being levied on all the coffee drank in them; and three years later they were regularly licensed at the Quarter Sessions, like common taverns. In 1668, when Ray, the distinguished naturalist, published his "History of Plants," he tells us they were as numerous in London as at Cairo; and they became so great a nuisance, on account of their political associations, that, in 1675, Charles the Second endeavoured to suppress them by proclamation, calling them seminaries of sedition; but the keepers of them were sufficiently powerful to make him revoke the prohibition. The history of these houses would form a curious chapter in politics and literature, for they are associated with the earliest development of free political discussion, and with the greatest names in English literature. Among the oldest of them is the "Grecian," where Shakespeare and Rare Ben were frequent visitors; and hardly less ancient is "Wills," where Dryden held forth with pedantic vanity, and where the foundation was laid for that critical acumen which soon became a distinguishing feature in English literature. In the city, too, there was the "Rainbow," by Temple Bar, and "Garraway's," near the Exchange, where not only was tea first sold, but where, in Defoe's time, "foreign banguiers," and even ministers resorted to drink it. "Robins" and "Jonathans," and the "Cocoa-nut Tree,"

in St. James street, were also famous, and had their distinguished followers. Nor is the social and political history of tea, with all its brilliant and intriguing gossip, a wit less interesting; for to go no further with it than the brief interval which elapsed from the introduction of tea into England, in 1666, by Lords Ossery and Arlington, to the date of that fatally obnoxious duty on it, in 1767, which led to the riots in Boston, and to the American War of Independence, the fashionable charm of the tea-table had been the means of associating the beauty, the wit, the genius, and the learning of a remarkable period of English history.

In the *Treatment of Animal Food* there are several points for consideration. In the first place it is always best to prepare the animal for the shambles by fasting it for a few hours before it is slaughtered, as partially digested food, and the food recently absorbed into the system, quickly pass into a state of putrefactive decomposition and taint the whole carcass; besides which, a day's repose is often necessary to quell the excitement occasioned by the journey or voyage which the animal may have made on its way to the place of slaughter. In the second place, it is proper to remove as much blood from the body as possible at the time of killing, as this also is apt to pass into a state of decay. The regulations of the Jews in this particular are most effectual, and are derived from very ancient statutes in Leviticus, which ordain that no manner of blood, whether it be of fowl or of beast, shall be eaten by man; and with the view of letting as much of it flow away as possible, the practice is to slaughter every animal by cutting its throat with a sharp knife. There are, indeed, the most precise rules for this purpose. In some countries, however, the blood is regarded as a very nutritious part of the animal, and great pains are taken to prevent its escape. Dr. Livingstone says, that many of the South-African tribes kill the beast by thrusting a javelin into the heart, so as

to prevent the loss of blood. But in these cases the meat is never kept, but is eaten directly after the animal is slaughtered. A proposition has also been made in this country for killing animals by letting air into the pleural cavities, whereby the lungs collapse, and so cause almost instant death by asphyxia, without loss of blood; but the practice is objectionable, not merely because of the liability of such meat to quick putrefaction, but also because of the difficulty of discovering disease in it.

In the third place, it is proper that the carcass of the animal should be allowed to cool and set thoroughly, before it is packed for conveyance to the market. If this is not properly attended to, it soon decays. It should also be packed loosely, or even freely exposed to the air, as the colouring matters of the blood and muscles continue to absorb oxygen, and to breathe, as it were, for some time after death, and while this goes on decay is arrested.

Lastly, all meat should be kept a little short of decomposition before it is cooked, or even until decomposition has just commenced, as the tissue then becomes loose and tender, and very digestible.

As to the culinary treatment of animal food, it may be remarked that every nation has found from experience that the cooking of meat, not only renders it more palatable, and more tempting to the sight and smell, but it also makes it more digestible, provided the operation has not been carried too far. Nowhere, therefore, except among savages, who have no fuel, as the Esquimaux and Samœides, is the flesh of animals eaten in the raw condition. In most cases where the art of cooking is in a rudimentary condition, the meat is either broiled or roasted; but in a more civilised state of society, the process is more complicated, for the objects of it are fourfold, as—

1st. To coagulate the albumen and blood of the tissues, so as to render the meat agreeable to sight.

2nd. To develop flavours, and to make the tissue crisp, as well as tender, and therefore more easy of mastication and digestion.

3rd. To secure a certain temperature, and thus to be a means of conveying warmth to the system; and

4th. To kill parasites in the tissues of the meat.

Now, as the researches of Dr. Beaumont and others have demonstrated that meat, when overdone, is always rendered more and more indigestible in proportion to the prolonged action of heat, it is highly necessary that the temperature should not be continued beyond the point necessary to accomplish these objects. Liebig says that a temperature of 133° F. will coagulate albumen, and that the red colouring matters of the blood and muscle are coagulated and destroyed at from 158° to 165° (say 170°). He therefore advises that all cooking operations, in respect of meat, should be limited to 170° . His directions are that, in *boiling* meat, it should be introduced into the vessel when the water is in a state of brisk ebullition, and that the boiling should be kept up for a few minutes. The pot is then to be placed in a warm situation, so that the water is maintained at from 158° to 165° . The effect of this is, that the boiling water coagulates the albumen and tissue upon the surface of the meat, and to a certain depth inwards, and thus forms a crust which does not permit the juice of the meat to flow out, nor the water to penetrate into the meat. The flesh, therefore, retains its savoury and nutritious constituents, and is not too sodden; but if, on the other hand, the meat be set upon the fire with cold water, and then slowly heated to boiling, the flesh undergoes a loss of soluble and savoury matters, while the soup becomes richer in them. The albumen, in fact, is gradually dissolved from the surface to the centre of the joint; and the fibre loses, more or less, its quality of

shortness or tenderness, and becomes hard, tough, and indigestible; and of course the thinner the piece of flesh is, the greater is its loss of savoury constituents.

This explains the well-known observation, that that mode of boiling which yields the best soup gives the driest, toughest, and most vapid meat; and that, in order to obtain well-flavoured and eatable meat, we must relinquish the idea of making good soup from it, for it is impossible to have the nutritious elements of meat in the joint and in the soup at the same time.

Even in *roasting* meat, the heat must be strongest at first, and it may then be much reduced; for if carefully managed, the juice, which at first flows out, evaporates from the surface of the meat, and gives to it the dark brown colour, the glaze-like lustre, and the strong aromatic taste of well-roasted meat. It is doubtful, however, whether the heat of 170° is sufficiently high to ensure the destruction of the parasites of meat, and, therefore, I would advise that the temperature should be as nearly as possible to that of boiling water (212°).

Of the four methods of cooking which are commonly practised in this country—namely, *boiling*, *baking*, *roasting*, and *frying*, the former is undoubtedly the most economical, and produces the most digestible food, but the flavour of the meat in most cases is not so well developed, and it is altogether unsuited for many descriptions of meat, as, for example, the flesh of young animals, which consists of an undue proportion of albumen and gelatine in the tissues—compounds which freely dissolve in water, and will, therefore, boil away to a large extent. The same is the case with soft, fatty tissue, like that of American pork, which sometimes loses 50 per cent. of its weight in boiling, whereas the pork of Denmark, Holstein, England, and Ireland will only lose from 25 to 30 per cent.; indeed, unless the process is well managed, there will always be considerable loss, as I have just stated, from the escape of albu-

men, gelatine, saline matter, and the rich alkaloids of meat, amounting sometimes to from 16 to 24 per cent. of the total weight of the joint; and that these are valuable constituents of flesh, is proved by the experiments of the French Academicians, who found that when a dog was fed daily upon half a pound of boiled flesh, which had been previously soaked in water and pressed, it quickly lost weight, as much, indeed, as one-fourth of its entire weight in 43 days; and in 55 days the emaciation was extreme. Of course, these observations do not apply when the liquor in which the meat is boiled is eaten with it, as in the case of hashes, stews, &c.

Dr. Pereira states that, at the Wapping Workhouse, where mutton (chiefly forequarters) and beef (consisting of the brisket, thick and thin flanks, leg of mutton pieces, and clods—all free from bone) were boiled, the average loss in weight was only about $17\frac{1}{2}$ per cent.; but this is under the common proportion, and shows that the meat was from old and lean animals. The ordinary loss of weight in cooking is about as follows in every 100 parts:—

	Boiling.	Baking.	Roasting.
Beef generally	20	29	31
Mutton generally	20	31	35
Legs of Mutton	20	32	33
Shoulders of Mutton	24	32	34
Loins of Mutton	30	33	36
Necks of Mutton	25	32	34
	—	—	—
Average of all	23	31	34

But although the loss of weight in baking and roasting is greater than in boiling, yet it is chiefly from evaporation, and from the melting of the fat. Flavours also are developed which give a pleasant relish to the meat; and these must have been recognised and esteemed in very early times, for burnt offerings are very frequently spoken of by Moses, as “a sweet savour unto the Lord;” and particular accounts are given of the manner in which

these offerings of the lamb and the kid, &c., were to be made acceptable, not merely, as it would seem, unto the Lord, but also unto Moses and Aaron who were to eat of them. How far back in history the flavour of roast pig was appreciated I know not, but it is immortalized in the graphic essay of Charles Lamb. And yet there are many disadvantages to these methods of cooking, as that the surface of the joint is often overdone, when the interior is almost raw; and that the action of the heat on the superficial fat frequently produces acrid compounds (consisting of *acrolein* and *fatty acids*) which are very distressing to a sensitive stomach. This is always the case when meat is fried or grilled, and is thus subjected to a temperature of 600° or more; in fact, all baked and roasted fatty foods are apt, on this account, to disagree with delicate stomachs; and it is often remarked that although bread and butter, boiled puddings, boiled fish, or boiled poultry can be eaten without discomfort, yet toast and butter, or meat pies and pastry, or fried fish, or roasted fowl will disagree with the stomach. The practice of covering poultry and game with lard, or oiled paper, or thin dough, or even with clay, (feathers and all, as is the Indian custom), and then roasting, is no doubt advantageous, as it modifies the temperature and prevents the formation of acrid fatty compounds. It was by some such device as this that Aristoxenes was able to serve up a pig apparently boiled on one side and roasted on the other—the savoury crackling being suited for stronger stomachs, while the more delicate side of it was best adapted for weaker digestions.

In deciding, however, on the proper method of cooking a joint, regard must always be had for the kind of flavour that is to be developed. Shoulders of mutton and fresh beef are rarely boiled, because of their insipidity. The same is the case with game and poultry, for the barn-door fowl and turkey are nearly the only examples of the latter which can be boiled, and there are no such

examples among the former. What should we think of a boiled grouse or woodcock? A story is told by a writer in the *Society's Journal* of a poacher who wished to seduce a bumpkin new poacher by a practical illustration of the fine flavour of game, and calling at his cottage one day, he left for him a hare warm from the chase, telling him to cook it, and to try if it warn't a nice dinner for nothing. A week after he called again, and asked him how he liked his dinner. "Didn't loike it at all," exclaimed the recipient. "Well, man," says the poacher, "how did ye cook it?" "Why, biled en in tarmuts, to be zure." I won't attempt to describe the disgust of the poacher. The same is the case with venison, although it may be boiled, especially when it is rather high, for about half the time necessary for cooking it, yet it must also be roasted, in order to develop its flavour. Hunters in the wild prairies of America are accustomed to cook the flesh of the deer by *brittling* it in the following manner:—They strip off the long muscles from each side of the spine, both above and below, and tie them up in a roll, after well smearing them with oil or fat; they then roast them, and baste them perseveringly with oil. If opportunity permits, they sprinkle them with lemon juice and a little cayenne before they are oiled and made up into a roll.

Almost all fresh-water fish, except salmon and eels, which have no need of extraneous flavour, are best cooked by *broiling* them; in fact, whenever there is a shadow of doubt as to the proper method of cooking a fish, it may be always safely settled by broiling it. Small fry of all kinds of fish are most savoury when, like white-bait, they are fried crisp in oil. A few of the coarser sort of fish, as pike and sturgeon, will bear cooking in an oven, if they are previously well stuffed; but the process of *baking* is not nearly so refined as that of broiling or roasting, although it has the advantage of regulating the temperature, and of keeping a dry sort of joint in a succulent condition.

Stewing is a delicate and safe process when the object is to retain the nutriment of meat, and to render it succulent and tender. All kinds of tough and strong-flavoured meat may therefore be cooked with great advantage in this manner. The process is, moreover, susceptible of very delicate treatment in the case of almost flavourless food. Many fresh-water fish, for example, as eels, perch, barbel, carp, lampreys, and even trout, may be cooked in this way, and the best medium for the stew is a light red wine. Coarser foods may be flavoured with vegetables and pot-herbs. In the case of tinned or preserved meats, especially when they have been somewhat over cooked in the process of preservation, the best method of dealing with them is to convert them into a stew or haricot—using a little fresh meat and a few well chopped bones, for the purpose of giving a flavour. These should be first stewed with vegetables and a few pot-herbs, taking care that potatoes and onions predominate in the case of mutton, and carrots and turnips in that of beef. When these are nearly cooked the preserved meat, previously cut up, should be added, and after simmering for a few minutes, so as to warm it thoroughly, it is ready to be served. Good pies may also be made of these meats, by cutting them into pieces and mixing them with cooked potatoes and a little gravy, or with boiled macaroni, and custard. Other more dainty forms, as rissoles, croquettes, &c., may be given to them, always taking care that they are properly cut up, and are daintily seasoned, and are not over cooked.

Soup is generally regarded as a light refreshment, and when delicately flavoured, is called the vestibule of the banquet. According to Hippocrates, it was invented because experience taught man that food which suits healthy people is not applicable for the sick: nevertheless it may be made so nutritious as to take the place of solid food. The savoury *pot au feu* of the French peasant, and the rich soup of the French soldier, are the chief rations on which they subsist; and so highly are they

esteemed, that the one is never absent from the fire, and the other is invariably preferred to solid meat. Experienced cooks are also aware of the high value of strong soup, which they call *stock*, and which they constantly use, not merely as a flavouring agent, but as a means of enriching all other kinds of food. They therefore, take the greatest pains to utilize the waste fragments of the kitchen, by boiling them down to a rich extract. It is surprising, indeed, that the experience thus acquired, as to the facility with which all sorts of scrap may be thus economised has not long since taught our poorer classes the value of soup as a daily ration with bread and vegetables; for, to use the language of Liebig, "the extractive substances of flesh, when added to food, do duty as true nutritive materials in the place of those substances which are otherwise produced from albumen." They cannot, perhaps, supply the place of albumen and fibrin in the nourishment of tissues, but they can replace the secondary products of albumen, which are concerned in the development of force; and as they are at once absorbed into the circulation, requiring no effort of digestion, they not only create force, but they also economise it. They are, therefore, among the most valuable constituents of food. I shall hereafter discuss the nature of these constituents, and the probable functions of them in nutrition.

The richest of all soups is obtained from finely-chopped lean meat, soaked for an hour or so in an equal weight of cold water, and then gradually raised to the boiling point. After simmering for about a quarter of an hour, it should be pressed and strained from the insoluble muscular fibre. In this condition it contains the whole of the soluble constituents of meat—amounting to about 5 per cent. of the meat used; so that a pint of soup from a pound of meat contains just four-fifths of an ounce of meat-extract. If the boiling is continued for a longer time, a little gelatine is dissolved, but the strength of the soup is not materially increased, and it

is apt to lose its rich meat-like flavour, which is so agreeable to the palate of the invalid.

Coarser, but still good and highly nutritious soup may be made from lean meat and bone, as the leg or shin of beef, or even a bullock's head. The meat should be carefully cut from the bone, and sliced into small pieces, and the bone should be well chopped. When in the stock-pot it should be just covered with cold water, and gradually heated to the boiling point. Vegetables should then be added, and it should be gently simmered for five or six hours, during which time it should be carefully skimmed—a little cold water being occasionally added to facilitate the rising of the scum—as this is essential to the making of a clear soup. After standing a little time to settle, it should be carefully poured off and strained; and when cold, the cake of fat which forms upon the surface should be removed. In this manner about four or five quarts of good strong soup may be made from a shin of beef, weighing 6 or 7 lbs., the soup of which contains about 600 grains of solid matter to the pint, and of this 39 grains are saline.

