IRIDIN, an oleo-resinous principle derived from Iris versicolor or blue flag, much used in America, and chiefly in diseases of the biliary organs. It possesses aperient, alterative, and diuretic properties, and is given in doses from one to five grains.

IRIS.—See EYE.
IRON, the well-known metal, is used as a medicinal agent in a great variety of preparations; it also forms one of the most common ingredients of mineral waters. tonic and strengthening properties of iron are well known, even popularly, and probably we have no remedy of the kind so generally useful and applicable in cases of debility; at the same time, it is not so much adapted for domestic use as many medicines of less value. The cases in which preparations of iron are most employed are not emergencies, they are usually constitutional affections of some standing, in which medical advice is not only requisite for the general treatment, but also as a guide for the administration of the iron, which, improperly given, may do much mis-thief. Persons who are habitually costive, who suffer from piles, or from determination of blood to the head, require to be specially careful with respect to the use of medicines containing iron, and should never take them without medical advice. The weak, the pallid, the delicate, may for the most part use them with greater safety, and very generally with benefit.

The tincture of the perchloride of iron, or, as it is called popularly, "tincture of steel," is one of the most generally used and useful preparations; in doses of from ten to thirty drops twice a day, in water, for an adult. It is not disagreeable, and children take it readily; the dose four or five drops to a child of six years of

of from half a grain to a grain dissolved in water, or made into pill with crumb of bread. The ammonio-tartrate of iron, the citrate, and the citrate of quinine and iron, are all useful preparations; the former is very soluble in water-dose, one, two, or three grains (see Citrates). Among other new preparations of iron, we may add the syrup of the phosphate of iron, a very serviceable compound, dose one or two tea-spoonfuls twice or thrice a day; wine of iron, a tea-spoonful to half an ounce, for a dose; the saccharine carbonate, and the arseniate of iron. The citrate of strychnia and iron is also a valuable preparation in atonic dyspepsia and in certain uterine derangements, dose five grains. For children, and, indeed, for some adults, a most excellent form for administering iron is in combination with potash liquor. For this the tartrate of iron is the most suitable. For a child of four years old, one scruple of tartarised iron, one drachm and a half of potash solution, and distilled water to make up to three ounces, forms a very suitable mixture, of which two tea-spoonfuls may be given in a small wine-glassful of milk twice a day. The above may be given even when the tongue is slightly furred; it has no unpleasant taste, and does not constipate.

The principal iron mineral waters, or, as they are usually called, chalybeate springs, in this country, are those of Tunbridge Wells, Harrogate, Isle of Wight, Holywell in Lancashire, Hartfell near Moffat, and Dunblane in Scotland.

When iron is really required by the constitution, it cannot probably be taken in any more beneficial form than that of a mineral water: at the same time, these natural sources of the medicine are open to the same objections and cautions as its artificial preparations, and many persons injure themselves by inconsiderately, and without advice, drinking these waters regularly, merely because they happen to be close to them for the time being. In mineral waters, iron is found in a state of great dilution, and the striking benefit which follows its use in this state in proper cases, justifies the fact that, when given artificially, it is found to be most serviceable in small doses in a considerable quantity of water.

Persons who are taking preparations of iron should pay extra attention to their teeth during the time, to prevent discolouration. evacuations from the bowels always assume a dark or black colour, during a course of iron, and particular attention is always required to keep the bowels in a perfectly open state during the continuance of the remedy. On this account the sulphate of iron is frequently combined with aloes, and administered in the form of pill.

dose four or five drops to a child of six years of age. This preparation is powerfully astringent, and in relaxation of the throat is extremely useful, applied by means of a camel hair brush. The common sulphate of iron, or green vitriol, attendants, but one for which every allowance

IRR ITC

and consideration ought to be made. Those | In the course of a few days the irritation ocwho have never suffered from the weakness of disease, especially such as affects or has affected the nervous system, cannot imagine in how many ways, which appear not only trifling, but absurd, to a person in health, the irritability of the invalid may be excited.

The term irritability is also used to express that property of muscular fibre, to which it owes

its powers of contraction.

**IRRITATION** may be defined as diseased excitement, not amounting to inflammation. Many of the diseases of children partake more of irritation than inflammation. What is called irritation of an organ may take place at a distance from the source of the irritation; thus, worms and other matters in the intestines may cause convulsive and other affections consequent upon irritation of the nervous system, or the irritation of the gums in teething may also cause convulsions, or spasmodic croup. The irritant action is in these cases in the first place felt by the brain, and thence reflected, so as to affect the muscles which are thrown into spasm.

Refer to—Convulsion.

ISINGLASS .- See GELATINE.

ISLE OF WIGHT.—The portion best adapted by shelter and situation for the residence of the invalid, is the Undercliff, of which Sir James Clark observes: "The continuous range of high hills which separates this district from the rest of the island, protects it most effectually from all northerly winds, while numerous short ridges, projecting from the main range towards the sea, break in a considerable measure the violence of the southwest winds.

"The defence afforded by this natural bulwark against northerly winds is, indeed, more perfect than anything of the kind with which

I am acquainted in England."

From the elevated position of the Undercliff fogs are rare, and less rain falls than in other parts of the island; and the soil being of sandstone and chalk, the ground speedily dries after rain has fallen. "The mildness and dryness of the climate during winter may be in some degree estimated by the circumstance of myrtles, geraniums, sweet-scented verbena, and various tender and green-house plants usually withstanding the winter in the open flower-

The Isle of Wight is undoubtedly suited to most of those cases where a mild winter resi-

dence is indicated.

ISSUE.—An issue is an artificial sore, from which a discharge of matter is kept up by artificial means; it may, therefore, be formed in various ways, such as burning with a red-hot iron, by caustics, by ointments, and a common form in popular use is the pea issue. made by pinching up a fold of the skin, and making an incision into it, which will admit the insertion of two or three peas, which are to be secured in the wound by adhesive plasters. | the consequence of dirt and uncleanness. It is

casioned by the peas causes discharge of matter; the peas are generally changed every day or two days, as long as the issue is desired to be kept open.

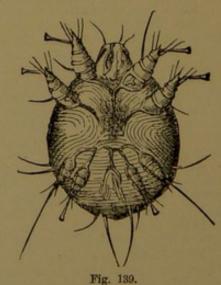

A very good issue may be formed by blistering the skin by means of one of the blistering tissues, and applying daily a piece of the same tissue to the sore, to keep up the irritation.

The seton is only another form of issue, made by passing a skein of silk through a fold in the skin, by means of a seton needle made for the purpose. Two or three threads soaked in blistering fluid and inserted through the skin placed behind the ear, form a convenient issue

in cases of eye or ear disease.

The principles on which issues, setons, and other means of counter-irritation are established, is that of producing derivative action, and to the article on that subject the reader is referred; also to Counter-irritation, Blister, dc. The strictest cleanliness must always be observed about an issue or seton, or any other discharging sore. It is perhaps superfluous to add, that an issue should never be made on a portion of the skin which is liable to be

ITCH, or Scabies. - This dreaded skin affection consists of an eruption of small pointed vesicles, which show themselves chiefly upon the wrists and between the fingers, but also at the bends of both the upper and lower extremities, the inner parts of the thighs and also upon the breech in children. attended with excessive itching, especially when the person affected gets warmer than usual, either in bed or after taking stimulating food or exercise. The itch attacks persons of all ages, of either sex, and is produced by an insect, the Acarus scabiei (fig. 139) which burrows under the cuticle where it deposits its eggs.

Unless caught accidentally by contact with the affected, the disease appears to be mainly

frequent among the poor, especially in those of bad constitution, who are also badly nourished and clothed, and it is apt to be mixed up with other eruptions, indicative of the im-

paired constitutional power.

Fortunately, the cure of this disagreeable affection is in almost all cases certain and quick; sulphur being the agent generally employed in the form of ointment, made by rubbing up one part of the common flowers of sulphur with four parts of lard. Before the application is used, the entire skin should be thoroughly washed with soap and water; the ointment must then be well rubbed in all over the body, and washed off again next morning; the person sleeping in a flannel dress, or between blankets, which in workhouses and hospitals are specially kept for itch cases. This process may be repeated two or three times if requisite. In persons of full habit of body, it is advisable for them to take an active purgative,

prior to using the sulphur ointment.

In a disease of so contagious a nature as itch, the utmost care is requisite in the avoidance, not only of contact with the person suffering, but with any article of dress, or otherwise, which he may have made use of; and when the person who has suffered is cured, it is requisite for him to exert equal care with respect to these things himself, until they have been purified, and disinfected. This may be done either by boiling water, by dry heat raised to a temperature of 200° Fahr., or by fumigation with sulphur—bearing in mind the effect of the latter agent in changing or discharging the colour of articles of furniture or If much irritation of the skin exists, it is admissible to employ a smaller amount of sulphur than that indicated above, which is the composition of the Pharmacopæial ointment, and to combine it with sub-carbonate of potash, in the proportion of one drachm of sulphur to halfa drachm of the latter, mixed with six ounces of lard. To avoid the dirty inconvenience of a greasy application, recourse is now often had to a lotion composed of sulphurated potash and water, or to a hot bath containing the same. The strength of the lotion should be two drachms of the sulphurate to a pint of water, and four ounces of the sulphurate will be found sufficient for a bath, with thirty gallons of water. The same precautions as to washing the body night and morning, with brown or soft soap and water, require to be observed with this treatment. When sulphur is used for the cure of itch, it may occasion some amount of irritation of the skin, which, being mistaken for the uncured disease, sometimes causes persons to go on rubbing long after the itch is cured, thereby keeping up unnecessary irritation and causing needless trouble and uneasiness. The itch mite, or acarus, as well as its ova, are commonly destroyed after the first or second application of the sulphur, but the eruption caused by its ravages may take a week to heal.

JALAP, so well-known as a purgative, is the root of a species of plant resembling a convolvulus, a native of South America, its name being derived from Jalapa, a town in Mexico, in the neighbourhood of which the drug is produced. Jalap is an active purgative, in dose of from ten to thirty grains, but with some persons it causes great nausea, and others it gripes severely. The best form for its administration is the compound powder, composed of jalap in powder five ounces, cream of tartar nine ounces, and ginger one ounce, well rubbed up together; the dose half a drachm to a drachm. There are purgatives more convenient for domestic use than jalap.

JAMES'S POWDER.—See ANTIMONY.

JAUNDICE is one of the secondary diseases, the result of a primary one. That is, some cause stops the flow of bile from the liver; and jaundice, which consists in the absorption

of the bile by the blood, is the effect.

This impediment to the flow of the bile may arise from whatever blocks up the canal of the gall-duct (see Gall-Bladder). The obstruction is mostly due to catarrh of the duct, secondary to catarrh of the stomach and duodenum; other causes are thickened bile and gall-stones in the interior of, and pressure by tumours Jaundice has someexterior to, the duct. times succeeded violent mental emotions. The presence of bile in the blood is quickly manifested by the colour of the skin, and also more particularly of the white of the eye; the shade of colour varying from the slightest perceptible tinge, to deep golden yellow, or even brown. At the same time, the stools become white and chalky-looking, and the urine—sometimes the perspiration—is deeply tinged with bile, the patient often describing it as like porter; the constitutional symptoms are generally those of disordered digestion, headache, and languor. For many reasons, jaundice is a disease which ought, when possible, to be under proper medical treatment, not so much from the danger of the affection itself, as from its being symptomatic of disorder elsewhere. Should gall-stone or spasm be the cause of jaundice, the case is generally plain (see Gall-stone), but should the presence of a tumour, or disease of the liver, be the origin, it requires medical examination for its elucidation.

The treatment of jaundice, which unprofessional persons may adopt in the absence of a medical man, is very simple: from five to eight grains of "grey powder" may be given at bedtime, either alone, or, if there is pain, made into pill with extract of henbane, and followed by a dose of castor oil or senna in the morning. When there is ruch acidity of the stomach, carbonate of soda may be given. A mild attack of jaundice will generally yield to an aperient like the compound rhubarb pill, taken every night for a few nights in succession. We also now possess most valuable aids in the treatment

364

of jaundice, in the comparatively recent medi- | affords almost immediate relief; and although cines, euonymin and iridin, which exert a most potent effect upon the liver functions. Moreover, in our native dandelion we have an agent capable of acting slowly but surely in the same direction. The writer has effected a complete cure of a case of jaundice of eighteen months' standing, which had resisted every form of treatment, by the free administration of a strong infusion of dandelion. The diet should be simple, devoid of milk, fat, or saccharine articles, whilst the jaundice exists, and all alcoholic stimulant avoided. Of course, when violent spasmodic pain indicates gall-stones, the measures recommended under the article on the subject must be adopted.

JELLY .- See COOKERY-GELATINE.

JELLY-FISH, STINGS OF THE. - The following interesting and instructive remarks of Dr. Greenhow, published in the British Medical Journal, may be of use to those who are fond of bathing, and who happen to be in

localities infested by jelly-fish:—
"Having formerly passed some years on the sea-coast, it used to happen that I was sometimes consulted by persons who had been stung whilst bathing, by some of the acalephæ, with which the ocean abounds at certain seasons. The immediate effect produced by touching the filaments of one of these creatures is a sensation of stinging, which extends up the affected limb for some distance from the point of contact. Presently the part becomes red, swollen, and tender; and occasionally, especially in young females and children, the entire limb, in the course of an hour or two, becomes much swollen, red, and exceedingly painful. The redness and swelling sometimes terminate in a well-defined border, resembling that of a wheal, but in other respects the ailment does not bear any resemblance to urticaria. These symptoms usually subside spontaneously, if allowed to do so, in the course of three or four days, but meanwhile they often cause considerable suffering, render the affected limb more or less useless, and, as they have a formidable appearance, often produce needless anxiety, especially to persons unacquainted with the nature of the Having previously found spirits of injury hartshorn, when applied early, a very effectual application for preventing the irritation caused by musquito bites, I was led to try an alkaline and stimulating lotion, consisting of a solution of bicarbonate of potash, sesquicarbonate of ammonia, and spirit of hartshorn, in these cases, with a most satisfactory result. I do not recollect the exact form of the lotion, but believe it consisted of one drachm of each of the salts, and half an ounce of spirits of hartshorn, to six ounces of camphor mixture. application, if freely used soon after the injury,

the benefit is more tardy if it be not applied until the effect of the injury has been thoroughly developed, yet even then its use rarely fails speedily to mitigate the suffering and swelling and to remove them almost entirely in the course of a few hours.'

JESUIT'S BARK .- See BARK.

JOINTS, -also called articulations. The joints, generally, from their mobility and exposed situation, are very liable both to accident and disease; in either case, much care on the part of the attendants, and much patience on that of the patient, is called for, as it need scarcely be remarked that the most perfect rest is, in most cases of disease affecting the joints, the essential, for which no other remedial measures will compensate. Serious disease of the bones and the other structures of a joint does not now, under the improvements of modern (and especially of antiseptic) surgery, necessitate the loss of the limb; the joint, such as the elbow, the hip, and the knee-may be excised or resected, and in the course of time, a tolerably useful member remains, a kind of new joint being formed. Apart from disease of the bones, the joints are liable to inflammation of the tissues which invest them, and especially of an important covering called the "synovial" membrane, which secretes a thick glairy fluid to lubricate the joint, as oil is used to make machinery work smoothly. Inflam-mation of this membrane is termed synovitis, and though common to all the joints it is most met with in the knee, and may arise from injury, cold, rheumatism, and many other causes. Like most membranous inflammations, it is accompanied by great pain, especially in movement, by swelling and tenderness, and some-times by fever of an aggravated type. When acute, much relief is obtained by the application of leeches to the part, followed by hot fomentations or bran poultices, and perfect rest; while, on the other hand, many surgeons pre-fer cold being applied to the joint in the form of ice bags, or of evaporating and spirit lotions. This refrigerating treatment is more applicable when the synovitis is due to injury of the Joints are also subject to scrofulous deposits in their tissues, causing pulpy degeneration and white swelling.

Refer to—Ankle—Dislocation—Hip—Knee -Skeleton, and the articles on various joints.

JOY .- This powerful and instantaneous mental emotion may act beneficially upon the body, but it may have an opposite effect. There are so many recorded instances, either of overturned reason, or of death resulting from excessive and sudden joy, that too great caution cannot be exerted in arousing it in persons of a nervous temperament, or in those who are debilitated by disease. Epilepsy has resulted

from sudden joy.

JUGULAR VEINS are the large veins which convey the blood from the head and

nal and internal.

Refer to-Neck-Veins, &c.

JULEP - an old name for mixtures in common use, such as Camphor Mixture-Mint

Water, &c.

JUNIPER .- The oil obtained from the fruit or berries of the common juniper, which grows in this country, is used either alone or more frequently in combination with other diuretic medicines for the various forms of dropsy. It is contained in Hollands and gin, which owe their diuretic properties partly to it. A spirit prepared from the oil, and which consists of forty-nine parts of rectified spirit to one part of oil, is introduced into the British pharmacopæia; dose of the spirit, thirty minims to one drachm; of the oil, two to ten minims.

KALI.—Potash.—See Potash.

KAMELA is a red powder scraped from the fruit of the Rottlera tinctoria, belonging to the same natural family as the castor oil plant. It is an excellent remedy for tapeworm, being almost, if not quite as efficacious as the oil of male fern, and having this advantage over it, that it is not so nauseous nor so apt to gripe or purge-dose, one drachm of the powder in treacle or orange electuary—taken fasting.

KIDNEY.—The kidneys, or glands whose office is the excretion of the urine from the blood, are situated on either side of the spine (fig. 140-1) in what is usually called the

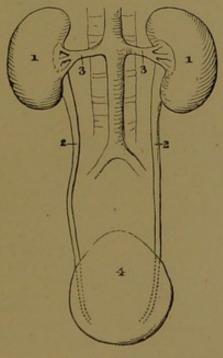

Fig. 140.

"small of the back," where they lie imbedded in fat. Each kidney is supplied with blood, by vessels (3, 3) which proceed direct from the aorta | previous to being collected into larger trunks

face, back to the heart. They are both exter- or main blood-vessel (see Aorta). From each kidney issues a duct (fig. 140-2, 2; 141-2) the ureter, which conveys the urine into the bladder (fig. 140-4). When cut open (fig. 141) the kidney presents, even to the naked eye, two very different structural arrangements; an outer one, granular looking, the "cortical" substance (fig. 141-5, 5), and an inner or

KID

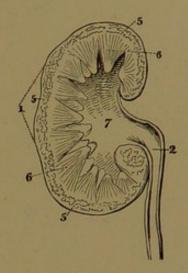

Fig. 141.

"tubular" structure (6), the latter being, as represented, arranged in pyramids or cones, with their bases situated upon the cortical substance and their points or apices, which are free, pointing inwards, and opening into a central cavity (7) the "pelvis" or basin of the kidney, which may be regarded as an expansion of the upper portion of the ureter (2). The entire kidney is enveloped by a sufficiently strong membrane or "capsule," and is lined by a smooth "mucous" membrane, continued into its cavity, by the ureter from the bladder. Those who are curious on the subject, may easily make out these particulars, by examining the kidneys of the sheep, which are about half the size of the human kidneys. When the minute structure of the kidney is microscopically examined, it is found to present a very beautiful arrangement. The tubular portion (6) is seen to consist of numbers of minute tubes about the diameter of a hair, and minute blood-vessels, placed side by side; these tubes, as they proceed towards the bases of the cone, or towards the cortical structure (5), become forked and twisted, and at last end in a minute globular expansion, in which the "capillary" or hair-like branches of the artery of the kidney are spread out in a kind of tuft. It is these globular expansions, each about the one-hundredth of an inch in diameter, which give this portion of the kidney its granular appearance. The minute blood-vessels, which had been spread out in a tuft, are again collected into one vein-and these minute veins are distributed amid the tubular structure,

KNE KIN

arrangement is this:-the urine is secreted from the blood, which is conveyed into the kidney by its own proper artery, the watery portion of the fluid being strained off, as it were, from the minute tutted vessels, described as being suspended inside the globular expansions. and the other constituents being separated by secreting cells from the blood, after it has been re-collected from these tufts, and as it passes among the tubular structure. The mingled watery and other constituents of the urine (see Urine) being thus separated from the blood, and united, pass down the straight tubes in the form of urine, which is discharged from the points of the cones (fig. 141-6) into the central cavity or pelvis (7) whence it is continually being drained off by the ureter (2) into the bladder (4). The ureter is about the diameter of a goose quill, is about eighteen inches long, passes behind the bladder, as represented by the dotted line (fig. 140), and enters that organ at its lower part.

The diseases of the kidneys could not be profitably entered into with unprofessional persons, and, when suspected, should, without delay, be submitted to proper medical care. In the meanwhile, should there be much pain in the back, the application of hot moist bran, or of heat and moisture in some way (see Heat) will be of service; a gentle aperient, such as castor oil, should be given, and also warm demulcent drinks and warm injections used. Should there be shivering and signs of fever, with much tenderness over the kidneys, and no medical advice at hand, a warm bath may be administered, or a few leeches applied and a dose of opium given. Renal calculus-either in one piece, or in grains-sometimes collects in the cavity (fig. 141-7), and causes pain in the back whilst it remains; when, however, it passes into the ureter (2), it causes extremely violent spasmodic pain, constituting what is usually called a "fit of the gravel."-See Urine

-Bright's Disease, &c. KING'S EVIL-a name for scrofula, which originated in the superstition that the disease was cured by the touch of a king. practice is said to have originated with Edward the Confessor, and it was continued down to

the time of Queen Anne.

KING'S YELLOW is a compound of

arsenic with sulphur. - See Arsenic.

KINO is the concrete juice of a tree, and is brought chiefly from the East Indies; it is an astringent closely resembling catechu, and is used for the same purposes. The tincture of kino is an excellent astringent. The powder of kino with opium contains one grain of opium inflammation generally. Blisters near the joint in twenty of the powder, and is a valuable should never be used in an early stage. preparation in certain cases of diarrhœa. - See

KNEE .- The knee is, perhaps, the most important joint in the body, and is certainly and degeneration of the joint tissues; this,

for the conveyance of the blood out of the | more liable to serious disease and injury than The object of all this elaborate other joints: it is formed of three bones (fig. 142), the extremity of the thigh bone or femur (1), the upper extremity of the larger leg bone

Fig. 142.

or tibia (2), and the knee-cap, or "patella," which lies on the fore part of the joint, but which is not shown in the figure. small bone of the leg, the fibula (4), does not enter into the construction of the joint. rounded ends of the thigh-bone rest in shallow excavations in the expanded broad head of the bone of the leg; the knee-cap protects the joint in front and enables the muscles of the thigh to act with more advantage and greater leverage in the movements of the leg; the entire joint being fitted and bound together by means of cartil-

ages and ligaments. - See Ligaments.

The knee-joint is liable to become the seat of inflammation, either acute or chronic, caused either by violence or wounds, or as the result of constitutional causes. In any case, the disease is of so serious a nature that it should as soon as possible be put under proper medical If the knee-joint has been opened into by a wound, the only course for an unprofessional person to pursue in the absence of a surgeon is to close it as quickly and effectually as possible (see Wounds), to put the joint in a state of the most perfect rest (which is best accomplished by a back splint secured by a loop of bandage placed above, and another below the knee), and to keep it cool with spirit lotion, ice bags, or cold water irrigation; the sufferer being put on low diet, and the bowels attended to. When inflammation of the kneeattended to. When inflammation of the knee-joint arises, either as the consequence of a wound, or from any other cause, very free leeching is requisite, along with fomentations and poultices, and the constitutional treatment of

White swelling of the knee, so dreaded popularly, consists of increased effusion of fluid into the joint, deposition of scrofulous matter,

LAR KOU

that they must be treated by the medical man. Till his aid is procured, the most perfect rest of the limb, the diminution of heat and swelling by cooling applications, the soothing of pain by warm fomentation or poultice, attention to the state of the bowels, and to the diet, is all that should be attempted. White swelling is connected with a weakened and scrofulous state of the constitution, consequently, all debilitating measures are, generally, to be avoided. The knee is sometimes the seat of a very unpleasant affection, termed "loose cartilage." which consists of a rounded gristle-like body lying loose within the joint, and which, from its mobility, is liable to be squeezed between the articulating surfaces of the bones, causes severe sickening pain, and may occasion the person to fall down when walking. The surgeon must

be applied to.

The knee-cap, from its exposed situation in front of the joint, is liable to various accidents, to fracture (see Patella), also to dislocation, being pushed to one side; it may be replaced, either by the knee being bent by a second individual, or by straightening the knee, and bending the thigh upon the body, so as to relax the muscles on the fore part of the thigh, within the tendons of which the knee-cap is situated. On the fore part of the knee-cap, between it and the skin, is placed a small "bursa" (see Bursa) which is liable to become inflamed in persons who have to kneel much on hard substances. The affection is called Housemaid's Knee, from its frequent occurrence in that class of servants, who kneel a good deal; it also occurs in thatchers, who press the knee upon the ladder when at work. Matter is liable to form in consequence of the inflammation, and in this case the treatment of abscess generally is requisite. If the disease be taken early, the knee should be rested, and the inflammation subdued by a few leeches and fomentations, &c.; a blister will frequently remove the swelling, or it may be painted over with tincture of iodine, once daily, for some time. Occasionally it remains in spite of treatment, and ultimately disappears of itself.

Refer to Leg—Patella—Housemaid's Knee.

KOUMISS—is the product of the natural fermentation of mare's milk, and has been used for ages by the natives of Tartary as an article of fluid food. It has latterly come into much favour in this country, as a nutritive remedy in cases of obstinate vomiting, attended with debility and emaciation. It is now prepared from cow's milk, and is a highly refreshing, agreeable, and valuable beverage.—See

KOUSSO or CUSSO-a remedy for tapeworm, is the product of a plant brought from Abyssinia. In two cases—which had resisted

however, and other chronic diseases of the kousso perfectly successful. At the same time, knee, require so much educated skill and care the oil from the root of the male fern, found so abundantly in this country, is equally successful, and more extensively employed as a worm

The preparation of kousso admitted to the British pharmacopæia is the infusion, which is made from the powdered flowers and tops of the plant, in the proportion of quarter of an ounce to four ounces of boiling water, and used without straining. Of the powder half an ounce may be taken on an empty stomach; and from four to eight ounces of the infusion, including the flowers, may be administered in a similar way. It is usually necessary to follow up the action of the kousso, by administering castor oil or other purgative to bring away the worms.

Kousso is now much reduced from the very

high price at which it was first sold.

LABOUR.—See CHILD-BIRTH.

LABURNUM .- The seeds, and also the bark of the common laburnum, are highly poisonous, and a few cases have occurred in which children have been seriously affected in consequence of their eating the former. Vomiting, with delirium, stupor, giddiness, pain in the head, pain in the stomach, and collapse are the consequences. Treatment similar to that recommended under Belladonna should be resorted to, and medical assistance procured without delay

LACERATION.—See WOUNDS. LACTATION.—The secretion of milk. LACTEAL.—See ABSORBENTS — DIGES-

LACTUCA.—See LETTUCE.

LAMB-like other "young meats," is not so desirable for invalids as mutton.

LAMENESS .- See ANKLE-DEFORMITY,

LANCET.—See BLOOD-LETTING.

LANGUOR is a very general symptom of disease, and may be either of a true or false character; it is sufficiently treated of under the head of "Debility."

LARCH, TINCTURE OF, has been prescribed by some in the treatment of hæmorrhage from the lungs. It has also been used in cases of chronic bronchitis. The dose of the tincture is from twenty drops to one drachm three times

LARD.—The fat of the hog, deprived of its connective membrane and purified by heat, besides being employed for culinary purposes, is largely used as a basis for ointments and liniments. From the extensive way in which pork is raised in America, our chief supply of lard is obtained from that country. It is said to be sometimes fraudulently mixed with beef or mutton fat, a fact difficult to determine, but all previous treatment—the author found the also doubtful, as the cost of the adulteration

368

LAR LAR

would exceed the value of the native product. | tions for the use of the instrument are given, Some ointments, formerly prepared with lard, are now recommended to be made with vaseline or lanolin.

LARYNGITIS, or inflammation of the lining membrane of the larynx, is caused by exposure to cold and wet, or by inhaling chlorine or other irritating gases. It is also occasioned by misadventure among children, by their attempting to drink boiling water from the spout of a tea kettle. In some respects, the disease resembles croup or diphtheria; but may be distinguished from either of these complaints by the cause which produced it, by the absence of the false membrane at the back of the throat, and by its limitation to the upper part of the windpipe. The symptoms are, great hoarseness and difficulty of breathing (caused by the swollen state of the glottis, amounting to a sense of imminent suffocation), lividity of the lips and pallor of the countenance, combined with an irregular and feeble pulse. In numerous cases, unless relieved by an operation (tracheotomy) which permits breathing to be carried on independent of the larynx, death is liable to ensue. All that the unprofessional can attempt to do in laryngitis is to advise

steaming of the throat

LARYNGOSCOPE.—This is an instrument used, as its name indicates, for the purpose of examining the interior of the larynx. Its introduction has added so much to our knowledge of the diseases of the throat and windpipe, that several new affections of these parts are now described in medical works for the first time. A description of these diseases, and of their recognition and treatment, would be unintelligible and uninteresting to the general reader; at the same time, it is satisfactory to know that many cases of marvellous success are now on record which could neither have been recognised nor treated without the wonderful instrument, which may truly be said to have enabled the "dumb to speak and the deaf to hear." The instrument has been of the greatest service in investigating affections of the voice in speaking and singing, such as morbid growths, cancer, warts, and other complaints of the larynx, as well as all deformities of and injuries to that organ and the throat generally, together with diseases of the nose, mouth, and windpipe. It has also enabled medical men to ascertain the presence of, and to extract foreign bodies, which have accidentally found their way into the larynx, and become lodged there.

The first idea of a laryngoscope seems to have emanated from the mind of our countryman, Dr. Benjamin Babington, as early as the year 1829, for he then submitted to the Hunterian Medical Society "an ingenious instrument for the examination of parts within the fauces, not admitting of inspection by the unaided sight." It consisted of an oblong piece of looking glass, are the best. The drawing shows the set in silver wire, with a long shank. Direction which the apparatus is employed.

and in the course of his remarks he says: "A strong light is required, and the instrument should be dipped in water so as to have a film of the liquid upon it when used, or the halitus of the breath renders it cloudy." The doctor proposed to call it the "glottiscope."

Afterwards the same idea was more or less carried into practice by several medical men both in this country and on the Continent. For instance, Professor Liston was in the habit of using an instrument of a similar kind to that above mentioned in examining the throat, as was also Dr. Warden, of Edinburgh. The chief merit, however, of introducing the laryngoscope in its present improved form into medical practice belongs to Professors Turck, of Vienna, and Czermak, of Prague; and certainly the highest praise is due to the latter of these gentlemen for the untiring perseverance with which he continued his efforts to perfect the instrument, and to make its use generally known and understood throughout Europe. Dr. Czermak visited this country in 1860, and was kind enough, personally, to instruct his professional brethren in the manipulation of an instrument, to the working of which he had himself devoted so much attention, and which, though still further improved and simplified from the suggestions and experience of others, has since become associated with his name as one of the most valuable aids to medical practitioners in the investigation of disease.

The laryngoscope consists of a little mirror fixed into a long handle. Before it is introduced into the mouth it should be warmed in hot water. Whilst this is employed, the throat is at the same time illuminated by means of a round mirror worn upon the forehead, so as to leave the hands of the examiner free. This is arranged with an elastic band, so that it can be adjusted to any position.

The patient or person to be examined is seated on a chair at one side of a table on which there is a good lamp. If the latter is furnished with a reflector, so much the better, or if good sunlight can be had, nothing does so well. The little mirror (previously warmed) is then introduced to the back of the throat, while a strong light is thrown upon it from the mirror upon the examiner's forehead (fig. 143). In this way, by a medical man, who has through practice acquired facility and dexterity in the use of the instrument, the mechanism of the human voice in health or disease may be studied, while, at the same time, disease, if present, can be readily detected, and the fitting remedy applied. For the latter purpose numerous new instruments have been invented for the removal of growths, and the application of medicaments of one sort and another. Of these it may be said that they are unnecessarily complex, and that the simplest are the best. The drawing shows the manner

LAR LAU

The above remarks may appear to many quite unsuitable for the general reader; still it may not be uninteresting even to him to know that medical science is every day progressing, and bringing many of its practical applications to the relief of human suffering and disease, and that of late years nothing has thrown more light upon matters hitherto obscure than this new instrument has upon diseases of the throat-a class of diseases, the importance of which can scarcely be exaggerated, when it is remembered that the loss of voice to many involves a loss not only of the enjoyment but of the means of maintaining existence.

As an illustration of the practical advantages to be derived from the use of this instrument,

the following case, one among many, may be cited. A young man had suffered for several months from gradual loss of voice, hoarseness, and occasional choking fits at night, so severe as even to threaten his life. His medical adviser attributed all these symptoms to chronic inflammation of the larynx, and treated him accordingly, but without the slightest effect in relieving his sufferings, which grew worse day by day. His general health also was much enfeebled, owing to the severe course of treatment to which he had been subjected. At this time he sought the advice of a gentleman, who examined his throat by means of the laryngoscope, and immediately detected a small polypus, or tumour, hanging by a narrow

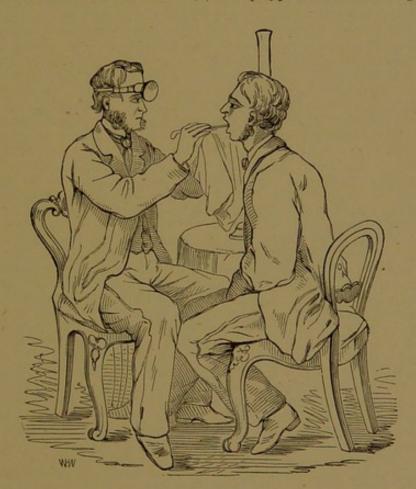

Fig. 143.

neck or pedicle in the air-passage, just at the | ful examination of the patient's larynx shows most important point where the mechanism of the voice is situated, or, in medical language, between the vocal cords. This polypus was at once seized with a pair of forceps, and extracted, with immediate relief to all the distressing symptoms of the patient, and the complete restoration of his voice.

Many affections of the voice in females are well known to be dependent entirely upon a hysterical condition, and when a medical man

him the absence of any morbid condition, and he at once concludes that the symptoms are entirely due to derangement of the nervous power governing the movements of the muscles. and vocal cords.

serious consequences; the fit of laughter might | work with lead or its preparations, are peculiarly pass into one of convulsions in a predisposed constitution; or in a child. The practice of tickling children, and thus keeping them in a state of laughter for some time, is strongly to be condemned, and may be attended with some mischief.

Refer to-Convulsion.

LAUREL.—The common laurel, more particularly its young shoots and leaves, contains a considerable proportion of prussic acid, and a few cases of poisoning have occurred by the use of the water distilled from the leaves. The practice of using laurel leaves in confectionery for the sake of the flavour is not to be recommended.

LAVEMENT.—A clyster.—See Enema. LAXATIVE.—See PURGATIVE.

LEAD .- This metal is of importance in a medical point of view, both on account of its medicinal and of its poisonous properties.

Of its various medicinal preparations, it will be sufficient here to notice three—the acetate, or sugar of lead; the solution of subacetate of lead, or Goulard's extract; and the lead plaster The acetate of lead is used both externally and internally. In the former case, in the pro-portion of from one to five or six grains to the ounce of distilled, or rain water, it forms one of the best cooling lotions; it may be used slightly warm, either alone or with the addition of one or two drachms of laudanum to the half pint of water. A weaker solution of sugar of lead, one or two grains to the ounce, is often used as an eye-wash, but is not preferable to zinc. Internally, sugar of lead acts powerfully as an astringent, and may be given in doses of from two to four grains, once in eight hours, in cases of emergency, by the unprofessional. It is generally made into pill with crumb of bread; often, quarter of a grain of opium is combined with it, and it is advisable to wash the dose down with a draught of weak vinegar and water. The few cases, such as hæmorrhage, in which, in the absence of all medical assistance, sugar of lead may be given domestically, are particularly noted when treated of in this work.

The solution of lead, Liquor plumbi subacetatis, is used as a lotion in the proportion of one teaspoonful to half a pint of boiled water or milk. It should not be applied to large raw surfaces, on account of the risk of absorption

and consequent lead poisoning.

Lead plaster is the most unirritating form of plaster we possess, and as such it is used as the basis for several other kinds, as the mercurial, iron, galbanum, and soap plasters. It is pre-ferable to diachylon on irritable skins: it is also one of the best applications in abrasions and bed-sores. Lead, when conveyed into the system in minute doses for any length of time, occasions serious constitutional effects, the most remarkable being palsy, and obstinate constipation, with colic (see Colic). Persons such as painters, type-founders, &c. (see Artisan), who the sulphates.

liable to be thus affected by it. The subject is sufficiently entered into in the articles above mentioned. Another very fertile source, however, of the introduction of lead into the system (in individual minute doses, but ultimately, by the accumulation of these, in poisonous quantity), is from the pipes in which water is conveyed for household purposes. This is especially the case when soft waters are conveyed through new leaden cisterns and pipes. Before using water of this character, it is well to empty the pipes of the water which may have remained

in them over night. - See Water.

The common use of lead or its preparations in the arts, either legitimately or fraudulently, is not an unfrequent cause of disagreeable, sometimes of fatal, attacks of illness, in consequence of the metal finding its way into the body. The use of lead as a glaze to earthenware vessels may prove a source of great injury, being liable to be dissolved off, especially when the vessels are new, either by fatty or acid matters (see Confectionery is sometimes col-Dripping). oured with the yellow chromate of lead, or with Turner's yellow or chloride of lead; or whitened by the most poisonous preparation of all, the carbonate of lead. Wine when sour has been sweetened by the use of litharge, or oxide of lead, and in consequence of this fraud, a fatal epidemic of colic at one time prevailed in Paris. Wine is also sometimes accidentally impregnated with lead, in consequence of shot, which had been used to clean bottles, having been left in them. Poisoning has occurred from this cause. New rum and cider are both apt to become impregnated with lead in the manufacture. Symptoms of colic have been brought on in persons living much in a room newly painted with lead colours. The white glazed cards are made so by means of lead, and might injure children, who are apt to suck them at times if they come in their way. Many of the hair dyes contain lead, and have caused injury. Putty used by glaziers, and putty powder employed extensively in glass works for the polishing of glass, is a fertile source of lead poisoning.

When lead is introduced into the system in

minute quantities, as in the cases above mentioned, the symptoms are generally those described under Colic; but when the dose is large, it quickly brings on painful colic, vomiting, and extreme depression. In such cases, the best measures to be pursued until medical assistance can be procured, would be the administration of vinegar in the first place, and in six or eight minutes after, an emetic of half a drachm to a drachm of sulphate of zinc; or some other sulphate, such as Epsom salts or Glauber salts, in quantity proportionate to the lead swallowed. The vinegar in the first place converts the lead into one of its least poisonous salts, and the one most easily decomposed by

LEE

The accumulation of lead poison in the system is in most cases denoted by the existence of a bluish line along the margin of the gums, at their junction with the teeth. This symptom should always be looked for when any suspicion exists. Lead paralysis and dropped-wrist originate from the same cause.

					Cubic inches.
Carbonic	acid,				2.103
Azote,					0.537
Oxygen,					0.075
					2:715

Containing thus a moderate quantity of chlorides and sulphates, the mineral springs of Learnington may be recommended for the same complaints as the Cheltenham waters, particularly stomach derangement without inflammatory complication, hepatic obstruction, acne, and other eruptions about the face, as also in chronic gouty cases, especially when constipation of the bowels co-exists.'

LEECH .- The general appearance of the leech it is unnecessary to describe, the soft, ringed body being common to all the tribe.
Two species only, however, are recognised in this country as fit for medical purposes; these are each distinguished by six greenish-yellow chain-like stripes disposed down the length of the animal on the back and sides, the belly being, in the one, dirty yellow spotted with black, in the other, greenish olive and unspotted. The former of these species of leech, is found sparingly in this country, but occurs throughout northern and central Europe.

Leeches fit for medical purposes abound in India and in many eastern countries. Many of those now used in this country are brought from Hamburg, where they are collected by the merchants from different parts of the Continent. The former of the two species mentioned, that with the spotted belly, and often known as the "brown leech," belongs to northern Europe, the other, unspotted, or the "green leech," is a native of the south of Europe.

The narrower extremity of the leech (fig. 144-1) is the sucking mouth, the broader is simply provided with a sucker (2) by means of which the animal attaches itself to any substance. The mouth is furnished with three "mandibles" (3), the edges of which are set with minute teeth, by means of which the animal perforates the skin by a sawing action, after it has been sucked up. The mandibles also, probably, keep the edges of the wound asunder, and form a sort of tube through which the blood passes. The invaluable properties of the leech as a local abstracter of blood are sufficiently well-known; at the same time, these are often, in a measure, neutralised, by unskilful and ignorant management in application. When leeches are required, it is always better to be provided with more than the number thought requisite, in case, as often occurs, some cannot be made to fasten. When persons can choose their own leeches, the readiest mode of selection is, to take a number up in the hand, and gently to close it upon them, the strongest and most vigorous of the animals will contract themselves into a tolerably firm ball; the same may

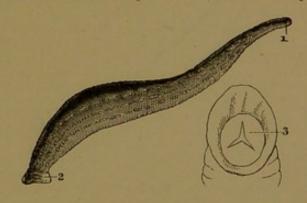

Fig. 144.

be done just previous to application. Some persons recommend leeches to be removed from the water in which they are kept, about an hour before they are wanted, being in the meanwhile laid upon a towel. The part to which leeches are to be applied, must previously be thoroughly cleansed with warm water, and when they are put on by the order of a medical man, it is, in many cases, better to have the space within which they are to be fixed, marked out with ink. Many methods of applying leeches are recommended, but none, perhaps, is so generally applicable, as confining them within the proper space, by means of an inverted wine glass; in situations where this cannot be done, they may be put on individually by hand, holding each one by the larger end by means of a piece of cloth, till it has fastened. In some situations, such as the interior of the mouth, a leech glass (fig. 145), made to enclose a single leech, is convenient. When leeches have fastened, they should be allowed to suck perfectly undisturbed, resting on the smooth skin, or some smooth surface; if they

LEE LEE

hang down upon hair, or any rough material, | thread (fig. 146), will stop further loss of blood; they are apt to get fidgetty, and to drop off too at the same time, the author must add that he soon. After leeches have come off, it is in most cases desirable to encourage further flow of blood, and for this purpose, hot fomentations or poultices of bread or bran are most useful; in situations and circumstances where the moisture is objectionable, pieces of soft linen or calico, made quite hot, will answer very well, applied, folded two or three times, upon the place. In children, and some persons who bleed freely, but little encouragement is required, the difficulty often being to stop the flow of blood.

The possibility of this occurrence should always be kept in mind when leeches are applied to such persons, and, as a rule, they ought always to be placed if possible over a bone against which pressure can be made, and never, unless for some very cogent reason, upon such places as the neck or abdomen; most of the

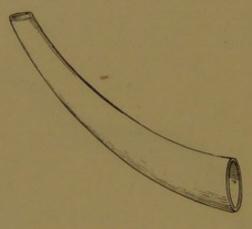

Fig. 145.

cases of fatal bleeding from leech-bites in children have probably occurred from want of attention to the above precautions.

When bleeding from leech-bites continues longer than is thought necessary, it may generally be stopped by introducing a minute piece of cotton wool into the wound, or placing a small pad of folded lint over it, and keeping up pressure with the finger for some time, provided there is the bone underneath to press against, and, if not, the compress may be secured by means of a bandage, and when the bleeding seems to be arrested, the little pad may be kept in its place by one or two strips of adhesive plaster. If the simple pad appears insufficient, it may be soaked in a strong solution of alum. Even should there be no bone underneath against which pressure can be made, the above plan may succeed, but it may not, and in such cases it is often recommended to pass a pointed piece of caustic into the wound; but this is not a very efficient plan, and the pain it causes, by making a child cry, increases the tendency to the flow of blood. In an extreme case, a sewing needle passed through the wound from side to side, and wrapped about with a for a quarter of an hour in water-temperature

never found a case resist pressure well and carefully used. Such cases ought, of course, to be attended to by a medical man, if possible; but at a distance in the country, it would be better for a mother to use the remedies stated, than to let her child bleed to death. Any other astringent remedies may, of course, be tried, if they are procurable (see Astringents and Styptics). A wire or skewer, heated to a white heat, has been employed for the purpose, by being passed into the wound.

It ought further to be remembered, that even after leech-bites have ceased to bleed in children, they may, especially under the influence of warmth, burst out again; and fatal consequences have ensued from children being placed in bed after leeching, and not looked at during the night; they have become completely drained of blood. On this account it is always desirable, when it can be done, that leeches should be put upon children in the fore part of the day, and also, that examination should be made from time to time after the operation is over, to see that all is right: if it

Fig. 146.

is night, a light should be burned in the room. It is not only the immediate consequence of excessive bleeding which is to be dreaded, but the unnecessary loss may make all the difference between a child's struggling through an illness or not.—See Blood and Hæmorrhage.

In a few individuals, the application of leeches is apt to be followed by inflammatory swelling of the skin, resembling erysipelas; of course this is an obstacle to their use on slight occasions; the swelling may be subdued by the lead lotion, cold or warm, as most agreeable to the feeling of the patient.

There is often considerable difficulty in getting leeches to fix where and when they are wanted; this may arise from various causes, the leeches may be sickly, or torpid from cold, or may have been recently used, or, as they are rather sensitive, the skin may be unclean, either from its own natural excretions, or from applications, such as embrocations, &c., which have been used to it. It is vain to attempt to apply leeches if this is the case; the skin, therefore, must be made thoroughly clean, and if there is hair on the spot, it must be shaved off clean and smooth; as a further inducement, a little cream, sugar and water, or blood, may be put on the skin. If cold is thought to have rendered the leeches inactive, their immersion 706—will be the best remedy; the addition of the bottom, and containing water, with two a couple of table-spoonfuls of porter to the half-pint of water will not unfrequently make them and to change the liquid daily till the fourth

more lively.

If it is wished to detach a leech before it has finished sucking, it must not be pulled off; a few grains of common salt sprinkled on its head, will cause it to drop off very quickly. When leeches come off, it is the common practice to put them upon a plate of salt, which makes them disgorge the blood they have sucked; this is better done by putting them into a little, not very strong, salt water, which is equally effectual, but does not injure them as the salt in substance is apt to do. After the greater amount of blood has been thrown up under the influence of the salt, the leech should then be "stripped," that is, its tail end being held firmly between the thumb and finger of the left hand, the animal is to be drawn between the thumb and finger of the right, nearly to the head; by this means it is freed from the blood, and is sooner fit for use. Blood which has been drawn by leeches, affords no guide to a medical man like that taken by the lancet; it therefore need not, as is often done, be kept for his inspection. After the leeches have been stripped, they should be put into some fresh water, which will require changing twice a day for the first two or three days, afterwards, only every four or five days.

The great expense of leeches renders it important that the best means of preserving them, and of rendering them, if possible, again quickly ready for use, should be known.

They are best kept in good-sized wide-mouthed jars or bottles, half filled with rain or pure spring water, or, what is better, in small aquaria in which there are river weeds growing, and having at the bottom a little clean sand or gravel on which the creatures can rub themselves, and so clear the skin of the slime which naturally covers it, but which they cannot get quit of in a vessel with smooth surfaces. The temperature of the water in which leeches are kept should never get below 50° Fahr.; if kept in a bottle the water should be changed every ten days or oftener, and the place in which they are kept must be airy and free from strong odours. Of course dead or sickly leeches should be removed at once from the healthy ones.

It has been stated that leeches which have been used, may be rendered in a few days as active and useful as ever, by dissolving a little white sugar in the water, and renewing this solution twice at intervals of twelve hours, and twice afterwards at intervals of a day. Dr. Christison says: "I have tried this plan, and found that the same leeches drew blood three times at intervals of three days, with scarcely any diminution of activity, and without a death among them." Another method recommended is—after stripping—"to put them into a vessel with half an inch of sand at

tea-spoonfuls per quart of French white wine; and to change the liquid daily till the fourth day, when pure water is to be substituted." With respect to the choosing of leeches, the following remarks of Dr. Christison are important: -"The gorging of leeches is a more common fraud than the substitution of spurious species. they are known by being less velvety in their coat, less flat when pressed, and by presenting a little tumour when squeezed between the fingers from the head to the tail. Leeches which have been used are often sold for unused, or 'virgin' leeches. These are best known by putting them on a white cloth, and dusting their fore-part with finely-powdered salt. In thirty seconds a little blood will be emitted, but not a particle, if the leech be quite fresh.

The greatest inconvenience connected with leeching, even when well managed, is the uncertainty of the amount of blood taken; but generally it may be calculated, that the application of a good leech should, on the average, including what the animal itself draws, and what flows afterwards, amount to about

half an ounce.

To remedy much of the inconvenience connected with the application of leeches, many attempts to make an artificial substitute have been made, but none have as yet been fully

successful.

In recent years the use of leeches has become very restricted; they are probably chiefly of value for the relief of pain. Nothing relieves the pain of a severe sprain so quickly as the application of six or eight leeches; and in acute inflammation of the tympanum of the ear and of the iris of the eye, both very painful affections, the employment of one or two leeches is often most efficacious. At the commencement of acute pleurisy they are also sometimes of great value.

Leeches accidently swallowed may be killed

by drinking strong salt water.

LEEK, as an article of diet, does not generally agree with persons of weak digestion. It is most wholesome when blanched like celery, and stewed.

The vapour from boiling water poured over leeks is sometimes used as a popular remedy in piles. The leeks are cut up, and put in the pan of a night-chair, or in a chamber utensil,

on which the person sits.

**LEG**, The,—the portion of the inferior extremity between the knee and the ankle,—is formed of two bones (fig. 147). The larger or main bone of the leg (1) is named the tibia; the smaller or splint bone (2) the fibula. The upper broad portion of the tibia (3) forms part of the knee-joint (see *Knee*), but the fibula does not; at the lower end of the leg, however, both bones are required in the formation of the ankle-joint (see *Ankle*). These bones may be broken together or separately; tracture more generally occurs below their middle than above.

Refer to-Fracture.

LET LEG

times named, or Phlegmasia dolens, is one of the most troublesome of the disorders which are apt to follow child-birth. It is also met with occasionally as a sequence of typhoid fever, of pleurisy, and of some other maladies. The immediate cause of the disease is somewhat uncertain. The symptoms of swelled leg may commence within the first two or three days after delivery, or may be delayed for some weeks. There is more or less fever, and the parts about the groin and thigh feel hot, stiff, and painful, swelling commences, and extends over the whole limb, which sometimes often increases to twice its normal size. The skin assumes a pale white colour, is shining and tense, and does not pit on pressure; at this time the pain

Fig. 147.

is often very severe. After a time, these symptoms are ameliorated; but the limb remains a long time swollen, painful, and comparatively

The above, it need scarcely be remarked, is a disease which requires proper medical assistance as soon as possible; in the meantime absolute rest in bed must be enjoined, as great danger is otherwise liable to follow. Leeches, fomentations, and poultices to the parts about the groin and thigh, will be at once the best and the most soothing treatment, the bowels being regulated either by mild aperients or enemas, and opium given, if the pain becomes severe: for this purpose ten grains of Dover's powder, with two of calomel, may be given at bedtime. Continued friction with simple oil is of much service in aiding the final removal of the swelling. During conval-escence, bandaging, friction, the salt water douche, and strengthening remedies and diet will be requisite; but these must be left to the regulation of the medical attendant.

LEMON .- This well-known fruit, and sick-

LEG, SWELLED, or white-leg, as it is some- | room luxury, is cultivated chiefly in southern France, in Italy, Sicily, Spain, &c. The best lemons are smooth on the skin, and have a thin rind; if packed in newly-slaked lime in closed vessels, lemons may be preserved good for a considerable time. The rind of the lemon, and the agreeable essential oil derived from it, are chiefly used in cookery and confectionery. The juice of the fruit, which owes its acidity to citric acid, is used as the most agreeable medium for the formation of effervescing draughts; the proportionate quantity required to be used with alkaline carbonates will be found under article Effervescing. Its use in the formation of lemonade is familiar to all (see Cookery for the Sick). The chief direct medicinal use of lemon juice is in the treatment of scurv (see Scurvy), but it has also been introduced by Dr. Owen Rees as a remedy in rheumatic fever, and there are many testimonies to its value in this painful, and often tedious affection. The author has reason, from his own experience, to speak favourably of its remedial power in the above painful disease. Lemon juice is not only a curative medicine in scurvy, but it is also a preventive; and it should, therefore, form part of the "sea-store" of all who are going a long sea voyage. The juice may be procured at a moderate price from confectioners in large towns. The best method of preparing it for keeping, is to add about one-tenth of spirits of wine, and to separate, by straining, the jelly-like matter which coagulates in consequence, and then bottle for use. "Salt of lemon," which is sold for removing the stains of ink or iron, is no preparation of lemon at all, but is a salt of oxalic acid: the name might lead to serious mistakes

LENS.—Crystal lens.—See Eye.

LENTILS belong to the pea tribe, and are used as food. The Egyptian lentil, known, when in the form of meal, as the revalenta, or revalenta Arabica, is not only nutritious, but possesses aperient properties, which render it, in some cases, a valuable auxiliary to treatment if it agrees with the stomach. Lentil meal made into soup is coming much into use as an article of food. It is very nourishing, and contains, like the meal from the seeds of other leguminous plants, peas, beans, &c., a much larger proportion of albuminoids, or flesh-forming substances, than meal made from the

LEPROSY .- See Skin, Diseases of.

LETHARGY—an unnatural tendency to sleep, is closely connected, as to cause, with languor and debility, and approaches apoplexy in character. It may arise from the opposite causes of over-fulness of blood, or from deficiency of circulation in the brain, from nervous exhaustion of that organ, or from actual disease in it, such as tumour or abscess. The lethargic state may also arise from an impure or poisoned state of the circulating fluid, such as precedes an attack of British or bilious cholera, or

LIF LET

sion of urine. It may also, of course, be the result of the action of narcotic drugs, or of alcoholic intoxication. These latter contingencies should be kept in mind in the event of lethargy coming on suddenly; in such a case, the treatment, with precautions, recommended under article Apoplexy should be adopted modified, of course, in some degree, on account of the milder character of the disorder. In the aged, especially, lethargy is always to be regarded with suspicion; but in any case, the cause should be investigated by a medical man as soon as may be.

Refer to—Apoplexy—Biliary Disorder—De-

bility—Languer—Paralysis, &c.

LETTUCE.—Two kinds of lettuce are used, the common garden or edible lettuce, and the stronger or medicinal lettuce. The botanical name of lettuce, lactuca, from lac, milk, is given on account of the milky juice which exudes from the plant when cut: this milky juice turns brown, and dries on exposure to the air, and is then called lactucarium, or "lettuce opium," from its narcotic properties, in some degree resembling those of opium. The milkiness of the juice of the lettuce, and its narcotic properties, are not fully developed until the period of flowering approaches; the plant, however, possesses them more or less at all stages of growth.

As an article of diet, lettuce is in very general use, and with most persons, agrees well, though some find it, in common with uncooked vegetables generally, disorder digestion; others find its narcotic properties—even in its mildest condition - inconvenient. Lettuce eaten at night has been had recourse to successfully, among others, by the celebrated anatomist

Galen, as an antidote to sleeplessness.

Extract of lettuce, or lactucarium, or lettuce opium, might be used in doses of from ten to fifteen grains, as a substitute for opium, with this advantage, that it does not confine the bowels: it is not, however, so certain in its action, and is now omitted from the pharma-

LEUCORRHŒA.—See WHITES.

LICE.—See PEDICULI.

LICHEN.—See SKIN, DISEASES OF. LICHEN ISLANDICUS.—See ICELAND

LIFE.—The word, here, is simply taken in its one sense of man's actual material existence in this world: that existence, which, however it may be regarded as but the prelude of another and more perfect state, all persons of healthy mind have an instinctive desire to preserveinstinctive, truly, it may be called at the present day; for the feeling with a large-a very large-class, seems to rise no higher. It seems to protect from immediate, urgent, threatened danger, but beyond that it appears not to go; and life is yearly, daily, hourly

diarrhea, or may be a consequence of suppres- | are perfectly under man's own control to prevent-by causes which it is utterly unworthy of intelligent and responsible beings should continue, or be allowed to continue, in operation amongst them. It is sufficient confirmation to reiterate the fact, that fever carries off yearly in Britain a larger number of victims than would fall in the course of a serious campaign; and that one-fourth of the children die before they reach the age of five years. As these tiny victims have been well called "drooping buds," they languish and die in the unwholesome dwellings of city, town, and village. And this need not be; for, fearful as the loss of life now is, it is less considerably than it was a hundred, fifty, or even twenty years ago; and might be much lessened still. It is enough to refer the reader to the case of the Dublin lying-in-hospital, mentioned under article Childhood, to demonstrate how quickly-how remarkably-the value of life may be increased by a few well-directed and comparatively simple measures. The whole science of medicine, surgery, the efforts of hygiene, sanitary precautions, even the object of such a work as the present, is the preservation and prolongation of human life; and that it is not preserved nor prolonged to a much greater extent than it now is, cannot be for want of knowledge, among Parliamentary commissions and all classes. "blue books," boards of health and sanitary cordons of all kinds, have diffused-or ought to have-information respecting those sources from which the curtailment of life arises; but indifference, self-interest, prejudice, all interfere, and the exertions of those entrusted with the good work are often frustrated by the apathy and even the opposition of those whom it directly concerns. At the same time, it is not the part of the people to wait till these things are wholly done for them; it may be, that the principles of a true political economy render the preservation of every man's life in the state, a duty, and a direct advantage to the community; but the individual must in the matter act for himself as far as lies in his power. The preservation and prolongation of life can never be simply a selfish consideration; man does not live for himself But if none can doubt that the duration and value of life might be extended far beyond what it now is, it is equally certain that it is much greater than it was formerly. A glance at the past in this respect may give hints for the future. One great cause for the short duration of human life among a barbarous or semi-civilised people, is the little value set upon it; hence it is sacrificed for the most trivial reasons-and, from the destruction of the weakly or unwished-for infant, so common, not only amid a savage people, but even among the comparatively civilised Chinese, to the abandonment of the aged parent on the prairie, by the North American Indian, or the destruction sacrificed in this country, by causes which of adults in public war or private quarrel, amid

LIF LIF

these nations generally-all tend to shorten | poor-rates-has to support more unproductive human life. True, the wars and revolutions of civilised nations even in Europe, cost many useful lives, but their occasional occurrence is not marked like the regular systematic cutting short of life in all its stages, which unceasingly goes on in uncivilised communities.

As a nation rises in civilisation, therefore, the lives of its members are in part prolonged, simply because they are not violently curtailed; other causes at the same time coming into action. Increased comfort of dwellings, and more effectual shelter from the weather, suitable clothing, more regular supplies of wholesome and better prepared food—all reduce the chances of disease and death. Improvements in the practice of medicine and surgery, more quickly and effectually alleviate the former when it does occur, and diminish the probability of the latter; and, lastly, for it comes last, increased-though far from sufficient-attention to hygienic and sanitary precaution counterbalances in some degree those unhealthy influences and combinations of circumstances which inevitably arise during, and advance with, the progress of civilised communities. Hitherto, the increase of the comforts of civilisation, though in one mode it has tended to prolong life, has nevertheless in some degree balanced this advantage by giving rise to other sources of disease. The wandering savages, or natives of thinly-peopled countries, if liable to suffer from privations and exposure, are nevertheless, in great measure, free from the fever-generating drain, and closely-crowded street or habitation; and in this and other similar ways it happens, that although the value or duration of life in a community ought to be a test of its civilisa-tion, the fact has not as yet assumed its full preponderance in the history of national progress. Ignorance of the laws of health, in the first instance, and obstacles to the carrying out of those laws in the next, have hitherto kept the average of life, in this kingdom at least, far below the average it ought to hold. Probably too, indifference as to the means of prolonging human life has partly arisen from the very common error, which supposes that the evil of premature deaths has some compensating advantage in removing a portion of surplus population; whereas, under ordinary circumstances, it is not the surplus, but the valuable portion of life that is thus lost. If a boy dies at some period between ten and sixteen, his existence has been an absolute cost to the community, and he was but just approaching the period when he might have become a productive member of it. If a husband dies in the early years of his married life, he leaves as burdens on the world a widow or children, for whom, under ordinary circumstances, if he had lived, he would have worked: "bearing out the fact, that a parish or country where life is precarious pays more

members-than its neighbours.

Connected with these remarks, are the facts elicited by the Registrar-General in his numerous reports on the health of the population. As an illustration of the improvement in the health of the people upon that which existed in former times, we may instance the case of the city of London, and compare it with what it is now and what it was formerly. From the bills of mortality we learn that, in the latter half of the 17th century, the mortality was as high as 80 in 1000 living at the period; that in the course of the 18th century, it diminished to 50 deaths annually in 1000; while the more accurate records of the present century give us only 24 in the corresponding number. But London, with its open spaces and complete system of drainage, is one of the healthiest cities in Europe, and ranks next to England, as a whole, including country and town, in its comparatively small death-rate. In Manchester and in Liverpool, two cities which approach most in magnitude to London, the death-rate, as calculated by Dr. Farr for the ten years 1861-70. amounted for males alone in the former city to 35, and in the latter to 40 per 1000 living; while in females it numbered in Manchester 30, and in Liverpool 36 per 1000. In 51 healthy districts, exclusive of towns, the average annual mortality taken over the same period was 17 per 1000 for males, and 16 for females; and ranging over the entire population between these extremes, Dr. Farr presents us with the following table calculated over a period of 34 years (1838-71), which gives the arithmetical mean of the several rates at different epochs of life. The figures of course represent the deaths

1000 living :-				
431			Males.	Females.
All ages, .			20	21
Under 5 years,			72	62
From 5 to 10,			8.7	8.5
,, 10 ,, 15,			5	5
,, 15 ,, 25,			8	8
,, 25 ,, 35,			10	10
,, 35 ,, 45,			13	12
,, 45 ,, 55,			18	15
,, 55 ,, 65,			32	28
,, 65 ,, 75,	100		67	58
,, 75 ,, 85,			147	134
95 05			805	279
,, 95 and up	ward	ls,	441	430

From this table it may be inferred, that life is at its best between the ages of ten and fifteen, after it has escaped the perils of childhood, and that its prospects darken with increasing years. It also shows unmistakably the advantage which the female possesses over the male with regard to life expectancy, and gives a clue to the reason why so many more male children should be born into the world than females.

The causes which affect life-which influ-

ence its mortality, are referred to in detail throughout the work, though broadly they may be stated to consist of two factors-(1) such as we cannot control, the effects of growth and decay, and local ailments; and (2) such as are contributed by our surroundings, and which are very much under our power to avoid. To the latter category belong the air, water, and food we consume, the dwellings we inhabit, the clothes we wear, and the occupations we follow. Perhaps no fact is more clearly brought to light in the Registrar's statistics, than the influence of locality combined with density of population in shortening life; healthy districts, whether in town or country, contain but few people to the acreage, and the most unhealthy are crowded with occupants. In the case of London, which is divided by the Registrar into numerous districts, the highest mortality numerous districts, the highest mortality (amounting to 30 per 1000) is to be found in the populous parishes of Whitechapel and St. George's in the East, and the smallest (16) in the less frequented district of Hampstead; and the same principle will be found to obtain in subdivisions of large towns and rural districts throughout the country.

In one of the Registrar-General's Reports, two districts are compared with each other, one of twenty-five towns, another of seven "The number of deaths in the former, from all causes whatever, was 51,492, while in the country districts it was 33,039. Yet out of this smaller number, the deaths from old age amounted to 4699; while out of the much larger amount of deaths in the town districts, the number that had survived causes of premature disease, to die of old age, was only 3525. In round numbers, a seventh part of the country population has thus been allowed to run the natural course of their days, while only a twelfth of the town population have had the same good fortune to avoid the snares which disease and accident have laid for them. The following tables from a Sanitary Report of Mr. Chadwick, show the different values of life in the different classes of people in the same districts :-

"We here find that in some communities—such as Whitechapel Union—there will be differences so great between the average duration of life in the different classes, that those born in the large house of the professional man, or independent gentleman, live rather more than twice as long as those born in the crowded houses of the small alleys which ramify hither and thither round it. It is a melancholy truth, resting on evidence only too strongly overwhelming, that the lives of the poorer classes, who inhabit the crowded districts of large towns, are liable to be shortened by a variety of causes."

And yet these things need not be; there is no possible reason why the duration of life in a district in which it is low, should not be greatly raised—the amount in some degree of course depending upon the nature of the district. Neither is there any reason why the standard should not be elevated in every dis trict. That such will be the case at some future day there can be little doubt; nor is it unreasonable to suppose, that there is yet a "good time coming," in which the value and "good time coming," in which the value and duration of life will be extended greatly beyond what it is at present-greatly beyond perhaps what we at present can foresee—when science and a wise legislation have corrected the errors and utilised the experience of an advanced civilisation; when sources of disease from without are removed, and when man has learned that health is better than great riches, and has ceased to sacrifice his own, or that of his dependants, at the shrine of mammon.

LIFE-ASSURANCE.—The security of a sum of money to the family or to the survivors of an individual whose death involves loss or diminution of income to those survivors, may become an important consideration, when the chances of death or recovery in severe illness are nearly balanced-when the tranquillity or disturbance of the mind, may make that balance incline to the one or to the other side. The racking thought of a wife and family left without provision, may drive away the sleep that would precede amendment-may give the last jar to the sinking nervous system. In this remedial point of view only, can this important subject be alluded to here, although the necessity of life-assurance on the part of those who have not had the opportunity of making a suitable provision for their families, or who are exposed to much personal risk from

LIFTING CHILDREN is a subject on which a few words are highly requisite. It is really surprising to see in what a cruel and dangerous manner children are often lifted about, not only by their nurses, but by their mothers; and the evil results are very commonly brought before medical men, in the shape of sprains, separations of "epiphyses" (see Epiphysis), dislocations, and even fractures. When a heavy child is perhaps seized by the hand or arm, and swung over a gutter, or the like, the wonder is, not when injury results, but that it does not always result, from the practice. Among boys, and even by those who are old enough to know better, there is a trick of lifting children or boys, by the hands placed under the chin and at the back of the head: this is most dangerous—dislocation of the neck, with instant death, has been the result.

LIGAMENTS are white glistening bands

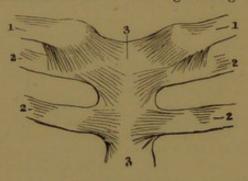

Fig. 148.

of inelastic fibrous tissue, which retain the different bones in position at their points of junction. There is also a yellow fibrous tissue,

which in some places is called a ligament, but which is extremely elastic.

It would answer no good purpose here to

their employment, cannot be too strongly in- The example (fig. 148) which represents the culcated. and upper ribs (2, 2) to the breast-bone (3), and the example (fig. 149) which exhibits the "capsular ligament" (1) which invests and connects the bones at the shoulder-joint, will sufficiently illustrate the use and position of these connecting media.

In their ordinary condition, the ligaments are not very sensitive; but when, in consequence of a strain of the joint, or *Sprain*, they are over-stretched, they become acutely so.

LIGHT .- "The prime work of God."-We know that the great source of light is the sun, and that we have sources of artificial light. We know that it is light by which we are enabled to take cognisance of the colour, size, shape, and position of various bodies, we know that this light is subject to laws which it is in our power to trace; but we cannot frame a definition of the agent itself. To enter into a consideration of the optical properties of light would be out of place here; its effects as a stimulant on animal life and development are extremely important. The stimulant action of light not being of such obvious universal necessity to vital action as that of heat; nor its effects and influence so prominently marked, its full power as an excitant upon animal and vegetable life has not been, until lately, sufficiently well recognised, although every day it is becoming more so. The effect of the deprivation of the stimulus of light in producing blanching, or etiolation, in vegetables, has long been practically applied, and the effect of the absence or diminution of the stimulus on animal development and health is now so fully recognised, that in all public buildings, such as hospitals, schools, barracks, &c., a considerable amount of window space is considered absolutely essential on at least two aspects of a building. Dr. Edwards, whose experiments upon the influence of light are well known, has remarked, that persons who live in abodes ex-cluded from the free access of light, are apt to produce deformed children. It has been stated on the best authority, that the cases of disease on the dark side of extensive barracks at St. Petersburg, have been uniformly for many years in the proportion of three to one to those occurring on the side exposed to strong light. Humboldt has attributed the absence of deformity among the Caribs, Mexicans, Peruvians, &c., to constant exposure of the body at large to strong light. It is now, therefore, a received fact, that a free supply of light is almost as necessary to health as fresh air or pure water; it is, too, a fact, which should not be lost sight of with respect to the laying out of dwellings, as dark dwellings are favourable to the growth of scrofula, consumption, and rickets. The powerful stimulant action of light upon the eye is evinced by the fact, that strangers in the Arctic regions are liable to suffer from inflammation enter into a detailed account of the ligaments. of that organ produced by the glare of reflected

light from the snow, and that from the same | cause the natives of those regions suffer from snow blindness. A similar inconvenience is felt by Alpine tourists, who provide against it by wearing smoke-tinted spectacles. Light, however, exerts different effects according to its colour; as is well-known, bright white, yellow, or red lights are much more apt to injure the eye than those of a blue or green tinge; when, therefore, persons find exposure to the former coloured lights injure the sight, it is usual to protect the eye by the use of glasses of a bluish or smoke-coloured shade.

Refer to Amaurosis—Blindness—Eye, &c.

LIGHTNING .- Injury or death from lightning, appears principally inflicted through the nervous system; although, at the same time, scorching wounds are not unfrequently produced. Persons who are stunned, but not killed, by lightning, generally suffer from temporary blindness and remain in a state of insensibility for some time, the breathing being slow and deep, the muscular system relaxed. In such cases it will be proper to use means for preserving the animal warmth, which has a tendency to become diminished, to keep up artificial respiration, as recommended under article Drowning, to use mustard plasters to the spine and pit of the stomach, to administer, from time to time, a little sal volatile in water, if the patient can swallow; if not, to give a warm enema containing half an ounce of turpentine-or to use such other means as are recommended under the articles Drowning and Carbonic Acid, which may seem best adapted to the case. It is a common idea that persons who have been killed by lightning do not stiffen, and that the blood remains fluid: it is erroneous. It would, considering how often the fact is reiterated, seem almost superfluous to point out the ordinary precautions which those who chance to be exposed to a storm of thunder and lightning ought to adopt; but not a summer passes without lives being lost from sheer ignorance. Harvest labourers and others will persist in sheltering under trees, people will continue to put up, even iron umbrellas in the midst of a thunder storm, and mowers walk unconcernedly home with their scythes over their shoulders. If an individual is overtaken by a thunder storm in a place where trees abound, he should avoid them as much as possible, and keep to the open field, a thorough soaking will be rather a protection than otherwise. If, on the contrary, the position is on a moor or wide plain, where the body is the highest object, lying down is the safest procedure. In any case, metallic objects, such as agricultural implements, should be laid aside and avoided. Under shelter, the most hazardous position appears to be in a draught or current of air, such as between a door and window, this seeming to exert conelectric fluid

LIME is one of the alkaline earths, formed by the union of oxygen gas with the metal or metallic base calcium; in its various forms of carbonate, such as marble, chalk, limestone rock, &c., it is very widely distributed over the globe. Quicklime is formed by expelling the carbonic acid from one of these carbonates, by means of heat. Its appearance, when freshly burnt, is familiar to all; it quickly, however, changes, if freely exposed to air and moisture, attracting both carbonic acid-for which it has a strong affinity-and water, and being again converted into a carbonate of lime.

Lime is used in medicine in its pure form; it is used as a carbonate in the form of chalk (see Chalk), as chloride of lime (see Chlorine), Pure lime is given in the form of lime water; this is made by putting some freshlyburned and newly-slaked lime into a bottle, and filling to the top with water, agitating slightly; when the lime subsides, it leaves the water above perfectly transparent, and holding a certain amount of lime in solution. When any of the lime water thus formed is withdrawn for use, all that is necessary is, to fill up quite to the top again with fresh water, giving the bottle a shake, and to cork tightly. This may be repeated for a considerable time before the lime requires renewal. Lime water is used as an antacid by some individuals, even habitually. It is taken in doses of from half an ounce to three ounces, generally in, or along with, milk, which it renders lighter, and more likely to agree with the stomach, whilst the milk covers the somewhat acrid taste of the lime. Carrara water, an effervescing beverage, which contains rather more lime than ordinary lime water, is a pleasant form of administering the medicine. Equal parts of lime water and olive or linseed oil form the well-known carron oil, so much used for burns. If lime water is exposed to the atmosphere, a pellicle forms on its surface, and it quickly becomes turbid, from attracting carbonic acid, the carbonate thus formed being less soluble than the lime itself. The same thing will be seen to take place more quickly if an individual blows through some lime water in a glass, by means of a quill, the water at once becomes turbid, demonstrating, at the same time, the presence of carbonic acid in the breath. If, however, the experiment is persisted in for some time longer, the water again becomes transparent, in consequence of the additional amount of carbonic acid redissolving the carbonate of lime, and making it a bicarbonate. Dr. Angus Smith's "ready method" of detecting an excess of carbonic acid in the atmosphere of a room, is by testing it with lime water. Half an ounce of lime water is poured into a dry, wide-mouthed bottle of ten and a half ounces in capacity, and afterwards corked, and the test siderable influence upon the course of the carbonic acid be in excess of the healthy standard-that is, should it exceed six parts

380

in one thousand of air, the lime water will on account of its cheapness, and is found to be become muddy and precipitate carbonate of lime on standing. In many hard waters, lime exists in solution, in the form of bicarbonate of lime (see Water). The property possessed by quicklime of absorbing carbonic acid, renders it valuable in cases where, such as in old wells, this noxious gas exists and requires removal (see Carbonic acid—Bed-room). Burns from lime are not uncommon; in such cases the best application is vinegar and water, or some other acid, if vinegar is not at hand-freely applied; the acid in this case converting the caustic lime into a harmless substance. The same treatment is to be pursued in the event of lime getting into the eye, the vinegar or acid being of course more largely diluted than when used to other parts. In any of these cases, the after-consequences, such as ulceration of the skin, or inflammation of the eye, must be treated as recommended in burns generally. -See also Eye.

LINCTUS.—Medicine made into a thick syrupy consistence. The form of linetus is not often prescribed in the present day unless in hospitals, where an opiate linctus is generally kept ready made, for ordinary coughs. A good opiate linetus may be made with ten minims of tincture of opium, the same amount of dilute sulphuric acid, six drachms of treacle and two drachms of water. Mix the treacle with the water, then add the acid and tincture. Dose from one to two tea-spoonfuls.

LINIMENT—an embrocation.—See Em-

brocation

LINSEED, or LINTSEED.—The seed of the Linum usitatissimum, or common flax, contains a fixed oil, well-known by its name of linseed oil, which is procured from the seeds by pressure; the seeds also yield, when boiled, or infused in boiling water, a thick, almost tasteless, mucilage. Linseed oil was formerly more employed in medicine than it is at present, its chief use now being in the formation of the carron oil, used by some in the treatment of burns. This is made by agitating together equal parts of lime water and linseed oil (see Burns). The infusion of linseed, or "linseed tea," may be made in the proportion of half an ounce of the seed to a pint of boiling water. The pharmaceutical instructions are 160 grains of the seed, sixty grains of fresh liquorice sliced, and ten ounces of boiling water (see Infusion). It is a cheap and very good demulcent remedy in coughs, and in irritation of the urinary organs. The meal of linseed is made by grinding the seeds, after the oil has been expressed from them; it is chiefly used for poultices .-

LINT, formerly made of old linen cloth scraped to give it a soft woolly surface, was afterwards manufactured on purpose, of new material, and of good width and length, instead of the bits and scraps in which it used to be sold. Lint ations of lithia are the carbonate and the made of cotton is now almost universally used. made of cotton is now almost universally used, | citrate. the dose of the former is from three to

equally serviceable with lint made from flax or old linen (see *Dressing*). Taylor's flax lint is thicker and more spongy than the other sorts, and, therefore, more suited for some purposes; it does not tear well, which is a disadvantage.

LIP .- The lips owe their colour to their extreme vascularity, and to the thinness of the skin by which they are covered, and their sensitiveness to an abundant supply of nerves.

The colour of the lips is closely connected with that of the blood, and also depends upon the vigour of its circulation. When the blood is poor and deficient in red globules (see Anæmia), the lips become pale; when, again, from failure of the heart's action, as in fainting, the blood is not circulated properly, the lips also become pale; when, from disease, the blood does not undergo its proper changes, the colour of the lips, instead of being red, inclines more or less to purple. The lips-particularly the lower-are apt to become the seat of cancer in old people; especially, it is said, in those who have smoked much from a short pipe. A continued sore upon the lip that will not heal, in an old person, should be examined by a medical man; if it is such as to require removal, this cannot be done too soon.

Refer to—Hare lip—Skin.

LIQUORICE and LIQUORICE ROOT.

-Liquorice root, which is long and creeping, is procured from a plant belonging to the leguminous, or pod-bearing tribe, a native, chiefly of Spain and of southern Europe, but cultivated in England. The extract of the root, known as hard "extract of liquorice," or "black sugar," or "Spanish juice," is used chiefly as a demulcent remedy in coughs and irritation of the throat, in irritation of the stomach and bowels, and of the urinary organs. Many persons take it largely, and find it useful, in heart-burn. It does not disorder the stomach, or cause thirst, like common sugar, even when used in considerable quantity. The extract is also employed to cover the taste of nauseous drugs, such as aloes, &c., and is added to demulcent drinks generally. It also forms the basis for various kinds of lozenge.

A soft extract of liquorice is used by druggists in the composition of pills, and the powder of the root is used for the same purpose.

LIQUORS. - See ALCOHOL-STIMULANTS,

LITHARGE is an oxide of lead, which occurs in the form of reddish-white scales. It is sometimes used to adulterate wine. - See Lead.

LITHIA is much used in medicine as a remedy for gout. It is also a good diuretic, promoting the elimination of urate of soda from the blood. In gravel and renal calculus de-

LIT LOB

six grains, and of the latter from five to ten | secretion which performs an important part in grains. There is also an effervescing solution of lithia containing ten grains of the carbonate to a pint of water, with carbonic acid added to it under pressure.

LITHONTRIPTIC—an old term applied to medicines which were supposed to possess the power of dissolving or disintegrat-

ing urinary calculi. Refer to—Urine.

LITHOTOMY.—The operation of cutting

LIVER.—The liver is the largest gland in the body, weighing, on the average, in man, about four pounds; it occupies the upper part of the abdomen (see Abdomen) just beneath the diaphragm or midriff, to which it is attached, or, as it were, slung, by what are called the ligaments of the liver. By anatomists the liver is divided into various "lobes;" but here it is sufficient to point out the general division into a larger, or right lobe (fig. 150-1) and a smaller, or left lobe (2) the former occupying the right hypochondrium, the

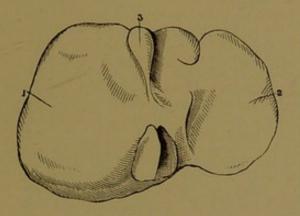

Fig. 150.

latter extending far into the left. The gallbladder (3) is seen occupying the fore part of the under side of the right lobe of the liver, in which aspect it is represented in the cut. The liver is made up of numbers of minute lobules, about the size of a millet seed, which are composed of the smallest or "capillary" branches of the blood-vessels, of the cells which separate a substance called "glycogen," a kind of liver starch, as well as bile, from the blood, and of the ducts which convey the secreted bile into the larger common ducts; these converge to the one main duct of the liver, through which the bile flows, either into the gall-bladder, or into the digestive canal, direct. The liver starch, which is stored up in the cells, and the bile are manufactured from the blood which has circulated through the organs within the abdomen, and which passes through the liver on its way back to the heart; in this passage these substances are separated from it, thereby elaborating the

the processes of digestion, and possibly in the body at large. This intimate connexion, however, of the liver, by means of the blood, with the other organs within the abdomen, and particularly within the stomach, renders it extremely liable to be disordered; and, indeed, there are few cases of disorder of the stomach or bowels in which the liver is not in some degree implicated, either primarily or secondarily. Probably, in no way is the connection between the stomach and liver more strongly manifested, than by the manner in which the latter is affected by the inordinate use of alcoholic liquors; in this case, the spirit being absorbed directly from the stomach by the veins, and conveyed directly to the liver, acts very powerfully upon it, particularly if the form in which the alcohol is taken be that of pure spirit, such as gin or brandy; in this case, if the use of the spirit be persevered in, a low form of inflammation is excited in the substance of the gland, which ends in the formation of what has got the name of the "gin-drinker's liver"—a disease, indeed of which the only traceable cause is the excessive use of spirituous liquors, and which proves fatal to many in this kingdom annually. Its symptoms and treatment could not profitably be laid before unprofessional persons, but its cause should be impressed on all. In its advanced stages, it generally causes dropsical swelling of the lower extremities, and of the abdomen.

Inflammation of the liver is attended by the usual feverish symptoms which accompany inflammation of internal organs generally, and must be managed on the same principles (see Inflammation) until proper advice can be obtained. The pain varies considerably in this affection, being usually very acute when the surface of the liver, with its covering membrane, is implicated, but less so, or of a duller character, when the substance of the gland is the part involved. As is the case in liver affections generally, pain is often felt liver affections generally, pain is often felt somewhere about the shoulder blades, most frequently in the right, but sometimes in the left, or between them, extending even to the back of the head. Inflammation of the liver is much more frequent in warm climates than it is in this country; and, in the former, is very apt to end in the formation of abscess. The disease, of course, requires the most active treatment of a medical man; but it should be known to those going to a hot climate (see Climate) that this, like other liver diseases, is much more likely to attack the free-living than the temperate man. For further information respecting liver-disorder, the reader is referred to articles, Biliary Disorder, Climate,

Gall-Stone, Jaundice, &c.

LOBELIA, or "LOBELIA INFLATA," is a starchy and saccharine elements of food ab-sorbed by the circulation, and affording a North America. It was one of the medicines

LON LOB

men in England as a remedy in asthma, and, in some instances, proves of service; but this is generally the case when its emetic action has been exhibited. It is not a remedy, how-ever, for unprofessional hands; for it may prove a powerful irritant poison. Lobelia has acquired notoriety in consequence of its being the medicine of a set of quacks, in whose hands it has, in more than one instance, produced fatal effects, and been the means of subjecting them to legal proceedings and punishment. The dose of the two preparations of lobelia, the alcoholic, and the ethereal tincture, is from ten to thirty minims. Its action is somewhat similar to that of tobacco.

for persons of weak digestion.

Refer to—Fish.

LOCHIA.—The "cleansings" after deli-

LOCK JAW is the popular name for a severe disease of almost invariably fatal character, known to medical men as Tetanus, in which not only the muscles of the jaws, but the muscles of the body throughout, are, more or less, extensively thrown into violent spasm, so strong indeed, that the teeth or bones are said to have been broken by it. The set of muscles most generally affected, after those of the jaws, are those of the back; the patient, by the spasm, is sometimes bent like an arch, so that often the back of the head and the lower limbs alone touch the bed, occasionally, however, the body is bent forward. Similar arise from strychnia poisoning. Similar convulsions The disease most frequently commences with a sensation of stiffness and soreness of the muscles of the neck and jaws; the latter become fixed, and the spasm extends more or less over the body. It is needless to add, that this extensive cramp is attended with the most severe pain, which is also, in most cases, experienced severely about the pit of the stomach, being dependent, doubtless, on spasm of the diaphragm.

The most usual exciting causes of lockjaw, or tetanus, are punctured wounds, especially of the hands or feet, but the very slightest injury is sufficient to develop the disease. In this climate, however, it is fortunately comparatively rare; in warm climates it is common; it is also liable to prevail among the wounded after battles, if exposed to much vicissitude of weather; indeed, cold will occasionally give rise to lockjaw independent of injury. lockjaw arises from a wound, it shows itself in from four days to three weeks after the injury. It is a very fatal disease, the greater proportion of those affected by it dying; some, however, recover. Of course, as soon as practicable, a medical man should be called to a case exhibiting even the slightest tendency to lockjaw after an injury; in the meantime, large doses of opium in the liquid forms of laudanum, or of sedative solution, may be administered, even

of the Indians. - It has been used by medical | by unprofessional persons; they may mitigate the sufferings of this dreadful disease. From thirty to sixty drops of laudanum may be given by the mouth, or what is better, morphia may be administered by subcutaneous injection, and repeated at intervals. No definite success has attended the numerous remedies which have been suggested and tried from time to time in tetanus, although much relief to the spasms has been obtained by sedatives and antispasmodics, especially by the inhalation of ether and chloroform at intervals. In addition, the application of ice-bags to the spine has frequently a calmative effect

It is caused by a bacillus which obtains entrance into the blood through the wound; LOBSTER, like most shell-fish, is unfit and an antitoxin has been prepared for subcutaneous injection, the early use of which has been in some cases followed by recovery; if obtainable it should always be used as early as possible, the strength being at the same time

maintained by nutrient enemas.

Refer to-Convulsion-Wounds, &c.

LOINS.—See LUMBAR.

LONGEVITY.—Prolonged life, it is wellknown popularly, is, in some respects, hereditary, the ages at which different members of a family usually die bearing a very near average to one another, notwithstanding the influence of occupation, habits, and condition of life, although these, undoubtedly, exert considerable influence in determining the period at which the component tissues of one or more of the organs begin to give way. Many tables and calculations have been made at different times, with a view of determining the extent to which the duration of life is affected, by the circumstances in which individuals may be placed. The following table from Casper, of Berlin, if it may not exactly apply to this country, shows, at all events, how greatly the average duration of life may vary in different

LONGING is the term applied to the almost morbid craving for certain articles of diet, with which some females indulge themselves during pregnancy; it is probably a phase of hysteria. Under the circumstances, it is only right and humane to yield to those fancies in some measure; but when there is any real or adequate reason for their being debarred, it may be insisted upon, without the risk of the consequences popularly supposed to follow.

LOSS OF BLOOD.—See Hæmorrhage. LOTIONS are liquid applications, principally composed of water, used either to the skin to wounds, or to the mucous surfaces, such as the inside of the mouth or of the nostrils. The variety of lotions, from plain water-which is often a most excellent oneto numerous medicated solutions, is very great. Lotions may be classed as (1) Cooling; (2) Stimulating; (3) Astringent; (4) Soothing; (5) Sedative; and (6) Antiseptic. Of the first, water is an example, either alone, combined with spirit, from half an ounce to an ounce to the half pint, or combined with vinegar. The lead lotion (see Lead) is another example of the cooling lotion, but in this case it is astringent at the same time. Water, with one-third or one-half spirit of wine, applied to the skin by means of lint, which is covered to prevent evaporation, is a good example of a stimulating lotion. Very cold water, the lotion of sulphate of zinc or white vitriol, in the proportion of from one to ten grains to the ounce of water, and other astringents in solution (see Astringents) form the astringent lotions; the various preparations of opium, decoction of poppies, decoction of hemlock, &c., are soothing lotions; the prussic acid lotion, a sedative one. Antiseptic lotions are composed of solutions of car-

The reader is referred to the various articles, such as Lead, Zinc, &c.

LOW DIET must necessarily be a comparative term, influenced by the previous habits of the patient, but generally it means the absence of all stimulants and animal food from the allowances, also of eggs, and generally a diminished amount of bread nourishment. Weak tea, bread, diluted milk, cocoa, gruel, arrow-root, sago, and such like preparations, generally constitute the staple of low diet in this country; to these, however, the cooling fruits may frequently be added. Half diet includes the characteristic fruits and the characteristic fruits a includes the above with the addition of puddings of milk and eggs, of broth, and it may be of a small allowance of meat.—See Abstinence

-Fasting-Hunger-Dietaries.

LOZENGE-a hard compound of sugar and gum, which contains either simple flavouring, or some medicinal agent. The system of giving medicine in the lozenge form, has come into more general use since various medicated troches or lozenges have been admitted into the British Pharmacopœia. There are ten such preparations, each containing a definite amount of active ingredients, namely, tannic acid, bismuth, catechu, reduced iron, ipecacu-anha, morphia, morphia with ipecacuanha, opium, chlorate of potash, and bicarbonate of soda, lozenges. The lozenge form of administration is a useful and agreeable method, particularly in affections of the throat, such as relaxation, when it is desirable to apply the medicinal agent gradually. In children, the lozenge form of medicine is useful, either for the administration of ipecacuanha domestically, or of morphia under medical sanction. The manufacture of medicated lozenges is now almost entirely transferred to the pharmaceutist, who, guided by the directions of the pharmacopæia, has the amount of the ingredients stamped on each lozenge. Lozenges are sometimes adulterated with what is called "mineral white," in other words, plaster of Paris: it cannot be regarded as a harmless addition.

LUMBAGO is rheumatism of the large muscles of the back, and, like rheumatic affections generally, is often extremely painful, the pain being increased by stooping, and again when the person attempts to rise. peculiar aggravation of the pain by these movements, is generally stated to be the distinction between this disease and painful affections of the kidney. In lumbago, relief is afforded by hot moist applications to the back (see Heat) continued from twelve to twenty-four hours at a time, and followed by the soap liniment combined with one-sixth part of turpentine, rubbed well into the back and loins. Ten grains of Dover's powder, with a couple of grains of calomel, given at bedtime, and followed in the morning by a dose of castor oil or infusion of senna, will expedite the cure. Whilst the perbolic acid, chlorinated lime or soda, boracic son is confined to bed, nothing is better than acid, iodine, &c.

LUN LUM

of flannel over the back and applying a smooth-ing iron as hot as it can be borne,—"ironing the back,"—and, at the same time, it will be advisable to give warm diluent drinks tolerably freely. In a severe or obstinate case of lumbago, a fly blister is often of service, or a liniment composed of equal parts of chloroform and laudanum rubbed over the loins. In such cases, however, the safest plan is to have medical attendance if possible. Should the urine be scanty or high-coloured, ten grains of carbonate of potash, with a tea-spoonful of sweet nitre, may be taken in a wine-glassful of water twice a day, with advantage. Persons liable to attacks of lumbago, should wear a flannel belt round the loins.

Refer to—Rheumatism.

LUMBAR .- Belonging to the loins. The term is frequently used in connection with abscess. In children of weak and scrofulous constitution, abscess in the loins, or "lumbar abscess," is apt to occur, and is often connected with disease of the vertebræ, or bones of the spine. Continued complaint of pain in the back, with any awkwardness in walking, particularly if accompanied with failure of the general health, should awaken suspicion, and give occasion for the child's being examined by a surgeon. Lumbar abscess may also occur in adults and is always a very serious disease.

LUMBRICUS—a worm. Applied to the

large round worms which occur in the intes-tines.—See Worms.

LUNACY.—See INSANITY.

LUNAR-CAUSTIC. - NITRATE OF SIL-

VER. - See Silver

LUNCHEON -a kind of intermediate meal, and therefore sometimes an unnecessary one. The English labourer as well as most domestic servants have their "lunch" between breakfast and dinner, generally between ten and eleven oclock A.M.: the English of the higher classes, particularly if their time is not well occupied, are apt to make luncheon a kind of dinner-a meal of animal food and stimulants, which, if superadded to dinner, is certainly unnecessary, and therefore productive of disorder. Either the luncheon should be made a bona fide dinner at an early hour, or it should be a meal without animal food-provided, of course, that an additional amount of animal nutriment is not considered necessary by a medical man, as a remedial measure. Fruit is generally more wholesome at luncheon than at any other part of the day.

LUNGS.—The organs of respiration. The lungs are two organs, each occupying its own side of the chest (see illustration, fig 151, which represents the left lung and air-tubes of the right), the left being rather the smallest, on account of the greater space taken up by the heart on the left side. The latter organ is situated in the space between the two the heart on the left side. The latter organ is situated in the space between the two lungs, which are separated from one another by a middle partition. Air passes into the latter organ butcher's shop, than from any description. In these, however, the mode of death, by bleeding, gives the lungs a much paler colour than their natural one. The tubes, the air

lungs by means of the windpipe, or trachea, to the top of which is fixed the larynx, or organ of voice; at its lower extremity the trachea divides into two branches, or bronchi, of unequal length, one for each lung; these bronchi on entering the lung subdivide into branches, and these again into still smaller tubes, until after continued division and subdivision, they end in the air-cells. These aircells are minute membranous cavities, on the membranous walls of which the blood circulates in a network of veins, in such a manner as to be brought into intimate contact with the air which is drawn into the lungs at each

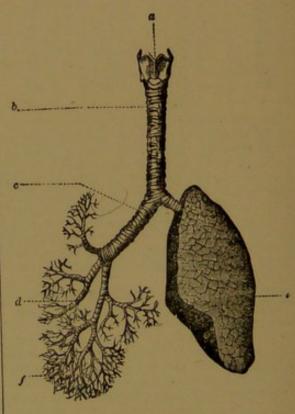

Fig. 151.

a. Larynx. b. Trachea c. Right Bronchus.

d. Bronchial Tube. e. Left Lung. f. Ultimate Bronchial Tubes.

inspiration; nothing, indeed, intervening between the blood in the veins and the air-cells, but a membrane so thin that it allows the transpiration of the gases and vapour, which takes place as the blood becomes purified by means of this air contact. In consequence of their structure being adapted for the admission of air into numberless minute cells, the lungs feel spongy when pressed between the fingers. Those who are curious on the point will learn more from five minutes' examination of the lungs and windpipe of a sheep or calf in a LUN LUN

cells, the blood-vessels, &c., of the lungs are elevating them, increase the diameter of the held together by "cellular" tissue, and the chest from before backwards (see Chest) and entire organ is enveloped by a membrane—the "pleura"—which covers its surface, and is thence "reflected" to cover the inner surface of the walls of the chest; in this way forming a shut pouch, or sac, the inner surfaces of which are in contact, and these being in the healthy state perfectly smooth, and moistened with a lubricating fluid, glide over each other in every movement of the chest and lungs. The trachea, and the bronchi at first, are composed of incomplete "rings" of cartilage, connected together by an elastic tissue; the former tube—the wind-pipe—as generally known, occupying the fore part of the neck, and lying in front of the

gullet. - See Neck.

The larynx, or organ of voice, which is placed on the top of the windpipe, extends to the root of the tongue; its situation is often strongly marked in thin men, especially if somewhat advanced in life, when it forms the prominence popularly called "Adam's apple." This prominence is caused by a cartilage which forms a main portion of the body, or box, of the larynx. Into the comformation of this wonderful instrument of articulate and vocal sound, various other cartilages, ligaments, muscles, &c., enter, and the whole is lined by a continuation of the mucous membrane of the mouth, which, after passing through the larynx, lines the trachea, or windpipe, and follows the branchings of the bronchi. The opening of the larynx is divided by a constriction of a triangular form—the glottis—and is protected from injury by a heart-shaped cartilage—the epiglottis-which, especially in the act of swallowing, when the larynx is drawn upwards, completely closes the opening. - See Throat.

From the above slight sketch, the general reader may derive some idea of the important organs of respiration. To recapitulate: situated at the root of the tongue, and protected from injury by the cartilage of the epiglottis, is the larynx, constricted in the centre, and ending in the trachea, or windpipe, which, descending in front of the neck into the chest, divides into the right and left bronchi; these entering their respective lungs, divide and subdivide, till the minute branches enter the aircells, on the thin walls of which the blood circulates in a network of veins, and undergoes purification by absorption of the oxygen of the atmosphere, whilst it frees itself from carbonic

acid and watery vapour.

The act of respiration is partly involuntary -that is, goes on, as during sleep, independent of any exercise of the will; it is, however, as all know, capable of being, to a certain extent, controlled by the will; this being, doubtless, a necessary adjunct to the power of the utterance of sound. The process of respiration is essentially effected by means which enlarge the capacity of the chest: these means are the vari-

chest from before backwards (see Chest) and also the diaphragm and muscles of the abdomen, which, by their downward and outward motion increase the capacity of the chest from below. The enlargement of the chest by these agencies, either in combined or separate action, has the effect of causing the air to rush in, or to be sucked into the chest, as it is into a pair of bellows. If the cavity was empty, it would rush into it; as it is, it rushes into the spongy distensible lungs, and distends them, it may be, assisted in some degree by the action of the lungs themselves. The air having been thus drawn into the chest by an active movement, is immediately thereafter expelled by a comparatively passive one; the active muscular movement ceasing, the ribs descend, and regain their position, by their own weight and elasticity. The movements, however, both of inspiration and expiration, may be increased-"forced"-by the will; and in this case other muscles are called into action, and those usually employed in the process are more strongly exerted. It is the necessity for these forced efforts in the asthmatic, which, after frequent repetition, gives the peculiar curve of the shoulders so often observable. The average number of respirations in a minute varies from fifteen to twenty-two in different individuals, and even in the same individual at different times. The object gained by the process of respiration -that is, the change which takes place in the blood, in consequence of its exposure to atmospheric air in the lungs-has been sufficiently entered into in articles Aeration, Blood, Circulation, &c.; it is therefore unnecessary to repeat it here.

The passage of the air into and through the lungs, gives rise to certain definite sounds perceptible to the attentive ear applied closely to the outside of the chest. These sounds vary but slightly in healthy individuals; conse-quently, any deviation from them is indicative of disease, experience furnishing the link which enables the physician to pronounce upon the nature of the disorder, from the character of the sound, or from its entire absence, which latter condition occurs, either when the lung is ren-dered so solid by diseased action, that air cannot penetrate its tissues, or when it is con densed, pressed together, by the presence of fluid within the chest. Moreover, it is evident that organs like the lungs, which, in their natural healthy state, are distended with air, must, when the side of the cavity within which they are contained is struck, give out a somewhat hollow sound; but that, should the lung become solid, or the cavity more or less filled with water, the sound, instead of being hollow, will be dull or flat. It is further evident that the power of conducting sound must be altered by the various alterations in the structure of the lungs, and that the voice must sound difous muscles attached to the ribs, which. by ferently to the ear applied to the chest, according

LUN LYM

will, perhaps, convey to the general reader, some idea of the means of judgment, and of the principles on which they depend, which the physician avails himself of, when he goes through the-to the unprofessional-somewhat mysterious-looking process of physical examination of, or "sounding," the chest.

The narrowness of the triangular chink in the larynx, through which the air passes, always renders disease of this organ a matter of anxiety and of danger, for that small opening cannot be obstructed for three or four

minutes without death ensuing.

The LARYNX is liable to be obstructed from swelling of its lining membrane, either from inflammation or other cause, from spasmodic contraction of its muscles, or by foreign bodies accidentally introduced into it. It is also liable to ulceration. Acute inflammation of the larynx, or laryngitis, though comparatively an infrequent disease, is a very fatal one when it does occur. - See Laryngitis.

Closure of the larynx, or rather of its narrow portion, the glottis, may be the result of swelling, extending to it from the throat; partial chronic swelling, causing permanent, or at least continued, loss of voice, is not an unfrequent and not a dangerous affection, and tubercular ulceration of the larynx, also causing loss of voice, is characteristic of a common

form of consumption.

Of the spasmodic affections of the larynx, that mentioned under the spasmodic croup of childhood, is perhaps the most characteristic, but the researches of Dr. Marshall Hall make it evident that in the nervous convulsive diseases, such as epilepsy, spasmodic closure of the larynx takes place, and that in aggravated cases, relief-by proper hands-may be given by the operation of opening the wind-When death does occur from any of the pipe. causes mentioned, it is by suffocation, or apnœa, just as if the person had been drowned or hanged; it may also take place in consequence of foreign bodies, or food, either getting wedged in the larynx itself, or in the gullet behind it, in which case, if of large size, they act by their mechanical bulk and compression. Foreign bodies are usually drawn into the larynx itself, in consequence of the person, often a child, laughing or crying whilst the substance or fluid is in the mouth. As all know, even the smallest crumb or drop of fluid getting into the larynx, or as it is popularly called, "going the wrong way," immediately (in consequence of the irritation of the extremely sensitive lining membrane of the organ) causes violent cough, and perhaps choking spasm; if the foreign body is large, those symptoms are severe in a corresponding degree, and may by their severity, prove the patient's safety, by expelling the offending substance. Should this not be effected, and if it is too large to pass through the larynx, death inevitably and lymphatic or absorbent vessels (see Absorbents)

to these alterations. These brief observations | quickly ensues; sometimes, however, the body passes through the larynx into the bronchi, as happened in the well-known instance of the half-sovereign in Mr. Brunel's case. When this occurs, the more severe suffocative symptoms subside, but irritating cough continues, with the constant risk of driving the foreign body back into the larynx. In such cases, unprofessional persons can do little or nothing, and unless proper surgical assistance is quickly procurable, there is much chance of a fatal termination; it would always be right, however, for some person to pass the forefinger as far back in the throat as possible, in the hope that the obstruction might be within reach; and also to adopt the remedies for choking laid down under article Gullet.

The various inflammatory affections of the air tubes, such as Croup, Bronchitis, Catarrh, Influenza, Laryngitis, &c., are treated of under their separate heads; inflammation of the lungs falls under article Inflammation; and other diseases of the respiratory organs, such as Consumption, Asthma, &c., are assigned to

articles throughout the work.

Circulation, &c.

LUPUS, the Latin name for a wolf, is used to denote a skin disease of an unusually destructive and inveterate type. There are two varieties of lupus, representing respectively the mild and the graver forms of the malady; in the milder form the eruption, which in nearly all cases is confined to the face, and especially to the nose, appears in red patches, raised slightly above the surface, which become encrusted, if left to themselves, with successive layers of scarf skin. The patches are composed of tubercular matter, and if they do not ulcerate, the skin between the patches becomes swollen and exhibits numerous red points. In the worst forms of lupus, sometimes known as "noli me tangere," the tubercles ulcerate, causing deep excoriations and cicatrices. The complaint, which is happily rare, is most likely to be met with among the poor, especially in such as are predisposed to scrofula. The treatment consists in attention to the general health, the administration of cod-liver oil, and tonics, combined with iodine or the arsenical solution. The local applications found most useful in the milder forms of lupus are the tar ointment, and the iodine ointment, or the tincture of iodine may be applied to the patches by means of a hair pencil; while the more serious skin affection must be treated with escharotics and caustics. It is scarcely necessary to add that professional aid should be sought when there is reason to suspect the existence of such a troublesome, and at times formidable, complaint.

LUXATION—a dislocation.—See Dis-

location

LYMPH .- The fluid contained within the

from the body, such as vaccine lymph, adhesive lymph, &c.

MACE.—The outer covering, or, in botanical language, the "arillus," of the nutmeg, and one of our pleasantest and most generally used spices, may when taken too largely, produce determination of blood to the head, and intellectual disturbance. The characteristic properties of mace depend upon an essential

Refer to Nutmeg.

MADEIRA. - Of this much frequented and most important resort for invalids, Sir James Clark thus speaks:—"Madeira has been long held in high estimation for the mildness and equability of its climate; in which respect it will well bear comparison with the most favoured situations on the Continent of

Europe."

Compared with the best of these: "It is warmer during the winter, and cooler during the summer; there is less difference between the temperature of the day and that of the night; between one season and another, and between successive days. It is almost exempt from keen, cold winds, and enjoys a general steadiness of weather to which the Continental climates are strangers. During the summer, the almost constant prevalence of north-easterly winds, especially on the north, and the regular sea and land breezes on the south side of the island, maintain the atmosphere in a temperate state. The sirocco, which occurs two or three times, at most, during the season, and then continues only for a few days (seldom more than three), sometimes raises the temperature in the shade to 90°. With this exception, the summer temperature is remarkably uniformthe thermometer rarely rising above 80°. The summer temperature averages 74° and the winter 64°. In consequence of the regular seabreezes, the heat is not so oppressive as that of the summer in England often is. Close sultry days are little known in Madeira, and there is neither smoke nor dust to impair the purity of the atmosphere. Such, indeed, is the mildness of the summer at Madeira, that a physician, himself an invalid, who resided for some time on the island on account of his health, doubted whether this season was not more favourable

to pulmonary invalids than the winter. "The spring at Madeira, as at every other place, is the most trying season for the invalid, and will require even there a corresponding degree of caution on his part. In March, winds are frequent; and April and May are showery;" but Sir James adds, "on the whole Continent of Europe there is no place with which I am acquainted, where the pulmonary invalid could reside with so much adventors. invalid could reside with so much advantage

The term is also applied to limpid exudations | dry wines, and contains, according to Hassall, sixteen per cent. of alcohol. It generally contains more acid than either port or sherry.

MADNESS .- See Insanity.

MAGNESIA, one of the alkaline earths, is largely used in medicine, in the form of the pure or calcined magnesia: also in the form of the carbonate, and of the light carbonate, which latter, being soluble, constitutes the fluid magnesia of the shops. In combination with sulphuric acid, it forms sulphate of magnesia or Epsom salts (see *Epsom Salts*). The compound rhubarb powder is composed

of two-thirds magnesia.

The principal use of magnesia is as an antacid in acidity of the stomach and bowels, it at the same time-provided it meets with acid—acts as a gentle aperient; it is often combined with rhubarb, Epsom salts, &c. The dose of magnesia, as an antacid, is from ten to twenty grains; and, as a purgative, from twenty grains to a drachm. The effectual manner in which magnesia neutralises acid in the stomach, and thereby relieves heart-burn and other uneasy sensations, has probably been the reason for its extensive use, and certainly for its abuse among dyspeptics generally, whereby much evil has resulted; for there is no question, that the continued use of magnesia as an antacid greatly impairs the digestive powers. Moreover, if used in the form of calcined magnesia, or of carbonate, should it not encounter sufficient acid in the alimentary canal to convert it into a soluble aperient salt, it is apt to accumulate, and, if taken regularly and largely, to collect into and form concretions in the bowels: on this account, persons who will take magnesia habitually, ought to be careful to clear out the bowels thoroughly, at intervals, by means of a dose of castor oil: the same rule being observed with regard to children, if magnesia is given regularly to them. These remarks do not apply to the comparatively pleasant and efficient preparation of the bicarbonate, or fluid magnesia, which has greatly, and with advantage, supplanted the other preparations.

Fluid magnesia, in doses of from half an ounce to two ounces, may be taken either alone, or in milk, -the latter mode being convenient for children, -or it may be given as an effervescing draught, with lemon juice. It has been already observed, that magnesia only acts as an aperient when it meets with acid; the author has found a dose of magnesia, taken after the garden rhubarb used as food, act very well as

a gentle aperient.

The citrate of magnesia is an elegant effervescing aperient now much known and used. It has the advantages of being very agreeable to take, and very gentle in its action as a saline laxative, much more gentle than the old Seidlitz powder, which it has largely superseded. The during the entire year as in Madeira." citrate of magnesia is now generally sold in the granular form—that is, made with large grains, MAL MAR

by which it is rendered much less liable to | health, independent of other considerations, undergo decomposition, but it is also prepared in solution with bicarbonate of potash, in corked and wired bottles. - See Effervescence.

The dose of the citrate is one, two, three, or even more tea-spoonfuls, in a moderate quantity of water. It may be taken at any period of the day, but morning is the best time. The dose of the liquor or solution is from five to ten ounces. Much that is sold for citrate of magnesia is a combination of other aperient salts.

Of the solid preparations, Henry's calcined magnesia is the best. Some kinds of magnesia, when kept for a time in mixture with water, are apt to form the whole into a solid mass.

Refer to—Children—Indigestion—Piles, &c.

MALARIA.—See AGUE. MALE FERN.—See FERN.

MALIC ACID .- The peculiar acid of the

MALIGNANT, a term applied medically to various diseases when they assume a fatally severe, or intractable form, such as malignant sore throat, &c.

MALT LIQUOR.—See BEER—PORTER. MAMMA. - The female breast. - See

MANNA is the saccharine exudation from a species of ash tree, and is chiefly brought from Sicily and Southern Italy. Flake manna is the variety used in this country, but is less used than formerly. It is gently aperient, but as two ounces are requisite for a dose, it is likely to disorder the stomach. As a laxative for young babies, half a small teaspoonful may be mixed with milk in a bottle.

MARASMUS. — WASTING — ATROPHY—

MARMALADE .- The well-known preserve, made from the Seville orange, is by some

regarded as a stomachic.

MARRIAGE.—The religious and lawful union of the sexes. Various observations go to confirm the fact, that the married state is conducive both to health and to prolongation of life; thus it has been ascertained, that married women at the age of twenty-five have, on the average, thirty-six years of life before them, whilst unmarried women of the same age have not, on the average, more than between thirty and thirty-one years; that in men, the mortality between the ages of thirty and fortyfive, amounts, on the average, to eighteen per cent. in the married, but to twenty-seven per cent., or one-third more, in the unmarried; and, further, that at the age of seventy, whilst there remain alive but eleven bachelors out of every hundred, twenty-seven married men out of the same number may be expected to reach the three score and ten.

It has also been shown from statistical returns, that suicide is very much more frequent among the unmarried than the reverse. On the score, therefore, of physical and mental but they are easily acquired by any intelligent

marriage is advisable; of course its advisability in individual cases must rest on the relative position of the parties. Certainly, however favourable other matters may be, it is a great evil for parties to enter into the married state too early in life; the female especially, if she commences child-bearing early, that is before the age of two or three and twenty, is liable to suffer in her own constitution, and almost necessarily to entail the acquired debility upon her offspring. In the case of those who have family when advanced in life, the trial is less to their own constitutions, but should the father be aged, the children are not likely to be strong. The reader is further referred to articles Disease, Hereditary Tendency, &c., for information respecting the influence which the health and constitution of the parents exert upon that of the offspring.

As regards physical and mental develop-ment, it is an undoubted fact, that the mixture of races, or at least of families totally unconnected with each other, tends greatly to elevate the standard of both. It has been remarked by Humboldt and others, that in South America, the progeny of the negro and of the native Indian, are greatly superior to the progenitors on either side; the superiority of the Caribs to other American Indians has been ascribed to their latitude in intermarriage with the surrounding tribes, and it is well known that the Anglo-Saxon attributes the position of his race in the vanguard of progress to the mixture of blood which has taken place, as a necessary consequence of the successive occupa-

tion of Great Britain by different races.

MARROW is the fatty matter which fills up the centre of the shafts of the long bones. As an article of diet it possesses the

marsh mallow is found on the Continent, and frequently in England, in marshes near the sea; it bears pale bluish-red flowers on an upright stem; the leaves are heart-shaped, cut at the edges, and, like the stem, are covered with soft, hairy down. The whole plant is mucilaginous, but the root is the part chiefly used; four ounces may be put into six pints of water with two ounces of raisins, and the whole reduced onethird by boiling; the mucilaginous decoction obtained is strained through calico before

MASSAGE is a term used to denote a mode of treatment by rubbing, stroking, "kneading," and otherwise manipulating the muscles, joints, and other parts. Its object is chiefly to stimulate the circulation, and increase the power of assimilating nourishment. In surgical cases it is applied to stiff joints, &c. The various "movements" of massage must be learned under a skilful operator, as they have, one and all, a definite physiological meaning;

MEA

of great use by nurses. Massage combined with systematic rest and excess of diet (mainly milk) constitute the Weir-Mitchell treatment for the cure of neurasthenia and other forms of

nervous debility.—See Shampooing.

MASTICATION .- The act by which the food is, or ought to be, reduced to a soft mass before swallowing, by the action of the teeth, and by admixture with the saliva. The importance of the proper performance of this act has been pointed out in article Indigestion. It has even been suggested, that the average of life at the present time exceeding that of former periods, is partly due to the improvements in dentistry, enabling the aged to masticate their food more perfectly. Mincing machines are to be had for dividing the meat into small morsels, so that it may be more easily masticated.—See also Digestion.

MATERIA MEDICA (MEDICAL MATE-

RIALS). - See Medicines.

MATICO is the term applied to the leaves of one of the pepper tribe, a native of South America; the drug has been recommended as a powerful astringent in cases of bleeding; the leaves especially being lauded as a certain remedy in obstinate bleeding from leech bites. The drug has also been employed as an aromatic stimulent. The author has not found in his own trials of it that matico possesses any advantage over other astringents, and that which he used came direct from the importers.

MAW-WORM .- See WORMS.

