OFA

REMARKABLE TRANSPOSITION

OFTHE

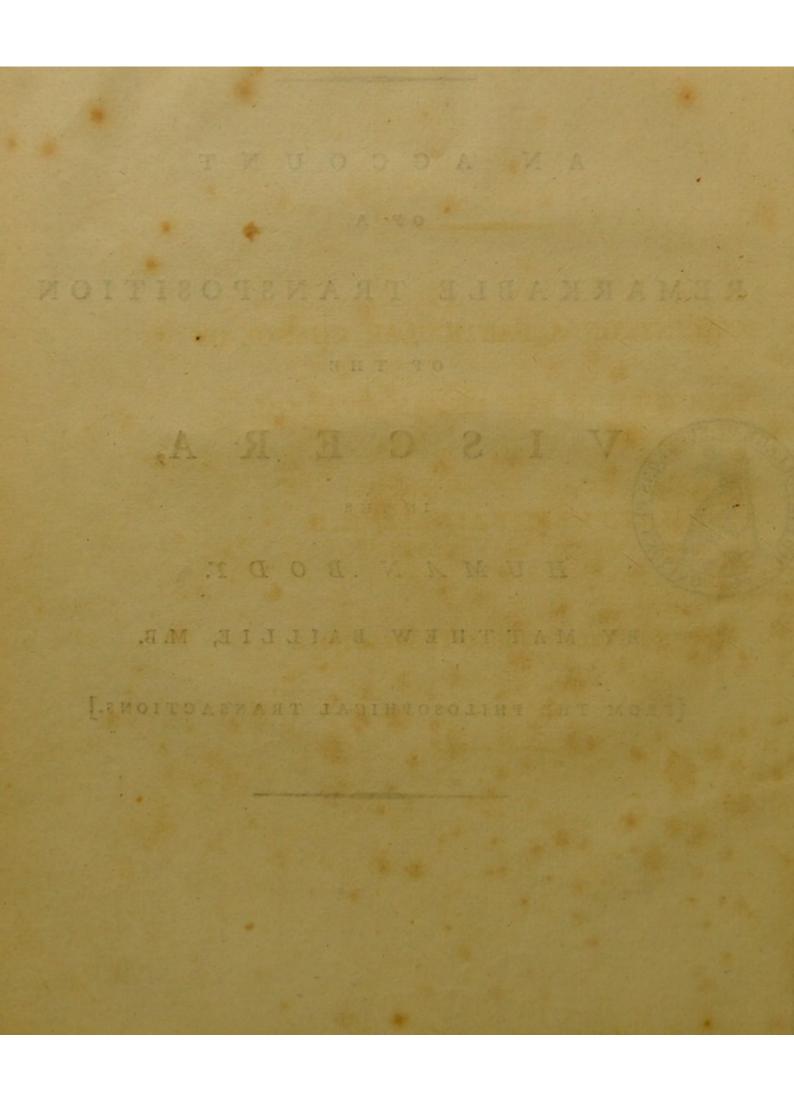

VISCERA,

IN THE

HUMAN BODY.

BY MATTHEW BAILLIE, M.B.

[FROM THE PHILOSOPHICAL TRANSACTIONS.]

TO JOHN HUNTER, ESQ. F.R.S.

DEAR SIR,

A VERY fingular variety baving occurred lately in the ftructure of the human body, I beg leave to communicate an account of it by your means to the Royal Society, if you should think it worthy of their notice. It happens by a very uncommon concurrence of circumstances, that while I am naturally led by the ties of affinity to apply to you upon this occasion, I can gratify my pride by thinking it is at the same time to the person who is possible of the first reputation for his unwearied researches in one of the most extensive, as well as interesting, parts of the fystem of Nature.

I am, Sc.

M. BAILLIE.

Great Windmill-street, April 12, 1788.

AN ACCOUNT OF A REMARKABLE TRANSPOSITION OF THE VISCERA, IN THE HUMAN BODY.

Read (at the Royal Society) May 8, 1788.