In the cooking depôts of our large cities, where soup is made for the poor, the materials are somewhat scanty, for, according to Dr. E. Smith, 100 rations of soup are thus prepared:—the meat liquor from 7 lbs. of beef and 1 lb. of bones; split peas, 13 lbs.; carrots and Sweede turnips, each $6\frac{1}{2}$ lbs.; onions, $5\frac{1}{2}$ lbs.; leeks, $\frac{1}{2}$ lb.; salt, pepper, and dried herbs enough to flavour: and the materials for 100 rations of Scotch broth are, according to the same authority, the meat liquor from 7 lbs. of beef, and 1 lb. of well-broken bones; $2\frac{3}{4}$ lbs. of split peas; $3\frac{1}{4}$ lbs. of Scotch barley; $3\frac{1}{2}$ lbs. of carrots; $3\frac{1}{2}$ lbs. of turnips; $7\frac{1}{4}$ lbs. of cabbage or other green vegetables; with sufficient salt, pepper, and dried herbs. Reckoning a ration at one pint, it would contain the nutriment of only about an ounce and a quarter of meat and bone, which is manifestly insufficient for dietetical purposes. The poor, therefore, have but little

respect for this sort of food, and very naturally associate it with charity and the workhouse. The same is the case with soup made from bones, for although they yield about 19 per cent. of their weight of gelatine and fat, yet they are totally deficient of the proper constituents of good soup. Dr. Edward Smith is in error, therefore, in saying that 6 lbs. of bones, broken small, and boiled in water for 9 or 10 hours, will yield a soup that contains the nutritive elements of 2 lbs. of meat as far as carbon is concerned, and of 1 lb. of meat in respect of nitrogen ; for although this may be so as regards the actual weights of carbonaceous and nitrogenous matters, yet it is far otherwise with their nutritive powers. In the well-known experiments of the French Gelatine Commission, it was found that the soup or jelly from boiled bones would not support the life of dogs, although raw bones in like proportion would ; from which it is evident that there is a great difference in the nutritive power of the gelatinous tissue and its cooked products. Gelatine, in fact, has never been discovered in the blood of animals, nor is it a constituent of eggs or milk, which are the two primary foods from which the tissues of the young are formed. It would seem, therefore, that it is not an essential article of diet, although it is probable that gelatinous tissues undergo digestion by being converted into peptones, which have a low nutritive power, about one-fifth that of albumen, but there is no satisfactory proof that cooked gelatine is of the same nutritive value. When associated with muscular tissue it may perhaps be assimilated, for the experiments of Bischoff and Voit have shown that when a dog weighing 80 lbs. was fed on 17·6 ozs. of meat a-day, he lost a pound in weight in four days, but when the same quantity of meat was associated with 7 ozs. of gelatine he gained in weight, to the extent of 4·7 ozs. in three days. Liebig infers from this that gelatine has considerable nutritive power when combined with meat,

and that its action is to economise albumen. Possibly it may serve in the direct nutrition of gelatinous tissue, or, by becoming oxydized, it may develope force ; for it appears to be transformed, like albumen and fibrin, into urea, and so leaves the system.

Other varieties of soup, as *ox-tail*, *kangaroo-tail*, and *turtle*, owe their peculiarities to flavour and composition, the last being rich in gelatine, which is mostly made from the waste chippings of calf skins, and carefully clarified as a stock for other rich gelatinous soups. *Ox-tail*, which is now a favourite and rather expensive soup, was at one time the humble fare of the poor Protestant refugees, who fled from France at the revocation of the edict of Nantes, in 1685, and settled in Spitalfields and Clerkenwell. In the extremity of want they purchased from the tanners of Bermondsey the ox-tails, which were then sold with the hides, and made them into soup. Accident brought it under the notice of a philanthropic epicure, who was on a mission of charity to the homes of the poor foreigners, and he proclaimed its virtues, so that ere-while it became a fashionable dish. *Kangaroo-tail soup* is hardly so well known, although its merits are considerable, for it has more body, and a richer flavour than the last. At present it is but scantily supplied from Australia, and it comes to us in quart tins, which are sold at three shillings a-piece.

Extract of Meat, according to the formulæ of Liebig, should be the concentrated essence of the juice of flesh, but much of the so-called extract in commerce is solidified soup, with more or less of gelatine. The chief supply of the genuine extract is from the manufactory of the Liebig's Extract of Meat Company, at Fray Bentos, on the River Uraqua, in South America, where the superabundant meat of the rich pampas, or grassy plains of the country is freely utilized. The manufactory is on a stupendous scale, for it is capable of dealing with the flesh of 80 oxen an hour, and all the appliances

Good extract of meat is always slightly acid, and it has a pale yellowish-brown colour, with an agreeable meat-like odour. It should be perfectly soluble in cold water, and should not contain albumen, fat, or gelatine.

In Poland and Russia an extract of meat, called *Tablettes de Bouillon*, is made from the flesh of game, which is very abundant in the country, as well as from ordinary meat; and, according to the analysis of M. Reichardt, the *tablettes* contain 73·31 per cent. of nitrogenous matter, of which 38·07 are soluble in alcohol, 4·75 per cent. of mineral matter, 0·22 of fat, and 21·72 of water. These *tablettes* are largely used for making soup. Again, in the Dutch East Indian possessions, as Java, Sumatra, &c., extracts of meat, fish, and even of crabs, have been used by the natives for centuries. They are called *petis*, and are considered to be so important in a dietetical point of view, that no kitchen in the Archipelago is ever without them; in fact, all sauces, soups, gravies, and native dishes are either flavoured or strengthened with them. They are made from the juice of raw flesh, or from the liquor which is pressed from some cooked material—the liquid being in both cases, carefully evaporated to the consistence of thick syrup. Dr. Pott has examined several of these extracts, namely, *petis kurban* (buffalo extract), *petis sapie* (extract from the Malay ox), *petis ikan lant* (fish extract), and *petis udang* (crab extract), and he finds they are all genuine extracts of meat, &c., with only a trace of gelatine and albumen. They vary in colour and in flavour, that of fish and crab being the least agreeable. A sample of buffalo extract contained 20·9 per cent. water, 62·7 extractive, and 16·4 ash, or mineral matter. These extracts are prepared on a large scale in the islands of the Archipelago, and are sometimes exported to Holland, the price of them being at the rate of half a gulden (less than a shilling) per pound at the place of manufacture.

False views have been entertained of the nutritive power of extract of meat, for, as one pound of it represents the soluble constituents of from 30 to 34 pounds of lean meat, or from 45 to 48 pounds of ordinary butcher's meat, it has been assumed that its nutritive power is in like proportion; but Liebig has taken care to correct this error, by showing that the extract, when properly prepared, merely represents the soup or beef-tea obtainable from that quantity of meat; and, as it is deficient of albumen, it must be conjoined to substances which are rich in this material, as beans and peas. No doubt the physiological action of the extract is due to the organic alkaloids and acids which it contains; and as the latter are very similar to the active principles of tea and coffee (theine or caffeine) in their effects on the body, it must be concluded that extract of meat is more of a vital restorative than nutritious food. It is from this point of view that Parmentier and Proust, long ago, and even Liebig himself, have regarded the physiological effects of such preparations. "In the supplies of a body of troops," said Parmentier, six-and-thirty years ago, "extract of meat would offer to the severely wounded soldier a means of invigoration which, with a little wine, would instantly restore his powers, exhausted by great loss of blood, and enable him to be transported to the nearest field hospital;" and in almost the same language, Proust remarked that "we cannot imagine a more fortunate preparation under these circumstances; for what more invigorating remedy, what more powerfully-acting panacea than a portion of genuine extract of meat dissolved in a glass of noble wine?" But, as in the case of soup and beef-tea, its nutritive power must be assisted by vegetables and other substances which are rich in nitrogenous matter. Conjoined, therefore, with wheaten flour, with peas or lentils, or even with the gluten obtained in the manufacture of starch by Durand's process, it may be made to have the nutritive

power of meat. Already, indeed, there is a preparation of it by Messrs. Peek, Frean, and Co., in which the extract is mixed with baked flour and pressed into small biscuits; indeed, as far back as the year 1851, Mr. Borden, jun., obtained a patent for combining extract of meat with flour, farina, or meal, and baking it in the form of biscuits. In this manner, by using the extract of 5 lbs. of meat with 1 lb. of flour, he produced biscuits which contained 32 per cent. of nitrogenous matter; and 1 oz. of the biscuit grated in a pint of water, then boiled and flavoured, made a good soup. The soup preparation of the Tapioca Beef Bouillon Company (Geyeine) is a mixture of extract of meat with tapioca in a dry granular form, and it makes a palatable broth; but in the case of Liebig's extract of meat, one pound of the preparation is sufficient, with the usual rations of potatoes and other vegetables, to make soup for 130 men; and a very strong broth is made by dissolving a teaspoonful of it (about 150 grains) in half a pint of boiling water, and flavouring with salt and pepper.

A still more nutritious broth, containing the albumen of the meat, as well as the soluble extract, is obtained by infusing a third of a pound of minced meat in 14 ozs. of cold soft water, to which a few drops (4 or 5) of muriatic acid, and a little salt (from 10 to 18 grains) have been added. After digesting for an hour or so, it should be strained through a sieve, and the residue washed with 5 ozs. of water and pressed. The mixed liquids thus obtained will furnish about a pint of *cold extract of meat*, containing the whole of the soluble constituents of the meat (albumen, creatine, creatinine, &c.), and it may be drunk cold, or slightly warmed—the temperature not being raised above 100° F., for fear of coagulating the albumen.

ECONOMY OF COOKING.

There are many questions connected with the economy of cooking which I have not time to discuss, but I may state that this Society has done good service in obtain-

ing valuable information as to the simplest and cheapest apparatus for the purpose. Foremost among them is the cooking-pot of Captain Warren. It is a sort of double saucepan, and is easily made by fitting a small covered saucepan into a larger one. The inner vessel contains the joint or other thing to be cooked, and the outer one has a little water in it, so that the temperature in cooking can never exceed 212° . By this means the joint is cooked in its own vapour without coming into contact with water or steam, and thus it cannot lose its soluble constituents; and if it be desired to improve the flavour of the joint just cooked, it may be afterwards roasted for a short time before the fire. The loss in weight under these circumstances is not nearly so great as in the common way of cooking, and the flavour and tenderness of the meat are considerably increased; besides which, there is the certainty of cooking the joint equally throughout, without over-dressing it. Moreover, by the adaptation of a steamer to the outer vessel, vegetables may be also cooked at the same time. When the meat is boiled by this process, there is little or no loss of weight, and even when it is afterwards roasted, for the purpose of improving its flavour, the loss is much less than when a joint is roasted in the ordinary way. In one experiment it was found that 15 lbs. of meat roasted in the usual manner, in the kitchen of the Cambridge Barracks, lost 4 lbs. 4 ozs. in weight, whereas the meat cooked in Captain Warren's pot, and then roasted, lost only 2 lbs. 15 ozs., so that there was a gain of 1 lb. 5 ozs.

Perhaps the cheapest, the cleanest, and in all respects the most economical method of cooking is by means of gas properly burnt. There are several kinds of apparatus in use at the present time, but the best of them have been designed and constructed by Mr. Leoni, of the Adamas Works, London, and they are contrived to suit the wants of a large or small family. One of his stoves has been in operation for some time in the kitchen of the London Hospital; and, to take a month's

work as an illustration of its capabilities, the following are the results:—

	Beef.	Mutton.
Number of cookings in the month	9	13
Average weight of meat before each cooking	153·2 lbs.	193·3 lbs.
Do. do. do. after do.	122·6 „	164·0 „
Average per centage loss of weight	20·0 „	15·1 „
Average time of each cooking	2h. 10m.	2h. 10m.
Average quantity of gas consumed	248 cub. ft.	236 cub. ft.

Smaller apparatus appear to be equally economical, for, according to Mr. Magnus Ohren, of Sydenham, who has made many experiments on the subject, a family dinner consisting of a joint of 8 lbs. or 9 lbs., with 3 lbs. or 4 lbs. of vegetables, and a fruit pie and a rice pudding, may be easily cooked in from 2½ to 3 hours, with a consumption of about 50 cubic feet of gas. The advantages of this method of cooking are its cleanliness; its economy, for not only is there less loss in weight, but the dripping is all collected; its certainty and regularity of action; and the facility with which it is put in operation in summer time, when large fires are objectionable.

Another apparatus of very great ingenuity is a cooking-pot from Norway, where the saucepan containing the joint and a little water is, after boiling for a short time, placed in a box lined with felt, and thus left for an hour or two to cook, the conducting power of the felt being so bad that the heat is retained in the most perfect manner. The apparatus is not only economical, but it is also excellently well suited for picnic parties, or for soldiers on the march, who may thus secure a hot dinner, cooked while on the journey.

The cooking appliances of the poor are very imperfect, and hence they resort to the cook-shops of their neighbourhood; but even then their meals are scanty and wretchedly cooked. In the poor districts of London three-halfpence is the usual expenditure for a dinner by children—a penny going in pudding, and the halfpenny in potatoes. If they pay twopence they are allowed to sit down, and have a little gravy with it. Everybody

has heard how the poor of Paris used to dine *à la squirt*, where the tin soup basins were nailed to the table, and where the attendant Leonoras drew up the seething soup from a hidden cauldron by means of a huge syringe, from which it was driven out into the customer's basin. The price of the meal (4 sous) was to be instantly paid down, or the callous handmaid sucked up the soup again into the monster squirt. Scenes like this, and even worse than this, in the abodes of the poor, have urged philanthropists to seek a better means of supplying their wants, without trespassing upon the dangerous ground of charity. In Paris an enterprising widow (Madame Robert) conceived the idea of giving a poor man a good dinner for twopence. Her daily bill of fare was cabbage-soup, a slice of bouilli (beef), a piece of bread, and a glass of wine; and thus, in the neighbourhood of the *Marché des Innocents*, she daily provided for some six hundred workmen, who took their dinners in the open air, but sheltered from the weather; and she gained a farthing by each guest. More recently M. Douval, whose large establishments for the sale of butcher's meat are among the sights of Paris, has succeeded in furnishing dinners at a reasonable price to the middle classes, who did not altogether like to be seen among the workmen at Madame Robert's, and yet could not afford the charges of a restaurant. In this country, also, with like benevolence, there has been set on foot, with more or less success, in different places, restaurants for the poor. In Glasgow, for example, the working-class dining-rooms, which are far above the rude accommodation of Madame Robert, are established to provide a substantial dinner for 4d. or 5d. Long ago the special correspondent of the *Daily Telegraph*, in writing about them, said that he obtained a capital dinner of good pea-soup, boiled beef, ten ounces of potatoes and pudding—more than he could eat—for the sum of 5½d.; and a writer in the *Times* also stated that for 4½d. he had a

pint basin of pea-soup, a plate of hot minced collops, a plate of potatoes, and eight ounces of bread; while his companion had, for the same sum, a pint basin of broth, a plate of cold beef, a plate of potatoes, and a slice of plum pudding, all excellent in their quality, and well cooked. The practice in these places is to provide daily a variety of hot foods, as soup, broth, potatoes, rice, cabbage, pudding, tea and coffee, besides bread and butter, ham, and cold pressed beef; and every ration, except meat, is so apportioned as to be sold at the uniform price of a penny. The meat costs three-halfpence; and, with the view of clearing off the remainder of the soup after the proper dinner hour, so that a fresh quantity may be made every day, it is the practice to sell the soup and broth at half-price, from six o'clock to eight o'clock in the evening, and then to give the remainder away. All the articles are of the best quality, and are well cooked. They are bought by contract at wholesale prices; and, although they are sold so cheaply, yet they yield a small profit, and so give the system the stability of a commercial enterprise.

Very recently, too, Mr. Riddle has proposed, in a paper which was read before this society, that arrangements might be made for cooking dinners on a large scale, and sending them out to the houses of the poor. He proposes to prepare, daily, good rations of roasted, baked, and boiled meat, with vegetables; and to send them out in 2-lb., 4-lb., or 6-lb. tin canisters, all ready for immediate use, and kept warm in little compartments of a properly-constructed cart. There would be no difficulty about this, and the meat might be delivered in excellent condition, and with great punctuality. None but those who are acquainted with the utter helplessness of the poor in the matter of cooking food, or who know the difficulties of even better classes of persons in this matter, can form any notion of the value of such a proposition; and I should be glad to see it realised.

LECTURE IV.

PRESERVATION OF FOOD ; UNWHOLESOME AND ADULTERATED FOOD.

PRESERVATION OF FOOD.

IT requires no argument to show that the preservation of food is a matter of great public importance ; for it not only enables us to provide against actual want in periods of unusual scarcity, but it also affords the means of equalising the distribution of food at all times, so that the excess of one country may be used in supplying the deficiency of another. In the pastoral districts, for example, of Canada, Australia, Tasmania, the Cape of Good Hope, Mexico, the Argentine Republic, and the Brazils, thousands of tons of meat are always available as food, and yet they are lost to us because of the difficulties of preserving it. In South America, at least two millions of beasts are annually slaughtered for the fat, skin, and bones, the flesh of which could be supplied here at less than 2½d. per pound. So, also, in Australia, the amount of meat available as food is practically inexhaustible. Last year, Mr. Philpott stated to the Food Committee of the Society of Arts, that he himself was in the habit of melting down from 1,000 to 1,500 sheep daily for four months together ; and that in

the vast districts of rich pasture-land from Victoria to Brisbane, there was an unlimited supply of the very finest meat—all of which was at present entirely wasted, because of the difficulty of disposing of the flesh; and, therefore, the carcasses of the animals were melted down for fat. A bullock in Australia, he said, costs only from £3 to £4; and legs of mutton, of the very best quality, were, when salted, sold for 3s. a dozen. If some simple and practicable means could be devised for preserving such meat, it might be supplied to our markets at less than 3d. a pound.