MEASLES is one of the eruptive fevers which most persons go through once in a lifetime, and generally during childhood; the disease usually occurs as an epidemic, and is contagious. The first symptoms of measles are those of a feverish cold; there is shivering, headache, loss of appetite, and perhaps vomiting; the eyes look red, and, as well as the nose, furnish increased watery discharge; there is hoarseness and cough. On the fourth day of the disease, or in from seventy to eighty-four hours after the first symptoms of illness have shown themselves, the peculiar eruption of measles begins to appear, generally first on the neck, then on the forehead and cheeks, afterwards extending to the trunk and extremities; at first the eruption shows only in red points, not unlike flea-bites, but these soon enlarge into rather broad, slightly purplish, spots, grouped in crescentic forms, and just perceptibly elevated above the skin. At this period, the skin is hot, there is a good deal of general fever, with thirst, and much hoarse cough, with quickened breathing. After remaining out about four days, the eruption-first, of course, on the face—begins to decline, and by the seventh day, it has generally disappeared, leaving the skin slightly roughened, followed by separation of the cuticle in small scales.

person, and a knowledge of them will be found | some amount of catarrh of the respiratory organs is generally present. The most common situation of this is the bronchial tubes, giving rise to bronchitis; it may, however, attack the larynx causing subacute laryngitis with hoarse cough and loss of voice; or it may affect the intimate tissue of the lung, setting up acute Different epidemics vary much in pneumonia their severity, and the same class of lung complications is apt to characterise individual epidemics. Thus in one epidemic severe bronchitis may occur frequently, while in another attacks of pneumonia may be more common. Occasionally very malignant cases occur, where death ensues within two or three days either from the fever itself, or from complications.

Measles is infectious during the whole duration of the disease; to the greatest degree in the early stage before the eruption appears.

In any case of measles, the safest plan is, of course, to have medical attendance; very many parents, however, in the humbler classes, when the prevailing epidemic is mild in character, take the matter in their own hands, and do little more than keep their children in bed for a day or two, if they do even that. There is no question that a mild attack of measles will get well without any treatment; but in even the mildest, ordinary care to guard against cold should be observed, this being, of course, requisite in keeping with the season of the year. If the attack be a smart one, the person should be kept in bed and moderately warm, allowed to drink freely of diluent and especially of demulcent drinks, such as barley-water; the diet should consist of milk and farinaceous matters; stewed prunes and rice, and such like may be allowed, the bowels at the same time being attended to, but not purged. Should the eruption of measles seem tardy in coming out, or the child be affected with drowsiness or other symptoms indicating the undue influence of the fever poison on the nervous system, or should the eruption come out small or insufficiently, or, after having shown itself, should it disappear again suddenly, and before the time of its regular decline, danger must be apprehended; the warm bath is at once the safest and best remedy, the child being kept in the water-temperature 98°-from ten to twenty minutes, according to age; in addition to this, to a child of five years old, a drachm or tea-spoonful of spirit of mindererus should be given in a little sweetened water every two or three hours, and warm drinks freely administered at the same time. A very pernicious practice prevails, especially in the country, among the poor, of giving children stimulants-"to bring out the eruption," and also in the course of the disease; in Scotland whisky is given, in England cowslip wine is the most generally employed stimulant. It is perhaps scarcely necessary to add, that none but the most ignorant and prejudiced could be guilty of so danger-In all except the mildest attacks of measles | ous a practice. In England there seems to be

a popular prejudice in favour of the virtues of or one fluid drachm only, or for one hundred the cowslip in measles, and when the wine is not used, it is very common to find the in-fusion, or tea of the "cowslip pips" or flowers, given; this, of course, is perfectly innocent, and may be permitted. When the feverish symptoms in measles run high, it is commonly in connection with the chest affection; in such cases, from four to six grains of ipecacuanha powder, and half a drachm of carbonate of potash, are to be made into a mixture with three ounces of water, and of this, a dessertspoonful given to a child of five years of age every four or five hours: in milder cases, ten or fifteen drops of ipecacuanha wine are to be Should, as often given in the same way. happens if the child has been permitted to take cold, symptoms of inflammation within the chest show themselves (see Inflammation), they must be treated as directed in the article on the subject, but in all such cases a medical man should be called. It must always be borne in mind, that measles does not bear much lowering treatment, and that blisters are apt to prove dangerous; a bran poultice is always a preferable application. An idea prevails, that persons affected with measles cannot be kept too hot; this is often a source of much mischieft certainly cold is to be avoided but mischief: certainly, cold is to be avoided, but free ventilation, with a moderate temperature of about 65° (see Bed-room) is always the most advantageous. The room ought to be kept comparatively dark, any glare of light being hurtful to the eyes, and the patient should be debarred from reading in bed, and be confined to one room until the catarrhal symptoms dis-When measles assumes a malignant or putrid form, the case must be considered as eminently dangerous; in this form the eruption is dusky and purple, or rather, livid, the patient extremely depressed, the tongue dry and black looking; medical assistance as soon as possible is, of course, indispensable, and even then, the hope of saving life is but small; nourishing meat broth, wine, or warm wine whey, must be given frequently, and those measures resorted to which are recommended under typhoid fever.

Convalescence from measles requires much care, if the weather is at all cold, for the disease leaves a susceptibility to inflammatory chest affection for some time. In children of weak constitution, measles, like the other eruptive fevers, is apt to leave a tendency to discharges from the ears, to weakness and red-

ness of the eyes, &c.—See Rötheln. Refer to-Catarrh-Inflammation, &c.

MEASURES .- Three kinds of measures are used by the chemist for smaller quantities of fluid, these are the drop or pipette measure, the minim measure and the ounce measure.

minims each, and may be made for sixty minims | glasses in the shape of a small graduated tumbler

and twenty minims or two fluid drachms, or for a greater quantity. A minim measure for sixty drops will be sufficient for domestic purposes. A minim, by measure, contains a larger quantity of fluid than a drop; the latter, too, is liable to vary in bulk according to the nature of the fluid, and of the lip of the phial or vessel from which it falls; on these accounts, it would be desirable that the measured minim

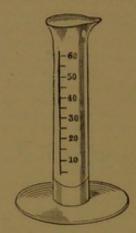

Fig. 152.

only should be used; but, as the measure glass itself must necessarily be frequently wanting, the drop is a more generally applicable mode of division. When the doses of drops of any medicine are measured in a minim glass, one fourth ought to be allowed for the greater bulk of the minim; thus, if the dose is twenty drops of laudanum by drop, by minim measure, it should be only fifteen.

The fluid ounce measure glass is graduated as represented (fig. 153), on the right side of

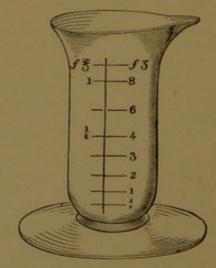

Fig. 153.

the perpendicular line into fluid drachms, on The minim measure is, or ought to be cylind-rical, as represented (fig. 152). It is graduated or marked with divisions equal to five or ten upwards. Extremely convenient measure MEA MED

by Maw, Son, & Thompson for the use of nurses and others who may require them. The cost of these essential articles for the sick room is from one and sixpence to two shillings.

The other fluid measures used by the chemist and adopted by the British Pharmacopæia, are the pint, which contains twenty fluid ounces, and the gallon, which contains eight pints. The following table of the Apothecaries' fluid measures, also shows the initial letters, by which, for the sake of brevity, these measures are distinguished in prescription:-

Fluid.		Symbol.
One gallon,		C = 8 pints.
One pint,		O = 20 ounces.
One ounce,		$\frac{3}{5} = 8$ drachms.
One drachm,		3 = 60  minims.
One minim,		mj

Besides these regular measures, there are a variety of less accurate modes of measurement for medicine, used on account of their convenience; these are, the tea-spoon, equal to about one fluid drachm, the dessert-spoon, to double, and the table-spoon, to four times that quantity, or to half an ounce. The wine-glass generally holds about two fluid ounces, a small tea-cup, about four ounces, the breakfast-cup and tumbler, about half a pint each. These irregular modes of measurement, however, are not only inconvenient, but they may, at times, be of serious moment. Spoons and glasses must vary greatly in size; what the poor call a "meat-spoon" and consider a table-spoon, barely equals an ordinary dessert-spoon in calibre: again, one person will fill a spoon till it runs over, another scarcely more than half, so that in one way or other, it is a great

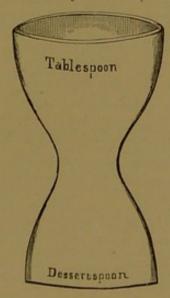

Fig. 154.

chance whether the patient gets the quantity the medical man orders. To remedy these evils, glasses marked in table-spoonfuls, and

and minim measure, packed in a case, are sold | hold a certain quantity, have been manufactured, and are certainly convenient when at hand; but by far the most certain method of apportioning the doses of fluid medicine, is by means of the moulded graduated bottles, now largely used; these being marked in fourths, sixths, eighths, &c., and the medicine being prescribed in these proportions, there is no further trouble; no spoon is required, a great saving to silver, which is apt to be stained, and the medicine is poured directly into the cup from whence it is drunk. Bottles of a peculiar shape, and fluted in an unmistakable way, are also made for poisonous medicines which may be prescribed for external application, and may be useful in preventing accidental poisoning. These graduated and fluted bottles are now beautifully made by the York Glass Co. and other firms, and are not higher in price than plain ones. A few of them would be found convenient in most houses.

MEAT.—See BEEF—FLESH—MUSCLE—

MECONIUM—the dark olive-green discharge from the bowels of a newly-born infant.

MEDICINE.—The science and practice of medicine is, in its highest and worthiest sense, the practical application of many sciences to the investigation of the numberless diseases and disorders to which the human frame is liable, and to their removal, as a result of that investigation, either by the direct action of medicine, properly so-called, by medicine as supplementary simply to the natural tendency towards health, or by other means which exercise a beneficial influence over the health of the body. To exercise well and truly this noble art, is perhaps the most difficult task in which a man can engage; but it would seem also to be the easiest channel through which the ignorant knave can mislead his fellow men. That it is so, however, cannot be laid to the charge of the science of medicine, but is the consequence of the thorough ignorance respecting the nature and requirements of their own bodies and constitutions, in which people, hitherto, have been for the most part content to rest; an ignorance which, strange to say, has been too often favoured by members of the medical profession, who seem to have laboured under a morbid dread, lest a patient should have, in the least, a rational idea of the nature of his own malady, or of the means, medical and otherwise, requisite for its removal. The effect of this mystery has been, in the eyes of the ignorant, to place the educated physician in many instances on the same level as the charlatan-more particularly in cases requiring long and judicious treatment. In a case admitting of rapid and successful cure, by the welldirected efforts of scientific medicine, even the most ignorant can see, and in some degree appreciate, the educated skill which has afforded the striking result; but should the porcelain measures (fig. 154) made only to case prove to be a necessarily tedious one-its

MED MED

flowing-the patient, and the patient's friends, unconscious of the nature of the case, and of the difficulties to be overcome, see nothing, perhaps, but mystery in the treatment. Looking upon the curative powers of medicine, as exerted in some undefined curative effect upon the disease; and seeing first one medicine pre-scribed, and then another, patients probably attribute the changes to the endeavours of the physician to "hit the complaint," whilst he is only making those changes requisite in every case of continued disease to meet the varying and varied symptoms which arise; and when, by the exercise of patient skill, the disease is cured, the last medicine reaps the credit of the whole; and if the patient has been whimsical, very probably the last doctor gets the full credit for that which was really effected by a predecessor in attendance. A patient often remarks: "If you had only given me the last medicine at first!" forgetting that the first medicine had to prepare for the last, which seemed to do all the good.

Now, while it is evident that the entire treatment of such cases may have been conducted on the most scientific, rational, and conscientious principles, to an ignorant or prejudiced patient-and there are many suchor to one kept in ignorance, the whole is unintelligible, quite as much so as the quack nostrum, as far as the method of cure goes; and, perhaps, if the physician be a conscientious man, holding out far less brilliant prospects of speedy cure, the quack's promises and lies carry the day against the physician's wellconsidered, and, perhaps, guarded opinion; for the simple reason, that the patient is without any true rational idea of the structure of his own frame-of the requirements of his own constitution-of the nature and tendencies of his malady, and, lastly, of the objects and intentions which regulate the necessary treatment

and direct its aim.

Quackery and deception, in connection with the treatment of disease, never will, and never can be extinguished by legal enactment—they flourish on ignorance alone. It may be said, that the higher and educated classes in this country are the chief supporters of quackery, legal and illegal, patent and secret, and undoubtedly there appears some truth in the indictment; the cause may be traced to their possession of that dangerous modicum of knowledge which arrogates to itself higher aims, and rejects the simple laws which regulate the working of that frame, so fearfully and wonderfully made, in which God has placed them to dwell on earth.

It is a reproach often brought against medidegree be inseparable from a science which is take advantage of it as a whole, but that each

progress slow, perhaps uncertain, ebbing and | not one of order, but of disorder; unli' e chemistry, astronomy, and the other exact sciences, medicine has to deal with that which is regulated by no fixed laws, but varies with the constitution, the habits, circumstances, and numberless other contingencies connected with the individual, whose constitution, on the other hand, has its own peculiar susceptibilities to the action of remedies. These considerations will show why medicine must be to some degree uncertain; but with this admission, it is contended, that its skilful practice is capable of conferring the most extended benefit on suffering humanity. If the science of medicine is yet uncertain in its nature and results, it is far less so than it has been, and it is daily adding fresh stores of knowledge to its already accumulated experience.

The practice of medicine or treatment of disease may be classed under the two divisions of Empirical and Rational. The former is rather the result of experience and experiment than of reasoning, and administers medicine which is known to remove certain symptoms, or sets of symptoms-constituting a disease -without any rational ground for the administration of the curative agent beyond the fact of its being known from experience to act beneficially in such cases. Rational medicine, on the other haud, looks less at the symptoms than at the causes, and endeavours to ground its treatment upon the observations after death, and upon microscopical, chemical, and other examination. The most efficient practitioner will probably be he who neglects neither method.

Refer to—Diagnosis—Disease, &c.

MEDICINES .- Under this head will be included all that would come under the more correct designation of Materia Medica. This term, which literally means medical materials -that is, the various agents used in the practice of medicine—may appear somewhat technical in a popular work, but it is the most conveniently comprehensive, under which to include the enumeration of all those agents, whether medical or surgical, which may be used domestically. It is unnecessary here to give more than an enumeration, the agents themselves being sufficiently treated of in the various articles devoted to them, either classified or individually. The following list is meant to include whatever, either in the way of medical or surgical material, an intelligent emigrant, in a remote district, might, with reasonable care and ordinary common sense, safely employ; thus constituting a "domestic materia medica, in its widest sense. At the same time it must be evident that, however desirable this latitude may be for the circumcal science and practice, that it is so uncertain, so full of doubt, so liable to error: if persons would but reflect for a moment, it would be apparent that this uncertainty must in some devices he insererable from a science which is should select whatever may appear most suited to his own circumstances. The articles in the list to which the asterisk is prefixed, are such as may most readily be dispensed with, in most instances. Of course, the list includes but a portion of the medicinal remedies mentioned throughout the work at large, neither does it include other agents used in medical treatment, such as heat, cold, electricity, &c.

List of most generally useful domestic medi-

\*ÆTHER-ETHER.-Spirits.-To be kept in a stoppered bottle, tied over with bladder, or with sheet gutta percha.

ALOES .- In the form of the simple drug.

ALUM,—Burnt, in powder.
\*Ammonia.—The carbonate of ammonia, to be kept in a wide-mouthed, stoppered, or well-secured

AMMONIA.-The aromatic spirit of ammonia, or sal volatile, to be kept in a stoppered bottle.

Ammonia.—The acetate of ammonia, or spirit of

mindererus.

ANTIMONY .- The tartrate of antimony, or tartar emetic.

Antimony.—In the form of James' Powder. \*ARNIC. -The tincture.

\*BISMUTH,—Subnitrate of,—called white bismuth.
\*BORAX.—In powder.
\*CALUMBA.—Root, and powder of root.
\*CAMPHOR.—In bottle.

CANTHARIDES—or Spanish blistering fly. In the form of the common blistering-plaster, or in the form of blister tissue, or of blistering fluid.

CARBOLIC ACID.—In coloured stoppered bottle.

CARBORIC ACID.—In coloured scopperson of the Cartechu.—The simple drug.

\*Charchu.—The coloured scopperson of the care acid.

\*Charchu.—The simple drug.

\*Charchu.—The simple drug

CHLOROFORM. CHLORODYNE. \*CINCHONINE.

\*CINCHONINE.
COTTON WADDING.—In sheets, or put up in balls or packets for blister dressing.
CREAM OF TARTAR.
CREASOTE.—In stoppered bottle, about two drachms.
COPPER,—Sulphate of,—blue vitriol.
DIACHYLON PLASTER.— Adhesive plaster; but not spread, if going to a warm climate.
DILL-WATER,—For infants.
EXTRACT OF HENBANE.

\*GALLS.—whole, or in powder.

\*GALLS, -whole, or in powder. GENTIAN ROOT.

GINGER.

GLYCERINE.

\*GUM ARABIC. -In mass and in powder.

HYDROCHLORIC ACID, -diluted, -spirit of salt, in stoppered bottle.

IPECACUANHA.—In whole root, and in powder.

\*IRON,—Sulphate of,—green vitriol.
IRON—Tincture, perchloride of, "tincture of steel."

\*JALAP.—Powder.

LEAD,—Acetate, sugar of.
"LEMON JUICE.—Bottled, if for a sea voyage.

\*LINSEED MEAL.

MAGNESIA.—Calcined or fluid.
MAGNESIA.—Sulphate of,—Epsom salts.
MERCURY,—Subchloride,—calomel.
MERCURY,—with chalk,—grey powder.
\*MERCURY.—Red precipitate.
MUSTARD.—It powder, in close canister, or mustard leaves.

\*MYRRH,—Tincture of.

\*MYRRH,—Tincture of.

\*NITRIC ACID.—Aqua fortis, in stoppered bottle.

\*OHL, CAMPHORATED.

OPIUM.—In powder.

OPIUM.—Compound tincture, with camphor—Paregoric

\*OPIUM .- In the form of Battley's solution, a small quantity, or in the form of muriate of morphia.

OPIUM.—In the form of laudanum.

PILLS.—Either in powder, ready mixed for making up, or made up with a small addition of glycerine to keep them soft, and kept in stoppered bottles. Blue pill in the mass, in a well-covered pot.

PILLS .- Compound colocynth pill.

Compound colocynth pill, with calomel. Compound colocynth pill, with hyoscyamus. Compound rhubarb pill.

Compound expectorant pill.—See Pills.

POTASH, -Bicarbonate, in powder.

POTASH, -Citrate of.

POTASH,—Nitrate of,—saltpetre, in powder. \*POTASH,—Solution of,—"liquor potasse," in stoppered bottle.

POWDERS,-Compound.

Compound chalk, with opium.
Compound powder of Ipecacuanha and
opium—Dover's powder.

QUININE. RHUBARB.—In root, and powder of root.

RHUBARB,—Tincture of. SCAMMONY.—In powder. \*SQUILL.—In tincture.

SENNA-leaves.

SILVER,—Nitrate of, or lunar caustic, in stick mould, in a bottle, or with gutta percha holder.

SODA, -Bicarbonate, in powder.

\*SPIRIT OF WINE. SPIRIT OF SWEET NITRE.

SPIRIT OF CHLOROFORM.

SULPHURIC ACID .- Oil of vitriol, diluted to medicinal strength, and kept in stoppered bottle.

\*TURPENTINE,-Spirit of.

VASELINE

ZINC,-Sulphate of,-white vitriol.

To the above medicines, or such of them as are selected, it will be requisite to add a set of scales with apothecary's weights, a couple, at least, of "graduated" glass-measures, a Dutch tile, a bone spatula, and one or two iron spatulas or palette knives, a filtering funnel or tun-dish, and a moderate-sized mortar and pestle of Wedgewood ware. The above may be said to be the necessary articles of the domestic laboratory, and it is advisable that they and the medicines should be included in a chest or box properly constructed for the purpose. Where expense is not too great an object, strong, glass-stoppered bottles, which are always preferable to corked, will be found quite the best receptacles for the various medicines, wider-mouthed ones being used for the pills and powders, and narrow ones for fluids. In addition to the above requisites, the following will be found convenient additions for all, but especially in the case of emigrants:—A measure graduated for doses, a few bottles of various sizes, from half a pint downwards, graduated, that is, marked into parts, such as fourths, sixths, &c., phial corks, filtering or blotting paper, and a few cut papers for powders, a glass rod for stirring.

The above mentioned articles may and ought to be included in a thoroughly furnished medicine chest; and those who would be completely equipped, should also provide the surgical materials mentioned below. All these, however, add to the expense, and as there are many persons, whether emigrants or others,

MED MED

who either cannot or do not wish to incur the | upon the contingent circumstances, present cost of providing so amply, but yet who would desire to keep beside them a stock of the most efficient medicines, and those most likely to be required on emergencies, an emigrant's medicine chest has been manufactured by Mr. Hooper, of Pall Mall, which is calculated to contain, in the most compact form, a stock of selected medicines, with the means of dispensing them, such as scales, measures, &c. chest is entirely constructed of japanned tin, this material being better calculated to resist the effects of climate, and the attacks of insects, than wood, and at the same time occupying much less space; indeed, the entire chest measures barely eight inches in length, and five in width, and the same in depth, and is to be sold stocked, at a cost of 30s., which will place it in the power of most. A larger form of medicine chest, made of oak, and calculated to contain surgical appliances, as well as medicines, has been constructed after the writer's design by Messrs. Maw & Thomp-son; and Messrs. Richardson, of Leicester, have stocked a very compact "Colonist's Medicine Chest," which is accompanied by a small "Guide" to the use of the contents, compiled by the writer.

The introduction into pharmacy of drugs in the form of compressed tabloids has increased greatly the portability of many medicines, while, at the same time, the risk of deterioration from the effects of time and climate is much diminished. A very large number of the most useful drugs can now be obtained in this form, the best known manufacturers being the firm of Burroughs, Wellcome & Co., Snow Hill, London, E.C., who supply specially prepar d

medi ine chests for emigrants.

In the case of emigrants especially, the author would advise those who are providing a medicine chest, to make themselves well acquainted, previous to purchasing, with the probable requirements of the climate and situation to which they are removing, or which they are likely to pass through; thus, for instance, quinine would be a much more indispensable article for the settler in some parts of America, where ague prevails, than for the Australian emigrant; or sulphate of zinc, for eye wash, would be an article not to be overlooked in the medicine store of the voyager upon the Nile; or, as another example, persons going to hot climates must not take their adhesive plasters ready spread. By reference to the articles on the individual medicines mentioned in this work, the requisite information on these points will be gained; it is unnecessary, therefore, to detail it here

To the surgical department belong, -Liut and old linen, oiled silk or oiled calico, or thin sheet gutta percha, vaseline, bandages, scissors; pins, &c. Instruments, properly so called (see Instruments), must entirely depend

and probable, and upon the inclination of the individual. Indeed, so much depends upon these, that it is impossible to lay down any uniform system of domestic materia medica; but it is trusted that the foregoing enumeration will be some guide in the selection. At the same time, the author would strongly advise parties, either resident in this country, or going abroad, to avail themselves, when possible, of the aid of a medical friend, or adviser, when furnishing the domestic labora-tory. They will thus be put in the best way of getting what they want, good of its kind: this is essential, for the money had better be kept in the pocket, than wasted upon cheap and worthless drugs; they will, too, have some guarantee when they obtain their stock of medicines from any respectable or well known firm, that the high prices will prove cheapest in the end (see Drugs). Further, although there are certain general remedies which none can err in providing, there may be others more especially adapted, either to the constitutional tendencies of the individual, or family, or, in the case of emigrants, to the nature of the climate, and of its peculiar diseases, to which they are about to remove. These are points on which a medical man only can give proper advice; and few are so friendless as not to be able to get it-indeed, the author knows well that none need want advice on these points; the members of the medical profession will always give, and give it freely, under such circumstances. This article is little more than an enumeration of our domestic remedies, the plan of the work rendering it necessary that the information connected with each should be given under the individual heads, and to these the reader is referred in particular, as well as to such articles as Bed-room, Dressing, Drugs, dc. Indeed, the reference may be said to extend to the work at large.

In accordance with the plan laid down at the commencement, whenever doses of medicine are given, they are, unless it is otherwise specified, such as are suitable for an adult; the following table is generally considered a sufficient guide in the apportionment of the doses

to the different ages :-

For an adult-Suppose the dose to be 60 grains or 1 drachm, 1 year the dose will be  $\frac{1}{12} = 5$  grains, . gr. v 2 ,,  $\frac{1}{8} = 8$  grains, . gr. viii 3 ,,  $\frac{1}{6} = 10$  grains, . gr. x 4 ,,  $\frac{1}{4} = 15$  grains, . gr. xv 7 ,,  $\frac{1}{3} = 1$  scruple, . 9 i 14 ,,  $\frac{1}{2} = \frac{1}{6}$  drachm, . 3 fs 20 ,,  $\frac{1}{3} = 2$  scruples, . 9 ii 21 to 60 years 1 drachm . 21 to 60 years, Above sixty-that is, in old age, the dose

gradually diminishes. The scruple and drachm weights are discon

MED

long use and convenience prevent them from being abandoned altogether; the former represents 20 grains and the latter 60 grains. The ounce is equivalent to 437.5 grains and the

pound to 16 ounces.

Although the above table is, and may be, accepted as an average rule, it must not, by any means, be adopted as an invariable one in practice, without reference to the constitution, state of health, &c., of the individual. A strong child at three years of age may require, and may tolerate better, a much stronger dose than a weaker or weakly one two years older. Moreover, in the case of many aged persons, purgative medicines especially, will often require to be used as actively as in the young. Again, in such a medicine as opium, the proportions given in the table would give rather large doses for children, whilst, on the other hand, in the administration of mercurials, such as calomel or grey powder, they would reduce them too greatly. These observations are made, as qualifications to what some might regard, from its being in the tabular form, as a complete guide in all cases. The variations are of less consequence, as sufficient information respecting dose is always given in the place or article in which it is directly requisite.

As a general rule, women require smaller doses of medicine than men, and at the same time, it is always requisite to keep in view the peculiarities, periodical and otherwise, of their constitutions; and in the case of matrons, the possibility of pregnancy. It is better to avoid the use of strong purgatives, and of astringents, during the healthy menstrual period. In some cases, all relaxing remedies, such as warm bathing of the feet, and diaphoretic medicines, are inadmissible during the same event. Temperament, in all cases, requires to be considered in the administration of medicine. - See Tem-

perament—Diathesis, &c.

There is some art—and a good deal depends upon it—in administering medicines properly, not only to children, but to adults. It is a very common popular saying, that "doctors do not give sugar-plums," and verily, unless it be the homocopaths, they do not. At the same time, much may be done to lessen the nauseousness of many drugs; the methods are generally pointed out when the medicines themselves are treated; the following do not occur under any regular head. The aromatic waters, such as peppermint, cinnamon, &c. are as much disliked by some, as they are liked by others; their addition to medicines may, therefore, generally-unless they are given as carminatives-be left to choice; as a rule, they do not render the medicine more palatable. The introduction, however, of glycerine and chloric ether into prescribing, has greatly increased the power of making medicines palatable; alkaline medicines which could not be modified by sugar, are now much improved by | tion, of the disorders, and of the accidents to

tinued in the British Pharmacopœia, but their | a little glycerine for children, or chloric ether for adults, especially when combined with an aromatic such as peppermint water or orange The same observation generally tincture. applies to sugar and syrups; in cough medicines and the like, sweetness may be agreeable, and an advantage, but in the case of a nauseous medicine, sweetening it only renders it more sickly to most patients. From his own experience, the author can testify that the fewer additions made to the essential medicine-what physicians call the "basis"—the better. In the case of children, bulk is always an objection to be guarded against, as much as consistent with utility. The fact is, perhaps, not sufficiently realized practically, that one most efficient method of avoiding the taste of nauseous medicine is to blunt for a time the acuteness of the nerves of taste: nothing does this so well and agreeably as the essential oil of orange or lemon peel. A small piece of the rind of either of the above fruits chewed, just before and immediately after swallowing the dose, is very efficacious.

The nature of the medicine and its form should, in some degree, bear a connection with the periods of the twenty-fours hours. Tonic remedies generally are better taken before meals; the time for taking purgatives should, in some measure, depend upon their nature. Unless for some special purpose, liquid purgatives, such as castor oil, senna, salts, &c., which, like liquid medicines generally, exhibit their action quickly, should not be taken late in the evening, when their action will probably disturb the night's rest; pills and powders on the other hand, which are slower in their action, may be, and generally are, taken at Although medical men order some medicines to be taken upon a full stomach for special purposes, the generality are better taken when the stomach is empty, or nearly so; tonics, purgatives, astringents, &c., particularly. In the first place, they are not so likely to interfere with the process of digestion, and in the second, their proper action is more readily and effectually manifested.

In conclusion, it might be thought by some that more, what medical men call prescriptions, and the public recipes, might have been given in this article, or throughout this work generally; but the author trusts that before this the principle of his system of safe domestic medicine has been manifested-that it is not to furnish a set of nostrums, one "good for" this complaint, and another "good for" some other, to be used without reason why or wherefore. Such a concession to a blind popular craving is truly mischievous, and antagonistic to the intelligent management of disease, more or less, according to circumstances, and which is based upon a true, even though a superficial, knowledge of the functions and requirements of the human body and constitu-

which both are liable. Under such a system, | no series of nostrums and mixed recipes is requisite; its safety and its efficiency rest, in the first place, upon the correctness and intelligent understanding of the anatomical and physiological knowledge, as far as it goes; upon the clear appreciation of the causes and nature of disease and accident, as far as they can be popularly explained; and lastly, upon the simplicity of the means of alleviation or of

cure, which can be legitimately pointed out.

The term *Medicine* is usually given to the substance in its prepared state; in its crude condition it is more generally called a drug.-

See Drugs.

The prepared forms of medicines are-

Cataplasm, or Poultice. Confection. Decoction. Enema, or Clyster. Extract. Infusion. Juices. Liniment. Liquors. Lozenges. Metallic salts. Mixture

Ointment. Pill Plaster. Powder. Spirit. Suppositories. Syrup. Tablets, or Tabloids.

Tincture. Wine.

Medicines are also divided according to their. actions as follows :-

Anæsthetics. Antacids. Antispasmodics. Astringents. Demulcents. Diaphoretics. Diluents. Disinfectants. Diuretics. Emetics. Emmenagogues.

Epispastics. Errhines. Expectorants. Escharotics. Narcotics. Purgatives Refrigerants. Sedatives. Sialagogues. Stimulants. Tonics.

To these might be added, external forces, heat, cold, and electricity.

MEGRIM, or MIGRAINE, is a species of nervous headache affecting only one side of, or one defined spot on the head, the forehead and temple, and is generally the result of debility. It is a periodic disease, appearing and disappearing at irregular intervals, and may be induced by the same causes as give rise to hysteria and ague. The immediate attack of megrim headache may be relieved by the application of flannel or sponge, soaked in hot water, or by the continuous application of ice over the part. The affection, which is often a very painful one, is likely to be removed by the improvement of the general health and strength, by good diet, air, and exercise, and by the use of bark, iron, and other tonics. A large dose of quinine, five or six grains, repeated two or three times in the course of twenty-four hours, will generally cut short an attack of megrim.

MELON, the well-known pleasant and highly esteemed watery fruit, much used in order, it may be, of a tendency to insanity.

warm climates as a food, as well as for quench ing thirst and allaying fever. It may be eaten by itself or with the addition of sugar, and sometimes with a condiment such as pepper or

MEMBRANE, in its purest form, is a thin expanded substance or pellicle, in which no trace of structure can be detected under the highest powers of the microscope; in this state, it is now known as "primary" or "base-ment" membrane. Membrane, however, may be constituted also, either of flat cells or of interlaced fibres. The surfaces of the serous or mucous membranes are spread over with layers of minute cells, which are concerned in, and adapted to, the functions of the particular membrane they cover; these layers are called the epithelium of the membrane, and resemble, in situation and purpose, the epidermis or cuticle which is spread over the skin.

Refer to—Skin.

MEMORY, the mind's record of the past, is, we have every reason to believe, imperishable. The power to recall what has been imprinted on its, to us, mysterious tablets, may not be always at command, but all know that it is more so at one time than another, and medical men not unfrequently meet with cases of disease, in which the memory of long-forgotten knowledge is again opened up; the scenes, the thoughts, and the language and words of the first childhood, pass again through the mind of the second; the thoughts and feelings of later times are unremembered, and the Greek exercise or Latin poem of the schoolroom are once more gone over correctly, by those to whom they have been unknown tongues for years. This resuscitation, as it were, of memory, as the effect of disease, is not less remarkable than its loss; in many instances, under the same influence, one man will remember numerals but forget letters, another the reverse; one can only recall the last syllables of words, a second stops short after repeating the first. Still more remarkable are the cases of double memory or consciousness, several of which are on record. In these, either in consequence of some acute disease, or mental shock, all memory seems to be swept away; the mind is left a perfect blank, and education, even in adults, has to be commenced anew; in such cases the individual has gone on for some time acquiring the simplest rudiments of knowledge, when, all at once, the old memory has returned, and with it all its mental stores, blotting out apparently the new; and this alternation of these two singular states of mind has occurred again and again. Loss of memory, exhibited either with respect to things that have hitherto been well remembered, or in unwonted difficulty in the acquisition of new ideas, must, unless well accounted for by advanced age, be regarded suspiciously, as the possible result of incipient cerebral disMENORRHAGIA. - See MENSTRUA-

TION. MENSTRUATION.—The monthly periodical discharge, the "catamenia," is one of, if not the most important of the facts con-

nected with female health.

Commencing usually in this country between the ages of thirteen and fifteen, its recurrence in health-except during pregnancy and nursing-is generally extended for a period of thirty years. It needs not to dwell upon the necessity for the maintenance of the regular and sufficient development of this function during those thirty years of life; females are generally sufficiently aware of it, although, sometimes, in carelessness or wilfulness, they neglect the temporary self-restraint it imposes.

It is a foolish error, or neglect, not uncommon with mothers, to omit all mention of the occurrence of this event to their daughters; the consequence is, that the symptoms which usually precede it, are ignorantly unattended to, and it may happen the development of the function is checked by imprudences which a little information might have prevented. Moreover, the unexpected appearance of the period is apt to excite much alarm, and the mental agitation, or other causes, may at once check a natural and healthy proceeding; it need scarcely be said, with how much probable injury to health. Mothers or female guardians should always forewarn those committed to their charge, and put them on their guard against those exposures to cold and fatigue, to mental excitement, or abuse of purgative medicines, which may interfere with the natural relief. There is, of course, considerable variation as regards the amount of the menstrual discharge, and also in the period of its continuance. The one is in this country from four to five ounces, and the other from three to five days, on the average.

Climate, temperament, habits, &c., all exert much influence over the function in different individuals, or even over the same individual at different times; but these variations may all fall within the limits of health, and do not require interference; and, although in the majority of instances the function is established before the sixteenth year, it may, coincidently with perfect health, be delayed two or three years longer. Generally, however, the delay, or non-development of the menstrual function, if not owing to structural deficiency, or to mechanical obstruction, is owing to some deep-seated constitutional defect, such as is usually distinguished as Chlorosis or Anæmia (see Anæmia). It may nevertheless be owing to peculiarity, and not to defect of constitutional power. In any case medical advice is requisite to give those proper directions for the improvement of the general health and strength which are necessary, or to investigate the cause, whatever that may be, of so important a deficiency

After the first appearance of menstruation, it is not uncommon for the second to be delayed for a considerable period, without the health in the least suffering; after its full establishment this can scarcely be the case. During the menstrual period, there is almost always some amount of irritation of the system, at least of an increased susceptibility to exter-nal impressions, and very often of increased tendency to hysterical affections; these facts always require to be kept in mind in the treatment of disease, and care taken that this does not interfere with the natural discharge, which, often in itself, proves no slight relief; indeed, there exists so strong a prejudice on this point among females themselves, that they will voluntarily stop a course of medicine at the time of their period. As well known, menstruction is generally absent during suckling; its occurrence and recurrence, whilst this is going on, should be a signal for weaning, for not only is the double drain most hurtful to the maternal constitution, but the milk undergoes alteration, becomes more serous and less nutritious.

Menstruation may be interfered with by causes from without, which check its development, and throw it, as it were, back upon the system; or by causes from within, generally incipient disease, such as consumption or general debility. In the former case, the stoppage is of the active, in the latter, of the passive character; in either case, the term Amenorrhæa is applied to the condition by

medical men.

When menstruation in a healthy female is checked by external causes, such as cold, the whole system exhibits symptoms of oppression; there is probably fever, much headache, torpor, pain in the back, loins, &c.; these symptoms being aggravated, and perhaps mixed up with hysteria, on return of each menstrual period. In such cases, relief is best afforded by those measures which tend to relieve the over-loaded system; free purgation by some of the more active pills, such as compound colocynth, or compound rhubarb, with or without calomel or blue pill, senna, jalap, &c., will be found of service, and effervescing draughts of carbonate of potash and tartaric acid may be tolerably freely taken. If there is much complaint of headache, or of pain in the lower bowels, leeches to the groins, or cupping at the bottom of the back will do good, but these must be used in the interval, not at the return of the period, at which time, immersion of the feet and legs in hot mustard and water, and hot hip baths will be most serviceable, the latter at the full heat of 98°, and repeated nightly for a few times, the patient remaining in for twenty minutes. Until the restoration of the function the diet should be moderate, especially as regards animal food and stimulants, and walking exercise regularly taken for a considerable time every day.

Amenorrhea. -- In Amenorrhea, or sup- | composed of the sulphate and carbonate of pressed menstruation from constitutional causes, the reverse of all these measures recommended above will probably be requisite; in such cases, the secretion is not thrown back upon the constitution, but the constitution, from some cause, has not power to bring it forward; it is evident then, that remedial measures must not be so much directed to the inducement of the function, as to the amendment of the debilitated constitution, and improvement of the general health; for these purposes, the plan recommended under article Anamia will be generally applicable, and to that the reader is referred.

In any case of suppressed menstruation, medical attendance should be procured if possible, but especially so in the last mentioned form, when the secretion ceases without any appreciable cause, and the constitutional powers seem to be impaired; in such cases, the threatening of some disease of debility is to be dreaded, which may, if detected early, be nipped in the bud. It is repeated, in such cases a medical examination cannot be too soon submitted to. Moreover, the distinction between suppressed menstruation with over-fulness, and that dependent upon debility, is not always clearly defined; such cases call for the most careful exercise of educated judgment. In cases of suppressed menstruation, the chance of pregnancy is, of course, to be kept in view; many mistakes have been made on this point (see Pregnancy). The time of life is, of course, to be considered, and the possibility of the secretion disappearing at an earlier age than common.

In some cases of suppressed menstruation, what is called a vicarious or compensating discharge is sometimes established from the nose, the ears, the lungs, the stomach, &c., some-

times from an open ulcer.

Dysmenorrhæa.—Painful menstruation, dysmenorrheea, is very common both among married and single, chiefly amongst those of an irritable constitution, and of indolent habits. It causes much suffering; the subjects of it are less likely to become mothers, and often miscarry. As regards the cure of this painful disorder, it is not a matter for the un-professional, it is generally tedious and difficult, or it may be unattainable, even by the For the relief of the best directed efforts. paroxysms of pain much may be effected. It may be relieved by the use of a hot hip bath for half an hour, after which warm fomentations or a poultice may be applied over the region of the stomach. To prevent the recurrence, everything should be avoided that might act injuriously upon the special organs affected. Thus riding, long walks, or fatigue of any kind must be avoided; especially when the period is expected, and for four days previously, it is useful in many cases to use the warm bath nightly. The bowels should also be kept gently open by means of a saline purgative, the best of which is the ordinary white mixture of consumption and other diseases of debility;

magnesia; indeed careful attention to the digestive organs will in some instances effect a cure. Opiates give relief; five grains of Dover's powder may be given twice or three times in the twenty-four hours, or ten drops of laudanum, or seven or eight of Battley's solution at the same intervals. Phenacetine is often of much service; its employment should be aided by rest and warmth. Ten grains may be taken for a dose, repeated if necessary in two hours. In

severe cases opium suppositories may be useful. In the slighter cases of difficult and painful menstruation, the hot bran poultice may be substituted for the hip bath.

Menorrhagia. — Profuse menstruation, or menorrhagia, like internal hæmorrhages, may be either of an active or passive character. Many varieties of the affection are recognised, but it will be sufficient here to consider it under the above two general heads. Those advanced in life are, as a general rule, most subject to the disorder. Constitutional tendency and the influence of climate both exert so much influence upon the freedom of the menstrual discharge, that they must not be lost sight of in the consideration of cases of menorrhagia; what in one person would be excessive may be only natural in another, and the usual amount in a warm climate would be accounted profuse in a cold one. Profuse menstruation of an active character is most apt to occur in persons of full habit of body; and in such cases, within certain limits, may be considered, and allowed to go on, as a salutary relief. When, however, it becomes so free as to tell distinctly upon the strength, medical assistance should be procured, and in the event of the case being a severe one, blood and clots being passed away in quantity, treatment similar to that recommended under the head of Abortion should be resorted to till proper aid can be obtained. Females liable to these attacks of profuse menstruation, if of full habit of body, ought in the interval to submit themselves to medical treatment; animal food must be taken sparingly, stimulants avoided, early rising practised, and active exercise taken during the day, the bowels being attended to by cooling saline aperients; a teaspoonful of Epsom salts, with fifteen drops of dilute sulphuric acid, taken every morning in half a pint of water, will form a most suitable dose. In the recently married the flow is not unfrequently profuse and long continued; the saline purge above recommended, taken till the bowels act frequently, will generally afford relief. Continued and repeated active menorrhagia may end in the passive form.

Passive menorrhagia is most general in persons of debilitated constitution, in whom every drop of blood is of consequence, and in whom the continued weakness resulting from the disorder is very apt to lay the foundation

MEN MER

care of a medical man. In the event of a sudden attack, means very similar to those employed in the active form are to be at once resorted to, the strength being supported by strong animal broths,—and, if there is much exhaustion, by stimulants. In such cases, the oxide of silver, as recommended by Sir James Eyre, in one-third and half-grain doses, is extremely useful, but must be given under medical sanction. In extreme cases, the injection of ergotine by the hypodermic syringe, will almost certainly check the flow. Ergotine is the active principle of the ergot of rye, and has to be procured specially prepared. Mr. Hugget of Liverpool, and Messrs. Richardson of Leicester, have both excellent preparations. In the interval, these cases will require a strengthening tonic treatment, animal food and broths freely, wine or malt liquor, bark and mineral acids, or "tincture of steel," in fifteen-drop doses, twice a day. It is repeated, there are so many modifications and varieties both of cause and effect, in cases of menorrhagia, that medical advice cannot be safely dispensed with, and should be resorted to as soon as practicable.

Decline of Menstruation.—The decline of menstruation usually occurs, as already noticed, about thirty years after its first establishment. The period is, and as such is always regarded by females themselves as, a critical era in their lives. With the cessation of menstruation the capability of conception also ceases. Such an important change cannot take place without causing some constitutional disturbance, in-deed, women themselves seem to think it a matter of necessity that they must have illness at this period. This is probably going too far, many do get over the change with comparatively trifling indisposition, and much of the disorder that does occur, may be traced to luxurious and artificial modes of life, perhaps also, to privation and over-work. However, disorder at the "change of life" is sufficiently common to make it a matter of expediency in all cases, of necessity in many, that the health should be carefully watched, and any symptoms of disease at once attended to. As might be expected, irritations of the nervous system, hysterical, hypochondriacal, and even symptoms indicating approaching insanity, are apt to occur; still more frequently, disorder, indicative of plethora, or over fulness of blood, such as headaches, or apoplexy, spitting of blood, piles, &c.; or the individual becomes corpulent. Lastly, cancerous diseases not unfrequently show themselves for the first time at the cessation of the menstruation. Moderation in diet, particularly in the use of animal food and stimulants, regular and sufficient exercise, strict attention to the state of the bowels by means of the compound colocynth pill alone, or with blue pill, or by senna, castor oil, or pearance.

such persons ought always to be under the | saline purgatives, are means which may safely and with benefit be carried out. A good remedy in this depressed condition will be found in the following mixture: - Carbonate of ammonia, thirty-two grains; treacle and tincture of lavender, of each three drachms; peppermint water, eight ounces; mix. Two table-spoonfuls two or three times a day. On the occurrence of actual disorder or disease, medical aid should be sought at once-any sudden attack being attended to according to its nature, and under the directions given for its management in the proper place.

nancy, &c.

MERCURY - QUICKSILVER - the wellknown metal, fluid at ordinary temperatures, furnishes some of the most important agents used in medical practice. Of these it will be sufficient to notice its preparations in the form of blue pill, and of grey powder, of calomel and of the red oxide or red precipitate, and of blue ointment. Corrosive sublimate, although a preparation of mercury used by medical men as a medicine, will only be noticed here with reference to its poisonous properties.

Quicksilver itself has been used in medical practice, not as a medicinal, but as a mechanical agent, in obstruction of the bowels; as much as a pound being administered at once under the idea that its mere weight in passing through the bowels would overcome the stoppage. The practice has been long since

abandoned.

In the forms of blue pill and of grey powder, mercury, according to some, exists merely in a state of minute division, but is more generally thought to be in a state of low oxidation. The former of these preparations is made by rubbing up metallic mercury in certain definite proportions, with conserve of roses and liquoriceroot powder, until the mercury disappears, or, as it is often expressed, is "killed," the entire mass assuming the well-known greyish-blue colour. Grey powder is similarly made by rubbing the mercury with chalk. These two forms are mild, but effective, and most useful preparations; the blue pill for adults, the grey powder for children, or where very gentle action only is required, it being milder than blue pill. It should be remembered in giving grey powder, that if given in preserve or treacle, the acid, meeting with the chalk, gives rise to effervescence.

Calomel is a compound of mercury and chlorine, and is a much more powerful preparation than either of the above; it occurs in lumps, but is generally met with and sold in the form of a heavy white powder. It is often adulterated.

Red precipitate is an oxide of mercury, and should be in the form of brilliant red, somewhat glistening scales. It is often adulterated with red lead, which has a much duller ap-

compound of mercury with chlorine, but with a larger proportion of the latter; hence, in chemical language, calomel is known as the subchloride of mercury, and corrosive sublimate as the perchloride. These terms are apt to create confusion, and might occasion dangerous mistakes, as the corrosive sublimate, except in minute doses, is a virulent poison. It is better, for medical purposes, to adhere regularly to the old and perfectly distinctive names of calomel and corrosive sublimate.

The medicinal uses of mercurial preparations are, perhaps, more numerous than those of any other single agent in the materia medica; for while, in itself, a mercurial acts as an alterative, as a purgative, as a stimulant, or as a powerful constitutional remedy, according to the mode in which it is given, when conjoined with other remedies, it appears to merge its action in theirs, quickening and strengthening that of the drug to which it is added. With the diuretic it is diuretic, with the diaphoretic it increases the determination to the skin, to the purgative it gives more energetic action. Not the least remarkable and valuable property of mercury is its power of controlling or of subduing some forms of inflammation; in many cases, it is often all that the practitioner can trust to; hour after hour he pushes on the mercurial, in the assurance that if he can get the constitution, however slightly, under its influence, the disease will succumb. This effect of mercury is more particularly manifest in inflammations affecting the serous membranes, or in the eye, as in iritis, in which, as through a glass, the whole process of inflammation is to be witnessed; and it is the curative effect of mercury which he observes in inflammation of the eye, which gives the physician confidence in administering the drug in other inflammatory affections.

The administration of mercury in various diseases being noticed when the diseases themselves are treated of, the reader is referred to

the proper articles. Mercurial Salivation. — The constitutional effect produced by mercury, known as mercurialism, or ptyalism, or salivation, is not a state to be lightly induced, and without good reason, by a medical man; certainly never by an unprofessional person. first symptoms of the constitution being affected by mercury, or of approaching salivation, is a sense of fulness and tenderness of the gums, the teeth feel as if they were elongated, and the person cannot bit any firm substance, such as a crust, as well as usual; coincident with these symptoms, the breath acquires a peculiar fœtor, which, once observed, cannot be forgotten, and the gums, if examined, are seen to be slightly swollen, and of rather a purple hue. If the medicine be now stopped, or given only in very small quan- not unfrequently induced by persons continuing

Corrosive sublimate, like calomel, is also a | tity, the constitutional indications do not become more developed, nor, indeed, does it serve any good purpose that they should be so; but if the medicine be gone on with as usual, the gums become much more swollen and tender, the tongue and glands around the jaws inflame and swell, and there is continued flow of feetid saliva from the mouth. At the same time, there is much constitutional irritationmercurial fever, as it is called—and, altogether, the individual under the action is in a most miserable condition. It is by no means requisite for the good effects of a mercurial course to be developed, that the influence of the medicine should be pushed thus far, neither is it desirable; all that is requisite is, that the gums should give indication of the constitution being affected. At the same time, in some individuals, any constitutional affection by mercury appears to involve this violence of action; indeed, there are some constitutions so susceptible of the action of the medicine, that the smallest dose cannot be taken without its producing free, or even violent salivation. Such cases are among the most vexatious which it falls to the lot of a medical man to encounter. He orders, perhaps, a mild, ordinary dose of some mercurial, and finds it has produced salivation, injuring the patient, and probably entailing days-it may be weeks-of discomfort. It is only experience of the fact which can point out the individuals to which this accident may happen; but, having once occurred, it ought always to be kept in mind, and any person thus liable, having occasion to change his medical attendant, should communicate the fact at the very first interview. Unfortunately, but little can be done to cut short, or even alleviate greatly, a course of mercurial salivation; cold, of course, is to be avoided, the alum wash for the mouth, or tincture of myrrh, or camphorated spirit in water, used to rinse the mouth, afford some relief. A lotion made with two drachms of chloric ether, to eight ounces of water, is also serviceable, and diminishes the fætor; solutions of chlorinated soda, or of permanganate of potash in the same proportions, will have the same effect. Chlorate of potash lotion, in the proportion of ten grains to an ounce of water, is much used in these cases as a wash for the mouth; and the same salt may be administered internally in fifteen or twenty-grain doses three times a day. Glycerine and tannin applied to the mouth and gums, by means of a hair pencil, is also found very serviceable as an astringent application. Saline aperients, such as Seidlitz powders, or Epsom salts, largely diluted, may also be given with advantage, if the patient can swallow them, and is not in a very reduced state. The excitation of mercurial action must always, as much as possible, be avoided in scrofulous constitutions; in such, mercury seldom acts as beneficially as in others. Mercurial action is

MER MER

these are prescribed by a medical man for a temporary occasion, warning should always

accompany the prescription.

Action of Mercurial Preparations. - When mercurial preparations are given in small doses, they exert an inappreciable—what is called "alterative"—action in improving the quantity and quality of various secretions. For this purpose, a grain of blue pill, or a couple of grains of grey powder, may be given twice in the twenty-four hours. Of all the organs on which mercurials exert their effects, the liver is most obviously affected; small alterative doses stimulate gently the flow of bile, and improve its quality if impaired; larger doses stimulate more actively, and increase the secretions generally through the bowels with a purgative action. This is more obviously the case when the liver has been in an over-loaded condition; then, a dose of mercurial, even a small one, opens, as it were, the flood-gates, and the rapid descent of bile, often in an acrid condition, causes diarrhœa, with severe griping. When mercurials are given with other medicines, not purgatives, it is generally in doses which will not purge, for, should that occur, the desired action is inter-When mercurials are given in fered with. frequent and not very small doses, either in inflammatory cases, or for the purpose of affecting the constitution, it is usual to combine with them small quantities of opium, a quarter of a grain in each dose, to check the purgative effect, or, as it is expressed, to prevent the mercury from running off by the bowels.

As an alterative, the doses of mercurials are, blue pill one grain, grey powder two grains, calomel half a grain; as a purgative, blue pill from five to eight grains, grey powder six to ten grains, calomel three to five grains. When mercury is given to act specially upon the liver, it is better given according to the Abernethy plan—that is, uncombined at night, and followed by a dose of liquid purgative, black draught, castor oil, or the like, in the morning. In this way the mercury is able to exert its full effect upon the liver, whereas, if combined with a purgative at first, it is hurried through the bowels too quickly to do

this.

In some persons, mercurials produce a state of great nervous irritation; in others, they cause deadly sickness and faintness. Children generally bear mercurial medicines well, in doses which are large when compared with those of adults. It is almost impossible to salivate a child-indeed, in most, it is quite so. The stools occasioned by the purgative action of mercurials, especially in children, are generally of a dark olive green.

Poisoning may be occasioned by any of the preparations of mercury, but corrosive sublimate is the most frequent agent of the class by not swallowed.

to take, inadvertently, aperient pills, which it is produced. This substance occurs contain small doses of the medicine. When in the form of a heavy, crystalline powder, and has a strong metallic taste. Three grains would be a dangerous, if not a fatal dose. Corrosive sublimate can scarcely be swallowed without the strong taste being quickly per-ceived; very shortly, violent pain in the bowels, succeeded by vomiting of stringy phlegm mixed with blood, comes on, the bowels act violently, and if the patient is not relieved, collapse or sinking is followed by death. Of course, in such a case, medical assistance should be obtained with all speed, but, fortunately, the most effectual antidotes are generally within easy reach; these are the white of eggs, given mingled with a little water, or if this cannot be at had at once, thick flour and water, or milk; free vomiting being, at the same time, encouraged by ipecacuanha, if at hand, or by a feather in the throat. The white of egg must not be given too freely; for, if in excess, the good effects of a sufficient smaller quantity are neutralised. If the quantity of the poison given be known, the white of one egg may be given for every three grains. Accidental poisoning, even by the mildest of the mercurials, may arise in consequence of violent constitutional affection, owing to peculiar susceptibility. Such cases are most frequent in children, and are usually accompanied with severe affection of the mouth, and mortification of the cheeks, gums, &c.; they generally occur in weak constitutions, and the best antidotes are wine, strong animal broths, bark, or quinine, with two-drop doses of muriatic acid every six or eight hours. Such cases must be put under medical superintend-

> Slow poisoning by mercury is apt to occur in those - such as looking glass silverers, furriers and others-who are much in contact with the metal in their daily occupations. They become liable to a peculiar shaking of mercurial palsy of the hands and arms, and sometimes of the whole body, which compels them to abandon their occupations; the same symptoms occur in those employed in quicksilver mines.

> Mercurial, or blue ointment, is prepared in a somewhat similar way to blue pill or grey powder. - See Ointments.

A sulphurate of mercury constitutes the

well-known pigment, vermilion.

The white precipitate, or ammoniated mercury, is only used as an external application in the form of ointment to destroy vermin in the hair. Powders containing grey powder, calomel, &c., and indeed, heavy powders generally, should either be simply placed on the tongue, or given in some thick vehicle; but a teaspoonful of milk answers very well for the administration of grey powder to children. Calomel, in a thin liquid, such as tea, &c., sinks at once to the bottom, and probably is

MESENTERY is a broad fold of the | certain and positive knowledge thus afforded, peritoneum, or covering membrane of the bowels, by which the small intestines are connected with the posterior part of the abdomen, and retained in their place. The mesentery contains the mesenteric lymphatic glands, &c. -See Digestion—Intestines.

METASTASIS.—The shifting of diseased action from one part of the body to another, the portion deserted being left free from disease. This occurs in rheumatism, in gout, in

mumps, &c.

MEZEREON. - The root bark of the Daphne mezereon, a shrubby plant found in shady woods, which flowers in February. is rarely used as a purgative and diaphoretic. The berries are poisonous. The bark is one of the ingredients in the compound decoction of sarsaparilla.

MIASMA.—See AGUE.

MICROSCOPE.—This well-known instrument, which enables us to examine structures far too minute to be even visible to our unassisted vision, has done, and is doing much every day, to render the practical applications of medicine more exact. Many of the conditions of the urine are appreciable only by the aid of this invaluable instrument; the nature of tumours, often a matter of serious import, when their removal by surgical operation is the question, is by it, in many cases, determined in a way that no other means of discrimination could admit of; many other instances might be cited; in fact, a medical practitioner cannot now be considered to avail himself of every resource of his calling, unless he uses the microscope. In medico-legal investigation it proves of the highest service; stains which, without the use of the microscope, could only be doubtfully distinguished, are, by it, so exactly discri-minated as to afford foundation for sworn evidence. Finally, as a rational and highly instructive means of amusement, every family should possess a microscope.

It may reasonably be doubted if any of the great improvements, or additions to our means of investigating the nature of disease, can take rank with the introduction of the microscope. Many diseases before unknown are now familiar as household words, and many also of which our knowledge was formerly very obscure are now, by its means, thoroughly understood, and capable of being scientifically treated. Perhaps the relation of a few instances will do more than anything else to illustrate the benefit we have derived from the microscope in various

We will suppose an obscure and difficult case, where the patient has repeated attacks of vomiting of blood. A drop of that blood being placed under the microscope is found to contain cancer cells. Now the causes of vomiting of blood are so numerous and complicated, that no one but a medical man can have any idea of the satisfaction afforded to his mind by the be made in the examination of diseased tissues

as to the exact nature of the disease. Or take the same case in another light. The patient complains of the same symptoms, and the same test is applied. This time, however, to the patient's dismay, it is ascertained beyond the possibility of doubt, that the blood shown is not human blood, but that of some one of the lower animals, and he is at once accused of feigning disease with, perhaps, some object in view. Again, a patient is suffering, perhaps, from indigestion, weakness, with intolerable depression of spirits, and other symptoms, which require to be felt to be described, and which have been treated by ordinary methods in vain. A drop of his urine is placed for examination under the microscope, a new light is immediately thrown upon his case, and the appropriate remedy prescribed, with the result of a speedy restoration to health.

In no way has the microscope proved of more value to medical men than in enabling them to examine with precision and accuracy into the various conditions of the urine and kidneys, which constitute the affection or class of affections called Bright's disease. Indeed, so remarkable is the advantage derived in treating

the kidneys, from an examination of the urine, that medical men can tell their condition all through the course of the disease, and can foretell before death almost the exact state in which those organs will be found in fatal

In affections of the stomach, or bowels, the microscope is very valuable in enabling us to ascertain the nature of vomited matter, if there be such. Pus and cancer cells and fibres, on being found, enable us to speak with great comparative confidence as to the nature of the disease. Animal, or vegetable parasites, may be discovered, or merely some functional error, or fault of digestion detected. The examination of the nature of the sputum in lung diseases is of the highest importance. In this way cancer, consumption, simple inflammatory disease, or inflammatory disease connected with some special local irritant, as we find in miners, and many other trades, may be successfully discriminated, and treated accordingly.

After a patient has had to submit to a

dangerous and painful operation, it may be for the removal of a tumour, the question is often anxiously asked of the surgeon—Is there no danger of its recurrence? Now this is a question which, by the aid of the microscope in enabling us to examine the tumour, we are in a much better position than formerly to answer with an approach to certainty, and we can thus give much more definite and valuable information to friends and relations as to the probability of other members of the same family being affected by the same disease.

A consideration of these remarks will also show of what importance the microscope may

MIC MIC

practice of medicine and pathology.

after death; in fact, it may be said that it is means of its aid, the fraudulent tricks of disalmost mainly to this method that we look for | honest tradesmen, in adulterating food, can be the means of extending our knowledge of dis- detected. For instance, arrow-root, which, ease upon a scientific basis, and that even now when genuine, is very expensive, is often such important discoveries are being made as adulterated with large quantities of potato seem likely to introduce a new era into the starch, the grains of which, when viewed under the microscope, present characteristics which Another way in which the use of the micro- at once, and with the greatest ease, distinguish scope may be said to be of value to all classes | them from those of any other starch. Numeof people is in the readiness with which, by rous other instances might be mentioned where

the tricks of trade are at once exposed by

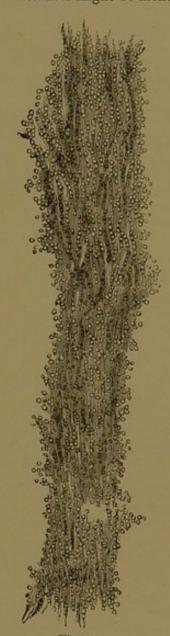

Fig. 156.

The discovery of the dependence of several its means. It is comforting also to think hitherto unknown diseases of the human frame that now-a-days, when diseased meat is so upon the presence of animal, or still more frecommon in our markets, many forms of parasitic disease can be discovered even by very efficiency of treatment consisting in the destruclow microscopic powers, and in the hands tion of the parasite which is followed by an imof any tyro; so that sanitary authorities are compelled to do what ought to have been This alone, had we derived no other benefits done long ago, viz., provide a proper system from its use, would entitle the workers with of inspection of markets throughout the the microscope to our lasting gratitude. The accompanying illustration (fig. 155), from Dr

MID MIL

Aitken's Practice of Medicine, shows, as seen microscope, it is found to consist of numberless under the microscope, a parasitic fungus growing upon, and constituting a well-known disease of the hair and hair bulbs, called Favus, or scald head. The next figure (156), also from the same work, represents a hair, as seen microscopically, loaded with diseased parasitic growth. This represents the morbid state of the hair in the disease familiarly known as ringworm of the scalp. From a consideration of the above figures it may easily be conceived how important an agent the microscope may become in determining the nature of a given disease, and in pointing to the remedies necessary to be used for its cure.

MIDRIFF. — The Diaphragm. — See Dia-

phragm

MILIARY—an eruption, consisting of numerous very minute vesicles, which is apt to appear intermixed with other eruptive diseases, but particularly in cases where persons have been perspiring very much, or kept too hot, in illness. Miliary eruption on the skin, used to be very common in women after childbirth, in times when it was the custom to keep them much too hot, and to stimulate. - See

MILK .- The nutrient fluid secreted by mammiferous animals for the sustenance of their young, through the agency of the peculiar "mammary" glands provided for the purpose, is the only material throughout the range of organisation prepared by nature expressly and solely for food; moreover, it contains within itself all that is requisite in food to maintain in health, and to build up the frame of a living animal. The milk of animals generally is characterised by certain general properties and constituents, although it varies much in the proportions of the latter which it of these ingredients in the milk of various When milk is examined under the animals:contains.

minute spherical globules (fig. 157), which are suspended or float in a colourless fluid. From these globules, which are of various sizes, milk derives its opaque whiteness; consequently, when it is diluted with water, and the fluid increased in proportion to the globules, the rich whiteness of pure new milk is destroyed, and the liquid assumes a more or less bluish or semi-transparent appearance. These globules principally consist of the oleaginous, fatty, or creamy portion of the milk, but they also con-

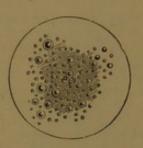

Fig. 157.

tain curd or caseine; this constituent, however, chiefly exists in a state of solution, in the serous or fluid portion of the liquid, along with the sugar and salts, chiefly phosphate of lime with salts of potash and soda, and in less

proportion, magnesia and iron.
Thus we have milk consisting (1) of water which holds the other constituents in solution; (2) of curd or caseine, the nitrogenous or flesh-

			Water.	Caseine.	Sugar.	Fat.	Salts.

than the milk of other animals. In the north of Europe, in Sweden and Denmark, sheep's milk is preferred; in Switzerland much goat's milk is used by the natives; in Tartary mare's milk (from which a fermented beverage called koumiss is also prepared) is much employed; while in Lapland the milk of the reindeer is less opaque and thinner in appearance than generally had recourse to.

Sugar of milk is not present in the milk of composition by that of the mare and ass.

Carnivorous animals as long as they are fed on flesh solely, but appears if they are made to varying from 1 026 to 1 034, and when good

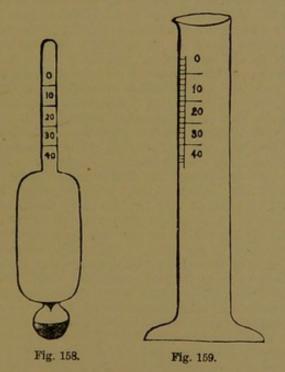

In some countries cow's milk is less used eat a portion of vegetable food. In the milk of the cow, the proportions of curd, of cream, and of sugar-that is, of the caseous, fatty, and saccharine ingredients-are about equal, the caseine rather predominating; in human milk, the saccharine and caseous constituents are proportionally greater than the fat. This milk is cow's milk, and is most nearly approached in

Fresh milk is alkaline, has a specific gravity,

MIL

ing, the light oily particles separate and float in greater or less proportion at the top of the fluid, in the well-known form of cream. If the milk be kept some time-more quickly in a warm situation-lactic acid is formed by a process of fermentation, and the curd separates, souring or curdling taking place. Various souring or curdling taking place. Various modes and instruments have been employed for testing the quality of milk as to richness, &c. The addition of a small quantity of carbonate of soda or boracic acid to milk retards its souring and curdling, if it be requisite to keep it longer than usual. When it is not thought advisable to make either of these additions, it is a good plan when the milk is received, to scald it, that is, to heat it in a sauce-pan to a temperature of 212°, but not to

Milk-dealers have been frequently charged with adding foreign substances to milk, to give

colour and consistence to the fluid after fresh milk has been abstracted from it, and water added; but these charges may in the main be dismissed as fanciful and groundless. The only fraudulent addition likely to be made to milk is water, and although the new Adulteration Act has done wonders in improving the quality of the supply of milk to towns, it occasionally happens that milk-dealers are found guilty of evading its provisions, and are pun-ished in consequence. As the chemical analysis of milk is a somewhat formidable operation, and can only be satisfactorily employed by an expert, it is desirable that some ready means of telling the quality should be within the reach of every one, and this desideratum has been supplied by the lactometer for measuring the density of milk, combined with the creamometer |

is at first perfectly homogeneous; after stand- for ascertaining the proportion of cream coning, the light oily particles separate and float tained in it. These instruments are now universally employed in public institutions where much milk is used, and where it is generally obtained by contract, and may be found useful tests in private households. The lactometer (fig. 158) is an ordinary specific gravity instrument, graduated from 0° to 40° of density, water being represented by the zero standard, and the creamometer (fig. 159), which is used along with it, is a cylindrical glass, marked off in 100 parts forty of which are marked off in 100 parts, forty of which are shown to give the percentage of cream. As a rule the milk may be considered as good, so long as its specific gravity does not go below 1026°, and after standing in the glass for twelve hours, the cream on the surface marks not less than ten per cent. These intruments are to be had from Mr. Casella, of Holborn Bars, to whom we are indebted for the illustrations. Parkes gives some practical hints on the specific gravities of milk adulterated with various proportions of water, which are subjoined. Assuming the density to range from 1026° to 1030°:-

9 parts of milk to 1 of water would indicate a specific

gravity varying from, 1023 to 1027 8 parts of milk to 2 of water, 1019 ,, 1024 7 ,, 3 ,, 1017 ,, 1021 6 ,, 4 ,, 1016 ,, 1018

Milk may vary much in the quantity of its constituents according to the time of the year, or even at the time of the day at which it is obtained, and still come under the designation of wholesome and pure milk. It may be influenced by the breed of the cow, the conditions under which the animals are kept, and the nature of the food they consume. With dry foods, such as turnips and oil cake, the milk is richer in solids; while cows fed on rich pasture land give a larger amount of cream. Alderney cows are noted for the large amount of cream in comparison with the quantity of milk obtained from them; while other breeds, notably short horned-cattle, give much milk with little cream.

The milk which is first secreted—formed after the birth of the young, varies from any that succeeds it, particularly in possessing a purgative property which acts beneficially upon the bowels of the offspring. In the cow this first, or "green" milk or "colostrum" is very nutritive, and contains much curd of a peculiar nature, which is coagulable by heat, like the albumen of egg. On this account it is used in the country parts of England, under the name of "beastings," for making a kind of custard pudding. The first milk, or colostrum, of the human female, is thin and serous looking. This first milk, or colostrum, in animals generally, if examined under the microscope, exhibits an intermixture of larger and different globules from those of ordinary milk.

It is perhaps needless to remark, that upon

MIL MIL

the health of the being or animal by which | others, who suffer from chronic chest affections, milk is afforded, the nutritive properties and wholesomeness of the fluid depend; in the case of mothers, therefore, who are decidedly unhealthy, or the subjects of any disease, scrofulous or otherwise, it is better for their offspring that they should not be nursed by them; and even in the case of the healthy mother, this secretion is so liable to be affected and deteriorated by irregularities in diet, by emotions of the mind, and by medicine taken, that the greatest care, as all mothers well know, is requisite to prevent such causes and effects being accidentally originated (see Children-Nurse). Milk has been proved on several occasions to have been the innocent cause of spreading disease, through the vessels containing it having been previously rinsed out with water contaminated with sewage poison. Several outbreaks of typhoid and scarlet fevers have been clearly traced to this cause.

In addition to the modifications which milk undergoes in the hands of the dealer, there are others besides those stated above due to the condition of the animal. The supply of water, and temperature, influence the state of the milk as regards quality and nutritive power; its wholesomeness depends upon the period after calving,-milk not being in good condition for three weeks or a month after this occurrence,and others depend upon the health of the cow. It was notorious that in many large towns, and in London especially, the mode in which extensive dairies of cows were lodged and fed was most unwholesome for the animals, and for those who use their milk; but these things are now in a great measure rectified by improved

sanitary administration.

As an article of diet, milk is for the generality of persons most wholesome, for children especially, of whose food it ought to form in some mode or other a large proportion: less heating than animal food, it is equally nutri-

tious .- See Childhood.

Some persons, both children and adults, find new milk too rich, but can take it after the oily cream has been removed by skimming, or if it is diluted with water, or boiled. The if it is diluted with water, or boiled. The addition of from one-third to one-half lime water, will often cause milk to sit more lightly on the stomach. Equal parts of milk and soda water form a nutritious drink which often agrees with people who can take nothing else. Hot milk, slightly sweetened, and soda water makes an admirable night draught for incipient colds, when stronger remedies are unnecessary, or even in addition to them.

When milk is taken largely without other food, there is risk of the formation of a mass of solid indigestible curd in the stomach, which may cause much uneasiness, and at times, in children, even alarming symptoms; its expulsion by vomiting is the usual means of relief. Some persons cannot take milk without suffering from stomach disorder and headache, and

find its use aggravate the symptoms. It need scarcely be added that, except in these peculiar cases, milk and milk preparations form one of the most valuable resources in the dietetic treatment of the sick. It is exceedingly useful when mixed with ice, as a cooling drink in fevers, to give strength and allay thirst, and with beef tea forms the staple diet of the fever patient. In giving iced milk, however, some caution is needful, for if swallowed hastily, or in too great quantity, there is the risk of an ice cold coagulum being formed, causing pain and depression, and even risk to life. Many invalids derive much benefit from the use of milk warm from the cow in the early morning; in some cases a small quantity of black pepper, or a tea-spoonful of rum or brandy, is added to the tea-cupful of milk with advantage.

A great step towards ensuring the public of the Metropolis, at all events, with milk of a high standard of quality has been made of late years by the establishment of dairy companies for the supply of all kinds of dairy produce on a large scale, in which every precaution is adopted, by testing chemically the milk before it is issued. With the facilities for before it is issued. chemical manipulation afforded by their chemical laboratories, these dairy companies have been able to supply several milk products hitherto difficult to obtain, and which may be had continuously at a reasonable price and free from any objection. The most important of these preparations is artificial human milk, first suggested by Dr. Frankland and Dr. Playfair, which can now be obtained in many towns of varied strength suitable to the age and digestive capacity of the infant. Milk thus carefully prepared is much superior to asses' or goats' milk; there is good reason to think that if these preparations were more generally known and used, much illness in the case of children who cannot be brought up at the breast would be avoided. Koumiss, an effervescing beverage obtained by the natural process of fermentation, is another article prepared by the milk company, in which the curd or casein undergoes partial digestion in the process, while the carbonic acid contained in the altered milk has a sedative effect on the irritable stomach. Koumiss has been extensively used, and is highly lauded as a remedy for obstinate vomiting and dyspepsia generally, as well as a remedy for consumption; and there can be no doubt of its being a highly nutritive food. As a means of still further promoting the digestion and absorption of the curd, a peptonised milk has been prepared by adding pancreatic extract to the milk to form a peptone. It is easy to see how a food prepared in this way must prove invaluable to children, and to many invalids whose stomachs would reject pure milk.

The whey, which is the serous portion of the

milk, freed from the curd, and a portion of the | cream, is light, nutritious, and aperient, and is perhaps too much neglected as a beverage; the same remark applies to buttermilk, which is freed from the cream, but retains the curd.

Those who desire more information on the subject of the above article, will find much in Dr. Edward Smith's treatise on Foods.

Cream-Food, &c.

MILK, PRESERVED.-Milk can be preserved in a perfectly sweet condition for an indefinite time by the process known as sterilization. It is now recognised that decomposition is caused by certain microscopic organisms known as bacteria. The bacteria in milk can be destroyed by being subjected for one or two hours to a temperature of about 170° F., or for about ten minutes to the temperature of boiling water, 212° F. The milk is placed in bottles and maintained at a temperature of about 170° F. for the required time, and the bottles are then hermetically sealed. The taste of the milk is practically unaffected by the process. This method is distinctly preferable to the older one of preserving milk by condensing it and adding sugar, the product of which is sold usually as "Swiss milk." Well prepared Swiss milk, however, is a valuable food when fresh or sterilized milk is unattainable, and has the great advantage of being very portable. Professor Church gives the accompanying analysis of milk preserved in the manner indicated, 100 parts of which contain:-

Water, 15.2 Casein, 11.2 Milk fat, 17.7 Milk sugar, 27.6 Cane sugar,

Mineral matter, . 2.
MILK FEVER, or WEED, as it is sometimes called, is a condition of febrile disturbance, which is liable to supervene a few days after child-birth, and is due to difficulties connected with the secretion of milk. The fever is usually of a slight character, and disappears in a few days when lactation is fully established. To obviate the occurrence, it is advisable to relieve the breasts by putting the child to them as soon as possible, and if this is not enough, to draw off a portion of the milk by the breast pump or other useful contrivance.

MIND—the immaterial part of our existence -exerts so marked, so powerful an influence over the conditions of our bodily health, that it makes the "tone" of the mind a weighty consideration in forming an opinion respecting the ultimate issue of many cases of disease. Under such articles as Faith, Home Sickness, Hope, Fear, &c., the subject has been entered into as far as is consistent with our limits.

MINERAL ACIDS.—See ACID. MINERAL WATER.—See WATER. MINIM.—See MEASURE.

MINT.—The mints constitute an extensive

tribe of plants, well known for their powerful essential oils. Two species of mint are used in medicine - peppermint, and green or spearmint. Of these, the first is at once the most energetic and the most extensively used as a stimulant and carminative, either in the form of its essential oil, of its distilled water, of its spirit or essence, or most generally of all, as a lozenge. Peppermint water is taken in doses of one or two fluid ounces; oil of peppermint, of from two to five drops on sugar; of the essence twenty mimims may be taken at once. A very powerful medicinal peppermint lozenge is made, which is extremely useful where the medicine is required.

Refer to—Carminatives.

MISCARRIAGE.—See ABORTION.

MIXTURES are medicinal compounds in the fluid form; they may be simply composed of various liquids mingled together; they may be solutions, or they may contain insoluble powders, as in the case of chalk mixture, iron mixture, &c. In the latter cases, the addition of gum or of gum mucilage is useful to prevent the powder subsiding as rapidly as it otherwise will do; but as it will not prevent this alto-gether, care should always be taken to shake up the sediment in any liquid medicine. In mixtures which are likely to be kept for some time, especially in warm climates, all saccharine matters should be excluded, to avoid fermentation; if this precaution is neglected, the bottles will certainly be burst. In forming mixtures with light powders especially, such as magnesia, ipecacuanha, &c., and indeed with any powders, it must be done in a mortar, adding at first only a very small proportion of fluid. If much water is used at first, the mixture can never be completely and properly effected.

Refer to—Medicines.

MOLES, or, as they are often called, "false conceptions," have not necessarily any connection with an impregnated condition of the womb, and may arise from causes quite apart from this state. The popular idea that these formations are always the results of conception requires correction, for it might lead to most erroneous and distressing aspersions on character.

MOLES ON THE SKIN. - See MOTHER-

MARK

MONKSHOOD.—See ACONITE.

MONOMANIA.—A species of insanity.— -Disordered or erroneous persuasions of the mind on one subject. The disease may occur either as acute or chronic, and take any form, suicidal, homicidal, &c., -and may lead to incendiarism or theft, to religious melancholy, or to the most absurd ideas and acts.

Refer to—Insanity.

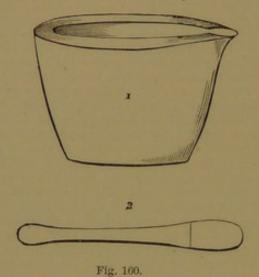

MONTHLY DISCHARGE.—See MEN-STRUATION.

MORBUS COXARIUS.—See HIP-JOINT DISEASE.

MORPHIA.—See OPIUM.

MORTARS and PESTLES are instru-

ments used for triturating, bruising, reducing | important part, the constitution exhibits signs to powder, &c., the different medicinal substances. They are made of various materialsiron, brass, marble, glass, Wedgwood ware, &c., the last being by far the most generally useful, and quite sufficient for all domestic purposes, at least in this country. In emigrant life an iron mortar might be found useful. The Wedgwood mortar is generally made of the form fig. 160-1, the pestle, 2, its head made of the same material as the mortar, being fitted to a wooden handle. The mortars with which medicine chests are fitted are generally too small, and are only suitable for

mixing powders, &c.; there should therefore be added to the domestic laboratory one of a larger size, one capable of holding about a pint will be most convenient. The great advantage of the Wedgwood mortar is, that whilst much stronger than glass, it is not, like marble or metal, acted upon chemically by different agents. It may, however, be broken, if struck sharply with the pestle. The pestle is used in the mortar sometimes with a beating or hammering action; but more generally it is used to grind or triturate, whilst firmly grasped. For simply mingling powders, a lighter hold by the forefinger and thumb is quite sufficient.

MORTIFICATION, or GANGRENE, or SLOUGHING, is the death of a portion of the living body occurring after violent or peculiar inflammation of the part; the appearance of the mortification varying according to the structure affected. A part in which inflammation is likely to terminate in mortification, is hot, painful, tense, and hard; the colour of the skin, at first dark and angry-looking, becomes mottled, and the surface exhibits blisters filled with dark fluid; at this time the previous heat giving way to a temperature lower than natural, and the pain diminishing; at last the part shrinks, becomes of a dirty grey or ash colour, and exhales a fœtid odour. Coincident with these local symptoms, if the

of collapse; the face is pinched, cold, moist; the pulse quick and feeble; the tongue brown; the mental faculties depressed or disordered; the natural functions are performed involuntarily; and hiccup is a very frequent accom.

paniment.

Some parts are more prone to mortification than others, but in all, impeded or deficient circulation of blood is the originator; this may be caused by weakness of the body generally, by weakness of the circulation of a part, such as occurs in paralysis, by impediment to the current of blood through the vessels large or small, by pressure on a main branch, as by a tumour, or on one spot, as occurs on the back, in persons confined by exhausting disease, and by intense cold or heat, which destroy the textures, or by the use of unwholesome grain (see Ergot of Rye, &c.). It may also occur from intense inflammation in persons of full habit of body. In the event of an inflamed part showing symptoms of mortification, if a medical man has not been in attendance, he ought to be called without delay; in the meantime, warm poultices may be applied, those made of oatmeal and bran are often useful, or the turpentine liniment may be applied, but the best applications, if pro-curable, are the carbolic oil, or carbolic acid lotion, or the solution of chlorinated lime; at the same time, the strength must be supported with wine, strong meat broths, &c., and rest procured by means of opium (see *Opium*). When a mortified or sloughing part of the body is separating, its loose and dead portions are usually cut away with scissors, to diminish the fœtor; poultices facilitate the separation, and after it has taken place, simple water dressing will generally be found most suitable. Senile gangrene is the mortification of the toes and feet, which sometimes occurs in the aged, especially among such as have lived too freely. It is caused by the degeneration or disease of the coats of the blood-vessels. - See Dressing.

MOTHER.—See CHILD-BED—CHILDHOOD

-HEREDITARY-NURSE, &c.

MOTHER-MARK.—The term is applied to stains, moles, and other marks, vascular and otherwise, with which a child is born, and for which many fanciful causes are assigned. The most important mother-marks are the vascular nævi. — See Childhood.

MOTION and MOTOR CHANGE. Movement in the living body is the result of contraction of the muscles influenced by the nerves, and is either voluntary, dependent on the will, or involuntary, as displayed in the movement of the heart and intestines. The force necessary to supply motion is developed by heat in the oxidation of the food, and, to a certain extent, by the tissues in the process of mortification be extensive, or situated in an | constant waste and reproduction peculiar to

animal life. The motive force in muscles was for a long time supposed to be due to a metamorphosis of the constituents of the elementary fibres, but recent researches show that the changes are rather the result of oxidation of the carbon of the blood in the tissues, than due to any special waste of the tissues themselves. Dr. Parkes considered (and his opinions are generally accepted) that during exercise the muscles appropriate nitrogen or flesh-forming matter from the blood, while the changes which take place are due to a transformation of the carbo-hydrates, which are consequently the main agents in the production of mechanical force. - See Animal Heat, Blood-Food, &c.

MOUTH .- The cavity which contains the tongue and teeth, in which is performed the important process of mastication, and by means of which articulate sound is formed, is inclosed by the lips and cheeks, by the upper and lower jaws, by the soft palate and tonsils, by the "fauces" generally, and by the mucous membrane, stretching from the tongue to the lower jaw; it is further surrounded by the salivary glands, which supply its moisture, and which open by their ducts into various parts of its cavity. The portions of the mouth are liable to different diseases. These, along with other necessary information, are detailed in the individual articles.

Refer to Aphtha-Palate-Saliva-Throat,

MOXA—a means of counter-irritation, derived from, and long practised in the East. The true moxa is a soft woolly substance, procured from the leaves of a species of mugwort, which is made into a cylinder, and burnt down upon the skin, causing a deep eschar. The moxa has been superseded by other counter-irritants.

MUCILAGE—a thick semi-fluid formed by the solution of gummy or starchy matters in water; such as mucilage of gum acacia, arrow-root mucilage, &c .- See Gum, &c.

MUCOUS MEMBRANE is a membrane which lines certain portions of the body, and which may be regarded as a continuation of the skin, deprived of its cuticle, into the internal passages. It is itself covered on the surface with an "epithelium" of flattened cells, from which is secreted the thick viscid secretion named mucus (see Mucus). are three great systems of mucous membrane, the one which lines the mouth, nose, eyes, throat, bronchi or air tubes, to which the term respiratory is given; the second is continued down the gullet, and through the stomach and bowels to the vent, and is called the alimentary; while the genito-urinary membrane lines the kidneys, bladder, &c.

The affections to which mucous membranes are subject, are sufficiently entered into under such articles as Catarrh, Diarrhaa, &c., when

MUCUS is the thick, somewhat viscid, glairy secretion, formed on the surface of mucous membranes; examined under the microscope, it is seen to contain numerous round granular particles or globules, believed to be the product of disintegrated epithelial cells, cast off from the surface of the membrane. When a mucous membrane is inflamed, its secreted mucus becomes thin and acrid, as all know it does in a cold in the head, which is simply inflammation of the mucous membrane lining the nostrils: when the inflammation is more intense, or of a peculiar character, the mucus secretion is apt to be converted into a purulent one.

Refer to—Pus.

MUMPS—a contagious epidemic disease, which consists of inflammation of the salivary "parotid" glands, situated on either side of the lower jaw, and is usually confined to children. It commences with more or less fever; shortly, swelling at the angle of the jaw appears, and spreads gradually to the face and neck, in the vicinity of the gland, causing much difficulty and pain when the jaws are attempted to be opened: on the fourth or fifth day the swelling begins to subside. Little treatment is required beyond confinement to the house, and the administration of some simple purgative. The patient is compelled to live on slop diet, from the impossibility of mastication; but if the person be delicate, good broth may be allowed. Hot fomentation and bran poultice to the swelling will give some relief, and if the pain and swelling are very severe, a couple or three leeches may be applied to each side. Pain and swelling in the testicle is not uncommon in boys after an attack of mumps, and ought to be treated by rest and fomentation, if necessary. In girls, the breasts are sometimes, though rarely, affected in a similar manner. Mumps is a disease quite devoid of danger, unless, as has occasionally happened, though rarely, the inflammation becomes suddenly transferred to the brain or testicle.

MURIATIC ACID, or HYDROCHLORIC ACID, or "SPIRIT OF SALT."—See CHLORINE.

MUSCLES and MUSCULAR FIBRES. -The muscles, properly so called, are the fleshy portions of the animal frame, by means of which, through the influence of the nerves, the various movements of the body are effected, in fact, all flesh is muscle devoted to this pur-The muscles are composed of bundles of fibres bound together by cellular tissue, and these fibres can be divided and subdivided under the microscope, until the "ultimate fibre" of muscle is arrived at; this ultimate fibre, containing within it other "minute cylindrical particles." These fibrillæ are marked with tranverse lines, and constitute the striated muscular fibre, in contradistinction to the nonstriated fibre, which composes the muscular coat of parts, such as the alimentary canal, the diseases of the parts they line are treated of. | which are not under the control of the will.

The muscles are attached to bones, &c., of poisoning by fungi, treatment similar to for the purposes of movement, by means of that recommended for Belladonna will be tendons; they are largely supplied with aerves (see Nerves), and with arterial blood, on the free circulation of which, indeed, the motor change of their elementary constituents, and consequently their power of action, depends. The muscles, like other parts of the body, are subject to disease, pain in a muscle or group of muscles is known as muscular rheumatism, and wasting of muscular substance is the common effect of paralysis and of diseases attended with great exhaustion. Progressive muscular atrophy is the name given to a complaint characterised by much local wasting of muscular substance, associated with a peculiar condition of the spinal cord. Hypertrophy of muscle, when confined to those of voluntary motion, can hardly be recognised as a disease, and is more the consequence of continuous exercise, as may be illustrated in the brawny arms of the blacksmith; on the other hand, hypertrophy or enlargement of the heart, the most important of the involuntary muscles, is a most serious disease.

-Tendons, &c.

MUSHROOMS.—The fungus tribe to which mushrooms belong contains a large proportion of poisonous members, and even those which are usually considered edible are not always above suspicion in this country. In France, Russia, &c., many species of fungus are used, commonly, and largely, as food, and are very nourishing, as they contain a large proportion of nitrogenous matter as well as fat. The true value, however, of the alimentary constituents is open to question, and where so much doubt exists as to the character of the different plants, mushrooms as an article of fresh mustard with water, as for the table, and food had better be avoided. Those who gather mushrooms for food should be very certain that they know what are mushrooms, and this will be best learned from those who are practically acquainted with the matter; it may be added, that even real mushrooms which grow under trees are generally considered unwhole-some, and also those in which the process of decay has commenced. The edible mushrooms grow in dry airy places, usually solitary; have a white or brownish colour; a compact brittle flesh; do not change colour when cut and exposed to the air, have a watery juice, an agreeable odour, and a pleasant taste.

The poisonous plants grow in dark damp places, have a bright green or scarlet colour, acquire a brown, green, or blue tint when cut and exposed to the air; exude a milky acid juice; have a powerful disagreeable odour, and an astringent and bitter taste. After poisonous fungi have been eaten, there is generally giddiness, dimness of sight, and debility, if the symptoms appear quickly; but if they are delayed they are more generally those of irritation, vomiting, purging, and pain. In a case

the best, in the absence, or during the delay in the arrival of a medical man. -See Belladonna.

MUSSEL.—See FISH, &c.

MUSTARD.—Black and white mustards are plants which grow wild throughout Europe, but are cultivated for use; they are often confounded with the common charlock. mustard has smooth seed vessels which grow close up to the stem, and contain reddish-black seeds. White mustard has tough seed vessels, which spread away from the stem, and contain yellow seeds. The seeds of the black mustard are more pungent than those of the white, but the two are very commonly mixed in the manufacture of the common "flour of mustard;" this is formed by crushing and pounding the seeds, and sifting. The sharp, burning acridity of black mustard depends upon a volatile oil, which, however does not pre-exist in the seeds, but is formed on the addition of water. There was perhaps no article in domestic use more largely adulterated than mustard, but since the passing of the Adulteration Act, the samples brought for sale have very much improved in quality. The materials which were used in the adulteration, and which are still occasionally met with, are wheat starch, linseed, plaster of Paris, and cayenne pepper, the latter

employed to give piquancy to the flavour.

Mustard, when used in moderation as a stimulating condiment, is wholesome. Its principal use in medical practice is in the wellknown mustard plaster, or cataplasm, as a counter-irritant. This application is made in various ways: when speedy energetic action is required, it is best obtained by mixing good spreading on calico or paper. It is well to interpose a piece of thin gauze or muslin between the mustard and the skin; this does not in any way interfere with the action of the application, and prevents portions of the mustard adhering to the skin, and irritating it, after the removal of the cataplasm. Some persons erroneously mix the mustard with vinegar, thinking to render its action stronger: this is a mistake, as it has the reverse effect. Others mix with one-third or one-half flour, or bread crumb, which modifies the power of the remedy, and is all very well when modified and longer-continued action is desirable, not unless. The usual length of time a mustard plaster can be borne, is from twenty minutes to half an hour, and even in this time it often produces blistering; it always leaves for some time a deep red mark on the skin, a fact not to be forgotten in the case of females. A tablespoonful of mustard added to a child's bath is very serviceable in bronchitis and in promoting the rash of the febrile eruptions among children, should it show signs of receding. Mustard is also beneficially employed in the

NAR

MUS

foot bath, and in cases of arrested menstruation it is of service when used in the hip-bath prior to the expected period. When mustard plasters are applied to any one in a state of insensibility from poisoning by opium or alcohol, they should be removed within the half-hour; if allowed to remain, should the person recover, troublesome ulceration may be the result. Mustard papers, or leaves as they are called, are now much employed as substitutes for the poultice, but though convenient for travellers, it is doubtful whether they are equally effective for domestic purposes.

From their familiarity and convenience mustard plasters are apt to be applied somewhat too indiscriminately, both domestically and professionally, and in many cases where a hot bran poultice would be much more sooth-ing and beneficial; they often cause much irritability, and if applied near the spot where inflammation is going on, as in the case of the throat, seem rather to aggravate than to relieve. In the case of a lady under the author's care, the application of a mustard plaster to the lower part of the spine gave rise to effects resembling those produced by the inhalation of laughing

As an internal remedy mustard is a safe and effectual emetic, in doses of one, two, or three tea-spoonfuls in six or eight ounces of water. The seed of the white mustard, swallowed whole in table-spoonful doses, was, some years ago, in much vogue as a stomachic remedy, but is now little used. It probably produced any benefit it effected by its mechanical action upon the alimentary canal.

Refer to—Counter-irritation.

MUSTARD LEAVES, referred to above, are prepared according to the Pharmacopæia by mixing one part of the powder of black mustard seeds with two parts of the officinal solution of gutta percha, strips of cartridge paper are passed over this solution, care being taken that only one side of the paper shall receive a thin coating of the mixture. The paper is afterwards exposed to the air to allow the coating to harden, and before being used it should be immersed for a few seconds in tepid water.

MUTTON, when tender, is the meat best adapted for invalids, and persons of weak digestive powers. The best mutton chops are those cut out of the centre of a leg.

MYRRH is a gum resin, the product of a tree native to Arabia, Abyssinia, and the countries bordering the shores of the Red Sea, from which the drug is chiefly brought. Myrrh is a stimulant expectorant, and enters into different medicinal compounds.

The tincture of myrrh forms one of the most agreeable washes in affections of the mouth, in the proportion of half an ounce of tincture to half a pint of water. A few drops of the

same way for common colds when put into the | lent habitual application in cleansing the teeth, especially if the gums are weak or spongy.

> NÆVUS, or as it is popularly called, Mother's mark, is often very troublesome and obstinate, and it is sometimes a very important and anxious question to settle, whether or not an operation should be had recourse to for its entire removal. There are various methods employed to effect this, should it be thought

necessary by the surgeon.

NAILS.—The nails, like the hair, may be regarded as prolongations from the epidermis, or outer skin; they are formed of flattened cells containing horny matter, and spring from a fold or matrix in the true skin, about two lines in depth. At the bottom of this groove or fold, there are numbers of papillæ, or little vascular points, from which the nail is developed, and is continually being pushed forward by the addition of new matter to its root. At first the nail is thin, but it acquires thickness in its progress forwards by the addition of new layers of cells to its under surface, these cells being also formed by papillæ, which likewise serve to retain the nail in its place.

Nails are apt to be cast off after injury, but the principal and most troublesome affection to which they are liable, and particularly the nail of the great toe, is "ingrowing"—that is, ulceration, formed by the edge of the nail, and constantly kept up by the irritation which produced it in the first instance. This, of course, requires to be attended to by a surgeon. To obviate the complaint, care should be taken to direct the growth of the nail, which is best done in the first instance by wearing shoes which give abundance of room for the toes. Next, a small piece of cotton wool, soaked in a solution of potash, should be inserted well into the corner and round the ingrowing part. this means the nail is softened, and the cause of the pain removed. At the same time, the centre of the nail should be scraped thin, and be kept so for some time. The nail should be allowed to grow square and large, the corners not being rounded off. Should this treatment fail, the nail must be removed, and its subsequent growth attended to. The appearance of the nails is often indicative of constitutional tendency, particularly the long curved or filbert nail of the consumptive.

Refer to separate articles.

NAUSEA, or the sensation of sickness, or of inclination to vomit, is best known from

individual experience of the sensation.

Although the feeling of nausea itself is referred to the stomach, and may be due to causes connected with that organ simply, it also very frequently originates in disorder in other and distant parts of the body, a fact which often constitutes it a valuable symptom. Causes which act directly upon the brain are among the most frequent originators of nausea, and there is every reason to believe that the sensation from which the term is probably derived —sea sickness—is primarily excited in the brain itself. As all know, a blow on the head occasions nausea and vomiting; severe injuries in other parts of the body, such as a disloca-tion, also occasion sickness by acting indirectly upon the stomach; the nausea of pregnancy is another example of this sympathetic nausea. Disgusting odours are instances of the same thing. The action of drugs of an emetic character must be accounted for by their influence on the nervous system, for they act equally well as nauseants, if injected in solution into the veins, as if they were swallowed. Lastly, the presence of indigestible food, or of bile, &c., in the stomach itself, will also cause nausea, which may also be produced by simple over-distension of the organ by gas or fluid. The instances given of sympathetic nausea, will explain, how it comes to be a valuable guiding symptom in the investigation of disease. Incipient or advanced affection of the brain, gallstones, stone in the kidney, disease of the womb, pregnancy, and many other conditions of various organs, give rise to the sensation of nausea, or to actual vomiting.

The complete relaxation of the nervous

system which occurs in an individual under the influence of nausea, renders its existence favourable to the performance of certain opera-tions upon the body, such as a reduction of a dislocation, or of a rupture. The means of relief in nausea, and its very frequent accompaniment, vomiting, must, of course, depend upon the cause. When dependent upon brain affection, remedial measures are of but little service, but in this, as in other cases, may be resorted to. Effervescing draughts, with lemon juice, or simply aerated water, will often be extremely useful. Spirit of chloro-

only narcotics in any way admissible in the domestic materia medica are:—

A tea-spoonful of magnesia in a glass of sherry has been found a good remedy, but one which is inadmissible in head affections; a mustard plaster to the pit of the stomach may be used with advantage. When the nausea is thought to be dependent upon the presence of bile or other matters in the stomach, it is soonest relieved by exciting vomiting, which is easily effected, either by means of luke-warm water alone, infusion of chamomile, or at all events by a small dose of ipecacuanha. After the stomach has been cleared, effervescing draughts will be at once grateful and beneficial. The nausea of pregnancy requires its own treatment.—See Pregnancy.

NAVEL.—See CHILD-BED — CHILDHOOD,

NECK. —The bond of connexion between the head and the trunk of the body is perhaps the most important region of the frame; certainly it is so in a surgical point of view, on account of the numerous important parts it comprises. The illustration (fig. 161), which represents a

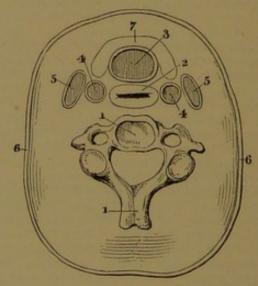

Fig. 161.

transverse section of the neck, will best show the position of the chief vessels, &c.: 1, 1, is one of the vertebræ of the neck, in front of which, somewhat flattened, as at rest, lies the œsophagus or gullet (2); and anterior to this, the windpipe (3); on either side are placed the great vessels of the neck; these are the great or "carotid arteries" (4, 4), and close to them—indeed, included within the same covering or sheath—the internal jugular veins (5, 5). All these parts, besides nerves, glands, the external jugular veins, and the muscles of the neck, are included within the surrounding skin (6, 6). The "thyroid gland" (7), which becomes enlarged in swelled neck, or bronchocele (see Bronchocele), lies in front of the windpipe.

Diseases which affect the parts situated form, in doses of twenty minims, is generally about the neck, such as its glands, &c., fall to

NER

be considered under other heads, and need not be enlarged upon here; and under such articles as Hanging, Gullet, which also includes Choking, Artery, &c., will be found information concerning the accidents to which this region and its parts are liable. There remains, however, for consideration, the effect of mechanical impediments to the circulation of the blood in the neck, connected either with clothing, or with those muscular movements of which the part under consideration possesses so wide a range. Some persons, particularly those with short necks, or with tendency to apoplexy, epilepsy, &c., are much more liable to be affected than others, by anything which, even for a very short time, checks the free flow of blood through the veins downward from the head; and such persons ought to be especially careful that nothing they wear about the neck becomes in the slighest degree tight, not simply when the face is looking straight forward, but when it is turned from side to side. It has occurred, that a person liable to head attacks, has fallen down insensible, in consequence of the simple act of turning the head rather more to one side than usual, and thus giving a little extra tightness to a shirt collar. It is well known, too, that the tight stock of the soldier was the cause of numerous apoplectic and other affections, in consequence of its effect in compressing the large vessels of the neck. similar caution is requisite with regard to the clothing of children, which ought always to be loose about the neck. From a similar cause arises the danger which men incur from sleeping without unfastening the usual clothing about the neck; apoplexy may result. But not only may head affection result from tightness around the neck externally, it may, in the predisposed, be the effect of the action of the muscles alone; these, if the head is turned strongly to one side, exert strong pressure upon the veins and impede the flow of blood, damming it up towards the head. On this account, persons who are liable to over-fulness of blood, ought to be on their guard against such sudden movements.

Wry neck is caused by the undue permanent contraction of one or more of the muscles on one side of the neck. It is remediable by surgical operation. A different form of wry neck, or, at least, of an affection closely resembling it, is the result of paralysis of the muscles on one side, permitting those on the other to draw the head towards their own side. Stiff neck is the result of rheumatic affection of

the muscles

NECROSIS .- Death of a portion of bone. -See Bone

NERVES and NERVOUS SYSTEM .-The possession of a system of nerve tissue is one chief distinction between the animal and the plant; the latter exhibits no trace of it, and even in some of the lowest tribes of animal life, which are scarcely distinguishable from

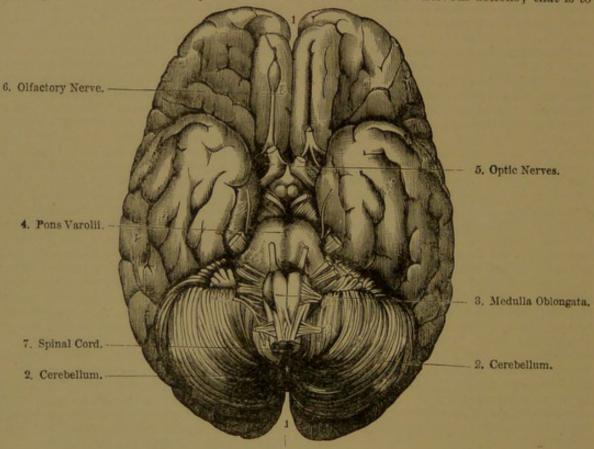

vegetables, it has hitherto been undetected. Where a nervous system does exist, it is always found to be composed of two parts, one of which is white and opaque in appearance, and when examined under the microscope, presents a tubular or fibrous structure; the other is of a reddish-grey colour, and semi-transparent, and consists of cells or vesicles filled with granular matter. The presence of these two forms of nervous substance seems essential to the working, so to speak, of the apparatus. In the larger nervous masses, such as the brain, the distinction is very palpable, and may be verified by any one who will take the trouble to examine the brain of a sheep. The opaque white nerve matter forms the larger proportion of the brain, spinal marrow, and nerves; the grey is more sparingly distributed, and is evidently the apparatus in which the nerve force is generated, the tubular substance acting the part of the conductor. This is more apparent when the latter is thrown into the form of the nerves, or cords of nervous matter, which are distributed throughout the body. These nerves, at their origin, are connected with the grey substance, with the vesicles of which their fibres are intermingled. Where this intermingling takes place, an enlargement, or as it is named a "ganglion" is formed. In the lower tribes of animals in which the nervous system is simple in a degree corresponding with the simplicity of their structure, these "ganglia," resembling knots upon the nerves, are all they possess in lieu of a brain; but as the scale is ascended towards man, we find the nervous system become much more highly developed, and the nerve substances collected or aggregated into masses, which are carefully protected from all external injury, and from which the nervous cords, or conductors, or as they are usually called "nerves," proceed to all parts of the body, each being enclosed within its own proper sheath, and dividing and subdividing to be distributed to every portion of the frame, although to some, such as the ends of the fingers, lips, &c., their branches are

more liberally allotted than to others. In man the great nerve masses are divided into the brain, or cerebrum (fig. 162, which represents its lower surface, or base), together with the cerebellum, or little brain (2, 2), the medulla oblongata (3), the pons Varolii (4), the origins of the optic (5) and olfactory (6) nerves —the longitudinal fissure (1, 1) dividing the brain into two equal halves or hemispheres. These parts are all contained within, and protected by the hard bony skull. Continued from the medulla oblongata at (3) there is the spinal cord, or marrow (7), which is contained within its own special canal, carried through the bodies of the vertebræ of the spine, and thus most effectually guarded. The brain (see Brain), which in man and the higher animals constitutes so large a mass of the nervous system, is itself destitute of sensation, for it may

be, and after accidents often is, cut, without | The cerebellum, or little brain, is believed to the individual, although perfectly conscious, be endowed with the function of regulating in having the slightest sense of pain. Neither unison, and harmonising, the various muscular does its presence appear necessary to the con- movements. The medulla oblongata is continuance of the mere animal life of the body; nected with the processes of respiration, mastifor if, as has been proved by experiment, the cation, swallowing, &c., on the due performance brain of such an animal as a rabbit be gradu- of which the preservation of life depends. ally and carefully removed, the animal still continues to live, and to perform the various powers of sight, smell, taste, &c., and, lastly, functions of animal life.

The brain is undoubtedly the organ upon which the manifestations of will, intelligence, memory, &c., depend, and by which the con-scious mind of the individual, possessing in scious mind of man or animal is linked with itself powers of sensation unconnected with the the processes and actions of the body, by means brain. These powers are exhibited in what are of other portions of the nervous system.

The ganglia of the special senses develop the the spinal cord appears to be most essentially connected with animal life, particularly with the powers of locomotion, independently of the called the "reflex" nervous actions; that is to

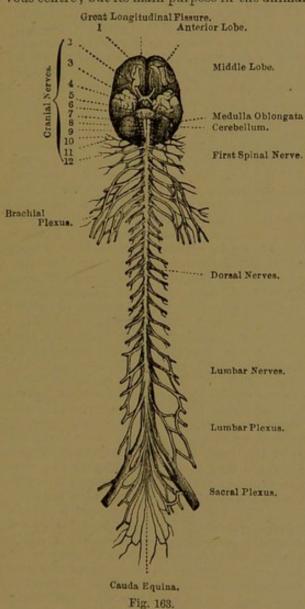

1, 1. Longitudinal Fissure. Fig. 162.

say, supposing-as sometimes occurs from in- surface of the brain with the twelve pairs of jury, or is done for purposes of experiment in cranial nerves proceeding from it, and the animals-the spinal cord is severed at any point, spinal cord or marrow from which thirty-one all sensation, all power of the will over the pairs of nerves originate, each nerve possessing parts of the body below the line of severance is two roots, an anterior, or motor, and a postotally lost; but yet, irritation, such as the terior, or sensory. These, however, soon totally lost; but yet, irritation, such as the terior, or sensory. prick of a pin, to such a part as the foot, will cause the leg to be retracted-evidently showing that the sensation excited by the pin was throughout the system. The cranial nerves, felt, so to speak, by the spinal cord through so named from taking their origin within the one set of nerve fibres, and "reflected" from it skull, are partly derived from the brain and again through another, causing contraction of partly from the medulla oblongata, the upper

coalesce to form single trunks, which, passing out between the vertebræ, subdivide and ramify the muscles of the limb—independent either of part of the spinal cord. They pass out of the the sense or will of the individual. The nextillustration (fig. 163) shows the lower possess a variety of functions; six pairs are

associated solely with motor power, others, as the nerves of smell, vision, hearing, and taste, are distinctly sensory, while several combine both functions in common. The nerves issuing from the spinal cord are named after the positions they occupy in relation to the spinal column, and in some parts form a plexus or network; this is especially the case in the upper and lower parts, the sites respectively of the brachial and the lumbar plexus. As above stated, the spinal cord is an independent neryous centre; but its main purpose in the animal

economy is to act as the medium of communication between the brain and the rest of the body.

In addition to the nervous system above described, there is the sympathetic, or ganglionic system, situated chiefly on the inside of the spinal column, and characterised by the possession of distinct separate ganglia and nerves, which are connected with the great nervous system on the one hand, and with the of digestion, &c., on the other. 416

As the diseases and disorders of the nervous system fall to be treated of under other heads, such as Paralysis, Delirium, &c., they require no further mention here.

Refer to—Neuralgia

NERVOUS DISEASE, or NERVOUSNESS. is a term usually applied to an indefinite affection-a mixture of mental and bodily disorder and irritability, generally the product of weakness. The active countryman, the hunter, and those who take much exercise in the open air, do not suffer from irritability, or nervousness, which attacks the sedentarythose who exhaust the brain by too great mental exertion, or the body by dissipation. Females are much more liable to nervous disorder than males, independent of hysterical affection, which constitutes one of the most marked phases of the malady, and many of the remarks on which apply to the present subject.

In nervous disorder there is usually great susceptibility to external influences; and at the same time mental emotions, whether of joy or grief, fancied or real, exert much influence over the body and its functions. palpitates, the hand trembles, the face flushes under the most trivial excitement; much of this is undoubtedly due to constitutional timidity; but it is also notably increased in debilitated states of the constitution; and those who have never been what is called "nervous," are apt to become so in some particular conditions of impaired health. affection, indeed, is very nearly akin to hypochondriasis; it is essentially a disorder of weakness, and is relieved by whatever increases temporarily or permanently the power of the nervous system. The temporary relief to nervous sensations which is afforded by alcoholic stimuli, is very apt to lead those who suffer from them to put too much trust in, and to resort too habitually to, the use of those palliatives - a practice which must be followed by pernicious consequences; sometimes, too, opiates are habitually made use of, and are no less injurious.

Undoubtedly, when properly employed, alcoholic stimuli, and even opium, are valuable in the treatment of nervous disease, but they must never be substituted for more permanent means of invigoration, particularly regular and sufficient exercise in the open air, on foot or horseback, good nourishing diet, with a sufficient amount of animal food, and attention to the bowels and the state of the skin. The producing cause, whether excessive mental exertion, sedentary employment, late hours, or excess of any kind, must of course be modified as much as possible. The shower bath is often recommended, and often useful in these affections, but some persons cannot bear the shock; when this is the case, the cold or tepid douche down the back does much good, partiviscera of the organic functions, such as that cularly if there be any tenderness of the spine on pressure, a fact which should always be

NET NEU

investigated; in those who suffer much from | of ammonia and sugar of lead, of each one nervous disease, it very commonly exists and is overlooked. When the tenderness is at all marked, it will require special treatment, by counter-irritation, &c.; but this, as well as the treatment of aggravated cases of nervous disorder, will be best managed under the care of a medical man. In addition to the regulation of the bowels by the warmer purgatives, or by injection, quinine and the preparations of iron are the most generally useful remedies; tincture of valerian, sal volatile, and stimulant carminatives may be used as palliatives during an aggravated attack, but should be sparingly resorted to.

Refer to—Hysteria—Indigestion, &c.

NETTLE.—The common nettle belongs to a tribe of plants which includes the fig, the hop, and others used as food, and is itself eaten when cooked as a wholesome, almost as a medicinal, article of diet, in some parts of the country. It is diuretic. The fresh juice of the nettle has been highly recommended in cases of internal hæmorrhage, particularly from the lungs and womb. The dose, one teaspoonful three times a day. The effect produced by the stinging of some species of nettles, especially those common to India, is painfully severe, and is aggravated by the application of cold water, which appears to increase the irritation from all kinds of stinging nettles.

Refer to-Hæmorrhage.

NETTLE-RASH.—Nettle-rash cannot be better described than as an eruption which closely resembles nettle stings, both in appearance and in the sensations it gives rise to. When acute, it is generally accompanied with more or less fever. The nettle-rash, in almost all cases, arises from disorder of the digestive organs, caused either by indigestible food, or in some persons by particular kinds of food. Kernels or seeds, such as almond, peach, &c., which contain prussic acid, seem especially apt to cause nettle-rash, and in some individuals even the pips of an apple have been known to produce the disorder. Fish, particularly shell-fish, also bring it on, or mushroom; also certain medicines, such as turpentine; teething, hurry and agitation of mind in adults, and other irritations, also give rise to nettle-rash. The generally known causes of this affection indicate the remedy-the removal from the alimentary canal of offending matters. If there is tendency to sickness, and if the eruption appears soon after a meal, an emetic is the appropriate remedy, but whether this is given or not, there should be given an aperient. As acid in the bowels often accompanies the condition, a dose of magnesia with rhubarb is very suitable, or some other antacid may be had recourse to, and, after-wards, castor oil. External remedies are comparatively of little service in the acute forms exciting causes; neuralgia has often, too, been of nettle-rash. A lotion composed of carbonate traced to anxiety of mind. Some sudden attacks

drachm, in half a pint of distilled or rose water, will give relief. Dr. Watson recommends flour dusted over the surface. If nettlerash takes a chronic form, that is, continues, and keeps recurring, after the use of such mild aperients as recommended above, and after regulation of the diet, the case should be seen by a medical man. An ointment composed of ten grains of boracic acid rubbed up with one ounce of vaseline, often gives complete relief.

NEURALGIA—literally pain in a nerve—is also known as "rheumatism of the nerve," or "tic douloureux," this affection being by far the most common form of severe neuralgia usually met with. It is perhaps one of the most painful affections to which the human body is liable. In most instances the pain is the only symptom; in some it is accompanied with marked constitutional or local ailment. The exact nature of neuralgia is obscure; probably, the one effect, pain in the nerve, may arise from a multitude of causes; it is certain that some of the most intractable cases have been connected with diseased growth of bone in different parts of the head or face, especially about the canals through which the nerves pass; other severe cases have been found to depend upon irritation, excited by foreign bodies acting upon some of the nerve branches; decayed teeth are not unfrequently connected with the disease. The most general seat of neuralgic pain is in the head or face; but the fingers, the chest, the abdomen, &c., may any of them constitute its site. When the great nerve of the leg is affected with neuralgia, the disorder is known as sciatica.

The pain of neuralgia is described as "plunging," darting pain of the most intense and agonising kind, but except in long-continued cases, there is no external mark—no redness, swelling, or heat, to indicate the disorder to others. After a severe attack of neuralgia, the skin is often left tender, and when the pain has recurred frequently, exquisitely tender swelling of the part has been known to come on. The access of the pain is usually sudden, its remission equally so, and it is generally periodical in its attacks; it is sus-pended during sleep. The suddenness of the pain, its character-often compared to severe toothache-the absence of inflammatory symptoms, and its periodical returns, sufficiently mark the disease.

The exciting causes of neuralgia are, especially, damp and cold; injury to a nerve by pressure or violence; carics of teeth; malaria, and gout; exposure to currents of cold air, especially if the individual is heated, frequently originates the disease: in this way, railway travelling has proved a fertile source of neuralgic affection. Debility of constitution renders the individual much more susceptible to those and other

NIG NEU

of neuralgic pain in various parts of the body, | to attack persons whose health is under par, have been traced to temporary stomach disorders, such as superabundant acid, and have disappeared as soon as the cause has been rectified.