HERE is nothing which tends more to illustrate the powers and the wisdom of Nature than the investigation of the structure of animals. We there find a most wonderful delicacy of mechanism, and exquisitely adapted to a variety of purposes. This, however, is not to be better seen by following Nature in her common tract, than by observing her wanderings. In these she often shews more particularly the extent of her powers, and throws light on her ordinary plans. It is such cir-

cumftances which give importance or value to the obfervation of fingular phænomena. The variety in animal flructure, an account of which I have the honour of prefenting to this learned Society, is a complete transposition, in the human subject, of the thoracic and abdominal viscera to the opposite side from what is natural.

It is fo extraordinary as fcarcely to have been feen by any of the most celebrated anatomists; and, indeed, has been but very generally noticed at all. The circumstance has been mentioned; but it has not been particularly defcribed fo as to make it thoroughly known, or to establish its certainty. It was hanging in the minds of many as doubtful, whether such a variety did really exist.

There is one circumftance that attends the account of the prefent cafe, which has not always happened in the record of fingular phænomena, viz. that the lufus has been examined by phyficians and furgeons of the first reputation in this large town; and has been in fome measure open to the gratification of public curiofity. Such a circumftance (were it neceffary) would give the ftamp of authenticity to appearances even much farther removed from the ordinary plans of Nature.

I have been at the pains to confult many authors upon this fubject, but with very little fatisfaction. I fhall not enter into a detail of what I have met with in the courfe of thefe refearches; but fhall briefly notice, that when any lufus of this fort is mentioned, it is commonly in a fingle fentence or two, and the transposition is not marked as univerfal, or it is a change in the fituation of fome viscus from difease. In fhort, I have only found this fingular lusus naturæ defcribed by Cattierius, M. Mery, and M. Daubenton; but by none of them is it fufficiently particular. Enough has been faid to point out that they had exactly met with the fame fort of monstrofity; but many circumftances have been omitted, which I hope will be fupplied by the prefent account, which I proceed immediately to lay before the Society.

The perfon who is the fubject of this paper was a male, near forty years of age, fomewhat above the middle stature, and of a clean active

shape. He was brought for diffection, in the common way, to Windmill-ftreet. Upon opening the cavity of the thorax and abdomen, the different fituation of the vifcera was fo ftriking as immediately to excite the attention of the pupils who were engaged in diffecting it; and Mr. CRUIKSHANK, as well as myfelf, were very foon informed of the fingularity. We were much furprized, as well as pleafed with the appearance; and I began immediately to examine every part of the change with confiderable attention : for this purpose, after defiring a drawing to be made of the appearances as they were found upon opening the body, I next day injected it. The repeated diffections have furnished various views, which are reprefented faithfully by drawings, and which I hope will enable me to give a tolerable diftinct account of this fingular lusus naturæ. I shall not enter in my description into unnecessary minutiæ : this would render the paper lefs fuited to the Society, would not convey more information to perfons thoroughly acquainted with anatomy, and would rather tend to obfcure what is more important to those who have not given so much attention to subjects of this nature. It may not be improper to obferve, that, befides the transposition in the vifcera of this perfon, there are feveral peculiarities which fometimes occur. I have taken notice of them in my defcription, although they are entirely independent of the transposition.

DESCRIPTION OF THE THORAX.

The mediaftinum, or anterior duplicature of the pleura feparating the two cavities of the cheft from each other, was found to incline obliquely downwards to the right fide, fully as much as it does commonly to the left fide of the cheft. The pericardium too inclined obliquely to the right fide. On prefing it gently away from the lungs, the phrenic nerves came diftinctly into view, in their common fituation; but the right phrenic nerve ran more obliquely, and was longer

than the left. The lung upon the right fide was divided by a fingle oblique fiffure into two lobes, having at the fame time a deficiency oppofite to the apex of the heart; and the lung on the left fide was divided into three lobes, exactly contrary to what is found in ordinary cafes.

On opening the pericardium, the apex of the heart was found to point to the right, nearly oppofite to the fixth rib; and its cavities, as well as large veffels, were completely transpored. What are commonly called the right auricle and ventricle were fituated on the left fide; and the left auricle and ventricle on the right. The pulmonary artery afcended towards the right fide of the cheft. The aorta was also directing its arch to the right; and the vena cava fuperior, as well as inferior, were feen opening into their auricle on the left fide of the fpine.