Until recently the only process employed for this purpose was the rude method of salting the meat; but the deterioration of it was so obvious, and the distaste for it so general, that it was only practised to a limited extent, and for occasions when fresh meat could not be obtained. The salt junk of the navy in olden time was a good example of the wretchedly unwholesome and indigestible meat prepared, for it could hardly be called preserved, by this process. Recognising, therefore, the necessity for a better means of preserving food, the naval authorities of every country appealed to science, and gave the largest encouragement to inventors. A further stimulus to invention was created by the necessity for supplying our Arctic explorers with good and wholesome food during their long winter residence in the frozen seas of the north; and as that inquiry was set on foot, not merely for the purpose of discovering a north-west passage to our possessions in America, but also with the view of prosecuting scientific research in almost inaccessible regions, an unusual inducement was offered for the preparation of such food. The demand thus created was soon acknowledged by science, and was also met by the practical skill of the manufacturer, so that the Arctic voyager went confidently on his journey, knowing that he had other food than the unwholesome junk of the navy, or the precarious supply of the polar

seas. The earliest preparations supplied to him were mixtures of dried meat with sugar and spice (*pemmican*), but after a time he was furnished with fresh meat, preserved in air-tight cases. At first the supply was chiefly for voyagers in cold countries, but when the value of this method of preservation became known, the European residents of hot climates, and notably of India, eagerly sought for the fresh foods which they were accustomed to use in their own country. Additional stimulus was thus given to this process of manufacture; and at the present time it has acquired gigantic proportions.

I have before me a list of the specifications of patents relating to the preservation of food from the year 1691 to the end of 1855, and I find that only one was described in the seventeenth century, and three in the eighteenth, while as many as 117 were specified in the first 55 years of the present century. Invention, however, has not been prolific of new processes, for it is mainly confined to an application of one or two simple elementary principles—26 of the patents, for example, are for the preservation of food by drying; 31 by excluding atmospheric air; 8 by covering the food with an impervious substance, as fat, extract of meat, gelatine, collodion, &c., and 7 by injecting meat with various salts.

But before we proceed with the examination of these processes, it will be advantageous to inquire a little into the circumstances which favour organic decomposition. It would seem, from experiment and observation, that three concurrent conditions are absolutely necessary for active putrefaction—namely, the presence of much moisture, the access of atmospheric air, and a certain temperature, as from about 40° to 200° of F.; for if any of these conditions are absent, the organic substance resists decay. All preservative processes must, therefore, depend on an application of some principle arising out of one or other of these conditions, and perhaps also of a fourth—

namely, the action of chemical agents. Let us review them in detail.

1st. *The preservation of substances by drying them* is of very ancient date. In our anatomical museums we have long known that specimens of the animal body may be preserved for an indefinite time by drying them, and then varnishing them so as to exclude moisture. Here is a dissection prepared in that manner, which has been used for lecture illustration at the London Hospital for more than half a century, and yet it is as sound as when it was made. In the chronicles of Froissart, dried yolk of eggs, powdered and rammed in barrels, are mentioned among the stores of provision laid up by the young king of France for the invasion of England in 1386. In warm climates it has been a practice for ages to preserve fish, and even meat, by drying them—the meat being cut into strips and exposed to the action of warm dry air. *Charqui*, or *South American beef*, which you see here, is an example of it. It is obtained from animals that are grass-fed; and they are killed by pithing, and then bleeding them. Directly the hide is taken off, the flesh is stripped from the bones and allowed to cool. It is then placed on a table, and jerked, or cut up into thin slices, which are piled up in heaps with alternate layers of salt. After standing twelve hours the meat is turned, and fresh salt is added where necessary. The next day the salted strips are placed upon hurdles, and exposed to the sun to dry. It requires two or three days to dry the meat thoroughly, and, for fear of damp, it is always taken in-doors at night. There are several varieties of this meat, as *pato*, which is the best and most free from sinew; *manta*, the second quality; and *tasajo*, the third, which is very thin and full of sinews. All the varieties require to be well soaked in water, and then to be cut small and cooked by prolonged boiling. The Nicaraguan peasants, who use it largely for food, cook it with some sort of fat in dripping or pork, and they flavour it

with herbs. The Chinese and Mongols, also, prepare and cook it in much the same way.

But animal foods are not well preserved in this manner, as they lose their flavour, and become tough and indigestible; the fat also gets rancid, and in damp weather the meat absorbs moisture and becomes mouldy and sour. Perhaps the lean parts of meat, as the heart, tongue, and strips of muscle, might be advantageously preserved in this way, especially in warm and dry climates. The Food Committee of this Society reported favourably of a specimen of dry powdered beef from Queenstown, which they said was in excellent condition, and contained about four times as much nutritious matter as ordinary meat. Generally, however, the fat is very rancid, even when pains are taken to prevent the substance from getting mouldy. It is for the same reason that all attempts to preserve milk and the yolk of eggs by drying have failed, although the dried white of egg will keep well, as in the process of Mr. Charles Lamont, where the albumen is dried in thin scales—forty-four eggs making about one pound of the preparation. Absorbent substances mixed with the fatty food will obviate the difficulty to some extent, as in the preparation of *pemmican*, where sugar and spice are added to the dry powdered meat; and in the several processes for preserving milk by evaporating it and mixing it with sugar, &c., as in the patents of Newton (1835), Grimwade (1847 and 1855), Louis (1848), &c.; as well as the process of Davison and Symington (1847), for preserving eggs by mixing the yolks and whites with flour, ground rice, and other farinaceous substance, and drying. Extract of meat may also be preserved in the same manner, as in the patent of Donaldson (1793), of Robertson (1851), and of Borden (1851), where the extract, after the separation of fat, is mixed with farinaceous matters; in the last case it is also baked in the form of biscuits. The meat biscuits of Messrs. Peak, Frean, and Co., consist of

Liebig's extract of meat and baked flour, pressed into small cakes. In the year 1854 MM. Blumenthal and Chollet obtained their patent for combining meat and vegetables in the form of tablets, by first drying the meat and vegetables, then pressing into cakes, and finally submitting them to successive immersions in rich soup—allowing them to dry in warm air after each immersion. When extract of meat is made without fat or gelatine, as in the case of Liebig's extract and the *patis* of Sumatra, Java, &c., it may be kept for a long time in a sound condition, without mixing it with farinaceous matters, although the preparation of it with baked flour, as already described, is a great improvement.

The process of drying is, however, best adapted for the preservation of vegetable substances, and it has been so used from time immemorial, as in the keeping of pot-herbs, in preparing the tea-leaf, in making hay, &c. In this country the first recorded patent for preserving vegetables by drying them was granted in 1780 to John Graefer, who sought to retain the flavours of vegetables by first dipping them in boiling salt and water, and then drying. Forty years later (1820) John Vallance obtained a patent for preserving hops by drying them, and then compressing them into a small space, as is the practice at the present time. Then came the patents of Edwards (August, 1840), for boiling, granulating and drying potatoes; and of Grillett (November, 1840), for preserving both cooked and uncooked potatoes by drying. Ten years afterwards (in November, 1850) Masson obtained his patent for preserving vegetables by drying them and forcibly compressing them, so that they were reduced to one-seventh their original bulk—a cubic yard containing rations for 16,000 men. This process has been very successful, and is still practised by Devaux, Chollet, and others; for it serves for the preservation of all kinds of vegetables, as potatoes, cabbages, carrots, cauliflowers, beans, apples, &c.; and when steeped in

water they re-absorb their natural proportions of moisture, and swell out to their original size. They are, however, somewhat deficient of flavour ; and they require prolonged boiling, as from an hour and a-half to an hour and three-quarters to cook them.

By a more careful process of drying, Mr. Makepeace has managed to preserve both the colour and the flavour of vegetables, especially of pot-herbs, as you may see from these specimens, which I have had for some time.

Altogether there are, or have been, about thirty-one patents in this country for the preservation of various articles of food by drying them.

2nd. *The preservation of organic matter by excluding atmospheric air* is, like the last, a very ancient process. The old practice of burying the dead in leaden coffins, and the still more ancient custom of swathing them in resinous bandages or waxed cloths (called cerements), owe their preservative powers to the exclusion of atmospheric air ; and it is remarkable, seeing the efficacy of the process, that the scientific principle of it was not long ago recognised and applied to the preservation of food. The first patent of the kind that I am acquainted with in this country, was granted to Francis Plowden, in June, 1807 ; and he describes it as a process for “ preserving butcher’s meat, animal, and other comestible substances, by encrusting them with a substance, which must not only resist the effects of atmospheric air, but must not communicate any noxious quality to its contents,” and for this purpose he employed essence or extract of meat. The substance being dressed, so that it may preserve the longer, is wiped dry, and put into a wooden vessel, and the hot extract, while in a fluid condition, is poured over it, so as to find its way into every vacuum. Three years later (in February, 1810), Augustus de Heine took out the first patent for preserving meat by exhausting the air from the vessel containing the meat ; and he contrived a machine for the purpose, as the

action of the common air-pump was tedious. Six-and-thirty years after this (1846), the late Mr. Warington, of Apothecaries' Hall, obtained his patent for the preservation of animal substances, by coating them with common glue, gelatine, or concentrated meat gravies, or otherwise by dipping them in warm solutions of such substances, or by wrapping them in waterproof cloth, or covering them with caoutchouc, gutta-percha, or varnish. These mark the starting points of the various processes now in use; for example:—

(a). Of those which owe their operation to the exclusion of air, *by filling up the vessel with something hot*, there are the patents of Plowden (1807), who used rich gravy or extract of meat; of Granholm (1817), who used hot fat, or hot animal jelly; and of Wothly (1855), who used oil, as in preserving anchovies. I am rather surprised, considering how easily the exclusion of air is effected by surrounding the substance with hot fat, that this method of preserving meat has not been adopted in Australia and South America; for as the fat which is prepared from wild cattle is sent to this country in casks, there would be no difficulty in sending with it the finer descriptions of joints, as legs of mutton, and good pieces of beef. The process should be conducted as follows:—When the fat is melted, and is at a temperature of from 240° to 250° F., the fresh joints should be plunged into it, and kept there for a few minutes, so that the superficial moisture might be thoroughly evaporated. They should then be immediately packed in sound dry casks, and filled up with hot fat, at a temperature of 200° or thereabouts. In this manner both the fat and the joints might be transmitted to this country.*

* Since this was written large importations of food, preserved in this manner, have been made by Mr. Tallerman, and by the Victoria Meat Preserving Company—the latter samples being very fine.

Vegetable substances are frequently preserved in bottles filled up with hot syrup, and the practice is a very old one. Hot water is also used for the same purpose, and this method dates from the year 1807, when this Society gave a premium to Mr. Saddington for his method of preserving fruits without sugar. His process was to gather the fruit a little before ripening, and to put it immediately into clean bottles—filling the bottles with the fruit to the neck. They were then placed in a vessel of cold water, and heat was applied until it rose to the temperature of from 160° to 170° F. After standing exposed to this temperature for half-an-hour, the bottles were filled up to within an inch of the top with boiling water, and were then immediately corked and covered at the top with cement. The action of the heat was not merely to expel atmospheric air from the bottles, but also to coagulate the vegetable albumen of the fruit. Fruits and green vegetables are still preserved in this manner, a little alum being generally added to the water in the bottle, for the purpose of hardening the tender skin of the fruit, and so preventing its disfigurement by bursting.

(b). A process not very unlike the preceding, is that which consists in *the destruction of the oxygen of the air in the vessel, by heating the substance in it.* This is the plan of M. Appert, who, in 1810 (three years after the publication of Mr. Saddington's method), obtained the reward of 12,000 francs, offered in the preceding year by the French Government, for the best method of preserving food. Here is the book which M. Appert wrote at the time, and he tells us to cook the food to some extent, and put it into strong glass bottles—filling them almost to the top. The bottles are then to be securely corked, and exposed for some time to the action of boiling water. To guard against accident from bursting, the corks are to be wired down, and the bottles wrapped up separately

in cloths. After this the corks are to be well covered with pitch, to exclude atmospheric air. A like process was patented in the autumn of the same year (1810), by Mr. Peter Durand, who, no doubt, derived it from the published account of M. Appert, dated nine months before; and since then, many such patents have been obtained, which I need not describe. Attempts have frequently been made to preserve milk by this process. Appert recommended that the milk should be boiled down to about half its bulk before putting it into the bottles; and in 1847 Bekaert tried to improve the process by adding carbonate of soda to the milk. Later still, in the same year, Martin de Lignac obtained a patent for preserving milk by evaporating it to one-sixth of its bulk before bottling it; and this is the practice at the present time in some places, where they wish to keep the milk for a week or ten days. A good deal of the condensed milk in America is of this kind, and it is thick like cream, but not very sweet. Then there were the patents of Symington and of Moreau (1853), but all these methods have failed in practice on account of the difficulty of preventing the separation of the butter.

Somewhat recently the milk from the rich pastures of Switzerland, Bavaria, Ireland, and England, has been preserved by adding to it about a third of its weight of sugar, and then concentrating it in vacuo until it acquires the consistence of thin honey. In this state it is run into tins, which are immediately soldered down, and thus hermetically sealed. At present there are many sources for the supply of such milk—the English market being chiefly supplied by the Anglo-Swiss Condensed Milk Company, whose works are at Cham, near Zug, in Switzerland; the English Condensed Milk Company, at Aylesbury; and the factory of Mr. Newnham, at Marlow, in Ireland. The following is the average composition of such milk.

TABLE XXVIII.

Composition of various Samples of Condensed Milk.

	Anglo-Swiss.	Vivis. Swiss.	Sassin Prussia.	Kempton Bavaria.	Ordinary Milk.
Casein . . .	18·10	15·96	14·24	14·90	3·64
Butter . . .	12·26	12·03	12·63	13·65	3·55
Sugar . . .	44·25	46·92	51·83	50·21	4·70
Salts . . .	2·41	2·67	2·48	2·43	0·81
Total Solids .	77·02	77·58	81·18	81·19	12·70
Water . . .	22·98	22·42	18·82	18·81	87·30
	100·00	100·00	100·00	100·00	100·00

So that the concentration of the milk has been to about one-third of its original bulk, and therefore if it be diluted with twice its bulk of water, it will make a good milk of ordinary strength. Of the sugar in the milk, from 14 to 18 parts consist of lactose or milk sugar, and the rest is cane sugar—hence the sweetness of the milk.

(c). The preservation of food *by exhausting the air from the vessel containing it* dates, as I have said, from the year 1810, when Augustus de Heine proposed to use a vessel with a valve in the top of it, which allowed the air to be drawn out by means of a special apparatus, but not again to enter. The exhaustion, however, was so imperfect that the process did not answer. In 1828 Mr. Donald Currie improved it by admitting carbonic acid gas into the vessel after it was thoroughly exhausted; and later still, in 1836, M. Leignette still further improved it, by filling the vessels containing the food with salt and water, and then letting out the liquid through the aperture, which remained open for that purpose, while carbonic acid gas went in. Six years after this (in 1842), Mr. John Bevan patented a process for drawing out the air by an exhausting apparatus, and then admitting a warm solution of gelatine; and in 1846 Mr. Rettie employed, in the like manner, a solution of common salt. But none of these

methods were successful; nor was the patent of Mr. Ryan, in 1846, for using gases, chiefly acetic acid vapour, and carbonic acid gas. The most perfect process of this kind was patented by Messrs. Jones and Trevethick. It consists of an apparatus whereby the exhaustion of the vessel containing the raw food is effected, while it is in an air-tight trough of water, and thus the entrance of air and the collapse of the sides of the vessel are completely prevented. After the exhaustion, pure nitrogen is admitted into the vessel, for the purpose of diluting the residuum of air, and it is again exhausted. Lastly, a charge of nitrogen, containing a little sulphurous acid, is let into it, and thus the last trace of oxygen is chemically absorbed. The vessels are now in a proper condition for removal from the air-tight water trough, and for having the apertures sealed with solder. Meat, fish, and poultry, preserved in this manner, have been found good after seven or eight years; and specimens of them of that age were exhibited in the London Exhibition of 1862.