The severe pain which attends neuralgia, quickly drives the sufferer to seek medical advice; and without doubt, the safest plan is to have the exciting cause of the affection detected if possible, and as soon as possible obviated, before the disease has become fixed. If the person is resident in a climate or situation likely to excite it, some change should, if possible, be made; this will probably be most beneficial if the removal be to a dry warm air; but should disease have commenced in a cold dry district, change to a moist, humid, but warm one, will probably offer most advantage. If disorder of the digestion exists, it must of course be rectified (see Indigestion) after that, if the disease still continues, quinine, given in large doses of from six to eight grains, every six or eight hours, will most probably be of service. Saccharine carbonate of iron, in from twenty to thirty-grain doses, is a most useful these are constitutional curative measures which will be most safely trusted to medical hands. Blisters behind the ears, or at the back of the neck, are often valuable aids in the treatment of facial neuralgia. The late Sir Charles Bell is said to have found the following most successful in some cases of obstinate neuralgia, probably caused by disorder of the alimentary canal. One to two drops of croton oil are mixed with one drachm of compound colocynth pill, and of this one-twelfth, or five grains, is given at bedtime, along with ten grains of compound galbanum pill. The remedy is more suited to persons of strong habit of body, than to the weakly.

During the paroxysms of agonising pain, anything which will, or is likely to, relieve should be tried, even in the absence of a medical man. A sponge or piece of flannel, dipped in boiling water, and applied as hot as it can be borne over the site of the pain, will often allay its severity, or remove it altogether. A similar good effect is produced by the continued application of ice over the part; or, in extreme cases, chloroform may be inhaled, and will probably continue to give relief after its ordinary anæsthetic effect has passed away. Chloroform, belladonna, aconite, and opium, are all used as external applications in the form of liniment, to relieve the pain; and opium in the form of morphia, is often given by subcutaneous injection, or by the mouth, in pills or draught, for a like purpose. Leeches over the pained part are frequently of service. Lastly, when other remedies fail, great benefit has been derived from the continuous galvanic current from a Leclanché battery administered along the course of the nerve. It is important

every care should be taken to promote the general health by tonics, and exercise. Codliver oil, quinine, iron, and the bitter infusions, act most beneficially. Valerianate of zinc, in three or four-grain doses, in the form of pill, administered two or three times daily, has acquired much reputation in the treatment of hysterical neuralgia. There are, however, two or three modern remedies for neuralgia, which deserve prominence. The one named above, morphia by subcutaneous injection, is at once the most effectual and speedy. The next is phosphorus. It has been said that neuralgia is "the cry of a hungry nerve for phosphorus," and most certainly, the supply of that important constituent of nerve-tissue is one of the most efficient curatives. Given in the form of hypophosphites, it often answers well, but to get its full effect, a solution of pure phosphorus is requisite. The Elixir of Phosphorus, and the Phosphorated Oil are both eligible preparations; the latter can be obtained in capsules. Gelsemium is another remedy useful in special cases.

Earache, common in children, is not a true remedy, especially in weak constitutions; but neuralgia, except occasionally as the result of diseased teeth. It is mostly due to catarrhal inflammation of the middle ear.

NEUTRAL SALTS are compounds of an acid and an alkali, in which the two constituents completely neutralise one another; the resulting compound having neither acid nor

alkaline properties.

NIGHT .- The period of darkness consequent upon the absence of the sun's rays, is one which unquestionably exerts considerable influence over the states and health of the human body. The effect of light upon the body, and the injurious consequences of its withdrawal, have already been treated of, and to the article Light the reader is referred for information, also to articles, Early Rising, Breakfast, Sleep, &c. With the exception of certain animals, fitted by their constitution for nocturnal activity, the majority, including man, are evidently intended by Providence to rest and sleep during the hours of darkness; animals, governed by instinct, do so, uncivilised man for the most part does so; but the member of a civilised community necessarily requires in some degree to modify these things, and is endowed with the capability of doing this, within certain limits, without injury to health; if these limits are exceeded, he suffers.

It is often asked: "Is it not the same thing whether I sleep in the day or the night, so that I get enough?" It is not the same thing. Independently of the argument that the natural laws of our constitution can never be infringed with impunity, and that man cannot, without injury to health, spend those hours in sloth and sleep, during which he ought to be active under the sanative influence of diffused dayto bear in mind that as neuralgia is most prone | light, experience has long testified, that during

NIG NIT

the night, many sources of disease act more | should be made, during the time of pregnancy, to energetically upon those exposed to them. One often recorded experiment sufficiently illustrates the fact. The colonels of two French cavalry regiments had to move their respective corps a considerable distance during be assiduously practised. The greatest sufferhot weather. One, thinking to avoid the heat of the day, moved his regiment during the night only, the other followed the reverse plan; the latter at the end of a week or ten days arrived with his men and horses well, whilst the other had many laid up with sickness.

As, however, in northern countries, in winter, the term of daylight is too considerably curtailed, and the hours of darkness too prolonged, to permit of their all being spent in sleep, it becomes a question which portion of the latter may most advantageously be devoted to wakefulness, under the influence of artificial light. Experience has proved, that to rise early and spend the morning hours by artificial light, is not by any means so salutary a custom, as to add to the latter part of the day by the same means. This is probably, in part, due to the greater activity of the nervous system in the after-part of the day, causing the absence of the stimulus of the sun's light to be less felt. While the calm and quietude of night exert, as a rule, a soothing influence on the sick, some diseases are well known to be attended towards evening, with an aggravation of the symptoms. This condition is named nocturnal exacerbation, and is characteristic of rheumatic fever, and other painful affections of the joints as well as of the bones. The night sweats of consumption are among the most exhausting features of the disease.

Refer to—Sleep.
NIGHT BLINDNESS is a symptom characteristic of certain forms of inflammation of the retina of the eye. It is occasionally the result of congenital disease; frequently it is epidemic in malarial districts and under insanitary conditions. Congenital cases often end in complete blindness; those of later life are, as a rule, more amenable to treatment. In all cases medical advice should be at once sought.

NIGHTSHADE.—See BELLADONNA.

NIPPLES.—The nipple of the female breast is chiefly composed of tubes which give passage to the milk. During pregnancy, and at child-birth, it ought to become more prominent and increased in size; but, sometimes, from the pernicious pressure of the stays in early life, it has become so embedded in the breast, that it cannot be developed, consequently, when the time of suckling arrives, it is perfectly impossible for the infant to seize it. This is a state of things which often gives much trouble, causes the individual much pain and suffering, and not unfrequently lays the foundation of abscess of the breast. When this condition of the nipple exists, every effort

get it into a better and more prominent state, ing, however, connected with the nipple during nursing, is in consequence of its becoming excoriated and chapped. This may be greatly prevented, if, during the latter months of pregnancy, trouble be taken to bathe the nipples night and morning, with a mixture of brandy and water, one part of the former to three or four of the latter. When the nipples are inclined to become sore from nursing, which is generally within the first fortnight; the best, and, indeed, almost a certain remedy, is the tincture of catechu (see Catechu). Care should be taken to keep the nipples perfectly dry. Various substances, such as cows' teats, prepared nipple shields, &c., have been used to cover the nipple in such cases, but it requires a very strong child to draw the milk through Glass shields with india-rubber teats them. attached are often found serviceable for the protection of sore nipples, If the nipples are harsh and dry on the surface, glycerine will probably be found of more service than catechu, and if they do not heal up under these or similar applications, the child must be kept from sucking for a short period, the breasts being emptied by other means, and the milk thus drawn, given to the child.

The late Sir Astley Cooper's favourite lotion in sore nipples was composed of borax one drachm; spirit of wine half an ounce; and water (soft) sufficient to make up the half pint

lotion.

Refer to—Breast—Child-bed, &c.

NITRATES are salts, such as nitrate of potash (saltpetre), nitrate of silver (lunar caustic), &c., of which nitric acid is one of the components.

NITRIC ACID, or AQUA-FORTIS, is one of the most powerful of the mineral acids, and is strongly corrosive; it is obtained from saltpetre by distillation with oil of vitriol. Pure nitric acid is composed of nitrogen and oxygen gases, in the proportion of one of the former to five of the latter, and should be colourless; it is usually met with in the shops of a light

straw colour, and contains water.

Nitric acid is used externally by surgeons as a caustic, or rather as a corrosive, and is often applied in its diluted state to foul sores in the mouth, and to sloughing patches of mucous membrane. Internally it is employed as a tonic, especially in some forms of dyspepsia and liver disorder, the dose two to eight drops well diluted with water. Diluted nitric acid, composed of one part of the common commercial acid, and four parts of water, is used as more convenient than the strong acid; of this, the dose is from twenty to thirty drops well diluted.

Poisoning by nitric acid or aqua-fortis some-

NOS NIT

similar to that recommended in poisoning by hydrochloric acid, under article Chlorine.

NITROGEN GAS is one of the elemen-

tary gases, important from its forming nearly · four-fifths of our atmosphere, and from its numerous combinations. - See Ammonia-

Azote-Nitric Acid, &c.

The existence of nitrogen in animal matters was formerly thought to constitute one great distinctive mark between them and vegetable substances, but this idea is now known to be erroneous. Certainly, the abundant presence of nitrogen in the constituents of the animal kingdom, is truly characteristic, compared with its more sparing amount in vegetables; but animals, in the first instance, derive the greater part of their nitrogen from vegetables, which constitute the medium for its conveyance to them from the inorganic kingdom.

Refer to-Aliment-Blood-Food, &c.

NITRO-HYDROCHLORIC ACID, or AQUA-REGIA, -as it has been called from its power of acting upon gold, is used in medicine as a tonic, and it is a very valuable one. Diluted nitro-hydrochloric acid, is the preparation most used. It is composed of three parts of nitric acid, four of hydrochloric acid, and twenty-five parts of water, and is much used in affections of the liver and skin, and in many cases of indigestion. It is also sometimes employed as a bath for diseases of the skin, especially when the latter are of syphilitic origin. The dose of the mixed acid is from ten to twenty minims, well diluted in water.

NITROUS ETHER, OF SWEET SPIRIT OF NITRE, is prepared by the action of nitric acid upon alcohol. When fresh and properly made, it is one of our most valuable diuretics, being also stimulant and diaphoretic, and is much used domestically as a remedy in common colds, &c., and to increase the flow of urine. The dose is from half a drachm to a drachm and a half, given either in water or gruel. When badly made, or too long kept, sweet nitre is apt to contain much acid, which may cause pain at the stomach; the fact may be known by the ether effervescing with carbonate of soda.

NITROUS OXIDE, or LAUGHING GAS, produced by the action of heat on nitrate of ammonia, is the anæsthetic now principally employed by dentists. It can only be employed for short operations, as its effects on the system are transient, but it is reckoned safer

that ether or chloroform.

NOCTURNAL DISCHARGES of seminal fluid, are apt to cause much mental uneasiness and physical debility in those, generally young men, who are the most frequent subjects of them. Unless very excessive, there is no reason that they should be regarded in the

times occurs, and must be treated in a manner | disuse of alcoholic stimuli, the avoidance of whatever may tend to excite the secretion in question, and the use of the tincture of perchloride of iron, in twenty or thirty-minim doses twice or thrice a day, will, in most cases, effect a cure. In the bromides now so largely used, we have a most valuable remedy for cases of sexual irritability. A dose consisting of fifteen grains of bromide of ammonia, and the same of bromide of sodium, taken in water at bedtime, will exert great control over the tendencies. It is of great importance, along with these measures, to keep the bowels perfectly open, and for this purpose, gentle salines, senna, castor oil, sulphur and magnesia,—from half a drachm to one drachm of each for a dose, in milk, -or cool injections, are preferable to pills which contain aloes.

> In such cases, one caution is of the highest importance: avoid the advertising quacks (see Quacks). The painfully nervous state of the mind in those who suffer from the above affection, renders them most timidly credulous, and this fact is made use of by designing knaves-first to frighten, by attaching exaggerated importance to every slight symptom, and then to fleece those they have thus deceived. Persons who are affected with the disorder in question, by confiding in some medical man may speedily be relieved.

> NODE is a tumour or enlargement of a bone, caused by inflammation of the bone itself, or of its covering "periosteum," and is usually the result of syphilitic disease, though sometimes of scrofula. The shin bone is very liable to the disease, but it may attack any bone, and is frequently noticed on the bones of the skull, on the ribs, and on the collar bone. active inflammation of the part is present, perfect rest, leeches, fomentations, poultices, are to be used, and other remedies which have a special action on the conditions of the system, such as mercury, iodide of potassium, cod-liver

oil, &c. A medical man should be called in.

NOISE IN THE EARS.—See EAR.

NOLI ME TANGERE.—See LUPUS.

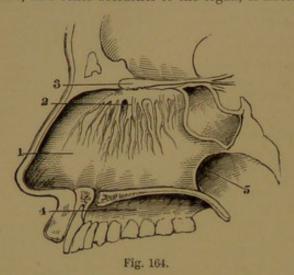

NOSE.—The organ of smell is so situated above the mouth, that by it the odour of whatever is put into the latter must be perceived in the first instance. The visible portion of the nose is chiefly made up of bone at the upper part or bridge, of cartilage (fig. 164-3) at the expansive nostrils (1). The internal portion of the nose consists of a cavity which communicates with the throat (5), formed in the bones immediately over the hard palate (4), which are expanded in such a manner as to offer a wide extent of the membrane (2) on which the nerves of smell are distributed, to the action of the air bearing the odoriferous particles. The two nostrils are separated from each other by a bony cartilaginous "septum," almost morbid way they often are. Abundant or division; they are lined by the mucous exercise, cold bathing, either general or local, membrane which secretes the peculiar mucus and where there is not much debility, the of the nose. This membrane is continuous

NOS NOS

with that of the eyes, through the canal or requisite, from within, by means of a firm "lachrymal duct" (see Eye), which conveys the superabundant tears into the nostril; it is also continuous with that of the throat. As might be expected, the nose, from its position, is

much exposed to accident.

Fracture of the bones is not uncommon, and, like other accidents to the organ, is liable

in shape and mobility of the parts, the nose apt to make the matter worse by pushing the may, if a medical man is not at hand, be foreign body further in; if, however, circumrestored somewhat to shape, by a bystander, stances render it desirable to attempt the exthe fingers on the outside being assisted, if traction without waiting, it must be done by

quill, or piece of wood covered with lint, passed up the nostril. After the displacement has been rectified, the person should be kept per-fectly quiet, the injured parts covered with cloths dipped in cold water; and if the habit of body is full, a sharp purgative administered, for the possibility of the inflammation excited extending to the brain, must not be forgotten.

Bleeding from the nose (see Hamorrhage). The nose, like the ear, is very liable to be made by children the receptacle for anything that will pass into it; beans, buttons, stones, or the like. A few minutes before commencing this article, the author was called upon to extract a considerable piece of tobacco pipe, which a child had pushed up the nose almost out of sight. When the things introduced swell, by absorption of moisture, there is often considerable difficulty in their extraction; sometimes they have been in the nose, unnoticed, for days or weeks, and are not discovered until inflammation of, and perhaps discharge of matter from, the lining membrane attracts attention, a reason, when such symptoms occur in a child, for always examining the to be followed by much bleeding; if the nature of the accident is indicated by the alteration always best done by a surgeon; others are very

means of the rounded extremity of a hairpin, | Sometimes, when the foreign body is not very

parts of the nose are subject are ozena and polypus. Ozena is a feetid discharge from the nostrils, caused by an inflamed or ulcerated condition of the interior mucous membrane, occurring in persons of a scrofulous disposition, or who are suffering from the effects of syphilis. It is a very troublesome and offensive complaint, and, when not checked, may run on to destruction of the cartilages and of the bones, causing great deformity of the nose. The treatmentemployed for ozena must, of course, depend on the cause of the malady. Iodide of potassium, cod-liver oil, and other means for altering the constitutional condition, should the disease arise from scrofula, will be indicated. Washing the interior of the nostrils with some antiseptic solution is absolutely necessary to destroy the disgusting odour; carbolic acid, chloride of zinc, Condy's fluid sufficiently diluted may be used, either with a glass syringe, or what is better, by the nasal syphon douche, an apparatus extremely useful in the treatment of this and other affections of the nasal passages.

The illustration (fig. 165) is from Arnold's catalogue, and shows the action of this simple

instrument.

Nasal polypus is a growth from the upper and inner part of the mucous membrane in the interior of the nose, which often attains a considerable size, and always interferes more or less with the ordinary passage of the air, and with the sense of smell. The only remedy is removal by the forceps or snare.

GESTION-FOOD, &c.

NURSE FOR CHILDREN .- The subject of wet-nursing, and the objections to it, have already been alluded to under article Childhood. When a wet-nurse is absolutely necessary and resolved upon, the selection is best left to the medical man, who will endeavour to procure one whose confinement was as nearly as possible at the same time as that of the mother's whose child she is to nurse; he may at the same time avail himself of the aid of the microscope in examining the milk, if there is much power of choice. The following characteristics of a good wet-nurse are laid down by M. Devergie: "A good nurse should be from twenty-five to thirty years old, of strong constitution, fullchested, of sanguine lymphatic temperament, brown haired, having white healthy teeth and well-coloured lips. She should have pyriform breasts, with well-formed nipples, and without too much development of veins. The milk drawn into a spoon should be white, with a slight bluish tint, its taste saccharine; it should not be too thick." In scrutinising, however, the physical qualifications of a wet-

The chief diseases to which the internal | mental ones-disposition, temper, &c .- should not be overlooked; for, independent of the influence which may be exerted upon the infant by the psychical qualities of the being from whom it draws its first nourishment, we know that the emotions of the mind always do affect the milk in some peculiar way, and injury to the child-nay, possibly death itself-from convulsions, may be the consequence to an infant whose mother has, shortly before nursing it, given way to violent passion. The late Sir Astlev Cooper held the opinion, that the anxiety of a mother for her child during teething, by acting on the milk, produced a salutary aperient action on the bowels. Again, all nurses well know how much the quality of their milk is affected either by food or medicine, and this is another reason why a wet-nurse should be selected, if possible, who is likely to have sufficient selfcontrol to regulate her diet. The difficulty in this, is one, at least, of the objections to wetnurses, especially if kept in the houses of their employers, where they are tempted with unaccustomed and richer food and drink.

The return of menstruation, in a nurse, is always an objection, although perhaps not an absolute one, if merely an occasional occurrence; the child, however, should be withdrawn from the breast during the period, and managed as if nursed by hand (see Childhood), the breasts being kept duly emptied by artificial means (see Child-bed). In the event of slight indisposition in a nurse, the same plan may be pursued. Perhaps no diet is more suitable for a wet-nurse than one which embraces a large proportion of milk and farinacea, with a moderate proportion of animal food, and much mischief is often done to both nurse and infant, under the idea that an extra allowance of stimulant is required during nursing, from the very first. Strong healthy women require it not, and are better without it; some derive much benefit from a moderate allowance of malt liquor, after the first two or three months, whilst others, who are deficient in vital and digestive power, require it from the very first. Perhaps nothing can show more strongly than these facts, which are well known to every medical man, the folly of laying down any fixed rule respecting the use of alcoholic stimuli by mankind generally. Medicines taken by the nurse may be so directed as to benefit the child, particularly such aperients as castor oil, senna, &c. Saline aperients and acids generally cause griping in the infant.

With respect to nurses who have the charge of children in the nursery, it is sufficient here to remark, that good health, at least, should be insisted upon, particularly if the children sleep with them.

Milk. de.

NURSES FOR THE SICK .- In the case nurse, it is of the highest importance that the of the sick, next to the attendance of the doctor,

NUR NUR

the services of the nurse come first in order of | cope with the changing aspects of disease and severe illnesses, to some respectable woman who made nursing her profession, but who probably had no vocation, and had certainly never received any training for the work. The first step towards improving the status of the nurse was taken by Mrs. Fry, the celebrated Quakeress and philanthropist, in 1840, when she established, in the city of London, on a purely unsectarian basis, an association called by the name of the Nursing-sisters, which still flourishes. Mrs. Fry's object was to obtain a respectable class of women to attend the poor at their own homes, as well as others who could pay for their services, and by holding out prospects of an increasing remuneration, and a fair pension after thirty years' services, she thought to secure their permanent interest. By arrangements with a large London hospital, the nurses spent a few months' probation in the wards, which gave them, however, only a partial insight into their work, and it was not till the period of the Crimean War, when the wants of the invalided soldiers became so painfully apparent, that public attention, mainly from the exertions of Miss Nightingale, was fully drawn to the subject. Most of the leading hospitals throughout the country had been endeavouring before this time to improve the position of the nurse; but the establishment of a School of Nursing at St. Thomas' hospital gave an impetus to the movement, and numerous associations were instituted on somewhat similar principles—all having the double object in view, first, of training the nurse by a lengthened period of probation in a public hospital, and secondly, by affording to the public the benefit of her services afterwards, either in private, in district, or in hospital work. Several of these bodies have been organised by religious sisterhoods in connection with the church of England; a much larger number have been founded on non-sectarian principles, while several enterprising institutions have done well as mere commercial speculations, drawing their supply of trained nurses from among those who had been dis-satisfied with the parent Association. The cost of a nurse to a private family is usually charged at the rate of £1 1s. a week, and in infectious cases 30s. or £2 2s., which is paid to the Home, the nurse receiving an adequate remuneration from the association, which keeps her when her services are not required. These charges cannot be called exorbitant for a trustworthy trained nurse, though they are far beyond the reach of the poor, who must either be content to do without the nurses assistance, or be indebted to some charitable organisation to supply their place.

precedence. In private life, this duty was in its momentary requirements, that the nurse former times usually delegated to the mother should have at least one year's experience of or other members of the family circle, and in hospital work. The training should be as hospital work. The training should be as thorough as possible, and should consist of (1) nursing in medical as well as in surgical disease and accidents; (2) in night as well as in day duty; (3) in the preparation of foods most used by the sick; and (4) it ought to be accompanied with some practical lessons in the Laws of Health, especially such as bear on ventilation, warmth, disinfection, and other means for the prevention of disease. Since nursing has become more of a skilled art, many persons of good education have taken to the work for the love of it, as well as for remunerative employment, and facilities are now given at most of the large hospitals to enable gentlewomen and others, on the payment of a certain premium, to obtain a practical acquaintance with nursing, under the direction of the sister, or head nurse, as she is more usually called. It is obvious that an educated intelligence must prove of greater service to the medical attendant than the ordinary nurse, who, for the most part, is on a par with the domestic servant; and that by first going through the ordinary routinework of nursing, the lady herself becomes better able to fill the office of matron, or superintendent of a ward, or hospital, or any other post to which she may afterwards be called, and where her nursing services may be of use.

The chief points to which the attention of nurses generally may be directed, are the counting the pulse and respiration, the condition of the tongue in health and in disease, the state of the skin, the temperature of the body as indicated by the clinical thermometer, various methods employed in dressing wounds, padding splints, and acting in emergencies. It is important also for a nurse to learn the use of trusses, pessaries, and other appliances used in the sick-room, to administer injections (either by the rectum or skin), electricity, medicine and stimulants in the manner prescribed by the medical attendant. It will also prove of much service, if, in addition, the nurse acquires a knowledge of the action and character of such drugs as are most generally employed, and of the natural functions of the

body in health.

It is sufficiently obvious that those whose province it is to wait upon the sick must prepare themselves for many disagreeable duties, entailing loss of rest, confinement, and much mental anxiety; for, although in public institutions these matters are well considered by a mutual division of labour, still, in private life, the nurse is expected in many instances to be constantly at her post, and it is unreasonable to hope that she can retain her faculties intact after days and nights of continuous watching. The nurse ought to have recreation, as well as Professional Training of Nurses. - It is sleep, and surely there are few cases which essentially necessary, in order that she may will not admit of some member of the family

NUR NUR

desirable that a woman should engage in nursing until she has arrived at a suitable age, twenty-three or twenty-four, and that she should have at least a month's time to test her aptitude, as well as her liking, for the work. It is a rule in most nurse-training establishments for the nurse to serve this short period without any remuneration, and at its termination, if found eligible, to enter upon a more lengthened period of probation, undertaking at the same time to remain with the association for a term of not less than three years. During the training period she is supplied with suitable uniform, for in and out of door use, with four good meals daily, with washing, with an hour or two for daily recreation, and with pay amounting to about £1 per month. The remuneration is increased during the second and third year to one-third more in amount, and gradually rises with length of service till it

reaches £25 a year.

It is oftentimes remarked, that, in hospitals at all events, a greater responsibility lies with the nurse at night than during the day, and if this be so, it is essential that the night nurse should be in no whit inferior to the other. Considering the irksome character of continuous night duty, it is well that it should be alternated with day work, for periods varying from a month to three months at a time, and that in order to obtain uniformity, this arrangement should form a part of the nurse's engagement. So long as sick-nursing is confined to diseases of a non-infectious nature, and consideration is given to the physical requirments of the nurse, it cannot be regarded otherwise than as a healthy employment, though it is the reverse of this when associated with contagious disease. Leaving individual susceptibility out of the question, the liability to contract infection is in relative proportion to the proximity which the attendant stands to the patient, and during epidemics, nurses, catholic priests and doctors are well known to suffer in greater relative numbers than any other classes of the community. We have We have already said that it is the practice of nursing associations to charge increased fees when their associates are called to attend cases of this character; but it does not appear that the nurses themselves are benefited by the arrangement, and it is usual in fever hospitals to give preference in the selection of nurses to such as have already had fever, and who may be supposed in consequence to enjoy further immunity; but the labourers are few in comparison with the amount of work required of them. The writer has often advocated the desirability of effecting a small insurance on the lives of those so employed, to continue in force so long as they are engaged in the hazardous service, as a measure incumbent on their employers.

taking her place at stated intervals. It is not | duty it is to wait upon the sick, to suffer the necessary confinement, loss of rest and other depressing influences, should themselves have health as good as possible, and be possessed of strength and stature sufficient to enable them to give all requisite aid in lifting, and in manual work, even that of scrubbing the floor, if need be. Activity and order and cleanliness, both in their own persons and about those they wait upon, are indispensable. All bad habits, such as waywardness of temper, forgetfulness, and, of course, addiction to drink, are insuperable objections; likewise the habitual practice of making unusual noises, such as humming, fidgeting and coughing. Neither should nurses be great talkers: some patients are much annoyed with the garrulousness of their attendants. A nurse ought to be a light sleeper, awake to the slightest call or movement, and no snorer; a light mover about a room.

A good and obliging temper is of course highly desirable; equally so, sufficient good judgment in the management of the whims and peevishness of the sick, and to direct any little conversation into proper channels, avoiding all narrations of previous experiences, which are very apt to be indulged in.

In enumerating the qualifications of a good nurse, it is not expected that all these are to be found combined and in perfection in one or every individual, but some approximation, at least, to them should be sought for. Whilst laying down the qualifications for good nurses, one word may be said to those who employ them. If active, cheerful attendance is required, it must not be forgotten, that this is almost physically impossible, if a nurse be kept day after day, and night after night, confined in a close sick-room. Even if averse to it both for her own sake and that of the patient, a nurse ought to be made to walk in

the open air at least one hour a day.

The great desideratum is that we should have in this country more training institutions for nurses of all classes-institutions into which no sectarian element should be allowed to enter, and which should have for their object the education of women in the art of attending to, nursing, managing, and cooking for the sick. for the sick. There are already, in this country, many such institutions, in connexion with some of the London and in several provincial hospitals, and it is very desirable that they should be more numerous, so that the whole country might be supplied with trained and efficient nurses. But this is not all that is wanted, we think it necessary that an attendance for a time, at such an institution, should be considered if not a necessary, at all events, a most desirable part of every woman's education, inasmuch as there are few women in this country who may not be called upon, at some time or other, to play the part It is sufficiently obvious, that those whose of nurse to a sick parent, brother, husband, or

child; and every medical man has witnessed | that is expected of domestic servants, still, a the regret exhibited by women in such positions, when, too late, they have become painfully aware how unable they are properly to fulfil those duties in which a little practice and training would soon have made them proficient. The objects, then, of a Nurses' Training Institution, should clearly be—1st, to educate a sufficient number of nurses to supply our hospitals and public institutions, as well as private families, with professional nurses, whose services can be obtained for hire; and 2nd, to afford private individuals, of all classes, an opportunity of becoming practically acquainted with the details of nursing, which lose much of whatever is disagreeable about them, even in the most trying cases, when the duty is performed in an orderly and efficient manner.

It is much to be regretted that in our large manufacturing towns, owing to the comparatively high price which female labour can command, it is oftentimes difficult to get women to undertake what they imagine to be a repulsive, and what is at all times a respon-sible and difficult office; but it may be confidently hoped that when such institutions as those mentioned above, are known to be well managed, and to turn out nurses whose services are properly appreciated, there will not be felt

the difficulty which at present exists.

It will be seen, too, at a glance, that should cottage hospitals become more general throughout this country, as is very probable from the success which has already attended their introduction, an immense advantage would accrue to the inhabitants of and around the villages in which they are established. For it might very easily be made a part of the system of these hospitals, to train and instruct one or two nurses, who should work under the direction of the female head of the hospital, be she styled "sister," "matron," "lady superintendent," or "head nurse," provided she herself has been properly educated at some such institution as described above. In this way a number of good nurses would be distributed over the country, whose services must prove of inestimable value to the sick, and who in their turn might be made useful in teaching others.

Rules and Hints for Nurses .- It is quite out of the scope of an article like this to enter into and detail the various duties of a nurse; suffice it to say, that there are several general rules which will admit of useful application by all. In the first place, then, a nurse ought not to stand too much upon the supposed dignity of her office, and refuse to do what are called menial offices, on the ground that it is not her "place," or her "business," so to do; she ought to remember that it is her duty to do the greatest amount of good to the sick person or persons intrusted to her care, and although it is not recommended that as a rule nurses should do the work of cleansing, scrubbing, &c., nurse that refuses to perform these offices when the good of her patient requires it, is, in nc

sense of the word, a nurse.

There is no more difficult subject upon which to enlighten the mind of nurses than ventila-They are very apt either to suffocate the patient, or, running to the other extreme, expose him to a draught, by means of which he gets some new disease, or aggravates the one he already is suffering from. All that is required is a little management and common sense in the opening of the windows of the sick-room; that is to say, when to open them, how much to open them, and how long to keep them open, according to the state of the atmosphere, wind, &c. It may be stated once for all, and the nurse will do well to remember it, that we have as yet discovered no effectual means of ventilating either a sick-room or ward, but by means of open windows. At the same time, these require careful and constant management, otherwise the patient in many cases will assuredly suffer. In connexion with the subject of ventilation, so far as it concerns the nurse, let it be laid down as an absolute rule, that no bed-room utensil should be emptied or cleansed in the bed-room, but should be at once removed to a suitable place for this purpose. Nothing is so irritating and offensive to the patient, and nothing is more prejudicial to his health, the effluvia given off during the process being most detrimental.

Another rule :- Never air the bedding or clothing, or do any cooking in the sick-room, if it can be helped. It is most annoying, injurious to the patient, and, it may be added, dangerous. The writer was once alarmed by the cries of a patient, and on rushing to the sick-room, which had been left by a careless nurse, was horrified to find some clothes which

had been put out to air, in flames.

It is to be desired that nurses would study to acquire a pleasing and agreeable modulation of voice, since nothing is so annoying to a patient as a discordant tone in speaking, "out of tune and harsh," while nothing has a more marvel-lously soothing effect than a low soft voice— "that marvellous thing in woman." Cheerfulness is essential, and "Job's comforters" should be banished from every sick-room, and never allowed admittance under any pretext whatever.

A nurse who, either from stupidity or officiousness, or from a desire to make herself appear wise and important, either adds to or detracts from the orders of the medical adviser, under whose care the patient is, is worse than

useless.

It is well to know that there are numerous cases in which the recovery may depend upon the regularity with which food and stimulants are administered, as ordered. This is a point upon which medical men have found great difficulty with inferior nurses, rendering it highly desirable that some supervision should be exercised upon them, to see that their orders

ingly carried out.

A popular writer, in one of our periodicals, thus feelingly expresses himself on the sub-

ject of nursing :-

"Nursing is a faculty, not a science. It is a gift, not an acquirement. There are some worthy, tender-hearted, highly estimable people, who can never make decent nurses. You love them, you are charmed with them in society; you wish them all imaginable prosperity, but would as soon think of introducing a French horn and a dancing bear round about your sick-bed, as of surrendering yourself to their best intentions. Let such people read every manual ever printed; let them walk the hospitals day and night, they would be no better for the experience. Nature forget the better for the experience. Nature forgot the pinch of kaolin which makes good nursing, when she mixed up the clay of which they are formed; and art cannot always bolster up that which nature has left imperfect. Not that I would undervalue the scientific teaching of nursing. Given improvable conditions, it helps towards perfection in the art; and that means one of the ineffable, inexhaustible, immeasureable blessings of humanity. But nothing comes out of nothing, and it nature had laid no foundation, how can art or science, or anything else, build up a superstructure? Pyramids are not raised downwards.'

This humourous and withal sensible writer classifies nurses under the following heads:-

"The good-natured, unscientific nurse, whose shibboleth is feeding, and who thinks that nothing can go well where there is not cheerful conversation and a busy kitchen; the muff, a precious creature for healthy homes, a tender, clinging, loving soul, whom everyone declares must make one of the best nurses imaginable, whose theory of nursing is comprised in incessant personal attention and incessant personal caresses; but who must be given up at the end of a week, if you do not wish to give

up the ghost.

"Then there is the conscientious nurse, hard and practical; the grimbones who cannot judge for herself, but must act up to orders, to the letter, whatever may have taken place in the meantime. There is also the watching nurse, whose eye is never off you, and who wants to know every five minutes what you will take now. And who does not know the gruesome nurse, with small, cold, stone-coloured eyes, with chiselled crisp curls, thin light lips, and long lined, granite-coloured countenance! And last of all, and best of all, there is the dear fairy nurse, who is never in the way at the wrong time, and never out of the way at the right time; who, when you wish for her, presently appears at your side; and when you want anything, never keeps you waiting. is always cheerful and kind, but never fussy; and owns the rare faculty of seeming fresher

are punctually and constantly, and persever- | rest of the household with their seven hours' bed."

Such a nurse is more easily described than found; but it is not too much to expect that a good attendant upon the sick should be gentle, and watchful, and firm; and whilst carrying a cheerful countenance, take care to avoid all fuss of manner, all hurried movements, all ill-considered talk to her charge; be quiet alike of foot and speech, wearing gowns that never rustle (cotton prints of a light colour are the best), and shoes that do not creak. She should keep everything daintily clean; all things in their proper place, so that in an instant her hand can be upon what is required. She should pay the strictest attention to the doctor's orders respecting the temperature of the sick-room, and regulate the lights with equal care; whilst every article of food she offers to the invalid should be most carefully prepared, and presented in the most inviting manner possible. This is our model nurse; but most active women, with good common sense, who are able and willing to learn, may soon, by judicious teaching and hospital experience, be made good nurses, and may be of more service than many whose training has served no better purpose than to make them conceited and troublesome. - See Childhood-Cookery—Hospital, &c.

NUTMEGS are the produce of a tree resembling the pear tree, which is a native of the islands of the Indian Archipelago generally, but its cultivation has been much circumscribed by the narrow policy of the Dutch. The nutmeg is the kernel of the fruit, which is about the size of a peach, and is inclosed in a shell, over which is spread the arillus, which is the mace of commerce (see Mace). The properties of the nutmeg depend upon a fragrant essential oil which it contains. This is sometimes partially extracted by heat, and the nuts afterwards sold as fresh ones, being covered with powdered lime. This covering with lime, however, is also sometimes resorted to simply to prevent the attacks of insects. The oil, as well as a spirit prepared from it, are used in medicine as aromatics and slight stimulants, but nutmegs are mainly employed

for flavouring in cooking.

As articles of diet, they possess the advantages and disadvantages of spices generally.

Refer to -Mace-Spices, &c.

NUTS.—See CHESTNUTS—FILBERTS, &c. NUX VOMICA is the seed of a treethe Strychnos nux vomica, a native of India and the neighbouring countries. Its active principle is strychnia, one of the most energetic poisons known, though a valuable remedy in proper hands.

Strychnia is now much used for destroying vermin, and occasionally proves fatal to the human subject by design or accident. The symptoms produced in poisoning, either by after sitting up with you all night, than the nux vomica or by strychnia, come on quickly,

in the form of violent spasms, affecting the entire muscular system, and death ensues from spasm of the muscles of the chest producing suffocation. The stomach pump, if it is available, if not, an emetic; chloroform inhalation, animal charcoal, fat, butter, or oil, and artificial respiration may be used in such cases, and, if available, chloral hydrate as an antidote. Medical assistance is urgently called for.

perhaps, for a few persons, a more wholesome one could not be found. In a few individuals, the use of oatmeal causes heart-burn, and occasionally sickness, and, of course, must then be abandoned. One of the most beneficial properties of the oat, especially in the form of the Scotch meal, is its aperient power; in many children, the use of oatmeal porridge for breakfast will entirely correct a tendency to

As a medicine nux vomica, either in the form of tincture or extract, or in its active principle, strychnia, is now largely used, as a nerve stimulant, as a general tonic, especially in some forms of nausea and vomiting, and it need scarcely be added that caution is required in its use. The extract is frequently added to ordinary aperient pills, such as compound colocynth, and compound rhubarb; when it is required to overcome habitual constipation. From one-fourth to one-third of a grain may be given thus for many nights in succession. As a tonic, five minims of the tincture may be given twice a day in water, and for obstinate sickness, one minim every hour in a tea-spoonful of water.

**OAK BARK** is a powerful astringent, and may be used for the same purposes as others of the class. For domestic use, it has the advantage of generally being easily procurable. It is used in the form of decoction, made by putting from an ounce to an ounce and a half of oak bark into a quart of boiling water, and boiling down one half. In relaxed sore throat it is a useful gargle.

Refer to-Galls.

OATS as an article of diet, are generally ranked next after wheat as regards nutritive power, the latter holding the first place, in consequence of its containing a larger amount of gluten; in some respects, however, the oat is the superior grain, especially as it is on the whole much richer in flesh-formers (see Grains). The oat is most largely used in Scotland; the seed is there "kiln dried, stripped of its husk and delicate outer skin, and then coarsely ground," in which state it constitutes "Scotch oatmeal." It may be thought that the cheapness of the oat might prevent its meal being adulterated; but it was found, at one time, that much of the oatmeal sold in London, was adulterated with barley-flour, a much less nutritious article of diet. In England, oatmeal is chiefly used for making gruel (see Cookery); but the meal, or rather oat flour, prepared in England, is of very inferior quality to the Scotch, and even when meal is made professedly in imitation of the Scotch preparation, it is a very poor substitute. In Scotland, oatmeal is most largely employed in the form of oatcakes and for the well-known "porridge, which constitutes the breakfast of a great proportion of the population, and almost universally of the children of all classes, and except,

one could not be found. In a few individuals, the use of oatmeal causes heart-burn, and occasionally sickness, and, of course, must then be abandoned. One of the most beneficial properties of the oat, especially in the form of the Scotch meal, is its aperient power; in many children, the use of oatmeal porridge for breakfast will entirely correct a tendency to constipation. The proper method of making oatmeal porridge is, to have the requisite quantity of water boiling upon the fire, and to sprinkle the meal into it from the hand, stirring constantly, not only at the time, but during the twenty minutes that the mixture should be boiled. Sufficient salt for seasoning is to be added during the process. In Scotland the stirrer is generally made of wood, and is known in every household by the name of the porridge stick. When the mixture is boiled sufficiently, it must be poured into a saucer or soup plate, till it is sufficiently cool. It is generally eaten with milk, but butter-milk. treacle, or beer are also used. A pint of water, and a tea-saucerful of oatmeal, will make a good soup-plateful of porridge. When oatmeal, coarsely prepared, is too largely used, especially in a dry state, it may cause concretions in the bowels (see Concretions); but this effect never follows its proper moderate employ-

OIL—from Oleum, derived from the name of the olive which yields the well-known oil.

Oils used in medicine are the products of either the vegetable or animal kingdom; they are divided into fixed oils—which also include the fats—and volatile oils. Oils are also divided into drying and non-drying, according to their power of solidification by absorption

of oxygen from the air.

Fixed oils vary from the most limpid fluid to the hardest suet, according to the amount of solid or fluid fatty matter in their composition; all fixed oils, and animal fats, being separable into two, and often three, different principles; one named oleine, remains fluid at the lowest temperature, the next, margarine, has a higher melting point, and the third, stearine, the highest of all. The separation—under the influence of cold—into oleine and margarine may often be witnessed in olive oil in winter. Fixed oils are further distinguished by their leaving a greasy stain on paper, which is not dispelled by heat, and by their power of forming soaps with the caustic alkalies.

127

OLD

ferous properties of the vegetable kingdom depending on their presence. These oils are generally limpid, should be colourless, but are for the most part slightly yellow; their taste is usually pungent. Like the fixed oils, the volatile oils cause a greasy stain upon paper, which, however, entirely evaporates under the influence of heat, thus affording an easy test of adulteration with a fixed oil, which is sometimes practised.

Some volatile oils, such as turpentine, oil of lemons, juniper, &c., are composed simply of carbon and hydrogen. Others, such as laven-der, peppermint, &c., also contain oxygen in addition—camphor belongs to this division and a third section, those of garlic, mustard,

&c., have sulphur added.

The principal fixed oils used in medicine

Almond oil. Croton oil. Linseed oil. Cajeput oil. Olive oil. Castor oil. Cod-liver oil.

They all possess more or less aperient properties. Almond oil is chiefly used as an external application. The reader is referred to the separate articles for further information.

Volatile oils are used chiefly for their pleasant flavour, and for their stimulant carminative and antispasmodic properties. They form a long list:—amber, aniseed, caraway, chamomile, cinnamon, cloves, copaiba, coriander, cubebs, dill, juniper, lavender, lemon, nutmeg, peppermint, pimento, rose-mary, rue, savin, spearmint, theobroma, and turpentine, are all entered in the British Pharmacopœia; and now we have Eucalyptus and others

OINTMENTS are greasy or unctuous preparations, about the consistence of firm butter; they are much less used as dressings in modern practice than they formerly were, and their number might be reduced with much advantage; they have been supplanted by the more elegant, cleanly, and in every way superior, water-dressing and lotions. Occasionally a greasy application is requisite, and then nothing answers better than perfectly fresh lard, or sweet olive oil, or when fresh, a simple ointment, containing spermaceti or wax to give additional firmness. The form of ointment for purposes of counter-irritation, inunction, &c., is sometimes convenient, but even this, as in the case of tartar emetic, might be often avoided.

The ointments most likely to be useful for domestic practice are, antimonial ointment, gall ointment, iodine and iodide of potash ointments, mercurial and red precipitate ointments, simple and spermaceti ointments, sulphur ointment, and zinc ointment.

head of the active ingredient they contain.

Volatile oils are of great variety, the odori- | ing together spermaceti five ounces, white wax two ounces, olive or almond oil twenty ounces, stirring continually till the mass is perfectly cold.

One of the great objections against ointments is, that so many of them, if kept, become rancid, and thus form a most irritating application; but this objection bids fair to be obviated by the substitution of vaseline as a basis for ointments.

Refer to—Dressing. OLD AGE .- Although the powers of life may have previously shown symptoms of decline, the period of incipient old age is usually fixed in women about the fifty-third, in men about the sixtieth year; after this, it generally becomes evident that the vigour of prime is giving way, and that the powers of the constitution are no longer able to recruit themselves, or to sustain exertion with the same ease as formerly; diseases, too, peculiar to this stage of life, begin to show their symptoms of approach, -symptoms which can scarcely be too soon detected, or too carefully watched. As time goes on, the individual becomes more dependent upon the affectionate care, and, equally important, the intelligent supervision of those around. The subject of the treatment of the aged has been a neglected one. A valuable work, by Dr. Day, has supplied the want of a special treatise upon it. Old age increases the liability to such hereditary diseases as gout, gravel, rheumatism, apoplexy, and paralysis; and in women, especially, to cancer. Now the effects of excesses and of dissipation in early life, which may have been unfelt during the vigour of manhood, too often add to the natural infirmities. Whatever may have been the previous modes of living, it is always a dangerous experiment to make any material or sudden change in them after age has begun to tell upon the constitution, -it should not be done but for important reasons, and under direct medical control. The natural sensations will gradually guide the individual to those modifications of previous habits, which accord with the altered structures and diminished powers; and this more particularly in the case of active or violent exertions, which the hardening and ossification of the various tissues, but more particularly of the coats of the arteries, render hazardous. The weakened digestion of advanced life should be considered in the food, which, while it is nutritious, ought at the same time to be lightly cooked, and every thing like hardening avoided. Where the teeth are deficient, meat should be well divided, either by mincing before cooking, or by the knife after. The table mincer is of immense assistance when mastication is defective. The meals light, not at too long intervals. If the dinner be early, as it ought to be The composition of these is given under the for the aged, who are not obliged to hurry off to business, supper, but a light one, should Simple spermaceti contraent is made by melt- always be taken. The skin of old people is

often most shamefully and disgustingly ne-  $|p\alpha a|$ , or olive tree, though used in the form of glected, and no point in their management is more closely connected with their comfort and health; it should frequently be sponged with tepid water, and well rubbed afterwards with a rough towel to promote reaction. It ought at the same time to be carefully protected by woollen clothing; old people are most injuriously susceptible of the changes of external temperature, particularly cold; indeed, a fall of a few degrees in the thermometer, may be the immediate cause of death in very advanced life, and the average number of old people affected by apoplectic or paralytic seizures, is apt to be notably increased at the setting in of frost. Exercise by the old should be continued as long as they are able to take it, but never should it extend to fatigue. Sleeplessness, so frequently and loudly complained of by aged people, is, in some respects, natural; as life advances, nature would seem to require less of the soft restorer. It is not well to endeavour to overcome it by narcotic medicines. If possible the time of sleep should, by habit, be kept to the early hours of the night, and, in summer especially, the tedium of the early morning may be relieved by reading, knitting, sewing, or some other light employment. even in bed. In advanced life, the urinary organs require the greatest care, the call to relieve them should never on any account be delayed; on the slightest symptoms of derangement, proper medical advice ought to be taken at once, it may prevent evils which too often render the latter years miserable. It is most important for old people to give themselves time to empty the bladder thoroughly; they do this with more difficulty than the young. The medicines prescribed for the aged should be, whenever it is possible, of a warm character, to counteract the tendency to flatulent distention: large doses of mercurials, neutral salts, strong purgatives, are all to be avoided. Alkalies, even when given to counteract a tendency to the acid of gout or gravel, must be carefully watched, and not too long continued; they may produce the opposite state from that which they are intended to correct—a much greater evil. Pills, especially if at all hard, are apt to pass through the bowels unchanged. When an aperient is required by an old person, none is more suitable than a moderate dose of infusion of senna, to which a little ginger, or a tea-spoonful of bark, or of gentian is added. Six to eight drachms of the compound decoction of aloes answers well, if there is no great tendency to piles. When the bowels are habitually constipated, an injection of a pint to a pint and a half of warm soap water, must be given occasionally as required; this counteracts the great tendency to feecal accumulation. The doses of medicine ought always to be diminished after the period of incipient old age. -See Age-Childhood-Life, &c.

OLIVES,—the product of the Olea Euro- ing their breaking.

preserved olives, is better known as the source of the well-known-

OLIVE, or SALAD, OIL, which is procured by crushing from the perfectly ripe fruit. Good olive oil is of a pale yellow colour, and should be almost free from either smell or taste. It is often adulterated with the inferior fixed oils. As an article of diet, olive oil agrees well with many, and some persons find it useful as an aperient, but it is very weak in action. In pregnancy, however, with irritable and yet confined bowels, it occasionally answers better than the usual castor oil. Olive oil is most used in medicine as an external application, both as an addition to ointments, and as a liniment.—See Ammonia—Camphor, &c.

OMENTUM, or CAUL, a membrane, more or less covered with fat, which is spread over the intestines. It probably acts as a protec-tion against cold. The great loading of the omentum with fat, is one of the chief causes of the protuberance of the abdomen in very corpulent persons.

ONANISM.—The crime of Onan—self-

pollution-requires no further notice here, than to put parents upon their guard respecting their children, in connexion with this ruinous vice, acquired at school, and indulged in, in ignorance either of its sin or evil consequences. Some of the most lamentable instances of youthful decrepitude, nervous affections, amaurotic blindness, and mental debility and fatuity in early life, which come before medical men, are traceable to this wretched practice. Whenever young people, about the age of puberty, exhibit unaccountable symptoms of debility, particularly about the lower limbs, with listlessness and love of solitude, look dark under the eyes, &c., the possibility of vicious practices being at the root of the symptoms, should not entirely be lost sight

ONION and GARLIC .- The former of these well-known vegetables may be considered either as a condiment, or as an article of real nourishment. In its raw state especially, the onion, by virtue of the volatile oil it contains, is a powerful stimulant, but one only to be used with advantage and impunity by the owners of strong stomachs, who intend for the time being to eschew civilised society; under this proviso, the onion may really, at times, prove, and has proved, of much value as a stimulant. By boiling, the onion is deprived of its pungent volatile oil, and becomes an agreeable, mild, and nutritious vegetable; it is less wholesome either fried or roasted, a portion of the volatile oil being retained, and empyreumatised, and thus rendered very irritating to the stomach. The onion possesses diuretic properties. A roasted onion, cut in half, and the centre scooped out, is a frequent domestic remedy applied to boils, with a view of hastenGarlie is a more powerful stimulant than onion; when applied to the skin, either fresh or in a pulp, it acts like a mustard cataplasm. Garlie is diuretic, and possesses other properties, but its abominable smell is quite sufficient to exclude it from use, when so many more efficient and agreeable substitutes are obtain-

ONYCHIA is an inflammation of the root or matrix of the nail of either a finger or toe, usually resulting in abscess, and occasionally in loss of the nail. It is often very painful, and the pain may extend up the arm or leg. The local irritation is to be treated with poultices and fomentations, and if the imprisoned matter nears the surface, it should be allowed to escape by a slight incision made through the skin; if the nail becomes detached it should be removed, and an antiseptic ointment applied. The repeated occurrence of onychia is usually an indication of depressed health.

OPHTHALMIA.—See EYE.

opinion, MEDICAL. — A medical opinion on a case of disease includes, first, the *Diagnosis* or conclusion arrived at respecting the nature of the disease; second, the conclusion as to the appropriate treatment; third, the *Prognosis* or opinion respecting the ultimate termination of the case. Under articles *Diagnosis*, *Medicine*, *Science of*, and *Prognosis*, these points are sufficiently entered into.

**OPIUM** is the milky juice, dried, of the seed vessels of the common garden poppy; it is, perhaps, the most useful remedy in the entire list of medical agents used by man, and has probably given more relief to human suffering, than any physical means we are

acquainted with.

Opium may be procured from other species of poppy, but that above named is its regular source. The drug is chiefly collected in Asia Minor, in Egypt, and in Hindostan, but has been prepared in Britain. It is procured by making oblique incisions about half through the external wall of the unripe poppy capsule or seed vessel, and allowing the milky juice to become partially dry, when it assumes a brown colour, and tenacious consistence; at this stage, the opium is generally gathered by scraping it off the capsule by means of a stick or some other instrument, by which it is transferred to the receiving vessel-a cocoa-nut shell or the like; it is then further dried, after which it is, in some places, packed in leaves, in masses of various size, or, as in Egypt, made into rolls, or small flat cakes. Opium, when bought as imported, is apt to contain much impurity; by far the best condition, therefore, in which to purchase it for direct use, is the properly prepared powder, which must be kept in a well-closed bottle. The preparations of opium used by medical men are very numerous; the most useful of these only will be referred to in this article.

Opium is most familiarly known in its action upon the human body, first, by its power of compelling sleep-its sedative, soporific, or narcotic property; and second, by its power of relieving pain, its anodyne property; these actions, however, are much varied, and others are developed in accordance with the influence of circumstances, either permanent or accidental, such as the dose, and mode of administration; the state of the person taking it at the time, whether physical or mental, his temperament, previous habits, &c. It is well known, that among the Orientals opium is employed rather as a stimulant, as we use wine, than as a sedative, and its use for this purpose has very widely extended of late years in this country. When taken with the above view, the dose requires to be small—that is comparatively so according to the habits of the individual—and if sleep approaches, it requires to be resisted; after this state, if it occurs, in those who are stimulated by opium, a state of unusual physical, and especially of mental, activity is excited, accompanied with exalted brilliancy of ideas, which after some hours subsides, leaving drowsiness, inactivity, and low spirits.

If, however, the dose of opium has been a large one, or if the individual gives way to the inclination to sleep which follows even a moderate dose, heavy slumber is the result, varying in duration according to the dose of the drug and other contingent circumstances. Such is the more ordinary medicinal effect of opium; but whether the effect produced be one of excited or sedative action, pain is either modified or wholly subdued for the time being. When the effects of an ordinary dose of opium are passing off, most persons experience some amount of uncomfortable sensation: dryness of the mouth, headache, low spirits, and sickness; this latter symptom, especially, is sometimes so distressing, as almost to debar the use of opium

in certain individuals.

Sometimes opium produces neither sleep nor the pleasing excitement so valued by its votaries, but gives rise to feverish restlessness, headache, thirst, &c. This may arise from constitutional peculiarity, from a state of previous feverish excitement, from the drug having been swallowed too soon after a meal, or from other causes.

In whatever way it is conveyed into the system, whether by the stomach, by the skin, by hypodermic injection, or by external application, opium seems to exert its peculiar effects upon the brain and nervous system; it further modifies the secretions, particularly those of the mucous membranes; it checks the flow of bile, and powerfully constipates the bowels; but it determines to the skin and causes sweating. The constipating action of opium is sometimes one of its chief inconveniences; but in those who consume it regularly, this effect generally soon passes off.

OPI OPI

The action of opium upon the system is in the first place greatly modified by custom; persons who habitually take it for purposes of intoxication, find it necessary gradually to increase their dose, if they wish to experience what to them is its agreeable influence; such persons, when consulting a medical man, ought always to inform him of their habit, otherwise, when ordering what would be only a suitable dose for the generality of persons, he may be prescribing little more than a tithe of the ordinary amount consumed by his patient. It is, perhaps, needless to point out that serious consequences might result. Again, the exist-ence of certain diseases, particularly of a spasmodic or painful character, very greatly modifies the power of opium over the system; this is peculiarly exemplified in such diseases as lockjaw, &c. Persons, even, who are ordinarily very susceptible to the action of opium, when suffering severe pain, can often take it in considerable quantity without experiencing its usual effects, or, indeed, any effect beyond relief to pain. Age is another circumstance, which, affecting the power of action of all medicinal agents, seems peculiarly to do so in the case of opium, its influence augmenting in a rapidly increasing proportion as the earliest epoch of life is approached; indeed, during the first two or three years of life, it is impossible to exercise too great caution in the administration of opium; many accidents are known to ensue from its careless, or ignorant, or criminal use, and doubtless many more there are which never come to light. A single drop of laudanum has been known to prove fatal to a young infant. To an infant under two months old, one-quarter to one-third of a drop only should be given at once, and repeated at intervals of an hour, if required; and even in this way, no unprofessional person should venture to exceed the amount of one single drop of laudanum to an infant under six weeks old.

Poisoning by opium, either by accident or design, is a very common occurrence. The symptoms generally set in from half an hour to an hour after the drug has been swallowed, but this circumstance depends partly upon the form in which the poison is taken, being delayed longer when solid opium has been employed, instead of, as more usually happens, its fluid preparation, laudanum. The symptoms are, giddiness and drowsiness, from which the person may be roused by noises, shaking, &c. ; but this quickly passes into apoplectic stupor and cema, with slow, "stertorous' breathing; and, ultimately, if the case proves fatal, into death, with or without convulsions: these being most common in children. addition to the above symptoms, the face is pale and ghastly-looking, the surface cold, but may be covered with perspiration; the urine is suppressed; the pupils of the eye are very much contracted; the odour of opium may possibly be detected in the breath.

The treatment of a case of poisoning by opium must, in the first place, be to procure the evacuation of the poison from the stomach. For this purpose a medical man may use the stomach-pump; but others must attempt it by emetics (see Emetics). If sulphate of zinc (white vitriol) be procurable, half a drachm should at once be given, dissolved in water; or five grains of sulphate of copper (blue vitriol), in the same way; or mustard or salt may be tried if neither of the above is at hand; or ipecacuanha combined with a stimulant-a couple of teaspoonfuls of sal volatile or of brandy; or the throat may be irritated with a feather. In some cases vomiting and even diarrhœa occur spontaneously, and certainly diminish the danger. When the stomach has been cleared, but not before, vegetable acids-lemon juice, vinegar, cream of tartar, may be given freely; or strong coffee, without either milk or sugar (see Coffee). At the same time, every means must be used to keep the patient from lapsing into lethargy; cold, or alternate cold and hot, water, may be dashed over the body; mustard plasters used between the shoulders, and continual movement kept up. This is usually, and very properly, done by keeping the patient in continual motion for many hours between two assistants. Lastly, galvanism or electricity may be used, and artificial respiration kept up. Perseverance in one or more of these measures is almost certain to resuscitate what would appear to the ignorant an almost hopeless case of opium-poisoning, and no efforts should be spared in impressing this fact on friends or relatives. The patient must be watched most carefully for some hours after apparent recovery, in case of relapse.

The quantity of opium required to destroy life may probably be stated at from four to five grains of solid opium as a dangerous dose to an adult, and from a drachm and a half to two drachms of laudanum, and upwards. The average time in which death ensues, in consequence of poisoning by opium, is twelve hours; but it may occur considerably earlier.

Opium as a medicine is useful in a great variety of diseases, but as its employment is mentioned under the separate articles it is unnecessary to repeat the information here. The most useful preparations of opium are:—

Opium powder.—To be kept in a well-stoppered bottle. Average dose for an adult, one grain. Tincture of opium, or laudanum,—which contains one grain of solid opium in 15 minims. Average dose for an adult, 15 to 20 minims, or about 25 to 30 drops.

Tincture of opium with camphor, now called compound tincture of camphor, or paregoric, —which contains one grain of solid opium to the half ounce. Average dose for an adult, one drachm to three drachms.

Compound opium powder with ipecacuanha, or Dover's powder,—which contains one grain of solid opium in ten. See *Dover's powder*.

431

OPI ORA

contains one grain of opium in forty. Aver-

age dose, twenty to forty grains.

As external applications, the opium liniment,

and the opium plaster, are both useful.

There are many other preparations of opium used, but the above would be ample for the best stored emigrant chest; and therefore for

any home use.

Laudanum and paregoric are best administered in water, Dover's powder in the form of pill, and the compound chalk powder in some thick substance, such as gruel. When solid opium is given, it is best in the form of pill, without admixture. Laudanum is sometimes used as an external application, being put into poultices, &c.; it is also used to rub on the gums in toothache. It must not be forgotten, that in any of these ways, if employed incautiously, or in excessive quantity, it may affect the system, and even prove dangerous. the use of laudanum in injections, the reader is referred to articles Enema and Hypodermy.

In addition to the preparations of opium above mentioned, two others require notice, one of these the valuable, though secret, Battley's sedative solution, will be found noticed under its special article; the other, morphia, is the special sedative or narcotic principle of opium. Opium is a very compound body, and includes other principles, on some of which its stimulant and other powers more particularly depend; morphia, therefore, being separated from these, is more purely sedative, and is not found so frequently to occasion the disagreeable after-effects which often follow the use of opium; in other respects, its action and applications are the same.

Morphia, on account of its insolubility, is generally prescribed in the form of the more soluble acetate or hydrochlorate or morphia. The latter is the best and more certain preparation: dose, from twenty to forty minims of the solution, which contains half a grain of the salt in each fluid drachm. The graduated morphia lozenge is a most effectual and comparatively agreeable remedy in irritable cough; ten or fifteen of the lozenges may be taken in the course of the same number of hours. Each lozenge contains the thirty-sixth part of a grain of

morphia.

Godfrey's Cordial, &c.

OPODELDOC is an old name, seldom used now by medical men, applied to external stimu-lating embrocations. The camphorated soap liniment is the form most usually indicated by

the term, popularly.

OPSONINS are certain constituents of the serum of the blood, whose existence has never been demonstrated by separation, but whose presence is inferred from influences which they are believed to exert upon noxious bacteria which gain admission into the blood. Physio-

Compound opium powder with chalk,-which | monstrated that the white corpuscles of the blood possess the power of absorbing and destroying noxious bacteria, such as tubercular and septic bacilli. Their capacity for doing this is found to vary under different conditions and at different times; and it has been proved that this is not usually due to any difference in the power of the white corpuscles, but to some alteration produced in the bacteria during their circulation in the serum of the blood. The serum of one person will act more strongly on the bacteria than that of another, so that when the white corpuscles are added experimentally to the serum charged with bacteria, in one case each white corpuscle may absorb only one or two bacteria, which in another case four or five may be absorbed by one corpuscle. Very delicate physiological investigation is necessary to demonstrate those differences resulting from opsonic action; and when, on comparing the action of white corpuscles on bacteria in the serum of an unhealthy person with the same action in the serum of a normal person, the respective number of bacteria absorbed is estimated, the result is expressed in the form of a fraction, which is known as the opsonic index of the patient for the time being.

It is chiefly in connection with tubercular bacilli that these investigations have been carried out; and further experiment has shown that when the opsonic index is low it can be raised by the injection subcutaneously of certain prepared vaccines (see Vaccine). is assumed, and observation has confirmed the assumption, that a high opsonic index is an important factor in recovery from tuberculosis, and in treating such cases with vaccines, such as the various forms of tuberculin, it is made an object to maintain the opsonic index at a

point as nearly normal as possible.

OPTICAL DELUSIONS or ILLU-SIONS—the result of diseased or of disordered action—are not uncommon. Under the term may be included the more obvious disorders of vision, such as those in which one-half of an object, or one-half of a word only, are perceived. From this state, up to that in which figures of persons, either known or unknown, are seen, either constantly or periodically, every form of optical delusion is met with. Such cases are generally connected with disorder in the head, either in the form of disease of the brain itself, or are occasioned by sympathy with disordered function in other parts of the body, more particularly the stomach—See Blindness.

ORANGE. - This well-known and wholesome fruit is imported chiefly from the countries bordering the Mediterranean. The two varieties-the bitter or Seville orange, and the sweet orange, are too well known to require descrip-The perfume of the orange flower is highly valued, and the distilled water is used on the Continent as an antispasmodic and anodyne; it is recommended as extremely uselogical observation and experiment have de- ful in hysteria, in doses of one or two ounces.

OVA ORB

ase of the orange is derived from the rind, which yields an agreeable, aromatic, stimulant bitter; the rind of the bitter orange is usually ordered, but that of the sweet may also be used, though it is less powerful. An infusion, a compound infusion, a syrup, and a tincture of orange peel as well as orange wine and orange water, are all used. A very good infusion may be made, simply, from an ounce of the dry bitter orangepeel, twenty ounces of boiling water being poured over, the whole allowed to stand for twenty minutes, and then strained; the addition of a quarter of an ounce of lemon peel to the above quantity may be made with advantage. The dose, as a stomachic, is a wineglassful twice a day. Of the sweet variety of the orange, the China, the Maltese, and St. Michaei's are best known in this country; the finest descriptions of the fruit have a smooth, thin, dark rind. The juice of the sweet orange contains principally mucilage, sugar, and citric acid, and is one of the most wholesome vegetable juices we possess, particularly in the chamber of sickness; the cellular pulp of the orange, however, in which the juice is contained, is very indigestible, and when swallowed, as it often is by children, is apt to produce disorder, passing through the bowels produced. It is a good plan in the case of unchanged. It is a good plan, in the case of young children, to give the orange juice squeezed into a glass.

ORBIT.—The cavity in the skull in which

the eye is placed.

OSMAZOME is the animal principle on which the peculiar and agreeable flavour of cooked meat depends. It is most manifestly developed in decoctions of meat, such as soups and beef tea, but as the term is now found to have no special signification, it has been aban-

doned in favour of aroma or flavour.

OSSIFICATION.—The formation of bone. "The first development of bone," according to Carpenter, "is commonly preceded by the formation of a cartilaginous (gristly) structure, which occupies the place the bone is afterwards to take; and it has been commonly considered, that the bone is formed by the ossification of the cartilage (gristle)." This, however, does not appear to be the case, for none of the peculiar substance of the cartilage-chondrine-can be found in perfect bone. The process of true bone formation always commences in the immediate neighbourhood of blood-vessels, which pass down into canals excavated in the substance of the cartilage; the spots where these vascular canals are especially developed, are termed centres of ossification. We usually find one of these in the centre of the shaft of a long bone, and one at each end; in the flat bones, there is generally one in the middle of the surface, and one in each of the principal projections. the period when a bone attains its full dimensions, the parts which contain distinct centres, are not connected by osseous (bony) union, but large size formed in the ovary. Since the in-

In this country, the chief direct medicinal | only by cartilage, so that they fall apart when this decomposes; the purpose of this is to allow an increase in the size of the bone by the growth of cartilage between its detached portions, which cartilage may give place to bony structure, when there is no further need of increase. - See

> After the formation of bone has been completed, the changes which take place in its component particles appear to go on slowly; but should injury be inflicted, either in the form of fracture, or as a consequence of disease, by which a portion of bone is destroyed, the formation of new bone is often extremely rapid, and in the course of time, extremely perfect; the new structure in every way resembling the old. The reunion of fractures by the formation of new bone has already been alluded to under

article Fracture.

As all are aware, the bones of young animals are much more cartilaginous than those of older ones; they contain much more animal matter, which, as life advances, diminishes, and gives place to a larger proportion of mineral ingredient. It is not, however, in the bones alone that this tendency to increase of mineral deposit-ossification—is observed; the body, generally, in old age, becomes more rigid, and bony deposit is found in structures that do not ordinarily contain it. Some structures are, however, much more obnoxious to this than others. It is matter of popular information, that the heart is very liable to be the seat of ossification, or more correctly speaking, of earthy degeneration in advanced life; this occurs more especially in the structure of its valves, and in connexion with them (see Heart), also in the coats of the coronary arteries which supply its own muscular substance; a change which is often found to have been associated with symptoms of "angina pectoris." This tendency, however, to the deposit of calcareous matter about the arteries of the heart, extends throughout the arterial system generally, causing these otherwise elastic tubes to become rigid, and thus impairing the important power they possess in health, and in early life, of assisting to propel each wave of blood which the heart-contraction commences through the body. The arteries, when in this condition, impart a tense wiry feeling to the fingers, and can be readily felt under the skin, and the pulse at the wrist, as well as the superficial veins, become more visible than they should be (see Circulation). This change in, and enfeeblement of, the power of the arteries, is one great and originating cause of many of the diseases of old age. Other parts, such as those connected with the larynx, &c., are liable to undergo this bony transformation, as life ad-The subject could not profitably be pursued further here.

Refer to -Bone-Cartilage-Fractures, &c. OVARIOTOMY is the term applied to the operation of removing a cyst or tumour of

troduction of chloroform, and more recently by the employment of antiseptic dressings, this operation, formerly considered very formidable and dangerous, is now attended with a large amount of success.

and Sanitary Authorities, to purchase and pull down habitations unfit for human dwellings, and to build others; but, as was anticipated, the vast expense attending the carrying out of the provisions of the "Improvement in Dwell-

OVARIUM, or OVARY, is the receptacle in which are contained, either in plant or animal, the germs of the future seed or egg. The ovary in the human female is liable to a variety of diseases, such as inflammation, irritation, dropsy, and tumour. Irritation of one or both ovaries often gives rise to many obscure symptoms in organs apparently quite disconnected with those which are the primary seat of the irritation. Dropsy of the ovary is one of the most general affections of the organ, and arises from an enlargement of one of the small vesicles of the organ, which fills with fluid until it frequently occupies the cavity of the abdomen. Tapping, or other operations, may be required for its relief.

OVERCROWDING.—The death-returns of the Registrar-General show conclusively, that wherever human beings are crowded together, the death-rate asserts a higher proportion to the population, than in houses and districts sparsely populated. The people living in densely-populated neighbourhoods do not alone suffer, for when epidemic or infectious disease occurs among them, as it is too prone to do, it more often than not extends to their immediate zone, the occupants of which may be living in comparative luxury. Dr. Gairdner has given us a table, showing how the deathrate increases, with mathematical precision, in proportion to the density of population. The first column represents the number of persons located in one square mile, in separate districts in England, while the second column gives the deaths per 1000 living, for each year:

All experience shows the detrimental effect of limited area on the health of the population, and the legislature has wisely enacted that in buildings under their control, such as factories, workhouses, schools, barracks, and hospitals, a given amount of space consistent with health, and efficiently ventilated, should be allowed to each individual, but the main difficulty felt is in dealing with the poor in their own homes, especially in the crowded courts and alleys of great cities. Considerable powers are now invested in municipal bodies, Boards of Works,

and Sanitary Authorities, to purchase and pull down habitations unfit for human dwellings, and to build others; but, as was anticipated, the vast expense attending the carrying out of the provisions of the "Improvement in Dwellings Act," has been a great bar to its working. The success connected with the erection of model lodging-houses, the Peabody gift, and other philanthropic agencies, proves how much private enterprise, aided by a wise charity organisation, can effect in the way of improving the dwellings of the poor. Perhaps no stronger illustration of the effect of airy dwellings can be found, than in the case of the nomad race of gypsies, who live for the most part either in the open air or under canvas, and, notwithstanding many privations, enjoy much better health than the denizens of the rookeries which exist so plentifully in all large cities.

**OVUM** literally, means an egg. The term is generally applied to the germ of the future being, after it has been fertilised by the male; previous to that, the term ovule is used. After fertilisation, the ovule of the plant becomes the seed; that of the animal, the egg, in which and from which the future animal is formed, either out of or within the body of the mother.

—See Egg.

**OXALIC ACID** is one of what are called the vegetable acids, being found ready formed in combination with potash-in various plants, such as the common wood sorrels, the common sorrel, the garden rhubarb, &c. It is also formed in some disordered states within the animal body, and is excreted in the urine, in combination with lime (see Oxaluria). Oxalic acid may also be formed by the action of nitric acid on sugar or starch, to which bodies it approaches, nearly, in composition, beng formed of carbon, oxygen and hydrogen, in certain definite proportions, or in other words, of carbon and oxygen, along with the elements of water. Oxalic acid is generally met with in the form of small white crystals. Oxalic acid is not now used medicinally; formerly, it was so, in the form of the wood sorrel, which was employed for the purpose of making febrifuge acid drinks, whey, &c.; but there are many substitutes, such as lemon juice, better adapted for the purpose, and less suspicious.

What is known in the shops under the name of "essential salt of lemons," or salt of sorrel, is a compound of oxalic acid with potash, and was formerly obtained from the wood sorrel.

Oxalic acid derives its chief importance here, from its frequent effect as a poison, either by accident or design. The accidents have generally arisen, in consequence of oxalic acid having been sold or taken in mistake for Epsom salts, the crystals of the two closely resembling one another; the precaution of tasting a single crystal would be sufficient to detect the difference.

vested in municipal bodies, Boards of Works, oxalic acid vary considerably. When a large

dose has been swallowed, the chief effect is ! complete prostration of strength, in fact, a state of collapse, accompanied with stupor, in which the patient dies, often within thirty minutes after taking the poison. Severe pain at the stomach usually comes on soon after the poison has been swallowed, but this, and vomiting which also generally occurs, and continues with great severity, may be absent. The vomited matters are strongly acid, and dark in colour. The rapidity with which death often ensues after a poisonous dose of oxalic acid has been swallowed, renders it almost impossible, in many cases, to procure medical assistance in time; it is, therefore, highly desirable that the most prompt measures should be adopted by those around. The principle of treatment is based on the fact, that the very soluble oxalic acid itself, forms, with lime especially, and with magnesia, insoluble and, therefore, compara-tively less hurtful compounds. Chalk or whiting, the carbonate of lime, mixed up with water, is the best possible antidote, and should be given freely; if this is not at hand on the emergency, a portion of old mortar should be in the form of pills, or in gelatine capsules. taken as a substitute, rubbed up with milk and water, and given as quickly as possible, or instead of it, magnesia. If none of these remedies can be procured, very copious draughts of water should be given to promote vomiting, which in any case should be excited, if it has not been already occasioned by the poison. There was formerly a prejudice against giving water largely in oxalic acid poisoning, from the fear that it might favour the solution, and passage of the salt into the blood; the practice has, however, been found advantageous, provided free vomiting is encouraged. Of course, whilst these measures are in progress, medical aid should be sought. Should the patient survive the poisoning, symptoms of irritation of the stomach and alimentary canal must be expected, which will require the most soothing treatment, chiefly by demulcent medicines and diet, and it may be by leeches to the pit of the stomach.

OXALURIA AND OXALIC ACID DIATHESIS are distinguished by the presence of crystals of oxalate of lime in the urine, which may either exist naturally after partaking of certain vegetables, as rhubarb, or wines, or malt liquors containing much carbonic acid, or the salt may be excreted as a morbid product from the kidneys, the result of disintegration of the tissues. The latter condition is associated with some forms of dyspepsia and often with hypochondriasis; occasionally, the salt gives rise to a concretion in the bladder or kidney, characterised by its rough uneven surface, to which the term mulberry calculus is given. The treatment in such cases consists in avoiding all articles containing oxalic acid, as well as sweet effervescing beverages, and the employment of the dilute nitro-hydrochloric acid, in doses of twenty drops, in some bitter infusion.

OX-GALL .- The gall or bile of the ox has been much lauded as a remedy in habitual constipation. A few years ago, it was extensively tried, and undoubtedly proved, and does prove, serviceable in certain cases, but, perhaps, having been over-praised, it seems to have become again almost too much neglected. In some cases of constipation in pregnancy it answers extremely well, and is very safe. Its preparation for medicinal purposes is simple, all that is required being, to place a quantity of fresh ox-gall in a flat dish, in a sufficiently warm situation-such as an oven-and permit evaporation to go on, till the gall becomes sufficiently firm to make it into pills, of which from five to ten grains weight may be taken once or twice a day. Besides acting as an aperient, ox-gall has been said to assist digestion; this may be, either from its bitter giving tone to the stomach, or from its giving its own chemical aid to the solution of certain constituents of the food. Ox-gall in its purified state is admitted into the Pharmacopæia; it is given in doses of five or ten grains

OXYDE OF BISMUTH.—See BISMUTH. OXYGEN GAS is one of the elementary bodies, and if one is more important than another, it, perhaps, is entitled to the first place. Its name, derived from two Greek words, was given in consequence of the erroneous idea that it was the sole cause of acid properties in bodies; it has also been named "empyreal air," "dephlogisticated air," &c. Oxygen gas, in mechanical mixture with nitrogen, constitutes the air of the atmosphere which surrounds our Globe (see Air), and on its presence in due proportion, depends the continuance of animal existence, the phenomena of combustion, &c. Whether the nitrogen gas with which oxygen is mingled in the atmosphere fulfils other objects or not, it certainly does the important one of diluting it, and of tempering its potent agency, which, were it not for this dilution, would act with such chemical energy, as must quickly prove destructive to organised life upon our Globe, as at present constituted.

Oxygen, in combination, forms what are called basic oxides. These are bodies such as potash, soda, oxide of iron, &c., which tend to unite with its next class of compounds, the acids. Besides these, oxygen forms compounds which do not exhibit aptness for entering into combination.

Further, oxygen, by uniting in different proportions with the same body-such as nitrogen -may give rise to a variety of very different compounds. United with hydrogen in the proportion of two parts of hydrogen to one of oxygen it forms water. The important part which oxygen plays in the various fulfilments of animal life and existence has rendered the foregoing notice necessary. Under such articles as Animal Heat, Air, Blood, Digestion, Motion, Respiration,

OZO

OXY

&c., the reader will find those fulfilments and effects sufficiently entered into. Oxygen (compressed into iron cylinders) taken by inhalation has been found to be a remedy of much value in some diseases. It has been found especially useful in cases where the breathing powers are impaired, adding to the comfort of the sufferer, and influencing favourably the general condition. From a series of experiments made recently by Mr. Hayem, and communicated to the Academy of Sciences, he has shown that when oxygen is inhaled in certain proportions with common air, it has the remarkable power of stimulating the nutritive functions, increasing the amount of red corpuscles in the blood, quickening the appetite, and adding ultimately to the weight of the body. It was found that the suspension of the inhalation checked these changes, but so long as they were continued, there was a decided improvement in the condition of the patients. The advantages of the inhalation were especially serviceable in persons suffering from anæmia and chlorosis; and in cases of dyspepsia accompanied with vomiting, it had the power of checking the vomiting, while in cancer of the stomach, and in phthisis, the

vomiting was rendered less frequent.

OXYGEN WATER.—This water owes its medicinal properties to the fact that it contains a large amount of free oxygen gas in solution. The amount of gas contained in the water, which was manufactured and sold at one time by a public company, was said to be about 13.5 cubic inches to each imperial pint, equal to 4.6 grains of gaseous oxygen by weight. Chlorate of potash is a remedy frequently prescribed by medical men, with the view of supplying oxygen to the blood. Now one pint bottle of this oxygen water contains as much of the gas as would be obtained from a dose of chlorate of potash equal to 21.4

grains.

Oxygenated water is a very pure, wholesome, and useful beverage, and is found to be a gentle stimulant to the functional action of the stomach, and the secretory organs generally. It is given in cases of indigestion, with loss of tone, feebleness, and irritability of the stomach, with tendency to nausea and sickness. It is also of value in cases of pulmonary consumption, and of diseases of the lungs and respiratory system, connected, or accompanied, with deficient æration of the blood.

**OXYMEL**—a mixture of honey and vinegar. Simple oxymel is made in the proportion of forty ounces of honey to five ounces of acetic acid and five ounces of water.

Oxymel of squill is made by mixing five ounces of squill vinegar with half a pound of

honey.

The above are pleasant and useful preparations in some forms of catarrh and cough, and may either be used alone, or combined with other medicines. **OXYMURIATIC ACID.**—The old name for chlorine.

OYSTERS.—Respecting the wholesomeness of this well-known shell-fish, difference of opinion exists among medical men; nutritious, especially when uncooked, they certainly are, but their digestibility in all probability depends greatly upon the person by whom they are eaten. Some, whose stomachs generally require much consideration, can eat oysters in moderation with impunity: Dr. Paris condemns them for invalids, but most authorities agree in considering that in their raw state they are admirably suited for weak stomachs. Oysters have been known, like other shell fish, to cause symptoms of irritant

poisoning.

**OZONE** is a substance of penetrating odour, which, according to M. Schönbein, who paid much attention to the subject, is constantly liberated in greater or less quantity in the atmosphere, according to the development of electricity. It is a substance which has a powerful effect in decomposing foul organic matters in the atmosphere, and its oxidising properties on metals are greater than those of oxygen. It is found in greatest abundance on land near the sea, and during snow and thunder storms, and its presence may be detected by its action upon paper moistened with iodide of potassium. which it renders brown by liberating the free It was thought at one time that ozone might be the cause of epidemic catarrh, on account of its energetic action on the air passages, but this theory was soon abandoned. Scientific men have speculated curiously as to the influence of ozone upon the health of mankind, and many ingenious instruments, called ozonometers, have been devised to determine the quantity of it present in the atmosphere which we breathe, under various conditions. It may, however, be truly said that, as yet, we know nothing definite with regard to it, although the most careful investigations have been conducted with a view to determine, if possible, its relation, if any, to the health of our large towns; or whether having any, and if so, what influence in favouring or producing the occurrence of the different epidemic diseases by which we are from time to time assailed. Ozone is believed, by the best observers, to be oxygen in a concentrated form, or, to express it in chemical language, an allotropic form of oxygen, just as the diamond and plumbago may be said to be allotropic forms of carbon. It derives its name from the Greek word, signifying a smell. It has been recommended to be given in medical practice in combination with other remedies, as, for instance, with cod-liver oil, and in the form of ozonised water, but the continued experience of medical men has not endorsed the high opinion that was once entertained of its curative properties. Ozone is made artificially, and is much used for bleachPAI PAI

ing purposes, and its well-known activity in | of the nervous system, such as occurs in hysdecomposing foul organic matter in the atmosphere, points to the probability of its uses being further taken advantage of in this way.

PAIN .- The sense of pain, like other sensations, originates in the nerves, and very generally appears to be located in the parts where their ultimate branches terminate; the perception of pain, however, by the sentient being, must depend upon the brain, the sense of it being conveyed to that organ by the nerves. This we know, certainly, to be the case, for if the nervous communications with the brain are cut off, as by injury to the spinal cord (see Nerves) or if that organ itself is oppressed, as in stupor, there is no sensation, and consequently no pain. There may be the appearance of sensation, and of pain being felt, in consequence of reflex action, as explained under the article Nerves, but it is appearance only. If any portion, almost, of the healthy body, is injured, pain is felt, because the universally-distributed nerve branches are injured in the process, and, as might be expected, the sensation is referred to the seat of the injury; but pain being felt in a particular part, or as if in a particular part, is not necessarily indicative of injury at the place where it is felt; it may arise from irritation of the nerve cord which supplies the part, at almost any part of its course. This is most strikingly exemplified in the cases of persons who have suffered amputation of a limb, and who often experience the sensation of pain, as if in the member they had lost. Similar, in some degree, to the above, are the sympathetic pains observed in some cases of disease; such, for instance, as the pain at the point of the shoulder from affection of the liver, the pain in the knee which is so general an accompaniment of hip-disease, or the pain in the legs which may result from acid in the stomach. Pain, therefore, although a most valuable guide in the investigation of disease, is by no means an unerring one, and must not be too implicitly trusted.

The faculty or power of feeling pain-the sensibility of the various parts of the animal body, when in a healthy condition-varies greatly, depending in a great measure upon the supply of nerves they receive; thus, such parts as bones, tendons, ligaments, &c., are generally but little sensitive; when, however, they become inflamed, they are acutely so. Further, it would seem that certain affections of the central parts of the nervous system greatly increase the sensibility to pain, as well as diminish it, more particularly affections of the spinal cord. Such is the case in hydro-phobia, lockjaw, &c., in which every portion of the surface of the body becomes painfully

sensitive.

teria, there is often intense susceptibility to pain, as well as to other outward impressions; but this evidently depends on very different causes, and requires very different treatment from the cases above mentioned (see Hysteria). Pain is not at all times referred to the terminations of the nerve, in neuralgia either of the head or face, or affecting the great nerve of the thigh and leg,—sciatica,—the pain is often complained of in the site of the main cord of the nerve itself.

Pain varies greatly in kind, as all know; it is dull and aching, sharp and cutting, throbbing, tingling, smarting, burning, &c., these differences depending in some measure upon the part affected. Inflammation of the skin is generally accompanied with pain of a burning, tingling, or smarting character; that of a "serous membrane," such as lines the chest, causes pain that is sharp and cutting, which is the case in pleurisy; the pain of toothache is dull, aching, and throbbing; the pain of spasm is sharp, but distinguished from that of inflammation by not being aggravated by pressure.

It is probable—and cases of hysteria justify the supposition-that some persons are much more acutely sensible of pain than others; it is certain that some bear it much better, both physically and mentally, than others. It is sometimes of importance to ascertain this; it may be done at times, by remarking, when it is necessary to apply a blister, how far the irritability, either mental or physical, is ex-

cited by it.

Pain is not an unmitigated evil; were it not for its warning, we should be liable, unwittingly, to inflict all manner of injuries upon our bodies. We see this in cases in which the sensibility to pain is impaired or destroyed, in consequence of disease of the brain, or of paralysis of the nerves of sensation. In the former case more especially, as has already been alluded to in this work, serious results may follow forgetfulness of this fact; the feet, either of an adult or of a child, may be parboiled, or a mustard plaster may be kept on the skin, till the most severe effects are produced, simply because the warning symptom of pain is, for the time being, in abeyance. This is no imaginary possibility, and it is one, the occurrence of which should deservedly bring down the censure of gross carelessness upon any one under whose management it might happen.

The absence of sensibility to pain, in connexion with cases of apoplectic stupor, &c., is what we may expect; it sometimes, however, occurs whilst the mental faculties remain active; this, when it does happen, is generally after some severe accident, such as an extensive burn or the like, which seems to overwhelm the nervous system; in such cases, the severest Lastly, in functional disorder, or irritability operations may be undergone without suffering,

but the symptom is one of the most fatal im-

The presence or absence of pain, or its alleviation, is by no means a light consideration in the treatment of disease; the mere sensation of it exerts a great call upon the system, and it is quite possible for a person to die from severe pain alone; hence the inestimable value of these modern discoveries, the anæsthetic, or pain-relieving powers, of chloroform and ether, which, by saving a patient the exhausting shock of the pain of a severe surgical operation, place him in a much more favourable condition for recovery than he would be without their aid-a consideration, which far outbalances the few and far between fatal accidents which have undeniably followed the use of the above agents. It is the fact of the exhausting tendency of pain, which renders opium so valuable a medicine, and one, the existence of which so abundantly testifies to the beneficence of our Creator, who, in conferring upon man the liability to suffer from the warning pang of pain as a necessary adjunct to his present being, has also given the means of its allevia-

Although, however, it may be advisable in most cases to alleviate or annul pain, and, when it is very severe, imperative to do so, it is possible to sacrifice too much to the one object. Generally speaking, it is not difficult, for a time, at least, to overwhelm the sensations of pain by powerful doses of anodynes; and although, as far as can be done, consistent with other means of treatment, suffering should be relieved, it may not be desirable totally to annihilate what is, in many cases, an index of the progress of a disorder; neither can it be advisable to sacrifice to the one object—the alleviation of pain-other considerations of more vital and lasting import. In other words, it would not be right to give, for instance, a large dose of opium to annul a present pain, with the risk or certainty of interfering with some of the secretions or excretions of the body, such as that of the bronchial membrane, the due performance of which must be absolutely necessary to the ultimate wellbeing of the patient. This point is dwelt upon, because it is one on which the public requires a little enlightenment. To unprofessional persons, the man who most quickly relieves that which every patient thinks the most prominent symptom of his case-pain-naturally, perhaps, appears to be a practitioner superior to one who does so more slowly; but yet, the latter may be following by far the safer, and one may add, more conscientious practice, and be much more likely to conduct his case, in the end, to a successful issue, than if he had sunk other considerations before the one—the relief being the remedies which are most likely, each side, is placed the tonsil (see Tonsil).

from their remarkable power of subduing pain, to be resorted to, to the exclusion of other really more important indications and methods of treatment. There are, however, other means of alleviation, which cannot strictly be called anodynes, but which may, in many cases, be used with much advantage, without being open to the objections which hold good against opium and the like. Of these, heat, especially when combined with moisture, is at once the most useful and generally applicable, as with a poultice or hot fomentation; cold may answer the same purpose in some cases, but not generally, except in pain affecting the head, where an ice-bag or evaporating lotion can be applied. The position of the body, or of a limb, the temporary loosening of a bandage, the mechanical support of a painful part, either to relieve its natural weight, or to take pressure off the site of the pain, and throw it on some sound texture, the friction of a pained part by the hand, the abstraction of blood by leeches, scarifications-as shown in the case of the gums, which, by relieving the swelling and tension, also relieves the pressure upon the extreme nerve branches-and many other remedies applicable to the relief of pain, are to be kept in mind. Lastly, the kind word and the gentle tone are anodynes, which, though they may not relieve real pain, will yet, either in rich or poor, make it more bearable, and whilst incapable of harming, give the double blessing on them that bestow and on them that receive.

PAINTER'S COLIC.—See Colic—Lead. PAINTER'S PARALYSIS.—See LEAD

-Palsy-Dropped Wrist.

PAINTS and PAINTING.—The injurious effects exerted upon the health of those who occupy newly-painted houses or rooms, is a circumstance too frequently overlooked. That living in, and especially sleeping in, rooms which have been newly painted with "oil colours," does occasion uneasy feelings, such as headache, &c., most can testify; but that the effect produced is more than transient uneasiness, is evident from the fatal influence the same circumstances exert upon birds. Children often upset their stomachs by sucking paints and paint brushes, as well as toys, the colouring matters of which become easily de-tached. Most green paints contain arsenic.

PALATES.—The palates are divided into hard and soft. The former is the ridged roof of the mouth, which, commencing behind the upper teeth, extends backwards, and merges into the soft palate, which is a fold or curtain of the mucous membrane lining the mouth, and from the centre of which depends the uvula, a small rounded projection which any one may see by examining his own throat in a glass. From each side of the uvula pro-ceed two arched "pillars" or folds of membrane, of the present pain. The relief of pain by anodynes (see *Anodyne*) has been chiefly alluded to in the foregoing remarks, these an anterior and a posterior, between which, on

The soft palate, during the act of swallowing, | of a fluttering sensation about the region of the prevents the regurgitation of food into the nose, whilst, at the same time, the arched pillars above described, by closing over the root of the tongue, keep the morsel from passing back into the mouth. The membrane within the mouth, which covers the hard palate, is liable to be the seat of small blisters, particularly in those who suffer from some forms of indigestion; in such cases, of course, the cause, and not the effect, requires treatment (see Indigestion). The hard palate is occasionally deficient at birth, and to so great an extent, as to require the introduction of a metallic plate to fill up the gap. In such cases, the fissure often extends through the soft palate, dividing the uvula into two parts. These "congenital" affections are usually associated with hare lip, and, like it, require the operative aid of the surgeon for their reparation. Fortunately, improvements in the mode of operating, particularly those introduced by the late Sir Wm. Fergusson, of King's College, have rendered the measures resorted to much more generally successful than formerly.

Refer to—Nose — Throat — Tonsils — Uvula,

PALLIATIVES are remedial agents which aim rather at relieving urgent symptoms, than at curing or removing the disease which these symptoms indicate. Too often it happens, that the palliative is all that is left for even the highest skill to administer; and if that skill cannot hinder the breaking of the "golden bowl," or the snapping of the "silver cord" which binds the living man to life in this world, it is much to be thankful for, that there are means and remedies which mitigate the pangs of fatal disease. There are diseases which baffle the most searching investigation, not only in the living body but in the dead, and there are others which, although recognised, are so only-in the present state of our knowledge—to tell that they are beyond the reach of human aid to cure; in such, the palliative only remains, and if this be the case with educated skill, how often, rather how generally, must it be so with the limited knowledge of the unprofessional! On this account, in a work like the present, addressed to the latter, palliative treatment occupies a large space amid the remedial measures recommended as being most safely usable by those who are put in possession of the information.

PALM-OIL, obtained from the seeds of the oil palm, is of a bright orange-yellow colour, and is brought to this country as a substance the consistence of butter. It is used as an external application for similar purposes to the olive and other oils, but is in no way

PALPITATION OF THE HEART is unusual action of that organ, of which the patient is sensible; it may take the form either | fancies, even in the time of exercise, which is

heart, perhaps extending into the throat, or it may amount to violent beating, either regular

or irregular.

The liability of the heart's action to be increased by exciting emotions of the mind, almost of any kind, whether of fear or of joy, renders palpitation a very common affection, and when it occurs only under occasional circumstances like the above, it cannot be considered otherwise than a perfectly natural occurrence. When, however, palpitation arises on every trivial occasion, either of mental emotion or of physical exertion, or without occasion at all, as it often does, even during rest in bed, then it requires attention, not solely on account of the discomfort it gives rise to, but because it may lay the foundation of disease of the organ which is so constantly subject to over-excitement. It has already been stated in this work, that heart affections have been observed to become more common after seasons of much public excitement of any kind, an effect traceable only to the frequent disturbance of the organ by the passions or emotions.

Palpitation of the heart, independent of disease, is most liable, indeed is very liable, to occur in the young of both sexes, and in females particularly, soon after the age of puberty, in the latter, being very generally associated with hysterical tendencies; in such cases, it is met with in its most aggravated forms, and often of such violence as to prove truly alarming. In any case, the tendency to palpitation is more common in the nervous temperament, and is increased by whatever gives undue predominance to that temperament, such as indolence, luxurious habits and the indulgence of feelings and imagination artificially excited; and, having once begun, it is kept up and aggravated by the continued attention with which the mind is apt to dwell upon the ailment; the individuals subject to it easily imagine themselves the subjects of heart disease, watch every motion almost of the heart, and thus, under the influence of their own imaginary fears, produce the very symptoms they dread. This nervous condition -for it is generally nothing else-is only to be got rid of by those measures which give a more vigorous and healthy tone both to mind and body; the false excitement of imaginative literature—if it has been indulged in—must be exchanged for a more healthy mental aliment-something which calls for some healthy mental interest. This must, of course, be regulated in some measure by the habits and tendencies of the person, but where it can be adopted, the pursuit of some branch of natural history, botany, geology, or any other out-door occupation, such as gardening or sketching from nature, are the best pursuits; they occupy the mind, and draw away from its own morbid

excitement which accompanies it. Along with these means, a system of diet (see Food), adapted to give good blood nourishment, should be adopted; heated and ill-ventilated rooms above all things are to be avoided, early hours observed, and if a feather bed has been habitually lain upon, a firm hair or wool mattress is to be substituted. One article of diet requires especial mention as being peculiarly injurious in such cases—tea of any kind is better avoided, but green tea is absolute poison; coffee is scarcely allowable, and cocoa or milk should invariably be substituted for either of the above more stimulant beverages. Wine or malt liquor may be injurious, or the reverse, according to the previous habits of the patient and the nature of the case: if depression or debility follows their withdrawal, the tendency to palpitation is certain to be increased. Smoking to excess often affects the nervous system to an extent to produce palpitation, and where there is this liability it ought to be forbidden. In addition to these measures, regulation of the bowels, the use of the shower bath, or, better, of the douche down the spine, and occasional mustard plasters on the chest or between the shoulders, are all useful, especially if, as frequently happens in cases of aggravated palpitation, any tenderness of the spine is found to exist. In cases of nervous palpitation, medicine is not much called for, unless to remedy other disorders, such as indigestion. Some patients derive much benefit from a tea-spoonful of the ammoniated tincture of valerian, taken twice or three times a day in water, to which, if there is much nervous irritability, ten drops of tincture of henbane may be added; sal volatile in tea-spoonful doses is often useful, especially if there is much flatulence: or ether, either sulphuric or chloric, may be taken in ten or fifteen-drop doses, either alone or with the above-mentioned remedies. The ethers, however, are more generally serviceable as remedies during an attack of palpitation, than when taken regularly. Night palpitations may be frequently relieved by a draught, taken at bedtime, composed of bromide of ammonia, bromide of sodium, fifteen grains each, and ten mimins of tincture of digitalis, in an ounce and a half of water. When palpitation is habitual and severe, a medical man should be consulted, especially if the mind is at all uneasy; his examination will detect the real nature of the affection, and his advice will be most likely to indicate with certainty the remedies which will most quickly relieve that which, though but a functional disorder, may, if neglected, become an organic disease. With respect to the power of motion palpitation dependent on disease of the heart, enough has been said in the article devoted to the subject of heart disease in general.

PALSY.—See PARALYSIS.

rendered doubly invigorating by the mental | all diseases; it is, perhaps, needless to add, an imaginary one—a "myth.

PAPILLA is a small eminence upon the surface of an organised body. The minute points visible upon the tongue are called the papillæ

PAPULE.—Papules or pimples occur as elevations from the surface of the skin, and are characteristic of some of its affections. eruption of small-pox commences with minute pimples, which are afterwards converted into pustules. As a rule, however, papules do not contain any fluid, and disappear after a time

PARALYSIS is loss of sensation, or of the power of motion, in parts naturally possessed of those endowments; the affection varies considerably in kind and degree. There may be loss of sensation, merely, either of a part, or of the whole body, without the power of motion PANACEA - a remedy capable of curing | being impaired, but this is comparatively rare;

PAR PAR

generally, it is the power of motion which is | symptoms in old persons, or in the predisposed lost or diminished, that of sensation being often | should never be neglected. not affected at all, and when it is, only slightly so. Paralysis of motion may be confined to a single finger, to part of a limb, or to the whole of one; it may extend only to the lower extremities, whilst the upper portion of the body is functionally unaffected; or one entire side of the body may be totally or partially deprived of the power of motion. In a few cases it occurs, that general paralysis of all the muscles of voluntary motion has taken place, life being carried on for some time by the involuntary functions solely. - See Nerves.

Palsy or paralysis of one side of the body, what medical men call Hemiplegia, is much more common than the other forms of the disease, and may occur at any age, even from infancy upward, but is most general after middle life, and more frequent in males than females; it takes place under very opposite and varied conditions of the system. When a person has suffered from an apoplectic attack, the result of congestion or of effusion of serum or blood into the substance of the brain, from the giving way of a vessel, recovery, if it takes place, is very generally trammelled with par-

alysis. - See Apoplexy

The rupture of a vessel in the brain is one common originating cause of paralysis; it is one, however, which may occur without there being any decided apoplectic symptoms at all; there may be slight effusion of blood in the brain, but not more than causes at the moment transient faintness and confusion; if the attack occurs during sleep there may not be even that; but either with or without it, paralysis is found to have occurred, either total or partial, and remaining partial, or gradually increasing for some time after its first appearance. Another form of paralysis is that arising from a more decided state of general debility, in which the brain partakes, and in which the structure itself gives way. It is often the disease of overworked literary men, or men of business, and is apt to end quickly, in a softened state of the brain, with mental imbecility, and perhaps general paralysis. Palsy may, of course, arise from other causes which act upon and injure the structure of the brain. the structure of the brain, such as tumours, violence to the head, &c., but the above are the most common, and are sufficient to notice here.

Whatever the cause, it is always found that when the brain proper is the seat of the disorder, the paralysis of the body takes place on the side opposite to that portion or

sphere" of the brain which is affected.

The symptoms which precede an attack of paralysis, are so very similar to those which have been described as being the forerunners of apoplexy, that it is needless again to go over them. The most frequent, however, is the complaint of numbness and prickling sensation throughout a whole limb, or affecting only a owing to the want of exercise which necessarily portion of it, such as a single finger. Such occurs, but partly also to the diminished power

When a person has suffered from a "stroke of palsy," or a "paralytic seizure" (by which is generally understood the paralysis of motion on one side of the body), the loss of power may be complete, the arm and leg lie perfectly inert as far as the will is concerned, and the face is generally more or less affected in a severe case, the side on which the paralysis exists having a rather relaxed appearance, whilst the features are drawn towards the other, in consequence of the muscles of the sound side still continuing active, and being unresisted by those on the paralysed side. This is much more visible under any of the mental emotions which usually affect the features, such as laughing, the muscles on the sound side only acting, whilst the paralysed side of the face remains perfectly unmoved. Under this condition of circumstances, the speech is affected, articulation is thick, in consequence of one side of the tongue being also paralysed, so that when this organ is protruded, it is pushed to one side; swallowing is, at the same time, in some degree

imperfectly performed.

These are the symptoms of a severe attack of paralysis, but they are often developed in much less intensity; the leg alone may be affected, or the leg and arm, leaving the face and head intact, and the mind perfectly clear. In a great number of cases, the paralytic symptoms after reaching a certain point go no farther, remain stationary for some time, and then begin to amend, the arm and leg recover power, the features regain their wonted expression, and the speech is well articulated. This amendment may go on to complete recovery, but, generally it stops short of this, and the person, though comparatively well, is not fully restored; the leg is not lifted as formerly in walking, but drags a little, the hand and arm do not regain their former skill and accuracy in executing accustomed acts, such as writing, even though the face, if it has been "drawn, is perfectly restored. In this state of partial recovery numbers continue for years, capable not only of enjoying life, but of executing many or most of its duties. It is a state, undoubtedly, which requires care, in diet, in exertion, whether physical or mental, and which involves many restrictions and selfdenials, but none perhaps, to which a well-regulated mind will not cheerfully submit; indeed, it does happen that individuals who, previous to an attack of paralysis, have been dyspeptics, or invalids, under a lax system of living, finding after its occurrence the vital necessity of greater carefulness, absolutely enjoy better general health than previously.

When a portion of the body, such as the arm, remains permanently paralysed, it usually, after a time, diminishes in muscular bulk, partly

PAR

of blood circulation through it, which certainly takes place. The difference in the power of the pulse in a sound and in a paralytic arm is very perceptible, and experiment has demonstrated that in the latter the animal temperature is habitually lower. In connection with these conditions of paralysed limbs, it should be borne in mind that they have less power of resisting differences in heat or cold; a variation in temperature which would not affect a sound limb being apt to injure a paralytic one, water which would not be too hot for the former producing a scald in the latter. In addition to the local effects of paralysis, there are general ones which often accompany the condition, these are usually connected with the excretions; the bowels particularly are apt to be very costive, and to require much care.

The mind may not be much affected at first, not perhaps for years, but the temper is apt to become irritable, a point which ought to be remembered with indulgence by others; as age, however, advances, in most cases the memory fails, and the mind, even the most powerful, becomes gradually weakened. It is enough to recall to the recollection the touching accounts of the last days of some of our great men, such as Sir Walter Scott, who have suffered from

paralysis, to illustrate this fact.

Such are the best marked symptoms which accompany and follow that very common disease, a paralytic stroke. Many of the warning symptoms of paralysis have been detailed under the head of apoplexy, and the precautionary measures pointed out; in the same article, too, the means recommended to be adopted in the different forms of apoplexy, either threatened or actual, will apply to the severer cases of paralysis. When a person becomes affected with paralysis without apoplexy being developed, when debility, faintness, and loss of power are the most prominent symptoms, it is not often that very active treatment is required; the cause of the disease is probably beyond the reach of art to remove, and the object must be to place the system in a state which will in no way favour a return or increase of the attack, but which will give every chance of recovery by the natural powers of the system. If the attack of paralysis has occurred in a person of very full habit, the chances are, that apoplexy has accompanied it, and if so, depleting measures will probably be requisite, these of course should be, if possible, under medical direction; but if this is unattainable at the time, they may be carried out as recommended, and under the precautions enjoined in the case of apoplexy.

When the attack of paralysis is accompanied with faintness and only partial loss of consciousness, in the absence of medical assistance, a tea-spoonful of sal volatile in a little water will be as suitable a remedy as any other, and may be repeated once or twice in the course of the

the individual should be placed in bed with head and shoulders tolerably well elevated, and kept perfectly quiet; if the bowels are confined, a gentle aperient of castor oil, or of rhubarb and magnesia, should be given, and light nourishment, tea, gruel, and the like. The warmth of the feet, and particularly of the affected side, must be strictly attended to. If, either at the time of the seizure, or afterwards, there is much pain in the head, flushing of the face and appearance of fulness, leeches, from six to eighteen, may be applied, or half a pint of blood taken from the back of the neck by cupping; but in these cases, much caution is always required in the abstraction of blood. In such a case as the last, more active purging will be admissible. Mustard plasters to the calves of the legs may in some cases be advan-The great essential, however, is the tageous. most perfect quietude; with this, time will be the best restorative, the diet being kept light and free from stimulants, and the bowels attended to. If the urine become scanty in quantity, cream of tartar drink—imperial—will be of service, or five grains of carbonate of potash, with five grains of nitrate of potash, may be given twice a day in a wine-glassful of water. Moderate friction with the hand to the affected side is not only soothing and comforting in most cases, but probably expedites the returning strength. Exertion of any kind must be very slowly and gradually resumed; but all this will be regulated by a medical attendant, under whose care the case must be placed. In some cases of severe paralysis the natural functions are performed involuntarily, and much trouble is required to preserve cleanliness.

The case in which the lower limbs are paralysed, the upper portions of the body being unaffected, is named Paraplegia; it is generally produced by disease or injury to the spinal cord or its membranes, or as a reflex symptom from affections of the urinary and generative organs. If arising from the former, it is generally a very hopeless disease. When the result of injury, the symptoms are of course developed at once, and, indeed, are so in some cases of disease; but generally they come on gradually, with weakness of the lower limbs or starting in them, very often with a sensation as if insects were crawling over the skin. Such cases always imperatively call for proper medical assistance; unprofessional persons can do but little beyond attending to their comfort in position, to cleanliness, which is apt to be much interfered with, and to the prevention of bed-sores, &c., which are very apt to form. -See Bed-Bed-sore.

Cases of local palsy are not uncommon; of these, the disease, amaurosis, already treated of, which is a palsy of the nerve of sight, is an example. One hand is not uncommonly affected with paralysis in the course of a single first hour or two. If the depression continues, | night; the affection is generally attributed to

442

special form of paralysis prone to attack children in their earlier years, first fully described in a memoir by Dr. Kennedy, published in a memoir by Dr. Kennedy, published in the Dublin Quarterly Journal for November, 1861, and read before the Obstetrical Society of Dublin. Paralysis in children may proceed from the same causes which are responsible for the disease in adult life, although degenerative changes of the tissue of the brain are very rare in child-hood. It may also be the result of convulsions due to irritation of the digestive system, or may follow upon an attack of St. Vitus' dance. In cases where the arm or leg of a child becomes suddenly paralysed, the possibility of the arrest of movement being due simply to pain account of the digestive system.

Paralysis of the nerves of special sense is not uncommon, and besides that of sight already referred to, we have loss of hearing, taste and smell either permanently or temporarily affected by organic or functional derangement of the special nerves. The power of articulation, or of swallowing, or both, is sometimes lost by the deprivation of the motor force of the nervous supply to the lips, tongue, and other organs within the mouth, and loss of voice, or aphonia, is not an uncommon symptom of hysteria, depending on a depraved condition of the nerve supplying the larynx.

Lead palsy usually occurs in those who have been long exposed to the influence of the poison, and the majority of those attacked have suffered from lead colic. The attack is preceded by lassitude and feeling of numbness, and of stiffness of the parts about to be affected, the loss of power gradually coming on. In a few cases, loss of sensation is also observed. Lead palsy is not confined to the hand and arm, but affects other portions of the body, although the former is its most frequent site. The most dangerous form of this disease affects the muscles of respiration which move the ribs, and proves quickly fatal. No treatment likely to be effectual could be undertaken by unprofessional persons, and the disease is not one likely to occur apart from medical aid. It is well here to reiterate the caution to those who are employed amid lead or its preparations, that they observe the utmost cleanliness, especially at meals, for there is good reason to believe that the poison often finds its way into the system from carelessness on this point.—See Colic—Lead, &c.

Shaking palsy, in one form, is generally the result of old age, in another it is more traceable to direct disease of the brain, and is very apt to occur in those who have drunk freely. It comes on very insidiously, and even under the best care is a very hopeless affection as regards cure. This is a different affection from the "mercurial tremor" with which those who work in mercury, such as gilders, are liable to be attacked.

Refer to—Apoplexy—Nerves—Brain, &c. paralysis, infantile, or Chil-DREN's PARALYSIS, is the name given to a bove.

the same causes which are responsible for the disease in adult life, although degenerative changes of the tissue of the brain are very rare in childhood. It may also be the result of convulsions due to irritation of the digestive system, or may follow upon an attack of St. Vitus' dance. In cases where the arm or leg of a child becomes suddenly paralysed, the possibility of the arrest of movement being due simply to pain caused by rheumatism or strains must always be kept in view. Such cases are common and often excite needless alarm. Tenderness on pressure, especially on the joints, some appearance of swelling, and complaint of pain, or, in young children, crying when passive movements are made, will serve to distinguish this type of disease. In such cases a dose of some active purge, with a little alterative medicine, will generally suffice to alter the state of the bowels, and the paralysis quickly yields to simple means, as the cold douche, with rubbing, and, perhaps, the appli-cation of gentle galvanism. The special form to which the name of Infantile Paralysis properly applies is of a very chronic and obstinate character, and apt to leave permanent effects. Usually the disease affects the lower extremities, and is more often than otherwise confined to one limb, which, in course of time, becomes wasted and deformed and comparatively useless. By far the best remedy in these cases, is the continuous current of electricity competently administered; but all such ought at once to be put under the care of a medical man, the fact being borne in mind that cases of infantile paralysis do occur as well as cases of St. Vitus' dance, and of convulsions, the cause of which is to be sought for in some external or internal source. Amongst the different causes of this form of infantile paralysis that have been enumerated, we may mention cold-from the child sitting or lying upon damp grass, local inflammation of any kind, the irritation of teething, the presence of worms, or of concretions in the bowels, violent cough, as in hooping cough, to which we must add congenital deficiency, &c.

It is well to bear in mind that palsy, of a limb or limbs, may arise from the above mentioned causes, as it has not unfrequently happened that it has been ascribed to a fall or blow, and the nurse, although quite innocent in this respect, has been accused of culpable carelessness.

The presence of tubercles on the brain or its membranes, and diseases of the spine, give rise to forms of paralysis which, if not incurable, are of the most serious import, and altogether different from the maladies described above.

PARAPLEGIA .- Palsy of the lower por-

tions of the body.—See Paralysis.

PAREGORIC, or PAREGORIC ELIXIR an anodyne. English paregoric is also called camphorated tineture of opium, or the officinal compound tineture of camphor; of this half an ounce contains one grain of opium. Scotch paregoric, also called "ammoniated tincture ' is more than double the above of opium, strength, containing two and a half grains of opium in every half ounce. These preparations should be purchased ready made.

Refer to-Opium.

PAREIRA is the dried root of the Cissampelos pareira, or velvet leaf, a plant which grows in South America and the West Indies.

The root is brown and wrinkled externally, and yellowish-grey internally. It has a sweetish taste, with a bitter after-taste. There are three preparations in the British Pharmacopœia, -decoction, and liquid and solid extracts of Pareira. The dose of the decoction is half an ounce to two ounces, and of the liquid extract from half a drachm to two drachms. It is a bitter tonic, but being in no way superior to other wellknown bitter tonics, it is seldom or never used for this purpose. Its main use in medicine has been in chronic inflammation, or catarrh of the bladder, in which it has been thought to be of decided service, prescribed either alone, or in combination with acids or alkalis, according to the state of the urine. Chronic inflammation of the mucous lining of the bladder is a disease so difficult to overcome, especially in old people, or in those who have lived freely, and are exposed to cold weather, that the patient is generally willing to try anything which will relieve the irritation, and diminish the mucous discharge, but the case should, if possible, be put in the hands of a medical man, who alone, from an examination of the urine, is able to prescribe the proper remedies and watch their effect.

PARENT .- See HEREDITARY - MAR-

RIAGE-IDIOCY, &c.

PARIETAL BONE.—See SKULL.

PAROTID GLAND is one of the glands which secrete the saliva. It is situated a little below, and in front of the ear, and fills up the space above the angle of the lower jaw. Its duct, which conveys the saliva into the mouth, opens between the gum and the cheek opposite the second double tooth. It is this gland which becomes swollen, inflamed, and painful, in the disease called the mumps.

PAROXYSM .- A periodical accession or aggravation of certain symptoms of a disease; an attack of toothache may be called a paroxysm; there are paroxysms of ague, of mania,

PARSNIPS contain a considerable proportion of flesh-forming as well as saccharine matter, and are nutritious, but often disagree with weak stomachs. They form a substitute for the potato when the latter cannot be had, but they are not so digestible.

PARTURITION.—See CHILD-BED.

PASSION.—It is sufficient here to allude to the serious effects which may follow the indulgence of violent passion. Those who give way to it are often themselves sensible, either during the paroxysm or at its close, of unusual sensations about the region of the heart. There can be no question that this important organ is much influenced by these violent mental emotions, one of which may lay the foundation of that disease which another may ripen into sudden death. And what a death!

PASSION ILIAC, or ILEUS.—See Colic. PASTILLES are used as an incense, and for destroying bad smells. They are composed of the aromatic gum resins, such as benzoin, with sweet-smelling woods and barks, as sandal wood or cinnamon, reduced to powder, and afterwards made into paste with charcoal and some of the essential oils, combined with a little gum arabic. They are then formed into small cones and burned, and may be used to diffuse a pleasant odour in a sick-room, or to dissipate a bad smell. Pilules composed of similar matter, but without the charcoal, are sold by chemists for perfuming the breath. A small quantity of cascarilla bark burned over some hot cinders on a shovel, is the readiest way to cloak an offensive smell, but it should be kept in mind that pastilles, although deodorants, are not antiseptics, and consequently have no power in destroying infection. **PASTRY.**—See Confectionery.

PATELLA, the knee-cap, or knee-pan, is the small, somewhat oval, or heart-shaped bone (fig. 167) which is contained within the

Fig. 167.

tendon of the "extensor" muscles of the lower extremity, serving at once to protect the important joint which it covers, and to give proper direction to the muscular power on the fore part of the limb. The knee-cap is very liable to be fractured, or rather torn across, in falls where the individual, in the endeavour to save himself, violently exerts the muscles of the limb; a painful shock, as from a blow, is felt, and the power of extending or advancing the limb is instantly lost; when examined, the deficiency occasioned by the absence of the upper half of the knee-cap, is at once apparent, this being drawn more or less up the forepart of the thigh by the action of the muscles. When the knee-cap is broken, as it, sometimes is by direct violence, the displace- | accounted for by the fact that, in a large pro ment is not so great, but the accident is generally more serious, owing to the violence injuring the knee-joint generally. The treatment of the transverse fracture of the kneecap, might, with care, be managed by an unprofessional person in the absence of a medical man. The principal object in the treat-ment of this accident is, to remedy the displacement or drawing upwards of the upper fragment of the bone, which takes place, in consequence of the muscles of the thigh with which it is connected, being set free from the counteracting power of their attachment to the upper part of the bone of the leg, their common tendon, in which the knee-cap is imbedded, being torn through, as well as the bone.