On the outfide of the pericardium the transposition of the larger vefiels was very striking. The longer subclavian vein was passing from the left side obliquely to the right, before the branches which are fent off from the arch of the aorta. The left carotid and subclavian arteries were found to arise from the arch of the aorta by one common trunk; the right carotid and subclavian to arise searches.

In the duplicature of the pleura behind, or what may be called the pofterior mediaftinum, there was a change corresponding to what we have already defcribed. The defcending aorta was found paffing on the right fide of the fpine. The œfophagus was before it, inclining more and more to the right towards its lower extremity; and it at length perforated the diaphragm fomewhat on the right fide of the fpine. The vena azygos was on the left fide of the fpine, opening in the common way into the vena cava fuperior, which we formerly mentioned to be alfo transposed in its fituation. The thoracic duct was feen in the middle, between the defcending aorta and the vena azygos, in fome places forming a plexus of fimall branches, in another dividing itfelf into two branches, which afterwards reunited in a common

7

trunk, and at length climbing up to terminate in the angle between the jugular and fubclavian veins on the right fide of the body. The recurrent nerve of the parvagum, on the right fide, paffed round the beginning of the defcending aorta, and on the left, paffed round the common trunk of the carotid and fubclavian arteries. The large intercoftal nerves being exactly under the fame circumftances on each fide, it was impoffible there could be any transposition in them. It appears then, from the foregoing defcription, that every thing admitting of fuch a change was completely transposed in the thorax.

OF THE ABDOMEN.

The liver was fituated in the left hypochondriac region; the fmall lobe being towards the right, and the great lobe in the left fide. The ligaments, uniting it to the diaphragm, corresponded to this change, the right transverse ligament being longer, and the left being shorter than ufual. The fufpenfory ligament could undergo little change, except that of being pushed to the left fide along with the liver. On preffing upwards the liver, fo as to exhibit its posterior and under furface, the gall-bladder was feen on the left fide preferving its proper relative fituation to the great lobe of the liver; and the veffels of the portæ were found upon diffection to be transposed, corresponding to the change of circumstances. The hepatic artery was found climbing up obliquely from the right towards the left, before the lobulus fpigelii, and entered at the portæ into the fubstance of the liver by two or three branches on the right of the other veffels. The ductus communis cholidochus was on the left of the other veffels, being formed from the ductus hepaticus and ductus cyfticus in the common way; and it passed obliquely downwards on the left, to terminate in the duodenum. What was most remarkable, of which indeed I never faw or heard of an instance before, it terminated in the forepart of the duodenum. The vena por-

tarum paffed behind the hepatic artery and ductus communis cholidochus, afcending obliquely towards the left fide.

The fpleen was fituated in the right hypochondriac region, adhering to the diaphragm in the common way. What was very remarkable was, there being three fpleens, nearly of the fize of a pullet's egg, found adhering to the larger fpleen by fhort adhefions; befides two other ftill fmaller fpleens which were involved in the epiploon at the great end of the ftomach. I never faw fo many fmall fpleens in any one fubject. The pancreas was found on the right fide behind the ftomach, running obliquely from the fpleen to the curviture of the duodenum, and had its duct entering in common with the ductus communis cholidochus into the cavity of that inteftine. The fplenic veffels were paffing along the upper edge of the pancreas to the right fide, correfponding to the change of fituation in the pancreas and fpleen.

The ftomach was fituated on the right fide, partly hid by the fmall lobe of the liver, was paffing to the left, and terminating in the pylorus, rather on the left fide of the fpine. The duodenum took a moft fingular courfe; it paffed to the right fide, behind the fmall end of the ftomach; it then turned upon itfelf, towards the left fide; it afterwards took its proper fweep to the right fide, paffing behind the fuperior mefenteric artery and the greater mefaraic vein. The mefentery began to be formed on the right fide, inftead of the left, as in ordinary cafes. The ilium terminated in the great inteffine on the left fide, and there was in it a diverticulum of confiderable fize, a lufus not unfrequently occurring. The cæcum was fituated on the left pfoas magnus and iliacus internus mufcles. The transverfe arch of the colon paffed from the left to the right fide of the body; and the figmoid flexure croffed over the right pfoas, to get into the cavity of the pelvis.

The kidnies had their veffels transposed, as we shall remark more particularly afterwards. The renal capsules had undergone no change, as no variety could be produced by a transposition.