(*d*). The most common method of driving out the air is *by means of steam*. The food is put, with a charge of water, into a tin case with a hole in the top, and when the water is boiling actively, and steam has displaced the air, and is escaping freely, the hole is stopped with solder. This process dates as far back as 1820; but the first patent for it was granted to M. Pierre Antonie Angilbert, in 1823. He had, however, a very rude method of applying heat to the tin vessels, and this was improved by Wertheimer in 1840. In the month of January of the year following Mr. Gunter improved it still further; and later in the same year both Goldner and Wertheimer obtained patents for using a bath of muriate of lime for heating the vessels. This is called the chloride of calcium process, and is, in fact, the practice followed at the present time by Goldner, McCall, Richie, Morton, and some others, who are largely engaged in the preservation

of food. The details of the process for effecting it are somewhat as follows:—

The raw meat and vegetables are put with a little water into the canisters and soldered down—a pin-hole aperture being left in the lid. The canisters are then subjected to the heat of the bath (a little above 212° .) until the contents are about two-thirds cooked; and then, while steam is blowing freely out, the aperture is dexterously sealed tight with solder. The heat of the bath is then raised to about 230° F., and after exposure for an hour or so to this temperature, the canisters are taken out of the bath and allowed to cool. They are then painted over with a stiff oil paint, and are placed for some time in the testing-room, where the temperature is sufficiently high to promote decomposition. If the canisters show no sign of bulging out from the generation of putrefactive gases, they are considered sound. Messrs. Hogarth and Co., of Aberdeen, use high pressure steam instead of the muriate of lime bath; in fact, the process which is generally used in Scotland, and which is called the water or Aberdeen process, is the old method of supplying heat by means of steam or boiling salt and water. The raw meat, vegetables, &c., are placed in tins, which are immediately soldered down perfectly air-tight. They are then placed in a bath of boiling salt and water, and kept there for a certain time, according to the size of the tin (about two hours and a half for a 6-lb. tin). At the expiration of this time the tins are removed from the bath, and the expanded air and vapour are let out through a minute aperture in the cover, by unsoldering it for a moment. Having been made air-tight again, they are returned to the bath of boiling brine, and kept there for the same time as at first, and the aperture is again unsoldered for a moment to let out the expanded vapour, &c. Once more they are returned to the bath, and after a like exposure they are taken out and allowed to cool. After which they are painted and tested in the hot cham-

ber in the usual manner. By this means the air is expelled, or is deprived of its putrescent property.

Meat preserved in this manner will keep for a considerable time. At the Exhibition of 1851 vouchers were given for some of the samples that had been preserved for twenty-five years; and at the Exhibition of 1862 I examined specimens of food that had been kept for more than thirty years. To-night, through the kindness of Messrs. Crosse and Blackwell, I am able to show you a specimen of preserved mutton which has been in the case forty-four years, and you will perceive that it is in excellent condition. It formed part of the stores supplied by Messrs. Donkin and Gamble in 1824 to his Majesty's exploring ship *Fury*, which was wrecked in Prince Regent's Inlet in 1825, when the cases were landed with the other stores, and left upon the beach. Eight years afterwards (in August, 1833), they were found by Sir John Ross in the same condition as they were left; and he wrote to Mr. Gamble at the end of that year, saying, "That the provisions were still in a perfect state of preservation, although annually exposed to a temperature of 92 deg. below and 80 deg. above zero." Some of the cases were left untouched by Sir John Ross; and after a further interval of sixteen years, the place was visited by a party from H.M.S. *Investigator*, when, according to a letter from the captain, Sir James Ross, "the provisions were still in excellent condition, after having lain upon the beach, exposed to the action of the sun, and all kinds of weather, for a period of nearly a quarter of a century." Messrs. Crosse and Blackwell have placed the original letters in my hands for perusal, and they show, beyond all doubt, that meat preserved in this manner will keep good for nearly half a century—in fact, the case of boiled mutton now before you has been preserved for forty-four years. There can be no question, therefore, as to the success of the process; and hence it is largely practised, not only in

this country, but also in our colonies, where food is abundant. In this way preserved salmon and lobsters are sent to us from Newfoundland, turtle from Jamaica, beef and mutton from Canada, and the dainty tail of the kangaroo from Australia. The trade, in fact, in preserved meats is fast acquiring enormous proportions. The Melbourne Company, for example, slaughtered in the six months ending March, 1871, about 85,000 sheep and 3,500 oxen; and the Victoria Company killed about 1,000 sheep a week, and sent over 240,000 tins. Besides which the Ramornie Company, as well as Mr. Tooth, sent over large quantities of preserved meat in tins. We are also getting it from New Zealand, through the enterprise of a Scotch Company. As an illustration of the rapid development of this branch of industry, it may be stated that in 1866 the value of tinned meats from Australia was only £320, whereas in 1870 it was £204,000, and in 1871 it exceeded half a million sterling. There are, however, two serious objections to the process, namely; the meat is nearly always over-cooked, and the cases are likely to buckle and crack from the constant pressure of the atmosphere—there being a vacuum within them. The over-cooking arises from a desire to ensure the complete exclusion of atmospheric air by the steam. Mr. Nasmyth, however, proposed in his patent of 1855, that a little alcohol should be mixed with the water, so that the boiling-point may be reduced; while Mr. McCall, taking advantage of the absorbent action of sulphite of soda on oxygen, recommended a less prolonged boiling, and the use of a little of this salt. The salt is contained in a small capsule, fixed by means of soft solder to the inner surface of the cover of the case. When the food is about two-thirds cooked, and steam is freely escaping, the hole in the lid is stopped with a very hot iron, which melts the soft solder of the capsule within, and so sets free the little pellet of sulphite of soda, which speedily absorbs the trace of oxygen left in the case. Mr. Richard Jones proposes to

exhaust the air from the tins, so that the boiling may be conducted at a lower temperature and for a shorter time. The tins containing the raw meat, &c., are connected, by means of a tube in the cover, with a vacuum chamber—the vacuum being produced by an air pump or by means of condensed steam. They are then placed in cold water, which is gradually raised to the boiling point; or they are placed in a chloride of calcium bath, and slowly raised to 270° Fahrenheit—the air being drawn out by the exhausting apparatus during the early part of the process. The time required to cook and preserve a duck in this manner is about two hours, and the result is said to be more satisfactory than that of the older processes.

The other difficulty, namely, the cracking of the case from atmospheric pressure, is obviated, as I have already explained, by the introduction of inert gases, as carbonic acid, nitrogen, &c., with a little sulphurous acid; and these have been the subject of many patents, as that of Currie (1828), Leignette (1836), Ryan (1846), Nasmyth (1855), and others.

(e). The last method of any importance for excluding atmospheric air from food, is *by coating it with some impervious material*. This plan, as I have already stated, was first suggested by the late Mr. Robert Warington, who, in March, 1846, obtained a patent for the use of "common glue, gelatine, or concentrated meat-gravies; or thin cream of plaster-of-Paris, which, when set hard, was to be saturated with melted suet, wax, stearine, &c." "The things were then to be wrapped in water-proof cloth; or covered with caoutchouc or gutta-percha; or coated with a varnish of these substances; or kept submerged in glycerine, treacle, elaines, oils, or other such matter not liable to oxidation." Nine years after this, in January, 1855, a patent was obtained by Messrs. Delabarre and Bonnet, for preserving meat, bread, eggs, vegetables, or pastry, by coating them with a varnish made from the flesh and bones of animals, by boiling

them, and obtaining a rich syrup. This, when clarified, was used to cover the parboiled meat or vegetables. In the month of February in the same year, a like patent was granted to Mr. Hartnall, for a process of preserving animal and vegetable substances by immersing them in baths, consisting of gelatine and treacle dissolved together in certain proportions; then drying, re-dipping, and covering with charcoal powder. Later still, in the same year (1855), Mr. Brooman patented the use of albumen and molasses, as a coating for meat, after the meat had been partially dried, and then suspended in an air-tight vessel charged with sulphurous acid. Lastly, in the month of December of the same year, Messrs. Bouëtt and Douein obtained provisional protection for the use of collodion, either alone or mixed with other suitable substance.

But the best example of this method of preserving meat is the process of Dr. Redwood, whereby the meat is first covered with paraffin, and then with a flexible coating of gelatine, mixed with glycerine or treacle. The joints are dipped into a bath of paraffin, having a temperature of from 240° to 250° F., and are kept therein until the surface moisture is evaporated. They are then transferred to a colder bath of paraffin, from which they receive two or three coatings, prior to their being covered with the last flexible covering of gelatine, &c. When the meat is required for use, the paraffin is easily removed from it by plunging it into boiling water, which dissolves the flexible coating and melts the paraffin. The paraffin floats upon the water, and, when cold, may be collected for future use.

Eggs may be preserved by covering them with a little oil or butter, or, as M. Martin proposes, with a thin coating of collodion dissolved in ether; but the most common method of preserving them is by putting them, when quite fresh, into milk of lime, made from recently burnt lime, rejecting those which do not readily sink in

the lime-water, or which are cracked. The preservative action is no doubt due to the formation of carbonate of lime within the pores of the shell, whereby the exclusion of atmospheric oxygen is secured. In illustration of the antiseptic power of lime, a writer in the *Journal de Pharmacie* says that some time ago, when a sacristy in the neighbourhood of *Lago Maggiore* was pulled down, eggs quite fresh were found embedded in the mortar, which had, perhaps, existed for three hundred years.

The common methods of preserving foods by forcing them into skins, as in the case of German sausages, lard, &c., is of very ancient date; although a patent was granted to Mr. Palmer, in 1846, for the preservation of the fat of beef, mutton, veal, or lamb, by melting them when fresh, then straining, and packing in bladders.

3rd. *The preservation of food by cold* is a well-known process, for every one is acquainted with the fact that meat will keep for a long time in the winter season without deterioration; but the extent to which this preservative power may be carried is not so well known. Animals, we are told, have been found in a perfect state of preservation in the frozen earth of the Arctic regions, where they must have been buried for centuries. Last year, indeed, a communication was made to the Royal Society, by Dr. Carl von Bear, of the fact that the entire body of a mammoth was found in the frozen soil of Arctic Siberia. How long it had been so preserved it is hard to conjecture, but it must have been there for ages. Another good example of the preservative power of cold was observed in Switzerland in the autumn of 1861, when the mangled bodies of three Chamounix guides were found at the lower part of the Glacier de Boissons. The flesh of the bodies was perfectly preserved, notwithstanding that 41 years had elapsed since the unfortunate men were killed. They were carried away by an avalanche from the grand plateau of Mont Blanc, in the month of August, 1820, while attempting

to ascend the mountain with Dr. Hamell ; and no trace of them was discovered until the corresponding month of 1861, when, by the slow descent of the mountain ice, their remains were brought to the lower glacier. So well is this preservative power of cold known to the inhabitants of Russia, Canada, and other northern climates, that it is a common practice to slaughter fat animals on the approach of winter, when fodder is getting scarce, and to preserve their carcasses by burying them in the ice or frozen earth ; and they are thus kept from the middle of November to the early part of May. We also have a practice of packing salmon in ice ; and we receive game and poultry from America, and send the like to India in boxes surrounded with ice. The application of this method of preserving food is almost without limit, for not only can we obtain a stock of ice for such a purpose in the winter season, but it may be brought to us at any time from the colder regions of Northern Europe ; in fact, the finest Norwegian block-ice can be obtained at the London docks in the height of summer for about twenty shillings a ton. Artificially made ice, as hard and as clear as that from Wenham Lake, may be obtained at a still lower price ; for there is a machine invented by Mr. James Harrison, of Australia, and made in this country by Messrs. Siebé brothers, of Lambeth, which is said to be capable of producing 8,000 lbs. of ice a day, at a cost, including all expenses, and with a good margin for profit, of 10s. a ton. Other machines have been constructed to produce it at a still lower price : thus, the machine of M. Tellier, which owes its action to the cold generated by the quick evaporation of liquid ammonia from compressed ammoniacal gas, will, it is said, make a hundred tons of ice a day at a cost of from 4s. to 5s. a ton—the ammonia being used over and over again in alternating cylinders ; and the apparatus of M. Mignot, of Paris, which is dependent for its action on the cold produced by the expansion of

compressed air (the pressure being about 60 lbs. upon the square inch), will yield from 40 to 50 tons of ice a day, at a cost of from 3s. to 4s. a ton at the utmost. So important, indeed, is the question of producing ice by mechanical means, that it was the subject of remark by Mr. Siemens, at the meeting of the British Association at Exeter in 1869, when, as President of the Section of Mechanical Science, he alluded to it in his inaugural address; saying that a machine had been constructed which could produce 9 lbs. of ice, or its equivalent in cold, for every pound of coal consumed. This is at the rate of 2s. 6d. per ton. How easy, therefore, it is to resort to the use of ice in the summer months for the preservation of food! Dealers might provide themselves with close rooms or cellars containing ice for the storage of perishable food; and we ourselves might use ice-boxes to any extent in our households. It might interest you to know that the first patent for the preservation of food in this manner was granted to John Lings in 1845.

On the other hand, a temperature of from 200° to 212° of Fahrenheit will also arrest putrefaction; and joints of meat may be preserved for a time by dipping them occasionally in boiling water.

The 4th and last method of preserving food is *by the use of chemical agents, called antiseptics*, which act by destroying infusorial and fungoid life, and by forming compounds which are not prone to decay. Foremost of these is *common salt*, which has been used from the earliest time; but unless it is carefully applied, it is not a good agent for the preservation of meat, as it extracts the soluble constituents of it, and makes it hard and indigestible: the brine, in fact, always contains albumen, as well as organic acids, alkaloids, and extractive matters of meat. To this extent, therefore, the meat is deprived of its stimulating and nutritive constituents. At one time, when the process was much more carelessly performed than at present, the loss of these important con-

stituents was often a cause of deranged nutrition and of cachectic diseases. This was the case with our sailors, when, on long voyages, they were obliged to feed on the hard salt junk of the navy; and even now among the Norwegians, who eat large quantities of salt meat and salt fish, scurvy and leprosy are common disorders. The process, however, is much better managed at the present time than formerly, and, considering how easily and how cheaply it is applied, it is not surprising that it is almost universally practised. In some parts of England and Wales, it is the custom of the better classes of agricultural labourers to fatten a pig during the summer, and kill it and salt it for the winter. In Scotland, also, it was, until recently, the practice in many agricultural districts to lay in a store of salt beef for the winter, by killing and salting a bullock or cow, called the *Mairt*, because it was slaughtered about the time of Martinmas. Hams and tongues are treated in like manner; and so are fish, when they are plentiful, among the inhabitants of our coasts. As far back as 1800 a patent was granted to Mr. Benjamin Batley, for curing and preserving herrings and sprats by salting them; and it would seem that his process was very successful, for in the following year he obtained a patent for the like treatment of other fish. The dainty *caviare* of the Russian is nothing but the salted roe of the sturgeon. Even vegetables may be preserved in salt and water, as in the case of olives; and almost all our vegetable sauces, as mushroom, tomata, Worcester, &c., are the juices of vegetables treated with salt.

Other saline substances, as *saltpetre*, *acetate of ammonia*, *sulphite of potash*, or *soda*, *muriate of ammonia*, &c., are also good preservative agents, and are the subjects of several patents. Here is a specimen of meat preserved by wetting it with a solution of one part of acetate of ammonia and nine of water; and here another, which has been similarly treated with a weak solution of

sulphite of soda. Bisulphite of lime is also a good preserving agent. It was tried in the summer of 1867 on eight sides of veal in Newgate market, with great success. It is only necessary to brush the solution over the surface of the fresh meat, and when dry it will leave the meat in such a state as to resist decay. In M. George's process, which is in use in La Plata, the meat is partially dried, and then steeped in successive waters containing hydrochloric acid and sulphite of soda. Instead of covering the meat with the solution, it may be injected with it, as in the patents of Long (1834), Horsley (1847), Murdoch (1851), and others.

After meat or fish is salted, it is frequently *dried* and *smoked* by exposing it in close chambers to the vapours of smouldering peat, wood, straw, &c., and in this manner it becomes impregnated with the dark brown empyreumatic oil of the burning wood. The chief agent concerned in the preservation of food thus treated is the *creosote* of the empyreumatic oil of the smoke, and this it is which gives the food a smoky flavour. A like effect may be produced by dissolving the creosote of wood-tar in vinegar, and brushing it over the salted joint. The creosote of coal-tar (*carbolic acid*) is also a powerful anti-septic, but its flavour is not agreeable, and therefore it is not much used in the preservation of food; although M. Boudet proposes to use it dissolved in water to the extent of from one part to five parts of carbolic acid in a thousand parts of water. The meat is placed in these solutions and kept in barrels or air-tight tins. The meat, he says, is not only well preserved, but it does not acquire an unpleasant flavour. Crude carbolic acid is extensively employed, in the form of coal-tar, dead oil, or creosote, in the preservation of wood, canvas, &c.; and the perfection of purity to which it is now brought by Dr. Crace Calvert and other manufacturers, encourages its use in medicine and surgery, if not in dietetics.