It must be evident to any one, that by placing the limb as represented (fig. 168), by which the aforesaid parts are rendered lax, not only will their tendency to draw up the upper fragment, be obviated, but the position will

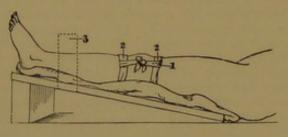

Fig 168.

permit of the bone being again brought down to its proper place; accordingly, the first part of the treatment of this accident is to place the entire lower limb, as represented, on an inclined plane made of any convenient material, and cushioned of course; this being done, and the displaced fragment drawn as nearly as possible into its natural position, and in contact with the lower fragment which does not undergo displacement, some additional means must be employed to keep the parts steady; for this purpose, many different kinds of apparatus have been used; probably the most easily managed, will be the simple one represented in the cut. This is formed by laying a strip of stout bandage, longitudinally, on each side of the injured bone (fig. 168-1) these strips are then secured by a few turns of two circular bandages (2,2) passed, one round the lower part of the thigh, the other round the upper part of the leg, close above and below the fractured bone; the ends of the longitudinal bandages (1) being then tied, the apparatus is complete. It will be advisable to add to the inclined plane some additional protection, as represented by the dotted line (3), to obviate the chance of the limb slipping off the apparatus. It has been observed, that those who have suffered fracture of one knee-cap, are more liable than others to suffer from a similar accident on the other leg. This is probably has been used in cases of worms.

portion of cases, the two fragments of the fractured bone, are not brought into close union, and that the person is, therefore, more liable to suffer a fall similar to that which produced the first accident. Some individuals, moreover, are more liable to suffer from rupture of the tendons and accidents of this nature than others. The knee-cap sometimes suffers displacement.—See Knee.

PATENT MEDICINE. - See QUACK-

PATHOLOGY.—The science of the nature of disease.

PEA.—The common garden pea, in its fresh or green state, and when eaten young, is wholesome and digestible, but when it has advanced towards ripening, the outer skin becomes very towards repenting, the outer skin becomes very tough and indigestible, and passes through the bowels unacted upon by the digestive organs. In this condition it is very liable to lodge in the folds, or "sacculi," of the colon, or large bowel. If old peas are eaten regularly, and the bowels are at all torpid, a large accumulation of these pea-skins may take place, and at length give rise to troublesome irritation and diarrhea. A dose of compound colocynth pill, or of castor oil, is the best remedy (see Diarrhaa). Peas in their young state contain a considerable amount of saccharine matter, but when ripe and dry, they, like others of the leguminous, or pulse tribes, contain much vegetable caseine—analogous to the curd of milk; indeed, so largely is this the case, that the Chinese make from peas a kind of cheese, which can scarcely be distinguished from that made from milk curd. Dried peas can, of course, only be used as human food with advantage when reduced to softness, and after being deprived of their outer covering by machinery, when they are employed under the name of split peas, for making pea soup and pease pudding. The dried peas, when ground into flour, make an excellent pottage as well as bread; and when thus rendered digestible, they contain more real nutriment, that is, plastic matter, adapted to building up the animal frame, that even wheat or oats. It is calculated that in 100 parts of pease meal there are 23 parts of caseine to 60 parts of starchy and saccharine matter, so that, chemically speaking, the pea is commercially the cheapest foodproduct we possess.

Refer to—*Diarrhwa*—*Grains*, &c. **PEACH**, the well-known fruit, is, when ripe, sufficiently digestible if eaten in moderation. The peach tribe derive their chief interest in a medical point of view, from the hydro-cyanic, or prussic acid, which is obtained from various parts of the plants by distillation. Peach kernels yield it largely, also the blossoms and the young leaves; preparations from these, therefore, must be employed with great caution. An infusion of the dried leaves of the peach

PEARL ASH is the name applied to the | with respect to other portions of the body, as potash of commerce

PEARL-BARLEY.—See BARLEY.

PEARS are apt to disagree with many

PEDICULI.—Ticks or lice, generally the result of filth, may show themselves upon the head or body during sickness, notwithstanding the most scrupulous care, and some kinds of skin disease and sores are with great difficulty freed from them. Cleanliness is the great preventive, but carbolic oil should be used to destroy the insects, and it will also render their nits or eggs abortive.

PELVIS, literally means a basin, the term having been given to the particular region of the body from its fancied resemblance to that utensil. The pelvis (fig. 169) is the

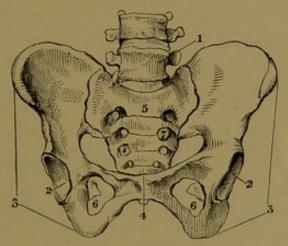

Fig. 169.

irregular structure of bone which supports the spine (1) and which rests upon the thigh bones, the round "heads" of which are fitted into the cups, or cavities (2, 2; see Hip). pelvis is composed essentially of three different bone masses; two of these, the ossa innominata (3, 3), form together, the sides and forepart of the pelvic cavity, being united in front (4). The back part of the pelvis is formed by the os sacrum (5), a triangular bone, which fits like the wedge or key-stone of an arch between the two side bones of the structure. arch between the two side bones of the structure. On the top of this bone, which appears, and may be regarded to be a number of vertebræ, or spine bones, cemented together, the spine is placed; its central canal, or cavity, which incloses the spinal marrow, being continued down the centre of the sacrum in which the holes (7, 7) give passage to small nerves. The side bones (3, 3), although in the adult they are united into one piece, are not so in early life, but are in three divisions; for the sake of convenience in describing, &c., anatomists retain these distinctions even in the adult bone. A little consideration will show any one how much strength is imparted to the important bony construction above described,

446

to throw the weight on those portions of itself best calculated to sustain it, and the whole upon the thigh bones in the most advantageous manner possible. Further, the whole structure of the pelvis is made as light as can be compatible with strength. The sacrum bone (5) is the lightest bone of the body for its size; and in the arrangements of these pelvic bones generally, wherever ligament can be substituted for bone, we find it is so; thus, for instance, the two holes (6, 6), instead of being filled up with bone, have merely a thin, light ligament

stretched across.

There is considerable difference in shape between the male and female pelvis; the latter being more broad, ample, and expanded than the former, in every way-a matter of necessity in child-bearing particularly, so as to afford sufficient room for the passage of the infant, the head of which is for the most part adapted to pass through the pelvic cavity by a series of The near adaptation, in most cases, of the infant head to the passage through the almost unyielding pelvic bones, must obviously make it a matter of the highest importance, that in the female these bones should attain their full expansion and development; this they do in the majority of instances, but in some cases, particularly in consequence of disease, the room afforded in the pelvis becomes seriously diminished, so as to make ordinary child-birth impossible. In such instances, the life of the infant is almost certain to be sacrificed, and that of the mother to be put in great hazard; in either case, a contingency which none should incur knowingly. If, therefore, either in consequence of disease in early life, such as rickets, or of natural deformity, or accident, there is reason to suspect deformity of the bones of the pelvis, the female who is the subject of it, should not enter into the bonds of marriage, without its first being as-certained that child-bearing is possible without danger to life. This can be ascertained by medical examination. Instruments called Pelvimeters are used by medical men for the purpose. If, after marriage, causes previously undiscovered, or which have come into action afterwards, should render ordinary child-birth hazardous from contraction of the pelvis, there yet remains the possibility of a living child being preserved by the induction of premature labour; it is, however, a question, how far it may be right to enter into marriage under such a proviso. The cavity of the pelvis is inferior to, but continuous with, that of the abdomen; the contents, or "viscera," of the two being continuous (see Abdomen). Fracture of the bones of the pelvis occasionally occurs in con-sequence of accident; it is always a serious mishap from the circumstance, that the violence which is capable of fracturing these strong bones must, in all probability, injure some of which is, moreover, so placed, or balanced, the important parts—the bladder especiallyPEM PEP

which they naturally surround and guard. | uncommon to meet with artificial pepper-The accident is not likely to be detected by an unprofessional person; if suspected, soothing measures to the painful parts, hot fomentations, poultices, and leeches would be advisable; the body being placed in the most easy posi-tion, and perhaps a bandage a foot broad sewed round the hips, surgical assistance being procured without delay.

Refer to-Abdomen-Bladder-Hip-Spine,

PEMMICAN is a preparation of dried meats, divested of fat and reduced to powder or paste. As it is very portable and easily pre-served, besides containing a large amount of nutriment in small bulk, it is useful for travellers, and has been supplied to troops as well as to the numerous Arctic expeditions.

PENNY-ROYAL is one of the mint tribe, found in wet places in England, and in Europe generally; it was formerly much more esteemed than it is now. It possesses the same properties as the mints generally. It is said to have the power of driving away fleas.

PEPPER.—Four species of the peppers are used by man-two dietetically and partly medicinally, the black and long peppers; two strictly medicinally, the cubeb pepper, and the matico (see Cubebs-Matico). Long pepper occurs in the form of cylinders, from an inch to an inch and a half in length, these being made up of numerous little pepper-corns, or berries, compacted together; it is often used as a substitute for the next species, the black pepper, both being brought from the East Indies and from the neighbouring islands.

Black pepper is the fruit of a trailing plant, the berries being produced on spikes or stalks to which they closely adhere. When half ripe, they are red, and in this state are gathered; in drying they become black and shrivelled, assuming the form of the common black pepper-corns. When allowed to ripen, they are divested of their husks, and then form white pepper, which is milder than the black. Its properties depend on an acrid resin, and on an acrid volatile oil more pungent in the black than in the white specimens. The aromatic stimulant, and carminative properties of pepper are too well known to require description, they may often be conveniently taken advantage of when stimulants are required; ten to twenty grains of ground black pepper may be given at once, if given in milk. Black pepper has been used as a remedy in ague, and might be tried in the absence of other more certain medicines. A confection of black pepper is used in tea-spoonful doses as a remedy in piles. When steeped in alcohol and applied to the skin, pepper acts as a rubefacient, and might be found useful in the absence of mustard.

corns." "This spurious pepper was made of oil cake, common clay, and a portion of cayenne pepper, formed into a mass, and granulated by being first pressed through a sieve, and then rolled in a cask." Of course the adulterations of ground pepper are more easily effected. In the report of the above investigations, an extract from Mitchell's Treatise on the Falsification of Food, states: "In the state of powder, pepper is nearly always adulterated, substances being sold for the express purpose. It is often mixed with the powdered husks of mustard, which are openly sold for this purpose, as are also the sweepings of the pepper warehouses, under the name of 'P. D.' or pepper dust." In addition to the above, linseed meal, white flour, pea flour, and sago meal, are also used to adulterate ground pepper, and were detected in various samples by the Lancet Commissioner. Most of the adulterations of pepper can be readily detected by the microscope. Jamaica pepper, or all-spice, is an agreeable aromatic, applicable to the same purposes as aromatics generally. The powder may be given in doses of from ten to thirty grains.

Refer to-Capsicum.

PEPPERMINT.—See MINTS.

PEPSIN, or PEPSINE.—There are two or three kinds of pepsin used at present by medical men, that prepared from the mucous membrane of the stomach of the calf or sheep, and that obtained from the pig's stomach

(Pepsina porci).

The latter is said to be four or five times stronger than the former, and is prepared according to a very good process by Mr. Bullock, and now adopted by the British Pharmacopœia. In recent years a great variety of pepsin preparations of various chemists have been introduced, such as "Lacto-peptine" "Pepsine Pancreatine." The dose of it is from two to five grains given with a meal. The powder, which is grayish-white, and possessed of an odour somewhat resembling baked flour, may be given between two thin slices of bread and butter, or in any other way agreeable to the taste of the patient. It may be dissolved in a glass of sherry wine, if preferred, and recommended to be taken in that way. Pepsine wine is to be had at all the principal chemists. The pepsin derived from the calf's stomach is not so highly coloured as the other, and is not so strong. Its dose, therefore, may be said to be about fifteen grains, and it may be given in the same way as recommended above. It has rather an acid and disagreeable taste and odour. Both kinds of pepsin are very valuable remedies in cases of indigestion, connected with loss of power and tone of the Peppers, even when whole, are liable to adulteration, still more when ground. In the in cases of pulmonary consumption where sickinvestigations of the Lancet Sanitary Commission, it is stated: "Some years since it was not vailing symptoms. Pepsin acts more efficiently

PER PER

in conjunction with dilute hydrochloric acid, and may also be given with iron in anæmia and chlorosis, when the functions of the stomach are disturbed as they frequently are in these diseases. Pepsin may also be given where there is imperfect digestion from organic disease of the stomach, but this, of course, would be only under the direction of medical

The method of preparing pepsin is as follows:-The stomach of the calf, or pig, is well washed with cold water, and the cleansed mucous membrane scraped with a blunt knife, and the viscid pulp, thus obtained, is spread out on a piece of flat glass or porcelain, and dried at a temperature not exceeding 100°. The dried residue, reduced to powder, is to be preserved in a stoppered bottle. Boudault's process of preparing pepsin, by means of lead, is

less employed.

It is not very easy to explain the undoubt-edly wonderful digestive power of pepsin, seeing that out of the stomach it is only able to dissolve a comparatively small amount of matters used as food. We must conclude that in the stomach it acts in some way as a ferment; that it has, to use scientific language, catalytic powers, that is, the power or property of resolving other bodies into new compounds, and so rendering them more easy of digestion and assimilation

PERCUSSION, in medicine, is the process of eliciting sounds from any portion of the body, by striking upon it, or some interposed medium, by means of the fingers, or by an instrument adapted for the purpose. The object of eliciting those sounds, and the mode in which, to the educated ear, they give information of the condition of the parts beneath, has been suffi-

ciently explained in article Lung.

PERFORATION.—The term in medicine is chiefly used to express the formation of an aperture in some portion of the coats of the alimentary canal, which allows the escape of a portion of the contents of the stomach or bowels, into the cavity or sac of the "Peritoneum," thereby causing agonising pain, severe inflam-mation, and in almost every instance death. As the escape of a small portion of the contents of the canal is sufficient to occasion these severe symptoms and fatal consequences, a very small opening may be the occasion of death. The most common sites of the perforation are the stomach, or the small bowel near its junction with the large, in the latter case, usually occurring in the progress of fever, and being occasioned by ulceration. - See Fever, Enteric. The occurrence of perforation in the stomach is often for some time preceded by dyspeptic symptoms, pain, especially after food, and perhaps vomiting. Females, especially those of a weak, lymphatic, or scrofulous constitution, are more liable to it than males; but it may happen in all constitutions, and without previ-

the contents of some part of the canal escape, there is sudden, intense, agonising, burning pain, perhaps vomiting, and there is extreme depression or collapse of the system generally. In such a case, the hope of saving life is very faint, even under the most skilful treatment, and of course a medical man should at once be procured. All that unprofessional persons can do is to mitigate the intense agony, which opium alone can relieve. Full doses of whichever of its preparations are most easily procurable may be given, and repeated at short intervals, until some relief is obtained. Heat to the bowels may afford some comfort. If there is much vomiting, the opium will, as in all similar cases, probably be best retained if given solid, in the form of pills-of one grain each; in such a case opiate injections, containing each thirty to forty drops of laudanum, may be serviceable. When there is great depression, if the person survives some time, stimulants, wine or brandy, are given.

Refer to—Inflammation.

PERICARDIUM.—The bag in which the heart is inclosed. - See Heart-Carditis, &c.

PERICRANIUM.—The membrane which invests and adheres to the bones of the skull; in other bones the corresponding membrane is named the periosteum.

PERINEUM.—The space at the fork of the lower limbs, between the fundament and

the generative organs.

At this spot the operation of cutting for the stone, in males, is usually performed. Falls, with the legs astride any body sufficiently narrow to allow it to bruise the perineum, are apt to be followed by serious consequences, bloody urine, or complete stoppage. For the same reason, the practice of "hoisting," carrying an individual astride upon a piece of wood, either in the way of practical joke or punishment, is seriously to be condemned.

PERIODICITY.—The recurrence at regular intervals of marked phenomena in the progress of vegetable, or of animal life, is at once one of the most interesting, one of the most certain, but at the same time—as to cause—one of the most obscure facts in the range of scientific inquiry. Among plants, a daily periodicity is so well marked, both as regards their opening and their closing, that it is familiar to all, even the children know when the daisies and the clover "go to sleep"; and the famous Linnæus constructed, or rather arranged, what he called the floral clock, from the times of the opening and shutting of certain plants. It is sufficient to allude to the different, but regular times of leafing and flowering of tree and plant, to the certain returns of seedtime and harvest, to confirm that what holds good in the revolution of the twenty-four hours, does so throughout the year. In the animal kingdom, periodicity is equally well marked, each kind carries its young a certain time ; with slight variation, ous symptoms. When perforation occurs, and the changes from the cradle to the grave in

man progress in well-marked periodical order. What is observed in health is seen also in disease. The regular return of the paroxysm in the quotidian, the tertian, the quartan ague; the regularity with which the eruptions of scarlet fever, small-pox, or measles, appear and decline, all tell of the same thing, the nightly hectic of the consumptive patient does so also. These are well-marked instances, so much so, that they cannot fail to attract attention, but there are doubtless numberless others in the progress of disease, equally interesting and important, but unobserved. The causes of periodical changes are generally very obscure; some, unquestionably, such as the lunar influences upon the tides, the effect of prolonged heat and light, as from the sun, in stimulating vegetation, we can readily distinguish and appreciate, but the majority are beyond our ken. Some may be connected with the hidden springs of life, others are more than probably linked with the barometric and electric changes, which are continually going on in the diurnal revolution of the twenty-four hours. The following table, drawn up some years since by Dr. Laycock, of Edinburgh, in some degree indicates the nature and connexion of periodical changes :-

Table of the Meteoric and Physiological Events occurring at the Barometric hours, during a solar day of twenty-four hours.

4 to 5 o'clock A.M.

Barometer at its minimum height.

Minimum of electric tension, nearly.

Intermediate minimum variation east of magnetic needle.

Minimum of temperature. Hour at which several flowers bloom. Certain moths escape from the chrysalis. Minimum consumption of oxygen.

Onset of cholera, epidemic diarrhœa, Egyptian ophthalmia, and quotidian ague.

Period of increased excitement in the insane

commences.

Hours of alleviation of symptoms and of sleep in hectic and infantile fever.

4 to 5 o'clock P.M.

Barometer at its minimum height.

Minimum of electric tension.

Minimum variation east of magnetic needle.

Certain moths escape from the chrysalis.

Termination of a paroxysm of quotidian ague.

Onset of a quartan ague.

Exacerbation of fevers; accession of hectic fever.

Period of increased excitement in the insane begins.

8 to 10 o'clock A.M.

Barometer at its maximum height.

Maximum of electric tension.

Maximum variation east of magnetic needle.

Maximum excitability of the circulation.

Maximum of muscular power.

Period of increased excitement in the insane ends.

8 to 10 o'clock P.M.

Barometer at its maximum height.

Maximum of electric tension.

Maximum variation east of magnetic needle.

Meteoric lightning and thunder storms appear.
Certain insects escape from the chrysalis.
Consumption of oxygen at its minimum.

Minimum of muscular power.

Minimum excitability of the circulation.

Hour of natural sleep.

Period of increased excitement in the insane ends.

Paroxysm of quartan ague ends.

In connexion with the above, Dr. Laycock remarks: "What effect have barometric variations on animal life, and especially on the phenomena of epidemics?" Huxham specially refers to the phenomena of intermittent fevers as being probably influenced by barometric variations, through the varying pressure of the atmosphere on the veins. More recently, Sir D. Barry took up both the pathological and physiological views of Huxham, and in the same spirit observes: "1st, It being now evident that the blood in the veins is placed under the influence of atmospheric pressure, it would be curious to trace the connexion which appears to exist between diseases generally, -intermittent fever, for example,—and the daily atmospheric variations." The reader will see at once that facts countenance these speculations. 2nd, Has the electricity of the air, or the magnetism of the earth, any influence on vital phenomena? If any, we may infer, à priori, that the results would be seen in the nervous Now, according to the table, the system. period of increased excitement in the insane commences when the electric tension of the air, and the variation east of the magnetic needle, are at a minimum, and vice versa. The unpleasant influence of thunder storms is well known to persons of nervous temperament, and to those predisposed to disease of the nervous system; and as these occur most usually in the evening, we should look for nervous attacks at that time.

The whole subject of periodical changes has hitherto been too little attended to, when its importance, and the magnitude of the scale on which these changes take place, are considered. Under article Influenza it was stated, that during the occurrence of that epidemic remarkable barometric changes were observed.

able barometric changes were observed.

PERIOSTEUM.—The membrane which closely adheres to, and invests the bones, except at their articular or joint-forming surfaces.

—See Bone—Node, &c.

PERISTALTIC.—The contractile, wormlike movements of the intestines.

PERITONEUM.—The peritoneum is the serous membrane which lines the abdomen,

covering both its walls and its contents-the viscera. The peritoneum is what is called a shut sac, -in its interior it contains simply the serous fluid which it secretes, and which facilitates the movements of its interior surfaces, and consequently, the various movements of the bowels and other organs upon each other; the parts which the peritoneum covers all lie exterior to its cavity, the outer sides of the sac being folded over them. In dropsy of the belly the water is effused into the cavity of the sac. Wounds which open into the peritoneum have within the last few years been regarded as much less dangerous than formerly, especially since the introduc-tion of antiseptic surgery. Operations, such as ovariotomy, and opening into the peritoneum, are now performed with comparative safety. Peritoneal Inflammation (*Peritonitis*) may be either acute or chronic, the latter being usually of tubercular origin. The acute form is described under Inflammation.—See Inflammation.

PERMANGANATE OF POTASH, or CONDY'S FLUID, is much used as a deodorant and antiseptic. It has a remarkable power of oxidising organic matters, but it cannot be regarded as an aerial disinfectant.—See Dis-

infectants—Potash, &c.
PERSONS FOUND DEAD.—See DEATH-DROWNING-HANGING-INQUEST.

PERSPIRATION is one of the functions of the skin, which is concerned mainly in the maintenance of the body at a uniform tempera-The skin contains innumerable sweat glands, the orifices of which open on the surface, and from these exudes, generally invisibly, sometimes quite visibly, a constant flow of fluid or watery vapour containing some salts in solution. When the body becomes warmer the flow increases, and the temperature is reduced both by the amount of watery fluid exuded and by the active evaporation which goes on from the surface. The induction of perspira-tion by means of drugs, such as spirit of Mindererus, spirit of nitrous ether, and anti-mony, is the most usual method of reducing temperature in the early stages of fever. As a rule, perspiration, even when excessive, is without odour, but in some diseases it becomes offensive, and frequent sponging with warm water containing some disinfectant, such as Condy's fluid or carbolic acid, may be necessary for the comfort of the patient and the sanitation of the apartment. A troublesome form of offensive perspiration is frequent in the feet of young people, more especially young women engaged in domestic service, who have to stand a good deal. The stockings and the soles of the shoes become quickly saturated with the offensive secretion, producing much annoyance both to themselves and to those near them. The most satisfactory treatment is bathing the feet morning and evening with a saturated solution of boracic acid, or with a lotion made practice. of one part of Condy's fluid to twenty parts of

with a powder composed of equal parts of boracic acid, oxide of zinc, and st rch. The stockings should be changed frequently and soaked in boracic acid solution after leing taken off: and removable cork soles should be placed in the shoes, to be taken out when necessary and placed in boracic acid solution. Perseverance in these measures will generally effect a satisfactory cure.

PERUVIAN BARK.—See BARK. PESSARY .- An instrument used to support the womb when displaced.—See Womb.

PESTILENCE.—See EPIDEMIC

PETECHIÆ are spots which appear upon the skin in certain forms of fever. often resemble and are mistaken for flea-bites. Petechiæ frequently assume different colours and forms, and may occur either in limited patches or disseminated over the body. presence forms one of the characteristics of

typhus and of cerebro-spinal fevers.

PETROLEUM, literally "rock-oil," a liquid bituminous substance which flows from the cleft of the rocks in some countries, and from the soil, or from deep wells in the oil regions of North America. It is now the general opinion of geologists that the oil is the esult of decomposition, both of animal and vegetable matters, and it has been found in the rocks of nearly all epochs Vaseline, a product of petroleum, is coming into general use as a basis for ointments. It may be prepared as a pure jelly, very soft and pleasant to the skin, and does not become ancid, so that it is likely to supersede lard and oil in the manufacture of numerous ointments and liniments, especially when employed for diseases of the skin. Like other oils, however, its origin is in the first instance vegetable. In Trinidad it occurs in beds or lakes. Petroleum has been recommended as an external application in rheumatism and in skin diseases.

PHAGEDENIC,—a term applied to a form of ulcer, which, from its rapid extension, gives the idea of the tissues being eaten away. Sloughing phagedæna is most common in persons of weak unhealthy constitution, who may be suffering from scrofula or syphilis, and is often the result of crowding together a large number of persons with open wounds. It occurs in the malignant sore throat of scarlet fever, and was at one time common in hospitals, where proper attention had not been paid to the sanitary condition of the inmates. It has also been known, under the name of hospital gangrene, to spread among the wounded after severe campaigns, in the camp hospitals erected for the combatants. The introduction of carbolic acid and other antiseptic dressing has, in a great measure, banished the disease from hospitals, and from military

PHARMACOPŒIA is a book or system water, and after drying them carefully, dusting which includes the medicinal agents, their

450

preparations, and mode of preparation, authorised by the principal, legally-constituted medical authorities of the kingdom; also the measures and weights which are to be employed in dispensing the medicines. inconvenience, confusion, and, indeed, danger of having three different Pharmacopæias for England, Scotland, and Ireland had long been felt by edical men, as well as by many of the general public, and it had for many years been thought desirable that they should be amalgamated into one the use of which, and of which alone, should be rendered compulsory in Great Britain and Ireland.

Accordingly, in 1864, after many tedious delays, the British Pharmacopæia was published, under the direction of the Gener l Council of Medical Education and Registration wax; it is very inflammable, and when cut or of the United Kingdom, pursuant to the Medical Act of 1858. The preparation of such a manual was no light task, and it was hardl to be expected that the changes in the nomenclature, and other novelties which the work necessarily involved, should a cet with universal approval, consequently, another edition was called for, which was issued by the council in 1867, containing among other improvements the doses of all the more important remedies. Reprints of the original edition, with an appendix containing the more recent drugs intro uced have been made from time to tim since 1867. The more important articles the entitled in the Pharmaconceia will be found enti ned in the Pharmacopæia will be found under heir respective headings in the Dictionary. See Weigh's.

medicines.

PHARYNX. - See THROAT.

PHENACETINE is the safest of a series of chemical preparations from coal tar which have been found very useful in relievin: pain and reducing the temperature of fever. Other drugs of similar character are antipyrin, exal-

gine, and antifebrin.

about ten grains for the relief of headaches, especially those of neuralgic or rheumatic origin; and in almost all forms of rheumatism it affords some relief. Not more than twenty grains should be taken within four hours, and it is not a line of the relief. it is not a drug to be used frequently, as its continued action is very depressing. Its remedial effect is greater if the sufferer rests quietly on a couch, with a warm covering, for at least an hour after taking the medicine. It is obtainable in compressed tabloids of five grains each, two of which should be crushed into a powder before being taken as a dose.

Refer to Headaches.

PHLEBITIS.—Inflammation of the veins.

-See Veins.

PHLEBOTOMY.—The cutting or opening of a vein for the purposes of blood-letting. See Blood-letting.

PHLEGM .- Mucus. - See Mucus.

PHLEGMASIA DOLENS. - See LEG,

PHLEGMON. - The term is generally used in connection with inflammation, as in erysipelas which affects the cellular tissue beneath the skin.

PHOSPHATES. - Compounds of phosphorie acid.—See Phosphorus—Soda, Phos-

phate of, de

PHOSPHORUS, classed among the elementary bodies of matter, is interesting in this work, less for its medicinal properties or preparations, than for the share it takes in the composition of animal bodies, and for its extensive economic uses.

When pure, phosphorus at an ordinary temperature looks and cuts like darkish-colour d

handled should be kept under water.

Phosphorus in the form of its salts, that is, phosphates of lime, magnesia, potash, &c., exists in the soil, whence it is, in this compound state, absorbed by vegetables, and is afterwards consumed by the animal creation; in the seeds of the grains, especially, phosphorus exists in

com aratively large proportion.

In the animal body phosphorus is an essential constituent of the albuminous (see Albumen) and fibrinous compounds; it enters into the composition of the substance of the brain and nerves in considerable proportion, and largely into that of the bones, to which the phosphatic earthy salts give m ch of their solid firmness. As phosphorus is contained in the various tissues of the body, it of course PHARMACY - the art of preparing exists in the blood, and in the milk, which is suited to be the sole nutrient of the living animal; it also exists in the excretions, as stated above, in the urine, and also in the dis-

charges from the bowels.

Phosphorus in its pure state is used in medicine in minute doses in the forms of diluted phosphoric acid and the phosphorus pill of the Pharmacopæia, the pill mass being made up Phenacetine is largely employed in doses of largely of tolu balsam and yellow wax, so that each pill of five grains should not contain more than an eighteenth of a grain of phos-Of late years phosphorus and its phorus. salts have been much used as remedial agents. The phosphates, under various forms, such as Parrish's Chemical Food, &c., have been most generally employed, but the hypophosphites of soda and lime now rank not only as most valuable remedial agents in pulmonary consumption, but as nerve restoratives generally; three grains of either of the above given thrice daily, in solution either simply or combined, is quite a sufficient dose. Free phosphorus is much more energetic in its action, and requires much care in its administration, it is moreover exceedingly difficult to procure in a dependable form for administration. There are many forms of phosphorus pill, but the writer has found them either slow or uncertain in action, and much prefers the liquid

forms. The Elixir of Phosphorus and the Phos phorated Oil are convenient forms for administration; the latter is to be had made up in capsules or perles, one of which forms a dose. These perles keep well and are practically tasteless. In some forms of neuralgia these preparations are in-

valuable in giving rapid relief.

Phosphates of Soda, Lime, Iron, and Ammonia (see respective articles). The large use made of phosphorus in match manufactories invests it with great interest, and the peculiar manner in which under careless management, it has been found to affect the health of a few of the work-people, demands attention from its hygienic importance. Some persons who have been employed for a length of time in a lucifermatch factory, become affected with disease of the lower jaw, portions of the jaw-bone become "necrosed" or die, cause abscesses in their vicinity, and are either cast off by the natural processes, or require to be removed by the surgeon. In some cases, nearly the entire jaw has thus been lost, and the ingenuity of modern surgery has done much to remedy this deformity. Probably, constitutional predisposition has something to do with the liability to this phosphorus disease, but, at the same time, there is no question that, in other manufac-tures, free ventilation of the places in which the processes are going on, and strict attention to cleanliness on the part of the work-people must prove great preventives. It is said that saucers filled with turpentine, distributed about the workrooms, by absorbing the phosphoric vapours, are a safeguard. These accidents are now, however, comparatively rare in consequence of phosphorus being used in its applied solely to purgative medicines. amorphous condition in match manufactures. The following account of the amorphous phosphorus is at once very interesting, and well a paper read by the late Dr. George Wilson, before the Royal Scottish Society of Arts, in

a poison when swallowed in the solid form, and as it occurs in this condition in lucifer matches, fatal accidents have more than once occurred singular change is the result of this heating, during which the phosphorus combines with caloric, and renders it latent, but does not otherwise undergo any chemical alteration. The original phosphorus was a pale yellow, or white transparent body, so combustible that ments of surgery, as well as medicine strictly

brought into the air grows luminous even at the freezing point, and enters into full blaze at a temperature of about 150° Fahr. By the prolonged heating it becomes a soft opaque mass, which is easily pulverised, and then forms an uncrystalline powder of a scarlet, crimson, purple-brown, or brown-black colour, so incombustible that it may be exposed in summer in the open air and handled with impunity; nor does it grow luminous till it is about to enter into full combustion at the temperature of 260° F." The following are stated as some of the advantages connected with the use of this form of phosphorus, that-(1) "It involved much less risk of destruction of life and property by fire; (2) It was more suitable for matches intended for warm climates; (3) It was not poisonous in the solid form, so that matches made with it would be comparatively harmless if sucked or chewed; (4) It gave off no vapour at ordinary temperature, so that it could not occasion disease in the matchmakers. The symptoms of direct poisoning by phosphorus, happily of rare occurrence, are inflammation of the stomach and intestines, and the best means of neutralising the poison are to be found in the free administration of milk, magnesia, and mucilaginous drinks, to prevent the formation of the acid and to envelop the crude phosphorus.

PHRENITIS .- Inflammation of the brain.

PHTHISIS.—PULMONALIS—PULMONARY

CONSUMPTION.—See CONSUMPTION.

PHYSIC (see Physician).—Among the lower orders, in some places, the term physic is

PHYSICIAN, "M.D.," or "DOCTOR OF MEDICINE."—These titles are rightfully assumed by those only who have undergone illustrates one of the most curious points in successfully the examination instituted by chemistry, the existence of the same body in Colleges or Universities, legally hartered to most opposite conditions, and possessing most grant such titles or degrees. The conventional opposite qualities. The extract is taken from meaning of the term physician is, one who treats internal diseases of the body alone, in contradistinction to surgeon, one whose pro-April, 1852:—
"Phosphorus, also, is well known to act as vince is the treatment of external disorders, and to accoucheur, one who devotes himself solely to the diseases of women, and particularly to the management of child-birth. To those may be from children sucking them. The red or amorphous phosphorus is much less combustible than ordinary phosphorus, and not at all poisonous. To prepare the new substance, ordinary phosphorus is melted in a peculiarly constructed retort, and kept for some hours different from what it is at present. The constructed retort, and kept for some hours different from what it is at present. The at a temperature of about 240° F. A very physician was the only educated man, as Chaucer says-

"In all this world ne was ther non him like To speke of phisike and of surgerie."

it must be kept under cold water, and when so called. The ordinary surgeon added to his

PHY PIC

emoluments by the trade of the barber, and | sanitary movement energwhere. In large cities, the apothecary was the mere vendor of drugs; the separate department of the accoucheur is comparatively of recent date. Time, and the tendencies and requirements of the age, have abundantly changed these old distinctions, chiefly with respect to the position and standing of the general practitioner; the physician and surgeon have been advancing in scientific requirements, but the general practitioner has approached them so closely, that all seem likely before long to merge in one profession in name, as they now, in great measure, do in practice. The surgeon cannot be a good surgeon, in the proper sense of the word, -not meant to designate a mere operator, -unless he is also a good physician; and the physician, if he does not handle the knife, must be a good anatomist to practise his profession properly. In large towns, and in certain districts, the distinction into pure physician and into pure surgeon is maintained, and, as at present, with advantage, at least when age, experience, or peculiar talent have fortified the titles; but the great mass of medical men must be "general practitioners," highly educated, and fitted for every duty of the healing art. With such a class the kingdom is rapidly filling, and many of its members, whatever their title, stand, and will stand, among the foremost in their profession, and must be the "consulting men" of future years, when time and experience, combined with talent and industry, have given them a claim to the honour; the high education of all medical men is now levelling every distinction. As long as the education of the physician was so infinitely superior to that of the medical profession at large, the prestige which attached to the title was its just due; it still is its just due as the tribute to the mark of high attainment, but it is not just, when paid to the exclusion of the profession generally, the members of which, as a body, whatever their title, must now be all as nearly on a level as the difference between man and man permits. more, the medical profession, as the education of its members is now conducted, must become the most highly intellectual body of men in the kingdom. The studies of a medical man must embrace the widest possible range, from the simplest truths of mathematics and of natural science, to the latest developments of practical psychology, and within this range their knowledge is real, true knowledge, the knowledge of the manifestations of God in His works; and their deductions from that knowledge must be the alleviation of the physical, and many of the mental, evils of fallen man, and higher still, their prevention. It must ever be to the honour of the medical men of the present age, that though their bread may be said to be got through the misfortune of their fellow men, they have been ever the foremost to point out how these misfortunes are to be avoided, they have been the first rousers, and the chief leaders of the

and in the metropolis especially, there always will be, probably in an increasing degree—and it is expedient there should—a division of labour among medical men; one will take the skin, another the eye, another the chest, and so on, as his particular department, and will attain such acquirements in connexion with his own special province, as will give him an extra claim to confidence when that is concerned, especially in obscure or difficult cases. But this cannot be with the kingdom at large; and in the provinces the great mass of disease must continue to be the care of the general practitioners, whose experienced leading members must, under the present system of education, become what the physician has been.

The above remarks may appear to some irrelevant to the present work, but the public generally require some enlightenment as to the present constitution of the profession, and on the bearing of its different members to one

times called.

PICKLES. - Vegetable substances preserved in vinegar. Even when well prepared they are not always digestible, and many of what are purchased are deleterious on another account—the more or less amount of copper which they contain, this poisonous addition being made to impart the fresh green colour so generally desired by the purchasers and consumers of these articles, and also by the action of the vinegar on copper vessels used in preparing them. The investigations of the Lancet Sanitary Commission on this subject, disclosed the fact, that all the pickles examined contained more or less copper; in some it existed in poisonous quantity. The slightest impregnation with this poison cannot be too strongly condemned but it is probably used at times in condemned, but it is probably used, at times, in ignorance, for even some cookery books openly advised its employment to "green" pickles. Fortunately, the detection of this adulteration, even in a small proportion, is easy. If a perfectly clear and bright piece of iron—wire will do—be immersed for a few hours in the vinegar of the pickle, if copper is present the metal will be deposited in a perceptible, though thin, crust upon the iron. "Another very simple and efficient method of detecting the presence of copper in pickles, is the following:-Put three or four drops of the suspected vinegar on the blade of a knife; add one drop of sulphuric acid, and heat the under surface of the knife over the flame of a candle; the vinegar, in evaporating, will deposit the copper upon the iron, if any be present." In the investigations of

the Lancet, it was ascertained "that the pickles which contain the largest quantity of copper, are those which consist entirely of green vege-

tables, as ghirkins and beans.'

When properly made, pickles form a wholesome and agreeable addition to the table, and
are aids both to appetite and digestion. They
are prepared from a great variety of vegetables,
the most popular of which are red cabbage,
beet-root, unripe walnuts and mushrooms.
The hotter descriptions of pickles are made by
the addition of spices and peppers in varying
proportions, such as capsicum pods, pepper
corns, mace, ginger, and cloves.

Sulphuric acid, which is detected in pickles, comes more under the head of vinegar adultera-

tions. - See Vinegar.

PILES, or HEMORRHOIDS, are tumours which form at the verge of the anus or fundament, and may be situated either within or without the bowel; they are either what are called "blind," or they are bleeding piles. Piles are often induced by an enlargement or "varicose" condition of the veins situated about this part, this enlargement being caused by whatever tends to obstruct the return of the blood through the veins of the abdomen generally; thus, affections of the liver, consti-pation, with overloaded bowels, pregnancy, &c., are all frequent causes of this form of piles, in which the swellings are generally smooth, and of the colour of the surrounding skin. Generally, the tumours vary in size, according to the operation of the acting obstruction; if they have occurred in consequence of pregnancy, they diminish or disappear after child-birth; if loaded bowels have been the cause, a dose of suitable aperient medicine relieves the effect. Sometimes the enlarged veins become filled with a fibrinous deposit from the blood, and then the tumours are permanent. Another form of pile is more of the character of a morbid growth, in it the tumours are more generally internal, and are red, florid, and uneven on the surface, and often very painful. From the causes of piles already stated, it may be imagined that the sedentary, those who are most liable to suffer from constipation and liver disorder, are also most likely to be the subjects of piles; the same may be expected to be the case with women who have borne large families. If the causes which first produced the disease do not continue in active operation, or are guarded against, the hæmorrhoidal tumours may continue long quiescent, and give little trouble; but if from any cause, whether neglect of the bowels, cold, the abuse of purgative medicine, &c., they become inflamed, much suffering is induced; the state is then called a "fit of the piles," which lays the individual up from active exertion. In other cases, instead of inflammation, bleeding may occur, and every time the bowels are relieved a considerable amount of blood may be lost by stool.

The preventive treatment of piles is of the first importance, and the causes of the disease pointed out will at once suggest the remedies, which are, chiefly, a sufficient amount of exercise, and proper regulation of the bowels, with avoidance of food of too heating and stimulating a nature. If the liver is apt to get too loaded, it must be regulated (see Biliary Disorders), but in doing this, and also in regulating the bowels, it is of some importance what aperient medicines are employed; preparations of aloes, from their power of acting upon the rectum or lower bowel, are often said, when taken too constantly, to produce piles, but their effects in this way have perhaps been somewhat over-rated. Certainly, if taken habitually in quantity to irritate, they will both cause piles and aggravate them when existing; but on the other hand, the effect of existing; but, on the other hand, the effect of aloes, in thoroughly unloading the lower bowels, and in stimulating the liver, renders the medicine a very efficient remover of the cause of piles. The moderate use of aloes, therefore, when an aperient is often required, need not be entirely eschewed by those who suffer from piles, unless they find by ex-perience that the affection is aggravated by the use of the drug. The other aperients most useful in piles are, when active effect is required, castor oil, or senna infusion; when a milder action is required, rhubarb and magnesia, in the form of Gregory's powder, the confection of senna, or the saline medicines, such as Epsom salts, in small doses largely diluted, will be found useful. Sulphur, combined either with an equal part of cream of tartar, or of calcined magnesia, forms one of the best of the mild aperients in piles; of either mixture a tea-spoonful may be taken for a dose, the first in treacle, the second in milk. It must be remembered, that except for unavoidable purposes, purging is to be avoided in those subject to piles, and that mild easy action of the bowels is to be encouraged; above all, such a state of bowels as permits the fæcal mass to become so hard as that it irritates or scratches the piles in passing, must be avoided. This is apt to occur if the bowels have been constipated for a day or two, in which case it is advisable to use a small enema of warm water, so as to soften the contents of the bowel previous to evacuation; indeed in those subject to piles, injections-if care be taken not to irritate with the pipe of the instrument-form a most valuable adjunct to other means of prevention or of treatment .-See Enema.

When from any cause, inflammation, or a "fit of the piles," is induced, the first essential is rest in the horizontal posture, so as to give every facility for the return of the blood from the affected parts; the diet should be reduced, made as cooling as possible, and the bowels kept lax by some of the means pointed out above. If the inflammation is severe, four or

five leeches may be required; if not, warm fomentations and steaming will often give their removal.

Refer to—Rectum—Leeks—Veins, &c. or an ointment made with half a drachm of goulard extract, rubbed up in an ounce of lard, | or the gall and opium ointment of the Pharmacopœia, will be most serviceable. When piles show a tendency to bleed, and indeed in any case, when they are decidedly developed, a medical man should be consulted; not solely on account of the pain and inconvenience resulting from the presence of the tumours themselves, but because of the constitutional tendencies they exhibit. The treatment of bleeding piles is often a delicate matter. If the loss is so great as to be manifestly weakening a patient, there can be but little doubt that it must be stopped, and it may be with safety; but at other times it is a safety-valve which cannot without hazard be closed, as long as the cause, which first opened it, continues. That is to say, instead of stopping the loss of blood from the piles by direct applications, it must be done by constitutional remedies, adapted to diminish the plethora, either local or general, which originated the disorder; in this case, the preventive treatment of piles generally, as already stated, must be resorted to. Apoplexy and other diseases have followed upon the unwary closure of bleeding piles. After constitutional treatment, however, piles may continue to bleed merely from local causes; in this case, the drain is injurious, and must be stopped. Many remedies for the stoppage of bleeding piles are used. Common pitch, rolled into three-grain pills, and two of these taken twice a day, is sometimes very efficient. Cream of tartar alone, in tea-spoonful doses, taken stirred in water, answers well in some cases. Astringent lotions composed of sulphate of alum, zinc, or copper, have been found very useful in restraining hæmorrhage from piles, and may even be employed in a diluted form in the proportion of one grain to two ounces of water in the form of injection. Hazeline, the active ingredient of the American witch hazel, is strongly recommended as a local application in cases of piles. It should be mixed with water and applied to the parts three or four times a day, and a piece of lint dipped in the solution should be retained at the anus during the intervals. Equal parts of hazeline and water (one to two table-spoonfuls of each) may be, with great advantage, injected into and retained in the lower bowel; astringent suppositories, such as those of lead or tannic acid introduced into the bowel once or twice daily are also in the course of a few days or a week, may be very useful. When inward piles are protruded at the evacuation of the bowels, it is very important that they should be returned to their proper site as soon as possible, otherwise they are very liable to inflammation and strangulation. A piece of linen, well oiled, is the best medium for exerting the pressure requisite for above, a few drops of glycerine may be added

Refer to—Rectum—Leeks—Veins, &c. PILL.—This well-known and convenient form for the administration of medicine is a mass of medicinal substance, of such consistence as to permit of its retaining the globular form into which it is made. Pills may be made simply of the active ingredients they contain, with the addition of a little syrup, gum mucilage, or treacle, to give coherence; but when the active ingredients, as, for instance, calomel, are not sufficient, either as regards bulk or consistence, to form a pill in this way, then some additional substances must be used; the most common are bread crumb, hard or Castile soap, soft extract of liquorice, or conserve of roses. Of the above, the pills made with conserve of roses, or with treacle, retain their softness for the greatest length of time; pills made with bread crumb especially, soon become very hard; it is, however, very convenient for the extempore preparation of some pills, such as those of calomel, and quinine. When used, the bread, which must be stale, is crumbed in the mortar with the fingers; it is then rubbed well up with the active ingredient; and, lastly, formed into an adherent mass by the addition of a few drops of gum mucilage, or of syrup. When hard soap is used to form pills, it must first be scraped into thin shavings before it is mingled with the other substances. The soap may be in sufficient quantity to form a mass without other addition, or a little mucilage, or syrup, or glycerine may be required. Soft extract of liquorice, or conserve of roses, generally require to be simply rubbed up with active ingredients. Glycerine has recently been used as an addition, in small quantities, to pill masses, for the purpose of keeping them moist, and answers very well for the purpose. A little fixed oil of any kind will also preserve softness. - See Glycerine.

After the composition of the pill, its size and consistence are important considerations. Pills are frequently made too large, that is to say, five grains in weight. Not only is a pill of this dimension uncomfortable to most to swallow, but there is some chance that the whole does not become dissolved in the stomach. A pill of three grains in weight will generally be found the most convenient and effective size. A pill must neither be too soft nor too hard, but in the matter of consistence, something must depend upon the length of time it is to be kept; pills that will be used made with less attention to this object, than those which are to be kept an indefinite period. When the latter is the case, conserve of red roses may be employed, or spirit of wine added to pills, such as the compound colocynth, which contains resinous matters, or as stated this operation. When piles reach a certain to the pill mass before rolling. It is not likely

PIL PIL

that for domestic purposes a "pill machine" would be procured; the best method, therefore, of dividing a mass into separate pills will be, to weigh out twenty-four grains of the pill mass at once, and to divide this as nearly as possible into eight equal parts, or pills, rolling each between the finger and thumb, and when they are put together, adding a little flour, magnesia, or liquorice powder, to prevent their adherence. Pills which are likely to be kept for some time before use, should be preserved in a well-stopped or corked bottle, but never in a box; in the latter, they often get so hard as to be completely useless, and, in the aged especially, are apt to pass through the bowels perfectly unchanged. For domestic use, either in this country or in emigrant life, it is the most desirable plan to purchase compound pills, either in the mass, or ready rolled; as, however, it may prove useful, the composition of some of the most generally serviceable pills will be here given.

Within the last few years the manufacture of pills of all kinds has become a separate business. If procured from respectable houses, they are quite to be depended on both for effici-

ency and keeping, especially if coated.

The most useful purgative pills for domestic

store are :-

The Compound Rhubarb Pill. - Mild aperient. The Compound Colocynth Pill .- Active ape-

The Compound Gamboge Pill.—Very active

Blue Pill. - Best procured and kept in mass. The Colocynth and Hyoscyamus Pill.—Mild aperient.

The Aloes and Iron Pill. - Tonic alterative

and aperient.

Expectorant, or Cough Pill.—See Influenza. Many other forms of pill are ordered, and used, but it would serve no good purpose to burden either the memory or the medicine chest with them, especially as their composition is given when they are recommended in this work. Those above enumerated will be ample store, others may be made up as re-

The Compound Rhubarb Pill, one of the best, mildest, and safest aperients, is thus

made:-Take of

Rhubarb, in powder, 3 drachms. Aloes, in powder, Myrrh, in powder, Hard soap, scraped, 2 dr. 15 gr. each, 11 drachms. Treacle, 4 drachms. Oil of peppermint, 11 drops. Mix the powders with the oil, then add the treacle, and beat the whole into a uniform

The dose of the compound rhubarb pill is Reduce the sulphate of iron to powder before

it may be kept in a soft mass, wrapped in oiled silk, or ready rolled. Persons going to warm climates would find the form of powder the best in which to keep this pill, preserving in a well-stopped bottle.

The compound rhubarb pill may be taken alone, or, in some cases, combined with onethird either of blue pill or calomel, especially

in cases of biliary disorder.

The Compound Colocynth Pill is, perhaps, more extensively used in this country than any other purgative of the kind. It is considerably more active than the compound rhubarb. The compound colocynth pill is thus best made:-

Take of

Aloes, in powder. - See Aloes.

Scammony, in powder, of each, 2 drachms. Colocynth, in powder, . 1 drachm. Sulphate of Potash, . 15 grains. Oil of Cloves, . 15 drops.

Water sufficient to beat the whole, when mixed,

into a mass.

As the remarks, both as to combination, keeping, &c., which have been made on the compound rhubarb pill, apply exactly to the compound colocynth, it is unnecessary to repeat them. A very good addition to the compound colocynth pill is that of a drachm of ipecacuanha powder to the quantities given

The Compound Gamboge Pill is of less moment, as a store pill, than the above, but it is valuable for very strong individuals, who require powerful medicine, and where economy

is an object: it is thus made:-

Take of

Gamboge in powder, Compound powder of of each, 1 drachm, Cinnamon, . Hard soap in powder, . 2 drachms,

Syrup, a sufficiency,

and beat into a mass to form pills. The dose is from three to twelve grains.

The Colocynth and Hyoscyamus Pill is used when it is desirable to prevent griping, which often occurs with the compound colocynth pill. It is made from the

Compound colocynth pill mass, . 2 parts, Extract of hyoscyamus, and beat into a uniform mass. Dose, five to ten grains.

The Pill composed of Iron and Aloes is pre-

pared in the following way :-

Take of 1½ drachms. Compound powder of cinna-

Confection of roses,

from three to twelve grains. It may be kept either in powder to be made up with treacle (or symp or gum mucilage) when required, or

In cases of Obstinate Constipation the fol- | Minor, Turkey, and India are the countries lowing pill is strongly recommended :-

Extract of nux vomica, 6 grains. 24 Watery extract of aloes, " Compound rhubarb pill mass, 30

Mix and divide into 12 pills, two to be taken every evening if required.

Expectorant, or Cough Pill, as given under

article Influenza, is thus made :-

Take of 25 grains. Opium, in powder, . . 80 Squill, 33 Ipecacuanha, ,, (see Camphor ,, Powder), Gum Ammoniac, in powder, 120 " Rhubarb,

The above pill will keep well, either in powder or rolled, and will be found the most useful and convenient form of cough or expectorant medicine, either in emigrant life or elsewhere, particularly in chronic cough.

Many other combinations of pill might be enumerated, but the above, along with the information scattered throughout the present work, ought to be guide sufficient to any one of moderate intelligence. Pills may be made, either in a mortar, or if the substance used is in small quantity, on a slab or Dutch tile, by means of a spatula.

After-birth.

PLAGUE.—This disease, so well known to all by name, and, happily, by name only in this country, belongs to the class of malignant fevers. Its contagiousness has been disputed, but is testified by the best authorities who have had practical acquaintance with the subject. The last time the plague visited this country was in 1665, the period of the Great Plague of London; since then, however, it has appeared in, and ravaged various parts of appeared in, and ravaged various parts of Europe, as in Marseilles in 1720, Moscow in 1771, and Malta so late as 1816. Egypt, Asia

now chiefly liable to the visitations of this fearful scourge; and, whatever other influences may be at work to foster its germs -the bacilli which produce it - there cannot be the smallest doubt, that the total neglect and ignorance of the simplest laws of health

materially dd to the evil.

The symptoms of plague are thus described by Dr. Gregory:—"A feeling of great languor and lassitude ushers in the attack of plague, which for the most part happens towards evening. There is always a cold stage, though it is seldom of long duration. Heat of skin, headache, and giddiness succeed. The pain of the head is referred to the temples and eyebrows; the eye appears heavy, dull, and muddy. The expression of countenance changes in a remarkable manner. Sometimes there is a wild and furious look; sometimes a look claiming commiseration, with a sunk eye, and contracted feature. The most striking of all the early symptoms of plague is the staggering, and the sudden extreme prostration of strength. A strong tendency to void the urine is generally noticed. The stomach is very irritable, and rejects almost everything presented to it. The tongue is white and moist. The bowels are sometimes torpid, and at other times loose, the evacuations being always highly offensive. The speech falters. The pulse is at first small, hard, and quick; but after the appearance of buboes it often becomes fuller and softer. It is sometimes intermit-tent; in point of frequency its average may be stated at 100. The heat of the skin is seldom very intense. The head is occasionally perfectly clear and collected; at other times, stupor occurs immediately after the formation of the hot fit. Some cases of the disease are ushered in by a violent fit of mania; the greatest indifference with regard to recovery prevails, and is always reckoned a most unfavourable symptom.

"After one, two, or at the furthest three days, pains in the groin and arm-pits announce the formation of buboes. Those pains are often highly acute, and unless speedily followed by the swelling of the gland, the patient dies delirious. In women, the arm-pit, in men the groins, are chiefly affected. Carbuncles appear at the same time, but indifferently on all parts of the body. Petechiæ and vibices are much more frequent than carbuncles, which, it appears, do not occur above once in twenty cases. The fatal termination is sometimes preceded by violent hæmorrhages from the

mouth, nose, or intestines.

"The duration of the disease is very various. A few cases are on record where the patient died within a few hours from the invasion. To many it proves fatal during the first paroxdanger. The former is the usual period of the appearance of bubo; the latter, of the abatement of the febrile symptoms. If the patient survives the fifth day, and the bubo is fully formed, he may be considered as nearly out of danger. The convalescence, indeed, is always very tedious, from the extreme debility which the disease leaves; and the patient's life is not unfrequently again put into imminent hazard from the occurrence of gangrene in the extremities.

"In the malignant form of plague every variety of treatment has been tried, but with so little effect, that it may be considered as a disease nearly beyond the reach of medicine. The violent headache which occurs during the first twenty-four hours seems to point out the propriety of blood-letting, and it is recommended by the general custom of Turkish practitioners; but in the hands of English surgeons it proved of no avail. In the cases in which it was tried it did not appear, however, to make matters worse. Where mercury can be brought to affect the mouth, it appears to be of some service, but it is seldom that sufficient time is afforded for this specific effect of the remedy. Ether and laudanum are valuable medicines in allaying the irritability of the stomach. Wine and opium are of no use during the violence of the disease, and bark can seldom be retained. This is much to be regretted, for whenever it can be made to stay on the stomach, even in those severe cases where carbuncles and vibices appear, its good effects are conspicuous. Camphor, bark, and wine are given with much advantage during the period of convalescence. Emetics, purgatives, and the cold affusion have been tried, but it does not appear that they are of any service."

"The latest period of the contagion of plague, or that between communication with an affected individual and the appearance, is extremely short, and liable to very little variation. It is scarcely ever less than three days, and it seldom exceeds six. Instances indeed are recorded of the disease not appearing until the tenth

day, but these cases are rare.
"The contagion spreads to a very small distance only from the body of the patient. The consequence of which is, that the disease is seldom, if ever, communicated, except by

"The contagion of plague is readily imparted to fomites, in which it may lurk for a long time, more particularly if excluded from the air."

It is now universally understood, that even so formidable a disease as plague can be prevented by the adoption of habits of cleanliness, free ventilation, moderate living, and freedom from communication with those attacked.

Recent investigations have directed attention to the agency of rats in the spread of plague, the active agents in the transference of the infection

ever, upon the whole, those of the greatest | atic extermination of rats has done much to limit the extension of plague. Various vaccines have been prepared from the bacillus and used with some success as prophylactics; they have been tried also in the treatment, but with not very satisfactory results. Refer to Fomites, Vaccines.

PLASTER OF PARIS-SULPHATE OF LIME, GYPSUM—has been noticed in various parts of this work as an occasional adulteration in confectionery, &c. It is often used in the treatment of fractures, for diseased joints where perfect rest is required, and in the formation of the jacket-splint for persons suffering

from spinal curvature.

PLASTERS are compounds of adhesive Many are, principally, tenacious substances. compounds of an oxide of lead and oil, others of wax and resin. "Plasters should not adhere to the hand when cold; they should be easily spread when heated; and should remain tenacious and pliant after they are spread; but should not be so soft as to run when heated by the skin. All plasters become too consistent and brittle when long kept; but in this case, those which are unctuous may be re-melted by a gentle heat, and some oil added to them.' Plasters are not so commonly used as mere external applications as they were at one time, but among the poorer classes they are still very favourite and much-trusted remedies, and in some cases are unquestionably serviceable.

Plasters may be either simply adhesive, such as the common diachylon or the isinglass plaster; they may be protective, such as the lead; warm, like the galbanum, and strength-

The most useful plasters are—

Adhesive, resinous, or diachylon plaster.

Anodyne. Belladonna, Blistering. Cantharides,

Warm and stimulant. Galbanum, Iron or chalybeate, Strengthening. Lead, Protective.

Absorbent. Mercurial, Anodyne. Opium, .

Pitch, Warm and stimulant.

Adhesive. Soap,

Refer to separate articles.

The above plasters may be employed for the purposes indicated, and should always, if possible, be procured ready spread. As a general "strengthening" plaster, the chalybeate or iron plaster is perhaps the best, and undoubtedly gives much comfort and support in many cases, especially those in which there is much weakness of the back. In such cases it cannot be used in better form than that spread on brown holland or glazed calico, which is now sold as prepared by machinery. It may, however, be spread on leather. Either the pitch (Burgundy) or galbanum plasters may be used for the same purposes, and be prepared in the same way, but they are more stimulant, and sometimes produce uncomfortable or unbeing the fleas which infest the rats. System- bearable irritation on delicate skins; indeed,

458

any plaster will cause this with some people; lead is least liable to do so. To avoid the irritation which doubtless arises from the imprisoned perspiration, it is well to remove the plaster every few days and carefully cleanse the part.

Lead plaster, spread on soft leather, calico, or best of all, felt, is one of the best protectives in the tendency to, or formation of bed-sores. If kept long after it is spread, however, it becomes brittle, cracks off, and is useless; it is therefore better kept in roll, and spread when wanted. With the exception of the adhesive plasters, required in the treatment of wounds, &c., all the others are but occasionally required, and may for the most part be dispensed with. The most useful adhesive plasters are, the common diachylon, and the soap plaster. These may be bought beautifully spread by machinery, and in this country this will always be the most advantageous mode of procuring them; travellers, such as emigrants,

proceeding to warmer climates, should never get them thus prepared, otherwise when they come to unfold their plaster for use, they will find it one adherent mass, and perfectly useless; they should take the plaster with them in roll, as it is sold; it can then, when required, be spread on any material, such as calico, or even paper, by means of a heated knife, or flat piece of iron, if no better instrument is at hand. The common plaster iron (fig. 170) is neither expensive nor cumbersome, and might very well be added to an emigrant's outfit. When used, it should be heated sufficiently to melt the plaster, when the flat surface (fig. 170—1) is applied to the end of the roll; the melted plaster being allowed to drop on the material on which it is to be spread. When sufficient has been melted, it is then Fig. 170. to be spread evenly and thinly by

means of the edge of the instrument. When spread plasters are warmed for application, the unspread side should always be held to the heat. When plasters are to be removed from the skin, they should always be well warmed through by warm water.

It is a common popular error to suppose that the plasters used in the treatment of wounds exert some healing influence; whereas, they are only used to keep the severed parts in as close apposition as possible, in order that the natural healing power may be exerted. It is requisite to notice the error, for it might in some cases interfere with the use of substances, such as gums, &c., as plasters, which might be advantageously used as such. It is no uncommon thing to see wounds which, had they been left to themselves, would have healed kindly, kept open by means of sticking plaster. Refer to—Blister—Dressing—Wounds, &c.

PLEASURE. —The cheerful excitement of the mind by what is called pleasure, is rather a preservative of health, than a remedy in real sickness, when the less stimulant but cheering tonic of hope is the better adapted mental remedy. Pleasurable relaxation there must be, both for mind and body, and especially for the young; and they act unwisely, who, instead of directing the mind to sources of, and leading it to find its happiness in innocent, cheerful, well-directed relaxation and pleasure, would make this world one never-closing workshop, or have it a perpetual valley of tears.

Refer to-Dancing.

PLETHORA-FULNESS-is the term applied to that condition of system in which the blood is superabundant, both in quantity and quality, over what the requirements of the body call for. It is a condition not uncommon among the well-fed and indolent, in whom the digestive organs continue in full vigour. Individuals of the sanguine temperament, whilst leading a life of mental activity and anxiety, have greater powers of activity than most others, but they, in many instances, border upon plethora, and if they become so placed that their former activity is either uncalled for or interfered with, provided there is not much mental anxiety, they quickly become plethoric; the vessels are over-loaded with rich blood, and instead of the former power of exertion, oppressive languor and inactivity succeed; in fact, the whole of the functions, and the brain and nervous system especially, are weighed down and clogged; there is mental sluggishness, heavy sleep, and inaptitude for exertion. This last symptom is too often mistaken for weakness; the person labouring under the mistake resorts to additional food and stimulants, it need scarcely be added, only to increase the evil. An individual in this condition, it may be said, is ripe for inflammation; if cold be taken, it is very likely to light up inflammatory action somewhere, and once lighted up, the action is very liable to be of the severest kind.

Should febrile disease of any kind, as for instance small-pox, or erysipelas, or rheumatic fever, be excited in the constitution, the symptoms run high, and the case is very likely to become one of danger. For similar reasons, accidents are not well borne—at least their after-effects are often such as to put life in

danger.

Persons who are in a plethoric condition, not unfrequently get relieved by some natural effort: piles show themselves and bleed, or the nose bleeds, or spontaneous diarrhœa comes on, and instead of the individual being weakened, he feels stronger and lighter than before—a true indication of the real state of matters. The evil results of mistaking a state of oppression from plethora, or false debility (see *Debility*), for one of weakness, must be evident to all. Even the pulse is liable to deceive, and, in these states of oppression, to seem low and weak, but

459

POD

debinity. The latter, if the finger is pressed even slightly upon it, is extinguished at once; but the pulse of oppression seems rather to resist the pressure, to become stronger, and to beat up against the finger, rather than to give way. As might be expected, plethoric individuals are often the subjects of apoplexy, and in a less degree of affections of the heart, lungs, liver, and kidneys. A state of plethora must always be one, if not of danger, at least of hazard, and ought to be guarded against; its well-known causes naturally direct the atten-

tion to the best modes of prevention.

If a person suffering from plethora is threatened with an immediate attack, such as apoplexy, the condition cannot be too soon or too actively removed. Bleeding in some way, free purging, and low diet are the immediate remedies; but in the absence of any threatened attack, it is not advisable to invoke the aid of these powerful agents; the condition should be reduced gradually and steadily, by the formation of, and perseverance in, modes of living suited to counteract the tendency. When a man, suffering from the effect of plethora, gets rid of his unpleasant symptoms by a coup, such as the loss of a basinful of blood, by a few calomel pills and black draughts, he is probably highly pleased to be so easily rid of his enemy, and by means which involve no self-restraint, or giving up of indulgences; so, trusting to the repetition of the same remedial measures, he puts no check upon himself, and when the plethora again reaches a certain height, he again bleeds and purges, and this goes on till he is overtaken some day with an apoplectic attack, or till he becomes the subject of organic disease. It is a false and most precarious security.

Persons who have a tendency to plethora must have exercise, they must use up their blood and muscle in active motion; but in doing this, especially at first, they must beware of overdoing it; it will not do for a plethoric man to commence a new system of living for health, with violent exertion, otherwise he may precipitate the very evil he dreads; some over-loaded vessel may yield under the increased tension caused by the muscular exertion and excited circulation. Plethora, to be reduced, must be so, steadily, but gradually; active exercise, increased as the ability to take it increases, must be balanced with aliment proportioned to the amount taken, stimulants being rarely if ever permissible, or required, and animal food in very moderate proportion. Early hours, and curtailment of the time devoted to sleep, is desirable. In most cases, tepid bathing is preferable to either hot or cold, and either by it or by sponging, the skin must be kept active. The bowels require especial attention, and are substance of the lungs. - See Lungs. better rather lax than otherwise; any slight tendency to plethoric oppression being counter-

it is essentially different from the pulse of | colocynth, or compound colocynth and blue pill, or by small, largely diluted, doses of Epsom salts, or by Seidlitz powders. If the kidneys are inactive, the infusion of broom, or of dandelion, carbonate of potash, or the nitrate of potash (saltpetre) may be taken, or the acid-tartrate of potash (cream of tartar) used in the form of imperial, as a common drink.

Refer to—Apoplexy—Debility—Fat, &c.
PLEURA. — The "serous" membrane which lines the chest and covers the lungs. Each lung is separately invested, and like other serous coverings, the membrane is double, one layer lining the cavity of the chest, and the other the lung; the inner surfaces of each being lubricated with serous exudation, which enables the lungs to contract and expand smoothly. When the serous fluid is largely poured out (as in pleurisy), water in the chest, or hydro-thorax, takes place; and when matter is formed in consequence of inflammation of the membrane, the disease is termed empyema. -

PLEURISY is the name given to inflammation of the pleural covering of the lungs. It is not an uncommon disease, is distinguished by sharp catching pain confined to one part of the chest, and is usually attended with a dry cough.—See Lungs—Inflammation.

PLEURODYNIA is a rheumatic or neuralgic affection of the muscles between the ribs, characterised by acute pain, occurring sometimes in paroxysms, but sometimes continuous. When continuous, it is more probably due to circumscribed pleurisy, and to old adhesions of the pleura to the chest wall, in which case it will yield to the application of a few leeches, or to some slight counter-irritation. the pain is periodic, a liniment, containing chloroform and opium, applied two or three times daily, and the administration of quinine, will probably give relief. A sheet of cottonwool worn next the chest will also prove very useful; but the most speedy and effectual remedy is a small dose of morphia introduced by the hypodermic needle.

PLICA, or PLICA POLONICA.—A peculiar disease of the hair which occurs in Poland and

the adjacent countries.—See Hair.

PLUMMER'S PILL, also called compound calomel pill, is one of the most useful alterative and gently diaphoretic pills or remedies in general use; it rarely acts on the bowels, and may be taken for a considerable time without affecting the system. Besides calomel, it contains sulphurate of antimony, and is made into a mass with guaiacum resin and castor oil. The dose is from three to ten grains.

Refer to—Mercury—Pill, &c.

PNEUMONIA. — Inflammation of the

PODOPHYLLIN is a pale greenish-brown resinous powder obtained from the Podophylacted by acting upon them by the compound | lum pellatum, or American May apple, which is

well known in the United States, where it is | heads of irritant, narcotic, and narcotic acrid sometimes called Mandrake.

The dose of podophyllin is from one-sixth of a grain to half a grain, given in pill, either alone, or in combination with other remedies, such as the compound colocynth pill mass, henbane, or some other corrective, to prevent the troublesome griping pain which sometimes accompanies its use. It acts somewhat like jalap, as a drastic purgative, and is thought to be of peculiar service in cases of congestion of the liver, or in cases where that organ is overloaded with bile. It may be combined with calomel, in order to produce smart purg-ing, with a gentle flow of bile; or with cream of tartar, or bicarbonate of potash, in cases of

Upon its first introduction to medical practice, it was thought that it would supersede all other ordinary purgatives, but it has not in any way realised the expectations that were formed in its favour, being somewhat uncertain and capricious in its actions, and above all, causing in some persons intolerable, griping

Podophyllin is sometimes given along with ox-gall, in cases where it is desired to promote the flow of bile, and to increase the action of the liver and bowels. The following prescrip-tion is recommended for use in such cases, and will probably be found of benefit:—Take of purified ox-gall two grains; podophyllin half a grain; compound rhubarb pill mass, or powdered rhubarb, two grains. Mix. Pill, to be taken at bedtime, occasionally. N.B.-For some persons the dose of podophyllin would require to be much smaller, perhaps one-fourth to one-sixth of a grain.

Podophyllin is now greatly superseded by euonymin and iridin, either of which drugs acts quite as energetically on the liver without the unpleasant griping and teasing action

of podophyllin.

POISON.—Considerable difficulty has been experienced in giving such a definition of the word poison as shall, whilst sufficiently inclusive, be sufficiently precise. Some substances, such as strychnine, corrosive sublimate, &c., can never be considered otherwise than as poisons, in every sense of the word, but when cayenne or common pepper, cream of tartar, even common salt, and other substances not unusually used in food, have been found in large doses to act as poisons, it becomes very difficult to frame a correct definition of the term. Dr. Taylor, in his Manual of Juris-prudence, says:—"Perhaps the most comprehensive definition which can be suggested is this: 'A poison is a substance which, when taken internally, is capable of destroying life without acting mechanically on the system."" Some substances, however, act as poisons through the skin, such as those of infectious diseases, others, probably, through the lungs. Poisons are usually classed under the three moment, the poisoned food, or whatever has

poisons. Of the first, arsenic and the mineral acids are examples; of the second, opium and

henbane; of the third, alcohol and strychnine.
As a general rule, it may be acted upon in cases of poisoning, that the sooner the ejection of the poisonous agent from the stomach can be procured the better. In the majority of instances, perhaps, nature effects this in a more or less perfect manner before any remedy can be employed; indeed, the occurrence of vomiting is often the first symptom of the action of

the poison.

These natural efforts, however, must not be alone trusted to, even if they take place, and, in almost every case, the best thing that can be done is to excite full, free vomiting. This may be brought about by any of the emetic substances so often mentioned, but sulphate of zinc, or white vitriol, when it can be procured, is the agent generally preferred for the purpose. In its absence, salt or mustard may be used. and are almost always procurable; indeed, any other emetic at hand should be resorted to, -an infusion of the root of the sweet violet, in the absence of others, or chamomile tea, or warm water in abundance; the action of vomiting being also excited by irritating the throat with the finger, or with a feather.

Next to the evacuation of the poisonous substance, its neutralisation is important; indeed, in the case of such poisons as the mineral acids, it is to be the first object. It is unnecessary to repeat here the proper remedies which more especially neutralise the effects of different poisons, as they are given in their proper places, but, as a general rule, milk, oleaginous substances, and demulcent fluids, such as linseed tea or barley-water, or hasty pudding, will be useful, if given freely, in protecting the coats of the stomach from the contact of the poison, and by interfering with the absorption of the latter into the system.

Lastly, it must be an object to counteract the effects of the poison upon the system at large; as in the case of opium, the narcotic influence is combated by forced exertion, by strong coffee, &c., or in poisoning by prussic

acid, by stimulants and cold affusion.

When poisoning is known or suspected to have occurred, the first thing is to procure proper medical assistance as quickly as possible; nothing must stand in the way of that: the next is to ascertain the nature of the poison, if possible, and the amount taken, the remedial measures which may be known, either by reference to such works as the present, or from other sources of information, being adopted as quickly as possible. All vomited and other matters-such as evacuations from the bowels -which may contain trace of, or afford clue to the poison, must be reserved for the inspection of the medical man. Sometimes individuals, from throwing away, in the excitement of the

POI

been taken, have found themselves unpleasantly | situated, and objects of suspicion. If there is any idea that there has been criminal proceeding connected with the poisoning, some responsible person should secure whatever may guide in the investigation of the truth, and place all under lock and key, and seal, till the arrival of the authorities; food and vomited matters

should be sealed in suitable vessels.

The symptoms which would give rise to the suspicion of poisoning having taken place, are those of sudden illness shortly after taking food or medicine, the individual having previously been in good health, or at least free from the peculiar, and generally violent, symptoms developed, particularly those indicative of irritation of the stomach and bowels, or of narcotic or irritant influence upon the nervous system. When poisons are either given or taken for criminal purposes, the symptoms usually show themselves quickly and severely, on account of the dose of the deleterious substance being generally large. At the same time it is to be remarked, that the presence of much food on the stomach, sleep, and intoxication, have all been known to retard the development of symptoms from even large doses of poison. If a number of persons who have partaken of the same dish are seized shortly after with symptoms of illness, the suspicion of poison is, of course, greatly strengthened.

It is perhaps necessary, however, to caution all, against a too hasty assumption of the fact of poisoning, at least as far as the criminal implication of others is concerned; if there is suspicion, it will in any case be better to take such measures as may be thought requisite, as quietly as possible, until the bearings of the case have been examined by competent

persons.

This caution is necessary, for there are diseases, such as British cholera, which not unfrequently first break out shortly after a meal, and spasms of the stomach are not uncommon with some after food; perhaps the disease which has most frequently given rise to suspicion of poisoning-doubtless on account of its all but universal fatality-is Perforation, alluded to

a few pages back.

In connexion with the above remarks, the following from Taylor's Medical Jurisprudence is important:—"It seems highly probable, that the mere fact of a person eating a full meal after long fasting will give rise to symptoms resembling those of irritant poisoning. "Mr. Holland, of Manchester, has communicated two cases of this description. In one, the symptoms were very violent and the patient nearly died, in fact was laid out for dead: the other patient suffered from severe gastralgia -nervous pain in the stomach-for several weeks. Poisoning was at first strongly suspected, but the suspicion was removed by the fact, that others in health had partaken of the

gravy, without any injury, and there was no reason to suppose that any irritant poison could have been mixed with the food. The two who suffered were extremely weak and exhausted from long fasting, and were observed to eat their food, which was quite wholesome, voraciously." Further, it must be remembered, that although symptoms of poisoning may be distinctly traceable to the effects of a meal recently eaten, it by no means follows that the poisoning has been the consequence of something added, either intentionally or accidentally, to the food; it may be the consequence of changes which have taken place in the food itself: many casualties from this cause are recorded. In Germany, numerous deaths have occurred in consequence of sausages prepared in that part of Europe undergoing a peculiar kind of putrefactive fermentation, which renders them highly deleterious. In this country the flesh of animals which have died from disease has not unfrequently been known to give rise to symptoms of poisoning. Fat or oily food, when in a state of decay, seems peculiarly injurious; salmon, bacon, &c., having in this state been found poisonous. a festival held in the Canton of Zurich some years ago, at which about 600 persons were present, nearly two-thirds of the number were affected with symptoms of poisoning, in consequence of partaking of meat which had become slightly tainted, and of hams-probably the injurious article-which had been badly cured; -some of the number affected died. Shellfish, it is well known, will, in some persons, produce symptoms of poisoning at any time, and in certain states are probably deleterious for all (see Mussel-Oyster-Copper, &c.). A recently noticed source of poisoning requires mention. It is that which might ensue from the flesh of game birds-partridges especiallywhich have been destroyed by feeding on grain steeped in arsenic and scattered about for the purpose of destroying other birds. It is said that partridges thus destroyed are not found lying on their sides like dead birds generally, but are found sitting as if in life. It is to be feared that birds found thus, fresh, and in good condition, might, by unscrupulous or ignorant persons, be sold as other game.

It has been mentioned that the common garden rhubarb contains oxalic acid, -not in sufficient quantity to injure in the moderate use; but when used largely, especially in some constitutions, it may give rise to unpleasant

symptoms connected with the kidneys.

Liebig records a singular mode of fatal poisoning, which occurs in Germany, "from the drinking of what is called the feather-white wine." This poisonous wine is wine still in a state of fermentation, which is increased by the heat of the stomach. carbonic acid gas which is disengaged penetrates through the coats of the stomach, same food, principally potatoes mixed with through the diaphragm, and through all the

intervening membranes, into the air cells of | small doses of tartar emetic, but which can the lungs, out of which it displaces the atmospheric air. The patient dies with all the symptoms of suffocation caused by an irrespirable gas. The best antidote in this form of poisoning is the inhalation of ammonia. The development or formation of poison within the body itself is a subject which has been but little investigated. The characteristic ingredient of the urine, urea, if retained in the circulation, acts as a narcotic poison. Oxalic acid is certainly formed within the body; perhaps prussic acid. When the fæcal contents of the alimentary canal, especially of the large bowel, are long retained, and reabsorbed into the circulation, as they undoubtedly are, they exert effects somewhat akin to poisoning, and the author believes he has traced extreme temporary depression of the system to this cause alone.

Although the antidotes to be immediately adopted in cases of poisoning by various substances are given under separate headings, it may be convenient to tabulate the principal in this place. The data are taken from Dr. Garrod's work on Materia Medica.

Poisons.

## Antidotes.

Magnesia, chalk, and diluted solutions of alkaline car-Acids, bonates. Vinegar and water; oil. Alkalies, Finely divided animal char-Alkaloids, Decoction of bark and other preparations, containing Antimony, tannin in solution. None; but charcoal may be given, or magnesia and Arsenie, . hydrated peroxide of iron. Olive oil freely, emetics, fol-Carbolic acid, . lowed by stimulants. Chlorine, Ammonia, magnesia. Iodine, Lead salts, Sulphate of soda or magnesia. Mercurial White of egg. salts, . Common salt and other Nitrate of sil-Chlorides. ver, charcoal, which Animal Opium, . absorbs morphia. Chalk and copiwater Oxalic acid, ously.

In connexion with poisons, the fact-more than once alluded to in this work-must not be lost sight of, that it is possible for the longcontinued daily reception of even minute doses of certain poisonous substances, at last, by "accumulation" to exert pernicious effects upon the system (see Mercury-Lead, &c.). This must not be confounded with the criminal, secret, slow poisoning, so often recorded as the practice in ages gone by, a crime which has been occasionally imitated in the present day, hardly be practised without detection.

Before leaving the subject of poisoning, it is requisite to advert to the influence which habit exerts over the effects exercised by poisons on the human subject. All know how largely the habitual consumers of opium can increase their doses, and that the same is observed with respect to other drugs, chiefly of the narcotics; but the most remarkable instance of this power of habit, is in the case of the "arsenic eaters" of Styria and adjacent provinces, of whom it is an ascertained fact, that they habitually consume large and poisonous doses of solid arsenic, not only without injury, but with, it is alleged, apparent benefit to health. - See Wounds, Poisoned, and the various articles on

poisonous agents.

POLYPUS is a tumour, usually pearshaped, the result of the morbidly excessive growth of the mucous membrane lining a cavity. It is most frequently met with in the nose and in the womb, but also occurs in the ear, the rectum, and in the larynx. Polypi vary much in texture, in some cases being easily torn, and bleeding after the least injury, at others being firm and almost cartilaginous; their colour is usually grey or yellowish, and they possess but little sensibility; they are generally attached to the surface whence they spring by a narrow neck. The chief inconvenience which results from polypus in the nose, is the interruption to breathing through the nostril, at night especially; the affected person can only lie with the mouth open, which therefore becomes most uncomfortably parched. When polypus, however, in this situation, increases to a large size, it necessarily displaces the adjacent parts, such as the soft palate, or distends the nostrils. In any case, polypus is so uncomfortable a companion, that its removal is generally sought. This must, in all cases, be effected by the surgeon, by means of ligatures, scissors, or forceps, and, therefore, proper surgical advice should be resorted to. Occasionally, polypus in the nose will yield to the persevering use of astringent powders, such as that of burnt alum, or it may be regularly touched twice a day with tincture of steel, by means of a camel hair brush. Polypus of the womb cannot possibly fall under the cognizance

of unprofessional persons.

POMEGRANATE. — This anciently known tree—a native of Asia and Africa, is cultivated in warm countries generally. The flowers, the rind of the fruit, and the bark of the root, have been used in medicines as astringents, but the most general remedial use in modern medicine, has been that of the root bark, as a remedy in tapeworm; for this purpose it is extensively used in India. Christian says, "it seems scarcely ever to fail if properly used." The original mode of adbeen occasionally imitated in the present day, ministering it is to steep two ounces of the specially by long-continued administration of fresh bark in two pints of water for twelve

P 0 0 P 0 0

and to give a wine-glassful of the strained decoction every two hours, till the whole is taken. "Sometimes joints of the worm begin to come away in less than an hour after the last dose; but often the doses must be repeated several successive mornings before they take effect; and it is right to repeat them occasionally for four or five days after joints have ceased to come away." Laxatives should be administered from time to time. The remedy sometimes causes nausea and vomiting. The fresh root is most efficacious, but as it is almost impossible to obtain it in its fresh condition in this country, its employment as a worm destroyer has been almost entirely superseded by the more active kousso and the root of the male Still it is possible that in many situations abroad, fresh pomegranate root may be procured, where the other remedies cannot be When given in powder, the dose of pome-

granate root is twenty grains.

POOR .- Whilst poverty is so great an aggravation of the evils of sickness, it is, unfortunately, too often one of its most general causes. It is a perfectly well-ascertained fact, that physical deprivation and physical disease are to one another as cause and effect, and, however sad the reflection, that the insufficiently fed and clothed, and hard-worked labourer, has much less chance of prolonged health and life than those more fortunately placed. The following extracts from Dr. Combe's Physiology of Digestion put this in a strong light:— "If over-feeding be the prevailing error among the middle and higher classes of the community, the opposite condition is as unquestionably that of a large proportion of the labouring poor. Pressed upon all sides by the powerful competition both of constantly improving machinery, and of a superabundant population, the manual labourer is compelled to undergo an amount of ever-recurring bodily exertion, which far exceeds the natural powers of his constitution, even when supported by the fullest supply of nourishment; and when, as often happens, along with this excess of labour, his food, from inadequate wages, the size of his family, or his own injudicious management, is defective in quantity or in quality, the consequences to his health and happiness are disastrous in the highest degree.

"To those who have never reflected on the subject, it may seem like exaggeration to say, that, as a general fact, at least nine-tenths of the lower orders suffer physically, morally, and intellectually from being over-worked and under-fed; and yet I am convinced, that the more the subject shall be investigated, the more deeply shall we become impressed with the truth and importance of the statement. It is true that very few persons die from actual want of food; but it is not less certain, that thousands upon thousands are annually cut off,

hours, then to boil the whole down to one pint, | excess of labour and deficiency of nourishment. It is a rare thing for a hard-working artizan to arrive at a good old age. They almost all become prematurely old, and die off long before the natural term of life. It is in this way that, as remarked by Dr. Southwood Smith, the mortality of a country may be considered as an accurate indication of the misery of its inhabitants. According to Villermé, the rate of mortality among the poor is sometimes double that among the rich. Thus it is found, he says, that in a poor district in France, one hundred die, while in a rich department only fifty are carried off; and that, on taking into account the whole population of France, a child born to parents in easy circumstances has the chance of living forty-two and a-half years, while one born of poor parents can look for no more than thirty.

"These are striking facts, and their truth is confirmed by every day's experience in Britain as well as in France. Many causes concur to produce this melancholy result, but among the principal is, unquestionably, the disproportion so generally existing between toil and nutrition. During epidemics, too, the poor, from their impaired stamina, almost invariably become victims in a proportion far exceeding that of the more wealthy classes. This is, no doubt, partly owing to their greater intemperance and want of cleanliness; but even these vices often derive their origin from the same root—the want of adequate repose

and comfortable sustenance.

"The bad consequences of defective nourishment are not confined in their operation to the bodily constitution of the labouring poor. Their minds also are deteriorated. The pressure of poverty is unfavourable to the growth of refinement and morality, and crime and turbulence are never so much to be dreaded as during times of scarcity, and manufacturing or

agricultural distress.

"Among the poorer classes the children as well as the parents suffer both physically and morally from insufficient food. Their diet, being chiefly of a vegetable nature, and consisting of porridge, potatoes, and soups, with very little butcher meat, proves far from adequate to carry on vigorous growth in the one, or repair waste in the other; hence arise in the young an imperfect development of the bodily organisation, a corresponding deficiency of mental power, and a diminished capability of resisting the causes of disease. In workhouses, and other charitable institutions, ample evidence of these deficiencies obtrudes itself upon our notice, in the weak and stunted forms and very moderate capacities of the children.'

Happily, recent changes and improvements with respect to the working of the poor law have modified in some degree the force of the above observations, but they still hold good in whose lives have been greatly shortened by too many instances. The fact of the connexion

POP POR

and the production of disease, ought ever to be kept in mind by those who have the management of their inferiors in intellect, or in

worldly means.

Many of the evils attendant on poverty are, unquestionably, out of the power of the poor themselves to rectify, but many others, connected with the subject of ventilation, cleanliness, and attention to natural laws, which do so much to ward off the incursions of disease, are in most instances in their own hands.

Those who are taken, either by the calls of duty, or by the dictates of benevolence, to visit the poor in sickness, have many prejudices, theoretical and practical, to encounter. It is marvellous the dread of fresh air or of cold water, the faith in quack nostrums and old women's recipes, the constant anxiety that food should be taken and stimulants administered, and the perverse disobedience to the directions of a medical attendant. All these, and many others which are met with, ought to be special objects for good advice, for kind and rational explanation. The more leisurely visits of a clergyman, or of others who visit the poor, may well be in part devoted to instruction on these points, if the power of imparting the information is possessed, as it ought to be, by every educated person.

POPLITEAL SPACE.—The hollow of

the ham behind the knee.

POPPY, Papaver somniferum, or opium poppy, is the common cultivated poppy of the gardens, of various hues, varying from red or purple to white. Its principal produce, opium, has already been treated of. The capsules or seed vessels of the poppy, when dried, are used for their narcotic properties, owing to the opium which they contain. In order to have the dried capsule in the most efficient state, that is, containing the largest amount of opium, it should be cut green before it is fully ripe. When the seeds have been matured, the seed vessel is much exhausted. Poppy capsules are principally used in the form of decoction for purposes of fomentation. To make the decoction, rather more than an ounce of the capsules, well broken up, is to be added to each pint of water, and the whole boiled for a quarter of an hour. This preparation often proves soothing and relieves pain.

Syrup of poppy is made from the poppy capsule, but is a preparation which should be absolutely abandoned as dangerous. There is always considerable variation in the amount of opium contained in the capsules, and this variation is necessarily entailed upon the syrup prepared from them, a most dangerous contingency in a preparation of opium,—for such it is,—the use of which is in a great measure confined to children: half a tea-spoonful has proved fatal to a child six months old, and yet | ness. in lieu of hops; capsicums and grains of

between deficient nourishment, clothing, &c., | larger doses are often given. The calculation of the proper strength of syrup of poppies is about one grain of opium to the ounce. If an opiate syrup is to be employed, it ought to be made with as definite proportions as any other preparation of the drug.

Although the poppy seed vessel possesses such powerful narcotic properties, it is remarkable that the seeds are entirely free from them, and are mild and pleasant in flavour. They contain a fixed oil, and in some parts of Asia

are converted into bread or cakes.

Refer to—Opium.

PORK.—The flesh of the hog is generally and justly considered the most indigestible animal food in common use. In Dr. Beaumont's table, showing the average time required for the digestion of different articles of food, pork, fat and lean together, is shown to require about five hours for digestion. There is no doubt that much of the indigestibility of pork is due, not only to the fat, ostensibly existing as such, but to the large amount of fatty matter mixed with the muscular fibres; at the same time, pork more than other meat seems to exert marked injurious effects. In some few cases even symptoms of poisoning have followed the use of pork as food, but, in these, there probably must have existed some peculiar "idiosyncracy," or the meat must have been diseased. It is by no means unfrequent, however, for severe diarrhœa to be the result of a pork diet, continued for two or three days in succession. This often occurs in the families of the poor. The parasite which sometimes infests pork is called the *Trichina spiralis*, it produces the disease known as trichinesis. trichinosis.—See Trichina. Refer to—Bacon.

PORRIGO—a disease of the scalp.—See

PORTER, the well-known beverage, is brewed from malt highly dried. Dr. Paris says :- "Much has been said upon the fraudulent adulteration of this article, but we are inclined to believe these statements have been exaggerated." Mr. Donovan, however, affirms that, until the interference of the legislature, porter was liable to every species of adulteration. In a medical periodical the following observations occur in connexion with this subject :- "If we are to believe the assertions of previous writers, supported by the evidence adduced in connexion with numerous excise prosecutions, during the last few years, the adulteration of malt liquors has been practised to a very considerable extent, both by the brewers and the publicans. The following is a summary, exhibiting a list of the substances said to have been thus employed, together with the effects they are intended to pro-

Quassia, gentian, wormwood, broom tops, nux vomica, and strychnine, to impart bitter

paradise (in concentrated tinctures), ginger, | corianders, orange-peel, and caraway seeds, to give pungency and flavour; opium, cocculus indicus, nux vomica, tobacco, extract of poppies, and the tincture and juice of henbane, to communicate intoxicating properties or "strength"; molasses, colouring, sugar, burnt sugar, and corianders, as substitutes for malt; sulphuric acid (oil of vitriol), alum, green vitriol, and common salt, to impart an appearance of age; and "foots," pearl-ash, Scotch soda, and some of the articles before named as "heading," or to give the beer the property of bearing its head, or froth.

The following list of articles, said to have been seized at different breweries and brewers' druggists' laboratories, is copied from the "Votes and Proceedings of the House of Compublished some years since. In many cases heavy penalties were inflicted on the offending parties :- Cocculus indicus, multum (an extract of cocculus), colouring, honey, hartshorn shavings, Spanish juice, orange powder, ginger, grains of paradise, quassia, liquorice (root), caraway seeds, copperas, cap-

sicums, and mixed drugs (various).

Some of the articles in the above lists are virulent poisons. Such are opium, nux vomica, henbane, tobacco, cocculus indicus, and extract of poppies. We have reasons for stating, that the three latter are those only which we may suspect meeting with in beer at the present day. The use of cocculus indicus has been recommended by several writers on brewing. One of these conscientious gentlemen (?) states that "it is impossible with pure malt and hops alone to produce a strong-bodied porter, and then directs the employment of cocculus indicus, grains of paradise, and nux vomica for that purpose." Another author, equally base and ignorant, orders "three pounds of cocculus to be used for every ten quarters of malt;" and adds: "it gives an inebriating quality which passes for strength of liquor; it prevents second fermentation, and consequently the bursting of the bottles in warm climates." The latter assertions are utterly unfounded, and are mere excuses for adulteration. Another author informs his readers, that "six pounds of roast sugar and one pound of corianders are equal in strength and intoxicating qualities to a bushel of malt." In a work published many years since, it is stated that "cocculus indicus is commonly smuggled out of the hands of the druggist into those of the brewer, in common soda barrels, with three or four inches of Scotch soda at the top and bottom of each;" and also, that "it forms the principal ingredient in B.E., or black extract, which is ostensibly prepared for tanners, but its real destination is the beer cask."

Of course, the fact that fraud and adulteration may render such an article of human consumption, as porter, most deleterious, does not

when properly and truly manufactured, and there are few medical men who will not testify to the highly beneficial effects which follow the use of good porter in many cases; it is, in fact, a most admirable tonic, superior to any other form of malt liquor, and especially so, because it is less likely to disagree and to become acid on the stomach than the other varieties of malt beverage; neither is it so likely to give rise to gravelly deposits in the urine in the predisposed. Dr. Prout recommended the use of porter in diabetes, not only for its tonic properties, but as less likely to prove injurious in many cases of that disease than any other drink.

In convalescence from acute disease, porter is a strengthening medium, most grateful to the patient. In order to prove of service, porter must not be flat; it is, therefore, better for invalids, at least, to drink it bottled.

PORT WINE belongs to the class of "dry and strong" wines, being put down in Brande's tables, as containing an average of 22.96 per cent. of alcohol. The colour of port is due to the colouring matter of the grape husk, which is pressed out in the preparation, along with a considerable amount of astringency and extractive matter, from which the white wines are free. The large percentage of spirit contained in port wine is, of course, not the result of the natural fermentation, but is added on account of the depraved taste, which has rendered it necessary for foreigners to add spirit to the genuine wine, to render it marketable in Britain; spirit, too, which for the most part must remain in the wine in an uncombined condition. Probably, no wine imported into this country, or in many cases professed to be imported, is liable to the same extent of adulteration as port wine, an immense amount of deleterious stuff being sold under the name, especially when retailed in small quantities, or direct from the wood. In such cases the poor often suffer; probably, after illness, they may be able, or enabled to purchase, it may be one, or perhaps a couple of bottles of port; the liquor being frequently drawn from the cask and put into their own bottles, it need scarcely be added, that it is often worse than useless. There are few, medical men at least, who will decry the virtues of port wine, as a remedy, either in some stages of acute illness, or in periods of convalescence, but if it is to be of any service it must be genuine; those, therefore, who charitably interest themselves in the wants of their poorer brethren, should keep this in mind, and, if inclined to aid with the often most welcome gift of a little wine, send it from their own cellar, instead of giving money for its purchase. Good port wine is often one of the most valuable remedial agents in the hand of the physician: it is beneficial in the low stages of fever, in diseases of debility generally, and in convalescence from most of in any way afford an argument against its use the exhausting diseases. Gargling with port

wine in relaxed sore throat is a good, but | dependent parts. In the lungs especially this perhaps somewhat unnecessarily expensive, remedy. Owing to the high value of genuine port wine, it has been largely supplanted in this country by a cheaper class of red wines from the south of France and from Spain. The most generally approved of these substitutes is the wine known as Tarragona, grown on the east coast of Spain; it at all events possesses the virtue of purity combined with cheapness, which is more that can be said of the numerous so called port wines which are foisted on the market.

POSITION .- The position, either of the whole body, or of the affected part, in those suffering under illness, or from the effects of accident, is one of the most important considerations connected with treatment; it is, moreover, one frequently overlooked, particularly by unprofessional persons. Although the structural arrangements and vital activities of the living body counterbalance the influence of gravity under ordinary circumstances, the latter force is apt, more or less, to exert its power when weakness and long constraint in one posture diminish the powers of its counteragents. It is undoubted that the muscular movements, which are continually going on with most persons in health, tend greatly to assist in regulating and equalising the distribution of the blood and other fluids; even in the healthy the temporary want of this assisting power is shown in the liability of the feet or legs to become slightly swollen, in consequence of long sitting or standing in one posture.

In regulating position, it has for the most part to be done, either with reference to the relaxation of the muscles, to facilitate the flow of the blood or other fluids within the body, or to obviate pressure on any portion of the

The regulation of position with reference to the relaxation of certain muscles, or sets of muscles, is most generally required after fractures; and the principles on which this relaxation is to be adopted have been sufficiently alluded to under the article (Fractures) itself. This muscular relaxation may also be an object in the treatment of wounds which run transverse to the fibres of the muscle directly underneath, such as transverse wounds of the thigh.-See Wounds.

The regulation of position with reference to the flow of the blood or other fluids is often of immense importance, and too often neglected. The blood may have a tendency to gravitate towards the most dependent parts of the body, either from general or from local causes.

In some diseases, accompanied with great exhaustion, and, indeed, in many aged people,

is the case, and there is every reason to believe that congestion or accumulation of blood in these organs in the first place, giving rise to a kind of inflammation in the second, may be the consequence of long continuance in one position, as on the back. In such cases, care ought to be taken, when practicable, to change the position. Stagnation or congestion of blood occurs in the majority of instances, from some obstruction to the circulation, either at its centre, the heart, or in consequence of mechanical impediment acting upon the veins of the part or parts involved, such as happens from the pressure of tumours, or of the pregnant womb, upon the large veins of the abdo-

Again, at all times, in the healthy body, when in the erect posture, there is the force of gravity to be overcome in the return of the blood from the parts lower than the heart to the heart, and for this, special provision is made, most remarkably in the numerous valves with which the veins of the lower extremities are provided; any deficiency in these valves (see Veins) favours the gravitation of blood. In all the above named instances, position is of the very highest importance, not only as regards the comfort of the patient, and the treatment of the disease, but sometimes as a matter of

safety. - See Veins.

Whilst position is to be considered and taken advantage of as a means of facilitating the flow of blood through the veins, it is also a useful auxiliary in regulating its passage through the arteries, for it makes a very considerable difference whether the propulsion of the blood by the heart and arteries is exerted against the force of gravity or not. This is well shown when there exists from any cause a tendency to fainting. This condition, as pointed out in the article on the subject, depends upon diminished circulation of blood through the brain; it must, therefore, be evident to all, that in the erect posture, when the blood has to be driven upwards to the head, against the force of gravity, a much greater exertion of power is required, than if it had merely to be sent in a horizontal direction as it is when an individual is lying down, and, consequently, that in fainting, in which the action of the heart is much enfeebled, the usual treatment of laying a person almost flat is the most rational plan which can be adopted; it, moreover, illustrates well the influence of position. In a tendency to apoplexy, or to overfulness about the head, on the other hand, it is a matter of safety that all positions, such as stooping when awake, or sleeping with the head low, which favour the arterial flow to, or impede the venous flow from, independent of disease, it would appear as if the forces which circulate the blood lost the power of counteracting the force of gravity, even in the horizontal posture, consequently, the blood is apt to accumulate in the most that in the case of an artery being wounded,

the most rational mode of preventing, -which it will do entirely sometimes, -or at least of impeding, the effusion of blood, must be to place the wounded part in such a position that the force of gravity must act as strongly as possible against the force of the circulation; in other words, that if an artery of the hand is wounded, less blood will be lost by holding the hand and arm straight upwards, than in any other position (see Artery), and that, in this position, less pressure will be required to arrest the hæmorrhage. It might also seem as if common sense alone would be suffi-cient to teach persons generally such simple facts, but it is not so. It is on record (and similar cases are constantly occurring) that a woman nearly lost her life, in consequence of the giving way of one of the veins of the leg from ulceration, -she almost bled to death, because not one of those around had knowledge sufficient to lay her flat down, to elevate the bleeding leg above the level of the rest of the body, or to check the flow of blood with the thumb (see Emergencies). The regulation of position, with reference to the escape of fluids, such as matter from any part of the body, requires attention: surgeons generally take care that it is properly seen to, but it might escape the notice of unprofessional persons. As a general rule, parts should always be placed so that any discharge from them may have as free escape as possible. It is this fact, in cases of abscess, which often makes the artificial opening of the surgeon preferable to the natural one of the disease; he chooses the point for his incision where the matter can have the readiest escape; that is, the lowest portion of the abscess, in the natural and unconstrained position of the portion of the body in which it is situated.

Position, with reference to pressure upon different parts of the body, particularly in persons long confined to bed, requires much attention; it has been already alluded to under

articles Bed, Bedsores, &c.

The position, or in medical language the decubitus of disease, is of great interest to the physician, as in fact the posture assumed by the patient in certain affections is often quite characteristic, and speaks a plain and intelligible language to the medical attendant. Thus for instance, a patient suffering from abdominal disease with pain, lies on his back with the legs drawn up. One with heart disease, and difficulty of breathing, sits up in bed, and refuses to lie down. One with water in the chest lies on the affected side, to give the sound side room to move freely, and cannot perhaps lie on the sound side. A patient with rheumatic fever lies on his back utterly helpless and immovable, &c.

There are many other points connected with the important subject of position, but the fore-going remarks—directed rather to principles that to details-will probably serve to attract

considerations so closely linked, not only with the comfort, but with the safety and well-being of the sick and infirm.

POSSET—an old form of domestic preparation for the sick, made with milk curdled

by means of treacle, beer, &c.

POTASH, or POTASSA, or POTASHES, or VEGETABLE ALKALI.—One of the fixed alkalies and a compound of the metal potassium with oxygen, is very widely distributed throughout nature; in the soil, in vegetable and animal bodies, it is an almost constant ingredient.

Many preparations of potash are used in medicine; the most generally useful are:-

Potash, in its pure forms of caustic potash, especially in its solution the liquor pot-

Carbonate and bicarbonate of potash.

Acetate of potash.

Bitartrate, or acid tartrate of potash, or

cream of tartar. Chlorate of potash. Nitrate of potash. Iodide of potassium. Citrate of potash. Bromide of potassium. Permanganate of potash.

Potash derives its name from its source and mode of manufacture. It is procured by "lixiviating," that is, mixing and steeping vegetable ashes in water, and evaporating the solution or "ley" which results. From this solution, potash in the form of a carbonate is obtained, but the process being very roughly carried out, yields, of course, a very impure material, the "pot-ashes" of commerce, which are brought chiefly from Russia and North America. The rough potash is purified in various ways, either in the country of its manufacture, or after importation. When imported in a purified state it is sold as "pearl-ash," and after purification in this country, as purified pearl-ash, or carbonate of potash. This must not be confounded with the bicarbonate of potash, which is the most generally used medicinal preparation. There is great variation in the amount of carbonate of potash obtained from various vegetables, but weeds yield it most abundantly, after burning. For example, whilst call wood yields but 1552 and beach whilst oak-wood yields but 1.53, and beechwood 1.45, in every thousand parts, the fern yields 6.26, thistles 35.7, wormwood 73.0, and the common fumitory 79.0, in every thousand. Pure carbonate of potash is sold in the form of a white, granular salt, which is very deliquescent; that is, becomes moist or partly dissolved, in consequence of attracting moisture from the atmosphere.

Bicarbonate of potash occurs in crystals, but is more generally sold in the form of a white powder. It is, whilst applicable to the same purposes, a much milder preparation than the carbonate.

Liquor potassa or the solution of pure potash, a little more attention than is often given to is very similar in its medicinal action to the

468

above preparations; in its undiluted condition |

it is caustic, and a violent poison.

All the above preparations of potash are antacid, diuretic, and cooling; the simple carbonate, however, is but little used as a medicinal agent. The bicarbonate, in doses of from ten to twenty grains, dissolved in a couple of ounces of water, may be given when its antacid action is required; for diuretic purposes, the doses must be at least double the above. dose of the "liquor potassæ," or potash solution, is from ten to twenty drops, diluted in the same way. The bicarbonate of potash is often used, along with an acid in forming effervescing draughts, in febrile diseases; for the amount of acid requisite see article Effervescence. 1n some disorders of the liver, and where there is a tendency to the formation of red gravel in the urine, potash, especially the liquor potassæ, is one of our most useful remedies. A very good combination is fifteen drops of the solution in a teaspoonful of dandelion tea: this may be taken at least twice a day. The effervescing potash water supplied in bottles or syphons is very uncertain in its strength; when used medicinally a guaranteed strength should be insisted on. It is requisite that those who regularly, or for any length of time, take these preparations of potash on account of red gravel, or other diseases, should be on their guard, lest too long-continued a use of the remedy may induce other disorders, as bad, or probably worse than the existing one. The author could, in one case, trace a sudden break up of the nervous system, with alkaline and phosphatic urine, to no other cause than the long and incautious use of potash to obviate a tendency to red gravel. As mentioned under article Fat, the use of potash solution tends to diminish that constituent of the body. Potash is preferable to soda, as an antacid, in gout, from its forming a more soluble compound with the peculiar acid of that disease. - See

Caustic Potash is usually moulded into white sticks or pencils, to be available for medical purposes. It is only used for external application, as a caustic for sloughs and warty growths. It has also been made into a paste to decom-

pose cancerous and other tumours.

Poisoning by potash solution has sometimes occurred; in this case, vinegar, lemon juice, milk, demulcent drinks, or oil, will be the

best remedies.

The acetate of potash, a compound of acetic acid and potash, is chiefly used as a diuretic, and as a remedy in skin diseases, -the dose from thirty grains to sixty, well diluted in

water: it may act upon the bowels.

Chlorate of potash is generally sold in the form of flat, white crystals; it is cooling, diuretic, and a good saline remedy in inflammatory fever; it is most valuable, however, as a remedy in thrush or "aphtha" (see Aphtha), and in cases of sore mouth generally,-the dose five to fifteen grains, dissolved in water, for an formed; the walls lose their coherence and

adult. Chlorate of potash lozenges contain each five grains of the salt, and can be highly recommended in various affections of the throat and mouth. There are also compressed tablets of the chlorate, and a combination in glycerine jujubes, which some find the most

agreeable form.

Bitartrate of potash, or cream of tartar, is a compound of potash with tartaric acid. In its impure state, in which it forms a grey or brown concretion, it is known by the name of argol or winestone, and is formed inside the casks in which new wine is kept. The coloured, impure, crude tartar is purified, dissolved, and the solution gradually evaporated; in this process crusts form on the surface of the solution, which are successively skimmed off, whence the name "cream of tartar" is given to the purified preparation; this is generally sold in the form of white powder, which feels gritty in the mouth, and gives a pleasant acid taste. Cream of tartar is used to form the cooling pleasant drink, imperial, which, by most persons, may be taken freely. In doses of from sixty to one hundred grains of the salt, stirred into half a tumblerful of water, -it will not readily dissolve,-it is one of the best diuretics we have; in doses of two or three drachms it acts as a powerful purgative (see Jalap). Some persons cannot take cream of tartar in any form without suffering from irritation of the kidneys. An over-dose might produce inflammation of

Nitrate of potash or saltpetre, a compound of potash and nitric acid, is now brought chiefly from India, where it is obtained by "lixiviation," or by dissolving the nitrates of lime, soda, and potash, out of the soil, in which they exist in large quantity; the lixiviation being conducted over wood ashes. In this way the other nitrates are decomposed by the potash of the ashes, and nitrate of potash or saltpetre formed. Nitrate of potash may be also formed artificially, as it was in France during the war, when the British cruisers interrupted the foreign supplies to the country, at a time when the salt was so largely required in the formation of gunpowder. It is made by throwing up large compost heaps, containing lime in some form or other, either mingled with decaying animal matter, or watered regularly with urine. These heaps are allowed to remain two or three years unmoved, during which time, by slow decomposition, nitric acid is formed in combination with the lime, and the nitrate of lime being then dissolved out by water, is easily converted into nitrate of potash by decomposition. At present, however, "a great part of the nitre (nitrates of potash), used for the manufacture of powder in France, is obtained in Paris, from the lower stones of the houses, which are constantly in contact with the liquids of the streets and drains. The lime of the walls is gradually dissolved by the nitric acid

POT

firmness; hence the name of wall corrosion, | given to this injurious formation of nitre. The potash of the nitre is generally derived from bricks, and even the mortar contains some potash which gradually decomposes the nitrate of lime, aided by the superior crystallising power of nitre, so that the latter salt is formed. But, generally, in order to obtain all the nitric acid, as nitrates, potash must be added to the liquid obtained from the scrapings of the walls, by lixiviation with water.

Saltpetre is usually sold in crystals of various sizes, or in the form of crystalline powder; its taste is peculiarly cooling. In doses of twenty grains, dissolved in two or three ounces of water, it increases the flow of urine, and is most frequently given for this purpose. In large doses, such as half an ounce or more, it occasions pain at the stomach, and vomiting, with extreme depression of the system, and may thus prove fatal. Free dilution with some demulcent, such as thin gruel or barleywater, induction of vomiting, and counteraction of the depression by stimulants, would be the

most appropriate treatment. Iodide of potassium is a compound of iodine, or rather of iodic acid, with potash; it occurs in the form of white and, when well-formed, cubical crystals. It is a preparation now much used by medical men for syphilis, and as a means of eliminating mercury, lead, and other foreign matters from the system, but is not a remedy calculated for domestic administration. It may, however, be used in the form of its ointment and liniment in swollen joints, the effect of chronic rheumatism, and in enlargement of the glands, especially in bronchocele

or full throat. - See Bronchocele.

Bromide of potassium is prepared in a similar way to iodide of potassium, substituting bromine for iodine; it resembles the latter in appearance, but has a more pungent saline taste. It has come much into use of late years as a remedy for numerous nervous affections, particularly epilepsy, and is largely used in cases bordering on delirium tremens from mental excitement and over-worked brain. It is also frequently used and recommended to check the craving for drink in dipsomaniacs. The dose is from ten to twenty grains, and if

necessary to forty or sixty grains.

The citrate of potash is the result of an admixture of carbonate of potash with citric acid, and is a soluble white powder, very deliquescent and crystalline. It is an exceedingly pleasant, safe, and useful remedy, rapidly absorbed and decomposed in the blood, increasing the flow of urine, and acting slightly on the bowels. Citrate of potash is employed with benefit in red gravel, and it possesses valuable properties as a remedy against scurvy. The dose is from thirty to sixty grains.

Permanganate of potash-better known in its liquid state as Condy's fluid-is the result

of chlorate of potash, peroxide of manganese, and caustic potash, and presents to the eye dark purple crystals, a grain of which is sufficient to colour deeply an ounce of water. It is largely used as an oxidising and antiseptic agent, either as an external application to foul sores, or as a gargle in aphthous ulceration of the throat, and as an injection in feetid discharges from other external passages. Condy's fluid, the solution of permanganate of potash, consists of four grains of the latter to an ounce of water. A tea-spoonful of the fluid to a tumbler of water makes an excellent wash for the mouth at the morning ablution, and a small quantity poured into the wash-hand basin frees the hands of the medical man or nurse from unsavoury smells.

POTATO.—This well-known tuber, introduced into Ireland in the sixteenth century, from South America, by Sir Walter Raleigh, not only forms a daily article of food throughout a large proportion of the civilised world, but, unfortunately, owing to the ease with which it is cultivated, has become the staple article of nutriment to millions. As an addition to other and more nutritive food, the potato is most invaluable; as the sole article of diet although capable of supporting life), it is a wretched substitute, and any combination of

circumstances, which induces or compels a population to depend upon it in too great a degree, must be regarded as most unfortunate. The potato, undoubtedly, contains the ele-

ments of nutrition, that is, starchy and gummy matters (see Food), capable of sustaining the animal heat and respiratory processes, and also albumen and fibrin, adapted to build up the muscular and other constituents of living animal bodies, but those plastic materials are so deficient in quantity, their amount is so small compared with that of the other constituents of the tuber (which, moreover, contains a very large amount of water), that a man living solely upon potatoes must consume a very large quantity to keep himself in health and strength, even if he can do the latter, when undergoing anything like exertion. Prior to the potato famine, when potatoes were almost the universal diet of the Irish peasantry, from seven to ten pounds of potatoes per day was by no means an unusual amount for a labouring Irishman to consume; but the ten pounds of the root contained no more real nutriment than one pound and a half of good wheaten bread, notwithstanding the abundance of heat-giving matter which the former possessed. In consequence of the less amount of muscular "plastic" nutriment contained in his food, the Irish labourer is less adapted for continued exertion than the Englishman on his bread and meat, or the Scotchman on his oatmeal (see Oats). Moreover, it has been remarked, that the constitution of the Irish labourer is apt to give way earlier in life than of a chemical combination caused by the union | that of the men of the sister kingdoms, and he

is certainly more liable to be the victim of | tapioca," is a very wholesome preparation, and epidemic disease.

The following represents the chemical com-

position of 100 parts of potato :-

Water, Flesh-formers, 2.3 Starch, 15.4 Gum, . 0.3 Cellulose, Mineral matter,

The small amount of flesh-formers in comparison with starchy matters shows the necessity of combining the potato with other nitrogenous materials, and perhaps the simplest and most economical would be found in

the addition of butter milk.

There can be no doubt that as an addition, simply, to other varied and more nutritious aliment, the potato must be esteemed most valuable; it supplies the natural desire for vegetable food, and affords it of a kind well adapted to promote the health of the system, in one of its most digestible forms. The appearance of true sea scurvy in so many parts of the kingdom during the period when, in consequence of the potato blight, the population generally were compelled to use a variety of substitutes, sufficiently indicates how much we owe, in the matter of health, to the regular intermixture of the potato with our ordinary diets, and it is a questionable system of dietetics which, except from some very cogent reason, excludes the well-cooked potato from the dinner table of the invalid—the well-cooked potato, for nothing can be more indigestible than a badly-cooked one. It is, perhaps, superfluous to point out that a well-boiled potato should break down in a mealy form to its very centre; by well boiled is not meant excessively boiled, for when this is done, much of the nutriment of the root is lost. In Dr. Beaumont's tables, roasted and baked potatoes are said to take but two and a half hours for digestion, whilst boiled potatoes take an hour longer. The water in which potatoes are boiled contains some of the deleterious properties of the natural order to which the plant belongs (Solanaceae), and ought to be thrown away. The potato itself should be freed from water when eaten.