9

The aorta paffed between the crura of the diaphragm into the cavity of the abdomen; and adhered, in its courfe to the fpine, on the right fide of the vena cava inferior. Its branches were directed in their courfe, corresponding to the peculiar fituation of the viscera. The splenic and coronary arteries were passing to the right fide; and the hepatic artery obliquely to the left. The superior and inferior mesenteric arteries were directed to the right fide. There were no change in the spermatic arteries; any transposition in the testicles (if such a thing could take place) not being capable of affecting them. The lumbar arteries could also undergo little change, except that the left lumbar arteries must necessarily, from the peculiar fituation of the aorta, be the longest. The vena cava inferior perforated the tendinous portion of the diaphragm, and adhered in its course to the spine on the left fide of the aorta.

The right emulgent vein was much longer than ufual, paffing from the right kidney, before the aorta, to terminate in the vena cava fuperior; and the left emulgent much fhorter, paffing from the left kidney to the vena cava, which was fituated on the left fide of the fpine. The right fpermatic vein was found to open into the right emulgent; and the left into the vena cava inferior, about an inch under the left emulgent. The vena portarum was changed from its natural courfe, paffing obliquely upwards to the left fide; and its large branches, viz. the vena fplenica, mefaraica major and minor, were all directed towards the right fide of the fpine.

There was no change in the intercostal nerve within the cavity of the abdomen; nor does it seem to be capable of being affected by any transposition of parts. We see then, that there was a complete transposition of the abdominal viscera, each of them preferving its proper relative situation to the others.

I examined the brain, the organs of fenfe, of generation, the muscles and blood-veffels of the extremities, but found nothing in them remarkable. Indeed, I had no expectation of it; for all these parts are perfectly

independent of thoracic or abdominal vifcera; but I did it to fatisfy myfelf and the curiofity of others, who might wifh to put fuch a queftion, or have fuch a queftion arifing in their minds.

The perfon feems to have used his right hand in preference to his left, as is usually the cafe, which was readily discovered by the greater bulk and hardness of that hand, as well as the greater fleshiness of the arm. It was not to be expected he should be left-handed; but I mention this circumstance too, with a view to fatisfy a curiofity which I know has been excited in many who have heard of this lusue.

I have been at confiderable pains to learn fomething of the hiftory of this perfon during life; but the particulars I have heard, are applicable only to the circumstances of common men, having no connection with fingularity of ftructure; and therefore, I think, it would be abufing the time of the Society to give any account of them. One thing it may be right to mention is, that the perfon, while alive, was not confcious of any uncommon fituation of his heart; and that his brother, whom I have feen, has his heart pointing to the left fide, as in ordinary cafes. Indeed, there was little reafon to expect that we should meet with any thing particular in the account of his life. His health could not be affected by fuch a change of fituation in his vifcera; nor could there arife from it any peculiar fymptoms of difeafe. Still lefs could there be any connection between fuch a change and his dispositions, or external actions. He might have known that his heart was directed towards the right fide ; but if we confider how little every perfon, especially those of the lower class, are attentive to circumstances not very palpable, it was fcarcely to be expected he fhould know it. If I had met with any thing in his life which was at all referable to the fingularity of ftructure, I should have been very glad to have gratified the public curiofity by giving an account of it*.

* Since the above lufus has occurred, I have feen, in the poffeffion of Mr. Payne, furgeon, a fœtus at the full time, with the vifcera transposed. In the Anatomial Collection of Chrift Church, in Oxford, there is a heart transposed that had belonged to a very finall fœtus; but the fœtus itself is not preferved.

Every fingular phænomenon in animal ftructure is worth remarking, even if it should not lead immediately to any useful observation; but it becomes more important if it fhould tend to throw any light upon the principles of Nature in the formation of animals. It is reafonable to think, that Nature should follow fome general plan in her operations. There is fome effect which fhe has in view, and fhe will generally employ the fame means to produce it. In the structure of any animal, her view is to form fuch a combination of parts as to render the animal fitted for certain purpofes. She will commonly form the fame combination where the fame purposes are to be ferved; or, in other words, there will be the fame structure in the fame species of animals. The fame effect, however, may be produced, without a strict adherence to the employment of the fame means, as we find to be the cafe in all human inventions; and therefore there is no reafon why Nature should not fometimes deviate from her ordinary plans. Accordingly we find there is much variety in animal ftructure; but this does not commonly affect the animal functions. Under this reftriction, the variety is fo great in the appearances of every part of an animal, that it is almost impossible to examine any two animals of the fame fpecies without remarking many differences.