Spirits of wine and vinegar are other preservative

agents which owe their antiseptic power to their destructive action on infusorial life, and to their combining with the albuminous constituents of food. Cherry brandy and pickles are good examples of this; and so are the wines and vinegars of chilies, tarragan, and shallot, which are used for flavouring purposes.

Lastly, I may state that the fumes of burning sulphur (*sulphurous acid*) are very powerfully antiseptic; and many patents have been taken out for their employment in the preservation of food. In the spring of 1854, Laury obtained a patent for it, the gas being introduced into the vessel containing the substance to be preserved. Later in the same year, Bellford received provisional protection for the use of sulphurous acid with about one-hundredth of its volume of hydrochloric acid—the object being to prevent the sulphurous acid combining with the alkaline salts of the meat, and so giving it an unpleasant taste. The acids were to be used in solution, and the meat immersed in it for twenty-four hours. In the following year (1855) there were three patents—those of Brooman, Demait, and Hands, for the use of the acid in a gaseous form; and in the specification of Demait it was directed that the substance should be preserved by hanging it up in a chamber, and exposing it for a time to the action of the gas. Professor Gamgee has revived this process in a recent patent, with certain modifications. He recommends, for example, that the animal should be made to inhale carbonic oxide gas and when it is nearly insensible, it should be bled in the usual way. After the carcass is dressed, it is to be suspended in an air-tight chamber, which is to be exhausted of air, and then filled with carbonic oxide gas, to which a little sulphurous acid has been added. It is to remain exposed to these gases for twenty-four or even forty-eight hours, and is then to be hung up in dry air, after which it is said that the carcass will keep for many months, without perceptible change in taste or appear-

ance. The process has been tested by killing meat in London, and sending it to New York; and after the lapse of from four to five months, the meat has been pronounced good by a practical butcher. I am very much inclined to think that the real preservative agent is the sulphurous acid, and that the highly poisonous carbonic oxide gas might be advantageously excluded from the chamber.

And now, in leaving this part of the subject, I cannot refrain from saying that the history of these patents for the preservation of food affords very striking instances of the necessity for an amendment of our patent laws; for not only is there a frequent absence of all scientific principles in the construction of the patents, but in many cases there is also a total disregard, or else profound ignorance of what has already been done by others in the matter. Repetitions, therefore, occur again and again of the same process, nearly always imperfectly specified; and, on the other hand, the most ridiculous propositions often assume an importance, as if for no other object than that of obstructing invention. Out of the 121 patents for the preservation of food which I have had an opportunity of examining, there are hardly a dozen that can be regarded as either useful to the community or profitable to the patentee.

UNSOUND FOOD.

I come now to the last division of our subject—namely, that which relates to the sale and use of *unsound* and *adulterated food*; and perhaps the most important of this kind of food is *bad meat*—that is, meat which is unwholesome on account of putridity or disease. Food of this description has always been a subject of legal prohibition. Among the Jews the prohibition dates from the time of Moses, who is supposed to have received from the Lord, during his sojourn upon Mount Sinai, certain oral commandments respecting the slaugh-

tering of animals for food, and the examination of their bodies for disease. There is no account of these commandments in the written law, but they were evidently communicated to the people of Israel by Moses, for he says, "Thou shalt kill of thy herd, and of thy flock, which the Lord hath given thee, *as I have commanded thee*" (Deut., chap. xii., v. 21). It is presumed, therefore, that these instructions were very specific, and have been practised by the Jews from that time until now. The Hebrew law is that no flesh shall be eaten, except of animals that have been killed and searched, or examined, by the officer (*bodek*) appointed for that purpose; and the most precise rules are laid down for his guidance in these matters. In fact, he is bound by very solemn obligations to declare of every animal that he kills, whether the flesh is proper to be eaten (*caser*), or is unfit for food, by reason of its being diseased or torn (*trefa*). This expression appears to have been derived from an ordinance of Moses, that no flesh should be eaten that is torn in the field (Exodus, chap. xii., v. 31); the word torn (*trefa* or *terefa*) being supposed, according to the traditions of Hebrew sages, to apply not only to animals torn in the chase, or by wild beasts, or by the bungling act of the butcher, but also to those affected with any disease that would shorten their lives; and as it is thought that such disease is always indicated by the condition of the lungs, the utmost care is taken by the searcher or *bodek* in the examination of these organs. His rules or instructions for this purpose are very strict; but generally it may be said that he condemns as unlawful, or unfit for food, the flesh of all animals in which the lungs present the following appearances:—Certain deficiencies, excess, or displacement of the lobes; adhesions, or false membranes; tubercles, or abscess containing matter or opaque water; discolourations which do not disappear when the lungs are inflated; ulcers, holes, and abrasions letting air through them; consolidations that

are impervious to air, and rottenness of tissue. Many of these are, no doubt, unimportant evidences of disease, and, therefore, although the flesh of such animals is rejected by the Jew, it is freely consumed by the Christian. The Jews, indeed, make a sort of bargain with the unorthodox butcher to take only such animals, when slaughtered by their officer, the bodek, as he considers lawful, and the rest are sold to the public. I dare say this has been the practice at all times, for there are occasional references to it in our legal and domestic records. In *Liber albus*, for example, there is a memorandum to the effect that on the 24th of June, 1274, certain discreet men of the city were summoned before the king's council, to answer the question as to what was done with the unclean flesh of the Jews, and whether it was lawful for Christians to buy and eat the same. Their answer was, that if any citizen bought such flesh of a Jew, he would be expelled from the city, and if convicted by the sheriff he would not only forfeit such flesh, which would be given to lepers or dogs, but he would also be heavily fined. To which the council replied that they commanded them, in the King's name, to have the custom strictly observed. I fear, however, from the legal records of *Liber albus*, that less attention was paid in those days to the sale of diseased meat than to that of putrid meat; for, on examining the accounts of the citizens made and rendered in divers courts of the King, I find that while "judgment of pillory" is recorded in twenty-one cases for selling putrid meat, poultry, or fish, there is not a single instance of a like punishment for selling the unclean meat of the Jews.

In ancient Rome there were overseers appointed to examine the meat in the public markets before it was sold, and butchers were often fined for neglecting the law in this respect. Mr. Charles Reed has given us an example of this from the *Acta Diurna*, or Roman Gazette, of 585 years after the building of Rome, which,

when translated, runs thus:—A. U. C. DLXXXV. Fourth of the kalends of April. The fasces, with Licinius, the consul, and Lertinus, ædile, fined the butchers for selling meat which had not been inspected by the overseers of the markets. The fine is to be employed towards building a chapel in the temple of the goddess Tellus.

In modern times, also, severe regulations have been made in all the States of Europe for the government of this matter, and in many cases particular instructions are given as to the kind of disease which renders meat unfit for human food—it being the practice to examine the animal while alive, and its carcass when dead. This examination is entrusted to properly-qualified officers, who are bound to condemn diseased and putrid meat, as well as the flesh of animals that have died otherwise than by the hand of the butcher; and no meat can be sold until it has undergone such an examination. In this country, however, although there are laws prohibiting the sale of unsound and unwholesome food, yet there is no provision for the systematic inspection of meat, even when it has reached the public shambles. All that the law declares is, that the local authority may, if it pleases, appoint an officer for that purpose; and as the appointment would cost money, and is not compulsory, it is rarely made. Practically, therefore, there is, except in a few places, an almost unchecked traffic in diseased and unwholesome meat; and the worst descriptions of it are generally sold to the poor at night.

Our forefathers made stringent rules to prevent this; for, among other things, they ordained “that butchers shall close their shops before candle-light, and shall not sell flesh meat by light of candle.”—(*Liber albus.*)

Within the city of London the inspection is performed as carefully as it can be, but, nevertheless, amidst the confusion of business in the early hours of morning, a

great deal of unsound meat escapes the notice of the inspectors. In fact, if it were not for the assistance afforded to them by the salesmen of the markets, it would be absolutely impossible to check, to any large extent, the sale of unwholesome meat; for, in the four markets of the city—Newgate, Aldgate, Leadenhall, and the New Meat Market—as much as 400 tons of meat are sold daily. It is brought from all parts of Great Britain and Ireland, as well as from Belgium, Holland, and France, and even from the ports of the Baltic. Of this a large quantity is diseased, coming chiefly from our own country towns, where it is a common practice to forward to London everything that is unsaleable at home. I cannot say what is the actual proportion of bad meat to good, but we seize and condemn about two tons a week, and this is in the proportion of one part to 750. Last year the amount of meat condemned as unfit for food was nearly 129 tons, and in the preceding year it was more than 152 tons. In fact, during the seven years which have expired since the inspectors were appointed under my recommendation, we have seized and destroyed 1,567,810 lbs., or just 700 tons of meat as unfit for human food. Of this quantity, 805,653 lbs. were diseased, 568,375 lbs. were putrid, and 193,782 lbs. were from animals that had not been slaughtered, but had died from accident or disease. It consisted of 6,640 sheep and lambs, 1,025 calves, 2,896 pigs, 9,104 quarters of beef, and 21,976 joints of meat; besides which, there were also seized and condemned in the city markets, on account of putridity, 19,040 head of game and poultry, 207 quarters of venison, and above seven millions of fish, together with thousands of bushels of sprats, whelks, shrimps, periwinkles, &c.

It is to be regretted that in the various Acts of Parliament which relate to the condemnation of unsound meat, there are no special rules for the guidance of the officers appointed to investigate this matter—there being

only a very loosely-worded general provision to the effect that the medical officer of health, or the inspector of slaughter-houses, or the inspector of nuisances, may, at all reasonable times, inspect and examine any animal, carcass, meat, poultry, game, flesh, fish, &c., exposed for sale, or deposited in any place for the purpose of sale, or in preparation for sale, or intended for the food of man; and in case it appears to the medical officer of health, or the inspector, to be diseased, or unsound, or unwholesome, or unfit for the food of man, it shall be lawful for him to seize the same, and for a justice to order it to be destroyed. In this regulation there is no particular reference to the kind of food which is unwholesome, or to the circumstances which render it so, and, therefore, much is left to the discretion of the officer who examines it. In the city of London the practice is to condemn the flesh of animals infected with certain parasites, as measles, flukes, &c.; and of animals suffering from fever or acute inflammatory affections, as rinderpest, pleuro-pneumonia, and the fever of parturition, and of animals emaciated by lingering disease; and those which have died from accident or from natural causes; as well as all meat tainted with physic, or in a high state of putrefaction. A little practice is required to distinguish meat of this description, but, generally, it may be said that good meat has the following characters:—

1st. It is neither of a pale pink colour nor of a deep purple tint, for the former is a sign of disease, and the latter indicates that the animal has not been slaughtered, but has died with the blood in it, or has suffered from acute fever.

2nd. It has a marbled appearance from the ramifications of little veins of fat among the muscles.

3rd. It should be firm and elastic to the touch, and should scarcely moisten the fingers—bad meat being wet, and sodden, and flabby, with the fat looking like jelly or wet parchment.

4th. It should have little or no odour, and the odour should not be disagreeable, for diseased meat has a sickly cadaverous smell, and sometimes a smell of physic. This is very discoverable when the meat is chopped up and drenched with warm water.

5th. It should not run to water or become very wet on standing for a day or so, but should, on the contrary, dry upon the surface.

6th. When dried at a temperature of 212° or thereabout, it should not lose more than from 70 to 74 per cent. of its weight, whereas bad meat will often lose as much as 80 per cent.

7th. It should not shrink or waste much in cooking.

Other properties of a more refined character will also serve for the recognition of bad meat, as that the juice of the flesh is alkaline or neutral to test-paper, instead of being distinctly acid; and the muscular fibre, when examined under the microscope, is found to be sodden and ill-defined.

The signs of parasitic diseases are not always observable without careful examination. In the case of the fluke in the livers of sheep, and of measles in pork, and of hydatids in the brain or liver, the nature of the disease is at once discoverable, but it is not so with the smaller measles or cysticerci of beef and veal, and it is still less so with the trichina of pork—the microscope being required to reveal their presence.

And here, perhaps, we may ask, *what are the effects of diseased or putrid meat on the human system?* The question is undoubtedly very difficult to answer, for while, on the one hand, we have abundant evidence that such meat may frequently be eaten with impunity, so on the other we have many remarkable instances of injury occasioned by it. In Scotland there is a disease called *braxy*, which attacks the sheep and lambs in spring and early summer. It is the cause of at least half the deaths in the flock during the year. The disease kills the animals

very quickly, by causing stagnation of blood in the most important vital organs; and as the carcass is the perquisite of the herdsman, he almost invariably eats it—taking the precaution to remove the offal, and to cut away the darker portions of the flesh where the blood has stagnated. He also salts it before he uses it; and if questioned on the subject he will tell you that the meat is not unwholesome. Every now and then, however, when perhaps the diseased parts have not been entirely removed, or when the salting has not been sufficiently prolonged, or the cooking has not been thoroughly effected, the most serious consequences result from it, insomuch that many medical practitioners, who are acquainted with the habits of the Scotch shepherds in this respect, and have seen the mischief occasioned by the meat, declare that braxy mutton is a highly dangerous food for man. Again, it is a common practice with farm labourers to eat the flesh of sheep affected with staggers, which is a parasitic disease of the brain, and even of animals dying from acute inflammatory diseases. There is a story told on the authority of Dr. Brücke, the professor of physiology in Vienna, that some years ago, when the *steppemurraïn* was prevalent in Bohemia, and the infected animals were killed and buried by order of the government, the poor people dug up the carcasses of the dead bullocks, and cooked them, and ate them, without injury. During the siege of Paris, also, when there was but little choice of animal food, no one paid the least attention to the condition of the meat as regards disease; and, as far as observation went, no ill effects resulted from it; in fact, M. Decroix, who has published his personal experience of the matter, states that the flesh of horses affected with farcie or glanders was eaten with impunity; and that if there had been any real danger from the use of diseased meat all the population would have suffered. His notion is that the morbid action of diseased meat is overrated, and that

when it exists it is destroyed by cooking. This, he says, he has himself proved by eating the diseased meat which had been seized in the abattoirs, and sent to the Jardin des Plantes for the use of the wild carnivorous animals which are kept there. Again, in this country, during the prevalence of *rinderpest* in 1863, enormous quantities of meat from the diseased animals were sent to market, and sold and eaten. The same has been the case with the carcasses of animals suffering acute *pleuro-pneumonia*; and if, as Professor Gamgee says, the practice of making salvage out of diseased animals is so common, that at least one-fifth of the meat which is sold in the public markets is diseased, we may well ask, in the words of Mr. Simon, how it is that some sort of pestilence is not bearing witness to the fact?—How it is that cattle having all the foulness of fever in their blood, or having local sores and infiltrations, that yield one of the deadliest of inoculable morbid poisons, or having their flesh thronged with larval parasites, do not, when slaughtered and eaten, produce a general poisoning? Parent Du Chatelet has commented in very forcible language on the apparent immunity from disease even when the most foul and loathsome of animal foods are eaten. But is it not possible that the danger is averted by the operation of cooking? Not that the human stomach has not also a wonderful protective power in its own natural functions; for the deadly poison of the cobra or the rattle-snake may be swallowed with impunity. It is possible, however, that these safeguards may fail us occasionally; and then it is, perhaps, that the most serious consequences arise. I have often had to investigate cases of mysterious disease which had undoubtedly been caused by unsound meat. One of these, of more than ordinary interest, occurred in the month of November, 1860. The history of it is this: a fore-quarter of cow-beef was purchased in Newgate Market by a sausage-maker who lived at Kingsland, and who immediately converted it

into sausage-meat. Sixty-six persons were known to have eaten of that meat, and sixty-four of them were attacked with sickness, diarrhœa, and great prostration of vital powers. One of them died; and at the request of the coroner, I made a searching inquiry into the matter, from which I ascertained that the meat was diseased, and that it, and it alone, had been the cause of all the mischief. Dr. Livingstone tells us that when the flesh of animals affected with pleuro-pneumonia is eaten in South Africa, by either natives or Europeans, it invariably produces malignant carbuncle. He states, indeed, that the effects of the poison were often experienced by the missionaries who had eaten the meat, even when the presence of the disease was scarcely perceptible; and in many cases when the Backwains persisted in devouring the flesh of such diseased animals, death was the consequence. The virus, he says, is neither destroyed by boiling nor by roasting, and of this fact he had innumerable instances. Now, it is a remarkable circumstance that ever since the importation of this disease (pleuro-pneumonia) into England from Holland in 1842, the annual number of deaths from carbuncle, phlegmon, and boils has been gradually increasing. In the five years preceding that time the mortality in England from carbuncle was scarcely 1 in 10,000 of the deaths; from 1842 to 1846 there is no record of the disease; but in the next five years, from 1846 to 1851, the mortality rose to 2·6 per 10,000 of the deaths; and in the next five years it amounted to 6·2 per 10,000; and in the succeeding five years to 5·4. In the case of phlegmons, the increase in the mortality is still more remarkable, for it rose from an average of 2·5 per 10,000 of the deaths in the five years preceding the importation of the disease, to 81 per 10,000 in the ten years from 1847 to 1856. The Registrar-General of Scotland has directed public attention to this fact, saying that the deaths from carbuncle are on the in-

crease, and that the mortality from it has been getting larger and larger ever since the lung disease of cattle was imported into Scotland. This accords with the experience of medical practice; but as it is very difficult to trace the immediate connection of bad food with subsequent disease, there being so many circumstances to weaken the connection, it is not surprising that differences of opinion should exist as to the morbid effects of unsound meat; nothing, in short, but an experimental inquiry into the subject, as has already been done in Germany in the case of parasitic diseases, will bring the question to rest; and I see no reason why such an investigation should not be made on the persons of those who send diseased meat to the public markets for sale; for, as the common defence of their conduct is, that the meat is good for food, they cannot surely object to the penalty of being made to eat it. Here, for example, is a specimen of pork covered with pustules of small-pox; it was seized by one of the city officers on the road to a notorious sausage-maker, and it may, notwithstanding its disgusting appearance, be good and wholesome food; then why not put the question to the proof by making the vendor of it eat it? In the year 1862, when small-pox was prevalent among the sheep in several parts of England, it was a common practice to send the carcasses of diseased animals to the London markets for sale as human food. Later still, in 1863, there was an epidemic of what seemed to be scarlet fever among the pigs of this metropolis, and their carcasses, with all the bright crimson look of the disease, were invariably sent to market for sale as food. Since then the London pigs have been the subject of a virulent spotted fever, of the nature of typhus, and these also have been killed in the last stage of the disease, and sold for food. Abundant illustrations of this kind are constantly coming under my notice; and I feel that the question of the fitness of such meat for food is in

such an unsettled state that my action in the matter is often very uncertain, and I should like to have the question experimentally determined; for, as it now stands, we are either condemning large quantities of meat which may be eaten with safety, and are, therefore, confiscating property, and lessening the supply of food, or we are permitting unwholesome meat to pass almost unchallenged in the public markets.