Potatoes which boil "waxy" are peculiarly unwholesome, and often pass through the bowels unchanged. The same may be said of early potatoes; not the early kinds when matured or ripe, but, as they are generally used, in an immature condition. Mashed potatoes do not generally get sufficiently mingled with the saliva to secure the full digestion of their starchy constituents (see Digestion). Potatoes soaked with gravy and dripping from roasted meat, though suitable for persons of strong digestion, are very liable to disagree with dyspeptics.

is cheaper than most starches

Potato spirit or brandy, a liquor frequently made and consumed in the northern regions of Europe, has been found more than usually deleterious.

POTENTILLA TORMENTILLA. -See TORMENTILLA.

POULTICE. - A poultice is generally understood to be an application adapted to afford moisture, and generally warmth, through the medium of some soft substance; or rather, it ought to afford these essentials, for, too often, cold dampness, or hardness and irritation, are the only derived effects from the illmade and badly-applied poultices with which ignorant people are apt to indulge their charges.

As above stated, any soft substance which will retain heat and moisture, may be used to form a poultice; but some materials are better adapted than others for the purpose. The substances most generally used for poultices are, bread, linseed meal, oatmeal, charcoal, hemlock, yeast, &c., and combined with these numerous antiseptics are often employed, such as carbolic oil, solution of permanganate of potash or of chlorinated soda; with these, bran, so often recommended in this work, as a medium for applying heat and moisture, can scarcely be considered as a poultice properly so called. The mustard cataplasm is also sometimes called a poultice, but improperly. The name cold poultice is also used.

The essentials of a good poultice are, that it shall be perfectly smooth and free from lumps or hardness, that it shall be as soft and moist as possible without being sloppy, and that it shall have sufficient bulk to retain both its warmth and moisture, without being too heavy. No material, perhaps, offers more domestic facility for making a good poultice than bread, and accordingly we find that the

Bread Poultice is, perhaps, more commonly used than any other. It is made either with water or milk, but the latter is a very doubtful addition, and the same may be said of the grease or lard often added to this form of poultice. The milk is apt to turn sour, and can answer no better purpose than the water; and when a greasy poultice is used, the bread is not requisite. The best mode of making a bread poultice is to break the crumb of bread into a hot basin, pour boiling water over it sufficient to soak it thoroughly, and allow it to stand covered over for a few minutes by the side of the fire; any superfluous moisture being drained off, the pulp should be thickly spread upon a piece of cloth of the requisite size. In some cases it is advisable to interpose a piece of thin muslin between the poultice and the surface on which it is placed. The temperature at which a poultice is to be applied must Potato starch, in the form of "British vary according to circumstances, but gene-

POU POU

rally the best is that which is most agreeable | to the patient; occasionally it is useful to have it as hot as it can be borne. After a poultice is applied to the body, it is a good plan to cover the part, either with a fold of flannel or with oiled silk, to assist in retaining the warmth and moisture; the latter, moreover, prevents the moisture, which necessarily exhales from the application, damping the clothes, &c., often a very great inconvenience in badly applied poultices. Indeed, the bad management of poultices generally, among the poorer classes, constitutes a serious objection to their use; they are often either made so sloppy as to wet everything around, and to put the patient in great risk from cold, or they are made so small and stiff as very quickly to become caked and hard upon the surface, particularly if not sufficiently often renewed. Even in the most favourable circumstances, a poultice requires renewal at least three times in the twenty-four hours.

The cold bread poultice is often convenient, and must be made simply with cold instead of

hot water. The bread poultice may be made the medium for various medicated applications; thus hot decoction of poppy "heads," &c., may be used instead of hot water, or goulard solution may be added to the cold poultice with advantage. It is a necessary caution, that the material used for these medicated poultices should not, after use, be thrown where it can be picked up by poultry. After the bread poultice, pro-

bably the Linseed meal poultice is more generally recommended by medical men to be used than any other. For this purp s, ground linseed, free from grit, should be procured. To make the poultice, a sufficient amount of boiling water is to be poured into a hot basin, and the meal stirred in till the whole is of the proper consistence; the mass, being beaten smooth before use, is then to be spread evenly upon the cloth. This forms a very smooth poultice when well made, and the oil, which the linseed naturally contains, tends to keep it soft. It is rather more stimulating than the bread poultice, -occasionally it is made by mistake, of the whole seed instead of the meal.

The oatmeal poultice may be made in a similar way to the linseed, but, although oats contain a considerable amount of fatty matter, it is not sufficient alone to make an oily poultice like the linseed; it is, therefore, very common to add a little lard; this, however, must not be done when the oatmeal poultice is, as very generally it is made, the medium for the

Charcoal poultice, which is often applied to sores where there is much offensive discharge, and powdered charcoal is frequently sprinkled over the surface of common poultices to destroy fætor. The charcoal poultice is directed to be made with half an ounce of charcoal, two ounces of bread-crumb, one and a half ounces

of linseed meal, and ten ounces of boiling water. The bread is macerated in the water for ten minutes, the linseed meal being gradually added and stirred till the mass assumes the consistence of a poultice, after which onehalf of the charcoal is to be added, while the remainder is sprinkled over the surface of the poultice when spread on lint or linen rag.

The hemlock poultice, so frequently recommended to relieve pain in cancerous and other painful wounds, is made with one ounce of the powdered hemiock leaf, three ounces of linseed meal, and ten ounces of boiling water. The hemlock and linseed meal, thoroughly mixed, are to be added to the water gradually, with

constant stirring.

The yeast poultice has a reputation for absorbing and neutralising fætor from wounds, especially in cases of gangrene. The British Pharmacopœia directs it to be made with six ounces of beer yeast, fourteen ounces of flour, and six ounces of water, heated to a temperature of 100°. Mix the water with the yeast and stir in the flour, keeping the mass near the fire till

The chlorine poultice is also an excellent deodoriser and cleansing application. It is made with four ounces of linseed meal, two ounces of the solution of chlorinated soda, and eight ounces of boiling water. The linseed meal is to be mixed gradually with the water, constantly stirring, after which the antiseptic solution is to be added.

Bran poultice.—See Bran.

Other substances, such as carrots, turnips, &c., are often recommended and used as poultices, but they possess no advantage over those already named, and are objectionable from their smell; they may, however, be used, and indeed any soft substance, consistent with cleanliness, which will retain warmth and moisture, when bread and meal are not procurable, or when their use in this way is an When medicated poultices are reobject. quired, as mentioned above, it is better to make the bread poultice with the infusion or decoction of the medicinal agent.

Honey, treacle, &c., are not desirable addi-

tions to a poultice.

Few applications are more generally used, either in regular or domestic surgery, than poultices, and, in their proper place, few are more useful. It is worthy of remark, that the most ancient poultice on record is that of figs, applied to King Hezekiah, by the direction of

the prophet Isaiah.

In painful swellings, attended with inflammation, such as boils, in inflamed wounds, and the like, or for promoting the discharge of matter, no application is more suitable than the poultice. To the use of poultices, however, there is a limit, not always well observed -particularly in the case of wounds and ulcers. Up to a certain point they are most valuable, beyond it they do harm; instead of soothing

472

and encouraging sufficient discharge, they | more soluble in the stomach, but it is far from attract the blood too strongly to the part, increase, beyond due measure, the discharge, and encourage the formation of "proud flesh." It is only practical experience which can teach the appearances indicative of the precise time when a poultice should be left off, but it may be guessed at, when healing processes, which have been going on favourably, seem to come to a stand-still, or retrograde; when the dis-charge rather increases than diminishes, and the surface and edges of the sore seem to become full, and at the same time pale and

flabby.

After poulticing has been carried sufficiently far, the simple water dressing (see Dressing) is in most cases most suitable, it is cooler, pleasanter, and not so like a hot-bed as the common poultice. Mr. Liston, the celebrated surgeon, was the first to substitute water dressing for the poultice, which he held in great abhorrence. That Mr. Liston carried his prejudice against the poultice too far, may be learned from the fact that many of the first surgeons of the day continue to take advantage of it; but that the water dressing may be substituted in most cases is unquestionable, and it is certainly a much more elegant and agreeable application in every way. It does not, however, in all cases answer the purpose of the poultice; indeed, that it does not act in the same way is evident from the fact, that when a sore has been stimulated, as above described, by over poulticing, the substitution of the water dressing quickly gives it a more healthy character, thereby proving its less excitant character.

Somewhat similar, in principle at least, to the lint and oiled silk application, is the Spongio Piline, introduced a few years ago as a substitute for the poultice. This, the invention of Mr. Marckwick, consists of sponge cut up into fragments, and felted into a mass with cotton wool, a layer of this mingled material being backed with a waterproof varnish. The mingled sponge and cotton will of course absorb moisture freely and retain it, and therefore in some measure act en a poultice. The author, however, cannot from his own experience speak favourably of its effects; in moderate-sized pieces it certainly does not answer well, but where large sheets of the material—as for a whole limb—are required and used, it may probably be very useful.

Poultice-bags made of thin waterproof and muslin are very convenient. They are made of all sizes, and may be used over and over

again.

Refer to—Dressing —Heat, &c.

POULTRY as food, must be considered under the divisions of the oily and non-oily. The flesh of the first class, including ducks, geese, &c., is certainly difficult of digestion, and perfectly inadmissible, even when plainly cooked for invalids. The flesh of the non-oily kinds, such as common fowls, turkeys, &c., is

being so easily digested as generally imagined, certainly it is not equally digestible with tender mutton. The flesh of this description of poultry, as of chicken, for example, is more likely to agree if boiled rather than roasted. The flesh of poultry, when digested, does not, probably, prove so stimulant to the system as that of the larger animals, it is therefore more useful in many cases of convalescence, when animal food is first permitted.

"In the boiling or roasting of poultry, the flesh of which is white, and contains little blood, the temperature of the inner parts, when the flesh has been well cooked, seldom exceeds 130° or 140°. The flesh of poultry or game is, therefore, sooner dressed than flesh which contains much blood, such as beef or mutton" (Liebig's Chemistry of Food). The broth made from chicken or fowl offers one of the best forms for giving animal nourishment in early convalescence.

POWDER.—The form of powder is a very common one for the administration of medicines, as in this way the peculiar actions of the drug are more readily and certainly de-veloped. Powders generally are prepared on the large scale by drug grinders, but as in the process, the drug is sometimes liable to extensive adulteration, some persons prefer preparing their own powders, although it is a very troublesome process. As drugs are more liable to spoil in the form of powder, emigrants and others may, in some instances, find it an advantage to powder their own. An iron mortar is generally used for powdering crude drugs, and if these are at all acrid, or indeed in any case, it is an advantage to have it fitted either with a wooden cover, or with a leather fastened round both mortar and pestle; a fine sieve is required to separate the finer portions of the powder from the coarser. Sir R. Christison remarks in his *Dispensatory*:—"The most prompt and effectual mode of obtaining fine powder is to use the mortar and sieve alternately-that is, to sift away the finer particles as soon as partial pulverisation is accomplished, to pound, or triturate again what remains on the sieve, to sift this as soon as a little more fine powder is formed, and to repeat the alternate trituration and sifting frequently, till the whole substance has passed through the sieve. In this way much time is saved, and much less of the finest powder is lost, by being driven off in triturating or pounding the coarser residue." As simple powders of the majority of the drugs used in medicine are prepared, it would take up unnecessary space to enumerate them here. The most useful compound powders admissible for domestic use are the-

Compound Cinnamon powder. Aromatic powder of chalk with opium. Compound powder of ipecacuanha or Dover's powder.—See Dover's Powder. Compound jalap powder. - See Jalap.

These are better purchased, particularly the compound chalk with opium, but may be made.

The compound cinnamon powder is made by reducing to fine powder equal parts of cinna-

mon, cardamom seeds, and ginger.

Powders ought always to be kept in wellclosed bottles, otherwise they lose their medicinal properties; some, such as squill or aloes, become damp and caked into a mass.

Powders are generally administered in some thick vehicle, such as preserve, thick gruel, or the like; if given in thin fluids, such as tea, &c., they are apt to sink to the bottom, and

are partly lost.

PRACTICE.—The old saying that "practice makes perfect," is applicable to the practice of medicine, but it is with some reservation; a reservation which is not always taken into account by the public, nor admitted by a certain class, the "practical men," in the profession. Without practical experience, it is certain no man can be either physician or surgeon, however great his theoretical knowledge; but it is equally certain, if practical experience alone be trusted to, it will do but little to bring its possessor up to his proper position as regards medical science, and must often leave him at fault, when he ought not to be so, particularly in cases which differ from the ordinary routine. Neither years, nor ex-tent of practice, can make the man a good practitioner, or at least as good a practitioner as he ought to be, if he neglects those aids and appliances in the treatment of disease which the industry and investigations of his numerous brethren are daily bringing forward. public may draw their own inferences.

PRACTITIONER, GENERAL.—The term "general practitioner" has come into use as the designation of those belonging to that large majority of the medical profession who practise their profession in all its branches, in contradistinction to the physician, who eschews the lying-in chamber or the knife, to the pure surgeon, whose province is the treatment of external diseases or of such as require operative procedure, and to the accoucheur. These distinctions, useful in themselves, under certain restrictions, can only be followed out in large towns, or in isolated cases in particular districts: the mass of the profession must still continue to be general practitioners, apt for all that comes under their care. The term in question has superseded the old name of apothecary, which had become perfectly inapplicable to the practitioners of medicine in this kingdom, who, although sprung in the first instance from the apothecaries or chemists, the mere dispensers of the prescriptions of the physician or surgeon, have, by means of their high education and the stringent examinations of the various Licensing Boards, taken the place of the medical advisers generally of the

entitled to. What is now required to complete the position of the general practitioner of medicine is, that they should as a body, except, perhaps, in the country, where it could not be conveniently acted upon, eschew the dispensing of their own drugs, and, certainly, in every case, cease to base their remuneration for advice and skill upon their medicines.

PRECIPITATE. - Something thrown down; in chemical language the term is applied to a substance which is separated in a fluid by decomposition, and which falls to the bottom.

PRECOCITY—untimely maturity—is occasionally seen in the development of the body, and can only be regarded as a form of disease. Precocity of mind is by no means uncommon in children, and in too many instances is causally significant with andre why stances is equally significant with undue physical development, and is much to be dreaded. The morbid excitability of brain is but the result of disease, and gives no promise of supereminence in after life. As a general rule, a precocious, or "strikingly clever," child, cannot be too much kept back from mental exertion; every effort should be made to divert the tendency to cerebral excitement, and by encouraging physical exertion, to divert the nervous power to the body at large: too often the

reverse system is practised.

PRECORDIAL REGION.—The fore-

part of the chest over the heart.

PREDISPOSITION. - See DISEASE-HEREDITARY TENDENCY-MARRIAGE, &c.

PREGNANCY is the condition of a female between the periods of conception and delivery. The state is to be considered, both as regards the symptoms which usually indicate its existence, and also with respect to the bodily disorders which are most commonly associated with it; some of the symptoms, moreover, are also disorders. It is usually considered that pregnancy cannot take place before the establishment of menstruation; and, as a general rule, it does not, but cases are recorded in which it has done. The suppression of the above function, also, is always regarded as one of the most unequivocal proofs of pregnancy, but it is not by any means invariable; cases have been known, in which the secretion has appeared during the whole period up to the time of delivery, and in many it is manifested for one, two, or three months after conception. The swelling of the breasts, another sign of pregnancy, does not always occur, in a marked manner, if menstruation goes on, and may also be excited sympathetically by the presence of tumours, or by other causes of irritation connected with the womb. The breasts, also, may increase, simply from accumulation of fat; in this case, they do not people of all ranks-a place they are fairly afford the somewhat knotty feeling to the

hand that they do in pregnancy, but are smoother and more uniformly increased in size; probably, too, the increased deposition of fat is general. For the first few weeks of pregnancy the abdomen is flatter than usual, that is, before it begins to enlarge. The countenance undergoes an alteration, better known than to be described; the features look sharper, and the eyes larger than heretofore; these appearances, however, are more strongly manifested in some women than others. Among the earliest and best known of the symptomatic disorders of pregnancy, is nausea, with sickness. This is sometimes developed very early in the condition, occasionally within the first few days, but more generally not for two or three weeks; it is most usual in the morning, on the female first rising, but in some cases, is almost constant, and is then very distressing. Toothache is not an unfrequent attendant on pregnancy in all its stages. Salivation, that is, a constant flow of saliva into the mouth, causing constant spitting, is another though not very common symptom. Irritability of the bladder is common. Heartburn is most general in the later stages of pregnancy, but may be suffered from in all. In many, there is no very definite symptom, but a general feeling of unrest, with irritability of temper, &c. As pregnancy advances, other symptoms, or symptomatic disorders, show themselves; but, frequently, after the first few months, the health which has been disordered undergoes a remarkable change for the better, and continues good up to the period of child-birth; when this change occurs, as a sequence to symptoms of the first stages of pregnancy, and the general symptoms of the condition remain, any doubt of the true state of the case, if such has existed, may be laid aside. Some women never enjoy such regular good health, as they do during the entire nine months they carry their child. About the sixteenth week, a little before or after, the symptom of "quickening" occurs. This is popularly, but erroneously, thought to indicate the period when the child first becomes endowed with life; indeed, so fully has this error been embraced, that upon it, a principle of English law involving life and death has been established. The child is living from the commencement of pregnancy, the symptom of quickening is occasioned by a sudden change of the position of the womb, consequent upon its increase in volume; after quickening, however, the movements of the child are more perceptibly felt. Quickening is generally accompanied with temporary sickness and faintness, and with a sense of alarm for a short time. After its occurrence, the abdomen enlarges more perceptibly. Milk is now, or even before this found in the breasts, and the capability of its expression from them, may be taken as a corroborative, but not as an absolute sign of pregnancy, for it may occur independent of become swollen, or their veins to enlarge, from that condition, and in women who have already | the same cause acting upon the large veins

borne children, milk is apt to linger in the breasts for a considerable period. The nipple is sensibly enlarged after conception, and in most cases is surrounded by a more or less coloured ring, the "areola," as it is called by medical men. In some females, especially those with dark hair and skin, the areola is often extremely deeply coloured, of the deepest brown-from this shade it is of every variety, and in some is absent altogether; it, therefore, is not an invariable sign of pregnancy, for the reason, more especially, that it is sometimes witnessed without that condition.

The urine is found to be in some cases altered during pregnancy, particularly in the later months. If a portion of the secretion is allowed to stand four and twenty or six and thirty hours, a greasy-looking scum, with a cheesy smell, and presenting peculiar appearances under the microscope, is found on the surface. This does not show in all cases.

From the remarks above made it may be gathered, that although there are many signs and symptoms of pregnancy, there is, probably, not one which can by itself be depended upon in doubtful cases. In most instances the combination and perfect development of a certain number of the above symptoms make the case certain; but it may happen that there is much difficulty in coming to a satisfactory conclusion, especially in the earlier stages, and if there is any desire for concealment. Medical men are often unjustly blamed, and now and then laughed at, for having in the earlier stages of pregnancy treated the disorders thence resulting as ordinary ailments, characterised by the same symptoms. Where there is reason, as in the case of marriage, to expect pregnancy, this is not likely to be the case; for if the examination of the practitioner did not lead him to the fact, it is probable the female herself would intimate the possibility of her symptoms arising therefrom; in those cases, however, in which pregnancy can neither be expected nor suspected, and especially if there is reason for and attempt at concealment, it must be obvious to all how little comparatively there may be to lead to a conclusion which is not looked for; and further, how delicate must be the position, and how guarded the opinions of a medical man so situated. Were these matters better understood, and their difficulties more appreciated, his-often only apparent-errors in these matters, would be more charitably regarded.

By the fifth month of pregnancy, all the symptoms have for the most part become evident, but there are disorders which more generally show themselves during the latter part of the period. One of the most frequent of these is costiveness, occasioned, doubtless, in part by the mechanical obstruction caused by the enlarged womb. The legs are apt to

the flow of blood also exhibits itself in the formation of piles, which may cause much inconvenience during the last months of preg-

Cramp in the lower limbs, caused by the pressure of the enlarged womb upon the nerves, often causes much annoyance, and sympathetic nervous pains throughout the body are not uncommon. Irritability of the bladder is apt to be much increased at this time; headaches, too, occur in some women, and may be of great severity, threatening convulsion. The above is rather a formidable array of the ailments from which many pregnant women may suffer, and some unquestionably do suffer, and severely so; but very many are free from the majority of them, except perhaps in slight degree; as said above, some women never enjoy such perfect health as they do when "in the family way."

The proper management of the disorders incidental to pregnancy will certainly do much

to alleviate their inconveniences.

The first which generally requires attention is the sickness. This may in some measure be prevented by attention to diet, and by the avoidance of all articles of food which were known to disagree, or which are found to disagree; for the rule which holds good in the ordinary state does not always do so in preg-Effervescing draughts of soda or nancy. potash water, or made at home with soda and lemon juice (see Effervescing), are useful, and to each may be added from half to a whole teaspoonful of sal volatile. A medical man may possibly add a drop or two of the medicinal prussic acid to each dose, but this must be left to medical regulation. If there is much acidity, the bicarbonates of soda or potash, or the fluid magnesia, will be found useful, and at the same time check the vomiting. In cases of debility, a tea-spoonful of calcined magnesia, in three parts of a wine-glassful of sherry, may be given with advantage. In obstinate heartburn and indigestion, with or without vomiting, a wine-glassful of the infusion of calumba, in combination with soda, potash, or magnesia, is one of the best remedies, and may be taken twice, or, if requisite, thrice a day. In cases of extremely obstinate vomiting, creasote (see Creasote) may be tried, or spirits of chloroform in doses of twenty drops at a time in a little water. Small pieces of ice allowed to melt in the mouth may also prove of advantage. In some cases of obstinate sickness the writer has found the administration of one drop of ipecacuanha wine, in a tea-spoonful of water, given every hour, of the most essential service. The tincture of nux vomica, in twenty-drop doses, will very likely prove serviceable, but can only be given with safety by a medical man.

The costiveness of pregnancy is often more

within the abdomen. The impediment to | ent aperient pills are inadmissible, on account of the aloes they contain.

Castor oil is the most generally useful and safe aperient when it can be taken regularly, but very many find it impossible to continue its use for long, in consequence of the nausea it Those whose bowels are very easily moved sometimes find the finest olive or salad oil answer well in table-spoonful doses. Senna infusion may be safely taken in the pregnant state, and in those who are of full habit, small well-diluted doses of the neutral salts, such as Epsom or Rochelle, are extremely useful. Rhubarb and magnesia is a safe combination, but generally too mild. The regular use of some form of injection (see Enema), which is found to be sufficiently efficacious, is one of the best methods of regulating the bowels in pregnancy, and regulated they must be in some way; there is nothing more likely, not only to increase the uncomfortable sensations incident to the condition itself, but to render delivery more difficult, and recovery from it more liable to accident, than a habitually constipated condition of the bowels. When piles occur, it is generally in connexion with costiveness (see Piles). Irritability of the bladder, characterised by constant desire to pass urine, is sometimes very obstinate, and, in the later stages, in which it depends on the mechanical pressure of the enlarged womb, very difficult to remove. It is most likely to be alleviated by the use of a broad belt or band passed round the abdomen, so as to give adequate mechanical support to the enlarged womb; indeed, the belt will not only often relieve the above troublesome symptom, but will remove many of the other uneasy or painful sensations which accompany the latter stages of pregnancy. When, along with irritability of the bladder, the urine is scanty, high coloured, and deposits red sediment on standing, ten-drop doses of the solution of liquor potassæ taken in barleywater, twice or three times a day, will probably give much relief; in weakly and debili-tated constitutions, ten drops of the tincture of perchloride of iron, in a wine-glassful of water, twice a day, will be perhaps a better remedy. Malt liquor is apt to increase the urinary irritation, and must therefore be avoided; and, if stimulants are required, wine and water, or weak brandy or gin and water substituted.

Cramp, being dependent on a mechanical cause, is difficult to remove; it may, however, be alleviated by the use of the abdominal belt, and by strict attention to the state of the bowels and digestive organs; indeed, during the whole period of pregnancy, carefulness and moderation in diet will be found to influence, greatly for the better, many of the casual inconveniences. The author can speak highly of the great value of the abdominal belt in relieving many of the uncomfortable sensations connected with pregnancy. These belts are troublesome to manage, as the usual conveni- manufactured in different ways by the makers,

but patients may make very efficient ones,

with a little care, for themselves.—See Cramp.
Swelling of the legs, and of their veins,
being dependent, like cramp, on mechanical causes, is to be relieved by attention to mechanical modes of treatment, particularly by care that no unnecessary accumulation in the bowels adds to the obstruction to the return of the blood through the veins; keeping the feet and legs up as much as possible, bandaging, friction, &c., are all useful in relieving the condition .- See Veins.

The breasts should be left as free as is consistent with appearance, and the nipples especially attended to (see Nipples). Headache, if continued and severe in pregnancy, is a symptom which must not be overlooked; it may simply be owing to costiveness, or other slight temporary causes, and be easily removable; but if its severity continues, accompanied with flushing of the features, fulness or redness of the eyes, throbbing of the vessels of the head and neck, medical assistance should be sought without delay; in the meantime, the measures recommended in cases of threatened inflammation of the brain are to be carried out more or less actively, according to the severity of symp-Convulsions sometimes occur in pregnancy: a medical man must see the case without a moment's unnecessary delay, if possible; but if delay must occur, the patient should be managed as recommended under the article Convulsion, or as directed in the remarks upon the same affection after delivery (see Childbirth). Fainting is a symptom which may be of grave import: its cause should be investigated by a medical attendant; in the meanwhile it must be treated as fainting generally, unless it is dependent on loss of blood, as in abortion. - See Abortion.

Troublesome itching eruptions on the skin, sore and ulcerated mouth, are all apt to be attendant on the condition of pregnancy; they are to be treated in the ordinary method (see Aphtha, -Skin, &c.), but are often very intractable, and disappear only after delivery.

The above are the chief physical considerations connected with this most important phase of human life; but this article would be very incomplete without some allusion to those moral conditions and requirements which exert so powerful an influence over the well-being and well-doing of both mother and infant. And, it may be remarked, that without attention to the physical health of the body, the moral atmosphere is much more liable to be disturbed, and that the mind is much more apt to become irritable, especially if the digestive organs are disordered, as they often are by the too great indulgence of food, which is frequently thought to be not only allowable, but desirable in the pregnant state. The same effect follows the indolent habits so often indulged in. Unless prohibited for cogent prominent, especially in women of full habit, reasons, regular and sufficient exercise ought to and constitutionally disposed to embonpoint;

be taken daily, up to the time of confinement -nothing tends more to preserve the health of the body or the cheerfulness of the mind. It is not by any means desirable for a female, during pregnancy, to withdraw from the performance of the ordinary active duties of life; the mental engagement resulting therefrom is most beneficial, and prevents the thoughts from reverting, as they will do sometimes, to disagreeable or gloomy subjects. At the same time, a woman, during pregnancy, ought to be freed from any of the severer and more harassing occupations, and as much as possible kept from mental uneasiness, and spared, as far as can be, those things which excite unpleasant emotions in the mind. That the infant is affected by the mental condition of the mother, is undoubted; she cannot be too careful in keeping guard over herself, not for her child's sake solely, but for her own in future years, when that child may display tendencies which it owes to the maternal influence in the first period of its existence. The morbid longings of pregnancy have been already alluded to (see Longings).

The ordinary period of gestation is important, if only as a matter of convenience, to enable the mother to calculate and make the necessary arrangements for her confinement; but its precise duration, or the number of weeks or days required to complete its term, not unfrequently becomes of the most serious moment, as a point of law, on which may hinge the inheritance of fortune or of title, or the happiness and fair fame of families and individuals. The generally allowed calculation for the duration of pregnancy is forty weeks, or 280 days, from the last menstrual period; but evidently such a calculation must be liable to some variation; in law, all births which occur before the thirty-eighth week of pregnancy are considered premature; those after the fortieth week, as protracted cases. It is certain that cases are frequently protracted beyond the fortieth week of calculation at least, and that these generally

prove male births.

The subject of false pregnancy is of considerable interest and importance: the following remarks from Dr. Montgomery's Signs and Symptoms of Pregnancy are instructive, and may put some on their guard:—"It is necessary," says the author, "to notice a condition of the female system of a remarkable kind, most frequently observed about the turn of life, when the catamenia, becoming irregular, previous to their final cessation, are suppressed for a few periods, and at the same time, the stomach being out of order, nausea or vomiting is experienced, the breasts enlarge, become sensible, or even slightly painful, and some-times a serous or sero-lactescent fluid exudes from the nipples and orifices of the areolar tubercles; the abdomen grows fuller, and more

PRE

and the abdominal enlargement progressively increases, partly from deposition of fat in the integuments and in the omentum, but still more from distension of the intestines by flatus, which, passing from one part to another, communicates a sensation like that produced by the motion of a fœtus; the nervous system is generally much disturbed, and the woman feels convinced that she is pregnant, an idea which, at the time of life alluded to, is cherished by the sex with extraordinary devotion, and relinquished with proportionate reluctance, and not unfrequently at the end of the supposed gestation the delusion is rendered complete, and almost assumes the character of reality, by the occurrence of periodical pains strongly resembling labour.

The occurrence of abortion during pregnancy, and the precautions to be adopted when the tendency exists, or indeed at any time, having been already treated of under the head of Abortion, it is unnecessary to reiterate them

here.

Refer to—Abortion—Child-bed—Pelvis, &c. PREMATURE BIRTH.—One which occurs before the thirty-eighth week of pregnancy. In most cases the occurrence of premature confinement is to be sedulously guarded against, for it cannot be expected that children generally, born out of due time, can be as strong as those whose birth is in every respect regular. Cases, however, do occur in which, both on account of the mother's safety, and as the only possible chance of having a living child produced at all, it is necessary to induce premature labour (see Pelvis). The induction of premature labour can, of course, only be entrusted to the hands of the skilful.

—See Child-bed — Pregnancy, &c.

PRESCRIPTION.—A medical prescription is the form, with directions, in which a medicine or medicines are ordered or "pre-scribed" by a medical man. In England, both prescriptions and directions are usually written in Latin; in Scotland the directions are very generally given in English, and though, perhaps, the method is not so consistent as that which preserves the same language throughout, it is safer and more convenient. In former times prescriptions were much more complicated than they are now, generally at least, and certainly the simplicity may be regarded as a sign of increased medical knowledge, and of greater confidence in the action of medicines. Some persons even contend that in prescriptions there should be no intermixture of medicines, but that one only should be given with a certain definite object, and allowed to operate unembarrassed by the presence of others. It is not difficult to show how materially this would interfere with the efficiency of practical medicine, at least in the present state of our knowledge. The Pharmacopæia abounds with prescriptions containing combinations of remedies in various forms,

and there can be no doubt that it is desirable alike in the interests of patients and doctors that the formulæ there given should be adhered to when possible, but circumstances constantly occur which render a deviation from this principle necessary. Thus, a medical man may desire to combine a purgative with a diuretic, or a tonic with a sedative, in a state of graduation such as no officinal preparation presents, and he is consequently left to fall back on his own judgment, as to how he can best meet the peculiarities of each individual case. Another object of a prescription is to give directions relative to administration, so as to render the medicine least repulsive to the

recipient.

Many persons seem to imagine that because a medical man can sit down and write off a prescription in a few minutes, it is quite as easy for him to give it when requested. This erroneous impression does not extend so much to physicians practising only as such, but it often operates to the injury of the general practitioner, who is not unfrequently, when persons are leaving his vicinity, either temporarily or permanently, asked for his prescription of medicine they have been taking, while at the same time there is but little idea of its being paid for. A moment's reflection will show that this prescription is as much a work of skill, and the result of previous labour, as the design of the artist, and that, moreover, in furnishing it the medical man is probably interfering with his own remuneration at some future time, when the prescription is made to stand in lieu of his advice. Some general practitioners refuse their prescriptions alto-gether; this they are not justified in doing, but if they do furnish them, they are quite entitled to their guinea fee. Another error with respect to prescriptions is, that one having been found of service at some former time, is very generally had recourse to at another; in some few cases the act may not be followed by any particular injury, but, generally, it is a very foolish system, and persons who can afford to fee a physician, but prefer, instead, to take advantage of some old prescription, deserve to pay in a little inconvenience for their stinginess.

PRESERVED PROVISIONS.—The tendency of all dead organised matter which contains moisture is, at ordinary temperatures, to undergo chemical change (see Putrefaction), or, in other words, the various vegetable and animal products, when deprived of life, decay. When these products are such as are employed for food, it of course becomes a matter of considerable importance to counteract this tendency to decomposition, by which the articles are specially rendered useless. It becomes of importance to preserve them as perfectly, and for as long a period as possible. The preservation of provisions may be effected—1st, by cold, that is, by keeping them at a tempera-

478

ture below that at which putrefaction takes ness, it acts much more perfectly as a preserva place; 2nd, by heat, which acts by hardening tive, as is shown by the preservation of the and coagulating the albumen and other constituents, so that they are more disposed to resist chemical change, or by heat and dryness combined, so that the water, which is essential for the process of putrefaction, is removed; 3rd, by the use of certain agents, or antiseptics (see Antiseptics), which impart the power of resisting decomposition; and 4th, by excluding the action of the atmosphere, the oxygen of which is requisite for the putrefac-

tive process.

The preservation of articles of food by keeping them at a low temperature is sufficiently well known; and among such nations as the Russians, whose climate during the winter months is one of unvarying frost, the preservative action of cold is largely taken advantage of. Cattle, poultry, &c., are killed at the commencement of frost, allowed to become frozen throughout, and in this condition are brought to market at the large winter fairs; fish are treated in the same way, and are thus preserved for months in a perfectly fresh and wholesome state; provisions thus preserved only requiring the precaution of being gradually thawed, before use, by immersion in cold water. In this country ice has always been largely used to pack salmon, and fish generally, in summer time, but it is only within the last few years that the process of preserving meat by refriger-

ation has come into general use.

The importation of dead meat from America in vessels fitted with chilled chambers, has now become an extensive and rapidly increasing trade, bidding fair to revolutionise the sale in this country, as well as in those parts of the world where mutton and beef have been hitherto scarce and expensive. In the methods employed it does not appear to be desirable to expose the meat to a temperature sufficient to freeze it, though it is essential that the air should pass readily through the chambers at a temperature a few degrees above freezing. It is easy to see how much waste of meat, including fish and perhaps poultry, could be avoided, if such cold storage chambers were annexed to our chief provision marts, to preserve the meat until it was wanted. With such an arrangement, the irregularity of the demand and atmospheric changes would not entail the losses they now do, both to retailer and consumer. More recent attempts to introduce frozen meat from Australia hold out hopes that the sources of supply may be still further enlarged, notwithstanding the prejudice which exists among many persons against partaking of meat that has undergone congelation.

The action of an elevated temperature, such as is employed in cooking food, must be regarded rather as a retarder than as a complete preventive of putrefaction; it is therefore inapplicable, except as a mere temporary expedient. When heat is combined with dry-

tive, as is shown by the preservation of the bodies of men and animals who have perished in the African deserts; and also in the practice, more especially of the Indians and others of the South American Pampas, who preserve their beef by cutting it in strips and hanging it to dry in the hot sun in a current of air; preserved in this way it will keep for a considerable time.

In the case of vegetables, which contain so large an amount of water, in proportion to their solid and nutrient material, the process of drying is peculiarly applicable, and seems likely to be largely employed as the means of furnishing fresh vegetable food for ships in a compact and easily carried form, when, in addition to the dessication, compression is also resorted to. This double process "appears to have been put into execution with very considerable success, under the patent of M. Masson, head gardener to the Horticultural Society of Paris. This gentleman has succeeded in preserving in a very perfect manner various descriptions of vegetables and fruits; the substances thus preserved are dry and shrivelled, contain but little water, and it is evident from their appearance that a very essential part of the process of preservation consists in the abstraction of the water, which forms so very considerable a portion of the weight and bulk of nearly all vegetables and fruits. vegetables thus prepared are immersed in water for some time, they swell up, become soft and tender, and resume, to a great extent, the appearance, colour, and flavour proper to them in the fresh state. M. Masson has managed to preserve completely spinach, Brussels sprouts, cabbage, beans, peas, sliced carrots, parsnips, potatoes, apples, &c.
"It is stated that a cubic yard of these dried

and compressed vegetables contains as much as 16,000 rations; and that they are of better flavour, and much cheaper than the vegetables

preserved in canisters.

The preservation of provisions by their impregnation with antiseptic agents, such as salt, is perhaps more extensively practised than any other method. Salt, sugar, spices, vinegar, spirit, and fumigation by burning wood, which is in fact preserving by means of creasote, are the most common preserving methods, and for many purposes answer perfectly, both as regards the agreeability, and within certain limits of use, the wholesomeness of the food to which they are applied; they have, however, the drawback of being partly, in themselves, chemical additions to food, and also of inducing chemical changes, which modify, at least, the quality and digestibility of the aliment. Moreover, salt extracts, "draws out," from meat some of its most important nutrient constituents. Liebig, in his Chemistry of Food, remarks:—"It is universally known that in the salting of meat, the flesh is rubbed and sprinkled with dry salt, and that where the

PRE PRE

amounting in bulk to one-third of the fluid contained in the raw flesh. I have ascertained that the brine contains the chief constituents of a concentrated soup, or infusion of meat, and that, therefore, in the process of salting, the composition of the flesh is changed; and this, too, in a much greater degree than occurs in boiling. In boiling, the highly nutritious albumen remains in the mass of flesh; but in salting, the albumen is separated from the flesh; for when the brine from salted meat is heated to boiling, a large quantity of albumen

separates as a coagulum.

"It is now easy to understand, that in the salting of meat, when this is pushed so far as to produce the brine above mentioned, a number of substances are withdrawn from the flesh which are essential to its constitution, and that it therefore loses in nutritive quality in proportion to this abstraction. If these substances be not supplied from other quarters, it is obvious that a part of the flesh is converted into an element of respiration-certainly not conducive to good health. It is certain, moreover, that the health of a man cannot be permanently sustained by means of salted meat, if the quantity be not greatly increased, inasmuch as it cannot perfectly replace, by the substances it contains, those parts of the body which have been expelled in consequence of the changes of matter, nor can it preserve in its normal state the fluid distributed in every part of the body, namely, the juices of the flesh. A change in the gastric juice, and consequently in that of the products of the digestive process, must be regarded as an inevitable result of the long-continued use of salted meat; and if, during digestion, the substances necessary to the transformation of that species of food be taken from other parts of the organism, these parts must lose their normal condition.'

From the above objections, the process of preservation by exclusion of the action of atmospheric air is free; it does not preserve by inducing change, but, like cold, by preventing This mode of preserving food is yearly assuming more importance, and being more largely practised. The action of the atmosphere may be prevented in various ways, as by covering the articles with melted fat, &c., but the most perfect method, and that which is most largely resorted to, is the inclosure of the food in cases from which the air is then expelled, and which are made so impervious as to prevent the access of air; upon the perfection of the airexcluding process, both at the time and permanently, depends entirely the preservation of

the article.

The following description is taken from the Lancet: - "The article to be preserved is placed, sometimes in the raw state, but generally cooked, in a tin canister, the lid of which is soldered down, but is perforated with a small

salt and meat are in contact a brine is formed, | the action of either steam, boiling-water, or a amounting in bulk to one-third of the fluid | muriate of lime bath, until the contents of the canister, if not previously dressed, have become about two-thirds cooked. The aperture in the cover is then closed, and the canister and its contents are once more submitted for a shorter period, that is, until the article is completely dressed, to the operation of heat. As soon as it has become cold the canister is covered over with a coating of paint; its preparation is then completed, and it is removed to the provingroom. The proving-room is simply an apartment the temperature of which has been raised to the degree most favourable to decomposition. If the operation has been well performed, the top and bottom of the canister, as also, in some cases, the sides, will have fallen in or have collapsed to some extent; this indicates the exhaustion of the air within, and is regarded by the manufacturer as a tolerably correct proof that the process has been properly conducted. If, however, after some days' exposure in the proving-room, the top and bottom of the canister first become flat and subsequently even convex, it is a certain sign that the contents have not been well cured, and that they are not in a condition to keep for any length of time; such canisters have therefore to be either rejected, or else subjected to the process over again. It should be known that it is not only boiled provisions which may be preserved by the above process, but roasted also, with but a little extra care.

The preparation and employment of provisions preserved in a fresh condition are important both in a sanitary and in an economic point of view; independent of the means of luxury which is thus afforded, it might be, and

will probably be, of cheap luxury.

In all situations, as on board ship, where access to fresh provisions in their usual state is necessarily curtailed or denied, the preserved provision store is most invaluable as a means of maintaining health, and those, such as emigrants, who meditate a long sea voyage, unless they are satisfied that the ship they embark in is well supplied with fresh preserved food, ought, if possible, to have a small private store. It has occasionally happened that tinned meats have turned out badly, from defects in their preparation or from other causes, and this fact might prejudice some against this description of meat; but with the improvements now made. in the process of preservation, as well as the tests to which the canisters are subjected before being offered for sale, there is little to fear from the meat turning bad.

As regards the economic advantages to be derived from the employment of preserved provisions, it is sufficient to advert to the facts, that in South America the cattle are sometimes slaughtered for the sake of their hides, horny parts, bones, &c., and that the flesh is wasted; that in Australia sheep have been boiled down aperture, or pin-hole. It is then subjected to for the sake of their tallow alone. The extensive

preparation of Liebig's and other extracts of meat, | surfaces of the body, if long continued, is to and notably the importation of large quantities of Australian tinned meats have, however, in a great measure, checked these abuses.

Charcoal, from its remarkable power of absorbing gases, is sometimes used as a preservative in which articles of food are packed. Lastly, such preparations as the patent meat biscuit, meat lozenges, and soups of various kinds, dessicated and moist, offer other forms in which nourishment may be preserved in a concentrated state. The meat biscuit is a useful preparation of concentrated meat and bread, and can be prepared for use in the shortest time as a soup. One pound of this meat biscuit, contains the nutriment of five pounds of the best beef, the extract of which is combined and baked with the finest flour, forming a most portable and convenient diet. It is eminently adapted for emigrants, travellers, and for ordinary use in families, &c. Its easy digestibility and highly nutritious properties render it very valuable for invalids and con-valescents, and generally for use in hospitals. Brand's essence of beef is a costly but valu-

able preparation, which has not undergone any chemical transformation. The other essences and extracts, such as Liebig's, Whitehead's, Gillon's and Moir's, no doubt represent a quantitive value out of all proportion with the bulk of the essence, when compared with the amount of meat expended in their preparation; but it must not be supposed on that account that such essences exhibit an equal amount of

Pemmican, which "consists of the muscular fibre of beef, baked and reduced to a coarse powder," is another form of preserving animal food worthy of attention. - See Pemmican.

PRESSURE. — The effect of continued pressure upon the living body may be regarded either as a cause of disease or as a curative agent. For some centuries pressure to death by loading a prisoner with the weight of chains was occasionally had recourse to, and pressure from the thumb-screw and the boot were among the most excruciating means of

The effect of pressure in altering the shape, &c., of even the hardest portion of the animal frame, is well known: the savage Carib employs it to flatten the skull of his children into a hideous deformity, by him thought beauty; and the civilised female too often has recourse to it, with equally false ideas of proportion, to mould the ribs at her waist into a state of permanent contraction. Both instances show how even the bones may be affected by pressure from without, applied over an extended surface; when the surface of pressure is small the bone is absorbed, as evinced by the hollow often formed in the breast-bone of shoemakers, who have for many years pressed the "last" against affection in India, is often quoted :- "The the one spot. The effect of pressure upon the sensations arising from prickly heat are per-

cause thickening, as seen in the horny hand of the labourer, or in the corn from the tight shoe. When, however, pressure is too suddenly and continuously applied to surfaces unused to it, especially in debilitated states of body, instead of giving rise to thickening, it is apt to occasion mortification, or, at least ulceration. This effect of pressure is one of the most serious complications of long-continued illnesses, in which the difficulty, and often almost the impossibility, of moving a patient, or at least of preventing continued pressure upon the most prominent points of the body, are a source of much suffering on the one hand, and of anxiety on the other. In a long case of fever it may happen, especially if there is neglect, and, at times, under even the most attentive management, that ulcerated or "sloughing" spots form on the back of the head, the tips of the ears, the points of the shoulder-blades, over the hips, &c. To alleviate these effects, there are the various inventions of spring and water beds, elastic cushions, &c.—See Fever, Enteric—Bed—Bed-sore—India-rubber, &c.

The effect of pressure, as a curative agent, is often valuable. Thus, when swelling of a part, or of a limb, has followed from weakness in the circulation, the continued and even pressure of a bandage, or of an elastic covering, will do much to hasten its reduction. Tumours, such as bronchocele, will sometimes disappear under well applied pressure. Bleeding which threatens life may be stopped by pressure properly applied (see Artery), and for many years past, pressure instead of operative interference has been successfully employed as a remedy in aneurism, acting by interrupting the circulation of the blood through the vessel with which the aneurismal tumour is connected. The writer had the satisfaction some time since of completely curing by long-continued pressure, extending over two years, a large vascular nævus on the side of the neck, so evidently connected with an artery beneath, that the surgeons, in the country and in London, to whom it had been submitted, refused to interfere with it.

The continued pressure of the atmosphere upon the surface of our bodies at ordinary elevations, by its variation, as indicated by the changes of the barometer, probably exercises a greater influence upon our health and sensations than is generally suspected. The distressing effects experienced from the diminished pressure, in part at least, by those who ascend great heights, is well known.—See Air.
PRICKLY HEAT is a peculiar affec-

tion of the skin which affects those who live in hot climates, especially when first resident, and which also occurs in hot summers in this The following description of the late country. Dr. James Johnson, from his experience of the

PRO PRI

pricking, itching, tingling, and many other feelings for which I have no appropriate appel-"It is usually, but not invariably, accompanied by an eruption of vivid red pimples, not larger in general than a pin's head, which spread over the breast, arms, thighs, neck, and occasionally along the forehead. This eruption often disappears in great measure when we are sitting quiet, and the skin is cool: but no sooner do we use any exercise that brings out a perspiration, or swallow any warm or stimulating fluid such swallow any warm or stimulating fluid, such as tea, soup, or wine, than the pimples become elevated, so as to be distinctly seen, and but too distinctly felt."

In reference to the imagined dangers of repelling this eruption, Dr. Johnson continues, "Indeed, I never saw it even repelled by the cold bath, and in my own case, as well as in many others, it seemed rather to aggravate the eruption and disagreeable sensations, especially during the glow which succeeded immersion. It certainly disappears suddenly, sometimes on the accession of other diseases, but I never had reason to suppose that its disappearance occasioned them. I have tried lime juice, hair powder, and a variety of external applications, with little or no benefit; in short, the only means which I ever saw productive of any good effect in mitigating its violence, till the constitution got assimilated to the climate, were light clothing, temperance in eating and drinking, avoiding all exercise in the heat of the day; open bowels, and last, not least, a determined resolution to resist with stoical apathy its first attacks. To sit quiet and unmoved under its pressure, is undoubtedly no easy task, but if we can only muster up fortitude enough to bear with patience the first few minutes of the assault, without being roused into motion, the enemy, like the foiled tigers, will generally sneak, and leave us victorious for the time.

is probable that privies must continue to exist, but in towns and large villages it is high time that this filthy system of excretal disposal should be abolished. Efforts are being made in some districts to bring this about, and the recent introduction of an appliance by which the slop water of houses is made use of as an automatic flush for a form of out-door watercloset has greatly simplified the question. A description of the slop-closet will be found in the section devoted to water-closets.

If circumstances forbid the adoption of a better mode of excretal disposal, the privy should be constructed on the lines laid down in the model Bye-laws of the Local Govern-These requirements differ in ment Board.

fectly indescribable, being compounded of feet, whereas in the latter the movable receptacle should not exceed 2 cubic feet. is also requisite that both the floor of the fixed receptacle, and the floor of the compartment which receives the movable receptacle, should be at least 3 inches above the level of the surface of the ground, and it should be flagged or asphalted; the sides also must be constructed of flagging, slate, or good brickwork, 9 inches thick, rendered in cement.

It is important to remember that a fixed receptacle is inadmissible unless the ashes of the household are applied to the excreta. By keeping the contents dry these tend to retard decomposition, and so limit the nuisance which is inseparable from the system even under the most favourable conditions. The privy itself should be ventilated, should be placed at least 6 feet from any dwelling-house, and the

contents should be removed regularly.

PROGNOSIS is the opinion of a medical man respecting the ultimate issue, possible, probable, or certain, of a case of disease. The formation of a prognosis involves a great variety of considerations. Independent of the nature of the disease itself, the constitutional tendencies of the patient, hereditary or acquired, must be duly weighed; the age, the mental condition, the external circumstances, and many others have all to be taken into account. for instance, in a person threatened with consumption, who has lost relatives, more or less, from the disease, the prognosis must be a more unfavourable one than when the disease is apparently, if we may so speak, accidentally developed; or, again, in a case of disease of the heart, occurring in a man forced to engage in bodily labour for his bread, the prognosis will be of a graver character than when the same disease affects a man at ease as regards this world's goods.

When a medical man sees a patient, if the case be at all serious, either the individual, or surrounding friends, are usually very anxious PRIVIES .- In scattered rural districts it | for a prognosis, an opinion, as to the ultimate issue of the case. In many cases it is possible to give this decidedly, and at once, and if it can be, it ought to be done; but, in many cases, it is quite impossible to come to any conclusion, and at least a second visit, if not more, must be paid before a just idea of the

termination can be approached.

Some medical men are in the habit of giving, generally, a bad prognosis, that is, they express their opinion of the worst possibilities. This may arise from constitutional tendency to regard the dark side of matters, but more generally it originates in a selfish wish to serve their own reputation; if the patient dies, they are right; if he recovers, they have the more accordance with whether the receptacle is course, it is neither considerate nor honest, for credit in the cure. a fixed one, receiving ashes and excreta, or it sacrifices the feelings of relatives at least, to movable, for excreta only. In the former case a selfish expediency, and causes unnecessary the admissible capacity amounts to 8 cubic anxiety. In some measure, however, the

PRO PRO

public are themselves to blame in the matter, greased cloth, the person being of course laid from the little consideration often shown to a medical man, if his prognosis of a case turns out to be erroneous, especially if a favourable opinion has been given, and an unfavourable event ensued. It ought to be remembered that even in health, day by day, sudden changes to severe and dangerous illness, or to sudden death, are not unfrequent, -and if in health, how much more in illness, -changes, which it is impossible for the most skilful and observant Again, a medical man is often to foresee. most undeservedly censured in another way. A case is perhaps submitted to his examination at an early stage, before its more marked characteristics have shown themselves, and he perhaps gives an encouraging opinion; after a time, the case gets worse, more serious symptoms are developed, another opinion is taken, and this time the sentence of the first consulted is reversed; the last given prognosis proves correct, and, too often, without reflecting upon the altered aspect of the case in the one and in the other examination, the gentleman first consulted falls under the unjust imputations of those connected with the patient. The case is a common one.

The habit of giving a favourable prognosis when not justified by the state of the case, cannot be too strongly condemned. It is often practised with a view to sustain the spirits of the patient and others; but whilst every reasonable cheerful hope is to be held out, if death must close the case, for the sake of higher considerations than those of this world, for the sake of sparing the aggravated shock which must fall upon relatives when the fatal truth in all its intensity, and all its nearness, comes upon them, a tempered, it may be, but yet a true prognosis should be given.

Refer to - Death - Diagnosis - Opinion,

Medical.

PROLAPSUS is a slipping or falling down of any internal portion of the body, so that it appears externally. The term is most commonly used with reference to prolapsus, "falling down," of the womb (see Womb, &c.), and also to prolapsus or eversion of the lower gut at the fundament, "coming down of the bowel," as it is often called. This accident is bowel," as it is often called. This accident is not uncommon in childhood, and in the aged, but occurs at any age, frequently in con-nexion with piles. Coming down of the bowel often happens from children being permitted to sit too long on the chamber vessel, after a movement of the bowels; it is often, too, a consequence of straining, of irritation from worms, or of stone in the bladder. The extent to which the gut is protruded, varies from the slightest possible, to a considerable length, causing a red or purplish swelling, according to the length of time the protrusion has existed.

If quickly attended to, the protrusion is usually easily returned by pressure exerted by usually easily returned by pressure exerted by the hand through the medium of a piece of such as internal piles, which require a surgical

in the horizontal posture; or the forefinger should be oiled and introduced into the anus, when it will probably convey the protrusion with it, if, however, the protrusion has been neglected, and allowed to continue unreduced for some hours, it becomes in a measure strangulated, congested with blood, and consequently swollen, and is then sometimes very difficult to return; in such a case a medical man will probably be required, and, indeed, ought to be called; in the meanwhile, by gently squeezing the neck of the protrusion, and exerting gentle pressure upwards, having previously freely applied grease of some kind to it, efforts may be made to effect its return. When protrusion of the gut occurs habitually,

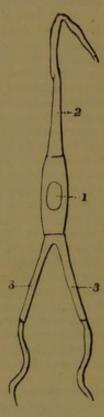

Fig. 171.

a medical man should investigate the cause, so that any source of irritation may be removed; the bowels should be kept perfectly lax, so as to prevent straining, and in children, especially, too long sitting at stool prevented, the seat being made so high that the legs cannot touch the ground.

Cold injections, and astringent lotions injected into the bowel are often useful. As recommended by Mr. Vincent, a small quantity of a solution of one grain of sulphate of iron to the ounce of rain or distilled water, may be thrown into the bowel after each relief, and retained. Bathing the loins regularly with cold water will be of service.

PRU

prolapus of the gut often experience much comfort from wearing the form of bandage, fig. 171. This consists of a sponge, which must be moistened, or a pad of some soft or smooth firm material, which is applied to the fundament, and kept in place by means of straps, which are best made of elastic material; the strap (2), fastening behind and (3, 3) in front to a belt passed round the body. A bandage something similar to fig. 22, article Bandage, will, with the requisite pad, answer the purpose.

Refer to-Piles-Rectum, &c.

PROSTATE GLAND.—See BLADDER. **PROTEINE**—a name formerly (and still) employed to denote the basic constituents of certain animal and vegetable principles of first importance in connexion with food and the structure of the body, and which are synonymous with the albuminates, albuminoids, or uitrogenous elements, as distinguished from such as contain no nitrogen. They comprise albumen, fibrine, and caseine, which are alike common to the animal and vegetable kingdoms, and other products such as syntonin, globulin, and keratin, exclusively belonging to the animal kingdom. Proteine bodies are identical in their chemical composition, containing always the same proportions of the four principal elements with a varying proportion of sulphur, though not exceeding 1.6 per cent. Soluble in their natural state, they are rendered in oluble, or, in other words, are coagulated, by heat and the mineral acids.

PROTRUSION of various portions of the body may take place either through natural or artificial openings. - See Prolapsus - Rupture,

PROUD FLESH. - See GRANULATION-ULCER, &C.

PROXIMATE CAUSE, in medicine, is the most immediately traceable cause of the symptoms of a disease, or of the death of a person; thus, dropsy following disease of the kidneys, liver, or other organs, or disease of the heart following rheumatism, become the proximate cause of the suffering, and very probably of their fatal termination.

PRUNES,—the dried fruit of the common plum, contain a considerable quantity of sugar, and when cooked, as stewed, are wholesome, and at the same time laxative (see Purgatives). Unless softened by stewing, prunes are indi-gestible. The bark of the Virginia prune is said to be sometimes used as a remedy in inter-

mittent fever.

PRURIGO-a papular affection of the skin, attended with troublesome itching. - See

PRURITUS.—Itching of the skin.—See Skin.

PRUSSIC ACID, OF HYDROCYANIC ACID, exists in the distilled waters, principally of the peach tribe, as of the bitter almond; but

operation for their removal. Persons liable to | pound of the three elementary gases, nitrogen, hydrogen, and carbon. Although called an acid, its acid properties are but feebly developed. The odour of hydrocyanic acid is powerful and peculiar, and pungent to the nostrils; it is often compared to that of the bitter almond. Pure prussic acid is sometimes prepared, but quickly decomposes; it is usually met with in a diluted form, and that which is used in medicine is, or ought to be, made of a certain regular strength. The uses of medicinal prussic acid in the hands of a medical man are most valuable; it acts as a powerful sedative, allaying pain, sickness, and nervous irritability; it is, too, a most admirable addition to lotions for various purposes; but in any form could not safely be had recourse to as a domestic remedy. Poisoning by prussic acid or by cyanide of potassium, a preparation largely used by photographers and containing prussic acid, is, unfortunately, not of rare occurrence; in most cases, life is destroyed so rapidly that little if any time is afforded for the employment of antidotes, at least, by a medical man; it is, therefore, important that the best remedies in such cases should be immediately had recourse to, although too often, from the powerful nature of the poison and the quantity swallowed, all is in vain.

When a large dose of prussic acid has been swallowed, "the symptoms may commence in the act of swallowing, or within a few seconds. It is rare that their appearance is delayed beyond one or two minutes. When the patient has been seen at this period he has been perfectly insensible; there is convulsive respira-tion at long intervals, and he appears dead in the intermediate time. The breath commonly exhales a strong odour of the acid. The finger nails have been found of a livid colour, and the hands firmly clenched. When a small over-dose has been taken, the individual has first experienced weight and pain in the head with confusion of intellect, nausea, and a quick pulse; although these symptoms are sometimes

slow in appearing."

Many antidotes have been proposed for employment in cases of poisoning by prussic acid, but few of them are likely to be available in so sudden, and generally so unlooked for, an emergency. The cold affusion—that is, water as cold as it can be procured, dashed freely over the body, the head and spine especially—is a remedy generally available. Ammonia, either in the form of sal volatile, or hartshorn, &c., is to be given and its vapour inhaled; or better still, but not so likely to be at hand, chlorine in some form. Thirty drops of the solution of chlorinated lime, or of chlorinated soda, may be given at once in a little water, their vapour being at the same time inhaled; this may be more abundantly evoked by the addition of an acid. Artificial respiration (see Opium) should be had recourse to. is usually formed artificially. It is a com- and galvanism, if available. To repeat: the

best antidotes are-cold affusions; chlorine, | and Health into one, with a Minister of State swallowed and in vapour; ammonia, swallowed

and in vapour; artificial respiration.

PSOAS.—Belonging to the loins. psoæ muscles are large muscles connected with the loins and spine. A psoas abscess is one originating in the loins.

PSORIASIS—a peculiar disease of the skin. - See Skin.

PTISAN, or TISANE—a vegetable infusion or docoction, generally of a mucilaginous character, which may be drunk freely by, and is given freely to, the sick. Barley-water is a ptisan. Ptisans are extensively used in France, and in many different forms. - See Drinks.

PTYALISM, or SALIVATION. The increased flow of saliva produced by the action of mercury on the system .- See Mercury.

PUBERTY is that important transition epoch in human life, when childhood passes into youth, the forerunner of manhood and womanhood. In English law, the time of puberty is considered in the male to be at fourteen years of age, in the female, two years later; but these periods must be generally considered quite sufficiently early, as regards this latitude at least; in warmer climates the period of puberty probably arrives a little sooner, but not so much so as has generally been imagined; as a great deal depends upon the natural constitution of the individual, and upon the influence of external circumstances. The important changes and excitements undergone by the constitution at the period of puberty, necessarily render it a critical period, when disease, to which a latent tendency exists, may be roused into activity. At this time, therefore, a stricter watch than usual should be kept upon the health of the young, and any unusual symptoms at once submitted to the judgment of a medical man. - See Menstruation.

PUBLIC HEALTH .- Progressive in most respects as this country is, it has been slow to initiate measures of a comprehensive and stringent character for the protection of the lives of the community, not so much from the apathy of the legislature as from the absence of unity of action and authority on the part of the separate bodies to whom such measures were Vestries, Boards of Guardians, relegated. Poor-law officers, with occasional instructions from the Privy Council, as well as Acts passed from time to time on the advent of an epidemic, or famine visitation, constituted the main apparatus for battling with disease in a national sense; and, as a consequence, legislative enactments passed for the benefit of the community were embarrassing in their operation, and too often became a dead letter. Until the Act of 1872 was passed, establishing the Local Government Board, and consolidating the various departments bearing on Poor-law relief | tion of a system organised by so many separate

for its president, it cannot be said that the Health of the Community was fully recognised

as an object of legislative control.

The Public Health Act of 1875; Powers of the Local Government Board:—The Act of 1872, followed by the Public Health Act of 1875, conferred large powers on the Board, to enable it to deal with subjects in relation to health, which had been but imperfectly attended to before; and as an important step towards unity of action, the country was divided into Rural and Urban districts, supervised by local boards, termed Sanitary Authorities, with Medical Officers and Inspectors of Nuisances attached, all subject in a greater or less degree to the central authority. To these separate agencies are referred the power of passing rules or bye-laws for the administration and building of workhouses, infirmaries, and asylums for contagious diseases; the planning of streets and houses; the direction of sewers, and the arrangements for water supply, for vaccination, and for the prevention of disease in its widest acceptation. In addition to these subjects, which have special reference to health, there are numerous clauses in the Act having a less direct application, and which deal more with the habits and customs of the people, -such as the regulation of markets, hackney carriages, public baths, and pleasure grounds, together with the removal of public and private nuisances,-the central authority being possessed of the power of enforcing its enactments through its Inspectors. The Board has also authority, should it appear necessary, to obtain money through the public funds on the security of the local rate to carry out all necessary improvements in a district.

Duties of the Medical Officers of Health:-The Medical Officers of Health appointed to separate districts are required to report periodically on the health of the population, the rate of mortality, the existence and incidence of epidemic disease, and the means of its prevention, or of checking its extension. They are armed with sufficient power to inspect premises where they have reason to believe a nuisance exists, and to take proceedings for its removal; to seize meat of any kind exposed for sale which they may deem unsuitable for human food; to inspect premises known to be in an over-crowded condition, and dangerous from the accumulation of filth and the want of suitable means of ventilation; to remedy or suppress nuisances arising from noxious vapours and offensive trades; to ascertain the course of drains and their numerous ramifications; and to give advice on all matters relating to the health of their several districts.

Bye-laws of the Local Government Board .-In questions involving so many complex problems, and public as well as individual interests, it was easy to foresee that the unifica-

PUB

sanitary authoriries must be a work of time | the house, the memorandum explanatory of the and labour, and accordingly the Public Health Act of 1875 provided for the issue, from time to time, of a series of Model Bye-laws by the Local Government Board, for the guidance of sanitary authorities, to aid and supplement the provisions of the Statute law. Apart from other Acts bearing on the Sale of Food and Drugs, on Workshops, Factories and Mines, and the Vaccination Acts, the Mcdel Bye-laws of the Local Government Board have special reference to thirteen distinct departments of the public health, of which the following is a summary :-

- Removal of nuisances.
- Prevention of nuisances.
- Common lodging-houses.
- 4. New streets and buildings.
- 5. Markets.
- 6. Slaughter-houses.
- 7. Hackney carriages.
- 8. Public bathing.
- 9. Baths and wash-houses.
- 10. Pleasure grounds.
- Pleasure boats and vessels.
- 12. Horses, &c., standing for hire.
- 13. Houses let in lodgings.

It will suffice, however, to refer here briefly to the Model Bye-laws which concern the first four sections of the above list, and it may be as well to state at the outset, that the Act of 1875 defines a nuisance to be any thing which by fouling the air may prove injurious to health.

- 1. Removal of Nuisances.—The first section respecting the removal of nuisances enacts that the occupier of any premises fronting the street is bound to cleanse the footways daily, and to remove weekly all house refuse from the premises; that he shall once, at least, in every three months, cleanse every earth closet and cesspool on such premises, and once, at least, in every week, cleanse every ashpit and every privy furnished with a movable receptacle for fœcal matter.
- 2. Prevention of Nuisances. The second section enacts that occupiers are bound under penalties to remove nuisances that may arise from snow, filth, dust, ashes, and rubbish of all kinds, in and around their premises, at reasonable intervals of time; and the law specially refers to the abatement of nuisances caused by keeping animals whose condition, if not carefully guarded, would prove injurious to health.
- Common lodging-houses, and the Dwellings inhabited by the Poor .- The Model Bye-laws of the third section, which relate to common lodging-houses, are equally applicable to other buildings inhabited by the poor, as they refer to conditions of wholesomeness for occupied buildings generally, and specially to the arrangements necessary to prevent over-crowd-

scope of the Bye-laws specifies that "the house should be dry in its foundations, and furnished with proper drainage, guttering, and spouting, and that its drains should have their connexions properly made, and that they should be trapped where necessary, and adequately ventilated. Except the soil-pipe from a properly trapped water-closet, there should be no direct communication of the drains with the interior of the house. All waste pipes from sinks, basins, and cisterns, should discharge in the open air over gullies outside the house. The soil-pipe should always be efficiently ventilated. The closets or privies, and the refuse receptacles of the house, should be in proper situations, of proper construction, and adapted to any scavenging arrangements that may be in force in the district. The house should have a water supply of good quality, and if the water be stored in cisterns, these should be conveniently placed, and of proper construction to prevent any fouling of water. The walls, roof, and floors of the house should be in good repair. Inside walls should not be papered. The rooms and staircases should possess the means of complete ventilation, windows being of adequate size, able to be opened to their full extent, or, if sash-windows, both at top and bottom. Any room that has not a chimney should be furnished with a special ventilating opening or shaft, but a room not having a window to the outer air can seldom be proper for registration."

accommodation in lodging-houses, the Memorandum states that in rooms of ordinary construction-that is to say, with means of ventilation by windows and chimneys-300 cubic feet of space ought to be secured for each person. "The house should possess kitchen and day-room accommodation, apart from its bedrooms, and such rooms as are partially under ground should not be used as bed-rooms. The amount of water supply, closet or privy accommodation, and the provision of refuse receptacles, should be proportionate to the numbers for which the house is registered. If the water is not supplied from works with constant service, a quantity should be secured for daily use on a scale per registered inmates of not less than ten gallons a day where there are water-closets, or five gallons a day where there are dry closets. For every twenty registered lodgers, a separate closet or privy should be required. The washing accommodation should, wherever practicable, be in a special place, and not be in the bed-rooms, and

With respect to the amount of sleeping

486

spread of such disease," by isolating the patient | thick; and if the flue is intended for use in in a separate room from the other inmates, or by seeing to his removal to a hospital at the request of the health-officer, and after death, or removal, shall have the room which the affected person occupied, together with the articles in it, cleansed and disinfected.

4. New Streets and Buildings.—The Model Bye-laws which refer to new streets and buildings, are of a most comprehensive character, and relate in detail to (a) the level, width, and construction of new streets, and the provisions of the sewerage thereof; (b) to the structure of walls, foundations, roofs, and chimneys of new buildings, for securing stability and the pre-vention of fires, and for purposes of health; (c) to the sufficiency of space about buildings to secure a free circulation of air within and without; (d) to the drainage of buildings, to water-closets, earth closets, privies, ashpits, and cesspools in connexion with buildings, and to the closing of buildings or parts of buildings unfit for human habitations, and to prohibition of their use for such habitation.

(a) Laying out of New Streets.—The Bye-laws enact that every new street should be laid out so as to afford the easiest practicable gradients, that if intended for a carriage-way, the street shall not be less than thirty-six feet in width, and if not intended for this purpose, the width shall be twenty-four feet at the least. also specified that, on each side of such street, a footway of not less than one-sixth of the entire width of the street should be constructed, sloping toward the kerb, which should not be less than three inches above the highest level

of the carriage-way.

(b) Erection of New Buildings.—With respect to new buildings, the Bye-laws prohibit the builder from constructing a foundation upon any site impregnated with animal or vegetable refuse, until such soil has been removed, and the ground surface asphalted or covered with a layer of concrete at least six inches thick, that the materials used for the building should be of the best quality, and that the footings of the walls should project on each side to an extent equal to one-half of the thickness of the wall at its base. A damp-course of slate, or other durable material impervious to moisture, must be placed beneath the level of the lowest timbers, and at a height of not less than six inches above the surface of the ground. The strength of the walls of new buildings is determined by the height of the respective stories, and varies from nine inches in thickness, in the one-story building, to twenty-six inches in thickness at the base, and up to the height of the first story, in a building one hundred feet high, gradually diminishing as it ascends through the different floors. danger of fire from smoke-flues becoming ignited, it is rendered imperative that, unless the flue is constructed of fire-proof piping of stone-ware, it shall be secured in cement at least one inch | the removal to them of persons suffering from

connexion with a close range, stove, or steam boilers, for purposes of cooking, or for manufacturing, or business purposes, it must be surrounded with brick work, at least nine inches thick, for a distance of ten feet at the

least in height from the floor.

(c) Area for Ventilation .- With respect to sufficiency of area to admit of free ventilation, the Model Bye-laws enact that, in building a house, provision shall be made that it shall be free in front to a distance of not less than twenty-four feet, and that a space of not less than 150 square feet exclusively belonging to such building shall be left open in the rear, free from any erection save a privy or an ashpit. To insure interior ventilation, it is provided that in the wall of each story of the house which fronts the open spaces, there shall be a sufficient number of windows communicating directly with the external air, that in every habitable room a window shall be placed, and in the event of the room being without a fireplace, a flue, properly constructed, is to be provided, with a sufficient aperture or air-shaft, giving an unobstructed sectional area of one hundred square inches at the least. It is also expressly enacted that the rooms on the ground floor of a new building shall be provided with a boarded floor, under which there shall be a clear space of at least three inches in every part, ventilated by means of air bricks in the walls.

(d) Drainage and Disposal of Sewage. -The Model Bye-laws are minute in their details with respect to the drainage of buildings, and enact that every one erecting a house shall cause the subsoil, if damp, to be drained by earthenware pipes in such a manner that they will not communicate readily with any drain containing sewage; that all drains intended for sewage shall have an internal diameter of not less than four inches, to be laid in a bed of concrete with a proper fall, and shall be furnished with water-tight joints. That such drains, unless any other mode of construction is impracticable, shall not pass under any building; that they be furnished with suitable means of ventilation at points between the main drain or other drains of the building with which they may communicate, such ventilating openings in every case to be situated on the side of the trap nearest to the building. Numerous other arrangements with regard to drainage and disposal of sewage are given in detail, besides minute instructions respecting water-closets, earth closets, ashpits and cesspools in connexion with buildings, which our limited space forbids us further referring to here.

Hospitals for Contagious Diseases.—One important function of the Sanitary Authority, however, must not be omitted in this summary. It relates to the power which the Public Health Act allows for the establishment of hospitals for the isolation of infectious disease, and for infectious complaints, who cannot be conveniently or safely treated at their own homes. It also empowers the Sanitary Authority to destroy infected bedding and clothes, to disinfect, cleanse, and whitewash premises which have been occupied by persons suffering from infectious disease, and to erect mortuaries in populous districts, or wherever they are likely to be required.

The Act likewise makes provision to enable the Sanitary Authority to obtain a suitable water supply for a district, and requires that measures shall be taken to prevent its pollu-

tion from extraneous causes.

This short summary of the more important provisions of the Public Health Act, in addition to what are furnished by the Vaccination Act, and other Acts of Parliament bearing on various trades as well as the customs of the people, shows the large powers which the legislature has conferred on the various local authorities throughout the country, for the prevention of disease, and of the causes which occasionally lead to its extension. The metropolis is now governed by the Public Health (London) Act, 1891.

Throughout the kingdom, the various sanitary enactments have been the silent means of doing an immense amount of good in saving life, and in promoting the health of the population, and it mainly rests with the people themselves still further to increase their usefulness by aiding the exertions of those to whom the duty of superintending their operation is entrusted.—See Air—Drainage—Earth Closet

-House-Ventilation-Water-closets, &c. PUDDINGS are articles of diet, the principal ingredient of which is some farinaceous material, at least such ought to be the case, when they are made for invalids. The puddings most generally admissible, and best adapted for the sick-room, are, the light egg and flour, or "twenty minute" pudding, as it is often called; the simple rice, sago, or tapioca pudding, the boiled bread pudding, &c. In making baked puddings, the eggs are generally put in previous to baking, and in general cookery this may answer very well; but when nutriment, and at the same time extreme lightness, are requisites for an invalid extreme lightness, are requisites for an invalid, it is better to cook the farinaceous article, such as sago, bread, or whatever it may be, thoroughly in the milk, and whilst it is perfectly hot, to break the egg into it, and beat them well up together; in this way the egg is quite sufficiently cooked, but its albumen is not hardened, as it must inevitably be, when baked along with the other materials.

Of course, greasy puddings generally are unsuited for invalids, and for the same reasons butter or sauce must be forbidden.—See Cookery for the Sick.

PUERPERAL. - Connected with childbed. - See Child-bed.

PULMONARY. — Connected with the lungs.

PULSE.—The term pulse may be applied to the beating of the heart and arteries generally, but it is more usually restricted to the sensible beat or stroke of an artery which is felt by the finger placed over and slightly pressed upon the vessel; popularly, the pulse is considered to be confined to the wrist alone. The pulse or beat of an artery is felt simultaneously, or nearly so, with the beat of the heart, which takes place as each contraction of that organ sends a wave of blood through the arteries; the elasticity and muscular properties of those tubes, influencing in a considerable degree the "character" of the pulse. — See

Artery-Circulation-Heart, &c.

The sympathetic connexion of the central organ of the circulation, and indeed of the circulating system at large, with changes and states of the whole system, renders the pulse a most important guide in the investigation of those states and changes; it is, however, a guide which it requires much education and no little practical experience fully to take advantage of. It may have appeared to some, that throughout this work generally, when different diseases have been treated of, the state of the pulse has been comparatively little noticed; the previous sentence affords the explanation, which is, that to feel a pulse properly, and to gather from the feeling, any real, definite, trustworthy information, requires more practical knowledge than unprofessional persons usually possess; consequently, the author has preferred directing attention, in most instances, to symptoms more palpable, more easily appreciated, and less likely to mislead the uninitiated. If the frequency of the beats of the pulse were an unvarying indication of the state of the system, and if the knowledge as to frequency, or the reverse, were all that could be gathered from feeling it, the case would be abundantly different; but with certain reservation, the frequency of the pulse is, in many cases, a far less important piece of information to a medical man than its rhythm or tone; whether it be full and bounding, or jerking, or soft, or wiry, or compressible, feeble, or remittent, or intermittent; all these and other varieties of pulse convey impression to the mind of a medical man, but the ability to receive these impressions, and to form conclusions from them, is only the result of daily, almost hourly practice. It is unnecessary to say more to show how very slight and imperfect the information must be which a casual feeler of the pulse can gather from the operation. At the same time, the author would not discourage persons, such as the clergyman, or nurse, or the intelligent emigrant, from endeavouring to gain some practical knowledge respecting the pulse; but the above will show that useful knowledge must be attained, either assisted or unassisted, by practical attention and persevering availment of opportunities.

The average pulse of a healthy man in the

488

prime of life, may be taken as beating 72 times | the same disease, and which are also influenced in the minute; but from this average there is every possible variation, and even in the same individual the pulse varies greatly, according to the period of the twenty-four hours; according to the times of meals; to the posture, whether recumbent, in which it is slowest, or sitting or standing, in which it is most frequent; it varies also according to physical exercise or mental emotion, and also according to external temperature.

In some persons the pulse is always quick, ranging at 90, or even more; in others it is slow, perhaps does not exceed 40 beats in the minute. Age influences greatly the frequency of the pulse. The following is the table drawn

up by M. Quetelet:-

Age.				Average of Pulsations per minute.	
Birth,					136
5 years,					88
10-15,					78
15-20,					69
20-25,					69
25-30,					71
30-50,				-	70

According to other observations the pulse in many children is found not to be more frequent than it is in adults; as a general rule, however, it is so. It is, moreover, a generally received opinion, that the pulse of the aged is slower than that of the young; the reverse is the fact.

As a general rule, when the system at large is in a state of excitement, feverish or otherwise, the pulse is increased in frequency, and modified; in depressed states of the system, unless accompanied with irritability, the contrary takes place. In affections of the brain causing pressure on, or oppression of that organ, the pulse is usually slow. If a particular por-tion of the body be inflamed, such as the hand or foot, the pulse in the artery going to the part is increased in force, or in the power of its beat, but of course not in frequency, unless the entire circulating system is equally excited.

Most are aware that the pulse is distinguishable at the wrist, about an inch above the ball of the thumb, the pulsating artery lying by the side of the strong tendon of a muscle of the fore-arm. The pulse is felt by the fore and

middle finger together.

Disease, of course, increases or diminishes the pulse, but other causes have a corresponding influence, such as the mental emotions expressed by fear, joy, or anger; while many people have constitutionally slow, rapid, or irregular pulses. All these refer to the question of counting, but apart from the quickened or retarded action of the heart, the impressions conveyed to the fingers by the pulse are often of the greatest importance. The three best marked characters are the hard, soft, and wiry pulse, which occur often in various stages of edly, also by the mechanical bulk of their

by external causes, such as heat or cold, or from within by stimulants and the action of remedies. We naturally look for a slow pulse in persons suffering from extreme weakness, either from privation or exhaustion; but when the debility is extreme, as in profuse hæmorrhage, the pulse becomes alarmingly quick, and the symptom must be regarded as dangerous. The quick pulse, conveying every variety of feeling to the fingers, is the ordinary accompaniment of all inflammatory complaints, as well as fevers of every description. The irregular and intermittent pulse points generally to disease of the heart, though not necessarily so, as it is not uncommonly met with among people of low nervous tone, and is often a symptom of hysteria. Lastly, the pulse becomes imperceptible in the fainting state from failure of the heart's action, and if not restored, death from syncope must ensue, a comparatively rare occurrence, but the absence of pulse always shows the necessity of prompt action to restore animation. In such cases, the best stimulant is plain cold water, dashed on the face, but if internal stimulation is thought to be necessary, those agents are to be preferred which act promptly by diffusing their action throughout the system, such as ammonia, ether, and strong spirits. Pulse glasses, for counting the pulse on the principle of the sand glass, and which run for fifteen seconds, are sold by the instrumentmakers. These are found useful for nurses and others interested in the sick, and who may not be possessed of a watch with a minute hand wherewith to count the pulsations.

Refer to—Artery—Circulation—Heart, &c. PUMP, STOMACH, is an instrument which ought only to be used by a medical man,

PUMPS, for water, when made of lead, are apt to prove dangerous. - See Lead - Water,

PUNCTURED WOUNDS.—Refer to WOUNDS

PUPIL.—See EYE.

PURGATIVES are medicinal substances which excite and accelerate the muscular movements of the alimentary canal, and increase the discharge therefrom. For the sake of convenience, under the head of purgatives, aperients generally are treated of. These are divided into:

Laxatives—Purgatives—Drastic Cathartics. A further class of "hydragogue" cathartics is also recognised (see Hydragogue). Laxatives, which gently increase the natural movements of the bowels may be arranged as dietetic, mechanical, and medicinal. Dietetic laxatives are chiefly vegetables and fruits of various kinds, honey, treacle, preparations of the grains, cold water, malt liquors, bacon, &c., but many of these act mechanically also. Most succulent vegetables and fruits act upon the bowels by virtue of their peculiar nature, but, undoubt-

PUR PUR

refuse. Of the mixed dietetic and mechanical laxatives, the farinacea or grain substances are the most important; these owe their property entirely to the presence, either whole or ground, of the external covering or testa of the grain, as in the case of bran bread, or of Scotch oatmeal. The flour of the Egyptian lentil, or Revalenta Arabica, is almost medicinal in its power of relaxing the bowels. The seeded fruits, such as currants, gooseberries, &c., fall under the head of mixed dietetic and mechanical laxatives.

The purely mechanical aperients are not numerous; whole mustard seed, and the common dried currant, as it is often given domestic-

ally, are examples of the class.

Injections may be classed under the head either of purely mechanical or of medicinal aperients, according to their nature (see Enema). The following table includes the principal aperient and purgative medicines which may be used domestically :-

I. LAXATIVES.

Almond oil. Cascara Sagrada. Cassia pulp. Cream of tartar.

Honey. Magnesia. Manna. Olive oil,

Phosphate of soda.

Prunes. Sulphur. Tamarinds.

II. PURGATIVES.

Aloes. Castor oil. Epsom salts. Euonymin (according to dose). Glauber salts. Iridin (according to dose). Jalap.

Blue pill. Mercurials { Calomel.

Grey powder.

Rhubarb. Tartrate of potash and soda. Senna.

III. CATHARTICS-DRASTIC.

Colocynth. Scammony.

The two cathartics put down may be used domestically,-indeed, the first is every day used in the form of the compound colocynth pill. Croton oil, elaterium, gamboge, and podophyllin are included in the drastic cathartics; but, except under peculiar circumstances, ought only to be administered by a medical man. For details respecting the various aperient agents above mentioned, the reader is referred to the individual articles.

Purgative or aperient medicines are, unquestionably, much more generally had re-

than any other form of remedial agents, but while it is undoubted that their use is great, it is also certain that they are, and have been, very greatly abused. It is intended to consider, first, the use of aperients, and, secondly, Under such articles as Alimentary the abuse. Canal, Digestion, &c., it has been sufficiently explained how the food mass, after undergoing its principal digestion in the stomach, is gradually propelled through the entire tract of the bowels, and how, during this propulsion, its nutrient constituents are absorbed from it, the refuse being left for discharge; it has also been explained that the discharge from the bowels does not consist simply of the food refuse, but contains also various secretions and excretions thrown out into the bowels from the general system, which excretions cannot be retained in the system without injury to

From these considerations it must be obvious to all how great the importance, not only that the bowels should be active as regards the excretions into them, but as regards their own discharge, both of these excretions and of the food refuse. When the bowels are inactive in these respects, the state is termed Constipation, or costiveness. As, under the former term, the reader will find the evils which result from this condition, and also its most frequent causes, &c., sufficiently explicitly stated, it is unnecessary to repeat the information here. the same article will be found an explanation of those general remedies which are most useful in removing the condition; and, indeed, when they prove sufficient, are certainly to be preferred to medicinal agents; when they do not prove sufficient, either as temporary or permanent means of relief, the purgative or aperient medicines must be employed-under the general rule that they should never be used stronger than requisite. By this it is not meant that because manna, or sulphur, or magnesia are classed in the laxatives, they are always, when possible, to be substituted for the purgative aloes, or castor oil, or rhubarb, or senna; such a distinction could not be observed without other and greater counterbalancing inconveniences; but the rule should be, that relief to the bowels is to be afforded with as small an amount of purgative action as possible, unless that purgative, or, in other words, lowering action, is called for as a part of the treatment, as it is in persons of very full habit of body, &c.

Where aperient medicines are either taken or given domestically, there is often too little care in the selection: unless it be in pregnancy, or in consequence of individual experience, the idea seems to prevail with many, that one aperient is as good as another. This is far from being the case.

Except in persons whose bowels are very easily acted upon, or in such cases as those course to, both by medical men and the public, where the aperient is taken rather to give addi-

tional action than to open the bowels, the affections, free purging is one of our most "laxative" aperients are scarcely sufficient as general aperients; those classed as purgatives, and the cathartic colocynth, under the form of its well-known compound pill, are in daily use.

There are few ailments in which increased action of the bowels is called for, in which one or other of the aperient remedies in the list will not be applicable. Aloes is valuable for certainty of action on particular portions of the bowels, for the small bulk of its general dose, for its tonic bitterness and continued effect even after frequent repetition, but it must be used carefully in pregnancy, piles, and other affections situated about the lower part of the canal. Castor oil is recommended by its safety in almost all cases, by its certain, perfect action, and like aloes, by its not losing effect by repetition; but, unfortunately, it is too often the medicine most disliked and sickened at. It is one of the greatest desiderata in medicine to obtain an article which should combine all the advantages of castor oil with a less disagreeable taste, and with less tendency to cause sickness, as well as being less bulky. It has been sought for in vain among the numerous oils belonging to the same natural family, for although some of them are very good, they are uncertain in their action. The lately introduced "Tasteless Castor Oil" of Messrs. Allen & Hanbury, has done much, however, to do away with the objections to such a useful medicine.

One of the most useful substitutes for castor oil is the syrup of the Rhamnus frangula. It is pleasant to take, gentle in action, and tolerably certain. Epsom salts require much discretion in use, but have deservedly thrown Glauber salts into disuse. Jalap is certain and active, but is apt to gripe and to sicken, and its bulk is an objection. Mercurials alone, or followed by easter oil or senna, or combined with aloes, rhubarb, or colocynth, although most valuable, are most abused. Rhubarb, mild, and with some persons effectual, is also tonic, but is apt to heat, and its bulk and taste are an objection, especially with children. Rochelle salts, similar to Epsom salts in action, is pleasanter. Senna, the medicine of the nursery, is invaluable, and if properly prepared, is safe and certain.

Colocynth, in its well-known compound pill, forms part of the most generally used and useful purgative in costive habits. Scammony is, in many of the affections of children, especially when combined with a mercurial, our most valuable purgative, and is recommended by the small bulk of its dose. - See articles on all the above-mentioned.

Purgatives, however, are used, not only as a means of clearing the bowels of their contents, but also as agents for the relief of those organs, such as the liver, which are closely connected with the bowels; and further, as remedies calculated to relieve distant parts,

powerful remedies; in congestion of the liver it is most serviceable; in overfulness of the system at large, it relieves greatly. To the above fact, nature strongly points in those cases in which sudden and striking relief often follows an attack of spontaneous purging or diarrhea.

The abuse of aperient medicines owes its origin, probably, to a variety of causes. Constipation, either alone, or as a concomitant of disease, is so obvious and common a symptom; it so often occasions distress, or at least uncomfortable sensations, its removal is generally so simply effected, and often is so sensibly felt as a relief, that it cannot be matter of surprise if both doctor and patient, habitually almost, look to the action of the bowels by purgative medicines as almost the requisite preliminary to all other treatment, and within certain limits they do right; but the fatal facility of the treatment, assisted moreover by the powerful advocacy which it has received in years gone by, has certainly produced a far too general use of aperients as purgatives, not simply in the treatment of acute disease, but as a general rule of daily life. If the question be put-Which is the greater evil of the two, to have the bowels habitually confined, or habitually to take aperient medicines? there can be no question, if the choice must lie between the two evils, that the latter is the lesser one; but there are few cases in which the choice is so circumscribed. The bowels probably are confined, but they are so because the general conditions requisite for their healthy action (see Constipation) are neglected, and because the aperient medicine is used as the readiest substitute for a little trouble and perseverance. Thus used, the aperient is abused, and injury, more or less, is inflicted upon the system, according to the nature of the medicine, the frequency of its use, and the strength of the dose. One most general effect of the abuse of aperients, is the weakened digestive power of the stomach, another, the weakness of the system at large; and a third, not unfrequently, is continued irritation of some portion of the alimentary canal. The weakened digestion which follows the abuse of aperients may not be obvious at first; indeed, if the digestive organs have been overloaded and oppressed, instead of being weaker after an aperient, they are actually more active, and this apparent increase of activity is very apt to lead to a too frequent renewal of the remedy, and too often, trusting in the remedy, to a continuance of those habits of excess which caused the first disorders (see Indigestion and Pills). The debility of the system which follows the abuse of aperients is the natural result of the digested food mass being hurried too rapidly through the bowels to admit of its nutrient portion being taken up and conveyed into the system; debility is also the result of the too frequent employment or the system generally. Thus, in many head of purgatives, such as the salines, which in-

PUS

crease unnecessarily the discharges, especially | of the serous portion of the blood, into the bowels. Further, the too frequent use of purgatives irritates the bowels by depriving them of their natural protective mucus; in this way

ulceration may result.

As a natural consequence of the food mass and of the secretions and excretions, such as the bile, being hurried too quickly into and through the bowels, and also of the mucus being carried off too abundantly, the stools, under the continued use of purgatives, assume an unhealthy character; perhaps contain too much bile, &c., and in consequence of this unhealthy appearance, and with a view to its correction, persons are too often induced to continue the very cause of its production, and go on purging. This is a very common case.

In connexion with the foregoing article, the reader is referred to Alimentary Canal-Biliary Disorder—Digestion—Indigestion — Con-

stipation, &c.
PURGING FLAX, the Linum catharticum, deserves especial notice from the fact of its being a plant commonly native to this country, and often used as a domestic remedy, although not generally prescribed by medical men, nor, indeed, as much as it might be, for it is well understood to be an "excellent cathartic." The purging flax is a slender plant, about six or eight inches in height, with smooth, narrow leaves placed opposite upon the stem; it blossoms about the end of June, and the flowers, which are small and white, are "grace-Every part fully drooping before expansion." of the plant is bitter. One drachm of the dry powdered leaves, or two or three drachms of the fresh plant, in the form of infusion, will, according to Sir R. Christison, act briskly upon the bowels, without causing either sick-

ness or griping. PURPURA, popularly "The Purples," is a disease in which the blood escapes from the smaller or capillary vessels; it is best known from its outward manifestations on the skin, on which account it is often, but erroneously, classed as a skin disease, whereas it is truly a constitutional affection, which, although most visibly manifest on the skin, yet exhibits its effects in various internal portions of the body. The attack of purpura may be sudden, or it may be preceded for a week or more by symptoms of general illness, lassitude, feebleness, &c. Purpura generally first shows itself on the legs, in the form of red or purple spots of various sizes, which do not elevate the skin, and do not disappear on pressure; in the course of a few days these spots become changed to a brown or greenish-yellow; in fact, they go through the same changes in colour that we see in a bruise, in which, as in purpura, effusion of blood has taken place beneath the skin. The above description applies to purpura in perhaps its mildest form; when more

the body, and blood is discharged from the mucous membranes of the nose, mouth, stomach, bowels, bladder, &c., and in fatal cases it has been found effused into the substance of the brain. The hæmorrhage is always a dangerous symptom, and may occur either alone, or in connexion with other diseases, such as fevers, measles, small-pox, &c. Such a disease as purpura is of course not one for domestic management, and ought, if possible, on its earliest appearance, to be confided to proper medical care. It may occur in the strong and plethoric, in which case, of course, lowering measures, perhaps bleeding, may be called for, or at least free purging, with calomel and jalap, or calomel and colocynth; the administration, two or three times a day, of one or two drachms of Epsom salts, dissolved in water, each dose being acidulated with fifteen drops of diluted sulphuric acid, would be very suitable treat-

Most frequently purpura is a disease of debility, and requires treatment the very reverse of lowering; quinine in grain doses, three or four times in the twenty-four hours, will be useful, along with strong animal broths, wine, or porter, and tonic remedial measures gene-Turpentine in ten or fifteen-drop doses, rally. given three or four times in the twenty-four hours, or tannic or gallic acid in six or eightgrain doses, three or four times daily, have proved invaluable remedies. Having been found useful in different species of hæmorrhage, the juice of the common nettle might, in places where other remedies are not procurable, prove

of service.

Where the tendency to purpura exists, with debility, means of strengthening should be resorted to which have been recommended under article Debility. In every case, however, whether threatened or actual, a medical man must be called without delay.

PURULENT-consisting of pus or mat-

ter.—See Pus.

PUS, or MATTER, is, or rather ought to be a smooth, yellow, cream-like fluid; when warm it exhales a faint sickly odour. Under the microscope, pus is seen to consist of granular corpuscles, somewhat larger than the globules of the blood, which float in a transparent serous fluid. The above are the properties of healthy pus, which, however, may differ very greatly from the standard; it may be thin, and serous, or flaky as it is in a scrofulous abscess; it may be bloody, it may be feetid, &c. Pus is a consequence of inflammation, its formation is, in fact, the "termination" of that process by "suppuration" (see Inflammation), and may be formed in various situations and textures. It is the most general secretion from an ulcer. When contained in a cavity formed in the substance of any of the bodily tissues, it constitutes an abscess; it is a frequent consequence of inflammation, either of mucous or of severe, the spots or blotches are spread over serous membranes, in the one case constituting

e purulent discharge, in the other, a purulent | it continues after death. The most remarkable effusion, such as takes place into the chest. In some cases it is extremely difficult to distinguish the mucous, purulent, and mucopurulent discharges from mucous membranes, from one another. Less importance is now attached to the distinction than formerly.

Refer to — Abscess—Inflammation — Ulcer-

PUSTULES are elevations on, and partly in the skin, which contain matter. A pustule may commence as such, when it is usually conical in shape, or it may commence as a vesicle, as in the cases of small-pox or cowpox; the vesicle, in the first place, containing transparent lymph or fluid, and its contents afterwards becoming purulent, constituting it a pustule.

Refer to-Skin, Diseases of

PUSTULE, MALIGNANT, sometimes known by its French name, Charbon, is a species of carbuncle produced by inoculation from some infected source, such as the sting of an insect, or the cut of a poisoned knife, or from eating the flesh of an infected animal. The part affected proceeds rapidly through various stages to gangrene, and often causes death by blood poisoning. The treatment consists in the destruction of the infected part by caustics, or by the introduction of carbolic

acid into the swelling. This may be done either by threads saturated with the acid passed through, or by the hypodermic needle.

PUTREFACTION, or PUTREFACTIVE FERMENTATION, is the peculiar chemical change undergone by many organised bodies after death. The following extracts on this subject from Liebig's Letters on Chemistry, are full of interest and instruction:—"The are full of interest and instruction:-"The proximate cause of these changes, which occur in organised bodies after death, is the action of the oxygen of the air on many of their consti-This action only takes place when water, that is, moisture, is present, and requires a certain temperature. This influence of atmospheric oxygen is very distinctly seen in fruits and other soft parts of vegetables, when, by an injury to their surface, the juice comes into direct contact with the air. When an apple is bruised at one point, a process of decomposition begins from the injured part; a brown spot appears, which increases in a regular concentric circle, till at last the whole apple becomes rotten, or is changed into a brown, soft, viscid mass." "In like manner, a process of decomposition sets in, after death, in the bodies of men and animals, which begins in the inside, in those parts, such as the lungs, which are in contact with the air. When there are wounds, it spreads from them, and in diseases from the diseased part; so that, in many cases, death itself is nothing else than the result of a decomposition going on in an inward part; with the disease, of which it is the proximate cause, this process begins, and | duced to the following:-

of these phenomena is certainly this, that in many cases, the change once begun in organic matters, continues when, after transient contact with the air, the atmospheric oxygen is entirely excluded." "All these processes of decom-position which begin in a part of an organic substance, from the application of an external cause, and which spread through the whole mass, with or without the co-operation of that cause, have been called the processes of putrefaction." "The number of substances occurring in nature which are truly putrescible, that is, capable of putrefaction, is singularly small; but they are everywhere diffused, and form part of every organised being. Before all other substances, this property of putresci-bility belongs to the highly complex matters of the animal and vegetable kingdoms, which contain nitrogen and sulphur, such as albumen, fibrine, caseine, gelatine, and the like." One of the most remarkable properties of putrescible substances is their power of excit-ing fermentation in bodies capable of this

change. - See Fermentation.

"The grand natural process of putrefaction, of the dissolution of all compounds formed in living organisms, begins immediately after death, when the manifold causes no longer act, under the influence of which they were produced. The compounds formed in the bodies of animals and of plants undergo, in the air, and with the aid of moisture, a series of changes, the last of which are the conversion of their carbon into carbonic acid, of their hydrogen into water, of their nitrogen into ammonia, of their sulphur into sulphuric acid. Thus their elements resume the forms in which they can again serve as food to a new generation of plants and animals. Those elements which had been derived from the atmosphere take the gaseous form and return to the air; those which the earth had yielded return to the soil. Death, followed by the dissolution of the dead generation, is the source (medium?) of life for a new one. The same atom of carbon, which, as a constituent of a muscular fibre in the heart of a man, assists to propel the blood through his frame, was, perhaps, a constituent of the heart of one of his ancestors; and any atom of nitrogen in our brain has, perhaps, been a part of the brain of an Egyptian or a negro. As the intellect of the men of this generation draws the food required for its development and cultivation from the products of the intellectual activity of former times, so may the constituents or elements of the bodies of a former generation pass into and become parts of our frames.

"Finally, by a knowledge of the causes of the origin and propagation of putrefaction in organic atoms, the question concerning the nature of many contagions and miasms becomes capable of a simple solution, and may be re-

498

PUT

"Are there facts which prove that certain | states of transformation or putrefaction in a substance are likewise propagated to parts or constituents of the living animal body; that, by contact with the putrescent matter, the same or a similar condition is produced on such parts as that in which the particles of the putrescent body are? This question must be decidedly answered in the affirmative.

"It is a fact that dead bodies in dissecting rooms frequently pass into a state of decomposition, which is communicated to the blood in the living body. The slightest cuts with the scalpel used in dissecting often cause a very dangerous, and even fatal, disease. The observation of Magendie, that putrid blood, brain, bile or pus, when laid on fresh wounds, produce in animals vomiting, languor, and death, after a longer or shorter interval, has

not yet been contradicted.
"Further, it is a fact, that the use of various articles of food, such as flesh, ham, sausages, if in a certain state of decomposition, is followed in healthy persons by the most dangerous and even fatal symptoms.

"These facts prove that animal matter, in a certain state of decomposition, is capable of exciting a morbid action in the body of healthy individuals. Now, since by the term products of diseased action, nothing else can be meant than parts or constituents of the living body, which are in a state of change, in form and quality different from the normal one, it is evident, that so long as this state continues, and the change is not completed, the disease may be communicated to a second or third

individual, and so on.

"Besides, when we consider that all those substances which destroy the communicability or arrest the propagation of contagions and miasms, are likewise such as arrest all processes of putrefaction or fermentation; that under the influence of empyreumatic bodies, such as pyroligneous acid, which powerfully oppose putrefaction, the diseased action in malignant suppurating wounds is entirely changed; that in a number of contagious diseases, especially in typhus, ammonia, free or combined, is found in the expired air, in the liquid and solid excreta-in the latter as ammonio-phosphate of magnesia-it seems impossible any longer to entertain a doubt as to the origin and propagation of many con-

tagious diseases.

"Finally, it is an observation universally made, and which may be regarded as established, that the origin of epidemic diseases may often be referred to the putrefaction of great masses of animal and vegetable matters; that miasmic diseases are found epidemic where decomposition of organic substances constantly goes on in marshy and damp districts. These diseases also become epidemic, under the same circumstances, after inundations; and also in places where a large number or so-called zymotic diseases.

of persons are crowded together with imperfect ventilation, as in ships, in prisons, and in besieged fortresses. But in no case may we so securely reckon on the occurrence of epidemic diseases, as when a marshy surface has been dried up by continued heat, or when extensive inundations are followed by intense

In connexion with the above, the following instructive anecdote is related in the appendix to the publication from which the foregoing

extracts are taken :-

"In order to procure a roast for Easter, C-, in R-, desired his family to set a snare for a roebuck. Accordingly, one of these poor animals was caught in the snare, which as its head and breast had passed through, held it by the hinder part of the body, the abdomen and pelvis being enclosed in the cord, so that it must have succumbed after a most agonising struggle. It was found next day dead.

"The master and mistress of the family ate on Easter-day the best part of the dainty; the servants had little; the remainder was laid in

vinegar, but not eaten.

"On the same day, all in the family who had eaten of the venison observed a striking dryness of the mouth, oppression at the stomach, and nausea; the features in all became anxious and pale; all complained of oppression of the head, giddiness, and great weariness of the limbs. The master lost his sight for several days, and, in short, there now began a series of remarkable symptoms, requiring in many ways the assistance of a medical man. The husband was only restored to health in July, but the wife never recovered: she lingered more than two years, and at last died after severe sufferings. The daughter, the man servant, the maid who had eaten little of the tortured animal, were soon cured. The symptoms in many respects recalled those of the effects of the bite of rabid animals, and of the sausage poison of Würtemberg.'

Modern research has established conclusively that putrefaction is always due to the action of microscopic organisms known as bacteria. If by means of exposure to heat or by chemical antiseptics the bacteria are destroyed or rendered inactive decomposition ceases to take place; on the addition of the bacteria the processes of putrefaction recommence. The bacteria when present under suitable conditions reproduce and multiply with extraordinary rapidity; when conditions are not favourable for their action they may exist for long periods of time in a dormant condition. As they abound in atmospheric air and in all kinds of dust they are always ready to attack any putrescible substance. Of recent years the study of these organisms has become a science known as bacteriology, and much light has been thown on their action, not only in promoting putrefaction, but also in relation to infectious

The extreme interest and importance which | is doubtful; it is sometimes derived from surround the processes of putrefaction, must be the apology for the length of the above extracts on the subject, from one of the first authorities on these matters. Whether we regard putrefaction in a sanitary or medical point of view, as the originator of disease, when favoured by man's ignorance or carelessness, or as the process by which the material atoms of a generation which has passed away are again started on their mission to furnish material clothing for a generation living or to live, our attention is alike deserved.

Refer to—Fermentation—Germs of Disease. PYÆMIA, SEPTICÆMIA, and BLOOD-POISONING, are used often synonymously to denote a morbid condition of the blood attended with fever, consequent on infection from wounds, suppurative inflammation of bones, the puerperal condition, and surgical The blood is poisoned by its operations. absorption of disease products, and abscesses form in the internal organs, especially in the lungs and liver, often in the joints, and occasionally in the skin. In many cases the large veins in the neighbourhood of the primary wound become subject to inflammation, and from this cause the disease was at one time termed phlebitis. As a rule, pyæmia is a disease of an acute and alarmingly fatal character, though it occurs occasionally in a chronic form, continuing for months and without any wound or injury to account for the symptoms. It commences with rigors and high temperature of the blood, followed by copious perspiration; the countenance is anxious and depressed, and there is great sleeplessness and restlessness present. True pyæmia is almost invariably fatal, but some of the milder forms of the disease, to which the term Septicamia is applied, recover. Pyamia and other forms of Septicæmia or blood-poisoning are primarily due to the introduction into the blood of various forms of noxious bacteria. whose presence can frequently be demonstrated by microscopic examination combined with methods of culture. These bacteria may enter the blood from the air through an exposed wound, or may be introduced by the contact of septic hands or instruments; not improbably in some cases they find entrance through the alimentary canal. Since the introduction of antiseptic surgery by Lord Lister, the disease, as a cause of death after surgical operations and injuries, is a rare event.

QUACK, QUACKERY, and QUACK MEDICINES.—The origin of the term quack

Quacksalber, the German for a quack, or vendor of quack medicines, which, again, may perhaps be traced to Quecksilber, quicksilver, or mercury, which was first used by irregular practitioners. However that may be, the terms "quack" and "quackery" are not now confined to medical matters, but are applied generally to those who pretend to exercise functions of which they are incapable, and who support their pretensions with deceit, and generally with impudence.

History has proved, and facts of the present day testify, that of all the openings for deception and chicanery in connexion with the dealings of man with man, medicine opens one

of the widest.

In former times, when even the learned entertained most crude and erroneous ideas of much of the structure, and of most of the functions, of the living body, and when the mass of the people were in the most perfect ignorance on these points; when, moreover, superstition was rife, when charms and king's touches were trusted to cure disease, when occult virtues, dependent upon all sorts of fancied and fanciful conditions and circumstances, were considered to be active or not according to the observance of these conditions and circumstances; when, it is observed, these things prevailed, it cannot perhaps be matter of surprise that people believed the man who could lie most glibly, and who held out the most specious promises, in connexion with that dearest possession of man-dearest, at least, when lost-his health. The most natural thing for ignorance and superstition was to believe the tricked-out mystery. But is it natural, or rather reasonable, that the foolish belief in mysterious cures and quack panaceas should still prevail at the present day, and that the most notorious quacks should amass immense fortunes, simply by deceiving the many foolish? Reasonable or not, the fact is incontrovertible; reasonable or not, it is to be accounted for by the almost perfect ignorance which still prevails, even amongst the most educated classes, of the structure and functions of their own frames, of the requirements of their own constitutions, and of the true principles on which the latter are to be preserved in soundness and health, or to be treated when afflicted with disease. Moreover, the principles of health, in health, also extend, or ought to extend, to the management of illness, when health is sought to be restored. These principles are too frequently dwelt upon in the various sanitary articles in this work to require reiteration here, but, it is once more repeated, they ought to be part of the education of all. The diffusion of such knowledge can, and will, put an end to quackery; and yet the diffusion of such knowledge is dreaded and condemned, even by some medical men who seek legal enactments against the irregular

idea that these will prevent the credulous and ignorant from resorting to the man who lies most to their ignorance, or flatters their blind

prejudices most unscrupulously.

Quacks, generally, may be divided into those who quack for profit, and those who are merely amateurs, the latter class including the Lady Bountifuls and others, who, not content with using such simple means of alleviating disease or suffering among their neighbours as can be safely employed, must, without necessity, get handling such edged tools as antimony, calomel, &c., and with considerable vigour too, very often, without having given themselves much trouble to get any idea of the proper mode of, and reasons for, the administration of what they prescribe. Such practices cannot be too strongly condemned. When such a combination of circumstances occurs that the immediate care of dangerous accident or illness devolves upon some intelligent or responsible individual, in the absence of, or at least until the arrival of, a medical man, it is quite admissible to use even active measures, such as are often recommended in the present work, if proper precaution be observed; but this is very different from persons, without necessity, and for the mere love of amateur quackery, taking upon themselves the management of cases of serious disease. "Without entering upon that difficult ground which correct professional knowledge, and educated judgment, can alone permit to be safely trodden, there is a wide and extensive field for exertion, and for usefulness, open to the unprofessional, in the kindly offices of a true domestic medicine, and in the timely help and solace of a simple household surgery.

"But when it is remembered how the nicest judgment that observation and experience can form, the most patient attention, aided by practised ear and eye, by microscope and test tube, are frequently necessary, to enable the conscientious physician to judge of his case before he can apply the remedy, it is evident how great must be the responsibility of those who, in rashness or ignorance, venture upon the treatment of serious disease, either in their own persons or in those of others; incapable of judging of its nature, still less capable are they of selecting the appropriate treatment." There is, however, a vast difference between the management of real disease, and of ordinary ailment-between endeavouring to strike at the root, or only to relieve the symptoms. Any unprofessional man, or woman either, in this kingdom, who, with all the facility that there is for procuring skilled advice, ventures to take the medical management of a case of real illness, acts most unwarrantably. Still less justifiable is interference with cases upon which a medical man is already in attendance.

-See Advice, Medical.

practitioner and his practices, in the vain | divisible into those who sell some nostrum, and those who profess to investigate and prescribe for diseases.

> The quack medicines sold as such under the seal of Government are of every variety; some profess to cure everything, and therefore carry absurdity so plainly on the surface, that it is difficult to imagine any persons being sufficiently credulous to employ them; others are more circumscribed in their professions, but yet, so far as they go, are advertised as infallibles. One instance will demonstrate the danger of trusting to them. Under such articles as Debility, &c., it has been pointed out that there is a false weakness, to be distinguished from that which is really dependent on actual debility, both being accompanied with languid depression. For such a condition, many quack pills and the like are advertised, they relieve "languor, nervous depression, &c." Such pills are generally powerful purgatives, and by their strong action in this way, perhaps, relieve some individual suffering under the languor of an oppressed system; he is delighted at the change, and meeting his invalid friend, who is suffering from the real debility of incipient consumption, or from some other disease, persuades him to try the wonderful pills, -need it be said, with how great probable, perhaps irremediable, injury. It would be easy

to multiply instances; one is enough.

Of the prescribing quacks, some are so wonderfully skilful as not to require to see their patient; these include the "water doctors" -not the hydropathists, but the "casters" of the urine, those who require merely to see the urine, and therefrom pronounce the verdict of life or death, or send medicines accordingly. The chemical and microscopic examination of the urine is, indeed, to the physician, a most valuable aid in the investigation of disease, when taken in conjunction with the other symptoms of a case; but to imagine that its inspection yields any definite or trustworthy information to the ignorant and illiterate "water caster," ignorant alike of the nature of the secretion from which he or she-for there are female quacks of this kind-professes to derive information, ignorant of the structure or functions of the animal body, is too absurd. In such cases, as, indeed, in those of the prescribing quacks generally, the system of fraud is supported by lying assertions and promises, and by working upon the fears of the unfortunate dupes; this is especially the case in those who profess the venereal department, and who cannot be too carefully shunned. The most shameful impositions are practised by this description of quack, and the consequences are very serious. The conduct of newspaper publishers in giving currency to announcements connected with this obscene and disgusting phase of quackery is most reprehensible. Some quack prescribers follow their The quacks, whose sole object is gain, are business on the strength, real or pretended, of

popularly called, of some predecessor, regular or irregular. Even supposing such "receipts" were good for anything, it would be difficult to prove that their possession gave the faculty of applying them; but the fact is, with the exception of a few general medicines, such as the common aperient pills, every case of disease, every constitution almost, requires some modification in the medicines prescribed, and the same prescription is no more applicable to three or four different individuals than the same coat would be; moreover, almost every case of illness calls for changes and modifications of medicine, to meet the ever-changing symptoms which occur, but the quack panacea ignores such distinctions, and professes by its wonderful property of curing at once, to cut the Gordian knot,—well if it does not do this by cutting the thread of life at the same time.

As it is impossible for any man to treat disease with full advantage unless he has acquired by education a sufficient amount of the very varied knowledge, both theoretical and practical, which is now embraced within the limits of medical science; so, every man who undertakes the treatment of disease as a practitioner without such knowledge, necessarily falls under the designation of a quack, because he pretends to that which he does not possess-he deceives. It is true, many receive the necessary education, and yet follow out irregular theories and modes of practice; if, in doing so, they do wrong, it is unfortunate, but if the error is followed in sincerity, the follower cannot justly be called a quack. On the other hand, the upholder of the most orthodox medicine, may do so in a quackish manner, if, in his practice, he makes a display of methods, either of investigating or of treating disease, which are not requisite. Such things flourish because ignorance abounds. As any system of medical practice may be converted into one of quackery, so may any medicinal agent, even that which is safest when properly used, become, in the hands of the unprincipled empiric, an agent for evil. In fact, quack medicines generally are compounds of drugs which are regularly and daily prescribed by medical men; it is not in the composition, but it is in the application of the compound that mischief is done. If it be matter of indifference when a purgative, an anodyne, or any other medicine is taken, -what medicine of the class, so that it belongs to the class, is selected, -or if it matters not whether its peculiar action is suited to the case and constitution of the patient or not, and whether the same doses are suitable for all, then may quack compounds, each professing to do more than another, be permitted, unchallenged, to go forth on their errands of mischief, under the sign and seal of Government. But if a medical adviser requires to investigate his case, to weigh in his own mind the constitution, circumstances, and tendencies of his patient, and means dissent from the suppression of quack

having received the "receipts," as they are | finally to select from the stores of his own experience and that of others the best adapted remedy or remedies, it must be evident to every reflecting mind, either that these latter necessities enjoined upon the man of educated mind and sense are a tissue of deceptions and shams, or that the whole system of quack medicines must be founded upon fraud, and that it flourishes upon the credulity which believes specious lies, or puts trust in the easily obtained testimonials of some weak-minded individuals, such as are to be found in all ranks and classes. It is difficult to account for the eager credulity and secure indifference with which otherwise sensible persons swallow or use what they believe to be agents capable of acting powerfully upon their own bodies, whilst all they know of these agents is, that they are put forth by persons they know nothing of beyond their advertisements filled with assertions so impudent, or attempts at deception so palpable, that the wonder is they do not defeat their own ends. Perhaps few would be inclined to trust an individual whom they had detected in the attempt to cheat them by offering a forged cheque, with, perhaps, the precaution taken to place the would-be deceiver out of the reach of the law, by the change of a letter in a name; and yet people are deceived daily by some such devices, and eminent names, with some slight alteration in spelling, are made the attractions by which an unprincipled vendor seeks to puff off his wares. Come from what authority it may, as soon as a medicine, or combination of medicines, is held forth as a "cure," irrespective of contingent circumstances, it becomes a quack medicine; in other words, it becomes a source of danger to some, probably to many. The passion for gambling is a very widely distributed one; and as men will risk their fortunes, their liberty, upon the throw of the dice, so it can only be the same love of hazard, that induces many of them to risk the possibility of injury, against the possible recovery of some of those great goods, those prizes of health, which they have in time past thrown away, but which are now held out as the tempting baits of the speculator.
Solomon's Balm of Gilead, which was said to

be composed of nothing more than rum and milk, realised a handsome fortune for its promulgator, of whom the following anecdote is told:—Being asked how it was that people bought his medicine so freely, he replied, "Of ten men who pass my door, nine, at least as far as medicine is concerned, are fools; if you will give me the nine fools for customers, the regular practitioner may keep the one who is

wise in these matters.