In the bony compages of an animal we find little variety in the extremities of bones where there is the apparatus of a joint, becaufe a particular fhape is beft adapted to a particular kind or latitude of motion. In other parts of the bones, where a difference of features is not material, there is great variety, as in the foramina, depreffions, ridges, and futures of bones.

The fame general rule will apply to variety in mufcles. The principal object is a certain infertion near a joint, fo as to give a determined direction of motion. With refpect to fuch infertions, there is, comparatively fpeaking, little variety; but there is a great difference in the bodies and connections of mufcles, which have no fhare in the regulation of the motion.

There is no part of an animal where there is a greater latitude of variety than in the diffribution of blood-veffels. The reafon of it is very obvious. The only object in the diffribution of blood-veffels is, to carry blood to every part of the body, and bring it back to the heart. The parts of an animal, in order to be fupported, muft be vifited by fucceflive changes of frefh blood; but it furely cannot be an object of importance, whether the blood paffes by one route or another. Hence the variety in blood-veffels is extremely great. Still, however, there is a method in the deviations of Nature, fo that they may be marked or noted, the fame varieties occurring in different animals.

It cannot be at all important to the function of a vifcus, whether it be in one mafs, or in feparate portions. The ftructure being the fame, the fame action will take place. Hence we often find the two kidnies joined together, forming one mafs; and not unfrequently, two or three fpleens befides the common one. Neither can it be important, whether a vifcus fhould always be of the fame fhape, becaufe its functions do not depend on fhape, but on ftructure: we find accordingly, in this particular, much variety.

There are many of the viscera which are connected together in their functions, or by the junction of large blood-veffels, in such a way as to require nearly the same relative situation among themselves. This becomes also necessary in order to preferve the general shape of the animal. Accordingly we find, that when any important viscus is changed in its situation, it affects the situation of other viscera, requiring in them a corresponding change. We saw in the person who is the subject of this paper, that a change in the situation of the heart and liver was accompanied with a change of situation in the stomach, spleen, pancreas, and in short the whole abdominal viscera. This, however, is a great deviation in Nature; for it is nothing less than changing almost the whole vital softem in an animal; and therefore it rarely happens.

In fuch a change, it does not appear that the functions can be affected, as they depend on ftructure and fituation, which are both preferved. Hence the perfon, who is the fubject of this paper, arrived at the age of maturity; and might have continued to have lived to an extreme old age. The human machine might have been conftructed in this way generally; and, under fuch circumftances, what is now called the natural fituation of parts, would have been as fingular as the prefent phænomenon.

There appears to be lefs variety in the nervous fyftem of animals of the fame fpecies than in most parts of the body. There is fcarcely any difference in the appearance of the brain ; and much lefs in the diftribution of the nerves than of the blood-veffels. There is also little variety in the organs of fense: perhaps the mechanism in both these is nicer, fo that a confiderable deviation would interfere with their peculiar functions.

The moft common great deviations which Nature produces in the ftructure of an animal, are various kinds of monftrofity, by which the animal becomes often unfit for continuing its exiftence. This fort of imperfect formation, fo much below the ftandard of Nature's common work, is probably with a view to check the propagation of great varities, and thereby to preferve an uniformity in the fame fpecies of animals.

It has been much agitated, whether monftrofities depend on the original formation; or are produced afterwards in the gradual evolution of an animal. This does not appear to be a queftion of much importance; nor, perhaps, can it be abfolutely determined. But, upon the whole, it is more reafonable to think, that the fame plan of formation is continued from the beginning, than that at any fubfequent period there is a change in that plan.

It may be obferved, that it is exactly the fame creative action which produces the natural ftructure, or any deviation from it; for in cafes of deviation, the action is either carried too far, ceafes too foon, or is diverted into uncommon channels. This will explain the various kinds of monftrofity from redundancy, deficiency, or transposition of parts.

THE END.

eit no bine b eithortsam retticht beteine ehung under beite

whole it is more realized to think, that the fame alon of formation