As regards the injurious quality of meat infected with parasitic disease there can, however, be no question; and perhaps, of all such affections, the most terrible is the *trichina* of pork. Fortunately, it is a rare affection in this country, although it is often common in Germany. The pork infected with the worm is generally darker than usual, on account of the irritating or inflammatory action of the creature lodged in the muscles; and when the parasite is encysted, the meat presents a speckled appearance—the minute white cysts containing the worm being just visible to the naked eye. Here are specimens of it in both its encysted and non-encysted conditions; and this diagram represents the appearance of the worm when it is examined under the microscope. It is, as you see, a minute thread-like worm, about the thirtieth of an inch in length, coiled up in a spiral form; hence its name, *trichina spiralis*. It is generally found in the human subject in an encysted state; when it has passed beyond its dangerous condition, and has become harmless. In most cases, when thus discovered, there is no record of its action, and therefore it was once thought to be an innocent visitor; but we now know that while it was free—that is, before nature had barricaded it up in the little cyst, its presence was the cause of frightful disorder—killing about 50 per cent. of its victims in terrible agony. In Germany there have been frequent outbreaks of the disease, which, for a time, baffled the skill of the most experienced physicians; in fact, we hardly know how long or how often the disease has

attacked the pork-feeding population of Europe, for its actual nature was unknown until the year 1860, when Dr. Zencker, of Dresden, discovered the pathology of the disease. Since then there have been several visitations of it, as at Plauen, in Saxony, in 1862; at Hettstadt, near Eisleben, in 1863; and at Hedersleben, near Magdeburg, in Prussian Saxony, in 1866. In all these cases the same symptoms, or nearly the same, were observed; there was sometimes immediate disturbance of the digestive functions, but more commonly a day or two elapsed before any particular symptom was noticed, and then there was a feeling of lassitude, with a loss of appetite, and pains in the head and back. Then followed a serious disturbance of the alimentary canal, with vomiting and diarrhœa. This lasted for a day or two; and by the end of a week after the worm had been eaten fever had set in, which became more and more severe; and by that time the young worms, which had been hatched in the body, had migrated to the distant muscles, causing the most excruciating pains, so that the patient, fearing to move his inflamed muscles, would lie motionless upon his back. If he did not die in this state of the disorder, nature came to the rescue, and imprisoned the creature by surrounding it with a fibrinous cyst, where it lives for years, being ready at any moment to acquire activity when it is swallowed and released from its cell. Indeed, the way in which it becomes dangerous is this—flesh infected with the parasite is eaten; and the cyst being quickly dissolved by the gastric juice, the creature is set free. Finding itself in the midst of nourishing food it rapidly grows, so that in two or three days it is three or four times its original size, and may be easily seen, like a bit of fine thread, with the naked eye. The worms are of different sexes, and they rapidly come to maturity—each female giving birth to from 300 to 500 minute thread-like worms, which immediately set out upon their travels, piercing the

walls of the intestines and migrating to distant parts of the body, where they produce the terrible mischief I have described. Although the pig is the animal which is most commonly infested by it, yet it has been found in the muscles of dogs, foxes, badgers, sheep, moles, hedgehogs, rats, mice, frogs, and most carnivorous birds, all of which must have been subjects of the disease, but none appear to suffer from it like man; even children are less affected by it, for they seem to sleep it away. Fortunately, there is an easy method of discovering its presence in animals, for the most certain seat of the creature is in the muscles of the eye; we have, therefore, only to examine these muscles with the microscope to declare whether the meat is infected or not; and, at the present time, the sausage-makers of Germany have the pork examined in this manner by experts before it is used for food.

Other parasitic creatures, as *measles* in pork, and the smaller *cysticerci* of beef and veal, are found as little sacs or bladders diffused through the lean of the meat—the *cysticercus* or *measle* of the pork being easily seen, for it is generally abundant in the meat, and is as large as a hemp-seed. Here are specimens of it in a fresh condition, which were seized in the city markets to-day, for there is no lack of such meat. The *cysticercus* of other animals is much smaller, and is more sparsely distributed; it therefore requires careful exploration to discover it. In both cases the sac contains a little creature with a sort of tuberculated head, crowned with a coronet of hooks, and having a bladder-like tail attached to it. Soon after it is swallowed, the enclosing sack is dissolved by the gastric juice, and the creature being liberated passes into the intestines, where it fixes itself by its little hooks, and quickly grows, joint after joint, into a tape-worm. In the case of the *cysticercus* of pork, it forms the variety of tape-worm called *tenia solium*; and in that of beef and veal it produces the *tenia mediocanellata*, which is the

most common variety in the human intestines. It is very frequently seen where raw, or nearly raw, meat is made use of, as in Abyssinia and in Russia, where children are allowed to suck a piece of raw beef, on the supposition that it has a strengthening property. Each segment of the worm, whether it be the *tenia solium* or *mediocanellata*, is an independent creature, containing myriads of ova; and when passed by the bowels it gets with the manure upon the land, especially where night soil or sewage is used, and is eaten by pigs, goats, oxen, and calves. The ova are hatched in the warm stomach of the animal, and, as in the case of the trichina, they pierce the walls of the intestine, and migrate to the muscular tissues of the body, where they become encysted, and form the little sacs or measles, which remain dormant for years, though they are ever ready to become tape-worms directly the meat containing them is eaten by man. In this manner these creatures are perpetuated, first as tape-worms with joints, in the intestines of man, and then as measles or larvæ in the muscles of some meat-producing animal, and then again as tape-worms. By a like process the *tenia echinococcus*, or little tape-worm of the dog, becomes the *hydatid* in man and other animals. In Iceland the dogs are very liable to this infection, and the cattle and sheep, as well as man, suffer from the hydatid of it. The subject has been well investigated by Dr. Leared, who has shown that the practice of giving the diseased offal of the slaughtered animals to dogs causes tape-worm, and the dogs drop the segments of the worm, filled with ova, upon the pastures, and into running water. By this means they enter the bodies of cattle and sheep, and even of man; and then, as in the last case, the ova quickly become developed; and the young hydatid or larval tape-worm, piercing the walls of the alimentary canal, migrates to distant parts of the body, and finding a suitable nidus for its growth, it slowly becomes a large bladder-like *hydatid*. In the case of sheep it often

selects the brain for its habitat, and produces the disease called *staggers*; in oxen it grows in the peritoneal cavity; and in man it haunts the liver, occasioning frightful disturbance of the system, and causing one-sixth of the total mortality of that country. Here are specimens of the disease from the human subject, for it is not uncommon in England, as well as in Iceland.

Again, there is another class of parasites, called *trematoda*, or *flukes*, which infest the livers and intestines of men and herbivorous animals. The most common of them is the *distoma hepaticum*, or *liver-fluke* of the sheep. In wet seasons the animal is so constantly infested with them, and suffers so much emaciation from them, that the disease is called the rot. You have before you infected livers which were seized in our public markets this very day, for there is no difficulty in obtaining specimens of them at almost any time. In fact, a few years ago (in 1863), when Professor Brown was lecturing on the liability of animals to disease from the present mode of feeding them, he stated that once, when he wanted some animals for dissection, and applied for them to a large butcher, he received back five or six sheep, which, though in a bad state of rot, were dressed for the market. He was told, moreover, by a certain individual not far from London, that within the space of six months he had killed no less than 750 of such sheep in a state of extreme disease, and he believed they were all sent to market and sold for food. What becomes, he said, of the hundreds and thousands of rotten sheep which we see in the fields? To bury them would require whole catacombs; the real catacombs are the intestinal canals of the human body.

The way in which the fluke disease is produced in sheep is curious. Ova are passed from the gall-bladder of infected animals into the intestines, and are voided with the excrement upon the land: finding a moist situation they are soon hatched into ciliated circular

embryos, which swim or move about, and ere long become attached to some mollusc, as a small snail or slug, when they change their condition, and acquire the form of a small bladder-like hydatid, called a cercaria-sac, which soon gives origin to a multitude of young tailed cercaria. These undergo a variety of transformations, and at last, under favourable circumstances, become pupas, which are buried in the body of the snail. In wet weather the infected snails crawl upon the grass, and are eaten by the sheep, and then the pupa speedily changes its condition and becomes a perfect fluke. When it is found in the body of man it has, perhaps, been drunk with water, or eaten with some aquatic plant, as watercress, &c.

Our safety against all of these intruders is to cook the meat thoroughly.

The flesh of animals that have been excited before death, as by over-driving, or by torture, has frequently proved unwholesome. A remarkable instance of this is quoted by Liebig, in his "Letters on Chemistry," where a family of five persons were made seriously ill by the flesh of a roebuck which had been caught in a snare, and had struggled violently before death.

It is, moreover, a curious fact, that meat may be poisonous from the nature of the food made use of by animals shortly before they are killed; and this, too, without any indication of disorder in the animals themselves. Hares which have fed upon the *Rhododendron chrysanthemum* are frequently unwholesome; the same is the case with pheasants in Pennsylvania and Philadelphia, which feed during the winter and spring on the buds of the laurel (*Calmia latifolia*); and I have known many instances of serious mischief from prairie birds, which are now largely imported into this country from America, and I attribute it to the food made use of by the bird. In certain districts of North America, especially on the Alleghany mountains, the flesh of all the cattle

is poisonous, and so also is the milk they yield, and the cheese which is made from it. In Australia, also, it is not uncommon for meat to acquire a poisonous property from the animals feeding on the lotus, the wild melon, and the wild cucumber of the country. Sometimes the animals, and especially sheep, are themselves affected by it, but the meat is always unwholesome, causing extreme prostration, with sickness, purging, and severe pains in the limbs. Oysters, mussels, lobsters, and crabs have frequently caused disturbance of the human system; and the probability is that in many cases they were made unwholesome by the food which they had eaten. A singular case is recorded in the medical journals of France in 1842, where a whole family at Toulouse were poisoned by a dish of snails, the animals having been gathered from a poisonous shrub (*Coriaria myrtifolia*); and it is not at all uncommon for honey to be unwholesome, on account of its having been collected by bees from poisonous plants. The honey of Trebizond, for example, has long been notorious for its deleterious properties; it poisoned the soldiers of Xenophon during the famous retreat of the ten thousand. Pliny, too, speaks of it; and to this day its intoxicating effect is frequently witnessed. It arises, no doubt, from the plants, chiefly from the *Asalea pontica*, from which the honey is gathered. Mr. Barton has given us a similar account of the poisonous quality of the honey gathered by bees from the savannahs of New Jersey, where the *calmia* and *azalea* are the principal flowering shrubs; and, as was the case with the followers of Xenophon, all who eat of the honey become intoxicated to a high degree; and even when made into *metheglin*, it poisons all who partake of it, causing dimness of sight, giddiness, and then delirium, with sometimes a fatal termination.

Occasionally we have examples of food which is in itself poisonous. This is so with many of the fish of tropical seas, and especially of the West Indies. Dr.

Burrows has given us a long list of them ; and it would seem that the yellow-billed sprat (the Sardine doré of the French, and *Clupea thryssa* of naturalists), the toad or bladder fish (*Aplodactylus punctatus* or *Tetraodon* of Cuvier), and the grey-snapper (*Coracinus fuscus major*) are the most venomous ; and that being eaten by larger fish, as the *Baracosta*, and various species of perch, as well as the conger-eel, the dolphin, the globe-fish, &c., it causes them to be poisonous also. The yellow-billed sprat is so virulent in its action on the human body that both Europeans and negroes have been known to expire with the fish in their mouths unswallowed ; and the toad or bladder-fish is scarcely less dangerous. Sir John Richardson has described the effects of it on two sailors, the boatswain's mate and purser's steward, of the Dutch brig of war, *Postilion*, while lying at anchor in St. Simon's Bay, at the Cape of Good Hope, in September, 1845. The men were warned that the fish was poisonous, but believing that the liver was wholesome, and rather a delicacy, they cooked it, and ate it directly after their twelve o'clock dinner. In ten minutes the boatswain's mate was so ill that he could not stand ; his face was flushed, his eyes glistened, his lips were swollen and rather blue, his forehead was covered with a cold perspiration, and his pulse was weak and fluttering. He was, however, quite conscious, and complained of pain and constriction of the throat, and he had a desire to vomit. In a few minutes more he became paralysed, his eyes were fixed, his breathing was laborious, his face was pale, though his lips were livid ; and in seventeen minutes he was dead. The other man exhibited the same symptoms, and died in twenty minutes. Sir John Richardson says the fish was not more than six or eight inches in length, and the liver of it, which they had eaten between them, could not have weighed more than half an ounce.

The symptoms occasioned by the poisonous fish of the

tropics are always of two kinds—there is either great irritation of the stomach and bowels, like cholera; or there is rapid prostration of the vital powers, and death by syncope or convulsions. These effects have been long known both to natives and Europeans, and were called by the Spanish colonists of tropical America, *Siquatera*. They are more frequently observed at certain seasons of the year than at others, and hence they are thought to be due to certain physiological changes in the body of the fish, or to the food which it has eaten. In some cases the roe, in others the liver, or the digestive organs, are the most poisonous parts of the fish; and in the case of the *Maletta venenosa*, which inhabits the Caribbean Sea, it is only poisonous when the sea is covered with a green monad, upon which the creature feeds. Happily for us, these dangers are confined to the tropics, although we sometimes suffer from a milder form of disturbance, as irritation of the skin and bowels, from eating unwholesome shell-fish.