In advocating the doctrine that quackery is only to be successfully combated by imparting to people generally the information necessary to enable them to see through the deceptions of the charlatan, the author does not by any

QUA QUA

ery by the strong arm of the law, at present, as no less than thirty thousand pounds per annum a means of protecting the people till they can protect themselves; for, as it must be long before information is sufficiently diffused to patent medicines submitted to a board of effect the end proposed, in the meanwhile, the external guard ought to be substituted till the dictates of educated intelligence are sufficient for the purpose. Governments ought to protect the poor and ignorant in these matters, instead of throwing the "patent" protection over deleterious compounds, which destroy annually so many of the people. A case in point of the injurious action of quackery has come under the author's notice lately. labouring man, suffering from obscure internal disease for which he has been treated without relief both in private and in the wards of a general hospital, is induced, by the fair promises and lying opinions of an itinerant quack, to resort to him for advice (?), given whilst the medicine is paid for at the rate of five shillings a bottle, and paid for at the time; at the same time the poor man is applying for parish relief, and his family in want. He is to be cured in three weeks; that is, he is to pay fifteen shillings, and by the time the quack has reaped that amount, got together somehow, the patient may open his eyes, if he likes, to the fraud.

It is high time for the legislature of the country to interfere, seeing that heads of families often complain that books and pamphlets of the most offensive and indecent description are handed in at their door, or sent by post, and fall into the hands of those whose young minds they are meant and intended to pollute. Nothing also is more common than the obtrusion of certain advertisements meant to catch the eye of young people at a time when the constitution is undergoing natural changes, and enumerating a whole host of symptoms, on reading which the victim immediately supposes that he is the subject of some horrible disease, whereas a consultation with his family medical attendant would have at once procured him ease of mind and body.

The quacks are not so much to blame as the British public, which fosters and cherishes them; but if the public only knew the serious cases that daily come under the notice of medical men, cases where the maltreatment of quacks has produced deadly disease, they would be more chary in employing men who have nothing to recommend them to confidence but their own unblushing impudence

and assertion.

The sum expended by the public of Great Britain upon advertised drugs and nostrums of various kinds has been calculated at not less than from five to seven hundred thousand pounds per annum. Upwards of forty thousand pounds are paid annually into the revenue for stamps to enable the vendors to dispose of quack medicines, and it has been affirmed that patent medicines submitted to a board of censors competent to examine them before the stamps were issued, the public might be preserved in some degree from decidedly injurious

St. John Long, the great impostor, was a painter from Cork, who professed to be able to draw "Morbific matter" from the body. At his trial for manslaughter he was found to be completely ignorant of everything, even allied to medicine or surgery, though many noblemen, clergymen, and men of distinction came forward to swear to his great medical skill. One of these witnesses swore that he saw Long draw several pounds weight of a liquid, resem-

bling mercury, from a patient's brain!
"Nervous Cordials," "Balm of Gilead,"
"Balm of Mecca," "Botanical Syrups,"
"Guides to Health," So and So's "specific" or "drops," are being everlastingly introduced to public notice, the intelligent public all the while forgetting that if any one of these remedies was once able to cure all diseases, as was stated by its advocates at the time of its introduction, it should not have been superseded by any new remedy. It is a curious fact that medicines of a secret nature are generally said to be the property of some would-be benefactor of his species-probably a retired physician or clergyman who is willing, before he has "shuffled off this mortal coil," to part with his grand secret for a few postage stamps.

The most wonderful instances are on record of bone setters and cancer curers having made large fortunes by deluding the public, till they were found out, exposed, and forgotten. No class of quacks, probably, have been the cause of more immediate harm than the so-called curers of cancers, who generally profess to have discovered somewhere in the East, or elsewhere, a wonderful and certain cure. Their applications are either perfectly inert, and merely used as a means of dallying with the patient, or they consist of caustics of one sort or another which only eat deeper into the wound, without eradicating the disease, and often cause speedy death by opening into blood vessels. Their vaunted cures have not been cures of cancer at all; or, if so, have only been temporary or apparent cures, owing to the healing of a portion of skin over the cancerous wound.

The Government of this country, owing to an absurd and enthusiastic outcry as to the merits of a well-known nostrum called Stephen's Specific, was induced to vote five thousand pounds for its purchase, but, after its publication, no one could be found foolish enough to use it. The French Government also were induced to give a fair trial to a so-called cancer curer's method, and allowed him to choose seventeen patients afflicted with cancer, and one notorious vendor of a quack nostrum spends | place them in the Government Hospital of

undertook to cure the whole in six months; but, alas! at the end of two months seven were dead, and at the end of the six months all were dead but two, and those two were re-

ported dying.

But advertising goes a step further than recommending favourite remedies in the shape of medicines, elixirs, tractors, tar waters, life pills, at one shilling and three halfpence a box ! for most of the papers now inform us that we require "no more pills, or any other medicine," but that all manner of diseases may be cured by the use of some compound closely resembling pease flour, and, no doubt, equally efficacious in all respects. Surely the monstrous absurdity of such statements ought to be sufficient protection against their being believed

and acted upon.

QUARANTINE is derived from the Italian word signifying forty; forty days having been the usual space of time that persons or goods coming from places in which infectious disease, or disease thought to be infectious, prevails, or that have been exposed to the influence of any such disease, during a sojourn on board ship. The quarantine or isolation is either "performed" on board the vessel, which none are allowed to leave, or in a building called a "lazaretto," set apart for the purpose, and cut off from all communication with the surrounding country. The necessity of these restrictive measures is mainly felt, in Europe at all events, in the countries bordering the eastern and southern shores of the Mediterranean, and lasts usually for periods varying from six to fifteen or more days. Quarantine laws seldom require to be enforced in British ports, although they have been occasionally imposed by orders in Council. The Local Government Board has the power of taking strong measures with regard to the quarantine of vessels coming from suspected ports, and the Port Sanitary Authority may, if it thinks necessary, visit and examine such vessels, isolate those contagiously infected, destroy all material supposed to be infected, and detain the ship until it is fumigated and disinfected. Much difference of opinion has always prevailed respecting the laws of quarantine, and in some countries they are enforced often with little The term of isolation is discrimination. usually less than the forty days.

QUARTAN-a term applied to an ague, the paroxysms of which occur every seventy-

QUASSIA.—The quassia wood is obtained from a tree, native to Jamaica and other West India islands; it is named the Quassia excelsa, from its height, which is often one hundred feet. Quassia wood is usually sold in the form of chips, or raspings of a lightish yellow colour, it is intensely bitter, and forms a valuable tonic and stomachic lightish yellow colour, it is intensely bitter, acridity, as any one may prove who will chew and forms a valuable tonic and stomachic remedy. It is best given in infusion, made by

Le Charité for observation. He did so, and | infusing two drachms of the raspings in a pint of water for a couple of hours. The dose, one to two fluid ounces, twice daily. The infusion is poisonous to flies and other insects, and is often used as an injection to destroy thread worms. The root bark of another species of quassia, or at least what was formerly ranked as a quassia, is also sometimes used in medicine.

> QUICKENING .- See PREGNANCY. QUICKLIME.—See LIME.

QUICKSILVER .- See MERCURY.

QUINCE SEEDS, when boiled in water, yield a mucilaginous decoction, which is not, however, in any way superior to other more common preparations. Two drachms of the seeds are ordered to be boiled in two pints of water for ten minutes, and the decoction strained.

QUININE .- See BARK.

QUINSEY .- See THROAT, SORE.

QUOTIDIAN - a term applied to an ague, the paroxysms of which occur daily .-See Ague.

RABIES, as a term, is usually synonymous with hydrophobia or canine madness. - See Hydrophobia.

RADISH, the Raphanus sativus, like other vegetables which are eaten uncooked, is not suitable for persons of weak digestive

RADIUS, one of the bones of the fore-

arm. - See Fore-arm.

RAISIN .- The dried grape, in which the mucilaginous and perhaps acid constituents of the fresh fruit have been converted into grape sugar in the process of dessication. Raisins are used in the preparation of the compound tincture of cardamoms, and tincture of senna.

As an article of diet they are unwholesome only if the tough, indigestible skins are eaten.

In the case of children, much disorder is frequently caused by the undigested skins of raisins passing into the bowels, and lodging in the sacculi or little pouches of the large intestines, where they cause much irritation, and probably troublesome diarrhoa, which is only relieved when a dose of castor oil, or of some other aperient, clears out the offending accumulation. Raisin skins may thus lodge in the bowels for weeks.

RANULA is the name given to an encysted tumour situated under the tongue, and containing a glairy mucous fluid of a bluish colour. It is usually got rid of by incision or by snipping off a portion of the sac of the

RANUNCULUS .- The various species of ranunculus, or "buttercup," so common in this country, are chiefly remarkable for their

mustard plaster or blister, a fact, the knowledge of which might prove useful. plants completely lose their acridity by drying.

RASH is a popular term for eruptions on the skin, more especially such as scarlatina, nettle-rash, &c., which do not present either

vesicles or pustules.

RASPBERRY, the Rubus idaus is a native of this country, and grows wild in many situations, especially in Scotland, amid the stony banks of streams. The raspberry is one of the most wholesome fruits we possess, either in its fresh state, or preserved. In the latter form, it is a most grateful addition to the sickroom comforts. In fever, and feverish diseases generally, when the acid is not an
objection, the well-known raspberry-vinegar is
both an agreeable and salutary beverage. When
the acid is inadmissible, a pleasant drink is
made by mingling the preserve or is most with made by mingling the preserve, or jam with

RASPBERRY ACID.—Put six pounds of raspberries into an earthenware pan, and pour over them two quarts of spring water, previously acidulated with two and a half ounces of tartaric acid. Let them remain twenty-four hours-and not more, or they begin to ferment -then drain them, taking care not to bruise the fruit. To each pint of clear liquor add one and a half pound of lump-sugar, which melts easier and quicker for not being pounded. Stir it frequently. When quite dissolved, bottle the syrup. The whole process to be done cold. This quantity of fruit will fill two wine quart bottles. This recipe answers equally well for black currants, strawberries, or red currants.

REACTION, in medicine, is the recovery of the animal system from depressing causes; a recovery which tends not only to restore to the ordinary level of action, but to go farther, and to stimulate to action above that level; thus, after shock from an injury or collapse from hæmorrhage, the reaction gives a skin hotter than usual, a pulse quicker and probably stronger than usual; the same effect occurs in reaction after depression from other causes, such as after fainting or fright; in combating, therefore, especially by means of stimulants, the depression which in such cases at first seems almost to threaten life, the after reaction must not be lost sight of, and the means of relieving the depression administered with a sparing and judicious hand. When reaction can be procured by the natural powers or resilience of the system, by external warmth, and by warm, comparatively unstimulating, fluids, such as tea, &c., it is better effected than by the use of more powerful excitants. In some cases, however, the latter are absolutely necessary to preserve life, and then ammonia, in some form, but especially as sal volatile, alcoholic stimuli, such as wine and brandy,

applied to the skin, irritating, acting like a reaction. In some peculiar cases, emetics of mustard, by rousing the system, greatly assist reaction.

READING ALOUD and speaking aloud for a length of time are wholesome exercises for the strong, but if carried to excess, or even if only practised moderately, may produce in the predisposed injury to the lungs, spitting of blood, or affection of the throat (see Clergyman's Sore Throat). The modification of the respiration and circulation produced by continued loud speaking or reading, is also apt to produce unpleasant symptoms in those predisposed to apoplectic or head affections. exercise of reading aloud has been recommended as useful in cases of hysteria and nervous dis orders.

RECREATION, or the renovation of the powers of body or mind, after they have been exhausted by toil, is one of the highest pleasures enjoyable by man; a real pleasure, because it can only be purchased by those previous exertions, in the performance of which, although they are exertions, man feels that he is fulfilling the ends of his being. Those who live in a constant round of what is called pleasure, the idle, the saunterers after their work, do not know what true recreation is, cannot realise the thorough enjoyment with which the man who works in the true sense of the word, who, "whatever his hand findeth to do," does it "with all his might," throws off his toil, and takes to recreation in the same hearty spirit that he brings to his daily effort, whatever that may be.

Recreation is the enjoyment of man especially, and the higher he rises in the scale of true intellectual being, the more thoroughly must he enjoy it, the active pleasurable excitement of both mind and body, in contradis-tinction to "rest," which is the passive enjoy-

ment of repose after exertion.

The animal enjoys rest, but can scarce be said to enjoy recreation; the man of physical toil enjoys rest, and, if the mind be dull and untutored, finds his chief enjoyment in the intervals of labour, in rest, like the animal; rest, which recruits the physical powers, whilst the mind is comparatively vacant. But when the mind is at all inclined to activity, after the rest which follows action, comes the desire for reaction, for recreation, an active state, more useful in many respects than rest, because it is a state of stimulation, of wholesome excitation, if kept within proper bounds. Such a condition of moderate pleasurable excitement of the mental and physical powers, which act and re-act on one another, is highly conducive to health, is, in fact, a means of preserving health, to which man, except in a very artificial state, is periodically, almost instinctively impelled.

The subject of recreation involves a great practical truth. Those who do not work cannot know recreation; without the action there and the others, are all powerful promoters of can be no reaction, for the one follows the

REC REC

other as effect follows cause, and when all is | life are again returned to. It argues well, in order, as a necessary cause.

Again, recreation must alternate with work, if the power of working is to be retained. If recreation cannot be enjoyed without work, neither can work be enjoyed, or vigorously pursued without recreation; but the fact has been greatly overlooked in this busy age, and work is pursued unceasingly, until either body or mind sinks under the never-ending tension, or, if they do endure, until the power of taking recreation is lost, until the mind becomes so immersed in its daily engagements, in its daily routine, that it cannot divest itself of the trammels thrown around it. The man becomes so bound down in the pursuit of money, of power, of reputation, that he is a slave to his own desires, he grudges every moment abstracted from the advancement of his darling cares, he cannot recreate. This is neither the time nor place to point out how far this inordinate slaving is removed from the true ends of man's being in this world, or how little it is in accordance as a preparation for another. It is a system but little calculated to afford either continued health, or happiness, or usefulness, in man's daily life; the physical powers must eventually give way under it if persevered in, and dyspepsia, miserable hypochondriasis, paralysis, and cerebral disease will be the probable consequences; or, without the presence of tangible disease, the power of exerting the mind may be lost. A man who thus feels himself enslaved by work, should, by an effort, break through the restraint; an effort it will require, to cast off the morbid state of mind which is generally connected with the condition, but the effort must be made, and those from whom it is most required, are generally those who most have it in their power to avail themselves of the means of recreation to the utmost, -they are our wealthy, but overtasked in mind and body, merchants, lawyers, men of business, and in some cases medical men. They think they cannot leave their posts without everything going wrong; without risk of loss; risk of some rival taking up an investment, a cause, or a patient; and it may be so, but is the chance of such petty losses, a reason for sacrificing health, and life, and real happiness too? for that cannot be real happiness which is dependent for its continuance upon the same mill-horse round of actions. It is repeated, recreation is a duty which the man of real work owes to God, to society, to himself, and to his family, and it is a duty which he cannot altogether neglect, without risking the loss of both mental and bodily health.

The kind of recreation in which a man should indulge must of course depend greatly upon circumstances, but, generally speaking, a complete change of scene and air is desirable, such as will break in upon old trains of thought, give new ideas, and afford pleasurable recollections, when the active exertions of evident, or is suspected, from the non-passage

both for the physical and mental elevation of the population at large, that the means of recreation, the cheap trips, the excursion trains, the public parks, &c., are so abundantly taken advantage of, and are becoming yearly more common, for these must be regarded as part of the great sanitary movements of the age, the means of affording cheap and thorough recreation to classes, who, some years ago, scarcely dreamed of such a thing. It ought to be the duty of all, of every government, of every master, to give abundant facility for pure healthy-minded recreation to the people; to do so is true economy of that real wealth, social and political, the healthy mind, and healthy frame of every individual of the community.

Recreation, reaction after toil, or in other words, periodical stimulation of mind and body, in those who work, is so strongly instinctive, that it will be sought, and if not found in one way, -in the reading-room, the lecture, the concert, the garden, or even in the cricket ground-if not afforded in the fête or the excursion-will be procured in the tap-room, or

in degrading and vicious pursuits.

To sum up: the stimulus of recreation is one of those stimuli necessary for the continued healthy tone of both mind and body. It cannot be neglected without injury to both, and its gratification ought to be directed into those channels which will preserve its utility, because they preserve it in order, in moderation, and in purity.

Refer to-Exercise-Dancing-Pleasure-

RECTUM. - The rectum is the terminating extremity of the large bowel which opens at the anus or fundament. It derives its name from its straight course, as compared with the tortuosity of the other portions of the intestines; it is about nine inches in length, lies in front of the "sacrum" (see Pelvis), and expands into a dilatation just above the external opening, or "anus," at which it is closed by a "sphincter" muscle, which retains the contents of the bowel, unless, when under the influence of the will, it permits their expulsion, the latter act being effected by means of the muscular fibres of the gut itself, aided by the downward pressure of the diaphragm, and other muscles of the abdominal boundaries. The rectum is of course lined by a continuation of the mucous membrane which lines the intestines throughout. The rectum is subject to various diseases, which generally require efficient surgical assistance for their safe and speedy cure.

Infants are occasionally born with what is called "imperforation" of the rectum, that is, the gut instead of being an open canal, is closed wholly or partially, either at the exter-nal opening, or higher up. When "imper-foration" of the rectum in an infant is either

REF

wards, from the belly becoming tense and full, and from vomiting of the contents of the bowels, the child should at once be seen by a surgeon, for it is possible that a simple operation adopted, without loss of time, may rectify

the evil and preserve life.

Obstruction of the rectum, painful or otherwise, may occur either in adults or children, in consequence of the presence, either of hardened "fæces," in considerable quantity, or of foreign bodies which have descended after being swallowed, and become fixed in the gut, just above the lower opening, or which have been introduced directly into the canal, either by accident or design, and forming the nuclei

of indurated masses of fæcal matter.

The dilatation of the rectum just above the anal opening rather favours in some cases the accumulation of the hardened fæcal contents of the bowels, especially in the aged, a condition which is apt to occur from the repeated use of large injections, and to occasion much suffering and inconvenience. Such an accumulation may require the aid of the surgeon, who removes it by mechanical means, such as scoops, and such like instruments; or the handle of a spoon is sometimes used in the absence of the above. In proper hands the case is of course safe, but it would not be well for unprofessional persons to attempt such in-terference; much, however, may be done by the persevering use of injections of soap and water, of about half a pint of fluid at a time, which will first soften, and finally induce the discharge of the mass. Foreign bodies lodged in the lectum may produce distress simply from their bulk, or they may produce much suffering by lacerating the lining membrane by sharp edges or points, causing intense pain on any attempt being made to evacuate the bowels; children not unfrequently suffer in this way from the stones of plums, &c., which they have swallowed, and the author has seen a case in which the greatest agony was apparently caused in a child by the hard core of an apple becoming fixed at the opening. In all such cases it is advisable to get proper advice at once, but in the absence of this, injections of tolerably thick gruel may be used, or the finger well greased, may be carefully introduced within the gut, to ascertain, if possible, the presence, and assist the removal of any small body within reach, but no instrument can be safely used except by a medical man.

Obstruction of the rectum may likewise be the result of disease, generally cancer, which causes narrowing or "stricture" of its canal; this disease, which generally occurs after middle life, and which may either be of a simple or of a cancerous nature, is thus described by the late Mr. Syme, a high authority

of the natural contents of the bowel down- | evacuations of the bowels, the desire to empty the rectum continuing after the most powerful and prolonged efforts of expulsion, the discharge of fluid matters with great force, as if from a squirt, the appearance of the solid evacuations in the form of slender cylinders, or small round masses, and the admixture of a large quantity of mucus, often bloody, with the feculent excretions. The disease generally manifests itself very insidiously, and before long is usually accompanied with a distended state of the abdomen, which is owing partly to retention of the intestinal contents, and partly to a tympanitic condition, induced by the irritation thus occasioned. The desire to empty the bowels becomes at length almost incessant, and the frequent attempts which are made to do so, being seldom followed by any evacuation, except of fluids, there is a risk of erroneously supposing that the patient labours under diarrhœa; and with this view of prescribing medicines which have a tendency to increase the distension of the intestines." It is only requisite to add, that when such symptoms as the above show themselves, there is but the one course left, that of procuring the best advice as soon as possible.

Ulceration of the lining membrane of the rectum, fissure at the anal opening, and other diseases, especially the last named, which produce painful sensations, when the bowels are evacuated, can only be properly investigated

and treated by a surgeon.

Falling, or prolapsus of the bowel, and piles, have already been considered under their proper

articles.

Fistula is a disease connected with the rectum which often causes much inconvenience; it is the result of abscess, which, having formed and discharged at the side of the gut, remains unhealed and unhealing, and often opens both externally, and into the bowel, forming as it were a side passage, by which wind and fluids are apt to escape along with the discharge peculiar to the artificial passage. As may be imagined, such a state of matters gives rise to much annoyance, and calls for speedy removal, which can only be procured with certainty by operative procedure on the part of a surgeon; the sooner, therefore, this is submitted to the better, the bowels being in the meanwhile kept lax, and the unpleasantness of the condition alleviated as much as possible. Fistula is far more common in males than in females, and is often associated with consumptive tendencies. - See Intestines.

REFRIGERANTS, in medicine, are remedies employed to reduce the existing temperature of the body, either locally or generally. Internal remedies such as the vegetable acids, nitrate of potash or saltpetre, &c., have been used under the name of refrigerant, but it is difficult to trace to them any direct on the subject. "The symptoms of simple action, further than that of allaying thirst; stricture are slow, painful, and imperfect indirectly, they probably act by reducing the

force and frequency of the circulation. The its oxygen has been exchanged for the carbonic best and most direct refrigerant is the obvious acid with which the venous blood is loaded as one, cold itself, used through the medium of cold air, cold water, or ice, and in most cases, when the temperature of the body is raised above the natural standard, in some of these forms cold is useful. The late Dr. Currie, of Liverpool, established the practice of treating fever by the refrigerating action of cold, used very boldly, in the form of cold water dashed freely over the patient, and the practice has been again revived by some modern physicians, who go a step further than Dr. Currie, and add ice to the bath in which the patient is immersed until the body temperature is reduced to near its normal standard.

Refer to-Cold-Ice, &c.

REGIMEN is the regulation of the habits of an individual, with reference to health. Diet is properly included under the term, but is generally spoken of separately. The proper regulation of the regimen of an invalid is obviously a matter of great importance. It includes the prescription of the hours and kind of employment, of exercise or of amusement, of the times of meals, and of sleep, of dress, &c. As the particulars of regimen are sufficiently entered into under the various articles, it is superfluous to notice them further here.

RELAXATION .- See RECREATION. REMITTENT FEVER.—See FEVER. RENAL.—Appertaining to the kidney.

RESINS are vegetable juices, which are solid, are not soluble in water, but dissolve in alcohol; they are generally brittle, and more or less transparent. The resins best known, and which are used in medicine, are left after the distillation of the essential oil of turpentine; they vary in appearance, according to the mode in which the distillation has been conducted. Turpentine resin is only used in medical practice at present as an addition to plasters. It enters into the composition of the well-known Basilicon or resin ointment. Resins obtained by heat or rectified spirit are now extracted from guaiacum, scammony, jalap, and podophyllum, and admitted as remedies in the British Pharmacopœia.

Refer to—Basilicon—Plaster, &c.

RESOLUTION .- The term is used in medicine to designate that termination of the process of inflammation by which the affected part is left without obvious change of structure, in other words, is left in the same condition as it was previous to becoming inflamed.—See Inflammation.

RESPIRATION. — Breathing, in its widest sense, is the process by which atmospheric air is brought into contact with the fluids existing in the interior of organised beings, whether vegetables or animals; in man it is the function by which atmospheric air is introduced or drawn into the lungs or worn at varying intervals during the day. respiratory organs, and again expelled, after Fig. 172 represents a respirator for the mouth

it enters the lungs. Thus the process of respiration in man comprises, first the act of drawing in the air, or "inspiration"; and secondly, that of expelling the air, or "expira-tion." The acts of respiration in health number from sixteen to eighteen in a minute, each act being usually equivalent to four beats of the pulse. The amount of air inspired and expired each time is calculated to be from twenty to thirty cubic inches, while that remaining in the lungs during respiration, called the residual air, averages 100 cubic inches. As the reader will find all requisite information upon this vital function under articles Aeration, Blood, Chest, Circulation, Lungs, &c., it is unnecessary to repeat it here.

RESPIRATORS are instruments used to protect the air-passages from the direct effect of the air, especially when it is cold. They are, undoubtedly, when used with proper discretion, most valuable. The first instrument, probably, to which the name of the respirator was applied, was Jeffrey's well-known one, constructed upon the principle that the warm breath passing out from the lungs should impart its heat to a number of small already set wires the heat being taken small, closely-set wires, the heat being taken up at the next inspiration by the cold air, in its passage through those wires to the lungs. Jeffrey's respirators are made so as to protect the mouth alone, the nose alone, or mouth and nose together. In many cases of chest affection these instruments furnish a means of protection of the highest value, particularly for those who, suffering from delicacy of the lungs, cannot, by reason of their avocations, avoid exposure after nightfall, or to cold or foggy air of any kind. With warm clothing and a respirator an invalid may almost defy climate, particularly as the instrument not only protects the air-passages from the direct influence of the cold, but seems to assist in preserving the animal heat of the body generally. The nose respirator is principally intended to be worn during sleep, and enables persons who suffer from delicacy of chest to occupy, during winter, bed-rooms much more freely ventilated than they could without its assistance.

The curative properties of antiseptic substances, when applied to wounds, has induced medical men to test their efficacy by means of the respirator-inhaler in cases of consumption, even where the disease has advanced to an extent in which abscess cavities are formed in the lungs. Dr. Coghill, of Ventnor, recommends a respirator for this purpose, consisting of two perforated metal plates, between which is placed a pledget of lint, or cotton wool, saturated with the antiseptic solution, which requires renewal morning and evening, and oftener if necessary, the instrument being

RES RET

known as the oro-nasal. In order to obtain the full benefit of the agent, the person using it should be taught to inspire by the mouth only, and to expire by the nose, a somewhat difficult operation at first, but to be surmounted by a little practice. Carbolic acid, creasote, iodine, thymol, and eucalyptus, are among the best antiseptics for the purpose, their volatility being increased, if thought necessary, by the addition of a little ether or spirits of wine to the cotton wool. Dr. Coghill employs the following formula for moistening the respirator: -ethereal tincture of iodine and carbolic acid, of each two drachms, creasote or thymol a drachm, rectified spirit one ounce.

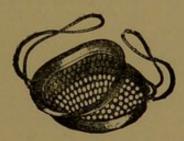

Fig. 172

When the cough is urgent and the breathing embarrassed, chloroform or sulphuric ether may be added to relieve urgency. In addition to the above, the compound tincture of benzoin, either alone or combined in equal parts with tincture of henbane, is specially useful in chronic bronchial affections, as well as in consumption, and is specially corrective

Fig. 178.

of any tendency to fœtor in the expectoration; fifteen to thirty minims of each may be used

upon the cotton of the inhaler.

The chief objection urged against ordinary respirators is, that they keep the air of respiration in too artifical a state of warmth and thus render the wearers peculiarly susceptible on the slightest accidental exposure, in fact, render them so sensitive of cold as to be almost entirely dependent on the instrument for com-

only; fig. 173 one for both mouth and nose; | Jeffrey's respirator is the best instrument, care being taken, of course, that it is not unnecessarily had recourse to. When a minor degree of protection only is required, it may be attained by some protective material worn across the mouth, which acts upon the same principle as the respirator above named. A handkerchief of silk or of woollen material is at once a simple and efficient respiratory protector, and various forms of respirators, made of woven materials, may be procured at the shops. Some persons find respirators of any close material so confining, as to cause difficulty of breathing; for such cases, open knitted protectors of Shetland wool are well adapted. Veils of the same material are made, which form an additional protection for females.

Persons who are not very delicate, but who yet find it requisite to wear a respirator, will often find it a relief, when walking, to slip the instrument off the mouth when they turn away from the wind, or in very sheltered situations, readjusting it whenever they again meet the wind, or pass into a more exposed situation.

The late Dr. Stenhouse introduced a form of charcoal respirator for the use of persons engaged in working amongst noxious gases. This antiseptic respirator, made to fit over the nose and mouth, has been occasionally found useful by nurses and others who have had to dress very offensive wounds. Oro-nasal respirators are also employed by workmen in various deleterious substances, to prevent the fine dust of foreign matter from being inhaled. They are also recommended for miners and firemen, who are enabled by this means to breathe in safety vapours of a deadly character, or to enter houses in the performance of their duty, no matter how dense the smoke is.

REST-Refer to SLEEP.

RESUSCITATION, the restoration to sensibility of persons apparently dead, is sufficiently treated of under articles Carbonic Acid or Choke damp—Cold—Drowning—Hang-

RETE MUCOSUM .- the internal layer

of the outer or scarf skin. - See Skin.

RETENTION OF URINE signifies a want of ability to pass the urine in the ordinary way, due to paralysis, obstruction, or functional derangement of the expulsive powers of the bladder. When the complaint is not of a severe character, relief is often obtained by the hot bath, or the administration of an opiate; more often it is necessary to relieve the bladder by means of the catheter. The symptom is not uncommon among hysterical women.

RETINA.—The retina (fig. 174) is the expanded sheet of nervous substance derived from the optic nerve, which forms the inner coat of the eye; it is the essential portion of fort, and health, and even for life. Notwith-standing these objections, when as full pro-without which, or in a diseased state of which, the visual organ, the mysterious link between tection as possible from cold air is required, all other arrangements for vision, however

perfect, must be futile. The eye may seem as rheumatism," is also included under the term lustrous as ever, its depths as clear, but if the rheumatism. retina or its nerve fail, all is dark,

"And knowledge from one entrance quite shut out."

The retina (fig. 175) does not extend quite to the fore part of the interior of the eye-ball, but only as far as what is called the "serrated

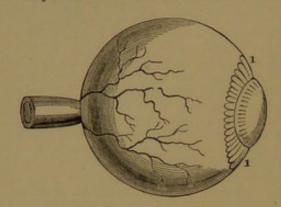

Fig. 174.

line" (3); in front of this serrated line, lie the ciliary foldings (2) of the coloured coat of the eye, and more anterior than these the "iris" (1), the posterior view of which is represented

in the drawing.

Blindness from disease of the retina is referred to under the article headed Aman-In a living, or perfectly fresh eye, the

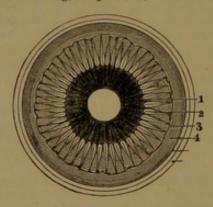

Fig. 175.

retina is transparent, but soon after death acquires an opacity somewhat resembling that of ground glass. The minute structure of this portion of a wonderful organ, is in itself most

wonderful and complex.—See Eye.

RHEUMATISM.—Under this known name are comprehended two forms of disease, differing greatly from each other, so greatly, indeed, as to be distinguished even by the unprofessional. The acute form of rheu-matism. frequently called "rheumatic fever," by medical men, is popularly named the "rheumatics," whilst the chronic form, the "chronic rheumatism" of the physician, is known to the public as simply "rheumatism," or in vulgar outer covering, but the lining membrane or parlance, as "the rheumatiz." "Muscular endocardium as well as the valves are also often

Acute rheumatism, or rheumatic fever, is characterised by symptoms of high inflammatory fever, there is shivering, great heat of skin, followed by profuse sour-smelling perspiration; the pulse is rapid and full; the tongue, covered with a white, creamy-looking fur, is red at the tip and margins; there is much thirst, and the appetite is deficient. The urine is scanty and high coloured, and deposits on cooling a large quantity of red sediment. Delirium does not often occur, unless the heart becomes involved. Coincident with the above constitutional symptoms, one or more of the large joints, or some of the tissues in the neighbourhood of a joint, become exquisitely tender, swollen, and inflamed, the skin over the affected part turning pink. Whatever may be the part or joint first affected in a case of acute rheumatism, it rarely becomes the fixed seat of the disease, which, before long, almost invariably transfers the site of its manifestation to some other joint, leaving the one previously affected entirely free, or nearly so; this shifting from one place to another, goes on during the whole period of the disease, and, indeed, constitutes its most characteristic and well-marked feature. Few diseases are accompanied with more pain and suffering than acute rheumatism, the slightest movement often causing the most exquisite torture; the patient lies in a state of helplessness more or less complete, according to the extent of the affection of the joints. A disease which, like acute rheumatism, can thus shift its local indications from one part of the body to another, must evidently be a constitutional one, and there can be no question that it is a blood disease; that is, that it is dependent on a morbid condition of the blood, or the circulation of a poison generated in that fluid. The near resemblance in many of their circumstances between gout and rheumatism, renders it probable that a similarity, at least of cause, may be expected. In the former disease, the blood poison, the "uric acid," not only separates itself spontaneously under the form of chalk stones, but it has been separated from the blood itself by Dr. Garrod. That a super-abundance of peculiar acid, probably lactic acid, does exist in the system, during an attack of acute rheumatism, is unquestionable. So long as an attack of acute rheumatism confines itself to the joints, and to the parts in their vicinity, it is a disease devoid of danger, but, unfortunately, in a very considerable proportion of cases, there is a tendency of the disease to attack some of the "fibrous" structures connected with the heart, which resemble those fibrous tissues, which, in the neighbourhood of the joints, are the common seat of the disease. These inflammatory rheumatic affections of the

involved. These diseases having been already referred to (see Carditis) require but little further notice here; it is sufficient to remark that they are complications of rheumatic fever which are always to be anxiously looked for, and their appearance is to be treated with the utmost caution. The heart affection is more liable to occur the younger the subject, and, indeed, the author has reason to believe, from a case which has come under his own notice, that where strong hereditary predisposition to rheumatic affection exists, the heart in a child may become affected rheumatically, and the foundation laid of future organic and incurable disease, without any of the usual joint affection of rheumatic fever being mixed up with the first attack, which has probably been passed over as a feverish cold. Probably, such cases are not common, but their possibility should put parents, who are aware of hereditary pre-disposition to acute rheumatic disease, upon their guard as respects their children. In considering the causes of acute rheumatism, the strong predisposition that exists in individuals and families hereditarily is most important; for in such persons extra care is always requisite, as they are liable to become the subjects of the disease from contingencies which would leave others quite unaffected. This circumstance of hereditary predisposition to acute rheumatic affection ought always to be considered by parents in directing or advising upon the future destinations of their children, who ought never to engage in any occupations which may involve much exposure to the vicissitudes of weather, for if they do, they almost certainly become the victims of rheumatic fever, involving long and painful present illness, and in all probability laying the foundation of years of future suffering, and of half usefulness, from heart disease. Indeed, so serious are the con-siderations involved in hereditary predisposi-tion to acute rheumatic disease, as to make it a question whether persons thus predisposed would not find it their best plan to leave the changeable and often damp climate of Britain, and make their home in one such as that of Australia, free from such objections; provided, of course, that after the move occupations are not engaged in which involve exposure. The question of hereditary predisposition to acute rheumatism is one which no Life Assurance Company should overlook.

Of the direct causes of acute rheumatism, there can be no question that cold and damp combined are the most usual; out of all proportion, consequently, the poor and ill-clad are they who suffer most frequently from the disease, although any person exposed to such influence is liable to be similarly affected. For the above reason, acute rheumatic affections are most prevalent during cold, wet weather; they are, however, by no means uncommon during the prevalence of extreme heat. This

that persons are apt to have the free action of the skin, the profuse perspiration, checked by incautious exposure in hot weather. Whatever the cause, the disease prevails. The author likewise believes he has traced attacks of the affection in the predisposed to unusual exertion, without any appreciable check having been given to the perspiration. The disease is most generally met with between the age of puberty and the fortieth year; it is more common among males than females.

The treatment of acute rheumatism is not either likely or desirable, except under peculiar circumstances, to be trusted to unprofessional management; the long continuance of the disease, its painful nature, and, above all, the possibility, almost probability, of so serious a complication as affection of the heart arising during its progress, all combine to render proper medical assistance from the first highly

desirable.

When an individual who has either suffered from an attack of acute rheumatism, or is hereditarily predisposed to it, or indeed when any one, after exposure likely to produce an attack, suspects the disease to be impending, the first efforts should be to excite the free action of the skin. If a warm or vapour bath can be procured, it is highly desirable; if it cannot, the best substitute will be a wellwarmed bed, with hot bran bags, or hot bottles, and the free use of warm diluent drinks. A draught, composed of half an ounce of spirit of mindererus, one drachm of paregoric, and fifteen drops of ipecacuanha wine, in a wineglassful of water, may be given every four or five hours, or a drachm of sweet spirit of nitre may be substituted for the mindererus. To the above draught, fifteen minims of liquor potassæ, or ten grains of the bicarbonate of potash may be added with advantage. Under the above circumstances, any stimulant diaphoretic may be given with benefit, even a little gin, or other spirit, or wine, well diluted with hot water; these stimuli being used, of course, only at first, and whilst fever is not yet present.

When an attack of acute rheumatism, characterised by the symptoms detailed at the commencement of this article, is unequivocally established, if medical assistance is not immediately procurable, the patient must be kept in bed, moderately warm, the thirst quenched by the free use of simple diluent drinks, and the diet reduced to a very low scale, anything like alcoholic stimuli, or animal preparations, being strictly forbidden, except in the cases of very debilitated persons, when animal broths, such as beef tea, may be permitted in moderation. If fever runs high, tartar emetic, in from an eighth to a fourth of a grain-dose, may be given every four, five, or six hours, and with this, from six to ten drops of laudanum may be combined to alleviate the pain. This will, circumstance is perhaps traceable to the fact however, under the circumstances, be better

effected by the use of from one grain to two | relieving pain, and shortening the malady. grains of solid opium, given at bedtime, along with five grains of calomel, the dose being followed in the morning by a purgative, a black draught, or senna alone, or, in a strong subject, senna combined with Epsom salts. The safest way of managing the opium will be to give a grain the first night, and if that does not procure sleep, gradually to increase the dose. If the mouth becomes affected by the calomel it must of course be discontinued. Instead of simple opium, Dover's powder, in doses of from five to twenty grains may be given, likewise combined with calomel, and followed in the same manner by the purgative. The above measures might with safety be adopted under peculiar circumstances in the absence of medical assistance; there are however many other modes of treatment—bleeding was formerly much employed. It has fallen into comparative disuse, at all events it could only be had recourse to legitimately by a medical man. The treatment by large doses of nitrate of potash, or saltpetre, has had its advocates, and may be tried: the mode of administration as laid down by Dr. Basham is, to dissolve two ounces of the saltpetre in two quarts of water, and to give this quantity in the course of the twenty-four hours. This treatment, which is said to be very successful at times, might be available in the absence at least of other remedies; of course, if symptoms indicative of irritation of the stomach or bowels came on, it would require to be abandoned. More recently, the treatment of acute rheumatism by lemon juice, as introduced by Dr. Owen Rees, has come into practice, and seems in many cases to answer extremely well; on this point the author can speak favourably from his own experience. This treatment has the advantage of being perfectly safe, and therefore, where the lemon juice can be procured, may without danger, be pursued in the absence of a medical man. One table-spoonful or half an ounce of lemon juice, is to be given every four hours. The "alkaline treatment" of acute rheumatism has been largely adopted on the authority of the lets. Dr. Fuller and many ather less lets. the late Dr. Fuller, and many other leading physicians, and has been found to be very beneficial in relieving pain and hastening convalescence. Bicarbonate of potash, in doses varying from twenty to thirty grains, given in milk or barley-water every four hours, may be employed alone, or in combination with the acetate or nitrate of potash. Most persons have heard of colchicum in connexion with the treatment of rheumatism, and in proper hands, properly used, it is at certain times most valuable, but its employment requires too much discrimination to make it safely usable, in this disease at least, by unprofessional persons. But the remedy which before all others has come of late years into universal use in rheumatic fever is salicine, as it has the remarkable power of reducing the temperature, so called, but it tends to modify any inflam-

Salicine and its preparation, salicylic acid, and salicylate of soda, are given in doses of ten, twenty, or even thirty grains every three or four hours. Dr. Southey, of St. Bartholomew's Hospital, administers fifteen grains of salicylate of soda every two hours till sixty grains are taken, and afterwards continues the same dose of the drug every four hours; while Dr. Maclagan, who first introduced the medicine as a remedy in rheumatic fever, gives fifteen grains continuously every two or three hours, till the symptoms are checked. It is important to notice that the administration of salicine, in large and frequent doses is often the cause of much mental excitement and aberration, and it may be necessary to discontinue it. As regards the local treatment of the inflamed joints, little is to be done in a disease which shifts its site so rapidly as acute rheumatism; for even if it can be driven from one joint, it must, as long as the poison is in the constitution, show itself elsewhere, it may be in the heart; above all things, leeching the joints, unless under peculiar circumstances, of which a medical man only can judge, is to be avoided -hot bran bags sometimes give relief, but probably the following plan laid down by Dr. Bentley Todd will be the most advantageous local method of treatment. When the joints are much swollen and painful, much ease may be given by enveloping them in a large quantity of the soft carded cotton—"cotton wool"-over which there is wrapped completely a piece of oiled silk or gutta percha tissue secured by a few loops of a bandage. By this air-tight covering, the joints are kept in a perfect vapour bath, and when it is removed after twelve or twenty-four hours, the wool will be found saturated with moisture which is strongly acid. Dr. Todd says this treatment affords great relief, supports and keeps the limb steady, and at the same time promotes sweating. It is also serviceable in gout. Of local medical applications, a mixed alkaline and opiate solution may be used as a fomentation, or the chloroform and belladonna liniment will frequently give relief, but the cotton wool applied as above is by far the best treatment.

There are few diseases so tantalisingly tedious as acute rheumatism; it may disappear quickly, possibly in a week, or it may extend its visitation, ebbing or flowing, to ten, twelve, or fifteen weeks, in spite of treatment, apparently the best directed; but yet, provided the heart, the diaphragm, the brain remain unaffected, it is free from danger, and, generally speaking, does not leave joints which have been severely affected worse than they were before. very rarely the case that matter forms in consequence of rheumatic inflammation. It has been said that there is a rheumatic predisposition: not only does this show itself in a tendency to attacks of acute rheumatism properly

RHE RHE

matory action in the body, as for instance in | with simple oil, or by means of the compound the eye, when it gives rise to the peculiar "rheumatic inflammation." The causes of acute rheumatism already pointed out will suggest to most persons the precautions to be adopted, especially when liability to the disease exists. Cold and wet are particularly to be guarded against, and, after exposure, the preventive measures already laid down adopted. Flannel or wool stuff worn next the skin, must always be regarded as one of the chief preventives; it should of course be proportioned in thickness to the season and temperature. Some persons imagine that their liability to rheumatism, either acute or chronic, is increased by flannel; if it is, it is probably because the wool keeps the skin in too excited a state, and by increasing perspiration increases the risk of suppression; in such cases, woven silk when it can be afforded, is useful, or spun cotton, may be used in winter: many rheumatic patients find their chief protection in an under dress of chamois leather. At all events, perfect warm clothing and protection against suppressed perspiration is essential in all such cases. Many of the above precautionary measures apply likewise to chronic rheumatism. Persons of full habit, liable to rheumatic attacks should eschew malt liquor generally, should take animal food sparingly, and avoid violent exer-tions which heat the body. Persons of spare or feeble habit, may live better, and indeed require to keep up the condition of the body to as good a pitch as possible.

Chronic Rheumatism .- There are various forms of chronic rheumatism, but that with which we are most familiar is the rheumatic affection of old people, associated with chronic pain, stiffness, and swelling of one or other of the larger joints, and which most frequently shows itself in persons who have been much exposed by the nature of their avocations to cold and wet. The symptoms are aggravated by change of season, east winds and exposure.

Another chronic form, named usually rheumatoid arthritis or rheumatic gout, is a disease somewhat resembling the acute form, accom-panied with but slight febrile derangement, if there is fever at all, and affeoting one or more of the joints, generally the smaller ones, which continue for a greater or less length of time swollen and tender, the inflammation either subsiding without effect, or after long continuance, causing permanent thickening around the joints, probably with permanent distortion; the process being more or less accompanied with pain. In this form of rheumatism, instead of heat, there is often a sensation of cold around the affected parts. The chronic nature of this disease must generally place it under proper medical control; the chief efforts of the unprofessional must be, to correct any slight deviations from the general health, to protect the affected parts especially from cold, by means of warm clothing, and to use friction, either | water, and applied to the skin, or by means of

camphor oil combined with soap and opium liniment, one-third of the former, to two of the latter. Much comfort is not only derived from friction, but if combined with proper exercise of the joint or joints, it may do much to prevent permanent deformity. In the class of cases relieved by warmth, guaiacum is often a valuable remedy. It is best given in the form of the ammoniated tincture, of which a tea-spoonful may be taken in milk three times a day, or the guaiacum mixture may be used in two table-spoonful doses three times daily. The vapour and Turkish baths are often found valuable remedies. In chronic rheumatism warmth of climate is of much importance, and as much should be done towards the attainment of this as circumstances will permit. Sir James Clark recommends Nice and Rome as the best European climates, but these, of course, are the resources only of the wealthy. Australia, however, is open to the poorer classes. Warm bathing, especially the saline bath, such as is furnished by Bath or Buxton, or Ashby-de-la-Zouch, is of the highest service in cases of chronic rheumatism, and in all cases of long standing should, if possible, be had recourse to. The charities connected with many of the baths

are available to the poor. Chronic rheumatism, properly so called, is such as above described, but the term rheumatism, or rheumatic pain, is also used to a great variety of anomalous pains, and from this has arisen considerable confusion. The best marked of these is "muscular rheumatism," which affects chiefly the thick muscles, such as those of the shoulders, arms, neck, loins, giving rise to such well-known complaints as lumbago and wry neck, &c. This form of rheumatism often comes on suddenly, after exposure to a current of cold air, sometimes after cold bathing; its chief characteristic is severe pain, when the affected muscles are thrown into action. This muscular rheumatism seems to be a purely local affection, and is generally removable by purely local amendian. Of these the best is a large hot remedies. Of these, the best is a large hot bran poultice, or some other means of applying heat and moisture, repeatedly applied over the affected part for eight or twelve hours; this often at once cures, care must of course be taken to protect the part to which the heat has been applied by a covering of flannel. After the hot application is removed, if the heat does not entirely cure, and even instead of it at times, a mixture of the soap and opium liniments, either alone or combined with onethird turpentine or cajeput oil added, may be used with advantage, two or three tea-spoonfuls being well rubbed into the part every six or eight hours. In situations where other means are wanting, counter-irritation, by means of pieces of metal dipped in boiling

Dr. Corrigan's hammer (see Counter-irritation), | flattish, many of them pierced with holes. may be resorted to. In rheumatism of the thick muscles about the shoulder the use of the acupuncture needles often removes the affection in a strikingly rapid manner, indeed,

sometimes in a few minutes.

Any notice of rheumatism at the present day must be imperfect, without some allusion to electric and galvanic agencies. That these appliances are at times of apparent service in cases of chronic rheumatism is undoubted, and if such is the case, we are not justified in rejecting their aid, because we cannot exactly explain the why and wherefore of their action. The effect of the acupuncture needles, above alluded to, in curing muscular, and also nervous rheumatism, such as sciatica, is sometimes almost magical, but how the simple introduction of a needle into the substance of the body acts so as almost instantaneously to remove a most painful affection, it is very difficult to say. In using electric or galvanic appliances for the use of chronic rheumatism, those apparently which keep up a slight but continued electric excitement are the most useful. The continuous current Leclanché battery is best adapted for this purpose.

Salicine—Electricity.

RHUBARB, MEDICINAL.—Rhubarb Root. Well known as this valuable medicine is, there is yet considerable uncertainty respecting which of the many recognised species of rheum, or rhubarb, yields the true medicinal drug. A species known as the Rheum palmatum is considered to be the most likely source of the best rhubarb, but it is not improbable that other species of the genus Rheum yield much of the rhubarb root imported from the East, and it is certain that different species of rhubarb are cultivated in this country and on the Continent both for adulterating the genuine article when in the form of powder, and for simulating it in substance, being "dressed up" in a manner similar to the real root. Dr. Royle says :- "The greater part of the rhubarb of commerce grows in Chinese Tartary, and is gathered in summer from plants six years old. When dug up, it is cleansed, peeled, cut into pieces, bored through the centre, strung on a string, and dried in the sun." A portion of this rhubarb goes to China, the remainder passes through Russia, and is known in this country as Russian or Turkey rhubarb. When genuine, this rhubarb is always a superior drug, chiefly on account of the care bestowed upon the examination of the samples before they pass the Russian factory, through which they are transferred to the European markets. At this factory the inferior samples of the root are, or ought to be, rejected. Russian or Turkey rhubarb "varies in shape, being irregularly roundish and angular, from the bark having been shaved off with a knife; some pieces are cylindrical, a few make the "tincture of rhubarb": Take of

Externally smooth, of a yellow colour; internally the texture is rather dense; fracture uneven, irregularly marked with white and red veins, having a strong and peculiar slightly aromatic odour, a bitter, rather astringent taste, feels gritty when chewed, and produces a powder of a bright yellow colour." The grittiness is owing to the presence of numerous crystals of oxalate of lime, that salt being found in the rhubarbs generally. Chinese, or East Indian rhubarb, is probably derived from the same source as the Russian, which it resembles in essentials, although less uniformly good. English rhubarb is cultivated chiefly near Banbury, in Oxfordshire. "It is the kind frequently sold by men dressed up as Turks, as genuine Turkey rhubarb. The pieces vary in shape, some being ovoid, others cylindrical, smoothed externally, and rubbed with a yellow powder, light, rather spongy, with a reddish hue. It is rather mucilaginous in taste, and a little astringent. Its odors in taste, and a little astringent. Its odour feeble, but unpleasant." Few medicines are more extensively used than rhubarb, few are more valuable or safer. The most characteristic action of rhubarb is that of a mild, but effectual, aperient, the action depending upon the amount of the dose; it rarely gripes; it exerts, moreover, a beneficial tonic action upon the stomach. On account of its astringency, rhubarb is apt to leave a tendency to constipation after its purgative effect is over.

Rhubarb may be taken alone, as an aperient,

in doses of from ten to thirty grains, either simply mingled with water, or made into pills. Some persons habitually carry a piece of the root in their pockets, and cut off small fragments as they think them required. Infusion of rhubarb is made, according to the British Pharmacopæia, by infusing for two hours a quarter of an ounce of the sliced root in ten ounces of boiling water. The preparation is too weak for an efficient aperient, but may be

used as a stomachic.

The compound rhubarb pill, one of the best

forms of common aperient we possess, has been already considered.—See Pills.

The compound rhubarb powder is better known as Gregory's Powder, or Gregory's Mixture (see Gregory's Powder). The tincture or compound tincture of rhubarb is an extensively used, and most valuable remedy, chiefly as a stomachic cordial and anti-spasmodic; it ought rarely to be given as an aperient, on account of the large amount of spirit which must necessarily be taken with it in this form by most persons, a few individuals, however, of weak habits, whose bowels are very easily acted upon, find it beneficial, not only for its

RIC

RHU

quarter of an ounce; coriander, a quarter of an ounce; saffron, a quarter of an ounce; proof spirit, twenty fluid ounces; macerate and percolate.

For infants and children, rhubarb alone, or combined with calomel or grey powder when requisite, forms a most excellent medicine; the chief objections are the bulk and taste, which render it sometimes difficult to administer. It should be remembered, that in persons who are taking rhubarb the urine acquires a deeper colour from the drug; so also the milk and perspiration. Rhubarb in small doses, combined with bicarbonate of soda, is an excellent alterative, and an invaluable remedy in many cases of indigestion depending on acidity and tendency to constipation. The dose should be about six grains of the former to ten of the latter, taken two or three times a day, and is all the better for being combined with a few grains of powdered ginger. A very elegant stomachic preparation is made by digesting, for a week, one ounce of rhubarb root sliced in eight ounces of liq. potassæ. Of this ten, fifteen, or twenty minims may be given in half a wineglassful of peppermint water, with ten minims of chloric ether

RHUBARB, GARDEN, is too well known in its numerous varieties to require description; its agreeable acid depends on the presence of the oxalic and malic acids, which it contains abundantly. As a cooling article of diet, it is wholesome for most persons, but some cannot take it without suffering after from stomach disorder, and others who have any tendency to certain urinary disorders must most strictly avoid it; indeed, if garden rhubarb is too freely indulged in, it may give rise to urinary irritation.

When used as food, garden rhubarb exerts an aperient action upon the bowels. This is increased, if shortly after it has been eaten, a moderate dose of magnesia be swallowed.

Refer to—Oxalic Acid.

RIBS.—The ribs are the curved bones which inclose the chest (fig. 176) and upper part of the abdomen. They are twelve in number on each side. Of these the first seven on each side (1, 1) are directly connected with the breast bone or "sternum" (3), and are called the true ribs, the remaining five are called the false ribs, of these the upper three are indirectly connected with the breast bone, by means of cartilages attached to the cartilage of the last true ribs; the lowest two (2, 2) are unconnected with the breast bone, or other ribs in front, and are therefore called floating ribs. The "cartilages" (4, 4) by which the seven superior ribs are connected with the breast bone, and by which the three upper false ribs are connected with the

rhubarb sliced, two ounces; cardamoms, a of the rib, is attached to the spine (fig. 177) by means of ligaments (1) which admit of a certain amount of movement. These ligaments are so strong as completely to resist displacement of the bone by violence, fracture, as is the case at

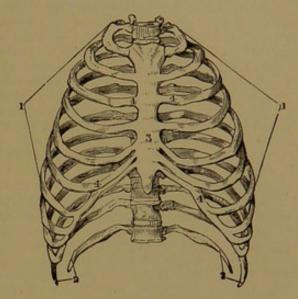

Fig. 176.

the ankle, taking place instead (see Fractures). The ribs are likewise attached in front to the breast bone by means of ligaments, and are connected to each other by short "intercostal"

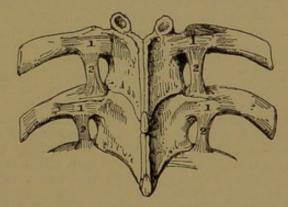

Fig. 177.

muscles, which act in the efforts both of in-

spiration and of expiration. RICE.—This well-known grain, although far below most others of the class in actual nutritive power, -not yielding more than three or four per cent. of plastic nutriment, -forms the staple article of food to millions in warm climates, especially in Asia, and is largely used as an occasional article of diet in this country. Its chief constituent is starch, of which it contains eighty per cent., and when it is cooked in water, it absorbs that fluid so largely, as to swell to many times its bulk in the dry state. It is unquestionable that rice is well adapted cartilage of the last true rib, are very elastic in as food for the inhabitants of those warm early life; as, however, age advances, they become less so, and ultimately are converted into bone. The posterior extremity, or head be conducive to health, whilst at the same

time its blandness to the palate and stomach | constitution will be requisite. If the situation can be corrected by the aromatic condiments which usually grow under the same climate as that which brings the grain to perfection. In climates like our own, rice probably could not form a staple article of food, but as an addition to other food it is of the highest value, and especially to the food of the young, in the form of puddings, &c., care being taken that the grain is thoroughly cooked, a point not always attended to; nothing can be more indigestible than half-cooked rice. In puddings and the like this is less likely to occur than when the grain is dressed as a vegetable, and required to present the distinctness of grain.

The property of rice, in tending to confine the bowels, renders it a valuable adjunct to sick cookery when such an effect is required; in this case it is most beneficial in the form of "ground rice," or of rice flour. In cases of diarrhœa, or of irritability of the stomach or bowels, rice water, that is water prepared from rice, as barley-water is from barley, is very useful as a drink. It may be flavoured with lemon peel, or any other condiment. If the

spoonful of isinglass or gelatine in every pint of the "water" is a useful addition.

RICKETS is a disease in which the bones are deficient in their earthy constituents, and consequently lose their natural hardness; they become soft like gristle, and somewhat brittle, so that they are not only easily bent, but easily broken. It is essentially a disease of infancy and childhood, resulting from delay in the natural process of ossification and hardening of the bones. Rickets is a constitutional disease, and is very generally associated with a tendency to scrofula, either hereditary, or engendered by poor living and unhealthy influences, such as deficient ventilation and light, impure damp air, and bad food. Rickets may show itself within the first few months after birth, but is more generally perceived when the child first attempts to walk, and the limbs give way under the weight of the body. By far the largest number of cases arise during the first two years of life. Coincident with, or rather preceding the evidence of weakness in the bones, the child's general health is observably impaired; there is languor and pallor, with dingy complexion, loss of flesh, tumidity of the belly, impaired or fickle appetite, and unhealthy secretion from the bowels; in fact, the child presents all the evidences of a depressed state of health. Not unfrequently there is an approach to the cretin head and features (see Cretin). It need scarcely be said, that a child showing the symptoms above detailed cannot too soon be placed under proper medical attendance, for life and future well-being are at stake. Every means for improving the considered as rheumatic.

is an unhealthy one, removal, if possible, should be effected; if the child is still at the breast, unless there is positive evidence that the milk is of good quality, it should be weaned. Animal broths will probably be required even for infants, certainly, along with animal food, for older children. Clothing will require attention as regards its warmth, and tonic and other medicines, especially iron, must be requisite. For a child of a year old, powders, containing half a grain of grey powder, and three grains of carbonate of iron in each, are a very useful remedy, given twice a day for some time. The above are only general directions, for such a disease as rickets ought always to be under proper medical care. In the later stages, when the bones are very soft, much care will be required in moving, to avoid inflicting either pain or injury. Very many children who become ricketty die, but a certain number recover, and though perhaps with distorted limbs, yet they grow robust in health, the bones becoming quite firm and strong, even more so than those of other persons.

Many children, without becoming the subjects of confirmed rickets, yet exhibit the tendency in an enlarged state of the extremities of the long bones, especially those of the forearm, at the wrist. Such an indication ought never to be neglected, every possible means, by change of air, by diet, clothing, and medicine should be used to improve the child's general health. The powders above recommended will be useful, or five drops of the tincture or solution of perchloride of iron may be given twice a day in water, the bowels being regulated by simple aperients, and an occasional dose of grey powder. To resume, it must be borne in mind that rickets is a disease of debility, and of an enfeebled constitution, which every means must be used to counteract. The deficiency of earthy matter in the bones, naturally suggests the use of lime, which may be given in the form of lime water, along with milk. The use of salt by the affected children should be insisted on. The saccharated solution of lime, in doses of from ten to thirty minims, may be used with advantage; or the syrup of the various phosphates, especially that known as Parrish's food, which contains lime, iron, and magnesia, and which should be taken immediately before meals. Cod-liver oil also suggests itself as a remedy, with change of air, especially to the seaside.

A disease somewhat resembling rickets in its effects occurs in adults, and is known under the name of mollities ossium. It is most common in females, and the pregnant state seems to favour its establishment and progress; it has also been thought to be dependent on the gouty and rheumatic constitution. The disease is often preceded by severe pains in the limbs and bones, which are apt to be

As in the case of rickets in children, bone- | different portions of the same head, by combs, softening in adults, requires every means to be used for invigorating the constitution, but the proper remedies, and their application, must be regulated by a medical man. When a female has at any period of life been the subject of rickets or bone-softening, the fact may seriously affect the capability of her becoming a mother, either with safety to her own life or that of her child; for as the bones of the pelvis (see Pelvis) partake of the general softening, and yield under pressure, the entrance of the child into the world may be rendered impossible or nearly so. The fact should not be lost sight

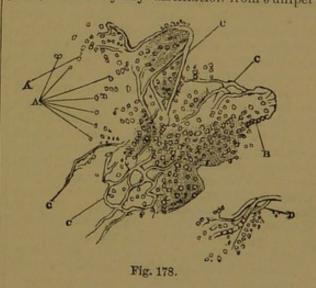

Refer to - Scrofula, Childhood.

RIGOR is the sudden sensation of cold, accompanied with shaking, or in other words, the "shivering" which precedes the inflammatory stage of many acute diseases. In an aggravated degree it is symptomatic of the development of suppuration in some part of the body. It is probably a nervous affection, for it occurs likewise in many states of the body in which there is neither fever nor inflammation. It is a common symptom of the presence of bile in the stomach; it is a concomitant on the passage of gall-stone or of renal calculus; it often occurs at the commencement of labour, and may even be caused in a slight degree by certain sounds.—See Shivering.

RING, FIXED.—See FINGER.
RING-WORM.—The real nature of this very troublesome affection of the skin is accounted for by the presence of a fungus which is developed between the scarf and true skin, and which forms a sheath round each separate hair. Inflammation of the hair follicles and their surroundings results, with the formation of purulent matter, which has the double effect of checking the growth of the hair, and caus-ing baldness. The sporules of the growth are to be seen in the form of white powder at the roots of the hair, and when examined by the microscope present the appearances figured in accompanying illustration (fig. 178). The most usual site of the disease is the scalp, but it is apt to extend to the forehead, to the beard, and also to other parts of the body. Generally, the first indications of the presence of ringworm are the falling or breaking off of the hair, which leaves a bald generally circular patch, and the itching which accompanies the disorder. If examined at this time, the patch will be found scurfy, slightly red, with the irregularly broken hairs protruding. If the disease be unchecked by treatment, it goes on If the extending, until at last it involves almost the entire scalp. The hair, which is not detached, on the affected parts, becomes lighter in colour and woolly in character. If pustules form, the discharge from them dries upon the surface in the form of scurfy scabs, or in crusts. That

brushes, &c., or by the nails, which children are apt to use freely on account of the itching. It is also very liable to spread in schools and among members of the same family.

Few diseases have given more trouble or vexation in their management than ringworm, nor was it until the true nature of its parasitic origin was fully understood, that the medical treatment of the complaint could be considered as at all satisfactory. The main object is, of course, to destroy the fungus, for if this can be successfully accomplished, the disease is cured; but the fungus will remain so long as the hair follicles are intact. It is therefore necessary to remove the hair, if it should not have already been destroyed by the disease itself, and then to apply some chemical agent capable of destroying the fungus embedded in the hair follicles and surrounding tissues. Te enumerate the various applications used would be a very lengthy business, and we will content ourselves with those which have of late years been most in favour. The oil of cade or pitch, derived by dry distillation from Juniper

A, A. Isolated Spores. B. Spores united at their ends. C, C, C. Empty Tubes. D. Sporular Tubes.

wood, was introduced by French dermatologists, and is still upheld as probably the best means of destroying the parasite; it should be combined with glycerine in the proportion of a drachm of the oil with an ounce of glycerine. Lotions composed of sulphurous acid and water, one part to three, or of hyposulphite of soda, one ounce to twelve ounces of water, are found very efficacious. Chrysophanic acid, the active principle of goa powder, has obtained much favour of late years in the treatment of ringworm; it is used in the form of ointment prepared with from ten to sixty grains of the acid to an ounce of lard or vaseline. Apart from shaving the scalp, it is often necessary to the disease is highly contagious there can be tweezers or depilatory forceps made especially remove each hair separately by means of no question; it is frequently, too, extended to for the purpose. The oil of cade is said to

possess the property of destroying the sensi-bility, and loosening the attachment of the hair, thereby rendering it easier of removal. In ringworm of the scalp an oil silk cap is necessary to prevent the evaporation of the For the microscopic appearances lotions. presented by the hair in ringworm see article Microscope.

The writer has treated successfully many cases of true ringworm with a solution of nitrate of silver in pure nitric ether, in the of boiling water. The infusion is slightly astrinproportion of two scruples to the ounce. The gent, and is occasionally used as a gargle, but solution is easily applied, and penetrates the its colour is its chief recommendation. Rose superficial structures, even blistering at times; six days will generally suffice. - See Scalp.

ROASTING, like broiling, is one of the most primitive methods of cooking; in the latter process, however, the surface of the meat is in , e quickly hardened, and the juices and far more effectually retained. During roasting, the watery portions of the meat evaporate, and much fat is melted out, at the same time the coagulation of the albumen, the usual result of heat on animal food, takes place. The loss of fat in roasting renders meat thus cooked more digestible. It retains, moreover, the gelatine, which is greatly dissolved out in the process of boiling. If, how-ever, the cooking is carried too far, the meat overdone, its nutritious propertie are impaired. On the other hand, if meat is underdone, although more nutritious, it is certainly less digestible. "By enveloping small pieces of flesh with a covering of lard, the extraction of the sapid constituents from the flesh by its juices, and the evaporation of the water, which causes hardening, are prevented; and the surface, as well as the subjacent parts, are kept in the tender state, which is otherwise only found in the inner portion of large masses of flesh" (Liebig). - Refer to - Boiling - Broiling, &c.

ROCHELLE SALT.—Tartrate of soda

and potash. -See Potash.

ROLLER.—See BANDAGES.

ROOM.—See BED-ROOM—HOUSES—VENTI-LATION, &C.

ROSE.—See Erysipelas.
ROSEMARY is chiefly used on account of its fragrant volatile oil, which is stimulant and anti-spasmodic. The oil may be added to liniments, as a fragrant stimulant addition to these applications. A spirit of rosemary is made, which may be used as an anti-spasmodic, in doses of thirty drops, in water or in sugar.

ROSE PETALS, or LEAVES .- The petals of the red rose are used in medicine, partly on account of the colour they yield; but their most valuable preparation is the confection, made by beating up one part of the fresh petals or flower leaves with three parts of refined sugar, and chiefly used in the formation of pills, for which it is well adapted, being less pills, for which it is well adapted, being less modic. Medical men certainly too much apt to harden than other materials used for neglect rue as a medicinal agent. In accuthis purpose. - See Pille,

When the petals of the red rose are dried for use, the white "claws" at one end should be cut off, and the red portion dried as quickly as may be, without too great heat being used. The petals should then be sifted, to remove dust, &c., and packed in vessels closed against light and air. Dried rose leaves are used in the form of an acid infusion, which is made with one-fourth of an ounce of the leaves, one drachm of dilute sulphuric acid and ten ounces water, distilled from the petals of the cabbage two or three applications at intervals of five or rose, is an agreeable substitute for pure water in mixtures and lotions.

ROSE-RASH.—Rose-rash occurs both in children and adults in the form of rose-red patches of various sizes, somewhat resembling measles in many cases, but of a redder hue. The disease is generally accompanied with some light constitutional disorder or fever, but the symptoms differ from those which accompany measles. It is devoid of danger, and generally subsides after the administration of a simple aperi-If it is rose-rash or nettle-rash connected with teething, the gums should be scarified.

ROTHELN, a variety of measles known also as German measles, is occasionally epidemic. It differs from true measles chiefly in the absence of bronchitis and other lung affections; the eruption, as a rule, is not so marked as in measles, and may resemble mild scarlet fever; especially if associated with marked sore throat and slightly enlarged glands in the neck. It is usually mild, but if the eruption simulates scarlet f ver medical advice is needed.

RUBEFACIENT—an application which reddens the skin. According to this definition, a great variety of agencies must be included in the class. When the irritant effect of any agent upon the skin amounts to blistering, or causes discharge of pus or matter, the action 's said to be vesicant, or suppura-All these agencies, therefore, are included under the one term, counter-irritants, the rubefacient action being the mildest of the three, and dependen, generally, upon the form and duration of the application; as, for in-stance, heat, mustard, ammonia, or other excitant agents, may be used so as to produce only the most transient redness, or may be made to cause either blistering or suppuration. The most commonly used rubefacients are :-Ammonia or hartshorn; friction; heat; mustard; spirit of wine, ether, and chloroform; turpentine, &c. Refer to-Counter-Irritation.

RUE—the Ruta graveolens.—This plant is too well known to require description.
It is valuable, and much used in domestic practice on account of its powerfully stimulating volatile oil, which is strongly anti-spas-

panites, a strong infusion of rue given as an | health, by the "living by rule," the weighing injection, is often of the highest service, and second only to assafeetida; in worms - the thread-worm—in the lower bowels, the infusion of rue, also used in injection, is serviceable. In suppressed menstruation, when stimulants are required (see Menstruation), the rue enema may prove of much use. Rue is abused when given, as it frequently is by nurses, to new-born infants.

RULE, LIVING BY.—There are few

departments of practical medicine which have been carried out to a more mischievous extent of refinement than that which is noticed in this article. Mischievous, because an important principle has been overlooked in the prescription or following out of petty detail. That principle is, that there is nothing more likely either to create or to keep up disorder in any of the organs of the body, which usually act independent of the will, than continued, especially, anxious attention directed to them whilst in active operation. It is unquestionable that in some diseases, such as diabetes, dysentery, &c., the strictest regulation of diet and regimen is absolutely necessary, neither can it be doubted that in most ailments, even in those of a trivial character, some general regulations as to living are required; it is not against such as these that these remarks are directed, but against the absurd "living by rule," the worse than useless clockwork regulation of every action of daily life, eating, sleeping, walking, &c., which many dyspeptic and hypochondriacal patients either adopt for themselves, or are advised into. In such cases, instead of a wholesome varied diet, the nature of the food is confined within an unwholesomely narrow compass, and its amount, if not weighed physically, is at least so mentally, by the trammelled invalid, who trembles lest, inadvertently, half an ounce more than the prescribed quantity should find its way into his stomach, and then, after his meal, disturbs the digestive process, by thinking how it is going on, and by directing his attention to the sensations of his stomach, which is petted, and considered, and allowed to choose its own work, and mode of working, till, of itself, it nauseates the uniformity of too regulated a diet, and sours even to mutton of the tenderest, and to the most unexceptionable brown bread. At last, forcing its miserable possessor to the conclusion that he is yet over-taxing its powers, the animal diet is perhaps eschewed, and farinaceous foods of different kinds are resorted to, as more digestible by the "very weak stomach." As already remarked rules of life, and stringent ones too, must often be laid down by medical men for persons labouring under serious disease, nor can they be too strictly attended to, but these cases are abundantly different from that numerous class of nervous and dyspeptic complaints,

and measuring, and considering every morsel of food, and every action of the body or mind. As said under article Indigestion, the stomach, and other organs too, must, in part at least, be brought up to their work by observation of the rules of health generally; the endeavour to bring the work down to the organs is worse than useless.

Refer to—Indigestion.

RUM .- This well-known spirit is distilled from the products of the sugar cane; when genuine it contains about forty-eight per cent. of alcohol. New rum is apt to contain lead, dissolved off the leaden worm of the still in which it is made. When this is the case, the rum is of course unwholesome, and may give rise to symptoms of colic; but after the liquor has been permitted to stand some time in casks of oak wood, it becomes freed from the lead, which forms an insoluble compound with the tannin of the oak, and falls to the bottom. Rum is a favourite domestic remedy in cases of incipient cold. It possesses, probably, no advantage over other stimulants, and in such cases the use of an alcoholic stimulant at all may do harm. A mixture of rum and milk was supposed at one time to be a remedy for consumption; it is, however, scarcely necessary to say that the milk should be taken without the rum.

Refer to-Colic-Lead, &c.

RUPTURE, by medical men called Hernia, is the protrusion of some portion of the bowels, or of the viscera usually contained within the abdomen, through any part of the walls of that cavity. Unless the skin is wounded from without, the rupture remains covered by it and by certain tissues which lie beneath it, at the points where the accident usually occurs, these points being at those portions of the walls which are naturally thinner and weaker than others, or at which there are openings naturally for the passage of blood-vessels, &c.

The existence of rupture is always a serious matter, and on the first suspicion of it, medical advice should at once be sought; it is, moreover, an accident much more common than is generally imagined. It has been calculated that ten per cent. of the population in Britain

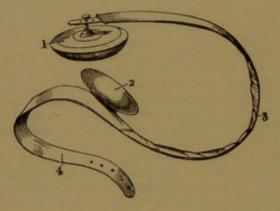

are the subjects of rupture.

It is sufficient here to notice the three principal kinds of rupture; of these, one occurs at the navel, two in the groin. Rupture at the navel is a very common accident soon after birth; its nature and management have been fully entered into in article Childhood. When it occurs in adults, it is not unfrequently the result of neglect in early life, but it may be of recent origin; in females it may be the result of pregnancy and child-bearing. Rupture at or near the navel is known by the presence of an class of nervous and dyspeptic complaints, elastic or doughy swelling, which is usually which are fostered by the too close attention to capable of being "reduced," pressed back into

RUP RUP

the cavity of the abdomen. When this form rupture occurs, that is when rupture becomes of rupture is discovered to exist, a truss should "strangulated," or assumes such a condition be applied without delay, under the direction of a medical man. The essential part of the truss is a pad made to fit over the site of the protrusion, this pad being kept in place by different contrivances of springs, or of elastic belts, &c. Fig. 179 represents "Salmon and Ody's" truss for the purpose; 1 being the pad which is fitted over the rupture; 2 a pad which is applied to the spine; 3 the steel spring; and 4 the strap which helps to fix the apparatus. The pads are made of various materials, sometimes of ivory, sometimes of padded materials, and also of caoutchouc bags, inflated with air, &c.

Rupture in the groin in adults is of two kinds, inguinal and femoral. In inguinal the swelling first appears above the fold of the groin, in femoral below it. The former is most

common in males, the latter in females; the affection generally, is, however, much more common among the former sex, the calculation being, that four men are the subject of hernia, Rupture in the groin also for one female. occurs in infants, it is "congenital.

It is found that rupture prevails most among those whose occupations involve strong muscular efforts. Rupture may come on gradually, or, suddenly, during some violent exertion. When its formation is gradual, it is preceded by some amount of pain and fulness in the part; at last, or when its invasion is sudden, a decided swelling generally shows itself, more or less painful, varying in size, and elastic or somewhat doughy under the pressure of the fingers, the swelling becoming tense and larger, and as it were pushed forward, when the person coughs or sneezes, and usually disappearing during lying down in sleep. It is proper, however, to caution our readers against the supposition that rupture must always be accompanied with swelling; sometimes the tact of the experienced surgeon is insufficient satisfactorily to detect the tumour, especially in stout people, and he is forced to base his treatment upon the general symptoms, when that accident which constitutes the danger of

that it cannot be returned into the abdomen, and is so tightly grasped at its "neck," by the sides of the ring or opening through which it is protruded, that the natural functions of the part are interfered with. A rupture may assume this condition at any moment, if it be permitted, for want of a truss, to continue "down," as it is usually called, that is in a protruded state. When a rupture becomes strangulated, distressing symptoms very quickly follow; all motion of the bowels downwards is prevented, and their natural movements becoming inverted, their feculent contents pass upwards into the stomach, and are rejected by vomiting; at the same time, there is severe pain, especially of a dragging character, from the back; there is thirst, and depression of the bodily powers. If the above state of matters be not speedily rectified, either by the return of the bowels into the abdomen, or by a cutting operation, the person speedily dies; generally, in consequence of the protruded portion of bowel becoming mortified.

It is needless to remark, that upon the first symptoms of strangulated rupture showing themselves, efficient medical advice should at once be sought. Every minute is precious. Until medical assistance arrives, however, some methods of relief may safely be tried.

When a surgeon first sees a case of strangulated "hernia" or rupture—if it has not been of so long continuance as to lead him to suspect the possibility of the bowel having become tender, and liable to be burst-he makes an effort to return the protruded bowel; this effort, conducted in a peculiar manner, is technically named the "taxis," it is in fact skilful manipulation. The first step in the exertion of the taxis is to place the individual in the position most favourable to the return of the bowel, this position is the horizontal one, with the shoulders half raised, and the legs and thighs bent upon the body, so as to relax as much as possible the walls of the abdomen, and the rings through which the rupture passes, and by which it is so tightly constricted. The above position having been assumed, the neck of the rupture, that is to say, the portion of it next the opening, from which it protrudes, is to be compressed by the fingers of the left hand with moderate firmness, whilst the right hand is used as gently as is consistent with the requisite effort to knead, or mould as it were, the protruded bowel through the opening. At first this process perhaps seems to have little if any effect, but if the rupture is returnable at all in this way, and if the taxis is properly made, after a time a perceptible diminution of the swelling takes place, which goes on till at last the rupture passes suddenly as it were, back into the abdomen, frequently with a gurgling sound. gurgling sound.

Such is the process of reducing a rupture by

RUP RUP

means of the taxis; it is one which, to perform | duced by the continued evaporation of ether well, requires both skill and practice, but it is one which may be safely tried for a short period by an unprofessional person, if medical aid is far distant in point of time, indeed, it is a process which persons who have suffered from rupture for some time not unfrequently perform for themselves. In a case of strangulated rupture, if medical assistance is quickly procurable, the best course is, with the exception of laying a person in the horizontal position, and the administration of twenty or thirty drops of laudanum, to leave the case entirely alone, and to avoid handling the swelling, for this only places it in a more unfavourable condition for the manipulations of the surgeon. When however, as said before, medical aid is far distant, the taxis may be tried, but must not be continued for more than twenty minutes or half an hour. In almost all cases, efforts are made by the patient, or by the persons around, to return the rupture; it is better that these should be made in an intelligent and efficient manner. If, by the taxis simply, the surgeon does not succeed in "reducing" a "strangulated hernia," he probably has recourse to other methods, with a view of assisting it. These methods are such as either assist the relaxation of the muscular parts around the rupture, or such as tend to diminish the size of the swelling. To effect relaxation, the surgeon may administer chloroform, or opium, or put his patient. in a warm bath, till faintness comes on, when he again has recourse to the taxis. Many of the means had recourse to by a medical man are of course quite inadmissible for the unprofessional, the two last mentioned, however, they may use carefully. Opium, given so as to affect the system, will sometimes greatly facilitate the reduction of a hernia; for this purpose twenty drops of laudanum, or one grain of solid opium, may be given to an adult, the former every hour, the latter every hour and a half, till three doses have been administered, taking care, of course, after the second dose, that the system does not seem too powerfully affected. The warm bath will generally produce faintness in less than half an hour; during the condition an attempt should be made to return the rupture; some surgeons, however, object to the use of the warm bath.

The chief means of facilitating the return of a rupture, by reducing the swelling, is the application of cold. For this the best agent is snow, or pounded ice, put in an icebag, which is laid upon the swelling. If snow or ice are unavailable, cold may be artificially produced by mingling five parts of diluted hydrochloric acid with eight parts of glauber salt in powder; or by mixing two parts of oil of vitriol with two parts of water, allowing the mixture to cool, and then mingling with five parts of glauber salt; or by mixing equal parts of muriate of ammonia and nitre-salt-

dropped upon a piece of lint laid over the swelling, or the cold douche may be used with advantage. Under the continued application of cold for from half an hour to an hour and half, a rupture may possibly "pass up," without any manipulation at all; if it does not, however, manipulation should be tried.

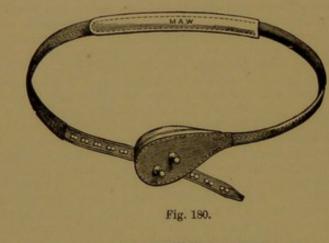

Such are the principal means which may be resorted to, by unprofessional persons, in the event of a case of strangulated rupture occurring at a distance from medical aid; they are pointed out, not to induce any one to hazard one moment's delay in procuring proper assistance, but as a resource, when that assistance is far distant, and when the suffering and danger of this serious affection render it advisable not to wait entirely its arrival. In a case such as might occur, when a surgeon could not be procured for many hours, it might be some days, the author thinks the treatment by opium most calculated to relieve, it is at least that most likely to afford comfort to the patient under so fearful a contingency. If the stomach will not retain opium given by the mouth, it can of course be administered by injections.

It sometimes occurs that purgative medicines are administered in cases of rupture. should never be done; they may greatly increase the distress of the patient, and they afford very little chance of relief. Neither can any good, but only harm, result from frequent efforts to return the rupture by manipulation after the first well-directed efforts have failed. Neither is it well to be too hasty in giving purgative medicines after a rupture which has been strangulated is reduced, -very frequently the bowels act of themselves soon after; if they do not in the course of a few hours, an injection, or a gentle dose of castor oil, or of rhubarb and magnesia, will be the most suitable aperients. The fact must be kept in mind, that after the existence of strangulated rupture there is always danger of inflammation of the bowels generally, and that consequently perfect quiet and low diet for several days is requisite. As soon as, from the symptoms as detailed in the first part of this article, any one suspects he is ruptured, however little inconvenience he may suffer, not a day should elapse without medical advice being sent for. Till this is obtained, quiet in bed is the safest plan—many a rupture has been strangulated in a long walk to the doctor. The same rules should be observed after the reduction of a rupture which has been strangulated. Every minute in the upright posture, passed without the protection of a truss, is one of peril. If there is any necessary delay before a proper truss can be procured, a pad composed of cloth, wrapped round firm material, and held in its place by a spica bandage (fig. 23, article Bandage), will be of some service during the confinement to bed. The selection of a truss petre-in water. Cold may likewise be pro- is always better left to the judgment of a medi-

In some cases, however, a Salmon and Ody's truss, somewhat similar to fig. 179, but modified to fit the similar to fig. 179, but modified to fit the groin, is found more useful. The peculiar feature of this truss is, that the circular or oval pad is attached to the spring by a ball and socket joint. In some persons, owing to flatness of the back, it is difficult, almost impossible, to make a spring truss fit at all; for such and other difficult, cases the spiral suppossible, to make a spring truss fit at all; for such and other difficult, cases the spiral suppossible, to make a spring truss fit at all; for some time at least but generally such and other difficult cases, the spiral supporters of M. Bourjeaurd (fig. 182) may proit it may be dispensed with during the horizontal

It is important that a truss fit well, otherwise Soldiers whose belts compress the upper part it is of little actual service, and is apt to of the abdomen, and cavalry soldiers, who at cause excoriations, &c. ; it is also requisite that certain times ride without stirrups, are not unthe strength of the spring be proportioned to frequently the subjects of the disease. It is the nature of the case. Further, it is import- also brought on by hard riding, or by leaping ant that the truss is not put on whilst any of the hernia is "down." When, as sometimes the hernia is "down." When, as sometimes in the least liable, should avoid all such causes; the happens, a rupture is "irreducible," that is, and those who wear a truss, should bear in cannot be entirely returned within the abde cannot be entirely returned within the abdomen, a bag truss suited to the nature of the case is requisite. The causes of rupture are various; in one sense it may be said to be hereditary, that is, some individuals inherit a tendency to weakness about those parts, which are the usual seat of rupture. The direct imperative on all who are the subjects of ruptures are such as induce undue pressure by ture, more especially as nothing is more likely either to cause or to aggravate the affection the walls of the abdomen upon its contained viscera, hence the disease is most frequent than the straining of constipation; at the

posture, being put on before getting out of bed. | among those who have to make strong exertions. mind, that if the natural support has given way, the artificial may also. It may become a question with a ruptured individual, how far the hazard of sea-sickness, and the consequent mechanical action of vomiting is to be incurred. Strict attention to the state of the bowels is RUP SAI

The danger of a rupture is not in proportion to its size; when small and recent, it is more liable to become strangulated. Ruptures may of course occur in both groins of the same person; in this case a double truss is requisite.

When rupture in the groin occurs in infants, it is usually of considerable size, descending into the scrotum, and becoming very tense whenever the child cries. In the early periods of life spring trusses cannot very well be worn, those made of elastic material will answer best, and frequently no truss is used. Strict attention to the bowels, and bathing the loins of the child every morning in cold salt water, will do much to prevent the disorder getting worse, and will sometimes effect a cure. In some cases where the ordinary truss-pad causes pain or irritation, the water-pad, as made by Mr. Pratt of Oxford Street, will be a comfortable

RYE.—This hardy grain possesses a nutritive power about equal to that of barley. It has slight aperient properties. The chief point of interest connected with this grain is the peculiar diseased or fungus growth, the Ergot of Rye, which is apt to be developed upon the seed.—See Ergot.

SACCHARINE—of the nature of sugar. —See Sugar

SACRUM, or Os Sacrum, is the bone of the pelvis which fits in like a wedge between the two irregular lateral bones; upon it the spine rests (see *Pelvis*). The bone derives its name from having been formerly offered in sacrifices, whence it was considered sacred.

SAFFRON is procured from the blue autumn flowering crocus, which is cultivated extensively for the sake of the drug, both in this country and in France, Spain, &c. In the centre of each crocus flower rises the "style," which terminates in three wedge-shaped, notched divisions (fig. 183) which are called

Fig 183.

"stigmata." These stigmata, with a portion of the upper part of the style, constitute saffron, being clipped off when fully developed, and dried carefully. Saffron is sold either in the form of "hay saffron," or of "cake saffron," the former being composed of the loose dried

same time, strong purgatives are not advisable. | a cake before they are quite dry. In eastern countries saffron is largely used medicinally; in this, except as a colouring matter in several pharmaceutical preparations, it is little employed. It is stimulant and supposed to be slightly anti-spasmodic. Saffron is liable to much adulteration from marigold and wallflower petals.

SAGE, like other plants which contain essential oil, is stimulant and carminative. It is a good deal used domestically in the form of "tea" or infusion, especially as a gargle, com-

bined with vinegar.

SAGO.—This well-known dietetic article is the produce of various species of palm tree being obtained from the cellular substance contained within the stems of that tribe of plants. The stem is split, the cellular substance scooped out, and stirred up with water to separate the fecula or starchy matter, which, while suspended in the water, is passed through a sieve, then allowed to subside, and, being dried, forms the "sago meal" of commerce. This sago meal, after having been made into a paste with water, "granulated," and again dried, constitutes the sago of the shops; common or "brown sago," or white or pearl sago, according to the mode of preparing. Sago is nearly pure starch, and closely resembles in composition arrow-root, for which it is a frequent and cheap substitute. The remarks made upon the nutritive properties and dietetic uses of arrow-root apply equally to sago, the chief difference is in the former being the more agreeable preparation of the two, and requiring a somewhat different mode of cooking. -See Cookery.

Refer to—Starch. SAINT ANTHONY'S FIRE—a popu-

lar name for erysipelas.—See Erysipelas.
SAINT VITUS'S DANCE, known to medical men by the name of Chorea, is a disease strongly indicative of nervous disorder; its precise nature, however, is at present obscure. Probably it may be occasioned by direct causes, that is, by causes seated in the great centres of the nervous system, or by in-direct causes, which act by "reflex action" (see Nervous System), in the same way that teething in infants produces convulsion; that is to say, irritation in some portion of the body, as in the bowels, may, in the first place, give rise to functional irritation of the brain and spinal cord, which irritation acting as if its original seat was in these great centres, is "reflected" on the body generally, or at least upon some portion of it, causing the irregular muscular movements of the disorder in question. St. Vitus's dance is, for the most part, a disease of youth, occurring before puberty, and usually disappearing at that period of life, if it has continued so long. It is more common in girls than in boys, in the proportion of three to one. It may, however, continue into stigmata, the latter of these parts beaten into adult life, but rarely occurs after twenty. It

rarely proves fatal; indeed, in those subjects of the disease who have died during its existence, it has been a question whether death has not been the result of other coexisting maladies, especially of heart disease, with which it is sometimes associated.

if the individual is of full florid habit. In any case no harm, but almost certain benefit, will result from acting on the bowels freely, more moderately, of course, in a weak subject than in a strong one. For this purpose, the compound colocynth pill simply, or combined,

The most manifest symptom of St. Vitus's dance is continued involuntary action of the voluntary muscles, to a greater or less degree, the extent of the muscles affected, and the intensity of their affection, varying with the severity of the disease. The movements, however, generally cease entirely during sleep, and in all cases certainly are diminished. The ordinary voluntary movements are still capable of being performed after a fashion; that is, in an unsteady, uncertain, and sometime grotesque manner. It seems as if, after the voluntary impulse had been communicated to them, an additional involuntary one interfered to throw the limb or other part out of the usual steady movement.

The disease generally commences with twitching about the face or neck, or in a particular limb, gradually extending to one side of the body, and in the vast majority of cases, ultimately involving the whole body. Pain is seldom complained of, but it does sometimes occur in the head. The appetite may remain quite good, but the bowels are possibly confined, and their secretions unhealthy. To this depraved state of the bowels, or to constipation, or to the presence of worms, the disease is often traceable; in females it is not unfrequently connected with the menstrual function, especially if it be delayed or imperfect. The irritation of the coming of the second teeth has been assigned as a cause; and there is no doubt that imitation, especially among females, may spread the disease, which is most general, as might be expected, in persons of a nervous tendency; and it is said those with dark hair and eyes are more liable to it than those of a blonde complexion. The duration of the attacks varies from ten days or a fortnight to months; but having once existed, it is, up to the age of puberty at least, apt to recur, or to be re-excited.

As regards the treatment of chorea, the best plan is, as soon as possible to submit the case to a proper medical examination, for, as already explained, it may be dependent merely on some casual irritation, which skill will at once detect and remedy. The disease, moreover, is one which is usually devoid of danger, and while there can be no question that many cases of it will get well without any treatment at all, there are others in which the cause and true nature of the malady can only be satisfactorily elucidated by a medical man.

Sir Thomas Watson says that when pain in the head exists, he finds benefit from the moderate abstraction of blood by leeches, and if persistent pain does exist, the application of four or five leeches might be had recourse to advantage.

any case no harm, but almost certain benefit, will result from acting on the bowels freely, more moderately, of course, in a weak subject compound colocynth pill simply, or combined, for two or three doses in succession, with calomel or blue pill, will be of service, or the blue pill and black draught, or compound decoction of aloes draught, may be given. After the bowels have been well cleared, if the subject of the disease be weak and pallid, iron will be required. In the disease in question the red carbonate of iron, as given by Dr. Elliotson, has been found extremely useful in large doses, from a drachm upwards, given twice or three times a day; other preparations of iron, however, may be given, or quinine. The author has also found the oxide of zinc of much service, but these are remedies which ought to be given under medical sanction. The shower bath is often serviceable in St. Vitus's dance, but for some individuals the shock is too powerful, and seems rather to increase the disease; for such, the douche down the spine may be substituted. Galvanism applied along the spine is also found serviceable in many cases. In all cases attention to the general health is required. Good diet, exercise, change of air, and attention to the hours of sleep, and to free ventilation of sleeping rooms, are all circumstances to be kept in mind in such cases.

Refer to—Convulsion—Nervous System, &c. SALADS generally, being composed of raw vegetables, are unsuited for persons of weak digestion; when, however, the stomach is capable of digesting them, the general effect on the system appears to be beneficial, particularly in salads derived from the tribe of the cruciferous plants, to which the water cress, radish, mustard cress, scurvy-grass, &c., belong.

Many persons with whom raw vegetables such as salads, cucumbers, &c., invariably disagree if eaten "undressed," find the addition of the ordinary salad, or "Florence" oil, correct the tendency. In this country some individuals have a prejudice against the use of oil. It is difficult to see why it should extend to the beautiful preparation in question.

SALEP is prepared from the bulbs of the Orchis mascula. It is imported chiefly from the Levant, but some is brought from India. It consists of a peculiar kind of gum termed bassorine starch, and phosphate of lime. In some respects it is more nutritive than either arrow-root or sago, and consequently is better adapted for the convalescent than for the sick. It is prepared by dissolving the powdered salep in hot water, with assiduous stirring, and adding to the solution sugar and milk. Prior to the introduction of coffee, salep was much used as a diet beverage in this country, and it might still be employed with advantage.

519

SAL SAL

cheap substitute for that expensive medicine, especially in the treatment of ague, neuralgia, &c. It has more lately come into extensive use as a remedy for acute rheumatism, and as a means of reducing the temperature in all tebrile conditions. It is also a powerful antiseptic, salicylic acid being employed largely to prevent feetor from gangrenous and offensive sores. That salicine is a most excellent tonic remedy there is no doubt, one, moreover, which is applicable to cases in which quinine is inadmissible, the former remedy being less likely to heat, or to cause headache; in such cases, however, as ague or neuralgia, it does not seem to exert the same powerful curative effect, although it might well be used, either in its prepared form or in the form of an infusion of the willow bark itself, in the absence of quinine or of cinchona bark. The dose of salicine as a tonic is from two to four grains given as a powder, or dissolved in water, or if a stimulant be required, dissolved in a little sherry. For neuralgia it should be given in still larger doses. Since Dr. Maclagan, of Dundee, first introduced salicine as a remedy for rheumatic fever, it has been employed with almost universal approval by nearly every medical practitioner. The pre-paration of the drug in most extensive use, because of its solubility, is the salicylate of soda, which, Dr. Ringer recommends, should be taken in doses of from ten to fifteen grains every hour, until the temperature is reduced. The medicine has also proved of much service in chronic rheumatism, lumbago, and sciatica; but it is to be kept in view that its free employment in many cases is attended with delirium, deafness, and headache, and though these inconveniences are not of a lasting character, the fact is enough to indicate that the remedy should not be used except on the recommendation of a medical man.

SALINES, or salts, are distinguished from other bodies by their general properties of incombustibility, aptness for combination, and a peculiar taste generally known as "saline." Salines are better illustrated by their many well-known examples and compounds, such as common salt, potash, soda, Epsom salts, pyretic saline, Eno's fruit salt, &c., than by any description. A good aperient saline powder may be made by combining half an ounce of sulphate of soda with the same quantity of Epsom salts, to which should be added eight grains each of chloride of soda and bicarbonate of soda. Dose from a tea-spoonful

to a table-spoonful as required.

SALIVA, or SPITTLE, the fluid which

moistens the mouth is secreted by glands, disposed around that cavity. These glands

**SALICINE** is a "peculiar bitter crystal-fisable principle," obtained from the bark of the willow. In some respects it resembles quinine, and has been brought forward as a upper jaw and the cheek, opposite the second double tooth. A second salivary gland lies deep below the tongue, its duct opening by the side of the bridle, or tie, of the tongue, just behind the corresponding front "incisor" tooth of the lower jaw. Where the duct opens there is a perceptible eminence, from which, when some individuals gape, a small jet of saliva is apt to be projected at least a foot beyond the mouth; this is caused by the muscles exerted in gaping, compressing the gland and its duct. The third salivary gland, the "sublingual," lies partly just below the duct of the last mentioned, its small ducts conveying the saliva into the mouth, close to the other. As, therefore, these glands are situated on each side of the mouth, there are six salivary glands in all. The saliva, or spittle, for the supply of which such ample provision is made, contains about one per cent. only of solid matter, which consists partly of animal constituents, and partly of saline. The saline constituents are similar to those contained in the blood, with the addition of a peculiar salt, a sulphocyanide. The animal principle, known by the name of "ptyaline," resembles in action the vegetable principle "diastase" in possessing the power of converting the starchy constituents of the food into saccharine aliment (see Digestion). When food is not being taken, the secretion of saliva is very greatly diminished, and in sleep seems to be almost suspended altogether; no sooner, however, is the appeasement of hunger by food commenced-and, indeed, previous to the food being taken-than the flow of saliva begins, the secretion continuing to be poured out as long as the meal continues. The amount of saliva secreted in the period of four and twenty hours has been estimated at from fifteen to twenty ounces, but it is very difficult to ascertain the precise quantity, and probably it varies.

The importance and the functions of the saliva in the process of digestion have been variously estimated by different observers. Its action upon starchy matter has been already noticed. The experiments of Dr. Wright, of Birmingham, detailed in his valuable papers on the saliva, tend to show that its alkaline properties are necessary to the perfect fulfilment of the digestive process generally. Dr. Wright observed that after a full meal the saliva became more strongly alkaline, and that if, instead of swallowing this alkaline saliva, he spat it out, there was manifestation "of abundance of acidity, with much pain at the stomach," but that if he neutralised the acid in the stomach, by a dose of carbonate of soda, the alkaline condition of the saliva quickly diminished, as if, being no longer required, the are three on each side. The principal, or alkalinity was withdrawn. The saliva, how-

SAL SAL

ever, is not constantly alkaline, it is frequently | who waste this fluid, suffer. Indigestion is a acid, especially during fasting; the acidity has | very common malady in America, and may in acid, especially during fasting; the acidity has been attributed to the mucus of the mouth, with which the secretion is necessarily intermingled. Dr. Wright performed a variety of experiments with the view of determining the influence of the saliva in the digestive process. From these experiments he formed the follow ing conclusions :-

That saliva has the power of modifying, and to a certain extent of digesting, vegetable

and animal substances.

That it has a more powerful action upon vegetable than upon animal matters.

That acids or alkalies added to saliva dimin-

ish or destroy its digestive properties.

That the presence of saliva in the stomach

is essential to healthy digestion.

Of course the saliva performs other functions beyond the simple assistance of digestion, it facilitates especially all the movements connected with mastication and speech. "tartar" which accumulates about the teeth is a mixture of the earthy salts and animal mat-

ter contained in the saliva.

The influence of the mind upon the secretion of saliva is very considerable; the popular saying of the "mouth watering" at the sight of tempting food, is an illustration of its increase from this cause; its diminution under the influence of painful emotion, such as fear, is well ascertained, and indeed, in some eastern countries, is practically acted upon as a means of detecting crime. If a crime, such as a theft, is committed, and a number of persons such as a staff of servants are generally suspected, the whole of the suspected are placed together, and caused to chew and then spit out a handful of rice in the presence of the examiner: it is said that such is the feeling in these countries with regard to the test, that the fear of the real criminal diminishes the secretion of his saliva to so great an extent, that the portion of rice chewed by him remains comparatively un-moistened. There is a peculiar affection of moistened. There is a peculiar affection of moistened. There is a peculiar affection of moistened. —See Chlorine—Soda, &c. peptic persons are liable, which the author has never seen described in any medical work, and which he believes is generally confounded with pyrosis or water-brash; it consists of the rapid flow of a quantity of limpid saliva into the mouth, or from it in a stream, if permitted, accompanied with a sense of constriction about the jaws, the flow continuing for a minute or two at a time. It is generally preceded by symptoms of indigestion, of heartburn, or of irritation in the stomach. It is in fact a symptom of indigestion, and an instance of "reflex" action (see Nervous System—Indigestion) or of irritation in the stomach acting upon the salivary glands, which seem to be peculiarly susceptible to irritation from such causes. The above remarks upon the use of the saliva may explain in some measure the disordered digestion from which many smokers, distance from the sea, and where from the ab-

part be occasioned by the well-known habit of "spitting," peculiar to the country.

SALIVATION is the excessive secretion of saliva from any cause. The term is best known in connexion with mercurial salivation (see Mercury); salivation, may, however, arise from other causes, a course of iodine medicines may occasion it, and nitric acid has the same effect; it also arises from constitutional causes. Salivation, that is, simple increase of the flow of saliva, is not an unfrequent concomitant of the first stages of pregnancy.

Refer to-Indigestion-Mercury, &c.

SALMON, like the other oily fishes, is less digestible than white fish generally for persons of weak stomach. Like other articles of food too, which contain oil, it is apt to prove highly injurious, if eaten in a state of decomposition. Indeed, death has been the result of a meal of pickled salmon which had become somewhat decomposed.

SAL PRUNELLE is saltpetre which has been fused by heat, and cast in a mould generally of a globular form. The preparation is used by some persons in incipient sore throat with advantage; the ball of the salt being

allowed to dissolve gradually in the mouth.

SALT.—The term salt is applicable to saline matters generally (see Salines). In this article, however, it is regarded in its conventional acceptation of "common salt," as used in daily life. Common salt is a compound of chlorine and sodium and water. formerly supposed to be a combination of hydrochloric acid with soda; but Davy clearly showed that this view was incorrect, as both substances, when in combination, underwent decomposition resulting in the formation of water, the chlorine of the first uniting with the sodium of the last, and forming chloride of sodium or common salt. Common salt is one

Common salt is most generally procured either from the salt mines, such as those of Cheshire, from saline springs, such as exist in America, or in Germany, or from sea water; in the two latter cases, by evaporation. However obtained in the first instance, salt generally requires to be purified from other saline ingredients with which it is usually mingled, and which particularly interfere with its keeping properties, causing it to become moist. Of late years the finer descriptions of salt have become so cheap that the coarser kinds are scarcely seen.

As regards the use of salt as a condiment, or as an addition to food, by man, there can be no doubt as to its beneficial effects; indeed, the desire for salt seems almost to be instinctive, as a necessity for health. In countries at a

sence of saline springs, salt is difficult to procure, as in the interior of Africa, it is most highly prized as a necessary of life. Many travellers have described a temporary deprivation of salt as one of their greatest hardships; and, to descend to the lower creation, the way in which the salt springs or "licks" in America are frequented by the wild animals is evidence of instinctive desire; and, indeed, the eager devouring of salt by, and consequent improve-ment of condition among, domestic animals, sufficiently testify, if not the absolute necessity for, at least the great benefit arising from the admixture of salt with food. Salt unquestionably assists, and renders more perfect, the process of digestion; moreover, it forms one of the constituents of the blood, and of the body generally. If salt be denied, the digestion is weakened; the general tone and nourishment of the body are impaired, and it is observed that worms are more likely to be generated in the intestines. Salt, therefore, ought to be an addition to the food of all, and attention should be paid to children in this respect; they should be made to eat a certain proportion of salt with their food—their greater liability to be infested with worms than adults is an additional reason.

It is, however, a very different thing to eat salt with food, and to live upon meat or fish which has been salted. In the latter case, it is well ascertained that certain chemical changes take place in the meat and its nutrient constituents by the action of the salt, which modify considerably the nutriment afforded to the body (see Preserved Provisions). Indeed, the effects of a continued diet of salted meat are most injurious (see Scurvy). The exclusive and continued use of salted provisions is here alluded to, not their moderate occasional employment. Salt may almost be regarded as medicinal in some cases of convalescence, in which the craving for it becomes intense. It should be allowed. It appears to act as a tonic. From one to two ounces of salt dissolved in half a pint of water forms a good, and not unfrequent domestic emetic. It may however purge, instead of causing vomiting. It is used in the form of enema to destroy worms, and to act on the bowels. An excellent domestic injection may be prepared with an ounce of salt and from half a pint to a pint of oatmeal gruel. The occasional use of salt in the treatment of typhus fever, and of cholera, &c., does not require notice here. Externally, salt is used in solution, generally as in sea or salt water cold bathing, in which cases it seems to exert a tonic effect; warm saline bathing is efficacious in rheumatism. For local bathing after injuries, such as sprains, &c., the salt water douche is well adapted to give strength. For the above purposes, a pound of salt dissolved in three gallons of water is a good average strength. The "brandy and salt" appli-

Salt is widely distributed throughout nature, forming a constituent of the animal and vegetable kingdoms.

SAMPHIRE.—This plant, which grows on rocks close to the sea, is used as a pickle, and is about as wholesome as pickles generally. -See Pickles.

SANATORIUM is an institution for the promotion and preservation of health, in contradistinction to a hospital, which is devoted to the cure of disease. The sanatorium as a home substitute for a warm climate is at present but little known, or brought into use, although probably it will become more so. The hospital for convalescents must be regarded as a sanatorium of the most useful description; and at the present time sanatoria for consumptive patients have been established at Torquay, Bournemouth, Ventnor, and other places on the south coast of England. The author, however, is not aware that these are on the plan suggested in this article, the nearest resemblance to which is (or was) the enclosed space of what is usually termed the Tropical end of the Crystal Palace at Sydenham. The beneficial effects of winter residence in a warm climate. in some cases of disease, have been too well proved in numberless individual instances to admit of doubt that such a change is not, in the cases adapted for it, in the highest degree serviceable; at the same time, there cannot be a doubt that change of climate, as it is usually resorted to, has been much abused, and that in numerous instances, uncalled-for sacrifices, not only of a pecuniary nature, but of the strongest feelings and affections of the human heart, are made, to give a beloved invalid the change of climate considered necessary for the restoration of health, or for the preservation of life. Not only doubt, but certain conviction. exists in many minds, that numerous cases which formerly would have been sent abroad, should now, and will now be kept among home comforts and home affections, to live or to die; but it must be matter of thankfulness that when the hope, too often the delusive one, of that last resource of "climate" is, to say the least, weakened, another and a better one is likely to open up, one which involves neither severance from home nor friends, and one which may be made the resource of the indigent as well as of the rich. The resource is the glass-covered sanatorium—the acres of age strength. The "brandy and salt" appli-cation, so much in vogue some years ago, is of climate which may be rendered more certain the same use as any other stimulant applica- and genial than any open to the winds of

heaven, which may be accessible to the delicate, | bene or turpentine principle common to all." and to the invalids, during a winter season in Britain. The various arrangements under which a glass-covered sanatorium may be made available are very palpable. With buildings such as the Crystal Palace at Sydenham, or the Alexandra Palace, but away from the London fogs and otherwise specially adapted for the purpose, it might be possible to connect the villas of the wealthy, in which invalids, though resident in the houses, and mingling in the society of their own families and friends, might yet enjoy in the winter and spring, the benefits of a free and genial atmosphere. even without the magnificence, wide extension, and consequent expense of such fabrics as we have named, it would be very possible to enclose glass-covered spaces of one, two, or more acres in extent, into which the windows of some of the apartments of adjoining houses might open, apartments to be occupied by the invalids, whilst the rest of the house, for a family generally, has the ordinary aspects and arrangements. Or under another construction, detached houses, or sets of houses, might be connected by covered glass or other passages with the general glassprotected garden, or promenade, or climate, as it may be named. The varied arrangements of which glass structures, for the benefit of consumptive and other invalids in this country, are capable, need not be entered into here. The possibility of such structures is certain, not less so, perhaps, the fact of their wide adoption in years to come; but, amid the various plans for glass structures in the vicinity of our large towns, for the purposes of pleasure or instruction, the author has regretted to see little or no notice taken of their important availabilities as regards health. This important point seems to be overlooked-their capability of supplying a great want, of serving as an antidote to our comparatively rigorous climate, which so often presents the apparent necessity of the young and the delicate seeking a home, and too often finding a grave, in a foreign climate, exposing them to the depressing, and therefore necessarily injurious, influences which severance from home scenes, home comforts and society, and home affections, cannot fail to produce in a greater or lesser degree.

It would be possible to dilate greatly upon the advantages offered by the glass sanatorium -perhaps enough has been said for the purpose.

SANITAS, now manufactured on an extensive scale, is becoming largely and deservedly used on account of its properties as a "disinfectant, antiseptic, and deodoriser." Its discoverer, Mr. Kingzett, became convinced by experiment that "the hygienic influence common to groves of pine and blue gum trees consisted in the constant evolution of peroxide of hydrogen, camphoric acid, and certain other camphoraceous bodies, caused by the volatilisa-tion of naturally secreted oils," dependent upon "the atmospheric oxidation of the tere- all classes of the community, cannot be too

Having arrived at the fact that "these purifiers can be produced from common turpentine, Mr. Kingzett set to work to manufacture them in such quantities as would make them practically available as antiseptics and disinfectants." In this he has by certain processes been completely successful, and sanitas, in all its varied preparations, in shape and form, "may find daily application in every house-hold." In one form the writer can bear testi-In one form the writer can bear testimony to its eminent value. A case of severe burning, involving extensive destruction of tissue of both lower limbs and one arm, was treated by means of the ordinary liniment of oil and lime water, to which was added not quite a fifth of sanitas oil. The patient, after seventeen days, succumbed to the injury, but, notwithstanding being in a small room and the weather being warm, the application completely extinguished the fœtor of the extensive sloughing surfaces. No better testimony could be given to the value of sanitas. It may be added that the sanitas fluid was also freely used over the dressings in the form of spray. The application caused no pain, indeed, the suffering patient described the sanitated liniment as more soothing than the liniment as first used without the sanitas.

SANITATION. - SANITARY OF SANA-TORY regulations and observances are daily acquiring more importance, both in a public and in a private point of view. The numerous Acts of Parliament passed with reference to the public health during the last twenty years, the various treatises on the subject both of a scientific and popular character, the authority given for local legislation on all matters appertaining to health, and the efforts made to educate the people at large to the necessity of adopting measures to ward off disease, are among the most noticeable features of the age we live in. But notwithstanding the increase of knowledge generally, combined with the best intentions on the part of the legislature, it is to be feared that the spread of true sanitary principles among the poor, who stand in most need of their aid, has been slow and limited. We refer mainly to matters which concern the individual himself, and which, as rational beings, every one is bound to consider, not on selfish grounds only, although these are all important, but for the sake of his family, his friends, and his neighbours. Comprised under this heading are one's daily and hourly habits, clothing, food, sobriety and moral conduct, in fact, every thing which contributes to develop "the sound mind in the sound body," and to make each unit of the population a worthy member of the commonwealth. Attempts to inculcate health principles among children in our Elementary Schools, and the dissemination of plain facts in plain language on the same subject among

highly commended. Though comprehensive, | so commonly met with, especially in childern, the knowledge need not be extensive, but should be made to embrace the fundamental facts relating to the physiology of the respiration, circulation, and digestion, as well as the causes of varying death-rates, and the measures necessary for the prevention of what are now usually termed "preventable" diseases. The principles of sanitation ought to be made part of all modern education; there are no situa-tions in life in which they would not be useful, while in some they would be invaluable. In fact, no educated man in any position of life, especially if he has either by courtesy or by appointment influence or command among his fellows, can with propriety be ignorant on these subjects. A more extensive acquaintance with them on the part of the clergy especially, would greatly add to their means of usefulness in their visits amid the poorer classes. In the words of Dr. Guy, who first introduced the subject of Hygiene to a class of students in divinity in King's College, "sanitation has to do with persons of every rank, of both sexes, of every age. It takes cognisance of the places and houses in which they live; of their occupation and modes of life; of the food they eat, the water they drink, the air they breathe. It follows the child to school; the labourer and artisan into the field, the mine, the factory, the workshop; the sick man into the hospital; the pauper into the workhouse; the lunatic to the asylum; the thief to the prison. It is with the sailor in his ship, the soldier in his barrack, and it accompanies the emigrant to his new home beyond the seas. To all these it makes application of a knowledge remarkable for its amount, and the great variety of sources whence it is derived. To physiology and medicine it is indebted for what it knows of health and disease; it levies large contributions on chemistry, geology, and meteorology; it co-operates with the architect and engineer; its work commends itself to the moralist and divine." Attention to the principles and practice of sanitary observances and regulations, included under the single word Hygiene, is so constantly enforced in the present work, that further notice here would be superfluous. The articles more especially devoted to sanitary matters to which reference should be made, are-

-Walls-Water-Water-Closets. SANTONINE.—This is a white resinous crystalline powder, obtained from the Artemisia santonica. It is an infallible remedy for "round worms," that is, for the long round

in certain localities. The dose of santonine is from two to six grains. It is tasteless, and may be taken in milk, or between thin slices of bread and butter. It should be given when the patient is fasting. Three doses may be administered at intervals of twelve hours. The powder may be mixed or made up with an equal quantity of sugar of milk, or it may

be given alone as above.

Nothing could be more certain than its action in killing or poisoning this kind of worm. Patients complain that, after having taken a few doses of the drug, they see things of a greenish-yellow colour, and are much distressed lest this state of things should continue permanent. It never does so. urine is tinged of a citron yellow colour and stains the linen. Amongst many other cases, the writer prescribed small doses of santonine to two children in a village where these round worms were very common. At the second dose the two children passed no fewer than ninety-two of these loathsome parasites. Altogether we must look upon santonine as one of the most valuable additions which has been made to our list of medicines, inasmuch as, by so effectually and speedily getting rid of these troublesome creatures, we are often enabled to cure patients of fits, and other affections, of which these worms have been the perhaps unsuspected cause. Moreover, the worms are dangerous in themselves, as they have been found perforating the walls of the bowels, and so causing death. Their effect, too, upon the general health of children, as well as adults, is oftentimes most pernicious. Patients troubled with them complain of pain in the region a little below and to the right of the stomach (i.e., in the bowel next to the stomach), of sickness, and often of a peculiar sensation of "rising in the throat," with sickness, and tendency to vomit. Sometimes, probably owing to the effect on the sympathetic nervous system from the violent movements of the worm within the economy, fainting fits, and other nervous seizures occur at intervals. After a dose of purgative medicines one or more worms are sometimes evacuated, in which case a dose of santonine should at once be taken. They are sometimes vomited also, but most frequently their presence remains undetected, till the continuance of such symptoms as those noted above induces a medical man to suspect their existence, and he prescribes for them accordingly. Santonine, though often administered for, has no destructive effect on the tape worm or on the thread worm.

The following prescription may be made use of by an adult, and for a child one half or less may be given:—Take of santonine eight grains; sugar, or sugar of milk, fifteen grains; mix, santonica. It is an infallible remedy for 'round worms," that is, for the long round to be taken every night, till the three are worms, like earth worms in shape, which are finished. A dose of castor oil, or some simple aperient, is generally necessary afterwards, but | of sarsaparilla chips in thirty fluid ounces of

it need not be given unless required.

SARCINÆ VENTRICULI.—"Sarcina vomiting" is the name given by physicians to a peculiar condition, accompanied with dilatation of the stomach, with sickness and vomiting, generally of a large quantity of acid frothy fluid, in which are discovered, with the microscope, numerous vegetable parasites, named as above. They are very often found accompanied with the yeast fungus, Torulæ cerevisii, and were first noticed and described by Professor Goodsir, who gave them the name of the "woolpack parasite," owing to the appearance they present under the microscope. They are met with in organic disease of the stomach, which causes the food to be long detained in that organ, and hence to undergo a sort of fermentation. They are also developed in the stomach, owing to the use of improper food, and in the course of various forms of indigestion, accompanied with acidity. The treatment proper can only be undertaken by a medical man. It consists in the administration of remedies which kill or destroy the vegetable growth, such as the sulphite or hyposulphite of soda. The patient's diet is also regulated, and it is recommended that unfermented

should be substituted for the ordinary bread.

The occurence of sarcinæ without organic disease of the stomach is most frequently met with in those who live almost entirely upon vegetable food, and the affection is consequently most common in some parts of Scotland and The accompanying indigestion is Ireland. sometimes the cause of the most intense hypochondriasis, and even suicidal melancholy.

SARDONIC SMILE, or GRIN, is a peculiar characteristic expression of countenance, which occurs in some diseases as in Tetanus and in other convulsive affections. The corners of the mouth are retracted, and the teeth ex-

SARSAPARILLA is the root of a tribe of creeping plants, natives of Central America, and of Northern South America. The drug is brought to this country in the form of the roots, tied up in bundles, which are distinguished by various characteristics, according to the place from whence they are imported. These roots are cut up into chips for retail selling. Medical men are greatly divided in opinion, not only as regards the medicinal properties of sarsaparilla, but as to whether it possesses any medicinal properties of value at all, while some contend that if the root itself has medicinal power, this is destroyed by the usual modes of preparation. Whatever the truth may be, sarsaparilla is not a medicine likely to be used domestically, that is without medical prescription; and when it is employed, it will be most efficaciously so as sold in some of the usual prepared forms of extract, infusion, decoction, &c. The decoction is ordered to be made by digesting two and a half ounces

boiling water, reducing the preparation down to a pint by heat. The dose of this preparation is from two to ten ounces. The compound decoction, to which sassafras and guaiac wood are added, has a better reputation, and largely employed by some surgeons in combination with iodide of potassium in the treatment of constitutional syphilis. dose of the compound is the same as that of

the simple decoction.

SAUSAGES, generally speaking, are indigestible as an article of diet, but they chiefly demand notice here from the liability, especially of some of the German forms of the preparation, to undergo a peculiar kind of decay, by which they are rendered highly poisonous; indeed, the defect goes by the name of the "sausage poison." Many hundred deaths have occurred from this cause in Germany. The sausages in question are generally made of liver, blood, with fat, &c., salted, and spiced, and smoked, and if properly prepared, keep well, and are wholesome for months. If badly prepared, they undergo the poisonous putre-faction, which is probably analogous to that which takes place in some descriptions of cheese, in bacon, salmon, and other oily articles of diet. The symptoms of poisoning from sausages are not very quickly developed; they are similar to those described under article Putrefaction.

SAVINE .- See JUNIPER.

SCABIES .- The ITCH .- See Itch.

SCALD .- See BURN.

SCALD HEAD, or, as it is technically called, "favus" or "porrigo favosa," is a disease of vegetable origin, mainly affecting the hairy scalp, though sometimes spreading to the face and neck, and occasionally attacking other parts. The parasitic fungus which occasions the disease, has its seat in the hair follicle outside the layer of scarf skin investing the root of the hair. There is another form of the eruption in which the plant is discovered in cells or depressions on the surface of the skin, giving it a honeycomb appearance, and from which it takes the name of favus. These plant cells form crusts and appear in crops or patches in different parts of the scalp, sometimes running together, but occasionally remaining separate and distinct. At an advanced stage of the disease, and when it has not undergone any medical treatment, the encrustation spreads over the entire scalp, presenting somewhat the appearance of a mask or vizor. The smell of the yellow encrustation is most peculiar, resembling that of the urine of a cat, or of a cage in which mice have been kept. The disease begins by itching, which is soon followed by a slight eruption of red pointed elevations which increase in size, and according to Dr. Aitken, "before twelve hours have elapsed, a yellow point forms on each of the apices. The surface

appears now as if covered with specks of a sulphur-yellow colour, and each elevation appears as if set in the skin with a depressed centre, and any fluid exudation concretes into a dry, brittle honeycombed scab." While increasing in size, the crusts preserve their circular form, and the hairs become dry and brittle, and having no hold on the scalp are easily detached.

Like ringworm, the great point in the treatment of scald head is the destruction of the fungus, which is best accomplished by removing the hair, applying poultices and fomentations to the scalp, and using the tar ointment to the affected parts morning and evening, taking care to wash the scalp thoroughly with soft soap and water, prior to each application. As it is barely possible to shave the head in the majority of cases, the hair must be cut as short as possible, and if the disease does not yield to the treatment recommended, it may be necessary to remove each hair separately by the forceps, and to follow up the treatment prescribed in the article Ringworm.

For the microscopic appearance presented by

the hair in favus, see article Microscope. SCALP.—The skin of the head is tolerably thick and firm, and is connected with the parts immediately subjacent by a rather loose cell-ular tissue. These circumstances often give a peculiar character to the effects of violence, and to wounds of the head, for the skin being firm, and the cellular tissue being easily torn, large portions of the scalp are occasionally separated in flaps, either entirely or partially. When, as the result of violent accident, a portion of scalp is separated, the best thing that can be done by a bystander is, provided grit or dirt have not been forced into the wound, to replace the parts as nearly in their proper posi-tion as possible. This will require a little care, for the skin is apt, from its own elasticity, to curl up. If the wound has got dirt in it, and if it is possible to procure surgical aid in the course of a few hours, the best plan will be to rest content with a superficial cleansing of the wound and adjacent parts, and then simply to lay the detached portion somewhat in its proper position, and to place over all a cloth wet with tepid water, till the arrival of the surgeon, who will clean the wound in the most effectual manner, a matter of some importance. If, however, surgical assistance is far distant, some one should endeavour, carefully, to free the wound of foreign matter, by means of washing with a soft sponge, and also by picking out small portions of gravel, or the like, if these are present, by means of forceps or tweezers. After the wound has been cleansed, the detached scalp must be fitted as closely as possible in its proper position; and if the hair around the wound has not been already clipped close off, this should now be done: in addition, it will be requisite in most cases to shave the scalp perfectly clean for some distance around.

place, if it be large, two or more stitches, ac cording to the size of the wound, may possibly be required (see Wounds) in addition to plaster; if the wound be small, strips of plaster laid evenly, so as to hold the edges together, will probably be sufficient; but in any case, in order that these may retain their hold, the hair must be shaved clean off. After the plasters are applied, a piece of lint, double, and wet with simple soft water, is to be laid over the wound, and over this, to retain all in place, a bandage of some kind. A handkerchief applied as represented (fig. 17, article Bandage) will generally answer every purpose, or a cap may be made to fit close upon the head; indeed, the cap or the handkerchief is better than any regular bandage, and generally more accessible. After the wound has been thus dressed, the person who has suffered from it, should, whether feeling ill or not, go to bed, keep perfectly quiet on low diet, especially avoiding stimulants for some days, and, if of full habit of body, take a dose of common purgative. A few hours after the dressing, the wound will probably feel hot and dry, but these symptoms must be kept down by the use of cold water, used so as to soak through the dressings without removing them. In the course of two or three days, according to circumstances, the wound may again be dressed (see Dressing). Simple incised wounds of the scalp are to be treated in a manner similar to the above, but of course they are less troublesome, the scalp not being detached. Some persons condemn the use of stitches and plasters, entirely, in the treatment of wounds of the scalp, and prefer the use of pads adapted, by bandage and otherwise, to retain a flap in its place; it is doubtful whether this method could be applied by a non-professional person, at least with sufficient accuracy. Bleeding from wounds in the scalp is often profuse, especially if an arterial branch has been divided; it may, however, generally be stopped by the use of cold, or by pressure. Even when a very large portion of scalp has been detached, it is often marvellous how quickly and completely it becomes reunited to the other parts; at other times, however, por-tions of the skin die, leaving a granulating wound to heal like other wounds of the same kind. One chief danger to be apprehended after wounds of the scalp-independent of the violence to the brain which is often a concomitant of such accidents-is the occurrence of erysipelas, which may set in, spread over the head, cause extensive formation of matter under the skin, and perhaps destroy the patient. Such a case must, of course, be treated as erysipelas from any other cause; but if a medical man has not before seen the patient, he ought to do so now without delay; it may require all his skill to save life. A method of treating scalp wounds has been highly spoken of in the surgical practice of the American army, which To retain the detached portion of scalp in its | certainly has simplicity as its recommendation.

SCA SCA

It consists of the union, by plaiting or braid- of the disease a lotion composed of two ing, of strands of the patient's own hair across drachms of bicarbonate of soda to the pint and the line of the wound or incision. This method is said to be highly successful, and is much more simple than the old method of shaving, stitching, and plastering scalp wounds, while in the case of females especially, it has the advantage of preserving the hair, and causing little or no disfigurement. The writer has tried this method in several cases, and has never failed to secure union by the first inten-

The scalp is often the seat of "encysted" tumours, which are at times conspicuous on the heads of aged people; they are perfectly harmless and painless, if they do not interfere with the wearing of the usual head covering. If desired by the patient, their removal is simple. Soft fluctuating tumours beneath the scalp of infants are sometimes met with immediately after birth, they generally disappear shortly, but it is better they should be examined by a medical man.

The scalp is the seat of different forms of eruption, or of skin disease, especially in children. For the more important of these, see articles Ringworm and Scaldhead. It would be quite superfluous and useless, so far as the non-professional are concerned, to attempt to enter into the numerous differences in the character of the various diseases of the scalp, and the treatment and its modifications applicable to each: general observations are all that can be offered with any advantage. The first great object in eruptions of the scalp is to get them under treatment as early as possible, the next to observe the strictest cleanliness. The variety and the obstinacy of the diseases in question are reasons for placing them under proper medical treatment as early as possible. When this cannot be done as possible. quickly, the first step should be to examine the head thoroughly, that no affected spot be undiscovered; the next to clip the hair moderately short, and around the affected parts, perfectly close. If the eruption is extensive, it is better to cut the hair close off altogether at once. The hair having been removed by clipping, in preference to shaving, washing with good brown soap, with warm soft water, night and morning, is a process which will cure many a scalp eruption, especially among those classes in whom deficient cleanliness is often the cause of the evil. When this does not suffice, an ointment made with ten grains of the red oxide of mercury to the ounce of lard, smeared slightly over the affected part, is often of much service. As long, however, as there are any scabs or incrustations on the head, there is no use applying either this ointment or any other application; these, therefore, should be removed in the first place by poulticing. In some kinds of scalp eruptions, alkaline washes are often of service. The late Dr. Hughes Bennett recommended in some forms and curd soap, dissolved in strong tincture of

drachms of bicarbonate of soda to the pint and half of water, to be applied to the affected parts, by means of lint soaked in it, and covered with oiled silk. Very many applications for eruptions on the scalp are and have been used; but if a disease of the kind does not yield to the simple measures above detailed, a medical man should see the case; moreover, in some forms of scalp eruption it is scarcely desirable that the eruption should be done away with, at least quickly, or without the constitution being acted upon by medicine; for it may happen that, after the disappearance or cure of a scalp eruption, a child has become the subject of convulsions, or of other affections of the brain.

In all cases of tendency to eruption on the scalp, the diet should be attended to, salted meats forbidden, and in those of full habit, the allowance of animal food curtailed, and milk and farinaceous diet substituted, more or less according to circumstances; on the other hand, in the weak and delicate, it may be requisite to improve the diet both in nourishment and stimulation.

In strong children, three grains of grey powder, given at bedtime, and followed in the morning by a dose of senna or other aperient, will often be useful; in more delicate children, half a grain of grey powder with two or three grains of carbonate of iron given twice a day for a week or ten days at a time, is a useful remedy. In all such cases, however, proper medical attendance is the best and safest plan.

When there is eruption on the scalp, the glands of the neck are liable to become enlarged

and painful.

SCAMMONY .- This drug, which belongs to the class of purgatives called cathartics, is obtained from a species of Convolvulus, a native of the countries of the Levant. It is one of our most valuable medicines, but from its high price, one of the most adulterated drugs in use; indeed, the scammony generally met with does not contain above fifty per cent. of the pure drug, and the doses are generally regulated according to this; consequently, if pure, or, as it called "virgin" scammony was generally attainable, the doses would not be above half what they now are. Scammony is generally met with in the form of a greyish mass, or grey powder; the adulterations are chiefly chalk, flour, &c. Scammony acts as an efficient purgative without griping, and is not liable, if properly given, to produce violent effects; its certainty of action is, however, increased by combination with other purgatives; on this account it forms a valuable addition to the compound colocynth pill. A compound scammony pill has been recently introduced into the British Pharmacopæia. It is prepared with equal parts of scammony, resin of jalap,

ginger and rectified spirit, the latter being | fevers; and is characterised by symptoms so evaporated by heat until the mass has acquired a sufficient consistence to form pills. dose is from five to ten grains. For children, when free purging is required, scammony is remarkably well adapted, combined with small doses of calomel or grey powder; moreover, its small bulk of dose, and the comparative absence of nauseousness, fit it for such administra-For a child of four years of age, four grains of ordinary scammony alone, or one grain and a half of calomel, or three grains of grey powder, with three grains of scammony, will prove a certain and active purgative. The twelfth of a grain of podophyllin mixed with two grains of scammony makes a good and safe purgative for a child of three years of age, or scammony alone may be given rubbed up with milk in the form of emulsion.

SCAPULA, or SHOULDER BLADE, is a flat triangular bone connecting the arm to the trunk of the body, forming a protection to the chest wall, and affording attachments numerous muscles of the arm and chest. -See

SCARF-SKIN, or EPIDERMIS, or CUTICLE. -See SKIN

SCARIFICATIONS are deep scratches, or superficial cuts, made generally upon the skin, or upon a mucous membrane. The chief use of scarifications is to give exit to blood or serum from parts in which there is an improper accumulation of either of these fluids. The scarification of the gums in children is not, as is often supposed, to assist the passage of the tooth, but to relieve the tension and inflammation of the gum by allowing the escape of blood from the over-loaded vessels and tissue. Scarifications of other parts act in a similar way.

Refer to—Childhood.

SCARLET FEVER and SCARLATINA are both designations for one and the same disease, although an idea prevails, popularly, that the latter is the name of a milder and less dangerous affection than the former. is a highly contagious disease; the person suffering from it generates a poison communicable by the atmosphere or by inoculation, and few persons at all susceptible to its influence fail to escape an attack when brought much in contact with the infected. There are also good reasons for supposing that under peculiar conditions connected with drainage and water supply, the disease is intensified in severity, and will spread as an epidemic among those subject to these conditions. The fact is unquestionable, that the contagion permeates everything that proceeds from the body of the patient, the clothes and the excretions, and is spread in a great measure by the tiny scales that are being continually thrown off from the skin, especially during the period of conval-

well marked that it can scarcely be mistaken for any other disease, even by unprofessional persons. Generally, the first symptom com-plained of in the incipient stage of scarlet fever, is sore throat, either accompanied, or quickly succeeded by the usual symptoms of a feverish attack, shivering, headache, loss of appetite, perhaps vomiting, followed by heat of skin, quick pulse and thirst. The eruption appears early on the second day after the first symptoms of indisposition; it first shows itself in the form of minute red points either on the neck, face, or chest, or on the arms, especially about the elbows, the points becoming more numerous, till they form one diffused surface of a tolerably bright scarlet eruption, which extends to the abdomen and body generally. On the second day, when the eruption is appearing, the symptoms of general fever, and especially the heat of skin, continue unabated, the throat is more inflamed, and the tongue assumes the appearance characteristic of the disease. It is probably covered with a white creamy looking fur, through which the "papille" on its fore part, about the tip especially, project like red points, resembling a white strawberry; this appearance may continue, but in many cases the fur comes off as it were in patches at a time, and ultimately leaves the tongue preternaturally clean and red, covered with the elongated papillæ, in some cases almost like a pile upon it. The eruption in scarlet fever generally looks more patchy upon the extremities than it does upon the trunk. In a moderately favourable case of scarlet fever the eruption begins to fade between the third and fourth day from its appearance, and with it the feverish symptoms, and other general symptoms of the disease, such as sore throat, &c. The patient of course is left weakened, but with moderate care, convalescence is for the most part speedy. The chief care is required until the desquamation of the cuticle, or peeling, is completed; during this period also the power of communicating the disease by contagion appears to be retained.

Although favourable cases of scarlet fever pass through the course nearly as described above, there are much severer forms of the disease. The feverish symptoms from the first may have a high inflammatory form; or the reverse may give evidence of an extreme condition of bodily depression, with tendency to malignant disease, and to a putrescent or typhoid condition. In such cases the eruption is tardy, and when it does appear, patchy and dusky in colour; the swelling of the throat is great, and if they can be seen, the tonsils are evidently ulcerated, the breath offensive, the tongue swollen, and swallowing difficult, if not impossible; offensive discharges take place Scarlet fever belongs to the class of eruptive evident extreme depression of the constitufrom the nose, and at the same time there is

SCA SCA

comparatively mild form first described, so mild indeed at times as scarcely to constitute a perceptible disease, and the malignant, scarlet fever is met with in every degree of severity. As a general rule, the severity or mildness of the attacks of scarlet fever depend greatly upon the type of the prevailing epidemic, which at one time may be so favourable that almost every case does well, whilst at another, the greatest fatality attends it, and sorrowing parents see their children carried off one after another with fearful

The great variation in the severity of the attacks of scarlet fever must render the variation in the treatment equally great. When the form of the prevailing epidemic is extremely mild, little if any treatment is required, and many cases get none at all, not even confinement to the house, and certainly not to bed. This is not well even for the sake of others, and should the weather be ungenial, or should cold be taken, a mild affection may be at once converted into a dangerous disease. A moderately smart attack of scarlet fever requires, certainly, confinement to bed, in as well ventilated a room as possible, kept at an average temperature of 60° Fahr.; the diet should be kept low, and should consist of milk, farinaceous articles, &c., and the thirst may be freely indulged with diluent drinks and iced water; the patient must not be loaded with bed-clothes, which will keep up feverish heat. If the heat of skin is great, which is usual in most cases of this disease, sponging the surface of the body with tepid water, with or without the addition of a little vinegar, is at once most beneficial and grateful to the patient. A gentle aperient should be repeated once or twice in the course of the disease, a table-spoonful of castor oil, a dose of magnesia and rhubarb, or from half to a whole Seidlitz powder, may be required, or in fuller habits, or where fever runs high, a more active purgative still, of calomel and scammony, or in an adult, calomel or blue pill, and colocynth.

The common effervescing aerated waters are often liked, and may be permitted in moderation to all; but more freely, and, indeed the salines generally, to persons of full habit. From five to ten grains, according to age, of chlorate of potash given every six or eight hours, in a little sugar and water, is one of the most appropriate cooling salines in this disease.

If the feverish symptoms run high, of course the lowering and cooling remedies must be more actively enforced. The throat affection is often the most serious to grapple with, and various local as well as constitutional remedies are employed for this purpose. Inhalation of the vapour of hot water, hot poultices and fomentations to the throat, gargles composed of chlorate of potash, nitrate of potash or

tional powers, with delirium. Between the | may be combined with rose water and tincture of myrrh. When ulceration occurs, the ulcerated points may be touched with a solution of lunar caustic, or with equal parts of turpentine and glycerine brushed on the parts with a camel's hair pencil. If the case be one of a malignant character, every method of supporting the strength by wine and beef-tea must be used. Diffusible stimulants, such as the aromatic spirit of ammonia, or the carbonate of ammonia, in six or eight-grain doses, given three times daily, are much relied on. But perhaps the best remedy, where the disease assumes a malignant aspect, is to be found in one or other of the preparations of chlorine. The author prefers the following mixture, which will probably be found equally efficacious in diphtheria: put ten grains of chlorate of potash finely powdered into a pint bottle, add one drachm of hydrochloric acid, leave five minutes with the cork loosely inserted, add one ounce of water and shake, gradually add water shaking the bottle till it is full. Dose for a child of eight years, two table-spoonfuls every hour when the case is severe.

Although the above directions are given for circumstances which might render them useful, it is not with the idea that any one in their senses would have recourse to them, if medical aid could in any way be procured. The fearful rapidity of a fatal case of malignant scarlet fever calls for the most energetic exertion of the highest skill, which is too often of no avail.

After the eruption has faded, the person may sit up, and gradually return to fuller diet, such as pudding, broth, fish, &c., the bowels being kept free, but not purged, and close attention given to the state of the urine as to quantity and appearance. At this stage, which is a very critical one as regards the communicability of the disease, on account of the peeling of the skin, much comfort will accrue by anointing the body with olive oil, which is all the better of being impregnated with camphor, sanitas oil, or carbolic acid. Some recommend the anointing to be done daily, and although the process may be both troublesome and inconvenient to the attendant, there can be no doubt of its efficacy, not only in checking the diffusion of the noxious atoms from the skin, but also in relieving the excessive itching which is liable to occur at this period. The anointing should be continued till the patient is well enough to have a warm bath, when the body should be well scrubbed with carbolic soap, the hair of the scalp coming in for an extra share. It is well to have the bath repeated, say every second day, till the end of a week, by which time the patient will in all probability be able to leave his chamber for the open air, and enjoy the benefit of nature's best disinfector. The occurrence of dropsy, after scarlet fever, is always a serious matter, and the possibility of it, a cogent argument for guarding against all those permanganate of potash, are much in use, and influences which, by interfering with the

perspiratory function of the, for the time, mor- | months, and should always be brought under bidly susceptible skin, tend to induce it. It is observed that the attacks of dropsy after scarlet fever are by no means in accordance with the severity of the attack itself, and this is sometimes assumed to be because those who have had only a mild attack are more careless as to after exposure than those who have suffered a severe one. It is probable, however, that the inflammation of the kidneys from which the dropsy results is an actual complication of the disease characterising some attacks, just as inflammation of the lungs occasionally occurs in other cases, although not so frequently as the former. The attacks of dropsy are most likely to occur from the end of the first fortnight to the end of the fourth week after the decline of the eruption. Its symptoms are generally those of languor and oppression, with headache, and it may be vomiting, the swelling coming on simultaneously. Usually, the face, the eyelids especially, is first affected, and the dropsical swelling may go no further, but generally the feet and legs, the hands, arms, chest, &c., become involved. Concomitant with these symptoms, the urine is scanty, high coloured, or "smoky" in tinge; it presents, moreover, peculiar chemical changes.

Little has hitherto been said about medical attendance in a case of scarlet fever. Although mild cases may be, and every day are, carried safely through with simple nursing, should the case be at all a smart one, it ought to be visited by a medical man; if it is severe, his presence is indispensable, equally so, whatever the case may have been, if the least symptoms of the after-dropsy show themselves. Should this last contingency occur, warm baths ought to be used to restore, if possible, the functions of the skin, hot bran poultices applied to the body, and if there is pain about the kidneys, blood taken by leeches or cup-The bowels should be well cleared, or rather purged, by the calomel and rhubarb, or calomel and colocynth pill, or better still, by calomel and compound powder of jalap; at the same time a draught consisting of a drachm of nitrous ether, half an ounce of spirit of mindererus, and ten or fifteen drops of ipecacuanha wine, in a wine-glassful of water, may be given every four or five hours. These be given every four or five hours. These measures ought to be sufficient till medical assistance is procured; if, as sometimes occurs, convulsions or delirium come on, they are to be treated as directed in the articles on those disorders. Besides dropsy, scarlet fever is liable to be followed by other affections, particularly in those of weak or scrofulous constitu-tion. If the affection of the throat has extended to the ears by the eustachian tubes, the structure of the organs of hearing may be materially damaged, and deafness, total or partial, be the result. Frequently, runnings

medical treatment. Of course, if a patient, after an attack of scarlet fever, remains weak, tonic medicines, quinine, or iron, with wine and good nourishment will be required, also warm clothing.

Measures for Disinfection .- The preventive measures to be taken to check the con-tagion of scarlet fever are of great import-ance, as few diseases retain the power of propagation longer; indeed it is impossible, in the absence of any precautions, to say how long the poison may remain persistent. The first precaution is to isolate the patient, to place him in a room apart from the other members of the family (the nearer to the top of the house the better), and to which no one should be allowed to enter but the immediate attendant. All superfluous material should be removed from the apartment; carpets, curtains. and all textile fabrics not absolutely required, may be dispensed with, as they are well known to harbour the germs of the distemper. The dress of the attendant should consist of cotton or linen in preference to woollen stuff, or at all events it should be made of some good washing material. The question of disinfection of the house must always be difficult so long as the patient is an inmate of it; still, much can be done to dilute the intensity of the contagious virus. The floor of the sick-room can be sprinkled with carbolic acid solution, or with a solution of chloride of zinc, and Condy's fluid should be always at hand wherewith to wash out cups, feeders, urinals, and bed-pans, for the ways in which contagion spreads are manifold and mysterious. Carbolic acid soap should be readily available for purposes of ablution, and all towels, handkerchiefs, body linen, draw sheets, and the like, should be steeped in a solution of carbolic acid before undergoing the usual washing. When the person has recovered sufficiently to be able to leave the house, we are in a position to deal with the infected apartment, and possibly to prevent the disease from committing further ravages. This may be done in various ways, the ordinary plan is to open the window wide, to limewash the ceiling and the walls (if they do not happen to have been painted or papered); and the floor, as well as all articles of furniture which can bear it, should be washed with carbolic acid soap. If the walls of the room have been painted, they should be washed down in a similar manner; and if papered, the paper should be stripped, and the walls covered afresh. If the room must be used at once for habitable purposes, it may be necessary to have recourse to an aerial chemical disinfectant, and the best of these will be found in sulphurous acid gas generated from bisulphide partial, be the result. Frequently, runnings from the external ear, from nose or eyes, continue long after the subsidence of scarlet fever, Such di charges may retain infection for many subject to the control of the Such di charges may retain infection for many | which burns like spirits of wine. It may be

SCI SCH

burned in an ordinary spirit lamp, or in lamps | specially contrived for its combustion, but the best apparatus is a simple metal cup into which the spirit may be poured, and afterwards set light to, care being taken that the vessel is raised on a metal stand a little above the centre of the floor, and that all windows, doors, and crevices, which could admit air to the room, are carefully sealed. In the process of combustion, sulphurous acid gas is liberally set free, and the atmosphere of the apartment is rendered so pungent that no human being could exist in it for long, but on the other hand it destroys all vestiges of the disease.

Scarlet fever is generally a disease of childhood, and is usually passed through once in a life time; but adults who have escaped it in early life are liable to be affected. attacks are rare. Although, however, those around persons suffering from scarlet fever may not have the disease, they are very liable to suffer from sore throat, often in a severe form. It is a serious thing for women to be exposed to the contagion of scarlet fever soon after child-birth; every means, therefore, should be used to guard against such a contingency.

Scarlet fever has sometimes been confounded with measles; a comparison of the described symptoms of the two diseases will

point out the complete difference.

SCHOOL .- It too often happens that, in consequence either of ignorance or of carelessness, the health of young people suffers irretrievable injury during the years of instruction. In day-schools, the chief source of injury is from deficient ventilation. The consequences of this, and the remedies, are sufficiently entered into under such articles as Air and Atmosphere, Bedroom, Ventilation, &c., and require no further comment here; suffice it to remark, that the effect of breathing an atmosphere deteriorated by the carbonic acid and organic matter exhaled from the lungs of a number of children into a small or badly ventilated room, must be to produce drowsiness and languor, and consequently to neutralise in some degree the exertions of the teacher.

In boarding-schools, the health of the pupils is of course subject to those general conditions and laws of health, which are commented on in the various sanitary articles; and parents would do well to assure themselves that due attention is paid to these, ere they commit the daily life of their children to influences over which they have no control. It is to be hoped that there are few seminaries for the young in this kingdom in which actual deficiency of food occurs; but it is possible, that in the selection and preparation of the food, there may be defects, which to strong-constitutioned chil-dren are of comparatively little moment, but which are of the greatest importance to the delicate. The point should not be overlooked. It is impossible in the limited space of this work to enter into particulars, but the reader in the twenty-four hours, often cure quickly;

is referred to the various articles on Food, Digestion, and the principles of Nutriment. Equally important with quantity and quality of food, is the permission of sufficient time for meals, not only for the mere eating, but for rest after, before school-work is resumed. The author is induced to notice this point especially, from having recently had his attention drawn to the regulations of a large educational institution, in which the time allowed for meals is so short, that the meal itself must be a scramble, independent of the injury which may result from the resumption of head work immediately after taking food (see Digestion and Indigestion). It does seem to be the case with some, that in seeking to cultivate the mind they forget the body, forget how dependent the activity of the instrument they seek to form is upon the well-being of its material clothing. There are many other points connected with schoolhygiene which are important, but, as before said, they fall under the heads of sanitary information generally, as already given in other parts of this work, and which space forbids to be reiterated.

Refer to—Air, &c.—Bedroom—Childhood— Education—Ventilation, &c.

SCIATICA is neuralgia or nervous rheumatism, affecting the great or sciatic nerve of the lower extremity. This nerve, the largest in the body, passes down the back of the thigh to the ham, a little above which it divides into two main branches. The nerve sometimes becomes the seat of severe neuralgic pain, felt down its entire course, or perhaps in the hip only, or sometimes in the foot and ankle only; the pain comes on in paroxysms, and is generally increased by exercise; in some cases, pressure upon the course of the nerve

causes pain. Sciatica is often attended with so much suffering, that it affects the general health to a considerable degree; moreover, it is frequently most difficult to get rid of. For these reasons, the case should be under medical superintend-The remedies used in sciatica are mainly those which are found of service in other neuralgic affections, keeping in view the causes and circumstances of the disease. Heat and counter-irritation, with mustard poultice, are frequently beneficial, but if the pain is severe, it may be found necessary to employ a narcotic in the form of a subcutaneous injection of morphia, which seldom fails to give relief; but as it is unwise to persist daily with this treatment, recourse is had to liniments of opium, aconite, belladonna, or veratrine. It has been found of late years that many cases, often defying the ordinary means of treatment, have yielded to the continuous galvanic current applied along the course of the nerve. The bowels being cleared by a purgative, if there is no tendency to fever, twenty-grain doses of the saccharated carbonate of iron, given three times

SCR SCI

quinine, in two-grain doses, every eight hours. There is considerable uncertainty in the effect of remedies in sciatica, even in skilful hands. In obstinate cases, the author has found much benefit from the use of the warm saline baths, such as those of Moira, or of Ashby-de-la-Zouch. Acupuncture is often of service in this disease, and is, perhaps, not so much employed as it might be. It may be done by a Duchenne needle, or by an ordinary large darning-needle which is thrust into the hip betwixt the great trochanter of the thigh bone and the bony prominence on which the body rests when sitting, with the view of transfixing the nerve. In all cases of sciatica, perfect rest of the limb is essential. Again, it is repeated, the obstinacy of the disease, the uncertainty of remedies, and the possibility of its being symptomatic of so he more deeply-seated disease, make it the safer and wiser plan to have the case treated by a medical man at once.

Refer to—Neuralgia.

SCIRRHUS—a form of cancer characterised by its peculiar hardness in the incipient stage of the disease. - See Cancer.

SCLEROTIC .- The outer thick coat of the

globe of the eye. - See Eye.

SCREAMING of infants, if continued, and if increased on particular movements of the body, should not be neglected. Intermittent screaming may be indicative of painful affection of the chest or abdomen, which incites the child to scream; whilst, on the other hand, the aggravation of the pain thus induced, compels it again to desist, thus giving the intermittent character. Screaming of children during, or on awaking from sleep, may arise from the irritation of teething, or of worms, &c., or from indigestible matters in the bowels; for these causes the suitable remedies are to be used, as directed in the proper places. Screaming in sleep may be simply a bad habit, untraceable to any cause, or may be attributable to dreams, or excitement of mind produced by fright during the day, excited accidentally, or by design, by foolish nurses. Lastly, screaming may arise from incipient disease of the brain. If the affection be persistent, its cause should be investigated by a medical man. It is said that, in some cases of screaming, a small dose of belladonna given to a child at bedtime is useful as a preventive. The author has no experience of the remedy.

SCROFULA is the name rather of a constitutional tendency, or Diathesis, than of a disease, although cases of scrofulous disease alone do occur, where the tendency is strong. That many persons may be tainted with scrofula, and nevertheless be free from those external signs which are usually considered to indi-

or turpentine, in doses of fifteen drops, given apparent, and often strikingly so. The followin milk, three times a day, may be tried; or ing description of the signs of scrofula in the two forms in which the complaint is likely to appear, by Dr. Phillips, one of the highest authorities on the subject, is peculiarly truth-"In the form of the body there is usually observable a want of muscular development; but even this is often absent. There is often an appearance of plumpness and roundness, which is the result not of muscular development, but simply of an infiltrated condition of the cellular tissue, and which rapidly disappears under fatiguing exercise, privation, or disease. Commonly, there is a general paleness and coldness of the surface of the body, which is owing to a feeble circulating apparatus; but in a large number of cases that paleness does not extend to the face. The colour of the hair is very variable, but for the most part it inclines to a dark tint. Of nearly nine thousand scrofulous children examined, a little over thirty-two per cent. had light hair and The abdomen is commonly tumid, discharges from the nose, the eye, and the ear, are common, the tongue has commonly a dirty whitish coating; the tonsils are usually enlarged, and they are often so tumid as to impress a disagreeable and frequently husky character upon the voice, and to cause snoring when the patient is asleep. The stomach and bowels are frequently disordered, and digestion is ill performed. Sometimes the evacuations are clay-coloured, very offensive, and of varying consistency, at others having a redundancy of bile. The skin, though often dry and hard, is frequently the seat of a considerable greasy exhalation, sometimes it is found to be fætid and sour. The scalp and other parts of the cutaneous integument are often the seat of eruptive affections. The absence of vascular and muscular energy often causes the child to lie and sit about much, and indisposes him to enter into the energetic games of his playfellows. As to the intellectual development claimed for scrofulous persons, that is usually wanting. That many scrofulous children present this character is quite true; but the result of very careful observation," says Dr. Phillips, "has convinced me that the overwhelming majority are without those superior intellectual qualities, which have been pointed out as their ordinary characters." Moreover, if the intellectual powers are forced, as too often happens. "and the nervous and intellectual systems have the vital actions concentrated on them too intensely, the sufferer loses flesh, the general health languishes, and the intellectual faculties may give way, destroyed by an opposite, but not less sure, - method than that which breaks down the poor man's child.'

As noticed above, the very common idea that scrofula is usually associated with light cate the tendency, is unquestionable, but hair and complexion, is far from being corgenerally, if the scrofulous diathesis is at all rect, the larger proportion of scrofulous substrongly marked, its evidence is sufficiently jects have dark hair and eyes, with a dingy

SCU SCR

common observer look robust; others with delicate skin, inclined to freckle, have red

Of the causes of scrofula, there can be no doubt that hereditary predisposition is the cause above all others; the fact is beyond dispute, and there are few families in this kingdom who have not, indirectly at least, practical connexion with the fact. It is to be observed, however, that the predisposition is strengthened, if a parent adds to the taint an acquired state of bad health, or if in a father the bodily powers are impaired by age; pro-bably the reverse holds good, that whatever conduces to health and vigour, even in parents tainted with scrofula, tends to improve the constitution of offspring as regards the predisposi-Further, it is undoubted, that whatever hereditary tendencies children may possess, they are greatly retarded or strengthened by the external conditions to which such children are exposed. If the climate in which they reside is dry and bracing, if they are so placed that healthy habitations, good clothing, and nourishing food are provided for them, and especially if their parents and guardians are awake to the importance of these things, of being on the watch for any tendency to failing health, or to disease, the chance of health and life are far greater than they are for children of even originally better constitution, who are exposed to a damp cold climate, and to the unhealthy influence attendant upon the circumstances of poverty. These, in fact, of themselves, especially cold, damp, badly-ventilated apartments, and unwholesome food, frequently engender the disease among children who have no hereditary tendency to it. It ought always to be an object in those predisposed to scrofulous disease, to maintain the highest possible conditions of health.

In children, the glands, those of the neck, chest, and bowels, are the most usual seat of scrofulous disease, though it presents itself in other parts, particularly in the joints, which often become the seat of chronic inflammation; in the bones, which are liable to carious ulceration; and in chronic affections of the eyes, known as scrofulous ophthalmia, and marked by extreme intolerance of light. In adults the lungs most generally suffer. Whatever disease affects a scrofulous person, whether it be, like enlargement of the glands, distinctly traceable to the scrofula itself, or some other ailment, it is apt to be modified in its course and appearances by the existing tendency. Purely scrofulous inflammation is slow in its gree by the usual phenomena of inflammation. When suppuration ensues, the matter is not always healthy pus, but is often more like whey or serum; if ulceration results, it is indolent, while the healing process is also protracted, leaving behind it an ugly puckered protracted, leaving behind it an ugly puckered acceptation of the term, which is applied to undefined cutaneous disorders, especially of a scaly character. The error has probably arisen from the dry scurvy appearance of the skin, which often precedes an attack of the real scurvy. True scurvy is a severe disease, unprotracted, leaving behind it an ugly puckered progress, and unattended in any marked de-

complexion, and some are ruddy, and to the cicatrix. The formation of tubercles or of tubercular matter is another characteristic of scrofula. This deposit so common in the lungs, may also occur throughout the body, consisting of a cheesy-looking substance, exciting inflammation, and formation of matter in the adjacent parts of the tissue, in which it is deposited. When this occurs in the lungs, the tubercles become as it were softened down in the surrounding matter, and the fluid or semifluid mass is discharged by cough.

Under the head of causes, sufficient has been

said to indicate the general course to be followed when a tendency to scrofula exists; when the disease actually breaks out, the same measures must be continued, and new ones of a more direct medicinal character adopted. These, to be thoroughly carried out, require the superintendence of a medical man. Flannel must be worn next the skin in all seasons of the year, and in winter it may be supplemented with a chamois leather jacket, while free exercise in the open air, when the weather admits, should be constantly enjoined. Iodine in its various preparations, especially that of the iodide of iron, also iron itself, with tonics generally, and above all the use of cod liver oil, are the principal remedies; and change of air, when obtainable, to the sea, or to a dry bracing air is always advisable. Season, as might be expected, exerts considerable influence over the scrofulous constitution; the early spring months being the most unfavourable. It is now established that scrofulous manifestations are the result of the presence of tubercles of the same nature as those which produce phthisis or pulmonary consumption. The scrofulous diathesis or tendency is simply the habit of body which predisposes to the development of tubercle, or which is congenitally less resistant to its attack.

SCURF.—See DANDRIFF.

SCURVY.—This disease, so well known and so fatal in times past to voyagers and others, has attracted notice in modern times by its appearance under circumstances which, in the present state of our knowledge concerning its causes, ought to have been all-powerful to prevent it. From the absence of vegetable salts and acids in the daily rations, the disease broke out among the allied troops during the Crimean War, as well as among the soldiers in the American Civil War, and more recently it is known to have afflicted the sledge parties of seamen engaged in recent Arctic expeditions. It is requisite here to explain, that what is meant by scurvy in this article is a very different disease from that implied in the popular acceptation of the term, which is applied to SCU SEA

blood, as a result of inappropriate nourishment, especially of nourishment unvaried by the admixture of fresh vegetables, and the mineral matter peculiar to them. Scurvy commences with languor and signs of general debility, and great depression of spirits, the gums become swollen, and spongy, red or purple looking, project over the teeth, and bleed easily, this tendency to the exudation of blood extending to the various mucous surfaces within the body, in bad cases, and showing itself in the discoloured patches of effused blood beneath the skin. The lower extremities become first stiff, then swollen and hard, the skin being as it were glued down to the parts beneath, and covered more or less with brownish or purple patches. If the case goes on unchecked, blood is passed from the various outlets of the body, and the patient sinks. Fortunately, for this formidable malady, we possess the well known and almost certain cure of lemon juice, but although this is the most strikingly speedy, and most certain curative agent, it is by no means the only one; as the deprivation of fresh vegetables or of milk, seems to be one chief cause of the disease, so a return to the use of these articles appears to be an antidote, and in this way, potatoes and vegetables generally, without medicine at all, are often sufficient to cure. Indeed in the epidemic of scurvy which prevailed in 1846, in the General Prison at Perth, the cases which occurred were cured, and the further progress of the disease arrested, by the addition of milk, and in some cases meat, to the usual dietary, showing plainly that scurvy may be caused by malnutrition, apart altogether from the absence of vegetables. Malt liquor is likewise found useful in diminishing the tendency to, and in arresting the progress of scurvy.

Of course, in a bad case of scurvy, when lemon juice is procurable it should be used; half a pint may be given in the day, alone or diluted. Until lately, the opinion has prevailed that the curative powers of lemon juice in scurvy depended upon its acid, and that the good effects of other vegetables arose from their containing that or other similar acids; the researches of Dr. Garrod, however, have thrown doubt upon this, and apparently go to prove, that the beneficial influence is rather due to the potash which exists in combination with the acid. This view is supported by the fact, that citric acid—the acid of the lemon when used alone, does not cure scurvy. It would appear, notwithstanding, that when the acid is combined with fresh vegetables and fruit, it affords a most efficacious remedy for this severe and often fatal affection. Although, however, it is certain that the disease in question depends for its development upon the deficiency of certain articles, or constituents of food, it is no less certain that its attack is greatly favoured by the deficiency of sanitary

subjected to confinement, as in a prison, or on board ship, especially if ventilation and other necessary arrangements are neglected, will much more quickly become the subjects of scurvy than those who are not exposed to the same depressing influences, even if the food be the same. Salt provisions alone will not produce scurvy, unless other conditions favour the disease. It has been observed that infants fed exclusively on milk which has been boiled or sterilised occasionally develop scurvy.

SCYBALÆ are hard lumps, generally

black-looking, of feculent matter.

SEA, SEA AIR .- The effects of the sea upon health have to be considered under the two aspects of exposure to "sea air," and of "sea bathing." That exposure to the air of the sea, especially in the case of persons unaccustomed to it, exerts a stimulant and tonic effect cannot be doubted. The freshness and, in summer, comparative coolness of the air in the vicinity of the sea contributes to this, and its impregnation with saline particles, the chlorides especially, probably adds to its tonic properties. Moreover, the average temperature of sea-coast places is more equable than of those inland, being generally warmer in winter. Although, however, the general character of sea air, and its effects upon health, in different places, are similar, it varies greatly, according to locality, as to particular influences; thus, at Torquay, the relaxing air is the opposite of the stimulating atmosphere of Brighton, which again is very different from Hastings. These differences, it is true, depend more upon land influences, such as formation of coast, the vicinity of hills, &c., than upon the sea itself, but still they modify the effect of the latter so greatly, as to make them a serious consideration when residence, either temporary or permanent, is chosen with reference to health. Under any circumstances, it is considered as a general rule, that invalids derive more benefit from sea air, at a little distance-quarter of a mile-from the water than they do close to it.

Refer to-Climate.

SEA BATHING, when properly employed, is a stimulant, in the first instance to the skin, and further to the body generally. The stimulant action upon the skin indeed, even proceeds so far as to cause eruptions, somewhat resembling scarlatina; in some cases the smarting from these eruptions is so severe, after each immersion, that the practice has to be discontinued, at least for a time.

affords a most efficacious remedy for this severe and often fatal affection. Although, however, it is certain that the disease in question depends for its development upon the deficiency of certain articles, or constituents of food, it is no less certain that its attack is greatly favoured by the deficiency of sanitary regulations generally, and that those who are

SEA

magnesia, or Epsom salt—sulphate of soda, or glauber salt; also muriate of magnesia and of lime, with salts of iodine and bromine." The above constituents are uniform as to presence, but are increased or diminished by locality and in proportion to the amount of evaporation from the surface; thus in the Mediterranean and within certain lines in the tropics, the saltness and with it the specific gravity of the water, is greatly increased, while in the Black Sea, the Baltic, and in the Arctic Regions, it is much diminished. "From the beginning of July the temperature of the sea is constantly on the increase and during the is constantly on the increase, and during the month of August it is at the highest, remaining the same with very little alteration till September, when the temperature again becomes less. The minimum temperature of the sea, for each day, is in the morning before ten o'clock, its maximum from twelve to five. Other circumstances being the same, the temperature of sea water is observed to be higher in proportion to the proximity of continents and islands." Moreover, the temperature of the sea on a line of coast is modified by the construction of the shore; if this be rocky, rapidly deepening, the temperature of the sea during summer will be lower than it is on a flatter shore, where the advancing tide travels over an extent of sand warmed by the sun, and vice verså in winter.

Persons who are unaccustomed to sea bathing may sometimes find it of service to take two or three tepid sea baths before going to the open sea. There is, however, no necessity, as some suppose, for a course of medicine beforehand, unless the individual is decidedly out of health, and then sea bathing should not be engaged in, before consulting with a medical man, who may give medicine for the existing ailment, but certainly persons in good health have no occasion for preparatory medicine. Individuals who are very plethoric, who are the subjects of any organic disease, or who have any tendency to fulness about the head, also aged persons, should not bathe without

medical sanction. If a person is in a state of body to benefit by bathing, and if the good effects are not counteracted by too long immersion in the water, the bath should be followed by reaction, which conveys a sensation of increased strength and spirits, a glow of warmth on the skin, and increased appetite; if, on the other hand, the reaction is tardy, if the skin continues cold and blue-looking, if the fingers and toes become what is called "dead," if there is bodily and mental depression, with languor and sleepiness, it is certain the bathing does not agree, from some cause or other.

Refer to—Bath.

When cold sea bathing does not agree, or is too depressing, the tepid sea bath is often of much service, and does not relax like fresh water tepid bathing.

Sea water, as may be expected from its saline constituents, acts as a purgative. The usual dose is half a pint, repeated once or twice according to effect. It may be gone on with, with less risk of depressing consequences than arises from the use of saline aperients generally; indeed, it exerts a tonic influence. In worms, both when taken by the mouth, and used as an enema, sea water is often useful. In his work on Materia Medica, Dr. Thomson states that "Sea water has been frequently taken in habitual costiveness, particularly by those of full habit who lead a sedentary life. In this instance, its stimulant properties are as useful as its purgative qualities. When it is to be given to children, they are easily persuaded to take the dose if its nauseous taste be covered with a little port wine. It is a curious fact, that by the continued employment of sea water as a purgative, although for a short time it produces emaciation, yet its secondary effect is to promote obesity.

"It is not easy to account for the fact, that no artificial mixture of the component parts of sea water produces a compound of powers equal to the natural." "Although sea water cannot be regarded as a purgative of much power, yet in some constitutions it operates when no other cathartic will take effect." "When it fails to purge, which it does in some habits, it produces fever of a low kind, accompanied with purple spots on the skin." Crystals of sea salt sold under the name of Tidman's and Brill's, dissolved in water, make an excellent substitute for sea water when the latter cannot be ob-

tained.

Refer to-Jelly-fish.

SEA SICKNESS.—See SICKNESS. SEASONING .- See ACCLIMATION.

SEASONS.—The influence exerted by the changes of the season upon man's health and life has been considerably elucidated by the researches of different observers, and by the statistical returns of this and other countries, but it is a subject so much mixed up with coincident influences and circumstances, that accurate results are with difficulty attainable. As, for instance, while, according to the returns of mortality in this kingdom, the winter months present the greatest average of death; according to the researches of Casper and Quetelet, summer is the most fatal season in Stockholm, in Montpelier, and in Berlin; and probably throughout Central Germany. These differences perhaps depend on local causes. Along with this uncertainty, however, there are certain general rules of climate, connected with the seasons, which are well ascertained; such, for instance, as extremes of temperature; thus the greater prevalence of inflammatory attacks, and of disorders of the respiratory organs during winter and spring; the frequent occurrence of apoplexy during frost, and the tendency to diarrhea and English cholera towards the close of summer and autumn, after

the high temperature and the new fruit season have permitted the accumulation of carbonaceous matter in the system. The influence of season is of course much less felt by the young, the robust, the well-fed, clothed, and housed, than by those who are exposed to the reverse circumstances. "At no period of life is the influence of the seasons on mortality more perceptible than in old age; and at no age less than between twenty and twenty-five, when the physical man, fully developed, enjoys the plenitude of power" (Quetelet). Of course, much is to be done by care, in guarding against the influences of climate consequent upon season, both in old and young.

Refer to—Acclimation—Climate—Clothing—

Cold-Heat, &c.

SEBACEOUS, GLANDS OF FOLLICLES, are glands situated in the skin, which secrete an unctuous matter; they are most common on the face, and about the nose. In many persons, especially in those who live in towns where there is much smoke, the orifices of these glands become black, constituting what are called "black-heads." When these are squeezed, the "sebaceous" matter is expelled in a worm-like form, and with the black head at the extremity, from its resemblance to a worm, has actually been taken for such. The sebaceous matter itself is not indeed a worm, but it has within the last few years been discovered by Dr. Simon, of Berlin, that it is the seat or "habitat" in many persons—according to Sir Erasmus Wilson, in all—of a minute parasitic animal (fig. 184). According to Sir

Fig. 184.

E. Wilson, the animal varies from \(\frac{1}{3}\) th to the \(\frac{1}{3}\) th of an inch in length. There are usually two, but often more, in the small mass of sebaceous matter squeezed out of a follicle. Even in the most healthy-looking skins they are said to exist, not causing irritation, unless

by accumulation in undue numbers.

When irritation takes place in a sebaceous follicle, it causes the inflammation, and formation of matter which constitute a common pimple. The formation of black-heads is best prevented by bathing with warm water, and then rubbing the surface well with a towel; frequently, however, the tendency is connected with disorder of the digestive organs, which requires rectification.

Refer to-Skin.

SECALE CORNUTUM.—See ERGOT.

**SECRETION.**—The term, as usually applied either to vegetables or animals, signifies the separation of a specific substance from the ordinary fluids of the organised body. In the stricter acceptation, it is more applicable to

such processes in animals as the secretion of the saliva or of the gastric juice, &c.

SECUNDINES. — The after-birth and membranes cast off after the birth of the child.

—See After-birth—Child-bed.

SEDATIVES are medicines which depress the activity and sensibility of the nervous system, without causing subsequent excitament; in this they differ from narcotics. There has been considerable diversity of opinion respecting the action of sedatives, and as to what agents belong truly to the class. Prussic acid, bromide of potassium (see Potash), aconite, carbonic acid applied locally, chloroform, inhalation, heat, and cold, are among the best examples of this class of remedies.

Refer to—Narcotics.

**SEDENTARY.**—The observations made under such articles as *Exercise*, *Motion*, &c., render comment upon the effect of sedentary

habits superfluous.

**SEIDLITZ.**—The waters of this well-known Bohemian spa owe their aperient activity to the presence of Epsom salts, or sulphate of magnesia, one hundred grains of which are said to be contained in every pint of water. It also contains lime in small proportion. These ingredients are very different from those which distinguish the commonly

used Seidlitz powders.

SEIDLITZ POWDERS.—These consist essentially of two drachms of Rochelle salt (tartrate of potash and soda), mingled with forty grains of carbonate of soda in the one paper, and thirty-five grains of tartaric acid in the other, usually the white paper. Seidlitz powders possess the advantages and disadvantages of saline aperients generally, except that they are pleasanter than most. The effervescing citrate of magnesia has greatly superseded the use of the Seidlitz powder.

Refer to - Effervescence - Purgatives - Sa-

lines, dec.

SELTZER WATER is chiefly distinguished by the large amount of carbonic acid it contains, in combination with alkaline carbonates, such as those of soda, magnesia, and lime, but chiefly soda; it also contains common salt. It is useful in some form of dyspepsia, gravel, &c. It cannot, however, be used habitually, as it is by some who are in good health, with any apparent advantage. It is now manufactured artificially on a large scale.

semola and semolina both belong to the class of farinaceous preparations. The former is deprived of most of its starch by washing in water, while the latter consists of the hard particles of wheat which escape being reduced to powder by the mill-stones, and consequently do not pass through the flour sieves. Semolina can only be prepared from the hard grain wheats of Italy, Spain, and Southern Russia; it contains a large amount of nitrogenous, or flesh-forming material, and is an excellent food for children and in-

animal food in its chemical constituents. Semolina is much used in France and Italy for making bread, in Britain it is most used for

SENDING FOR THE DOCTOR .-Under the head of Advice, Medical, a few observations applicable to the present subject have already been offered, a few more may be serviceable. In large towns, where distances are short, and medicines procurable in every street, it is generally of less consequence for a medical man to be strictly informed of the nature of any case of emergency, to which he is summoned, than it is in the country. In the latter, if the case is at all an urgent one, or if it is an accident, the message should always be, either clearly given to an intelligent messenger, or sent by note, which is the safer plan, giving such an idea of the nature of the case, as may serve to guide the practitioner in taking with him remedies or instruments, the immediate employment of which may save much inconvenience to all parties, much suffering to the patient, perhaps life. A medical man cannot, of course, at all times, even from the plainest message, form a correct idea of the case he is to meet, but he may in many. When a case is one of accident or emergency, of course any hour, night or day, is the same; and if medical attendance is required, it should be summoned at once; in other cases, however, much convenience to all parties may be secured by messages properly timed. Some persons have a habit of putting off till evening sending for a medical man; this, when it can be avoided, is neither just to themselves nor to their medical attendant; they get a man, jaded perhaps with a day's work, and with his energies less alert than in the morning, and they also perhaps subject him to unnecessary fatigue, which a timely morning message might have saved. Of course, cases of illness which have appeared slight in the morning, may, by becoming much more aggravated in the lapse of a few hours, and especially towards night, call for that attendance which before seemed unnecessary; these are not what are meant, but, in ordinary cases, it ought to be a rule, to let a medical man have the message as early as possible in the forenoon. It not only enables him to arrange his own business better, and when he is busy, the question of arrangement is no slight consideration, but it renders it probable that his patient will be earlier visited. Again, when a message is sent, care should be taken that there is no exaggeration.

The above advice may probably surprise some persons, but every medical man, who has been in general practice, must have experienced its want, not so much among the wealthier classes as among the poor; above all, the subject last alluded to, that of sending

Indeed, in some degree, it approaches | even in cases of comparatively slight, though sudden, illness, or of an accident, is an extremely common one in the country; and although when a practitioner has been deceived by such calls time after time, he gets more wary and takes them for what they are worth, it may occur, that the repeated "cry of wolf," will in some instance cause him unintentionally to overlook a case, by turning a careless ear to the call which has so often before proved untrue. Certain it is, that such is the real explanation of some of those cases of apparent neglect of the poor by medical men, which now and then come before the public. The general readiness of the members of the medical profession to attend to the poor, either by engagement or gratuitously, when such attendance is really requisite, might save them from some of the censure, public or private, with which they are occasionally visited for such omissions, by those who know little of the trials and vexations to which they are subjected.

It is not meant to say, that whenever an exaggerated message is brought, it is a wilful misrepresentation; in many cases, some relative or bystander, without waiting to ascertain the real state of matters, starts off in a fright to the surgeon; in other instances, however, among the ignorant, the system is one of deliberate forethought, under the idea that the medical man will make greater haste in attending to his patient. It has been shown, how, in the long run, this defeats its own end, and does mischief as well. Lastly, some persons send for the doctor by irregular channels, through third or fourth parties, or by leaving messages at houses, &c.; this is always uncertain, and often, by the message being forgot, inflicts disappointment. If a medical man is really required, send for him direct, soon in the day if possible, and if there is any distance to be traversed, by note, giving a clear account of the case to which he is summoned.

SENNA .- This most useful purgative is the leaf or rather leaves of different species of cassia. It is a very old medicine, having been used by the Arabians. Senna grows abundantly in Northern Africa, from whence large supplies are obtained; it is also cultivated in India, and a considerable amount exported thence, The most familiar designations of senna are Alexandrian, Tripoli, and East Indian senna; other varieties are known in commerce, but not

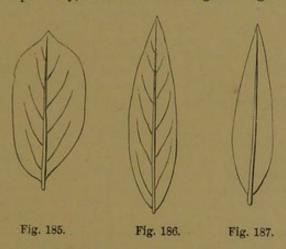

commonly in this country.

Alexandrian senna has the highest general reputation. It is brought chiefly from Nubia and Upper Egypt. As imported, its long lance-shaped leaves (fig. 186) are mingled with the pods, flowers, stalks, &c., of the plants, with the broad leaves of another description of senna (fig. 185), and with the leaves of a plant which is not a senna at all. The latter adulteration, which is always introduced into this description of senna to some extent, and exaggerated messages, requires notice. The message that a person is "dying," or "killed," sometimes largely, goes by the name of argel.

SER SEN

veins of the true leaf, and by the regularity of the leaf, which, it will be seen, differs from that of the senna, one side of which is more prolonged down the midrib than the other. The "picked senna" of the shops is chiefly the Alexandrian senna, from which the impurities, broken leaves, &c., have been removed.

Tripoli senna closely resembles the above, but probably, from more careless gathering and

packing, the leaves are more broken and the admixture of impurities greater. It is cheaper than the picked senna, but if the impurities are not very abundant, the mere fact of the leaves being broken up, if they appear to be properly dried, does not militate against the perfect efficiency of the drug; indeed, it is as good as the other.

Some varieties of East Indian senna, such as the Bombay, are of but low value, owing to being badly prepared; there is one kind, however, the "Tinnivelly senna" (fig. 188),

Fig. 188.

which is described by Dr. Royle, as "well grown and carefully picked; the leaflets of a fine, rather lively green colour; thin, but large, being from one to two inches in length, and lance-shaped." This kind is now highly esteemed, and is rapidly displacing the other sorts in many places. "It is mild in operation, certain as a purgative, and operates without

Senna, as a purgative, is safe, certain, and convenient, and deservedly holds a high place among domestic remedies. It is a pure aperient, does not depress or debilitate, and is admissible in most forms of disease, and at all times of life. Senna is often accused of grip-ing, but this effect generally results from

SERUM .- The serum is the watery portion

This leaf (fig. 187), may be known from the true senna by its being thicker and more given infused; if time permits, the infusion fleshy looking, by the absence of the prominent may be made with cold water, which in the course of a night, will fully extract the purgative principles of the leaf. When quicker preparation is necessary, the infusion may be made with hot water, like common tea, but should never be boiled; the higher the temperature employed in preparing the senna infusion, the more likely is it to gripe. Formerly, an idea prevailed, that the griping properties of senna depended on the presence of the leafstalks. It is erroneous. Additions, such as ginger, caraway, &c., are frequently made to senna to prevent griping, and saccharine matters are often added for the same purpose; the inconvenience is better rectified by attention in preparing, and no addition covers the slight nauseous taste of the drug so effectually as a small portion of common black tea infused along with it, with or without the addition of a little milk and sugar. Besides infusion, senna is given in the form of confection, tincture, and syrup; but none of these prepara-tions are so actively certain as the infusion, and they may disorder the stomach. The extensively used Prussian compound liquorice powder owes its laxative properties chiefly to powdered senna; it is an excellent preparation. The common combination of Epsom salts

with senna infusion, or, as it is called, black draught, forms a very active purgative, but is only suitable for the strong. The average dose of senna is a quarter of an ounce, infused in rather less than a breakfast-cupful of water; this will make a tea-cupful of infusion, and be a suitable dose for a child ten years of age. Confection of senna, the old "Lenitive Electuary," agrees well with some persons as a habitual aperient, particularly if they are liable to piles. It is also an agreeable form in which to administer the drug to children. The dose is two drachms or tea-spoonfuls.

SENSATION and SENSIBILITY .-See NERVES AND NERVOUS SYSTEM.

Refer to—Pain.

SEROUS MEMBRANES. - The enclosed cavities of the body are lined by serous membranes, which are closed sacs consisting of two continuous walls, one of which lines the cavity, while the other closely invests the organ. They are adapted to give protection and to facilitate motion. The most important serous membranes are those of the brain and spinal cord (arachnoid), the pleuræ investing the lungs, the pericardium, the heart, and the peritoneum, the bowels. Serous membranes are specially liable to inflammation, and suffer from an excess of fluid secreted from the inner surface of their walls, causing dropsy.

of the blood which remains after the clot has separated in the process of coagulation or clotting. The "water" thrown out in a blister is faulty preparation, or from the admixture of the | the most familiar example of serum. Whilst

SEW SET

"liquor sanguinis," or fluid of the blood, which is serum holding the "fibrin" in solution. When blood is withdrawn from the body, and allowed to repose, this fibrin separates, and in the act, entangling the globule, forms the red clot, the serum remaining as yellowish-looking fluid. In this state the serum still holds in solution "albumen," and earthy salts; if it be exposed to heat, the albumen is separated by coagulation (see Albumen), the remaining watery fluid still contains the salts of potash, soda, lime, and iron, which exist in all healthy blood.

Serum Treatment.—Of late years the serum of animals which have been inoculated with the micro-organisms or with the toxins of various diseases has been employed, chiefly by subcutaneous injection, both for the cure and pre-

vention of these diseases in man.

Most commonly the horse has been used for this purpose; and when a particular serum is required the animal is inoculated successively with increasingly virulent artificially prepared cultivations of the bacillus or toxin until it ceases to be influenced by the injection. The serum of its blood sterilised and filtered, is then used in the treatment or for the prevention of the disease with the poison of which the animal was inoculated, and to which it has become resistant.

Among the best known are anti-diphtheritic serum, anti-tetanic serum, anti-streptococcic serum and anti-plague serum. The treatment of diphtheria by this means has been remark-

ably successful.

**SETON.**—A seton is usually formed by means of a portion of a skein of silk passed under the true skin, so that it excites suppuration; it is in fact an issue. Its use is now

practically obsolete.

SEWAGE DISPOSAL .- The question of sewage disposal is too large a one to admit of profitable discussion within the limited space available here; still, as the subject is daily gaining in importance since County Councils were established as supervising authorities under the River Pollution Prevention Act, and as the public and members of Sanitary Authorities are often unaware of the principles involved, a short summary of these may serve a useful purpose. Before considering the methods of disposal, it is essential to explain the nature of the substance to be disposed of. It is popularly supposed that the term "sewage" is applicable to the fluid refuse of a household only when it contains excreta (fæcal matter and urine); in other words, that sewage is peculiar to places where water-closets exist. As a matter of fact, however, the sewage of watercloset towns differs only slightly, as regards impurity, from that of towns where the "pail" or "privy" system is in operation, it having been proved by analysis that the value as a manure of the two sewages is prac-

the blood circulates in the living body, it consists of the globule (see Blood) floating in the fore, that all sewage must undergo some purifying process before it is discharged into any stream or water course. The polluting material which has to be removed from sewage exists in solution as well as in a solid form, and any system of treatment which does not deal with both impurities is inadequate. It is quite possible to produce what appears to be a pure effluent by removing the solid matter only, but unless, in addition to this, the soluble impurities are disintegrated and rendered harmless, the putrefactive changes which afterwards take place will convert what seemed to be a pure effluent into a foul one, solid matter or sludge being deposited in the process. Appearance, therefore, is no test of purity, and mere clarification, or the removal of the solid matter originally present in the sewage, is not alone sufficient.

It is often asked—What is the best system of sewage disposal? To this question no definite answer can be given, as no single method is practicable in all cases. At the same time, it is the general opinion among engineers that the best results are obtained by land treatment, provided the land is suited for the purpose, and the area available is sufficient. In the absence of suitable land, some form of artificial filtration with or without chemical treatment must be resorted to.

No matter, however, what the system of sewage disposal in operation, to be effective it is essential that the unseen organic elements in the sewage should undergo a changebrought about by bacterial action on land or artificial filters-in the process of which they are converted into more stable substances which will not undergo further change in the stream into which the effluent is discharged. Unless this condition is fulfilled, authorities will not have complied with the requirements of the River Pollution Prevention Act, and will have to incur further expenditure. It is then that the full consequences of a mistaken policy in the first instance are realised; for, the money, which in the first instance might have accomplished all that was necessary, has been spent, and the question has to be considered de novo. The fact is, the problem is a chemical and bacteriological as well as an engineering one, and before any final decision is arrived at, a chemist should be consulted.

In all cases, whether land treatment or artificial filtration is the method adopted, it is an essential preliminary to remove, by precipitation or other means, as much as possible of the suspended impurity. The following short summary will enable the reader to form a general idea of the various methods most in favour at the present time.

Precipitation. - It must not be supposed that precipitation in itself will suffice, although, as already mentioned, it, or a substitute for it, is now generally adopted as a

SEW SEW

preliminary to further treatment. In the first | soil; at the same time, by an arrangement place, some precipitant, in the shape of lime, alum, salts of iron, or other substances, either singly or in combination, is added to the sewage, which is afterwards conducted to tanks arranged in a series, with weirs ex-tending across the whole width, which allow the top water only to pass on, while the large bulk of sewage remains comparatively quiescent. This enables the suspended matter to fall to the bottom of the tank, the precipitation process being greatly assisted by the chemical which has been added. The process is chiefly a mechanical one. The fine particles of carbonate of lime, and the flocculent particles which form from the salts of alumina and iron, by reason of their density, fall to the bottom of the tank, entangling and carrying with them the solid sewage particles. In addition to the mechanical subsidence thus brought about, the precipitants exercise a certain amount of chemical action upon the organic impurity in solution in the sewage, and in this way assist in the process of purification. The process of treatment has next to be carried further by one of the following methods :-

Intermittent downward Filtration.—The sewage having been clarified by the process just described, has to be further purified by the conversion of the organic matter it contains in solution into non-putrefactive inorganic substances. This, as already mentioned, can best be effected by land. It is important to remember, however, that all land is not equally well suited for the purpose. A rich loamy, porous soil of good depth is essential to successful treatment; clay has little purifying effect on sewage. The change that takes place is brought about by the action of the minute living germs (bacteria) universally present in the upper strata. These attack the organic matter in the sewage and split it up into less complex constituents, which are acted upon by the oxygen and carbonic acid present in the ground air, and converted into innocent salts by uniting with the mineral bases of the soil. In order that the soil may be thoroughly aerated, it is essential to allow it periods of rest-a water-logged soil exercises no purifying effect - hence the term intermittent applied to this form of land treatment. The rule is to apply the sewage on made use of.

The land has to be specially prepared for the purpose. It should be levelled and underdrained to a depth of from 4 to 6 feet, channels being laid on the surface, with sluices at various points, to allow of the sewage being directed on to any part of the filtering area. The chief object aimed at in 539a

of ridges and furrows, certain root crops may be cultivated, and in this way the purifying process is assisted, and a small return is obtained from the sale of the produce. With perfect soil and strict attention to preliminary treatment, the sewage of from five hundred to a thousand inhabitants may be dealt with on an acre of land.

Broad Land Irrigation differs from the method of treatment just described, in the fact that a larger area of land is made use of, and greater attention is paid to its cropping. The same quality of land is necessary in this case also, but it is not prepared in the same manner. It is underdrained, but only to a depth of from 3 to 4 feet, and the sewage is conveyed by carriers cut on the surface, about 30 feet apart, along ridges with a gentle slope on each side, to allow of the uniform distribution of the sewage. If the sewage is applied to the land without previous precipitation, one acre can only deal with the sewage of about one hundred persons, but with proper precipitation and careful distribution, the sewage of twice that number, or even more,

may be disposed of on that area. By way of emphasizing what has been said, the essential principles are: -(a) The land must be of a nature which is capable of effecting the necessary chemical change in the sewage; (b) it must not be asked to do too much; and (c) the sewage in its crude state should not be applied to it except, perhaps, in the case of very small populations. Stiff clay land is incapable of dealing with sewage; gravel or sand will answer better; but a rich loam, with a porous bottom of sand or gravel, is the soil which can best bring about the necessary change. The land should never be surcharged with sewage so as to cause waterlogging, and intervals of rest should be allowed to enable the soil to get freely aerated. Also, if crude sewage is applied to land, the sludge which is deposited on the surface in time chokes the pores, and so prevents the free penetration of

Artificial Filtration. - In the absence of suitable land artificial filtration must be resorted Until recently the method most in favour was that known as the International, the filtering medium being a specially prepared iron ore ment. The rule is to apply the sewage on one filtering area for eight hours, allowing it to rest for sixteen hours before it is again is now practically discarded in favour of less expensive and, at least, equally efficient materials, it is unnecessary to occupy further space in describing it. The materials now in favour for such filters are sand and gravel, coke breeze, and more recently ordinary coal. No matter what the materal may be, however, the active agents in the purifying process are minute organisms (bacteria) which form in the this form of land filtration is the purification substance of the filter, and which in the pre-of the sewage, and not the cultivation of the sence of oxygen have the power of rapidly con-

air into its interstices.

SEW SEW

verting the putrefactive organic matter in the attempts have been made to overcome the sawage into non-putrefactive inorganic substances. In fact, the process is the same as that which goes on in the soil, the only difference being one of detail, dependent upon structural arrangement, which allows of more rapid filtration than is possible in the case of most soils. As regards the management of artificial filters, success can only be achieved by strict attention to details. The filter particles should be as fine as is consistent with free and regular penetration; the depth of the filter should be about four feet; and the quantity of sewage applied should not exceed two hundred gallons per superficial yard per twenty-four hours; in other words, allowing for equal periods of rest and work, the process should be conducted at a rate not exceeding four hundred gallons per twenty-four hours while at work. To allow of regular intervals of rest for aeration, the filtering area should be cut up into a series of filters so arranged that each filter, or a combination of two or more according to circumstances, may be in use at the same time while others are resting.

There is no limit to the life of a sewage filter if attention is paid to its careful management and it is not allowed to become waterlogged by being overcharged with sewage. A few days' neglect in this respect, however, will destroy the filtering capacity for the time being, and necessitate its being thrown out of use for a longer or shorter period according to

the extent of the injury.

As regards the method of applying the sewage to the filter, some advocate the rapid filling of the tank while the outlet drains are closed, the sewage being allowed to stand in contact with the filtering medium for two hours and then run off. According to this method, while one tank is standing full another is standing empty to allow of its aera-Another method is to run the sewage on to the filter continuously at a slower rate, the effluent being allowed to run away as it passes through. According to this plan each filter is in use continuously, say, for eight hours, followed by eight hours rest for aera-From a practical experience of both methods the author has no hesitation in stating his preference for the latter.

In Staffordshire numerous trials have recently been made of ordinary coal, in fine particles, as a filtering medium, and without exception the results obtained have far excelled those of filters composed of other material, such as gravel, coke breeze, and ashes. Of course, in all cases bacteria are the active agents, and the probable reason why coal answers so well is that it forms

a good medium for bacterial growth.

So far we have been considering methods of purifying sewage which, in the first instance, has undergone a process of chemical precipitation already described which has resulted in the deposit of sludge in large bulk. Recently

difficulty of sludge disposal by abolishing the precipitation process altogether and substituting for it one of the two other methods as a means of preparing the sewage for first treatment (either by land or artificial filtration), both of which, it is said, entirely overcome the sludge difficulty. We here give a short description of both the new methods referred to.

Septic Tank System.—What is known as the

septic tank was invented by Mr. Cameron, of Exeter, where it has been at work, on an experimental scale, for about two years. It is practically a covered air-tight cesspool, large enough to hold from one to two days' flow of sewage.

The sewage while in this tank undergoes a process of putrefaction, brought about by anærobic bacteria. The solid organic matter is thus liquefied, and some of the organic matter in solution is got rid of in the form of gases. The resulting effluent is comparatively clear, but it must be further purified either by land treatment or by artificial filtration before entering a stream, this second stage in the treatment being conducted by ærobic organisms. As the septic tank effluent seems to require a larger filtering area for its final purification than a precipitated effluent does, and as the tanks have to be covered and are twice the size of precipitation tanks, even if the system proves to be successful on a large scale, it becomes a question whether the economy resulting from the simplification of the sludge difficulty is not more than counterbalanced by the capital outlay. Again, granting that the process has proved a success at Exeter, it does not follow that equal success can be looked for in towns where sewage may contain manufacturers' waste, which may retard or entirely prevent the preliminary putrefactive process.

Large-grain Bacterial Filters. - The alternative substitute for precipitation is the treatment of the crude sewage by filtration through large-grain bacterial filters, in which the sludge is liquefied by ærobic bacteria. This seems a more wholesome process than the other, and granting that the solid mineral constituents (road detritus, &c.) are got rid of by subsidence in small tanks—a condition which is equally essential in the case of the septic tank-it would seem that for the preliminary treatment of domestic sewage such filters answer very well. In the case of the sewage of some manufacturing towns, however, the same difficulty applies as in the other case, and as this may necessitate preliminary treatment before the sewage is applied to the filter, it may not after all be found to be an economical method. Under favourable circumstances, however, ultimately it will probably be found that large-grain filters afford the best solution of the sludge difficulty. After passing through these filters the purification process has to be completed either by means of land or fine artificial filters.

The sewage of individual houses in the

5396

SHE

sewers, can generally be disposed of on land

without much difficulty.

In the case of villages, however, it is not an easy question, as many are situated on low-lying land adjoining streams, so that the sewage cannot be distributed on the surface by gravitation. If the village is small, a pumping scheme which is not automatic in its action is out of the question on account of the cost, but if water-power is conveniently available, it can be utilised to excellent advantage. A miniature wind-mill may also answer the purpose, in fact, such has been tried with success in a village in Staffordshire; this, however, necessitates the construction of a storage tank capable of containing at least

six days' sewage.

It is essential in the disposal of the sewage of villages and small towns that sanitary authorities should not transfer their responsibilities to farmers who will consider their own interests rather than those of the authorities, and pass the sewage direct into streams except on those occasions when it is desirable, from a farming point of view, that the land should receive it. In practice, such an ar-rangement seldom, if ever, answers, and although in the case of small villages, it is not easy to see how it can be avoided, it should be understood that it is the duty of the sanitary officers to pay periodic and frequent visits to the farms and call the attention of the authorities to any irregularities that are discovered. Of course, in the disposal of the sewage of small communities, it is not reasonable to impose so high a standard as in towns; but, at the same time, no reasonable means should be neglected in order to insure as good a result as possible.

SEWER .- See DRAINAGE.

SEX .- With regard to the question of sex, in connexion with child-birth, there can be little doubt that a pregnancy in which the child is a male is likely to be more prolonged, than one in which it is a female. In his March of an English Generation through Life, Dr. Farr has shown the effect of the physiological law by which more male children are born into the world than female. In a million births registered in England and Wales, 511,745 are males, and 482,255 are females, but by the end of the first five years of life, the disparity is so much reduced by the larger mortality among the boys, as to alter the figures to 370,358 males, and 366,463 females. The higher mortality among the male sex is observable, though in a less degree throughout life. On the influence which the age of parents is sup-posed to exert on male and female births, Quetelet found from numerous researches made both in this country and in Germany, "that in general when the mother is older than the father, fewer boys than girls are born; the

country, where there is no general system of ages; but the more the father's age exceeds that of the mother's, so is the ratio of boys

The nearer the sexes approach puberty, the greater is the consideration required for the different tendencies of constitution, and after that period the peculiar differences, of the female at least, require constant consideration. As a general rule, females require medicine in smaller doses than men.

SHAMPOOING is a system of mechanical manipulation of various parts of the body for the cure of disease. In rheumatic affections, sprains, paralysed limbs, and especially in cases of wasting of the muscles from continued inaction, much benefit is occasionally obtained by the practice of shampooing and kneading the muscles. The practice has been recommended and adopted from the earliest times, especially in the East, but of late years it has acquired additional importance, partly in consequence of its being combined with galvanism or electricity, and partly from its being carried out in a more systematic manner. The main object of the treatment is to excite vascular action, and thereby infuse new vigour into the muscles, which is done at stated intervals by a process of alternate rubbing, kneading, and pinching with the fingers and palm of the hands. To this mechanical action of the joints and muscles, combined with a liberal system of diet, and absolute rest for some weeks in bed, the term "Weir-Mitchell Treatment" has been given, and from the success which has attended the practice in the hands of some well-known authorities in this country and abroad, it is likely to come more and more into general use. In many cases of severe nervous prostration, in hypochondriasis, and in some intractable forms of hysteria, the results have been found to be

most satisfactory.—See Circulation—Massage. SHELL-FISH generally are indigestible, and some, such as the common mussel, are at times even poisonous. The poisonous effects of mussels have been attributed to the presence of copper, and in some instances this metal has been detected in the fish which have caused symptoms of poisoning; in other cases, however, chemistry could afford no clue to the causes of the catastrophe-"it is probable that there is an animal poison present." The symptoms produced by mussel poisoning are described by Dr. Taylor, as uneasiness, and sense of weight at the pit of the stomach, numbness of the extremities, heat and constriction in the mouth and throat, thirst, cramps; or with swelling of the eyelids, heat and itching of the skin with nettle-rash eruption; also vomiting and diarrhoa, with colic. Emetics, followed by sal volatile, or stimulants, would be appropriate treatment.

Refer to—Crab—Oysters, &c.

SHERRY, one of the dry strong wines, contains, as imported into this country, rather same is the case where the parents are of equal | more than nineteen per cent. of alcohol. It is

SHI SHI -

free from the astringency of port wine, and ribs is relieved by opiate applications, such as generally agrees better with persons of weak tincture of opium, extract of belladonna, and digestive powers. To be good, it ought to be free from acid, or nearly so. Sherry is the only wine used in the numerous pharmaceutical preparations of the Pharmacopæia.

SHINGLES is a disease of the skin, known It consists of to medical men as Herpes. groups of vesicles situated upon inflamed patches of the skin. The "breaking out" upon the lips, nose, &c., which occurs after a cold, is an eruption similar in kind to that of shingles. Shingles is usually situated near the waist, surrounding one half of the trunk of the body, like a zone or belt; it may, however, extend in other directions over the trunk, and, but rarely, on the limbs; it is nearly always situated on one side, and that, generally, the right. The eruption of shingles is generally preceded by symptoms of general indisposition, and especially by severe darting pain in the parts where it is about to a pear. At first, red patches show themselves at the extremities of the site of the future eruption, and gradually become more numerous till they form a line, upon these patches shining points form, which gradually enlarge into vesicles, a little under the size of small peas, these vesicles containing a clear fluid, which gradually becomes opaque. At length, in the course of eight or ten days, the vesicles become darker in colour, and dry off in the form of scabs, or it may be, in very weak subjects, leave sores or ulcerations. The belief was formerly entertained among physicians, and still retains its hold of the popular mind, that if the belt of the cruption of shingles was continued round the body, so as to meet, the disease proved fatal. This is perfectly erroneous. In itself, shingles is a disease devoid of danger, except in old people, but requires investigation, on account of its frequently being indicative of depressed health. On this account, although the eruption itself may subside under the use of sin ple remedies, a case of shingles should be examined by a medical man.

When the disease occurs in the young and plethoric, the diet must be reduced to one of milk and farinaceous substances, and all sources of heat or excitement avoided. Five grains of blue pill at night, followed by senna, black draught, or Seidlitz powder in the morning, may be repeated once or twice; and, in the course of the disease, if there is much fever, five grains each of the carbonate and nitrate of potash may be taken twice or three times a day, dissolved in half a tumblerful of water; or the proportion of carbonate of potash may be doubled, and a tea-spoonful of lemon juice used to form an effervescing draught. painful itching of shingles often causes much distress. It may sometimes be allayed by simply keeping the eruption covered with a coating of collodion, or by dusting it over with starch or white oxide of zinc powder. The severe pain often complained of between the pint of stout each day, if ordered by the

tincture of aconite, either singly or in combination. In mild cases, cotton wool supported by a bandage round the chest is perhaps the

best application.

When shingles occur in the aged and debilitated, instead of the diet being reduced, it requires, perhaps, to be improved; at all events, the system must be sustained with nourishing broths, and probably with wine, along with quinine and medicinal tonics, the bowels being regulated, but not purged. In such cases, however, a medical man must be in attendance. Care should always be taken that the vesicles of shingles are not forcibly burst, as by lying upon them; if they are troublesome, ulceration may follow. Herpes is not contagious. As above mentioned, it is generally owing to constitutional disorder, which a medical man only can discover and rectify. Its occurrence has been at times apparently traceable to violent mental emotion, such as anger. In some cases the tendency appears to be hereditary.

SHIP.—The reader is referred to the article

Emigration in the present work for information respecting life at sea, and the preparations necessary before undertaking a long voyage. It is repeated that all intending to embark on a long passage should be convinced that the arrangements on board ship should be compatible with comfort and safety, and that the medical care of passengers and crew is entrusted

to proper hands.

In addition to the ordinary provisions, the following is a list of the supply of "medical comforts" which emigrant vessels are bound by order of the Board of Trade to be provided with for every hundred adult passengers:-

56 lbs. of oatmeal.

20 lbs. of West India arrow-root.

40 lbs. of Scotch barley.

100 lbs. of sago. 20 lbs. of tapioca.

30 lbs. of preserved boiled beef, in 1 lb. tins.

20 lbs. of preserved boiled mutton, in 1 lb.

400 pints of lemon juice, in wickered stone bottles, of five gallons each.

300 lbs. of sugar.

24 bottles of port wine. 12 bottles of sherry wine.

6 bottles of gin.

66 gallons of approved stout, including at least six dozen in bottles, the rest in 9 gallon casks.

5 gallons of brandy. 15 gallons of vinegar.

12 dozen pints of preserved milk.

2 cwt. of marine soap.

The above medical comforts to be issued at the discretion of the surgeon, whether for the sick,

SHI SHO

surgeon, and the surgeon is to make liberal use | of the preserved milk for keeping up the health

of the younger children.

SHIVERING, as a symptom of illness, is the sensation as of cold, which all must have experienced at the commencement of even a slight cold or ailment. When it amounts to actual shaking of the limbs and chattering of the teeth, it is more frequently called rigor. Among children it is often represented by convulsions. Most fevers commence with shivering, and the interval between the exposure to contagion and the rigor is reckoned as the period of incubation. The cause of the sensation of shivering arises from the nervous system.

Shivering, or rigor, is a symptom which frequently accompanies the formation of pus or matter within the body, in the course of

inflammatory disease.

SHOCK, in medical language, is the depressing impression imparted to the nervous system, and, through it, to the constitution generally, as a consequence of severe pain or injury. The extent of the shock, its duration, and even its fatality, often depends more upon the part or organ through which it is received, than upon the actual extent of the living body injured, or the pain suffered. Thus, a comparatively slight blow over the region of the heart, upon the pit of the stomach, or on the neck, in all which situations nerves are collected in numerous interlacements, is apt to be followed by immediate, and, it may be, fatal shock. The depression of the system which follows a blow on the head is of a similar nature. Again, injuries which involve large portions of the body in destruction, which cause severe pain, or much loss of blood, are all followed by shock. To this cause was attributed at one time much of the mortality consequent on severe surgical operations, but since the introduction of chloroform and other anæsthetic agents, deaths from shock alone have been of comparatively rare occurrence, and the number of lives saved in consequence must far outweigh the number of deaths which have been attributable to the use of these most merciful alleviators of human suffering.

When an individual suffers a shock from any of the causes above enumerated, he may die at once, as sometimes occurs from a blow on the pit of the stomach; life, as it were, is simply extinguished; but if the shock is not of this immediately fatal kind, the person becomes pale, perhaps falls to the ground, and it may be vomits, consciousness is partly or entirely suspended, the action of the heart depressed, till it is all but imperceptible. This state of shock may be recovered from in a few minutes, or it may continue for many hours, and terminate either in recovery or death, its duration depending on contingent causes, often

some cases of shock, in which severe pain has been suffered in the first instance, it appears as if the intense suffering had annulled the sensations of the nervous system, the sufferer undergoing even the most severe operations apparently without feeling. This is always a most fatal symptom. The immediate treatment of a person who has suffered a shock is similar to that recommended in cases of fainting, and of concussion of the brain, with the same precaution as to the use of stimulants. When the state of shock continues, stimulants by the mouth, although required to be gone on with, must not be too strongly pressed; it is impossible to lay down any rule beyond that of cautious administration. Ammonia in different forms, the ethers, and the most readily procurable alcoholic stimuli must be employed; but along with these should be joined the stimulation of heated fluids, of stimulant injections, and of heat applied externally; the latter, especially, is most useful on account of the continued coldness of the surface, and especially of the extremities, which accompanies such cases. Above all, any injudicious interference or movement during the first state of shock must be avoided, as likely to extinguish whatever remains of struggling vitality that may be left. The absurd, almost murderous practice which formerly prevailed, of surgeons, whenever called to a case of accident, bleeding the patient, has already been alluded to (see Blood). Whatever is requisite to be done for the treatment of the injuries of a person in a state of shock, should, if possible, be delayed till at least some effort has been made, by the use of stimulants, to rouse from the state of depression. In alluding to the shock sustained by the wounded on the field of battle, Mr. Hennen, in his Military Surgery, remarks: "Many lives might be saved, and the patients placed in a more favourable condition for undergoing primary operations, by the early administration of a small quantity of wine." Most surgeons of the present day give Most surgeons of the present day give the preference to hot brandy and water, and are guided in its employment by its effect upon the pulse and the temperature of the body.

SHORT-SIGHT .- See VISION.

SHOULDER .- The shoulder, in addition to the muscles and other soft parts, by which it is surrounded, is made up especially of the three bones, the shoulder-blade or "scapula" (fig. 189-1), the "clavicle" or collar-bone (2), and the "humerus" or arm-bone (6) (see Humerus), the round head of which fits to the cup (5) of the shoulder-blade (see Skeleton) to form the shoulder-joint (see also Ligament). The upper ribs (fig. 189-4) may also be considered as entering into the formation of the shoulder region generally. The whole formation and adaptations of this most important part of the on the fact whether there has been much effusion | body are singularly beautiful, made so as to of blood or not along with the injury. In give the most extensive motion, and yet that

those most perfect agents, the human arm and hand, of that most wonderful instrument, the human mind, are so specially adapted to fulfil the ends of the Creator of each. By means of the collar-bone (2), bearing at the one extremity on the breast-bone (3), and at the other upon a projection of the shoulder-blade, the shoulders are kept extended or "squared. It is this squaring of the shoulders which causes the chest to appear broader at the superior than at the inferior portion, whereas, in itself, the cavity of the chest is conical, the narrowest part above (see Chest). The comparatively

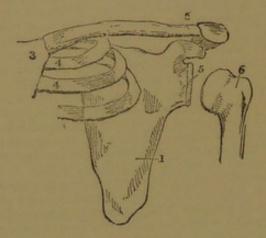

Fig. 189.

loose attachment of the great body of the shoulder-blade to the trunk admits of much freedom of motion, whilst the fullest extent of movement is secured to the arm itself by the nature of the shallow ball-and-socket joint, formed by the head of the arm-bone, and the shallow cup of the blade-bone (5). The shallowness of the cup, however, which is requisite to admit of this free movement, renders the head of the arm-bone, in some degree, liable to displacement or dislocation more frequently than other bones of the body.

Ligament-Skeleton-Axilla, &c.

SIALAGOGUES are medicines which increase the flow of the saliva, when they are chewed, such as horse-radish, ginger, &c. They are rarely prescribed.

SICKNESS.—See VOMITING.

SICKNESS, SEA .- The primary cause of the distressing affection, sea-sickness, has been a good deal disputed, but its dependence upon a peculiar condition of the brain and other nervous centres, brought about by the motion of the vessel, seems now very generally admitted. It has been imagined that the effect upon the brain was conveyed through the medium of the eye, and caused by the apparent movement of the objects of sight; as, however, blind people suffer from sea-sickness, the affection must be excitable by other means than matory affection of the pleura or of the lungs, Possibly, as has been suggested, it | but in this case will be accompanied with more the above.

fixedness and steadiness of action, by which | partly results from disturbance of certain portions of the brain which have for their function the preservation of the equilibrium of the body. That, however, sight is in some degree accessory to the excitement of nausca is evident from the fact, that some persons experience the sen-sation simply from objects appearing to move before them, as they do from a ship moved by the waves, or indeed, in some cases by the mere appearance of a waving pattern upon a wall paper. The affection is more readily caused by long heaving waves than by a short rough sea. The best preventives of sea-sickness seem to be the horizontal posture, as near the centre of the vessel, and therefore the centre of motion, as possible; that is, where the motion is least. Exposure to the open air renders the liability less. Stimulants, combined with sedatives, certainly appear to have considerable effect in preventing or alleviating the affection. A pill, composed of four grains of cayenne pepper, with two or three of extract henbane, taken at intervals, may be found useful. Creasote was formerly considered one of the best remedies for sea-sickness, but it has been displaced by chloroform, five or six drops of which may be taken on a lump of white sugar, or chloric ether may be used in doses of twenty drops, and repeated if necessary. In the course of a long voyage, and when other remedies fail, recourse should be had to Chapman's icebags, which, when placed along the spine, enjoy deservedly a high reputation for the relief of this distressing affection. The bromides of sodium and ammonium are also useful, fifteen grains to be taken in water and repeated at intervals of three or four hours. Some persons find themselves less liable to seasickness if they take food freely, with others the reverse is the case; the effect probably depends upon the state of the digestive powers of the stomach, temporary or permanent. these are vigorous, the excitement of digesting food acts probably as a counteragent to the cause of the nausea. Sea-sickness of itself is rarely injurious, but it should be a subject of consideration with persons who are liable, or likely to be, to head-affection, who are the subjects of rupture, prolapsus, &c., how far they should incur the risk of these being aggravated by the mechanical action of vomiting. Some who do not suffer from sickness while on the water, experience nausea and other uncomfortable sensations after landing, an effect, doubtless, due to a partial disturbance of the digestive organs, and probably to biliary disorder. One or two doses of compound colocynth, or compound rhubarb pill, will generally remove the inconvenience.

SIDE—PAIN IN THE SIDE.—This very common affection arises from a great variety of causes. If situated high up, in the region of the chest, it may be occasioned by inflam-

or less fever, and other symptoms indicative of | PAPER. -In this article we have a most con the disorder (see Lungs). It may, however, be caused, in the same situation, by a kind of rheumatism, or neuralgia of the muscles connected with the ribs, termed pleurodynia. this form there is not, generally, fever, and the usual signs of affection of the lungs are absent; the pain, moreover, is much more liable to aggravation by pressure externally, and by slight movement, than that of inflammation of the lungs. The affection requires, chiefly, the local treatment of rheumatism; bran poultice, and anodyne and turpentine liniment. The above pains may of course occur on either side of the chest. Pain on the right side, lower down, may be owing to affection of the liver (see Liver); on the left side, to disorder of the stomach (see Abdomen-Stomuch). Pain on the left side, however, often occurs as a sympathetic affection, sometimes of the heart or lungs, in either sex. It is most common in females, and is then very often sympathetic of disorder, functional or otherwise, of the womb. person becoming the subject of continued pain in the side should have the causes investigated by a medical man.

SIGHT.—See VISION.

SILK .- Some persons, who from irritability of the skin, cannot wear woollen material next it, find a woven silk texture a good substitute.

SILVER.—The only preparation of this metal, much used in the practice of medicine, is the nitrate of silver, or lunar caustic, and this principally as an external application; it is however given internally by medical men in small doses as a tonic in dyspepsia and in some convulsive affections. For convenient use as a caustic, nitrate of silver is cast in the form of small cylindrical sticks, which are carried generally in silver or silver-gilt holders; the best having a "quill" of the metal called palladium to hold the caustic, it being found that in time the nitrate of silver acts chemically upon the metallic silver of the holder. Cheaper holders of glass, gutta percha, and vulcanite are made. When nitrate of silver in the least degree moistened touches the body, it acts as a corrosive, and on the skin leaves a deep brownish or black stain, which is only removed as the outer skin is worn off, and renewed in course of time; or, if it is applied early, by iodide of potassium. If, however, the caustic be rubbed on the skin, it will probably cause blistering. The modes of using nitrate of silver being pointed out in the different articles, such as Erysipelas, Whitlow, &c., it is unnecessary to repeat them here. Oxide of silver is used for similar purposes internally as the nitrate, and the author has found it serviceable in some forms of stomach affection and in menorrhagia. It is not a remedy for domestic administration.

SINAPISM—a mustard plaster, or poultice.—See Mustard—Counter-irritation. SINAPINE

venient, elegant, and efficient addition to our means of treatment. The mustard paper, made by Mr. Cooper, of Abingdon Terrace, Kensington, and introduced by him to the notice of the profession, acts very quickly and energeti-cally, in the same way as a mustard poultice, without the disagreeables attendant upon that clammy and uncomfortable application, and it seems to leave less mark afterwards. From its energetic action, the time of application is necessarily shorter than when the old form of mustard poultice is used. There are, of course, cases and circumstances, however, when the old poultice may be preferable. - See Mustard

SINGING is open to the same objections, to the delicate chested, as reading aloud, to the remarks on which the reader is referred.

SINKING .- The sensation of "sinking" at the pit of the stomach is a nervous one, generally connected with disordered digestion, and often with overloaded bowels. Persons are too apt to have recourse to stimuli for its removal, which would often be better effected by the use of an aperient, and by regulation of the digestive organs. - See Indigestion.

SINUS, in anatomy, is a depression, or cavity, or covered tract. The large veins within the skull, which are partly formed by depressions in the bone, are named sinuses. In surgery, a sinus is a canal, the result of disease,

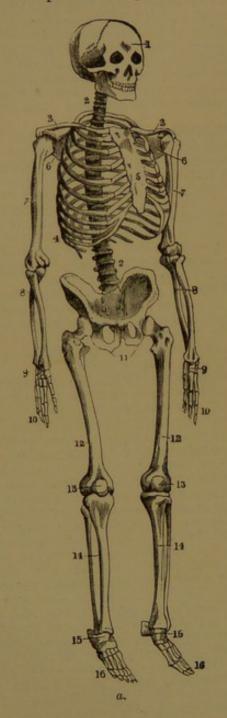

leading from a diseased part.

SKELETON, HUMAN.—The skeleton, or bony framework to which the muscles, cartilages, and ligaments are attached, is divided like the body itself into head, trunk, and extremities; and consists of upwards of 200 bones, united together by joints either of a movable or immovable character. In infancy and childhood, many of the bones consist of several parts, which unite together later in life, and form single bones, and this circumstance often gives rise to a discrepancy in the number of bones constituting the skeleton as given in books. The teeth, although possessing much of the structure of bone, are now usually described along with the tegumentary system. Bones are of various shapes and sizes, and are classified accordingly into long, short, flat, and irregular bones. They are invested, except at their articulating surfaces, with a tough, fibrous membrane, called periosteum, to which the muscles and tendons are attached, and in which the blood-vessels, which go to nourish the bony tissues, are distributed. When a portion of the periosteum is abraded (as happens more frequently from injury than from disease), death of the corresponding part of the bone is likely to ensue, in consequence of its supply of nourishment being cut off. Healthy bone consists of organic and mineral matter, in the proportion of one part of the former to two of the latter; but in infancy, bone is almost TISSUE, or MUSTARD entirely composed of animal matter in the form

SKE SKE

bones become brittle, and when broken are often difficult to unite. The mineral matter of bone consists chiefly of phosphate of lime and chalk, the phosphate being in the proportion of five parts to one part of carbonate of various parts to one another, and to the manner

of cartilage; while, in old age, the mineral lime. There are also small quantities of phos-constituents are so much in excess that the phate of magnesia and chloride of sodium in

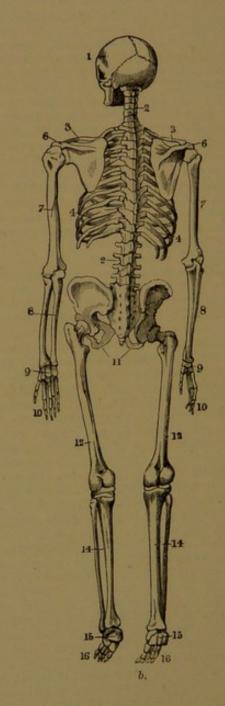

Fig. 190.

in which they subserve the object of their existence. When, moreover, the connexion of the different portions of the skeleton, by means of the ligaments, and the action, and mode of action simple and combined, of the various muscles of the machine at large, are considered; when we regard the protection given by the bones to important parts contained within the bones to important parts contained within the 544

sary to do more here than to point them out in place the various parts, serves also most by name, each bone having the same numbers, important purposes in the animal economy. on the adjoining figures (fig. 190, a and b), which give a front and back view respectively.

1. Bones of the skull and face, the former consisting of eight and the latter of fourteen bones, all of which (with the exception of the lower jaw) are united to each other by firm

and immovable joints called sutures.

2. The spinal or vertebral column, composed of twenty-four slightly movable bones, increasing in size till they reach the lowest part or sacrum. The spine supports the head and trunk, and rests on the pelvis or basin.

3. The collar-bones or clavicles, by which the shoulder-blades and arms are kept in their

places.

4. Theribs, twenty-four in number, comprise seven pairs of true ribs attached directly to the breast-bone, and five pairs of false ribs, of which three pairs are but indirectly attached to the sternum, and two pairs, called floating ribs, have no connexion except with the spine.

5. The breast bone, or sternum, to which

the ribs are attached.

6. The shoulder-blade, or scapula, containing the shallow cavity for the head of the arm-bone.

- 7. The arm-bone, or humerus.8. The bones of the forearm, radius and
- 9. The wrist or carpal bones, eight in num-

10. The palm and finger bones. The former are called metacarpal bones, and are five in number; the finger bones number fourteen, three to each finger, and two to the thumb.

11. The bones of the pelvis, comprising the two unnamed bones, the sacrum and the coccyx. They combine to form a girdle or basin, to support the contents of the abdomen, and to transmit the weight of the body to the limbs.

12. The thigh bone, or femur.

13. The knee-cap, or patella.

14. The bones of the leg—the larger, the tibia or shin; the smaller, the fibula or splint

15. The tarsal, or ankle-bones, seven in

16. The metatarsal bones forming the greater part of the arch of the foot, and the phalanges of the toes. These correspond in relative numbers to the bones of the hand.

The bones above enumerated nearly exhaust all the bones of the body, but in addition there are a few minute bones in the internal ear, one of considerable size, at the root of the tongue, called the "os hyoides," and sundry small bones called sesamoid, which are occasionally found in the tendons of certain muscles.

SKIN .- No less wonderful than the bony frame work of the human body, which we have just considered, is the covering of that body,

The skin consists of two distinct formations, the epidermis, cuticle, scarf, or outer skin (fig. 191-1; 192-1) and the dermis, cutis,

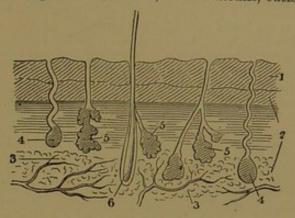

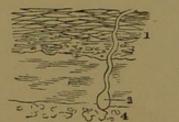

Fig. 191.

or true skin (fig.191-2). The skin is continuous with the mucous membranes at the openings of the various cavities, such as the mouth, nose, &c., its epidermis corresponding to the epi-

thelium of the membranes.

The epidermis is a thin, semi-transparent membrane, which is extended over the surface of the true skin of the body. Apparently, it is without structure, and indeed was long considered to be simply an exudation which became hardened by exposure to the air; it is now known to consist of regular series or layers of cells (fig. 192-1). The outermost layers of these

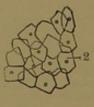

Fig. 192.

cells, which are exposed to general contact, and to the influence of the atmosphere, are comparatively hard, and are flattened as represented, becoming less flat, and softer, inward (fig. 192-1), as the surface of the true skin is approached, at which point the cells are quite soft and moist. This soft layer of the epidermis used formerly to be regarded as a distinct portion of the skin structure, under the name of "rete muco-sum." The intermixture, in this layer, of "pigment cells," that is, cells containing colouring matter, gives the varied hues to the skin of different races, as most strongly exemplified in the negro; and the appearance of freckles originates from the same cause. On the surface of the epidermis the flattened cells lie over one another, as represented (fig. 192-2), the just considered, is the covering of that body, outermost becoming continually detached and the skin, which, while it protects and retains worn off. When these detached scales are re-

SKI SKI

constitute what is called scurf or dandriff. When a blister forms on the skin, the layer of epidermis or cuticle is raised up, the fluid occupying the space between it and the true skin, and when pricked with a pin the cuticle will be found devoid of sensation. It varies considerably in thickness, on different parts of the body, even at birth, being much thicker on those, such as the heel, back, &c., which naturally require greater protection; it, how-ever, becomes immensely thickened on any portion of the body which is subject to continual pressure or friction; of this the hand of every workman is an example. As all are aware, the appearance of the skin varies according to age, from the soft skin of the infant, or of the bloom of youth, to the flaccidity and wrinkles of age; constitution also exerts much influence over the appearance of the skin. - See Complexion.

The cutis vera, dermis or true skin, which lies underneath the cuticle (fig. 191-2), is much thicker than the latter; it consists chiefly of connective tissue, that is, of interlacing fibres, which enclose the blood-vessels, nerves, &c., which make up the substance of the covering. The true skin being abundantly supplied both with blood-vessels and nerves, is extremely sensitive, so much so indeed as to require the protection of the cuticle as a necessity. All are aware of the painful sensibility of the true skin, when the outer skin has been abraded. At its surface, where it is in contact with the cuticle, the true skin is elevated into little eminences or papillæ, these are most manifestly developed, on the pulpy extremities of the fingers, and on other places where sensation is acute, each papilla being received into a corresponding hollow, in the soft granular layer of the epidermis. In the most sensitive parts, such as the lips and tips of the fingers, the papillæ in their central parts are furnished with minute bodies called "touch corpuscles," which increase their sensibility. The skin varies in sensibility in proportion to its supply of nerve fibrils, papillæ and touch corpuscles being greatest at the tip of the tongue and least in the skin of the back. Fig. 193 illustrates the position of these bodies in a papilla very highly magnified, as well as the subdivision of the nerve into tortuous nerve fibrils as it nears the surface of the true skin.

The deeper layer of the true skin is composed of interlacing fibres as already mentioned, and with these are mingled elastic fibres, and a peculiar form of muscular fibre, the latter being evidenced in action, by the occurrence of what is popularly called goose skin. The deeper layer of the skin, internally, rests upon the cellular tissue, fat, &c., beneath (fig. 191-3, 3;

Were the skin required simply for an elastic, sensitive, and complete covering to the body, the structures already mentioned might have It represents a vertical section of the skin.

tained, as by the hair, or by the clothing, they | been sufficient; but it has other functions equally important to perform, for which provision is made over its wide extent of surface. The most important, perhaps, of these func-tions is the discharge of the perspiration, which is going on continually. The perspiration is not, as might be thought, a simple exudation of fluid through the skin, but is a regular secretion, and excretion from the blood, by means of innumerable small glands (fig. 191-4, 4; 192-3), which are situated in the deep layers of the true skin. These sudoriparous, or sweat glands, are composed, as represented, of a rounded extremity formed by the convolutions of the tube, which opens to the surface by means of a spiral duct, about a quarter of an inch long. This duct, in many situations, makes its exit on the surface of the cuticle,

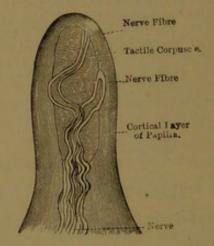

Fig. 193.

obliquely (fig. 192-3), in such a manner that it has, as it were, a valvular covering; it does not pierce the cuticle, but this latter membrane is continued down into it, as a lining. The open mouths of these ducts constitute the pores of the skin. In addition to the sweat glands, the skin is furnished with another set of excreting agents, which closely resemble the above, but which are named the "sebaceous," or oil glands (fig. 191-5, 5; see Sebaceous). The office of these glands is to separate certain matters from the blood, and to excrete them in the form of an oily matter from the skin, which oil or grease, although it is doubtless an excretion, serves also to lubricate the skin, and to keep it soft and flexible; on this account probably, the sebaccous glands are more abundant in the skins of natives of warm climates, to shield them from the drying effect of the heat. The sebaceous glands have been already alluded to under the article Sebaceous; they are often lobular in structure, frequently communicate with one another by a common duct, and in such situations as the scalp, one or two of them open into each hair follicle (fig. 191-6).

The accompanying illustration (fig. 194) will serve further to explain the foregoing remarks.

SKI SKI

As already mentioned, the skin contains blood-vessels and nerves abundantly; it also contains absorbent vessels. The number of the sebaceous and sweat glands, particularly of the latter, is almost innumerable, and some curious calculations have been made respecting them by Sir Erasmus Wilson, the well-known writer upon the skin, who says: "I counted the perspiratory pores on the palm of the hand, and found 3528 in a square inch. Now each of these pores being the aperture of a little tube about a quarter of an inch long, it | follows, that in a square inch of skin on the

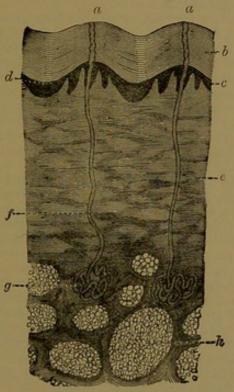

Fig. 194.

a, a. Corkscrew termination of Perspiration Duct. b. Epidermis. c. Deeper layer of Epidermis. d. Papilla on surface of Dermis. e. Dermis. f. Perspiration Duct. g. Perspiration Gland. h. Fat Cells.

palm of the hand, there exists a length of tube equal to 882 inches, or 731 feet." "To obtain an estimate of the length of the tube of the perspiratory system of the whole surface of the body, 2800 may be taken as a fair average of the number of pores in a square inch, and 700, consequently, of the number of inches in length. Now, the number of square inches of surface in a man of ordinary height and bulk is 2500; the number of pores, therefore, 7,000,000, and the number of inches of perspiratory tube 1,750,000, that is 145,833 feet, or 48,600 yards, or nearly twenty-eight miles.

From the above exposition of the perspiratory system, the reader will be prepared to learn that the skin is often the most abundant

generally trusted experiments, it is found that the average amount of watery fluid exhaled from the lungs and skin of the human body in twenty-four hours, at an ordinary temperature, is about fifty-four ounces, of which amount, thirty-three ounces are attributable to the skin, the remaining twenty-one to the lungs. This excretion of fluid is capable, however, of being largely increased, and it is an ascertained fact that a stout man undergoing strong muscular exertion, under high temperature, has, in an hour, lost as much as five pounds weight. The perspiration thus depends greatly upon the external temperature of the atmosphere; it is, however, considerably influenced by conditions of bodily health. Under ordinary conditions, perspiration takes place insensibly, that is, in the form of vapour, which passing off into the air as it is thrown out, gives no palpable indication of its presence; if, however, it is confined, as by an inverted glass, on the skin, a deposition of moisture at once occurs upon the glass. When the perspiration is so rapidly thrown out that it cannot be at once evaporated from the surface, it takes the form of sensible perspiration, or sweat, in greater or less abundance. It is evident, that when the external air is greatly laden with moisture, the perspiration will be much less quickly evaporated, and consequently much sooner evidenced than under the reverse circumstances; moreover, that as the kidneys alternate in some measure with the skin in the excretion of fluid, influences which increase the one must diminish the other, as in hot weather, when the cutaneous moisture is much increased, and the flow of urine lessened.

There is no doubt that the evaporation of the perspiration is one great means of keeping the temperature of the body down to its proper level, under exposure to heat; indeed, this is the secret by which persons have been able to endure, without injury, the heat of an oven of sufficient intensity to cook meat. It is not, however, a mere exudation of simple water which takes place in perspiration; the mixed fluid which is thrown out from both the sweat and the oil glands contains a considerable amount of free acid-lactic acid-earthy phosphates, and chlorides and phosphates of the alkalies. To these must be added carbonic acid and urea, which proves that the skin occupies an intermediate position as regards its functions between the lungs and the kidneys. The sweat is always acid, the sebaceous secretion alkaline, the predominance of one or other giving the characteristic chemical reaction.

Simple reasoning might be enough to convince us that the extensive perspiratory apparatus spread over so large an extent of skin, and in such active operation, must subserve some very important offices in the animal economy. excretor of fluid in the body, exceeding, at times, even the kidney, and always much aware, as the consequences of having this greater than the lungs. According to the most | secretion suddenly interfered with, prove that

SKI SKI

health of the system generally; and lastly, direct experiments have added to the proof. The experiments alluded to are those of M. Fourcault, who demonstrated, that if the transpiration of the skin of living animals was prevented by means of a coating of varnish, they speedily either died in a state resembling suffocation, or became the subjects of internal congestions of blood, especially of the liver. In addition to its excretory functions, the skin is endowed with other functions, becoming at times a medium for absorption of fluids, gases, or other substances into the system. The fact of gases being absorbed by the skin, adds to the importance of the body being surrounded by pure air; in fact, by some it is thought, that noxious effluvia, malaria, &c., are more readily absorbed into the system through the skin than through the lung. skin than through the lungs. If the body be immersed for some time in a tepid bath, it gains weight by absorption of water, and if thirst has existed, it is relieved. Certain medicines, again, such as mercury, Spanish flies, rhubarb, &c., affect the constitution through the skin. Probably, as suggested by Dr. Combe, even matter which has been once cast out by the skin, may be reabsorbed by it, and cause disease.

Enough, perhaps, has now been said to demonstrate to all of what immense importance the functions of the skin are to the animal system, to show, that while this most perfect structure fulfils the palpable office of a pro-tector and coverer of the entire system, it constitutes one of the great channels by which used up, and therefore noxious, matters are cast out from the blood, a channel, too, which cannot be interfered with without its internal coadjutors, the kidneys, or the lungs, or indeed any one or all of the organic functions of

the body, suffering in consequence.

Again, if it is reflected that every moment of our lives this exudation through the skin is going on, that while the watery fluid escapes, it leaves the more noxious particles behind, mingled with the scales and scurf of the epidermis, and added to this, the dust, and other foreign matter which must adhere to the skin, it will give some little idea of what there is to remove from the skin to keep it desirably clean, still more to preserve it in that state of healthy activity and freedom which is requisite for health.

The appendages of the skin are the hair and nails.

Hair-Nails.

SKIN, DISEASES OF THE .- The diseases and disorders to which the skin is liable, must necessarily be numerous. It is exposed, not only to many influences from without, to atmospheric vicissitudes, to the effects of neglect and dirt, to contagion and accident, but it is also liable to influences from within,

these offices are intimately connected with the | arising from those internal organs, with which it is so intimately connected, both sympa-thetically and in function, and it is excited by altered conditions of the blood, for which

it performs such important offices.

Very various classifications of skin diseases have been made by different authorities on the subject, with the view of facilitating their distinction from one another, and their treatment. In the following slight sketch the author has adopted the divisions best calculated to give a clear general idea of the subject; to attempt more would be quite at variance with the character of this work.

The exanthemata, or eruptive fevers, measles, scarlet fever, small-pox, and chicken-pox are each marked by a specific eruption, and are noticed in separate articles. Many other eruptive diseases are accompanied with febrile symptoms, but not of such marked peculiarity and uniformity as those which characterise the above; some authors, however, include in the class of eruptive fevers, erysipelas and erythema, nettle-rash and rose-rash, and even typhus and

typhoid fevers.

Skin diseases are very numerous and often perplexing, on account of their intractable nature, and tendency to partake of more than one type. They are best known from the anatomical character of the eruption, which may range from a slight blush or patch of redness to endless forms of alteration of the integument. The more important skin diseases are noticed in separate articles, but they may be all grouped under the following classes:-Erythema and erysipelas belong to simple inflammation of the skin; papular skin diseases are distinguished by minute and pointed elevations from the surface, terminating in scurf, of which prurigo, lichen, and prickly heat, referred to in a previous article, are examples. The latter are extremely troublesome, from the intense itching with which they are accompanied, and the obstinacy with which at times they resist treatment. The general directions as to diet, &c., given in the above articles may be useful when the affections occur. Tepid baths, with or without the addition of vinegar; or sponging with water, to each pint of which a drachm of diluted sulphuric acid has been added, may be tried as a temporary relief to the itching.

The vesicular class of skin diseases are also characterised by elevated points containing lymph or serum, clear and colourless at first, but afterwards opaque. They include chickenpox, which may be classed with eruptive fevers, also shingles and similar herpetic eruptions (see Shingles). One of the vesicular eruptive diseases, eczema or crusta lactea, has its frequent site upon the scalp and face (see Eczema). The class of "pustular" eruptions (see Pustule) also comprises various scalp diseases. In many of the affections of this class, however, the pustular eruptions extend over various portions

of the body.

which resemble those occasioned by a scald, or by the use of a common blister, and when broken, leave the skin red and inflamed. This form of skin disease is generally associated with

great debility of constitution.

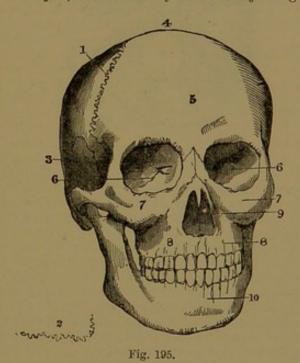

The "scaly" diseases of the skin are many of them extremely obstinate, and sometimes resist every form of treatment. Of these, lepra and psoriasis are characterised by elevated, scaly, circular patches, distributed in greater or less number over the skin. Lepra is a disease totally distinct from the leprosy of the Jews and other ancient nations. Tubercular diseases of the skin are equally difficult to get rid of, and often suppurate and ulcerate. Stains, mother-marks, or "nævi," freckles, &c., are all included in the category of skin affections: they are noticed under other articles.