Putrid meat is, perhaps, wasteful, rather than actually injurious; but there are plenty of cases in which it has caused disease. Foderé tells us that at the siege of Mantua, those who were shut up in the city, and were obliged to eat the half-putrid flesh of horses, suffered from gangrene and scurvy; and in Czant's history of Greenland there is an account of the death of thirty-two persons at a missionary station called Kangek, from a repast on the putrid brains of a walrus. Similar cases are recorded in all the books on legal medicine. Even game, when only sufficiently tainted to please the palate of the epicure, has caused severe diarrhœa in persons unaccustomed to it; but, as Dr. Christison observes, "the power of habit in reconciling the stomach to the digestion of decayed meat is inconceivable. Some epicures in civilised countries prefer a slight taint even in their beef and mutton; and there are tribes of savages still further advanced in the cultivation of this

department of gastronomy, who eat with impunity rancid oil, putrid blubber, and stinking offal." The French prefer meat, and even fish, when they partake strongly of the "*fumette*," which is highly relished; and the same is the case with the Esquimaux and the Hottentot. The Chinese, also, are fond of eggs that have passed into a high state of putrefaction, and they adopt a curious artifice to bring it about. They cover the eggs with a paste of tea-leaves, quicklime, sea-salt, and oak-ashes; and after keeping them in boxes packed in rice for three months, the eggs are ripe for the epicure. The yolk is green, the white is coagulated, and they emit a strong smell of sulphuretted hydrogen, which is greatly enjoyed. The Zulus of Natal, according to Dr. Colenso, are so fond of putrid meat that they call it *ubomi*, which literally means to be superlatively happy. But, as a rule, there is a natural abhorrence of tainted food, insomuch that with most persons the mere commencement of decay is sufficient to excite disgust; and rarely do we find, except among savages, that an entire meal is made of putrid flesh. A little game, or venison, or ripe cheese, at the end of a feast, with just a piquant touch of decay, is, perhaps, not objectionable; for it may, as Liebig supposes, promote digestion, by communicating its own quality of transformation to the rest of the food; but it is another thing to fill the stomach with putrid flesh, for if the corrective power of the gastric juice should fail, the effect of it might be serious. We have, indeed, abundant evidence of the terrible consequences of admitting putrid matter into the circulation, for they were once too common among those engaged in the dissection of the human body. In fact, the mere handling of decomposing animal matter for any time will often produce disease of the hands or other parts of the body with which it comes into contact. Our safety, perhaps, in using such food, is in the anti-septic power of good cooking; but this is not always an

easy affair ; for the tissues are generally so soft from decay, that they will hardly bear the common action of heat ; so that if they are boiled for any time, they fall to pieces ; and if they are roasted, they shrink up without forming that delicious crust of osmazome which is characteristic of good meat. Let them, however, be cooked as they may, they always require a nice adjustment of rather strong flavours to make them palatable ; and those who have dined in the cheap restaurants of Paris, or at the still worse table-d'hôte of a German watering place, will have experienced the art of the cook in this respect, in such dishes as *Turbot en vol-au-vent*, *Raie au beurre noir*, *Sole en matelotte normande*, and in the various forms of fish *au gratin* ; or game *ensalmis*.

But bad as this sort of tainted food is, it is nothing in comparison to the sausage poison, which is produced by a sort of modified putrefaction, to which the large sausages of Germany, and especially those of Wurtemberg are occasionally subject. According to an official return, there have been more than 400 cases of poisoning from these sausages in Wurtemberg alone during the last fifty years, and of these about 150 were fatal. The effects are generally observed in spring, and mostly in April, when the sausages become musty, and acquire a soft consistence in the interior. They have also a peculiarly nauseous and rather putrid taste, and are very acid to test-paper. If eaten in this condition, they produce dangerous effects in from twelve to twenty-four hours—the first symptoms being pain in the stomach, with vomiting and diarrhœa, and dryness of the nose and mouth ; then comes a feeling of profound depression, with coldness of the limbs, weakness and irregularity of the pulse, and frequent fainting. Fatal cases end with convulsions and oppressed breathing between the third and eighth day. The precise cause of these effects is still a mystery ; some have thought that rancid fatty

acids are produced during the decomposition of the meat; others, that in the process of drying and smoking acrid pyrogenous acids have been developed; others, that during the decay of the sausages, a poisonous organic alkaloid is generated. Liebig is of opinion that the effects are due to an animal ferment, which produces in the blood, by catalysis, a state of putridity analogous to its own, and that the molecular movements of the putrefactive change in the decaying meat are thus communicated to the living organism. M. Vanden Corput, who is one of the most recent investigators of the subject, attributes the morbid action of such meat to the presence of a minute fungus, of the nature of a sarcina, which he calls *Sarcina botulina*. This view is confirmed by the fact that there is always a peculiar mouldiness of the sausages; and the poisonous property is generally observed in April, when these cryptogamic organisms are most freely developed.

Similar effects have occasionally been produced by other kinds of animal food—as veal, bacon, ham, salt-beef, salt-fish, cheese, &c., and the food has usually been in a decayed and mouldy condition. It would be tedious if I were to detail, or even to enumerate the many cases recorded by medico-legal writers; but I may, perhaps, refer to a few of them. In 1839, there was a popular fête at Zurich, and about 600 persons partook of a repast of cold roast veal and ham. In a few hours most of the guests were suffering from pain in the stomach, with vomiting and diarrhœa; and before a week had elapsed, nearly all of them were seriously ill in bed. They complained of shivering, giddiness, headache, and burning fever. In a few cases there was delirium; and when the effects were fatal, there was extreme prostration of the vital powers. Careful inquiry was instituted into the matter, and the only discoverable cause of the mischief was incipient putrefaction and slight mouldiness of the meat. Dr. Geiseler relates an

instance where a family of eight persons were made ill by musty bacon ; and M. Ollivier has given an account of six persons who were poisoned by mutton in a state of modified decay—four of whom died from it within eight days. In Russia, where it is the practice to eat largely of salt fish in a raw condition, it is not at all uncommon to witness the dangerous effects of it when it has become mouldy or putrid ; and, in fact, it is within the experience of every one who is concerned in medico-legal inquiries, that serious symptoms are frequently traced to the use of food in a modified condition of decay. This is especially so with bad cheese, the effects of which on the constitution have been so severe, that official investigations have been called for, as at Schwerin (1825), Minden (1825), Hameln (1826), Griefswald (1827), Frankfort (1828), and elsewhere ; and they have been the subjects of interesting essays by Henneman, Hünefeld, Westrumb, and others. At first the effects were attributed to the copper vessels used in the dairies, and therefore the Austrian, Wirtemberg, and Ratesberg States prohibited the use of that metal for such purposes ; but the subsequent inquiries of Hünefeld, Sertürner, and other chemists, established the fact that no metallic poison was discoverable in the cheese. In the police report, which was published in Frankfort, in January, 1828, informing the public of numerous cases of poisoning in that city from spoiled cheese, it was declared that no poisonous principle could be detected by chemical reagents. Professor Hünefeld, and subsequently Sertürner, were of the opinion that the effects were due to certain poisonous fatty acids, analogous to, if not identical with, caseic and sebacic acids ; and they even describe the way in which they are produced in the cheese during the process of ripening—attributing them to the imperfect removal of the acid liquor from the curd when the cheese was made, or to the putrefaction of the curd before it was salted, or to the mixture of

flour with the curd, but it is far more likely that the poisonous effects are due, as Vanden Corput supposes, to the presence of a peculiar mould or fungus. I have myself seen the most terrible consequences from the use of such cheese, and have failed to discover anything unusual in the acidity or other chemical reactions of the cheese. Hünefeld says, it is commonly of a yellowish red colour, and is soft and tough, with harder and darker lumps interspersed throughout it, and it has a disagreeable taste, and an acid reaction. The symptoms which it produces are very much like that of sausage poisoning—namely, irritation of the stomach and bowels with great prostration of the vital powers. These effects have been witnessed not only in Germany, where the cheese is generally rancid and bad, but also in this country, and particularly among the small hill farms of Cheshire, where the limited extent of the daries obliges the farmer to keep the curd for several days before a sufficient quantity of it is accumulated to make a large cheese.

I have said nothing of the improper practice of killing very young animals, especially calves, for food, before the tissues have had time to change from their uterine condition. On the Continent it is unlawful to kill or to sell calves for human food unless they are more than fourteen days old, but in this country there is no such restriction, and it is a common practice to dispose of the carcasses of newly-born, or even foetal calves to the sausage-maker; and as the flesh is sodden and insipid, he strengthens it with old, tough, and sinewy flesh. It has the advantage, moreover, of being miscible with any description of meat, and of taking any variety of flavour; in fact, it makes just that kind of sausage where, to use the expression of Dickens, "It's the seasonen as does it." I cannot say that such meat is positively unwholesome, but it is nasty, and excites the same sort of disgust as an egg with a chick in it.

As regards vegetable foods, they are not so liable to

decay or even to parasitic infection as animal foods; for the *acari* or *mites* of flour and sugar, or even the *weevils* of biscuit are harmless. Perhaps the most important infection of grain is the fungoid disease of it, called *ergot*; which is the *muttercorn* or *roggenmutter* of the Germans, and as it chiefly infects the rye, it is named, from its appearance, *spurred rye*; but it also attacks barley, oats, wheat, maize, rice, and most of the grasses. It always appears as a black grain or spurred grain of larger size than usual, and it is mostly found in plants which grow upon moist clay soils, in damp situations, especially in the neighbourhood of forests. The district of Solonge, in France, between the rivers Loire and Cher, was once notoriously infested with the disease and the Abbe Fessier, who was deputed in 1777 to investigate the causes of the extraordinary prevalence of ergot in that district, attributed it to the poorness and wetness of the land, and to the dampness of the air from numerous forests. In bad seasons, as much as a third or a fourth of the crop was infected with ergot, and even in good seasons it constituted about 2 per cent. of it. The disease in the grain is due to the growth of a peculiar fungus, which the late Mr. Quekett named *Ergotetia abortifaciens*; and the effects of it on the human body are very serious. It acts chiefly on the nervous system, causing giddiness, dimness of sight, loss of feeling, twitching of the limbs, and death by convulsions; or it produces a creeping sensation over the surface of the body, with coldness of the extremities, followed by insensibility and gangrene. These effects are no doubt referred to by Ligebert in his "History of Gaul and France," when he says that the year 1089 was a pestilent year, especially in the Western parts of Lorraine, for many persons became putrid in consequence of their inward parts being consumed by St. Anthony's fire. Their limbs were rotten, and became black like coal, and they either perished miserably, or, being deprived

of their putrid hands and feet, were reserved for a more miserable life. Bayle, too, in his account of this sickness, says that the bread was of a deep violet colour. The like effects have been observed in other parts of the Continent, as in Silesia, Prussia, Bohemia, Saxony, Holstein, Denmark, Switzerland, Lombardy, and Sweden, where the creeping sickness, as it is called, has attacked whole districts of the country, sparing neither old nor young.

The remedy for the disease is in the hands of the miller, who should separate the ergotised from the healthy grains. Fortunately we have a ready test for its presence, not merely in the microscopic appearances of the flour, but in the circumstance that, as it is the lightest of all the constituents of flour, it will float upon a mixture of one part of chloroform and six of alcohol, and will appear as a scum of dark brown particles.

Another source of danger is the presence of poisonous grasses in the flour. The most important of these is darnel (*Lolium temulentum*), which the careless or slovenly farmer will sometimes permit to overrun his fields, and the seeds becoming mixed with the corn, are ground into flour by the equally careless miller. The effect of the seeds on man is a species of intoxication, with headache, giddiness, somnolency, delirium, convulsions, paralysis, and even death. Occasionally it excites vomiting, with irritation of the alimentary canal, and then its effects are not so serious. Many instances are recorded of the poisonous action of such flour. Christison, for example, tells us, that a few years ago almost all the inmates of the poor-house at Sheffield, to the number of eighty, were attacked with analogous symptoms, after breakfasting on oatmeal porridge, and it was supposed that the effects were caused by the presence of darnel in the oatmeal. A similar accident is mentioned by Perleb, as having occurred at the House of Correction at Freyburg, and still more recently the same effects

were produced on seventy-four persons at the workhouse of Beninghausen. Dr. Taylor states, on the authority of Dr. Kingsley, of Roscrea, that in the month of January, 1854, several families, including about thirty persons, suffered severely from the effects of bread containing the flour of darnel seeds. Those who partook of the bread staggered about as if they were intoxicated, and although they all recovered, yet they experienced a good deal of distress from giddiness, coldness of the limbs, and great prostration of vital power.

Unripe grain, as well as grain affected with the *rust*, and *mouldy flour* and *mouldy bread*, have also produced disturbance of the human system. M. Bovier attributed the epidemic of dysentery, which occurred in the department of the Oise, in the autumn of 1793, to the use of *unripe grain*; and corn affected with *brown* or *black rust* is thought by many to be unwholesome. *Mouldy flour* or *mouldy bread* is certainly injurious, for several instances are on record where not only men, but horses, have been poisoned by mouldy bread; and M. Payen has given a graphic account of the distressing effects of the mouldy ammunition bread supplied to the troops who were encamped near Paris in 1843; the mould on that occasion was a yellow fungus, the *Oidium aurantiacum*, but at other times it has been of a green colour, from *Penicillium glaucum*. Flour which has been packed in casks is very liable to become mouldy and sour from the partial decomposition of the gluten; and such flour is not only unpleasant to the taste, but it is also unfit for bread-making, as the dough is soft and clammy.

Mouldy food of every description is dangerous to use, and considering to what an extent the *spores* or *sporidia* of poisonous fungi are floating in the atmosphere, it is surprising that they do not more frequently taint our food and cause disorder of the system; for air washed with distilled water will always yield abundance of these germs, which are ready at any moment to spring into

activity when they come into contact with a proper nidus for their growth. A remedy for these hidden sources of danger is good and effective cooking.

ADULTERATIONS OF FOODS.

And now, in conclusion, let me make a few remarks on the subject of the *fraudulent sophistications of food*—a subject which has been very popular for the last fifty years, or rather, I should say, since the year 1820, when Mr. Frederick Accum published his treatise on “Adulterations of Food, and Culinary Poisons,” with the startling motto from the Book of Kings—“There is death in the pot.” As you may easily imagine, such a terrible announcement by a well-known writer, could not fail to excite alarm in the public mind, and to provoke anxious curiosity. The book, therefore, was eagerly sought for, and a thousand copies of it were sold within a month of its publication; so that, to use the words of the author, in his advertisement to the second edition—“there was sufficient inducement to reprint the work.” The singular success of Accum’s undertaking has been such a temptation to others, that the press has literally groaned with the efforts of sensational writers on this subject: and although I am ready to admit the importance of it, yet I am bound to state that it has often been grossly exaggerated, especially by those who have had but little practical knowledge to guide them, and who have been trading on the credulity of the public.

The objects of fraudulent adulteration of food are three-fold:—

1. To increase the bulk or weight of the article.
2. To improve its appearance.
3. To give it a false strength.

Among the first of these adulterations are the following:—

(a). The addition of *inferior starches*, as potato-starch or English arrow-root, curcuma or East Indian arrow-root, jatropha or Brazilian arrow-root, tacca or Tahiti arrow-root, canna or Tous-les-mois starch, sago-meal, &c., to *true maranta*, or *West Indian arrow-root*—of which Bermuda arrow-root is the most esteemed variety. A microscopic examination of the starch or fæcula will always discover the fraud.

(b). The mixture of *starch-sugar* or even *starch* itself to *common cane-sugar*. Starch-sugar, or as it is sometimes called grape-sugar, or glucose, is manufactured both in this country and on the Continent to a considerable extent. It is made from any description of starch, by boiling it for half an hour or so in water containing about one per cent. of sulphuric acid. The acid is then neutralised with chalk, and the liquor evaporated to a density of 1.28. While hot it is run off clear from the insoluble precipitate of sulphate of lime, and on standing in a cool place for a few days it crystallises or sets into a solid mass. This description of sugar has a low sweetening power—not half so great as that of cane-sugar—in fact, it is produced from the latter by the action of vegetable acids and heat, when cane-sugar is added to fruit in making a tart or fruit pie, and in making jellies and jams. It is false economy, therefore, to sweeten to any extent before the tart is baked. The sugar is known by many characters, as a want of sparkle from the absence of well-formed crystals; its less solubility in water, and greater solubility in alcohol than cane-sugar; and by its giving a deep port-wine tint to a solution of caustic potash, when it is boiled with it.

(c). The dilution of *milk*, *vinegar*, *alcoholic liquids*, &c., with *water*. This fraud is easily detected by the specific gravity of the liquid, and in the case of milk by the proportion of cream in the lactometer, and by the poor appearance of the milk when seen in bulk or under the microscope, or in a thin stratum. There are other tests

for diluted milk, as the specific gravity of the serum or whey, after the milk has been curdled with a little rennet and filtered, and by the per centage weight of the dry curd. These results are approximatively shown in the following table:—

TABLE XXIX.

Specific gravity of Milk, of Skimmed Milk, and of Serum or Whey, when diluted with different proportions of water.

	Specific gravity.	Per centage volume of cream.	Specific gravity when skimmed.	Specific gravity of the serum.	Per centage weight of dry curd.
Genuine Milk	1030	12·0	1032	1029	6·3
Do. with 10 per cent. water	1027	10·5	1029	1026	5·6
Do. „ 20 „	1024	8·5	1026	1023	4·9
Do. „ 30 „	1021	6·0	1023	1021	4·2
Do. „ 40 „	1018	5·0	1019	1018	3·5
Do. „ 50 „	1015	4·5	1016	1016	2·9

As I have already stated, the specific gravity of good milk ranges from 1028 to 1032; and any milk with a gravity below 1026 is either very poor in quality from natural causes, or it has been diluted with water. Taking all the tests together, there will be no difficulty in discovering fraud—whether it has been effected by skimming the milk or by diluting it; and as salt is sometimes added to milk to increase its gravity and to improve its flavour, it is proper that the ash of the milk should be examined. This ranges from six to ten parts in a thousand of milk, the average proportion being about eight parts. If, therefore, salt has been added, it will be discovered in the ash by the excess of weight, and by the salt taste of it. Carbonate of soda is discovered in like manner. Recent examinations of a large number of samples of milk from the metropolitan workhouses has proved to me that the milk is generally of poor quality, and has either been skimmed or diluted with from ten to fifty per cent. of water.

Similar tables have been constructed for showing, by means of the specific gravity, the per centages of alcohol and acetic acid in their respective solutions.

(d). The mixture of *dripping* and *other fats* with *butter*, and *water* and *starchy* matter with *lard*. Melted in a glass, butter and lard should always furnish a clear-looking oil, with but little deposit of water, salt, or other substance; and the flavour when warmed should be agreeable and characteristic—not like that of dripping or other cheap fat.

(e). The addition of *gelatine* to *isinglass*, which is sometimes so well managed that it requires a skilful analysis to detect it. Isinglass is an organised substance, and when examined with the microscope, exhibits a peculiar structure which is very characteristic of it; not so, however, with gelatine. A particle of isinglass put into cold water remains opaque, like a piece of white thread, and does not swell out; whereas gelatine becomes transparent, and enlarges a good deal in bulk. Jelly made from good isinglass has a slightly fishy smell, and is neutral to test-paper; but that from gelatine has a distinct odour of glue, and an acid reaction. Lastly, if a few grains of isinglass be burnt in a metal spoon until the ash alone remains, the ash will be very small in quantity, and of a reddish colour; while that of gelatine will be much larger in amount, and of a white appearance. Gelatine never agrees with the delicate stomach of an invalid like isinglass; and, therefore, it is often important to discover the difference.

(f). *Coffee* adulterated with *chicory* is readily detected by sprinkling the mixture upon water, when the coffee, which is slightly greasy from volatile and fixed oil, floats, while the chicory sinks, and gives a brownish tint to the water. The experiment is easily made, as you here see, in a tumbler of water, and you may, with a little tact, determine the proportions of the mixture.

(g). *Wheaten flour* is frequently added to *flour of mus-*

tard, and when the quantity passes beyond a certain amount, it is undoubtedly an adulteration, for the intention of it should be only to reduce to an agreeable extent the pungency of the mustard.

Of the second class of adulterations, where the object is to *improve the appearance of the article*, there are many examples, as :—

(a). The addition of *alum* to *bread*, by which, as I have already explained, inferior, and even damaged, flour may be made into a tolerable looking loaf. It is the property of alum to make the gluten tough, and to prevent its discolouration by heat, as well as to check the action of the yeast or ferment upon it. When, therefore, it is added to good flour, it enables it to hold more water, and so to yield a larger number of loaves; while the addition of it to bad flour prevents the softening and disintegrating effect of the yeast on the poor and inferior gluten, and so enables it to bear the action of heat in the process of baking. According to the quality of the flour will be the proportion of alum, and hence the amount will range from 2 ounces to 8 ounces per sack of flour. These proportions will yield from 9 to 37 grains of alum in the quartern loaf, quantities which are easily detected by chemical means. Indeed, there is a simple test by which much smaller quantities of it may be readily discovered. Infusion of logwood, as you here perceive, acquires a rich purplish carmine, or claret tint, when it is brought into contact with alum; you have, therefore, only to dip a slice of the bread for an instant, as I am now doing, into a weak, watery solution of logwood, and if alum be present the bread will speedily acquire a purple or reddish purple tint. I have already described to you the other properties of good bread, as that it should not exhibit any black specks upon the upper crust; it should not become sodden und wet at the lower part by standing; it should not become mouldy by keeping in a moderately dry place; it should be

sweet and agreeable to both taste and smell; it should not give, when steeped in water, a ropy acid liquor; and a slice of it taken from the centre of the loaf should not lose more than 40 per cent. by drying.

Sulphate of copper is found to act like alum in improving the appearance of bread; and, according to Kuhlmann, Chevalier, and others, it is commonly used by the bakers of the Continent, notwithstanding the severe penalties attached to it. In this country, however, it is but rarely employed. The fraud is sometimes discovered by the purple tint which the bread acquires when moistened with a weak solution of yellow prussiate of potash; and it is always known by the blue colour of the ash of bread when treated with a little strong ammonia.

(b). *The bloom, or glaze, or facing*, of green and black tea is generally artificial. In the case of green tea it is ordinarily a mixture of Prussian blue, turmeric, and sulphate of lime, or China clay; and in that of black tea it is not unfrequently a coating of black-lead. The tea prepared for the English market is notoriously subject to these adulterations; and it seems that it arises entirely from our own fancy, and not from any desire on the part of the Chinese to pursue such a practice. The adulteration is easily discovered by shaking the tea with cold water, and then straining through muslin, and allowing the fine powder to subside. Again, the ash of good young tea amounts to from five to six per cent. of the tea, and it contains, in 100 parts of the ash, about 39.2 of potash, and 14.6 of phosphoric acid—the remainder being composed of lime, oxide of iron, and silica in nearly equal parts; whereas old tea leaves, and leaves which have been exhausted by water, contain much less ash, and the proportion of potash and phosphoric acid are relatively much smaller. Exhausted leaves, and tea composed of foreign leaves, and of iron filings and other mineral matters, have been largely

imported into this country from China under the names of Maloo mixture, Moning Congou, Pekoe siftings, &c.; and they have been submitted to analysis by Dr. Stenhouse and myself. The flavour of the samples has always been bad, and frequently repulsive; and when the tea has been infused in boiling water, it has yielded a low proportion of extractive, as from 11 to 14 per cent. in the case of the Moning Congou, and from 19 to 21 per cent. in that of the Pekoe siftings, instead of from 24 to 25 per cent., which is the amount yielded by good Congou, or about 34 per cent. by average Pekoe. The *theine*, also, has amounted to only from 0.025 to 0.036 per cent. in the Maloo mixture, instead of at least 2.1 per cent, and from 0.24 to 0.38 in the Pekoe siftings, instead of about 2 per cent. These results show that the samples consisted of spurious matters and exhausted leaves, with only a little good tea.

(c) *Pickles* and *preserved fruits* are often made green with a salt of copper, it being the peculiar property of that metal to mordant, or fix in an insoluble form, the green colouring matter or *chlorophyll* of vegetables. If, therefore, the pickling operation is conducted in copper vessels, or if a little verdigris or sulphate of copper is added to the vinegar in which the vegetables are boiled, the colour of them is always retained. In some cases the quantity added has been so large as to give a coppery look to a steel fork or knife plunged into the pickle. In such cases, as might be expected, severe symptoms of poisoning have been occasioned by it. The presence of the metal is easily discovered by incinerating some of the pickles, and treating the ash with a little strong ammonia, when the characteristic blue tint is observed; or the ash may be dissolved in acetic acid, and then tested with a piece of clean bright iron wire, which will soon become covered with a layer of metallic copper.

(d.) *Ferruginous earths*, or *red oxides of iron*, are fre-

quently added to sauces, to anchovies, to cocoa preparations, and to preserved or potted meats, to improve their appearance.

(e.) *Mineral pigments*, often of a poisonous nature, are used in colouring confectionery ; and I have known the most serious effects from it. The yellow and orange-coloured chromates of lead are frequently employed for this purpose, and so are the mineral greens, but they are easily discovered by exposing the confectionery to the action of sulphuretted hydrogen, when the colours assume a dark brown or black appearance.

And, lastly, with the view of giving a *false strength to the article*, we have instances of *sulphuric acid* added to *vinegar*, *black jack* or *burnt sugar* to *coffee* and *chicory*, *catechu* or *terra japonica* to *tea*, *coccus indicus* to *beer*, *cayenne* to *peppers*, &c.

That many of these sophistications are dangerous there can be no doubt, and all of them are frauds on the public. Parliament has therefore attempted to deal with the matter by legislation, as in the "Act for Preventing the Adulteration of Articles of Food or Drink" (23rd and 24th Vict., cap. 84) of 1860 ; but as the Act is only permissive, little or no effect has been given to it. Even in those places, as in the City of London, where it has been put into operation, and public analysts have been appointed, no good has resulted from it, and it really stands upon the statute-book as a dead letter. Speaking for the City, I may say that every inducement has been offered for the effective working of the Act ; for directly it came into operation, in August, 1860, an analyst was appointed, and the public were informed by circular of the intentions of the Act, and were invited to aid in its execution—the poor being allowed to submit suspected articles of food to me for analysis free of charge ; yet, during the eleven years which have elapsed since the passing of the Act, there have been but 57 articles supplied to me, for examination, and of these 26 were of

bad quality or were adulterated. In many cases the genuine articles were brought to me with the knowledge of the dealer, and with the evident intention of obtaining a certificate for trade purposes; but in no case has there been any proceeding before the magistrate in accordance with the provisions of the Act; and, therefore, it has been of no practical value to the public. In olden time the remedies for such misdemeanors were quick and effectual. In the *Assisa panis*, for example, as set forth in *Liber albus*,* there are not only the strictest regulations concerning the manner in which the business of the baker is to be conducted, but there are also the penalties for failing in the same. "If any default," it says, "shall be found in the bread of a baker in the City, the first time let him be drawn upon a hurdle from the Guildhall to his own house through the great streets where there be most people assembled, and through the great streets which are most dirty, with the faulty loaf hanging from his neck; if a second time he shall be found committing

* The Assize of Bread was instituted in the reign of King John (1202), and was maintained, with certain modifications, until the year 1815, when it was abolished in England. According to *Liber albus*, an assay of bread was made in the city immediately after the Feast of St. Michael in each year "by four discreet men chosen from among the citizens and sworn thereto;" and "according to the proportion in weight set by such assay the bakers had to bake throughout the whole of that year." The following appears to have been the mode of assay practised:—The four men so chosen "had to purchase three quarters of corn, one upon the pavement in Chepe, one at Greschirche, or at Billingsgate, and a third at Queenhithe," of which corn they had to make "wastel" (or second quality bread), light bread, and brown bread. And "after with great diligence" they had baked the loaves, they had to present them, "while hot, to the Mayor and Aldermen at Guildhall, and here, while so hot, such loaves were weighed." The plan adapted for proving them to have been of proper weight seems to have been to make as many halfpenny loaves as there were halfpence in the total of the purchase-money.

the same offence, let him be drawn from the Guildhall through the great street of Chepe, in manner aforesaid, to the pillory, and let him be put upon the pillory, and remain there at least one hour in the day; and the third time that such default shall be found, he shall be drawn, and the oven shall be pulled down, and the baker made to forswear the trade within the City for ever." It further tells us that William de Stratford suffered this punishment for selling bread of short weight, and John de Strode for making bread of filth and cobwebs. One hoary-headed offender was excused the hurdle on account of his age and the severity of the season; and it would seem that the last time the punishment was inflicted was in the sixteenth year of the reign of Henry VI., when Simon Frensshe was so drawn. A like punishment was awarded to butchers and vintners for fraudulent dealings; for we are told that a butcher was paraded through the streets with his face to the horse's tail, for selling measly bacon at market, and the next day he was set in the pillory with two great pieces of his measly bacon over his head, and a writing which set forth his crimes. In 1319, in the judgments recorded in *Liber albus*, the Mayor and Aldermen adjudged William Sperling, of the "Stockkes Market," for attempting to sell two putrid beef carcasses, which had been sworn to by the "swornwardens" of flesh meat as "putrid and poisonous," to "be put in the pillory, and the said carcasses to be *burnt beneath him*." Other cases were heard in the following year (14 Edward II.) against William le Clerk, of Higham Ferrers, and Nicholas Schyngal, both of whom were convicted and condemned to similar punishment. There are, in fact, in *Liber albus*, twenty-three cases in which the pillory or the thew was awarded for selling putrid meat, fish, or poultry; thirteen for unlawful dealings of bakers; and six for the misdemeanours of vintners and wine drawers.

CONCLUSION.

And now, in conclusion ; having directed your attention to the nutritive values of different kinds of food ; to their functional and dietetical powers ; to the modes in which they are associated ; to the quantities required for ordinary labour ; to the manner in which they are digested ; to the effects of culinary and other treatment ; to the way in which they may be preserved ; and to the causes of their unwholesomeness, we may finally ask if any great generalisations can be deduced from our inquiries ?

In the first place, you will, I think, have observed that there are very striking evidences of design in the way in which organic matter is constantly kept in motion, for, whether living or dead, it is always in a state of molecular activity—either advancing towards the highest state of organisation, or retreating to the confines of the mineral kingdom. The result of this is that, with a comparatively small amount of material, and with but little expenditure of force, the work of the living world is fully and effectually performed. Starting from the mineral kingdom, as carbonic acid, water, and ammonia, the elements of organic nature pass through a succession of changes, first in the vegetable and next in the animal, until they reach the summit of organisation, when they again return to their primitive condition. In this manner a never-ending round of change is perpetuated, and the same material and the same force are kept moving in the same continuous circle. Through the efforts of the plant the crude materials are formed into vegetable acids, sugar, gum, starch, fat, albumen, and

tissue; and then the animal converts them into higher forms of structure, as gelatine, muscle, and brain; the two extremes, therefore, of these changes are, to use the words of Gerhardt, carbonic acid, water, and ammonia at one end; albumen, gelatine, fat, and cerebral matter at the other—but the transitions to these extremes are countless, and are as yet beyond the reach of science. Broadly, however, we may say that the chemical functions of the plant are those of reduction or deoxidation, whereby carbonic acid and water are deprived of their oxygen and moulded with nitrogen into food; while those of animals are of an opposite nature, for they destroy this food by oxidation. The plant, therefore, is the machine or medium whereby carbonic acid, water, and ammonia, are converted into new compounds, and light and heat are transmuted into chemical affinity; and the animal is the medium or machine whereby these compounds are destroyed, and their affinities changed into other manifestations of force, and finally into heat. In this way, the circuit of change is completed; and it is not difficult to trace the phenomena of vitality to the cosmical forces which the plant had imprisoned.* But

* Since these lectures were delivered, the illustrious chemist, and distinguished orator, M. J. Dumas, has thus expressed himself on this subject. “The first studies we pursue on the chemical phenomena of life teach us that plants create, and animals destroy, organic matter. The sun appears as the agent by whose means this matter is produced, and combustion by the air that animals breathe, as the process that destroys them, in order to restore their elements to the state of ‘brut’ matter. The chemical forces placed at the disposal of life descending on the earth under the forces of light, disappear by radiating off into space under the form of heat. An equilibrium obtains between the vegetable and animal kingdoms for receipts and disbursements, represented by these two forms of motion—light and heat; and the amount of animal life which may be developed on the globe is measured by the amount of food that vegetable life has prepared for it. The dark rays of heat appear to carry from the earth that which the radiant and

shall we ever be able to follow, through all the intricacies of change, the countless transitions of both matter and force in their passage from the mineral kingdom to the animal, and then back to the mineral again? It is easy to connect, by a correlation of force, the muscular movements of the animal body, and even the highest efforts of the human mind, with the sunbeam which the plant had arrested; but shall we ever be permitted to unravel those mysterious functions, those intermediate changes which constitute the phenomena of life? Why is it, for example, and how comes it, that the living cell of the plant is able to aggregate mineral matter in opposition to the common laws of affinity, and transform light and heat into cell-force? How is it, too, that the animal, in reversing the process, and so restoring the play of affinity, is able to transmute it into other manifestations of force? At present, the utmost we can say of it is, that organic matter is the appointed medium of all these changes, and is designed for the exhibition of vital phenomena, just as mineral matter is the appointed medium for the phenomena of electricity and magnetism. And yet to some extent, perhaps, we are able to penetrate the mystery; for by finding the clue to the peculiar action of the vegetable in reducing chemical compounds, we can, by operating on such substances as carbonic acid, water, and ammonia, produce a large number of organic principles: in fact, of the three great classes of alimentary

brilliant light has spread over it.”—(The Faraday Lecture, *Chemical News*, vol. xx., p. 4).

Baron Liebig, also, in his essay on the process of nutrition, has thus expressed himself: “The plant is a magazine of sun-force which has been accumulated in its parts during their development, and this force stored up in the food material of animals is again manifested in the animal body; it is the manifold action of this force which comprises and determines all phenomena of animal life. Hence the elucidation of the laws obtaining in regard to that force should, above all things, engage the attention of investigators.”

substances, to which I have so frequently directed your attention—namely, the oleaginous, the saccharine, and the albuminous—it may be said that the first is already within the manufacturing power of the chemist, and the second is nearly within it; so that there is abundant proof that the agency of a vital force is not necessary to the formation of organic compounds; and there is even hope that the fabrication of food may not be altogether beyond the capabilities of man.

INDEX.

- Aberdeen process of preserving meat, 194
Acid, carbolic, preservation of meat by, 203
Acid, carbonic, amount exhaled, 70
 ,, glycolic, 52