Skin diseases are derived from various sources, some from the animal, some from the vegetable kingdom; some occur associated with contagious and epidemic disease, others are peculiar to well-known diseases, which are neither epidemic nor infectious; while the majority depend on the constitutional peculiarities of the individual.

No description could possibly enable an unprofessional person to distinguish one chronic skin disease from another, nor would it answer any good purpose if the knowledge could be imparted. These affections are, in a majority of instances, indicative of some peculiar disordered condition of the blood, or of the digestive processes, primary or secondary, which requires the strictest investigation of a medical man, and, probably, a long-continued course of treatment, whilst even under the best directed remedial measures they often prove intractable. Very many chronic skin diseases are connected with debility, and of course, when such is the case, tonic remedies are useful; a smaller proportion are owing to a plethoric state of the constitution; some appear hereditary, and others are connected with the venereal taint. Whatever the case be, however, those who suffer may be assured that their best course will be at once to put themselves under proper medical advice, and, if they can, under the advice of a practitioner who has made the skin a department of special study. Above all things, let sufferers beware of quack ointments, lotions, and the like; they may inflict upon themselves irreparable injury. In the event In the event of any delay occurring before advice is procured, if the system is full, and inclined to fever, low diet is advisable, and one or two gentle mer-curials, followed by a saline aperient, may be taken with advantage. If the system be debilitated, whilst all sources of heat and irritation are avoided, nourishing diet should

The class of "bulke" are characterised by skin of any irritating matter, whilst it soothes; the development of "blebs," or small blisters, it is, at all events, generally agreeable to the it is, at all events, generally agreeable to the feelings of the patient. Another reason for the enforcement of tepid bathing is the fact that, although, as stated above, very many, perhaps the majority, of skin diseases, are connected with constitutional disorders, some are almost entirely due, and others much aggravated by, inattention to cleanliness, among certain classes.

—See Ablution—Bath—Skin. SKULL.—The skull (fig. 195) contains the brain, and forms the support for the face, and organs of the special senses. It is composed of twenty-two separate bones; of these, eight are devoted to the cranium or brain-case alone, the remaining fourteen are the bones of the face. These bones, with exception of the lower jaw, are united by means of joinings,

named "sutures." In one form of suture the margins of the different bones are, as it were, toothed (fig. 195-2), the toothed edge of one fitting into the indentations of another. At (1) is seen such a suture, which forms the junction between the frontal, or forehead bone, and one of the two "parietal" bones, which principally form the arched vertex, or crown, of the skull. At (3), where the parietal is joined to the temporal, or temple-bone, the suture is different, being formed by the thin margin of the latter bone overlapping the similarly formed edge of the former; where these bones overlap, their edges are roughened, so as to give greater adherence. In another form of suture, the adjoining edges of the bones are simply roughened. In fact, the form of the bones of the skull individually, be taken, and the bowels regulated. When milk diet agrees, it is very suitable in many chronic skin affections, and there are few in lightness at the same time; indeed, so strong which tepid bathing does harm, it clears the is the arch of the vertex, or crown of the head

(4), formed by the parietal and frontal bones, | seen the hollow for the nostrils, divided in the that in falls on the head, instead of this portion of the skull giving way, it is not uncommon to find that the fracture, if it occurs, is in the opposite portion of the skull where it is supported by the spine. When the skull is sawn through transversely, about its middle, it presents the oval form, as represented (fig. 196), and if the brain be removed, the in-

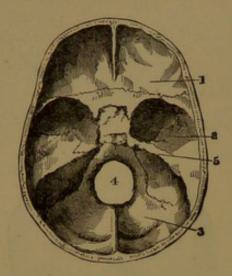

Fig. 196.

terior portion of the skull, or floor, on which the brain rests, is seen as in the cut, consisting of anterior (1), middle (2), and posterior (3) depressions or fossæ; the anterior and middle being adapted to receive portions of the larger brain or cerebrum; the posterior being the receptacle of the lesser brain or cerebellum, on the top of which the posterior portion of the larger brain is situated (see Brain). The larger opening (4) in the base of the skull gives passage to the spinal cord or marrow. There are a number of smaller openings in the base of the skull for the transmission of nerves, and for the passage of blood-vessels. Within the prominent portion of bone (5) is contained the internal auditory apparatus (see Ear). The interior surfaces of the skull are variously grooved and marked, more particularly for the accommodation of the bloodvessels, especially the large veins connected with the head circulation. The bones of the skull do not each consist of one solid piece of bone, but of an inner and outer "table" or plate of dense bone, separated by a lighter and more cellular portion, which is called the "diploe" (see *Diploe*). The depressions and hollows of the outer table do not entirely correspond with those of the inner.

The frontal or forehead bone (fig. 195-5), a bone of the cranium or brain case, is also a bone of the face, entering largely into the formation of the eye sockets (6, 6). These conical cavities (see Eye) are made up by the combination of other bones, such as the cheek bone (7), the upper jaw bone (8), &c. At (9) is blood in the head, caused by the compression 550

centre (see Nose). The lower jaw bone (fig. 195-10; fig. 197) of the figure represented, is jointed to the skull by means of the rounded heads (fig. 197—1, 1), which fit into correspond-ing hollows in the skull. This is a specimen of the hinge-joint. The shape of the lower jaw varies greatly during the different periods of life; it also differs considerably in different races of human beings, exhibiting, as well as the upper jaw, a tendency to become more

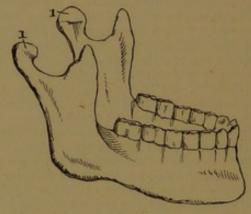

Fig 197.

projecting as the descent is made in the scale of civilization. The variations which are observed in the forms, and in the relative proportions of the different regions of skulls belonging to various tribes of the human family, form a study of the greatest interest. The bones of the skull and face are closely covered, like other bones, by a membrane or "periosteum," in this case called the "pericranium." The scalp is connected with the skull by means of a loose, easily torn connective tissue. - See Scalp.

Refer to-Brain-Fractures-Nervous System. SLEEP .- The explanation of the actual physiological condition which constitutes this periodical phenomenon of life has often been attempted, but the essential nature of the condition remains unexplained. The external phenomena manifested during the state of sleep are familiar, and, in some measure, those that take place within the body during the state are known; but there the knowledge

Sleep may be defined as a state of natural unconsciousness, in which the motor and sensory powers are in a condition of suspension, whilst the organic functions of nutrition, including the movements of the heart, lungs, and bowels are going on, increased, diminished, or unaltered, according to circumstances. The cause of the sensorial inactivity of the voluntary system, and of the apparent disconnexion of the mind with outward things, and as it appears to us on awaking from sleep, disconnexion with thought generally, has been variously explained. A kind of congestion of

was supposed to be the normal condition in sleep, but Mr. Durham has shown by experiment that the reverse of this is the case. The most general idea, is, that sleep is the consequence of exhaustion of the usual nervous stimulant in the services of the waking hours, along with waste of the tissues generally. As put by Liebig:-"Since in different individuals, according to the amount of force consumed in producing voluntary mechanical effects, un-equal quantities of living tissue are wasted, there must occur in every individual, unless the phenomena of motion are to cease entirely, a condition in which all voluntary motions are completely checked, in which, therefore, these occasion no waste. This condition is called sleep." Dr. Carpenter puts the same ideas somewhat in a similar manner, saying: "The occasional suspension of sensorial activity is requisite for the reparation of the destructive effects of that activity; so that, however unfavourable may be the external circumstances, sleep will supervene as a necessary result of exhaustion, when this has been carried very far." That exhaustion is one, perhaps the one great condition of sleep, is unquestionable; but that it is not the only condition is no less true, unless, indeed, the statement of Liebig be adopted unreservedly, that wine, narcotics, and other sleep-inducing agents, produce a state of artificial exhaustion, by putting a stop to the regular changes of matter, especially its union with oxygen, which is constantly going on within the body. Moreover, there is a state of over-exhaustion, both of mind and body, which tends to keep off sleep, rather than to Further, there is a most undoubted connexion between the periodical revolution of the twenty-four hours which constitute our day, and the periodical requirements and renovations of sleep.

It is observed by Dr. Whewell, in his Bridgewater Treatise, that "man, in all nations and ages, has taken his principal rest once in twentyfour hours, and the regularity of this practice seems most suitable to his health, though the duration of the time allotted to repose is extremely different in different cases. So far as we can judge, this period is of a length beneficial to the human frame independently of the effect of external agents. In the voyages recently made into high northern latitudes, when the sun did not rise for three months, the crews of the ships were made to adhere with the utmost punctuality to the habit of retiring to rest at nine, and rising at a quarter before six; and they enjoyed, under circumstances apparently the most trying, a state of salubrity quite remarkable. This shows, that according to the common constitution of such men, the cycle of twenty-four hours is very commodious, though not imposed upon them by external circumstances. No one can maintain with

of the veins in the neck by certain muscles, | ened or shortened without limit. We may be tolerably certain that a constantly recurring period of forty-eight hours would be too long for one day of employment, and one period of sleep, with our present faculties; and all whose bodies and minds are tolerably active will probably agree, that independently of habit, a perpetual alternation of eight hours up and four in bed, would employ the human powers less advantageously than alternations of sixteen and

eight.
"The succession of exertion and repose in the muscular system, of excited and dormant sensibility in the nervous, appears to be funda-mentally connected with the nervous and muscular powers, whatever the nature of these

may be. "The necessity of these alternations is one of the measures of the intensity of those vital energies; and it would seem that we cannot, without assuming the human powers to be altered, suppose the intervals of tranquillity which they require to be much changed.

The amount of sleep necessary for an individual depends greatly upon time of life, upon natural constitution, or upon acquired habits. The infant, it is well known, spends most of its early days in sleep; in adult life, the hours of repose are reduced to the moderate average of from six to eight hours; whilst in advanced life, that is before the period of decrepitude, the amount of sleep is still further diminished. By Liebig, this is reduced to a regular calculation. After giving the calculation, as computed in mechanics, of the force available for mechanical purposes in an adult man in a certain period, he says: "By the restoration of the original weight of his body, the man collects again a sum of force which allows him, next day, to produce, without exhaustion, the same amount of mechanical effects. This supply of force is furnished in a seven hours' sleep," provided, of course, sufficient nutriment has been given during the waking hours, from which the reparative powers can draw their supply of new material. Further, if the process of oxidation and waste goes on more briskly in the system than can be restored or repaired, during the seven hours, or whatever other amount of sleep is necessary, the strength must diminish. Practically, therefore, sleep is a periodical natural condition, in which the voluntary or exhausting powers, both of body and mind, being at rest, the involuntary or reparative powers have, or ought to have, time for restoring the material of the living body, which has been used up during the hours of wakeful activity. Such being the case, it is evidently most important, not only that a supply of sleep adequate to the reparative requirement of the system should be procured, but that the benefit derived from the sleep should not be impaired by contingencies likely to interfere with the processes which are actively carried on any plausibility that the period may be length- during the state of unconsciousness. These

SLE SLE

processes—devoted to the repair of the structures | remarkable aptitude to sleep at will, and an equal -must evidently be more connected with the secondary assimilation of nutriment, that is, with changes in the nutriment after it has entered the blood, than with the primary assimilation in the stomach. This, probably, is one reason why nourishment is usually more beneficially taken some hours before the ordinary night's rest; it permits the result of the digestion of the meal, not only to enter the circulation, but to be ready for the processes of reparation which take place during repose. It would almost appear as if these reparative processes were carried on at the expense of others which are more active during waking hours; for, during sleep, the respiration is diminished in frequency, the pulse is slower, the action of the brain, as has been already observed, diminishes. At the same time the temperature sinks, and the nervous power is evidently lowered, and with it the power of resistance to morbific influences, such as malaria. Indeed, as observed elsewhere in this work, this diminished condition of nervous power is not recovered for some time after waking, and by the weak not until food has been taken (see Breakfast— Early Rising, &c.). The perspiration, for obvious causes, is generally increased during

The amount of sleep required by different individuals varies greatly; as already stated, the infant requires most, sleeping at least twenty hours out of the twenty-four. The hours of sleep which are requisite, diminish up to adult maturity, when from six to eight hours is the average requirement during the most active periods of life. There are, indeed, instances of persons who could do well with a much smaller average of sleep-four, three, two hours, or even less; but these are exceptional instances, and the individuals have generally been persons of strong constitutional powers. The persons of strong constitutional powers. extension of the hours of sleep beyond the term of eight, or at least nine hours, is generally the result of habitual indulgence. Moreover, when sleep is thus taken excessively, more is required, or thought to be required, on account of the debility which arises from consequent excessive action of the skin. Women, as a general rule, require rather longer sleep than men, and it is said that tall and bulky people need more than those who are short and thin.

Many of the external conditions requisite for sound and healthy sleep having been noticed under Bed and Bed-room, it is unnecessary to repeat them here; it may be added that no portion of clothing which tends, either in the way of the wristband or of neck fastening, to confine in the least degree, should be worn. Especial attention should be directed, especially in the case of children, to the injurious effects of sleeping with mouth or head covered over with the bed-clothes. The practice is a common but most hurtful one.

Some persons have been known to possess a

readiness to awake at the right moment, as was the case with the first Napoleon and of the Dutch Admiral, who was said to sleep with one eye open; and the faculty has been quoted to prove that sleep is an active state rather than a passive one. It would rather prove that the mind has so far power over the body as to restrain the tendency to sleep until it can be conveniently indulged in, and that as soon as the powers of body and mind are surrendered to its influence, it at once takes possession of The power of certain external agencies in inducing sleep are well known; absolute quiet and the recumbent position are in most cases sufficient; but every nurse and mother has recourse to soothing sounds to aid the repose of the child.

In the above remarks, sleep has been considered as a natural healthy process, either the result of exhaustion, nervous or general, or the consequence of a periodical condition of the body. It has been regarded as a process tending to health, to recruit the exhausted powers of body and mind. But sleep is often not a natural process: it may be occasioned by excessive use of alcohol, or by narcotic drugs, by the action of heat, or by the depression of extreme cold; it may result from over-fulness of blood, or from deterioration of the vital fluid; in the latter case, generally, it is pro-bable, by the accumulation of carbonaceous materials, consequent upon imperfect aeration of blood in the lungs, or its imperfect elaboration in other organs (see Biliary Disorder). Again, heavy, very heavy sleep, is a common accompaniment of chlorotic or anæmic conditions of the system, producing a condition akin to coma (see Anæmia). In such cases, although the powers of the body are in some degree recruited by the sleep, it is not followed by the same feelings of health as the natural sleep of the properly but not over-fed-well-exercised, but not exhausted-worker of either mind or body, provided the mental worker neglect not the physical exercise.

Sleeplessness, technically termed insomnia, arises from various causes. It is often a distressing concomitant of old age (see Old Age), but mental causes, anxieties, excitements, distresses most frequently give rise to it, and especially intellectual exertion of the mind late in the evening, and just before retiring to rest. Want of due physical exercise also occasions sleeplessness; it is the result of dietetic errors, either eating heavy meals too late in the evening, or retiring to rest without sufficient nourishment, and especially is it caused by strong tea or coffee taken at a late hour, in some people at any hour (see Tea). If any of the above causes of habitual sleeplessness are suspected to be the origin of the evil, the most effectual mode of correction is of course to remove the cause; but except under the sanction of a medical man, who can discriminate how far

to impair the constitution, artificial, that is medicinal, modes of procuring sleep should never be resorted to. Early rising, moderate attention to diet, and moderate exhaustion of both body and mind by exertion, ought to be employed to bring back the soft restorer. Sometimes the mere alteration in the hour of a meal, a biscuit before retiring to bed, instead of going with an empty stomach, or some apparently trifling alterations in habits, are all that are requisite as a corrective. Continued sleeplessness is a symptom of delirium tremens, and some fevers; it is also often the forerunner and concomitant of some forms of insanity. In both these phases it requires to be dealt with

by a medical man.

Disturbed sleep is almost a constant attendant upon disorder of the digestive organs, either as exhibited in mere restlessness, or unpleasant dreams, or in the more aggravated form of nightmare, which is generally considered to depend upon impeded respiration and circulation within the chest, causing those disagreeable sensations connected with the condition, of which all must at times have been conscious. probable that the uncomfortable sensation in the chest, in the first place gives rise to the "suggestive dream" (see Dreams). Nightmare, if of frequent occurrence, may depend on disease connected with the heart or circulation, but more usually it is the result of causes much more easily removable, such as indulgence in heavy suppers, or excess of food generally-in fact, of indigestion. Disturbed sleep in children is very common, taking either the form of moaning or restlessness, with grating of the teeth, or talking; of awaking suddenly, frightened and screaming; or of getting out of bed, when it becomes somnambulism or sleepwalking. The excitability of the nervous system in children renders them liable to be thus affected by even slight disorders of the bowels, and especially by worms, &c. In such cases, therefore, it is always right to make sure that nothing offends in this way, by clearing out the canal by means of a smart purge; calomel and scammony is probably the best. If the affection does not seem to depend on disorder of the bowels, so much as upon general excitability, everything in the way of mental excitement which can increase this must be avoided; cold laving of the head every morning, and the cold douche to the back should be used, and the nervous system tired before bedtime by active but not exhausting exercise. Opium, especially in the form of chlorodyne, is frequently had recourse to, to produce sleep, but it is a narcotic which should not be rashly indulged in; chloral hydrate is another remedy much used for a similar object, and probably with less risk of injurious consequences, but neither drug should be used without medical sanction. The best remedies for sleeplessness

sleeplessness is dependent on disease, or likely suppers, if the latter meal must be indulged

Somnambulism, or sleeping-walking, in adults, belongs to the class of mental, or rather psychological, phenomena not yet generally understood; it evidently resembles, if it is not identical with, the mesmeric condition of which some, and generally the same class of persons, are susceptible. Where a tendency to sleep-walking does exist, it is perhaps scarcely requisite to remark, that every means of guarding the person so unfortunately affected from accident should be had recourse to.

Night is the natural season for rest; but in warm climates, a day sleep, both in man and animals, seems beneficial. In temperate climates, after the age of childhood, it is not an advisable custom. After any unusual fatigue, however, a short sleep before-not after-dinner, is often very serviceable.

Rising-Night, &c.

SLOUGH—a slough is a dead portion of tissue cast off from a living animal body. Bed-sores are usually the result of sloughing of the tegument and subjacent tissue. To assist the separation of the slough, and to destroy the fetor, it is generally necessary to dress the parts with antiseptics, such as the carbolic acid or chlorinated lime washes, or sanitas oil.—See Bed-sores.

SMALL-POX. - This dreaded disease belongs, like measles and scarlet fever, to the class of eruptive fevers; it is, too, like these diseases, characterized by its own special constitutional symptoms from the commencement, independent of the eruption which stamps its character.

Small-pox commences with shivering and languor, followed by heat, thirst, and headache; so far, these symptoms mark the beginning of most other severe febrile affections. Added to them, in the disease in question, there is usually either pain or great oppression at the pit of the stomach, and not unfrequently vomiting; there is severe pain in the back or loins, and in children not uncommonly, more rarely in adults, convulsions. On the third day after the setting in of the above symptoms, usually towards evening, minute red spots, somewhat resembling flea-bites, show them-selves on the forehead, the neck, the wrists and arms, the chest and abdomen, and finally on the extremities; this, at least, is the course of the eruption, but it does not reach the lower extremities till at least the fourth day. If the eruption on the parts first mentioned is dis-covered over night, by morning it is much more distinct, and the spots are much more numerous than they first appeared to be; they are, too, slightly and conically elevated—are, in fact, "papular." From this they continue enlarging. On the third day after their appearance, they evidently contain a little fluid on are early hours, active exercise, and light their summits, which gradually increases in

SMA SMA

quantity, giving either a globular form to the | eighth day, that is, when those on the face are spot, or an umbilicated or wheel-like form, the centre of the vesicle or pustule being depressed, tied down, as it were, in the centre. Towards the fifth or sixth day of the eruption this peculiarity of form disappears; the pustules become real pustules; they contain pus or matter. About the seventh or eighth day of the eruption they begin to "crust," that is to break, allowing their contents to escape, and then to harden into a crust or scale. At this period of the disease, that of "maturation" (the eighth day of the eruption, the eleventh of the disease), what is called the secondary fever comes on; the febrile symptoms, which had more or less abated after the eruption appeared, become again aggravated, and continue so for a few days. At length, if the case has progressed favourably, towards the end of the third week from the first showing of the eruption, some of the pustule scabs begin to separate and fall off, leaving either a pit or a stain of a deep red colour.

Such are the most prominent characteristics of small-pox, as they show themselves upon the face to the eyes of an observer. The progress of the eruption on the body generally must be reckoned as twenty-four hours, and even more on the lower limbs, later than on the face. Much of the severity and danger of small-pox depends upon the amount and character of the eruption : whether it is what is called "discrete," that is, each separate spot distinct from another; confluent, when the spots all run into one another, forming one mass of eruption; semi-confluent, a medium between the two former, or the hæmorrhagic, in which the eruption is in a measure suppressed—a very dangerous form of the malady. There is of course every degree of severity. It need scarcely be added, that the regular confluent small-pox is a most dangerous disease. As a general rule, the eruption of small-pox is thickest on the face, and its variety, confluent or not, is generally reckoned from its amount in the above situation. The skin surrounding each pustule is inflamed and swollen'; this inflammation and swelling being of course more severe according to the severity of the eruption. In consequence of it, the features are swollen and disfigured, and the eyelids closed. The eyes partake of the inflammation of the skin, and are apt to be much affected, discharge of matter taking place from beneath the eyelids. The nostrils, mouth, and throat are usually more or less affected with small-pox pustules; indeed, one of the most serious dangers apt to arise in the course of small-pox, is the throat affection, and any signs of impeded breathing are always to be most anxiously watched and cared for. Unless the attack of small-pox is extremely modified, as by previous vaccination, the pustules on the face almost all run through their regular course as above described; in many cases, however, they do not do so on the body; but on the requisite both to act more freely on the bowels

discharging their contents, those on the trunk and lower limbs begin to "go back," as it is called, or wither up, without the formation or discharge of matter.

When an attack of small-pox comes on with great severity, and when the constitutional powers are, as it were, overwhelmed, a person may sink early in the disease, but more generally the chief danger is about the time of the secondary fever, either from the violence of the poison, which interferes with the maturation of the pustules, or from severe inflammatory complications, especially of the air passages. When modified by previous vaccination, smallpox is, as a rule, an extremely mild disease, the fatal cases not amounting to more than five per cent. of those attacked; while the susceptibility to infection is lessened in proportion to the means employed to protect the system by effectual and repeated vaccination.

In the early stages, small-pox may be confounded with other eruptive diseases, especially with measles and chicken-pox, which in the first stage it somewhat resembles; this mistake, however, can scarcely occur if the distinct characters of the constitutional symptoms of the diseases are kept in view; when the eruption has advanced a little way there can be no confusion.

It need scarcely be said, that an attack of small-pox, of even ordinary severity, is not for unprofessional management. If the disease be prevailing, and if an individual exhibits the symptoms above detailed, small-pox may fairly be suspected.

The appetite, probably, is totally gone from the first; but in such cases, food of the lightest kind only must be taken, and cooling drinks; a couple of drachms of diluted nitric acid or diluted sulphuric acid added to a pint of water, and sweetened with sugar, makes an agreeable drink. Sir Thomas Watson recommends a drachm of chlorate of potash dissolved in a pint of water for a like purpose. Soda or potash water, or the effervescing saline mixture, may be given occasionally; and as it is necessary to keep the bowels lax without purging, some mild aperient, such as the Seidlitz powder or castor oil, must be given if required. But although the bowels should be kept easy throughout the disease, when the eruption is coming out all attempts at purging should be dropped, cooling saline medicines being continued. If the surface is very hot and dry, sponging with tepid water is useful and agreeable. Olive oil or carbolic oil, or, better still, the liniment called carron oil, composed of equal parts of olive oil and lime-water, smeared over the surface with a paint-brush, will generally be found efficacious in allaying irritation, and in relieving the severe itching, especially if combined with one fifth part of sanitas oil. When the secondary fever comes on, it may be

SMO

or by senna or Epsom salts, well diluted, or some of the aperient pills; while at the same time the distressing restlessness requires opium, twenty drops of sedative solution, or five-andtwenty of laudanum at bed-time. In some cases, if signs of sinking come on, with weak pulse, tardy eruption, and pustules not filling, all lowering measures are to be avoided, and good broths, wine, or brandy, may be administered, as the case may require. The principles of treatment are, in the onset of the disease, to moderate febrile action, and through it the eruption, by cooling aperients; when the eruption is coming out, to interfere but little beyond keeping the bowels easy, regulating the diet according to the strength; and again, in the stage of secondary fever, to purge moderately.

If much swelling and distress about the

throat should result in the course of the disease, leeches ought to be applied, in number pro-portioned to the age and constitution of the patient. This treatment, employed in a case far distant from medical aid, might save life.

In any case, small-pox is a fearful disease, and should be under medical care when possible; circumstances, however, may occur in which disfigurement which is apt to result in consequence of the marks left upon the face by smallpox, is an additional aggravation. methods for its prevention have been resorted to. The light, being supposed to exert some influence on the progress of the pustule, is often excluded from the room, and as the eyes are apt to be sensitive, the expedient is good in more ways than one. Opening each separate pustule with the point of a lancet, and touching the interior with a pointed stick of lunar caustic, has been supposed to be of use. mercurial plaster, or the common mercurial ointment, a plasma made of starch and glycerine, collodion, sulphur ointment, and guttapercha dissolved in chloroform, have each been spoken favourably of as methods of preventing pock marks, but it is doubtful whether any one of them is unattended with some objection. On the whole, it is better to trust to the ordinary method of inunction with olive oil, or the lime-water liniment, as previously recommended. It is generally some months before the stains of even a mild attack of small-pox disappear. Small-pox is highly contagious, and may even be communicated by the dead body. The attack generally comes on about ten or twelve days after exposure to contagion. As all, perhaps, are aware, until the discovery of vaccination by Jenner, the system of inoculating small-pox, as introduced into this country from Turkey by Lady Wortley Montagu, was generally followed, and certainly was a great boon; it substituted, for, to say the least, one of uncertain severity;

by means of the aperients already mentioned, | constitution which had by preparation been placed in a favourable condition for its reception, and for its development in a mild form. To counterbalance, however, these advantages, there was the serious consideration, that, although a case of inoculated small-pox might in itself be a trifling affection, devoid of danger, it was capable of originating the disease in another person in its most virulent form, and thus give rise to an epidemic. This drawback Jenner's discovery removed, and therefore, rightly, vaccination has taken the place of inoculation, and rightly, Government has put it out of the power of foolish people to do mischief, by imposing a heavy penalty upon the practice of inoculation for small-pox.

Small-pox is most fatal in early life. In the unvaccinated condition it is calculated that nearly fifty per cent. of those attacked die; and prior to the discovery of vaccination, one-tenth of the deaths among the population was attri-buted to this cause. For the history and pro-tective character of vaccination, see article

Vaccination.

SMELL.—See Nose.

SMOKE NUISANCE and ABATE-MENT .- The dire effects of the volatile products from coal combustion, whether from private houses, factories, or public works, have long engaged the attention of sanitarians; and reiterated attempts, both legislative and voluntary, culminating in a recent Smoke-abatement Exhibition in London, have been made with the view of reducing to a minimum the vicious influences of the smoke-laden atmosphere of our towns. However much opinions may differ with respect to the origin of the fogs which periodically cast a pall over London and other large centres of population, there can be little doubt that smoke constitutes a main factor in their production, and any feasible method of getting rid of the nuisance, provided it does not interfere with our proverbial proclivities in favour of an open and cheerful fire, cannot fail to be accepted as a boon.

The difficulties in the way of smoke reform are, however, great, since the remedies in best repute strike at the root of our social customs, and would necessitate, on the part of occupiers or owners of property, an entire change in the construction of the ordinary grate, as well as in the nature of the fuel employed. Among the numerous substitutes for smoky fires are comprised the various methods of heating by steam, hot water, coal gas, coke and smokeless coal; but it cannot be said that any one of these, singly or combined, though they might mitigate the evil, would effectually remedy it. Even to give the best of these substitutes a fair trial, it would be necessary to render the method compulsory on the conin almost every case, a mild form of the disease sumer, a condition that no Parliament would ever sanction, and it only remains to consider and, moreover, the disease was imported to a what may be best done by private enterprise.

SMO SMO

has hitherto been given to one or other of the numerous varieties of bituminous coal which by virtue of its elements (hydrogen and other volatile gases) flares up readily when kindled, discharging its sooty products into the already murky atmosphere. On the other hand, it is visibly shown that the variety of coal known by the several names "blind," "hard," "welch," and "anthracite," when used, as is commonly the case, in furnaces for smelting or for generating steam, throws off very little volatile matter, and contains more carbon, the amount usually averaging more than 90 per cent., and attributable to geological changes which the more inflammable coal has not yet undergone. As experience has long since shown the practicability of smoke consumption in the combustion of all kinds of coal, Acts of Parliament have been passed rendering it compulsory, in London and in a few large towns, on owners of furnaces to consume their smoke. This object is best accomplished by such a construction of the furnace and arrangement of the fuel as will insure, in the first instance, a full draught, and next will enable the smoke created to pass from the front of the furnace over the surface of the intensely heated fuel behind, and be consumed in its passage. Of course such an arrangement is impracticable in the ordinary household grate, but an approach to it may be seen in the slow combustion stove, or in a frequent adaptation of the ordinary grate, made by fixing an iron plate over the bottom bars, and igniting the fuel from above, thus causing the smoke generated in the combustion of the lower strata of coal to be burned in its transmission through a layer of red-hot coals superimposed. This arrangement, or a modification of it (which is perhaps best realised in Edwards' slow combustion stove), has many advantages on the score of economy and cleanliness, but it is somewhat difficult to light the fire from above, and in the process of lighting, as well as in renewing, the fuel from time to time, there must necessarily be a considerable discharge of smoke.

The only agents we have ready at hand to make a smokeless fire, are coal-gas, coke, and anthracite. Coal-gas fires have many advocates, and for bed-room purposes are most convenient and cleanly; but they are expensive, and except perhaps for cooking on a large scale, coalgas can scarcely be expected to take the place of coal. In numerous public places, in halls and waiting-rooms, where there may be a difficulty in getting the heating arrangements kept under control, or where there is a deficiency in the flues, the introduction of close gasheating stoves has been attended with good results. Besides being smokeless, they have the effect of warming the apartment, and retaining it at a healthy temperature, without imparting any of the deleterious products of imparting any of the atmosphere. When the gas combustion to the atmosphere. When the

For ordinary household purposes, preference | supply of fresh air is introduced to the stove by a flue communicating with the outside, and warmed there before its escape into the room, the closed stove becomes an excellent ventilator, not the least of its advantages being that it can be kept so readily under control. George's Gas Calorigen (see Stoves) is fitted on this principle, so also is the Euthermic Ventilating Gas Stove, designed by Dr. Bond, the health officer for Gloucestershire, of which a section is depicted in fig. 198. This stove is described as consisting of a cylinder, A, of thin convoluted sheet-iron, within which is fixed a metal cone, B, the upper and broader margin

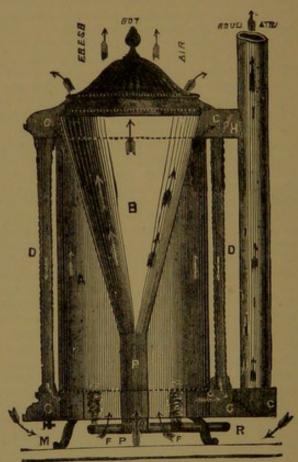

Fig. 198.

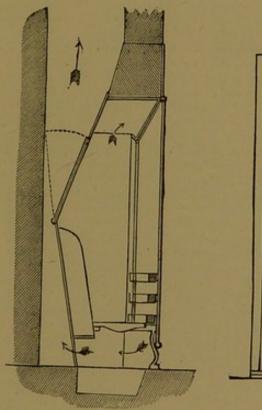

of which is attached in an air-tight manner to the upper part of the stove, whilst its lower and smaller aperture is connected by a tube, P, with the outer air. Around the cylinder a series of tubes, D D, in the form of columns, are fixed, the upper ends of which communicate by means of an annular chamber, c, with the space between the cylinder and the cone, and the lower ends open into a similar chamber which surrounds the base of the cylinder. From this chamber an outlet flue proceeds, which is also connected by a branch, near the top of the stove, with the upper annular chamSMO SMO

ferable arrangement, into an unused chimney | a little care and manipulation, anthracite gives chamber is a gas burner, F, which burns a mix-ture of air and gas, which is supplied by a pipe, R, connected with a gas supply.

The inlet of the cone may be supplied with fresh air, by connecting it with the outer air by means of a pipe running through the nearest outer wall of the room, or through the

Whether the mass of the population accustomed to bituminous coal will ever be induced to employ, for ordinary household purposes, the smokeless anthracite, is a question which

flue, closed at the bottom to prevent reflux into all the cheerfulness, and possesses more heat the room. At the base of the lower annular and staying properties, than bituminous coal; and staying properties, than bituminous coal; but notwithstanding much said in its favour, cooks and housemaids, to whom most people are under a species of domestic thraldom, rebel stoutly against its employment. jections are of course founded on the difficulty of lighting, and to remedy this inconvenience, which is no doubt a serious one, numerous plans have been devised. In Siemens' grate, the smokeless fuel is ignited by means of coalgas laid on to the fireplace, the flame being ex-tinguished as soon as the combustion is perfected; while numerous grates and fireplaces time alone can determine. Certain it is, that having the same object, are designed on the it has no lack of advocates, who assert that, by principle of the double flue, with the intention

of directing the current of air downwards and | As will be seen by reference to the sectional and backwards into the chimney, under and immediately behind the grate, when the lighting is attempted, and upwards in the ordinary way only when the fire is completed. Several grates of this description were exhibited at the late Smoke Abatement Exhibition, the best examples of which were manufactured by Messrs. Smith & Stevens, of Leicester Square, and Crane's patent register stove, shown by the well-known firm of Deane & Co., London Bridge. The advantages claimed for Crane's grate are, that it burns anthracite as easily as ordinary coal, that it gives a vast amount of

elevation illustrations (figs. 199, 200), the grate is fitted with a register door in the usual way, and a second opening, communicating with the flue, is made behind the ash-pit under the fire. The space on each side of the fireplace, usually filled up with brickwork, is occupied with side flues, which communicate with the bottom of the grate, and when the register door is closed, as it must be when the fire is being lighted, any products of combustion escaping in an upward direction are carried downwards through the side flues, and tend to increase the action of the flue behind the ash-pit. At the same time, heat with a reduced consumption of coal, and the entrance door to the bottom flue is opened that the smokeless fuel is easily set light to. to a greater or less extent, the effect of which

the fire from the apartment. This draught it is necessary to maintain until the fire is well lighted, when the ordinary register door can be opened, and the lower opening closed to check the otherwise unnecessary brisk combustion.

It may be considered foreign to the purpose of this work to refer in detail to the subject of smoke abatement, but the injurious effects on the respiratory organs, and on the body generally, from living in a smoke-laden atmosphere, as well as the fatal consequences of the fogs to which London and other great towns are periodically subjected (as shown by a marked increase on these occasions in the Registrar General's returns of mortality), are a sufficient reason why the subject should find a place in

harmless luxury for most adults, while in some cases it is decidedly beneficial. It acts as a gentle stimulant to the brain, and as a sedative to an irritable and excited nervous contains.

In symptoms which precede a fatal termination are faintness, vomiting, hurried breathing, and unconsciousness, followed by paralysis, coma, and occasional convulsions.

SNEEZING is a convulsive or space of the containing of the containi Experience has amply proved that it enables fatigue to be better borne, and alleviates the distress of hunger. With many persons, also, it is a distinct aid to digestion, and, more especially in elderly people, promotes the regular action of the bowels. Like most other luxuries it can be taken to excess with resulting pernicious effects. The most frequent of these are palpitation of the heart and nervous irritability; and these symptoms are frequently and a common cause of dyspepsia. As a accompanied by flatulence and other symptoms counter-irritant, in some forms of headache, of indigestion. Chronic catarrh of the throat snuff proves serviceable. - See Tobacco. with cough is a common result of excessive smoking, more especially of cigarettes; probably the catarrhal affections of infants. the temperature of the smoke as well as its character contributes to this ailment, which is often very intractable so long as the smoking is continued, and has a depressing effect on the general health. Sleeplessness also occasionally results from excessive smoking, more especially if indulged in late at night.

Smoking is undoubtedly injurious for growing boys and girls, interfering with their growth, exciting unduly the nervous system, and im-

eighteen years of age.

A form of cancer on the lower lip, known as "smokers' cancer," is occasionally met with in habitual smokers. It is the result of smoking a hot pipe, and of always keeping the pipe on exactly the same part of the lip. Clay pipes are most frequently the cause of this sore, which should always be removed by operation at an early stage. If this is done it very seldom

SMOTHERING.—See SUFFOCATION.

SNAKE POISON .- When anyone has been bitten by a snake of known or of even doubtful poisonous character, either on the arm or leg, a cord should at once be tied tightly used alkali is now manufactured almost en-round the limb immediately above the seat of the tirely from common salt, which is a chloride

is to create a strong draught through and under punctures, which should then be excised with a sharp knife and encouraged to bleed freely. The wound should then be sucked either by the mouth, or by means of a cupping glass. When no more blood can be extracted in this way, the wound should be thoroughly cauterised with a white-hot piece of wire or the blade of a knife heated. The ligature should be retained until the cauterisation is completed. If the bite is on any part of the face or body the ligature cannot be applied, but, otherwise, the same treatment is indicated. The sufferer should be kept as warm as possible, and stimulants administered very freely. Whisky, brandy, wine, and ammonia are all useful, and may be given in quantities considerably larger than could be taken with safety in health.

irritation of the lining membrane of the nostril, by which air is forcibly sent through the pas sage so as to expel any cause of irritation. Sneezing is one of the first symptoms of cold, of influenza, of measles, and of diseases which involve the air-passages. Continued sneezing is a spasmodic affection characteristic of hayfever, and is often relieved by emetics.

SNUFFLES-a name sometimes given to

SOAP is a compound of fat or olive oil with alkali, which is usually soda. Tallow and other cheap fats are used for the commoner soaps, and yellow soap has about a fourth part of resin and palm oil in its composition; it is the resin which makes it irritating to some skins. The best soaps sometimes irritate the skin of the face; and when this is the case, the irritation may be avoided by first dipping the face in water to which a little lime juice has been added. The writer has found Packer's pairing their digestive powers. As a rule, the pairing their digestive powers. As a rule, the practice should not be begun until at least treatment of eczema, where other applications treatment of eczema, where other applications have failed to relieve. As a non-irritating, simple, cleansing soap, the well-known "Pears" is perhaps the best. For soft soaps potash is used instead of soda, the medicinal soft soap being composed of potash and pure olive oil. Soap of any kind is an antidote in poisoning by the mineral acids, and might be used in the absence of better remedies. Medicated soaps of various kinds are now employed in the treatment of disease, and soap is an ingredient in numerous plasters and liniments.

Refer to—Castile Soap—Plaster, &c. SODA.—This well-known and extensively used alkali is now manufactured almost en-

of sodium (see Salt). Soda is best known in the form of its carbonate and bicarbonate; the former being largely used domestically, the latter medicinally, and for some domestic pur-The carbonate of soda, or, as it is commonly known, "soda," being more irritant, and not so pleasant as the bicarbonate, the latter is generally employed in medicine, its antacid properties being similar to those of potash, but rather weaker. It is usually sold

in the form of white powder.

Bicarbonate of soda is largely used for making effervescing mixtures along with citric or tartaric acid, and as an alterative remedy in combination with small doses of rhubarb. Many dyspeptic persons take it habitually, as an antacid. The habitual use of soda internally, even in comparatively small quantity, cannot be too strongly condemned; it undoubtedly exerts a most debilitating effect upon the stomach, and also upon the system at large; many persons injure themselves by its continuous use. The usual dose, as an antacid, is from

ten to twenty grains in solution.

SODA-WATER, properly so called, is water containing about thirty grains of bicarbonate of soda to the pint, and strongly impregnated with carbonic acid gas; but a good deal is made without the addition of soda at all. When used simply as a drink, this omission is unimportant, but not so when it is required as an antacid. As a drink in febrile diseases, sodawater is often beneficial, and much relished, but should not be given in too great quantities at once, otherwise the gas may cause injurious and uncomfortable distension (see Effervescing). The soda-water prepared by manufacturers in syphon bottles (and domestically in gazogenes), is simply water impregnated with carbonic acid gas. As the syphon principle permits of a small or larger quantity of the beverage being drawn off at intervals when required, it is infinitely preferable for the sick room, to the wire corked soda-water bottle, which is always liable to accident.

Milk and soda-water is thus made: "Heat nearly to boiling a tea-cupful of milk, and dissolve in it a tea-spoonful of refined sugar; put it into a large tumbler, and pour over it two-thirds of a bottle of soda-water. This is an excellent mode of taking milk when the stomach is charged with acid, and consequently is apt to feel oppressed by milk alone.

CHLORINATED SODA SOLUTION is made by passing chlorine gas through a solution of carbonate of soda. It acts as a disinfectant and deodorant, and in the latter capacity it is used as a lotion for fœtid wounds, and as a gargle for unhealthy sores in the mouth and throat.

PHOSPHATE OF SODA, or tasteless salt, is a mild aperient in large, and a diuretic in small doses. It possesses the advantage of having so little taste that it can be given in soup; the dose as an aperient is half an ounce, as a diuretic one drachm.

SULPHATE OF SODA, or Glauber salt, was for long the most common aperient in use, but has been displaced by Epsom salt, which much resembles it in action; the dose of Glauber salt is from half an ounce to an ounce, dissolved in water. The addition of a few drops of dilute sulphuric acid diminishes the nauseous bitterness.

HYPOSULPHITE OF SODA is a preparation often used in parasitic diseases of the skin, it possesses all the virtues of sulphur in this respect without its irritating effects.

There are other preparations of soda admitted into the Pharmacopœia but those named are

the more important.

SOLANUM .— See DULCAMARA.

SOLUTION, is a disappearance of a solid body in a liquid menstruum or solvent. The colour of the liquid may be changed, but if perfect solution has taken place its transpar ency is unaltered. The solubility of bodies, such as salts of various kind, in liquids, varies greatly, generally it is increased by heat, but not always. The minute state of division in which a body exists when in solution, renders this form especially favourable for the development of medicinal action.

SOMNAMBULISM.—See SLEEP.

SORE-THROAT. QUINSY. - Sore-throat. is not only a concomitant of other affections, such as scarlet fever, croup, and diphtheria, but is one of the most frequent effects of common cold. Some persons are peculiarly liable to it. One of the simplest forms of throat affection from cold is relaxation of the uvula (see Palate). Perhaps on waking in the morning, the sensation of there being something in the throat which requires to be coughed up, is experienced, and along with this, tickling cough, from the uvula irritating the top of the windpipe. The condition is easily discovered by means of a looking-glass, the uvula appearing longer than usual. Frequently the affection passes off in the course of a few hours; if it does not, the use of an astringent gargle (see Gargle) will remove it.

Sore-throat may be simply inflammation of the mucous membrane of the throat; there is an uncomfortable feeling of roughness or rawness about the fauces and tonsils, with some pain in swallowing, probably accompanied with constitutional symptoms of cold, shivering, &c. This form of sore-throat may pass away in the course of a day or two without going further, or it may spread by extension into the airpassages, causing cough and catarrhal symptoms. It is this form of the affection which is often quickly relieved by the use of the sal prunelle balls, one or two being allowed gradually to dissolve in the mouth. It is generally best treated as a common cold (see Cold), with the addition of hot poultices up the angles of the jaws, and the use of hot gargles of simple warm

SOR

hot water, or from one of the numerous inhalers sold for the purpose. This treatment is better than the mustard-plaster and hartshorn and oil, resorted to by some; these, however, may be advantageously used at a later stage. The worst form of sore-throat, apart from what occurs in the course of scarlet fever and diphtheria, is that which is attended with ulceration and sloughing of the tonsils and fauces. This disease is, as a rule, the result of blood poisoning, and requires the most active treatment on the part of the medical man. Tonics, such as the perchloride of iron and quinine, require to be liberally administered, along with port wine and nourishing food, while antiseptic gargles, and the application of caustics and acids to the sloughing parts, are the best topical

The sore throats of croup and diphtheria are

described under the respective articles.

In quinsy, the inflammatory action is usually deeper than in the above mentioned forms of the disease, and affects the substance of the tonsils and surrounding tissues. It usually ends in the formation of abscess. Quinsy is sometimes a most distressing disease, the swelling caused both by the inflammation and by the matter, preventing the swallowing even of fluids, which, when the attempt is made, instead of passing down, regurgitate into the nose; in bad cases the breathing is impeded, and when this occurs the case must always be regarded seriously. The feeling attendant on quinsy is rather one of extreme distress than of acute pain, except when the attempt to swallow is made, at which time the pain is often greatly complained of as shooting up to the ears. In some cases the swelling extends down the neck, and completely under the jaws, affecting the tongue and the salivary glands. When this occurs, the flow of saliva is generally profuse, and in all cases there is formation of much stringy mucus about the tonsils. The voice is thick and husky, the tongue very much furred, and the breath offensive. Along with these local symptoms of quinsy, there is always more or less fever, and if the disease be long continued, considerable depression from the deprivation of nourishment. The treatment of quinsy in the first instance, is like that of common cold. If the symptoms are severe, and if the person has suffered from the disease previously, from four to six leeches may be placed under the jaws at the commencement of the attack, bran poultices, hot gargles, and steaming being used, with saline aperients Dr. Aitken recombined with guaiacum. commends the following:-Epsom salts, six drachms dissolved in eight ounces of water, to which is to be added a drachm and a half of powder of guaiacum, and two scruples of compound powder of tragacanth. One sixth part of this mixture may be given every four hours till neck, should be avoided, for there is no more

water or gruel, or inhaling steam from a jug of | the bowels are freely moved. Tincture of aconite, in doses of five minims, for an adult, repeated every three or four hours, quickly checks sore throat in its inflammatory stage, and may, if necessary, be given for four or five times in succession, but with care and watching, lest it depress the patient too much. Of course, in the case of the young, though no less valuable, the dose must be proportionally less. A young child might have a quarter of a minim every two or three hours. If the patient can swallow it, medicine in the effervescing form always gives relief, by clearing the mouth and throat; nothing answers better than the common soda effervescing powder, with the addition of six or eight grains of nitre, in full habits; or of a tea-spoonful of nitrous ether in weak constitutions, in each dose. The above measures may be continued until the matter, if it forms, discharges. When this occurs, the distress, which has perhaps been great, disappears at once, and convalescence, generally rapid, commences. The discharged matter, which is usually offensive, may flow out in a perceptible gush, and be spat from the mouth, or it may be unnoticed, and ooze away, passing down the throat. The hot poultices and gargles should be continued to the throat for twelve or eighteen hours after the discharge of the matter, after that time an acid or astringent gargle will generally be most serviceable and grateful, and the poultices may be replaced by flannel, and perhaps by stimulant liniments. At this period, too, it is necessary to support the patient's strength by tonics and stimulants; good nourishment in the shape of beef-tea, eggs, and milk should be given freely, and wine if necessary.

Blisters are sometimes used in quinsy; at the very commencement they may be useful— the author prefers the poultice. It has been found that powdered guaiac, given in half-drachm doses every six hours, and even in the more agreeable form of lozenge, at the commencement of quinsy, will frequently cut

short the disease.

A person who has suffered from, or is subject to, quinsy, should, after an attack has passed off, use every means of strengthening the throat; by this the attacks may be greatly prevented. Any of the astringent gargles may be used after quinsy, but none perhaps answers better, or is more accessible to the poor, than the decoction of oak-bark. This ought to be used night and morning for some weeks, and when its use is dropped, the person should acquire the habit of gargling the throat with cold water at the above times, as a reqular practice, and at the same time should, habitually, lave freely with cold water, or salt water (at first at least) all around the throat. In this way a tendency to quinsy may be Further, all unnecessary greatly overcome. muffling, either by fur or otherwise, about the

fertile source of sore-throat (see Fur). Men who are liable to attacks of sore-throat may diminish and even eradicate the tendency by allowing the beard to grow all round. Should the disease owe its origin to frequently recurring enlargement of the tonsils, the erring parts may be snipped off by the surgeon. Doubtless, many cases of simple sore-throat may be well managed domestically; but the contingencies of erysipelatous or croupy sorethroat, or of quinsy, which may suffocate, must not be lost sight of. The attendance of a medical man gives the only chance for life in such cases.

SPASM is painful contraction of the involuntary muscular fibres, in contradistinction to cramp (see Cramp). There is cramp in the legs, spasm in the stomach or bowels, in the latter case constituting colic. Spasm of the stomach, owing to the presence of indigestible substances, is not unfrequent. It is characterised by sudden agonising pain in the region of the stomach, which, like other spasmodic pains, is relieved by pressure; there may be attempts at vomiting, and perhaps eructation of wind. The severity of the pain, in this form of spasm, makes speedy relief important, and for this, the general remedies noticed under Colic should be resorted to; in addition, if the presence of irritating matters in the stomach is suspected, an emetic should be given at once; and after it has acted, or in place of it, if it is not given, an antacid, magnesia, or soda, or potash, in combination with a stimulant, sal volatile or brandy, and also opium. Five grains of rhubarb, five of carbonate of soda, a tea-spoonful of sal volatile, and from ten to fifteen or twenty drops of laudanum, will form a dose, which may be repeated after half an hour, or at a longer or shorter interval if requisite. These measures may be followed out, and give great relief, before a medical man can be procured, which he ought to be if the attack does not yield at once, for it is possible that other disorders may be mixed up with it. After the immediate attack has passed away, the digestive functions will require attention. - See Indigestion.

Spasm in the bowels has already been considered under article Colic. Spasm of the heart is included under Angina Pectoris. Spasm of the urinary passages may occur as the result of gravel or urinary irritation. Medicines which relieve spasms are termed anti-spasmodics; but in all cases of spasm, it should be remembered that the application of heat by the hot bath or by hot fomentation is one of the best, and certainly is the safest remedy.

SPASMODIC DISEASES .- See LOCK-

JAW-ST. VITUS' DANCE, &c.

SPATHULA (fig. 201) is a blunt flexible knife, used by the apothecary, and in the various medicinal manipulations. It is usually made of iron, but bone spathulas are also used for substances that act chemically on iron. The most convenient size of spathula for a domestic chest is one with the blade about three and a half inches, and the handle three inches in length.

SPECIFIC is a term applied to a medicine which is known from experience to cure a particular disease or set of symptoms, the action by which it does so being unexplained. Thus, quinine is specific in ague and other periodic diseases-specific, at least, within certain limits. That is, it is generally successful, though not always so. This applies to other

specifics so called.

SPECTACLES .- See VISION. SPECULUM. - A surgical ap-

Fig. 201.

354

pliance for conveying light into internal passages with the object of examining visually their condition. The most commonly used are those for the examination of the nose,

of the ear, and of the womb. SPEECH .- Distinctness of speech, or arti-

culation, is so intimately connected with the full command and free movement of the tongue, that indistinctness is often a valuable leading symptom in the investigation of disease, especially of a nervous character. The "thick" articulation of the drunkard is an instance of the affection of the tongue from nervous disorder. The same thing occurs in paralysis and other diseases of the brain; in some cases, the power of expression is absolutely lost, or words are used altogether in a wrong sense. To this affection, which has been proved to be associated with disease of one of the left frontal convolutions of the brain, the term

Aphasia has been given.

Stammering in the speech cannot be said to be a disease, being rather a functional disorder; this is evident from the fact, that, under certain circumstances, a habitual stammerer does not stammer, and that cases have occurred in which most inveterate stammering has been completely cured—as history tells us in the case of Demosthenes—by the exertion of the will. Moreover, stammering is often caused either by imitation in children, or by nervousness in both children and adults. nervousness is often the result of debility, and of weak constitution—a fact which should not be lost sight of; for if such be the case, every means of strengthening should be used (see Childhood, &c). At the same time, whilst the general health is sustained, much may be done by checking children, and making them speak

SPI

at all times slowly. Much pains with children, called their body (fig. 202 A, B, C-1); on the and much perseverance and self-command in bodies rests the main weight of the parts adults, is required in the efforts to overcome the defect in question, but there is the encouragement that it has been effected. When it can be done, a child should be placed under the care of a person experienced in the moral and intellectual training of children thus afficted. Surgical operations on the tonsils and uvula have been proposed, even by high authorities, and practised largely for the cure of stammering, but it is doubtful whether they are of any practical value. Articulation is sometimes indistinct from the tongue being "tied," that is, too much confined in its motions by its natural bridle or "frænum" (see Tongue). When this is discovered in early life it is very easily rectified .- See Childhood.

SPERMACETI is a species of concrete oil found in the head of the sperm whale. Its appearance is sufficiently well known. It was formerly used internally, on account of its supposed healing properties; and according to this idea the "spermaceti draught" was a favourite lying-in-room remedy. Spermaceti is now used only as an ingredient in the ointment of that name, and in the preparation of

blistering paper. - See Ointment

SPHINCTER MUSCLES are muscles the office of which is to close the apertures round which their fibres run, usually in a

SPINACH.—This well-known vegetable · is one of the most wholesome we possess, and less liable than most others to disagree. The leaves of either the common beet-root or of the mangel wurzel, when cooked like spinach, form a substitute in some respects even superior to the former vegetable. In some places the leaves of the common chenopodium, or "Good King Henry," are cooked and used as spinach.

SPINE, or SPINAL OF VERTEBRAL COLUMN, is a chain of twenty-four bones, called the Vertebræ (see Skeleton), so beautifully contrived and fitted to each other, that while they permit the most extensive motion of the trunk of the body, they at the same time preserve itin man at least-firm and erect, and guard the spinal cord or marrow (see Nerves) against all but the most violent injury. The spinal cord, thus guarded, is enclosed in the spinal canal, which is continued through the vertebral chain, from the head downwards, to and into the "sacrum" bone of the pelvis. The twenty-four vertebræ are divided by anatomists into seven "cervical" or neck vertebræ, twelve "dorsal" or back vertebræ, and five "lumbar" or loin vertebræ; the vertebræ belonging to these divisions being distinguished by worke resultante and while of guished by marks peculiar to each, while at acters in common. All the vertebræ, except column, when examined in a living, and the single one next the head, have what is especially a thin person. In addition to the

above them; they are also extensively subservient to the motions of the spine. The bodies form the inner portion of the spinal column (see Chest—Skeleton). Attached to the body, one on each side, are "laminæ," or projections (fig. A, B-2) which serve to enclose the

canal of the spinal cord; from the junction of these laminæ proceeds what is called the spine or process of the vetrebra (fig. A, B-3). These "spinous processes" projecting backward, give the peculiar character of the spinal

SPI SPI

parts above named, there are what are called the "transverse processes" (fig. A, C—4). These processes are chiefly concerned in affording attachments to the muscles, and in the dorsal vertebræ, in giving firmness and support to the ribs (see Ribs). There are various other distinctions common to the vertebræ, which it is unnecessary to enter into here. The bodies of the vertebræ are separated from each other by what are called "inter-vertebral cartilages" (fig. C—5). These cartilages are endowed with remarkable elasticity, yielding with every

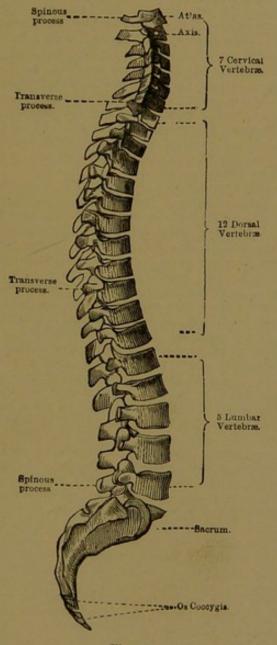

Fig. 203.

motion of the body, and breaking the effect of the shocks, which must have been communicated to the brain with every step, had the spinal column been all bone. Moreover, the variations in thickness of this component of the spinal column, contribute greatly to mould its different curves. In addition to being fitted to one another in a most beautiful manner, the vertebræ are firmly braced together by a series of ligaments of various kinds, which permit, but yet restrain motion. One of these ligaments is showr (fig. C—6), which runs down the bodies of the vertebræ externally; a similar ligament runs down the interior of the spinal canal, and

there are others (see Ribs).

The two upper cervical or neck vertebræ. which are more especially concerned in supporting the head, are peculiar. The uppermost one, named the "atlas" from its office (fig. 203). is little more than a ring of bone, with two lateral joint surfaces, on which the head moves in the performance of bowing motions. The second vertebra, called the axis (fig. 202 B), has, in addition to the ordinary body of a vertebra, a tooth-like process or projection (7), which, projecting upwards, rests within the bony ring of the first vertebra, and is kept in position by a strong "transverse" ligament, which, running across from one side of the ring of the first vertebra to the opposite, crosses the tooth-like process of the second vertebra, as at the dotted line. By this arrangement, as a moment's reflection will show, the side to side motion of the head is secured, which, in combination with the bowing motion exercised on the first or atlas vertebra, permits of that perfect capability of movement with which an all-wise Creator has endowed the noblest part of man. Should the above transverse ligament be broken by any chance, or by violence, as sometimes occurs in hanging, the tooth-like process, thus set at liberty, presses backwards upon the spinal cord, and instantaneously extinguishes life. It is the danger of this occurrence which the author adverts to in the article on Lifting Children.

The seventh or lowest cervical vertebra is remarkable for being more prominent than the others, and is by this easily recognisable in the living body. The dorsal vertebræ support the ribs; their spinous processes overlap one another like the tiles of a house (see *Ribs*), while the spines of the neck and loin vertebræ project outwards. The "lumbar" or loin vertebræ are the strongest in the body; the lowest of them rests upon the sacrum bone (see *Pelvis*); and, indeed, this bone is evidently a series of vertebræ consolidated to fulfil the

functions of their position.

The spinal column, constructed as above described, is not straight, but has various natural curves; the principal of these is one outwards, which increases the capacity of the chest, and one inwards at the small of the back, which assists in maintaining the equilibrium of the body, and also in supporting the contents of the abdomen (see *Chest*). The canal which runs through the entire spine is continuous with the cavity of the skull by the opening in the base of the head (see *Skull*), and the membranes and nerve substance of the

SPI

spinal cord are, through the above opening, continuous with the brain and its membranes (see Nervous System). The equilibrium of the spine, and therefore of the body generally, and the motions of the trunk, are effected by means of the various muscles attached in a longitudinal direction, chiefly to the posterior portions of the vertebræ.

DISEASES AND INJURIES OF THE SPINE .-Malformation .- The spine is liable to be the seat of a peculiar malformation at birth. This consists in the deficiency of the posterior por-tions of a certain number of the vertebræ, generally those of the loins, by which the membranes lining the interior of the spinal canal are left uncovered, except by the skin, both membranes and skin being distended into a livid-looking semi-transparent bag containing fluid. This peculiar malformation, to which the name "spina bifida" is given, generally ends fatally, but not so invariably as to justify the child being left to its fate without an attempt to save it. Surgeons have sometimes sought to relieve the complaint by cautious evacuations of the fluid in the tumour, and natural cure has occurred in consequence of the fluid being allowed to escape through an ulcerated opening; but the majority of medical men prefer to use only simple pressure of the tumour by means of a hollow pad and elastic bandage, or by a concave shield of pliable metal, which ought to be well padded, and every pre-caution taken to avoid irritation of the tender skin.

CONCUSSION OF THE SPINAL CORD is not unfrequent, as a consequence of heavy falls on the feet, especially on the heels, or of direct blows on the back. The usual symptoms are depression of the system, with loss of sensation and power of motion of the lower portions of the body, which either passes off in the course of a few days, or remains permanently, perhaps passing into disease. Occasionally, very acute pain in the lower limbs comes on. In cases of concussion of the spinal cord, the power of evacuating the urine is sometimes lost, in which case the use of the catheter will have to be resorted to by the surgeon, whose speedy presence is requisite in every case of the accident in question. The best thing that can be done until aid is procured, is to place the patient as carefully as possible in the most easy position, and to keep him perfectly quiet. Any symptoms of inflammation following such an injury will require the usual treatment of leeches, fomentations, poultices, &c., the bowels being acted on by purgatives given by the mouth or by injection. In patients confined to bed after injuries of the spine, bedsores are particularly to be guarded against; moreover, if sensation be much impaired, and the case be neglected, a sore may make considerable progress before it is discovered (see Bedsore). Even if a case of injury of the spine does well, it is apt to be tedious, and the lost | Exercise must be regular, but not carried to

powers are very slowly regained. Gentle friction of the body, the hand being moistened with a little warm olive oil, will often relieve any tendency to constipation of the bowels; while warm saline bathing, the douche, and gentle exercise of the limbs, are most beneficial remedies. Displacement of vertebræ can rarely take place without extreme violence, and, even then, fracture generally accompanies the accident, except in the case of the upper vertebræ of the neck, alluded to in the last article. Displacement is accompanied to a greater or less extent by injury to the spinal cord, and consequently by paralysis of the parts below: if the injury be high up, instant, or at least speedy, death is the result. In the event of any individual surviving, for a longer or shorter time, such an accident, all that others can do, till proper assistance is procured, will be to place the person in an easy posture, to administer stimuli with due caution, and to endeavour to preserve the proper heat of the paralysed parts, by friction and warm applica-tions, bearing in mind the cautions given under article Paralysis.

IRRITATION OF THE SPINE. -The spinal cord is liable to various diseases, such as inflammation, apoplexy of the cord, hardening, softening, &c., the latter being not an unfrequent concomitant of epilepsy. Pain in the part, and disorders of the functions of sensation and motion, and convulsive twitching, are the most usual symptoms. It is not possible that, beyond temporary soothing measures, such as bran poultices, &c., unprofessional interference in such cases can be usefully employed. In cases of severe pain, however, opiates may be cautiously given till a medical man sees the case. In some forms of fever, and of lock-jaw, the spine is affected. Functional disorder, and what is called "irritation of the spine, are extremely common, especially in females, and are often at the root of the obstinate palpitations, and many of the nervous and hysterical derangements of the sex. In such cases, if the back be carefully examined, a tender spot may generally be discovered somewhere in the upper part of the spine, and often there may be more than one tender spot lower down. In these situations, the spine may be simply tender on pressure, or pressure may cause pain to radiate, as it were, from the point round the body, or, in severe cases, may bring on hysterical symptoms at once, and fainting. Such cases are frequently overlooked. They are generally connected with debility of constitution, and require the welldirected treatment of a medical attendant. The use of the tepid or cold douche down the spine, followed by friction with a rough towel or flesh-brush, does much to relieve in such cases, often more than counter-irritation. The general health requires attention, and, generally, tonics, quinine and iron, are called for.

564

fatigue, which is injurious. In severe cases, | repeated small blisters applied over the spot

are frequently serviceable.

CURVATURE OF THE SPINE is far from being uncommon; it is of three varieties,-the angular curvature, lateral curvature, and curvature backwards. The first of these, angular curvature, or, to speak more correctly, angular deformity, is caused by disease (caries) of the bodies of some of the vertebræ themselves, which, permitting the bone to yield under the weight of the body, causes angular distortion at the seat of the affection. This disease, being sometimes at first accompanied with little pain, may be overlooked. It usually occurs in children, and in young people of delicate, and especially of scrofulous, constitution, and almost always follows an injury. Matter forms in connexion with the diseased bone, and, gravitating downwards, shows itself as abscess lower down, perhaps in the loins or groin. The first symptoms of this disease may be the child wincing or crying out from sudden pain in some movement of the spine. At the same time, a tender spot may be found in the back, and it will usually be discovered that an injury of some kind has been received here, often a blow, perhaps a strain; in other cases, the signs of the commencing disease are most obscure. The child is noticed to be stiff in its movements, to reach to the floor by resting one hand on the knee, or to walk in this position, or to bow for support upon the articles of furniture. In other cases, pain or uneasiness is complained of at a point far away from the disease; thus, sometimes, pain is felt in the chest, or in the stomach, or the child or even adult experiences a fulness after eating, or has a cough, with difficulty in breathing. All these symptoms disappear when the person affected is laid flat on the back, and by this the disease may be known. At other times, the child complains of pain in some part of the head or face, and at the same time of "stiff neck," Such complaints as the above, when persistent, should never be overlooked, for if the disease be taken in time, and strict rest enjoined, the hump-backs and other distressing results may be prevented, and the probability of the formation of abscesses and subsequent exhaustion lessened.

In the treatment much may be done by any intelligent person. Rest to the diseased part is the only method of doing good, and this is fortunately easily employed. It is necessary only to have a hard and even bed, to lay the child perfectly flat upon this, with a soft pillow, just large enough to fill up the hollow of the neck. In such a position the child should lie all day, as well as at night, if the case be severe. If the neck be the part affected, sand-bags should be placed round the head to keep

maintenance, means must be found for accomplishing it. In each particular case it will not be difficult to devise some plan, either by the use of splints or a broad band of cotton across the body, or by some other means to keep the

child quiet.

Of late, a plaster of Paris jacket has been applied to the body by Professor Sayre of New York, to give support to the diseased spine. In applying this, a thin jersey is first put on the child, which must fit closely without wrinkle. Underneath this, over the belly, is placed a folded handkerchief, to allow of the enlargement of the stomach after a meal. Next, the child, if small, is held up under the arms, and bandages three inches wide, made of "crinoline" muslin, into which plaster of Paris has been rubbed dry, are, after being soaked in water for a short time, applied first round the hips, and then gradually upwards round the body. After about three layers have been applied, the child is laid down till the jacket is dry. Usually, immediate relief is thus afforded, and the patient may be allowed to walk about, at least part of the day. These jackets may be worn for three months. In older children and in adults, an apparatus is constructed for raising them from the ground

during the application of the jacket.

Lateral curvature is not, like the above, the result of disease, but is the mechanical effect of repeated and continual malposition of the body. It is the form of spinal curvature from which nurse-girls who are put at too early an age to carry heavy children frequently suffer; it is also the affection met with among the pupils of injudiciously conducted female schools, where, from long standing, the habit of resting on one leg is engendered. It of course is most liable to occur in weakly subjects, but may take place in any young person who is compelled habitually to maintain the body, even without additional weight, in one position for any length of time (see Education-School), and, especially, if compelled to support a weight on, or to make undue exertion with, any one side of the body. The first thing, generally, which attracts attention in this form of curvature, is the appearance of the shoulder, which assumes the prominence popularly known as "growing out;" that is, it evidences the displacement from its symmetrical position, which it, in common with the ribs, experiences from the curvature of the spine. If the incipient curvature be neglected, as a matter of necessity, for the support of the head in an upright posture, a second curvature takes place in a direction opposite to the first, giving the spine the curves laterally in the form indicated (fig. 204), and distorting the body as represented. The causes of the above common deformity which it immovable. It will not be found easy to keep any one, especially a child, in such a position; but as perhaps life depends upon its carried, if exertion made, if injudicious school have been pointed out, naturally indicate that

SPR

or standing upright, has occasioned the deformity, it must be put a stop to at once. Such a course, with general tonic measures, rest of the body for a considerable portion of the day, equal exercise of the muscles connected with the upper extremities, and cold or tepid salt douche, with regular general exercise, will probably remove the tendency to curvature in incipient cases. The form of exercise most recommended is that of raising the body from the ground by the arms. For this purpose, a trapeze or horizontal bar trapeze is erected in the nursery,

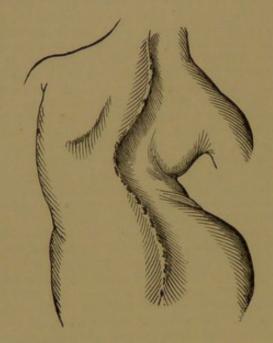

Fig. 204.

and daily practice enjoined. A trapeze is easily arranged, by suspending the side ropes from two hooks screwed into the top beam of the doorway, so that it may be removed at

pleasure.

In this deformity also, Sayre's jackets are most useful. If any one will lift a child affected with lateral curvature by the arm-pits, or watch the spine as the child hangs on to the top of the door, he will see it perceptibly straighten. In this position a jacket is applied, with the immediate result of increasing the height by half an inch to one inch. Together with this appliance, the exercise is essential. Other mechanical appliances are made for the eure of this deformity, all more or less com-plicated, and not to be attempted without

The curvature of the spine from before backwards occurs in weakly children, and constitutes the "stoop," or round-shoulder of the young. It is usually connected with general debility of constitution, which requires to be corrected by the ordinary means, the local deformity being should not be slighted; for should it be so, in relieved by the horizontal posture, by the some constitutions it may lay the foundation moderate use of a "back-board" when the of irremediable disease. Few, perhaps, have

management, such as too long continued sitting | patient is of sufficient age, and by the douche, friction, &c.

SPITTING OF BLOOD.—See HAMOR-

RHAGE-LUNGS, &C

SPLEEN, or MILT, is a body of variable size, which is situated in the left hypochondriac It is somewhat of a region (see Abdomen. It is somewhat of a spongy texture, and is capable of containing blood so largely, that its office in the economy, which even now is not yet clearly made out, has been supposed to be that of a blood reservoir. Disease of the spleen, especially enlargement, to which the organ is prone, is attended with an enormous increase in the number of white corpuscles of the blood, and a consequent loss of colour in the skin. The spleen is liable to become greatly enlarged in

cases of continued ague (see Ague).

SPLINT.—See FRACTURES.

SPONGE.—This well-known production of the animal kingdom is chiefly brought from Turkey and the Levant. The great uses of sponge in medical, and especially surgical matters, need not be dwelt on here; suffice it to remark, that sponges selected for such purposes should be free from the gritty particles which are often present in considerable quantity in inferior sponges. Burnt sponge was formerly the best remedy in cases of "bronchocele;" it is now known that its power of removing that disease depended on the presence of iodine.-See Iodine-Bronchocele, &c.

SPONGIO PILINE.—See POULTICE. DISEASES. — Diseases SPORADIC

which show themselves in individual cases, in contradistinction to epidemic and contagious

SPRAIN, or STRAIN.—This painful injury is the result of forcible overstretching of the ligaments (see Ligaments) of a joint. In their natural state, the ligaments are but slightly sensitive, but when overstretched they are acutely so. There are few, perhaps, who have not, in a greater or less degree, experienced the sickening pain of a sprained wrist or ankle, the two joints which are most frequently the seat of the injury; their liability arising from their immobility, compared with such a joint as the shoulder, which is more liable to dislocation. A sprain is attended with pain, which, perhaps, causes faintness or vomiting; when this passes off, it is found that the joint cannot be employed as usual, every attempt renewing the suffering; shortly, swelling comes on, followed by the heat and pain of inflammation. An injury of this kind, it need hardly be said,

566

either the power or the will to neglect a strain | cated, the discrimination of the accident in the at first; but very many are inclined to rebel against the rest and confinement necessary for its perfect cure, which ought to be effected before the joint is brought into active use. When a sprain has occurred, complete rest is the first necessity, accompanied by the soothing influences of fomentation and poultice, well and thoroughly made use of, from the very first; the early employment of the remedies doing much to alleviate the suffering. When, in the course of a few hours, inflammatory signs appear, six, eight, or ten leeches may be applied around the joint with advantage; and if the patient is of at all full habit, a few doses of purgative medicine should be given. To allay the pain, six or eight grains of Dover's powder, with a couple of grains of calomel, may be given at night, and followed in the morning by a Seidlitz powder, or some other purgative. After the joint has been soothed for some days by rest, with poultices, and fomentations, it will be advisable to change these applications for a bandage, which is to be kept wet with tepid water lightly applied to the injured part, which, if agreeable to the feelings of the patient, may be enveloped in some warm material. In such injuries, regulation of the temperature, the employment of heat or cold in the treatment, is always best ruled by the feelings of the patient. In some few cases, even from the beginning, cold lotions such as the lead or the spirit lotion, &c., are found most soothing, and then it is right to use them, at least as long as they prove agreeable; but more frequently warmth, with moisture, is preferred and preferable. The bandage, at first applied lightly, may gradually be used to exert more pressure, and to give more support, and the tepid applications may be exchanged for cold ones. As soon as it can be borne, friction night and merning, with the soap liniment, or soap and opium liniment, will be found agreeable and serviceable. Lastly, instead of the morning rubbing, the cold-water douche-the pump-is a common and very good form which may be used to give strength and tone. For the latter purpose, salt water or sea water is perhaps preferable to fresh: whatever is employed, it ought to be continued till the joint aches slightly, the after reaction being promoted by rubbing well with a towel. Should the swelling be long in subsiding, the application of a tight, and preferably an elastic bandage will hasten it. tincture of iodine may also be applied with benefit, or a blister may be used. Should it be essential for the person to move about, the use of an elastic bandage, such as a knee-cap or anklet, will be found to relieve the aching pain, and to support the joint. It is repeated, too great caution cannot be used in bringing a joint which has been sprained into use, and especially if the subject of the accident is at all of a scrofulous habit. Although the treatment of

first instance is sometimes by no means easy even to a surgeon; for when much swelling has supervened, and when every slight movement is torture to a patient, there is much difficulty in coming to a decision respecting the exact nature of the injury, and in deciding whether or not the sprain is complicated with more or less fracture or displacement. On this account it is desirable that these accidents should be early examined by a medical man; for it is too late, after weeks of poulticing, and bandaging, and rubbing, to find out that the so-called sprain is a fracture or dislocation. The swelling of a sprain is sometimes colourless, but more generally it is coloured from the effusion of blood under the skin; as this is gradually absorbed in the process of cure, the variation from "black and blue" to greenish and to

yellow, &c., takes place.

SPRUCE-BEER is a drink made from molasses or sugar fermented in water, and qualified by the extract from the spruce-fir; the saccharine, in fact, answering to the malt, and the spruce extract to the hop of common beer. Spruce-beer, when brisk in bottle, is not unpleasant, and is highly esteemed among some of the northern nations as a preventive of scurvy and other diseases. It probably owes any active properties to the presence of

turpentine.

SQUILL.—This drug is the produce of the Scilla or Squilla maritima, the bulb, which weighs generally from one to three or four pounds, being the part used. It is chiefly brought from the shores of the Mediterranean.

Squill is met with in the shops in the form of yellowish-white, semi-transparent pieces, made by slicing the bulb, and then drying the While perfectly dry, squill should be brittle; but from the readiness with which it attracts moisture, it is very often met with not

quite dry and rather tough.

Squill is popularly known and used as an expectorant medicine, and when properly employed it is invaluable; too often it is improperly given, and does mischief. It also acts as a diuretic, and may cause sickness or purging, in large doses. As an expectorant, squill is irritant and stimulant; it is therefore inadmissible when anything like inflammatory action or active irritation is going on in the bronchi or air-passages; in such cases, it aggravates cough, instead of relieving. As an expectorant, squill is most serviceable in cases of chronic bronchitis, especially in the aged, but indeed in all cases when the phlegm or mucus is tough, viscid, and separates with difficulty from the air-passages, causing long and severe paroxysms of cough before it can be expelled. Squill is most advantageously combined with ipecacuanha and opium; the latter drug does not seem to impair its expectorant properties, whilst it modifies its tendency to a sprain is perhaps neither difficult nor compli- irritate. From one to two drachms of pare-

STA SQU

in a wine-glassful of water, form a most excellent cough draught for night use; to which, if there is much debility, may be added one drachm of sal volatile. For diuretic purposes, squill is most generally given in powder, in from one to three grain doses, and usually in combination with mercury or digitalis. It is not adapted for domestic use with this view.

Squill vinegar is a frequently used preparation, made by macerating two and a half ounces of sliced squill root in a pint of distilled After straining and vinegar for a week. squeezing, an ounce and a half of proof spirit is added to ensure keeping, and the whole is filtered. Mixed with twice its quantity of honey, it forms the oxymel of squill, a favourite remedy for coughs, taken in doses of a tea-spoonful at a time. The syrup of squills is made by dissolving two and a half pounds of refined sugar in a pint of squill-vinegar by the aid of gentle heat. Its dose is from one to two drachms. Squill in powder is better purchased ready prepared; it requires to be very carefully secured in a well-stoppered bottle, and to be kept in a dry place, otherwise it quickly becomes useless from damp. The compound squill pill is often used, but in many cases irritates and increases cough instead of relieving. The author has found the expectorant pill, for which a prescription is given under article Pill, much more generally useful. In dropsy of the abdomen, a liniment composed of two parts of soap liniment, and one part of tincture of squills, rubbed into the skin to the extent of two drachms, twice or thrice in the twentyfour hours, is said to be serviceable.

Refer to—Expectorants.

SQUINT .- In the common form the eye is turned inward, both sometimes being affected. The affection usually begins between the second and sixth year. The cause lies in the fact, that the eye is too short for the lens, so that the rays of light are brought to a focus behind the retina, thus rendering the image of a near object blurred. In order to clear the sight, the lens, by the power of a muscle situated within the globe, is rendered more convex and so the rays are focussed more forward on to the When this power is exerted, the eyes are at the same time turned inwards. So that if a child be watched when examining anything intently, both eyes will be seen to converge. Next, from constantly employing the eyes, they are always turned inwards, and then the child finds that it manages easier by using one eye only, the other becoming permanently turned inward, so that the child uses but one eye. This can be proved by holding the hand before the "working" eye, when the squinting eye will move outwards to fix any chosen object, while the good or working eye will be found

The remedy first consists, when the child is young, in employing spectacles to correct the particularly the condition of the body as

goric, with twenty drops of tincture of squills | faulty vision; these should have convex lenses. After the use of these for some time, the muscles may regain power, and the glasses be used for close work or reading only. If the squint be permanent, the only way of curing the deformity is by dividing some of the muscles which move the globe. This operation requires great skill, and before the cure is complete has usually to be repeated once or twice.

There are other forms of squint, in which one eye is turned outwards or upwards, or in some other direction. This may arise in childhood, from convulsions during teething and from other causes, and in the adult from paralysis of the nerve supplying the muscles. In children, also, any form of squint may indicate the existence of grave disease of the brain; at the same time, however, there will be other

symptoms present.—See Eye-Vision.

STARVATION — deprivation of food, either total or partial. Under article Food, it has been pointed out that nourishment has, or ought to have, reference in its composition to two distinct ends-the nourishment of the bodily tissues, and the maintenance of animal temperature; moreover, in the above and other articles, Debility &c., it has been shown that to the latter, the support of the heat of the body, all other considerations must give way, for that fuel must be found, and if it be not furnished by periodical supplies of food, it will be taken from the component tissues of the body as long as these are capable of affording it. Every inspiration of the starving man, imparts to his blood the oxygen which is to be hurried to the consumption of his wasted and momentarily wasting tissues, every expiration gives out the carbonic acid and vapour, the smoke of the furnace within, which, like a steamer at sea run short of coal, is forced to consume its internal framework, in the effort to carry the hull to the haven of safety. The animal temperature must be maintained, or the person dies; hour by hour, tissue after tissue is used up for this end (see Animal Heat, &c.), and hour by hour the slow wasting of starvation goes on, till either relief comes in the shape of nourishment, or till the last available tissues have been exhausted, and the person dies, chiefly of cold. The fat, in the above process, goes first—its oxygen and hydrogen furnish the readiest fuel, the most easily burned material; the muscles next yield, and become soft and wasted; the nervous system falls before the pressure of necessity, and with it mental power; delirium ensues, and the vital power of resisting the ordinary pro-cesses of decay is lost.

A little consideration of the above will show that the process of starvation must be modified by various contingent circumstances, more

568

STA STA

so to speak-were the simple chemical changes incurred in maintaining heat only to be considered-would make the fattest man the best resistant to, and longest liver under, circumstances of starvation. This, however, will scarcely hold good; for there seems to be a power of endurance in the constitution-in the nervous system-of some, apparently a less susceptibility in the tissues to give way, that enables them to withstand a greater extent of privation than those who, according to the chemical theory alone, ought to last the longest. Again, external temperature influences greatly the effects of privation of food upon man. As shown under Cold and other articles, a man exposed to low temperature requires food, not only more abundantly, but of a more nutrient character, to preserve him in health, than an individual surrounded by and breathing a warm atmosphere: it follows, therefore, that a man exposed to cold, breathing a cold air, and especially if ill-clad, will be much more quickly starved to death than under the reverse circumstances. The above observations, especially if taken in connexion with the articles referred to, must make it clear that starvation is, in fact, the chemical union of the component particles of the tissues of the animal body, with the oxygen of the atmosphere carried through that body by the blood, and that the process is accelerated by whatever increases the amount of oxygen taken in by the lungs, whether it be cold, which gives a greater amount of oxygen in a given volume of the atmosphere, or exercise, which increases the rapidity of the respiratory process, and at the same time the oxidation of the tissues involved in the creation of force and performance of motion. - See Motion and Motor Change.

Happily, cases of starvation, from actual inability to procure food, are not frequent in this country; but medical men often witness an approach to a state of starvation in the progress of diseases, of fever especially, when patients lie for a great length of time without taking food. In such cases it occurs, that at last the patient is actually in danger of perishing from starvation, or rather from cold; the animal temperature begins to sink in consequence of the fuel tissues of the frame being all used up. Much, indeed, may be done to ward off this condition by the employment of strong broths and of gelatinous materials, which, by entering the blood, furnish materials for heating, and so protect the tissues; but, after a certain point, these are insufficient, and nothing but alcohol will do; nothing but spirit, with its readily combustible carbon and hydrogen, will give a chance of life to "him who is ready to perish" from the starvation of disease.

occurs under an inadequate supply. In the prior to death.

regards fat, &c. This internal supply of fuel, | first of these, Dr. Taylor says "there is pain at the stomach, relieved by pressure, the countenance is pale and cadaverous, the eyes wild and glistening, the breath hot, the mouth parched and dry, and the strength prostrated. After a time the body exhales a feetid odour, the mucous membranes at the outlets inflame, and life closes in delirium or convulsions."

In that gradual starvation produced by deficiency of food, the symptoms seem to be chiefly referable to depression of the nervous system, both the ordinary sensations and mental powers being in some respects blunted, although at the same time nervous irritability is present, and perhaps mental disorder. Dr. B. Holland, who has written on the subject, thus describes the condition resulting from continued deficiency of food: "The state is indicated by a sallow and dingy appearance of the skin, a soft and flabby feeling of the flesh, more or less emaciation, general debility, feebleness of the circulation, and swelling of the The stomach becomes disordered, the ankles. appetite defective, the digestion impaired. The individual feels languid and desponding, is soon fatigued, incapable of exertion, and has an irresistible disposition to fall asleep, from which he is apt to wake suddenly and in a The body is easily chilled, breathlessness and palpitation are experienced after slight exertion, attacks of giddiness, noise in the ears, and transient blindness, are common, and there is a peculiar forlorn and dejected aspect of countenance which is very characteristic." The above symptoms in a severe form occur in those who are so unfortunately placed as actually to want bread; in a minor form they are met with in those who for some reason accustom themselves to take too little nourishment, either as regards quantity or quality.

When total deprivation of food has extended even to twenty-four hours-when partial deprivation has gone so far as to produce pain at the stomach, and marked debility-return to a proper supply of nourishing food must be very gradual; the stomach and its sources of nervous stimulation partake of the general depression, and are no more fit for much exertion than the rest of the body; consequently, food must be given in small quantity, and in such a form as will most easily enter the circulation, such as broths along with a small proportion of alcoholic stimulant, very carefully given, and warmed. When partial starvation or continued deficiency of food has been in operation for some time, it lays the individual open to the attacks of epidemic and endemic disease, and, indeed, seems to be the exciting cause of disease, as observed in the "Irish fever" which followed the famine. This condition is apparently induced by the retention in the system Starvation has to be viewed as it takes place under total deprivation of food, and as it which is apt to supervene in the body even

STIMULANTS, ALCOHOLIC .-- Alcoholic stimulants are classed as Fermented and Distilled. The principal fermented liquors in use in this country are grape wines, domestic or home-made wines, liquors from the fermented juice of the apple or pear, eider and perry; and malt liquors from various grains, principally barley. To these might be added many more made and used among different nations according to the materials within their reach. Distilled liquors are not less numerous than the fermented; for man in every quarter of the globe has taxed his in-genuity, and generally with success, to find the means for their manufacture. The distilled liquors most commonly in use in Britain are brandy, whisky, gin, and rum, or preparations from these; but, like the fermented liquors, many other alcoholic products of distillation are used in different countries, according as their natural products offer facilities for their formation. Distilled liquors contain a much larger proportion of alcohol than those which are simply fermented; indeed, alcohol and water make up their constitution, the peculiar flavour of each depending chiefly on the essential oils, or ethers, derived from the materials from which they are distilled. As the special characters of the various alcoholic liquors in use are entered into under their separate articles, the following observations are directed to the action of alcoholic stimulants, generally, upon man, and to their employment by him-their "use and abuse." Pure alcohol itself (see Alcohol) is ranked among the narcotico-acrid poisons. If a large quantity of drink strong wines or spirits, derive little if strong spirit, or of alcohol, be quickly taken any stimulation from the weaker alcoholic into the stomach, it may cause immediate drinks; moreover, some conditions of the

death; indeed, many deaths from this cause are on record, and are frequently noticed in the public prints, as the result of foolish attempts to drink a large amount of strong liquor in a given time. If, in such cases, death does not immediately ensue, total insensibility generally supervenes, lasting for a longer or shorter time, either terminating in recovery, or passing into apoplectic stupor. In these cases of poisoning, the alcohol undoubtedly acts in the first instance by giving a shock to the nervous system through the stomach, similar to that which is produced by a blow on the pit of the stomach, or by a draught of cold water taken by a person in a state of heat and exhaustion. And, secondly, it acts upon the system generally, and especially upon the brain, in consequence of its absorption into the circulation. When this absorption occurs, it produces the phenomena observed in aggravated intoxication. To the article Intoxication the reader is referred for further information. There can be no question that in the form above stated, of concentrated or of pure alcohol, this agent acts as a poison; but to deduce from this, as is frequently done, the assumption, that under all forms, and in any dilutions or combinations, alcohol is a poison, is so illogical that it scarce deserves refutation.

Stimulants in Moderation.-The effect of a moderate quantity of diluted spirit, or of wine or malt liquor, is very different from that of poisonous irritant doses of alcohol, as different as the scorching flame is from gentle heat. When a moderate quantity of diluted alcoholic fluid, such as wine or malt liquor, is swallowed by a person in health, there generally ensues a feeling of warmth in and around the stomach, which is gradually diffused over the whole body, and is accompanied with slight increase of muscular and nervous energy, the functions generally being more actively performed, and the mental power increased. Such may be called the salutary effects of a moderate quantity of the stimulant. If the bounds of moderation be passed, the stimulation is increased, the pulse quickened, the cheek flushed, and the mind excited in excess; if the quantity of stimulant is still further increased, "a degree of torpor is induced, both mental and bodily"; perception is blunted, there is a general languor, giddiness, and obscurity of vision, incoherence of ideas, and incapability of exercising volition; the person is "drunk," and either sinks into a state of somnolence, half sleep, half stupor, or, by becoming sick and vomiting, recovers his senses quickly, sometimes at once. The amount of stimulation caused by alcoholic fluids varies, of course, according to the strength of the dose, but also in some degree according to the habits of the individual; for there is no question that those who habitually

STI STI

alcohol. In spasm, in fainting, in depressed states of the system, from fever or other such causes, persons often take with scarcely perceptible effect, doses of wine or spirit, which at other times would put them in a state of Although, however, intense intoxication. habit enables individuals to consume alcoholic drinks in greater quantity, and of greater strength, it by no means follows that this is done with impunity; if excess is habitually indulged in, the mucous membrane of the stomach becomes diseased, as the effect of a continued low state of inflammation, and even the other coats of the organ undergo changes of structure and indurations, while more important alterations take place in distant organs, notably in the various nerve centres, in the liver, in the heart and arteries, in the kidneys and in the alimentary canal; in fact, no organ of the body is exempt from the pernicious influence of the

poison.

Effect of Alcohol on the Blood.—There can be no doubt that most of the effects of alcoholic excitement, intoxication, and stupefaction depend upon absorption of the fluid into the blood, this having been found to take place very rapidly: that is to say, the alcohol passes as alcohol into the blood, and circulates as alcohol in the vital fluid, till it is got rid of by the usual processes of chemical change and of excretion. During this circulation, the most evident effects of alcohol are exerted on the nervous system; nor can this be matter of surprise, considering that after death from drinking spirit-gin-largely, there has been found within the brain "a quantity of limpid fluid distinctly impregnated with gin, both to the sense of smell and taste, and even to the test of inflammability." Moreover, there appears to be some special relation existing between the nerve tissues and alcohol.

With regard to the effect of alcohol upon the blood, it is unnecessary here to detail the various observations which have been made. One thing, however, appears to be well confirmed, which is, that the effect of intermixture of alcohol tends to keep up a venous condition (see Aeration-Blood) of the circulating fluid for a considerable time. According to Dr. Prout, after taking alcohol, the excretion of carbonic acid from the lungs is at first diminished; languor, yawning, and drowsiness being the consequence. There can be no doubt that the above effect of alcohol is in great measure owing to the elements of the spirit combining with oxygen in the body, and that its carbon and hydrogen are given off ultimately as car-bonic acid and water. "The oxygen which has accomplished this change must have been taken from the arterial blood; for we know of no channel, save the circulation of the blood, by which oxygen can penetrate into the in-terior of the body." The oxygen thus ab-

system modify greatly the stimulant power of | with the elements of alcohol, would under other circumstances have combined with the atoms of the muscular and other tissues, giving rise to development of muscular force, consequently, in this way, muscular power is rather diminished; there is languor. This statement may seem at variance with a former one, that alcoholic stimulants give rise to increased muscular energy. Both statements are true, it is circumstances only which alter the effects. This is proved by practical experience, thus: if an individual in good health, making active exertion in the open air, especially if it be cold, or, on the other hand, if he be perspiring freely in warm air, and consumes in either case a moderate quantity of alcoholic fluid, he experiences the excitant effect; that is to say, the special stimulation of the alcohol upon the nervous system is felt; but the activity of both the respiratory and circulating systems, and the consequent increased supply of oxygen throughout the body generally, counteract the chemical effect of the spirit elements on the blood, they do not permit the venous state above mentioned to be formed. On the other hand, if a person keeping quiet in the house, especially if the air be warm and ventilation deficient, takes but a small proportion of alcoholic fluid, how quickly does he become languid, sleepy, and unfit for exertion, either mental or bodily! In this case, even without alcohol, the circumstances are such as to favour carbonic accumulation in the blood, and with it muscular inactivity and mental hebetude; it is, therefore, much more likely that these symptoms will occur when the alcoholic influence is added. A clear understanding of the foregoing remarks will explain much of the usual effect of alcoholic fluid, observed either in one's own person, or in that of others. It is only necessary to keep in mind, that the first effects are those of special excitement of the nervous system, giving increased though temporary activity through that system to every function of the living body; but that this special excitement is apt to be interfered with by the chemical effect exerted by the elements of the spirit on the blood as above described, more or less, according as circumstances facilitate or not the introduction of oxygen into the vital fluid, and its transmission throughout the frame. attention may be drawn, as it has in other articles in this work, to the importance of this substitution of the alcoholic elements for those of the bodily tissues in exhausted states of the frame, as in fever, &c. (see Starvation), the animal temperature being maintained by the artificial "alcoholic fuel," so to speak, when the ordinary tissues are exhausted.

The less palpable effects exerted by alcohol. upon men who work out of doors, than upon those whose employment is of a more confining nature, probably influences in some degree the stracted from the arterial blood to combine statistics of its consumption, and for this

STI

reason Dr. Guy states "that men who work | climate; and a most remarkable diminution in out of doors are more addicted to drinking than men who are employed within doors." If the palpable general effects are not so great in the former as in the latter, it, however, by no means holds good that excess may not give rise to an equal amount of local injury to the digestive and other organs.

Effect of Alcohol on the Organs of Digestion. The effect of alcoholic fluids upon the digestive organs and their functions has been the subject of much discussion and observation. In the case of St. Martin (see Digestion), Dr. Beaumont observed that even under the stimulation of ordinary food, but in greatly increased intensity if extra stimuli were taken, "the colour of the lining membrane of the stomach changed from a pale pink to a deep red." The actual effects of alcohol upon the digestive functions probably vary according to the amount and strength of the fluid taken, and upon the habits of the individual. That immoderate doses of strong wine or spirit interfere with digestion is, perhaps, correct; but that the moderate employment of alcoholic beverages with their meals, is often beneficial in enabling many persons to digest their food properly, is perfectly certain, and in accordance with the experience of medical men generally (see Digestion). The requirement may not, perhaps, be that of a person in the full vigour of health, and placed in healthy circumstances; it is, however, one which we find closely linked with the every-day life and constitution of a large number of persons in this civilised, artificial, community of Britain; such being the case, it is folly to ignore its existence.

At the same time, although the admissibility, and in some cases the propriety of a moderate allowance of alcoholic beverage, is contended for as necessary to perfect digestion under the circumstances named, it ought never to be forgotten that the immoderate use, the abuse of these stimuli, exerts the most serious effects upon organs with which they come so immediately in contact, the effects, moreover, being aggravated rather by the concentration of the spirit in the fluid usually drunk, than by its gross amount. Ardent spirits, drunk regularly to excess, exemplify the baneful influence most strikingly; the most usual consequences being, as already mentioned, a low degree of inflammation of the stomach, followed by thickening of its coats, and great impairment of its digestive power; and along with these, a disrelish for food and a morbid condition of the system known as drunkard's The close connexion of the liver with the stomach, both in situation, function, and vascular communication, renders it liable to be affected equally with the latter organ, and, in fact, the liver-affection of drunkards, the "gin-drinker's liver" (see Liver), is matter of popular information. This affection, moreover, is liable to be increased by a warm persons who have once laboured under an

the occurrence and fatality of liver complaints among the troops in India has been proved, statistically, to follow the abridgment of the allowance of spirits. Again, disease of the kidneys is a frequent consequence of the abuse of alcoholic fluids, and with the kidneys the other urinary organs are usually implicated. The lungs, the heart, the arterial system generally, are not exempt from the evil influence. Sir James Clark remarks, that "the abuse of spirituous liquors among the lower classes in this country is productive of tubercular disease—consumption—to an extent far beyond what is usually imagined," and that not only is the tainted constitution acquired by the individual, but that it is transmitted with great certainty to the offspring. Not only, however, is the physical effect transmitted, but the mental and moral taint are so likewise; too often there is an inborn love of intemperance, which, if indulged, adds immensely increased power to the physical evil—the drunken child of a drunken parent is generally much the shortest lived of the two. Moreover, the child of a drunkard is very apt to suffer mentally as well as bodily from the vice of the

Alcoholism and Insanity .- If the abuse of alcoholic liquors is injurious to the body, equally so is it to the manifestations and tendencies of the mind. Passing over the milder forms of excitement, we find, under the influence of excess, that faculty which keeps the will subordinate to the judgment weakened, or for the time destroyed; there is produced, in fact, a state of temporary insanity; and so close is the resemblance, that, as remarked by Dr. Robinson, there is simulated "the raving delirium, the maudlin sensibility and groundless apprehensions of the melancholic, the bloodthirstiness of the homicidal, the cunning desperation of the suicidal maniac; the prostration of the moral feelings; the inflation of the mind with delusions as to dignity, wealth, and knowledge; and finally, in the last state of intoxication, may be noticed, the gradual disappearance of every manifestation of reason, until the vacant gaze and drivelling smile have for the moment stamped upon the countenance the fearful inanity of idiocy. Since, then, a single dose of an intoxicating substance possesses the power of temporarily disordering the intellect, perverting the moral sentiments, and even wholly suppressing the operations of the mind, it is not wonderful that the continued use of such agents should frequently induce permanent mental derangement. Continuance in that habit may occasion this effect either directly or indirectly. We possess no data by which to estimate its influence in predisposing to insanity; we can,

STI STI

attack of mania, are ever afterwards more liable | affected with the species of monomania to to excitement, and less capable of preserving their equilibrium whilst exposed to disturbing influences, than those which have never deviated from a healthy state. We have seen that each fit of intoxication is, in fact, a temporary attack of insanity. We notice in everyday life how frequently the intellects of habitual drunkards become impaired, and knowing these things, we cannot avoid the conclusion, that an excessive use of intoxicating substances will in time so enfeeble the mind as to render it incapable of bearing ordinary sources of disturbance, and thus act as a powerful predisposing cause of insanity.

Dr. Joseph Williams gives the following table as the proportion of cases of insanity caused by the "abuse of spirits," admitted

into various asylums :-

			Total admis- sions.	Proportion caused by intemper- ance.
Charenton, .			855	134
Bicetre and Salpêtrière, .			2012	414
Bordeaux, .			156	20
Turin,			548	93
Gard,		1110	209	4
United States,			551	146
Palermo, .			189	9
Caen,			60	16
Dundee, .			14	4
M. Parchappe,			167	46
M. Bottex,			288	54
			5049	940

Dr. Robinson has drawn up a table, showing the proportion which intemperance bears to other causes of insanity, as exhibited in the returns from ninety-eight asylums in England and Wales. From the table we find that intemperance constitutes the immediate cause of one-seventh of the cases contained in the English asylums. Dr. Robinson, however, considers the proportion estimated much below the real amount, which is marked by various contingent circumstances. Accordingly, another table is given, drawn up from the returns of twenty-five asylums. From the second table we learn that one-fourth of the cases of insanity admitted are referred to intemperance alone, and to it, in conjunction with vice and sensuality, nearly one-third. It is further remarked, that many of those cases entered in the tables as unknown might be added to the

Were it needful, much additional evidence

on this point might be adduced.

Dipsomania .- There is no doubt, when habits of intemperance have reached a certain point, that the unfortunate victim becomes

which the term dipsomania has been applied. All writers on insanity describe it as a morbid craving for drink, which generally occurs at intervals, in which persons are seized with an irresistible propensity to drink to excess, although conscious at the time of their misconduct, but are unable to control themselves. Change of scene, restraint, and moral management, may effect a cure, but relapses are very likely to occur.

Alcohol and Crime: their Connexion. - It is under the temporary insane excitement produced by abuse of alcoholic liquor, whether purposely or accidentally, that a large proportion of the petty, and many of the most fearful crimes are perpetrated by man. M. Quetelet, in his chapter on the Development of the Propensity to Crime, assigns to the excessive use of intoxicating drinks the increase of crimes against property and person in certain pro-vinces of France. But we need not go out of Britain to find evidences of the effect of the insane excitement of drink in stimulating to crime; every newspaper, every prison report, tells the same tale; but perhaps the most conclusive evidence on this subject-indeed, we need no other-is the collection of opinions expressed by many of our eminent judges on this head, who have publicly from the Bench declared as their deliberate opinion, individually, that drinking alone gave origin to by far the largest proportion of crimes that came before them for trial-crimes from which the perpetrators would have shrunk, but for the short-lived insanity of intoxication.

Forms of Alcoholic Stimuli. - In considering the effect of alcoholic stimuli upon the system, due attention must always be given to the form in which they are taken. It is certain that ardent spirits-which, it may be remarked, should never be taken but as medicine-will exert a much more narcotic effect upon the nervous system, both locally in the stomach and generally, than the fermented liquors. It is well ascertained that a certain amount of wine exerts less intoxicating effect than the spirit in the same quantity of wine would do, were it separated by distillation and then diluted with water; and, moreover, that "different wines, although containing the same absolute proportion of spirit, will be found to vary very considerably in their intoxi-

cating powers.

There is no doubt that the lighter wines of the continent, those which contain no more spirit than is yielded by the simple fermentation of the grape juice, are quite the most wholesome, and that the action upon the system of those stronger wines, such as port and sherry, to which spirit has been added, must in some degree resemble the action of distilled or ardent spirits-at least, it has been proved that spirit artificially added to a wine partly insane, at least so much as to become is not united with it in the same manner as

STI

of fermentation, which does not yield above eight per cent. In considering the action of the various kinds of wine, however, the influence of habit must not be lost sight of; for many who are accustomed to the use of the strong, dry wines, cannot change to the lighter and more acescent kind, such as the hocks and clarets, without risk of inducing disordered digestion, a tendency to gravel, and other similar complaints, which, however, does not prevail among those who regularly make use of these wines. The brisk sparkling wines affect the nervous system so rapidly, considering their small amount of spirit, that their effects have been in part attributed to the carbonic acid they contain, which renders their absorption more speedy, and their influence on the nerve centres more direct. Home-made wines are apt to disagree with many persons, in consequence of the amount of sugar they often contain, or from the presence of lactic and other acids. Many of the remarks on wine apply also to the malt liquors, to the articles on which the reader is referred for further information (see Beer-Porter). Attention has hitherto been confined to the actions of alcohol, and of its various preparations, on the system, without reference to external circumstances, and at the same time occasion has been taken to advert to the serious physical and mental evils which inevitably result from the abuse of the agent. It will now be pointed out under what external conditions and circumstances, and under what peculiar conditions of mind and body, the use of alcoholic stimulants is either serviceable or necessary.

Is Alcohol Necessary?—If the question be asked, whether alcoholic liquors form a necessary part of the sustenance of healthy men generally, it must be answered, certainly not; that they are not necessary is proved, not only by the history of many nations, both ancient and modern, but by the results of the total abstinence movement: numbers are well and active in mind and body who never touch an alcoholic fluid. But what is a rule for some, or even for many, is by no means universal, and the experience of medical men generally, including those whose names stand highest at the present time—and they, it is presumed, are the most proper judges of the case—goes to prove, that there are numbers under the present artificial positions and modes of life, in this country at least, who cannot eschew the use of alcoholic stimuli without the risk, or rather the certainty, of detriment to health. Probably there are few medical men who cannot reckon among their patients-the author certainly can-individuals who have seriously injured themselves by the unadvised adoption of, and rigid adherence to, total abstinence principles. In such cases, the abstinence principles. In such cases, the nervous system, the digestive organs, and nervous system, the digestive organs, and cases occur, in which persons are compelled bodily and mental vigour, gradually become by circumstances to make continued exertions,

the spirit formed in it by the natural process | weakened, and there is often great depression of spirits. It may be said that persons who require alcoholic stimulants to maintain their digestive and other powers, are not in a proper healthy condition, and possibly they are not; but they are in the state of numbers in this country at the present time-a state fostered by circumstances, by the debilitating effects of the deficient sanitary arrangements of our large cities, by the wear and tear of mental anxiety and overwork, by the struggle in the perpetual battle of life, in which most are engaged in the throng of competition—these influences and others, including perhaps deficient natural constitution, render the moderate employment of alcoholic stimulants often requisite for the preservation of the energies on which their livelihood and usefulness depend. The requirement may be artificial, but we cannot change the circumstances; at least, not quickly; and until they are changed, it is folly, and worse than folly, to refuse a beneficent provision. There can be no question-indeed, it has been proved-that the depressing influences of deficient sanitary arrangements are among the most powerful incentives to intemperance among the workmen of our large towns, who, unfortunately, instead of wholesome moderation, too often indulge in excesses, especially in the use of spirits, which entail upon them many diseases. Better is it, certainly, that a man should risk health, even if that should suffer by his becoming a total abstainer, rather than ruin both body and soul by intemperance; but better still, that he should be exposed to neither risk, by being placed beyond the influences of depression, and within the influence of those natural stimuli (see Excitement), which our Creator has made necessary to our healthful existence in this world.

There are accidental circumstances in which all may at times be placed, in which the question arises, whether the assistance of alcoholic stimulation may be had recourse to with benefit or not. Exhaustion by long exertion in extreme of heat is one of these-the skin acting powerfully, discharges immense quantities of fluid, which must be compensated for. As long as the energies remain unimpaired, the compensation should be made by unstimulating drinks; by these, the strength is in every way better preserved; but when the energies flag, if exertion must still be made, a small quantity of diluted alcoholic stimulant may be taken with advantage. Under continued exposure to the effects of intense cold, especially if symptoms of torpidity supervene, the use of undiluted spirit may save, and has saved, many a life. In such cases, however, the caution must not be forgot, that the spirit should not be had recourse to early, and not, if possible, till it is used to stimulate to the last effort to gain the place of safety. Other

STI

involving loss of the usual rest; in these, after | the vocations of life, and by the great absence a time, the moderate use of the stimulant is of provision for, and relish of, the harmless

highly beneficial.

The necessity for the use of alcoholic stimuli, under the various external circumstances which tend to depress or exhaust the bodily powers, is of course immensely modified by the constitution, hereditary or acquired, of the individual. Some individuals there are, who from birth upwards are always below par, who have no power of endurance. Such persons generally require stimulants habitually to enable them to keep up to life's duties at all, still more so, when exposed to conditions of depression or exhaustion.

The above have been considered irrespective of those cases in which long habit has rendered the use of alcoholic stimulants an acquired necessity, especially if excess has debilitated the constitution. There are, undoubtedly, many individuals of strong constitution and nervous power, who can at once lay aside the use of these stimulants without inconvenience; but there are others who quickly become depressed. This is especially the case if other depressing effects, such as an accident and its necessary pains and confinement, are in operation. Such cases, in hospital practice, are very common; the continued allowance of the alcoholic stimulant is necessary, not only for the reparation of the accident, such as a fracture, but even for the continuance of the functions of life.

The question of the propriety and benefit of alcoholic stimulation in the treatment of certain phases of disease is one which it is matter of surprise could ever be mooted in the face of the approval and enunciation of the highest authorities, past and present, in practical medicine—ignorance alone could ever have raised the doubt. As the use of alcoholic stimuli is noticed under the heads of the various diseases, it is unnecessary to enter upon

its consideration again.

Few subjects, perhaps, included in the present work, are more important than that which has just been discussed, briefly of necessity, but much too briefly to do it justice. The evils of intemperance in Britain are so deplorable, that every man who wishes well to his kind or to his country must earnestly desire to see them checked; and, when it is looked upon as a matter of temporary benefit and expediency, must regard the total abstinence movement as one fraught with immense benefit to numbers; at the same time, medical men, especially, are aware that its uncompromising dogmas are the source of evil as well as good; evil, not to individuals only, but to the community generally, by turning the attention from the great incentives to the abuse of alcoholic stimuli, the depressing influences to which all classes of the community are exposed, by deficient sanitary arrangements,

of provision for, and relish of, the harmless excitements. Excitement of some kind is necessary, and if men, uneducated, or partly educated, have not the natural stimuli of the light and air of heaven, and proper relaxation afforded them, if they have no mental stimulus presented to them as a change after the physical toils of the day, no object of interest with which to fill the vacuity of the mind, and no attraction, save that of a squalid home, most surely will they, in numberless instances, when they can, seek the artificial stimulus of alcohol, and the comfortable fire and comparative cleanliness of the tap-room. such reasons all right-minded persons must welcome the attempt now being made to substitute for the gin-palace and the beer shop, the coffee-palace or restaurant, replete with social comforts, where the working-man may obtain, at a small cost, the necessities of life, without being allured into vice and folly through the agency of drink.

STIMULANTS, GENERAL. - See

EXCITEMENT and EXCITANTS.

STINGS of BEES, WASPS, HORNETS, &c., are punctured, and at the same time poisoned wounds, the intense pain being caused by the acrid poisonous fluid, which is pressed through the tube of the sting at the moment it is inserted in the skin. The poison is contained in a bag at the base of the sting, and the latter is barbed on one side. After the first acute pain of a sting subsides, a severe tingling smarting remains, and the part begins to swell. The amount of swelling varies greatly in different persons; in some it is trifling, in others it is very great, and in a few individuals it extends over the entire body, whilst at the same time there is much sick faintness, &c., requiring the administration of sal volatile and other stimulants. If the sting has been inflicted about the throat, the swelling has been known to prove fatal. The domestic local applications to stings are very numerous. Oil is frequently applied, and gives relief; but alkaline preparations certainly appear to be most serviceable; the popular remedy of the "blue bag" is probably useful for this reason; soda is also employed; but ammonia or hartshorn, the weaker solution, is the best form of alkaline application; it may be used alone or mingled with However, before any remedy is used, care should be taken to ascertain that the sting does not remain in the wound, if it does, it must be extracted by tweezers or by squeezing. If the pain and swelling remain severe, the common lead lotion, or a tepid poultice, will relieve.—See Jelly-Fish—Wounds, Poisoned.

attention from the great incentives to the abuse of alcoholic stimuli, the depressing influences to which all classes of the community are exposed, by deficient sanitary arrangements, by the exhausting effects of competition in

STO

relieved by pressure.—See Side, Pain in.

STOMACH.—The form and position of this important organ have been sufficiently indicated in articles Alimentary Canal and Abdomen: to these the reader is referred, and at the same time to article Digestion for an account of the latter process. The stomach is made up of three different coats or layers, the outer one, being the "peritoneal" coat, which covers the contents of the abdomen generally (see Peritoneum). The middle layer is the muscular coat by which the churning and wavy motions of the stomach are performed during the process of digestion. The innermost layer is the mucous coat, which is con-tinuous with the lining of the gullet and mouth upwards, and with that of the intestines downwards. In the stomach, the mucous coat is thrown into folds or wrinkles, called in anatomical language "rugæ," which extend longi-tudinally along the organ. When at rest, the lining membrane of the stomach is of a pale pink colour, but whenever its peculiar functions are called into exercise by the presence of food, it becomes much reddened by the increased determination of blood towards it.

The chief disorders to which the stomach is liable have already been entered into under the head of Indigestion; and such affections as cancer, perforating ulcer, spasm, &c., have been sufficiently considered in the general articles on these subjects. Blows over the region of the stomach are often serious, and may be immediately fatal. - See Blows-Shock,

GASTRITIS. - Inflammation of the stomach is not a common disease in its acute form, and when it does occur, is usually the result of irritant agents, such as strong spirits, or poisons applied directly to the stomach itself. Fever, thirst, severe pain at the pit of the stomach, increased by pressure or by the pres-ence of food, vomiting, especially after food has been taken, hiccup, red tongue, followed by extreme depression of the system, are the usual symptoms. Leeches and poultices to the pit of the stomach-cold, sometimes iced water, or barley or gum water, to allay thirst, and injections, either aperient or opiate-will be the most useful remedies; but the disease is so serious in its nature, and so rapid in its progress, that it should at once, if possible, be put under regular medical treatment. - See Alimentary Canal-Poison.

STOMACH-PUMP.—See PUMP.

STONE.—See GALL-STONE—URINE, &C. STONE-FRUIT, generally speaking, is less digestible when eaten raw than the other descriptions of fruit; to healthy persons, however, when ripe, and consumed in moderation, it is not injurious. Plums have acquired a character for causing disorder and diarrhoea, which they scarcely deserve. Undoubtedly, poverish the blood. A course of iron tonics, with some persons they disagree, and, indeed, with a good supply of animal food, and, if need

attributed to affection of the diaphragm. It is | with all, if they are eaten immoderately or in bad condition; but that they, or fruits generally, are the cause of the regular autumnal or British cholera, is a fallacy which has been established in the popular mind, in consequence of the season at which plums are ripe, the "plum season" being coincident with that at which people in this country, who have been exposed to the effects of the summer's heat, are most liable to that outbreak of diarrhoea best known in this country by the name of British, or summer cholera. The fallacy is principally mischievous, because it closes the eyes of people generally to the real causes of a disease, which, with more or less severity, so regularly makes its appearance in this country, and thus prevents their adopting those measures of precaution which would insure them against its attacks.

Refer to—Biliary Disorder, &c. STONE POCK—a name applied to hard

pimples.

STOOLS. — The evacuations from the bowels always afford important indications of the state of the health; they are, therefore, generally watched by medical men in cases of illness, and as a general rule should be saved

for their inspection.

In infancy, the discharges from the bowels are generally lighter coloured than they are as life advances; this, perhaps, being partly, but not altogether, due to the usual milk nourishment, which, even in adults, if taken largely, tends to give a lighter colour to the stools. In infancy, moreover, the appearance of the natural evacuations is liable to vary greatly in colour, and, especially when there is disorder, acidity, &c., to assume a green tinge, either as directly passed from the bowels, or soon after exposure to the air, even if the motion has, in the first instance, been of a yellow or orange hue. The nature of these green evacuations is scarcely satisfactorily explained; they generally, however, follow attacks of pain, with superabundant acid. As children get beyond infant life, the stools, particularly in those with light hair and complexion, are apt to become either entirely or partially of a clay colour, evidently from deficiency of bile. In such cases, it is not uncommon for grey powder or calomel to be given, with a view of increasing the flow of bile, which these medicines certainly do, and for a few days the motions are im-proved in appearance, but only for a few days; they soon become as unhealthy looking as ever, the benefit derived from the mercurials being only fallacious, or worse—causing injury rather than benefit. The true cause of these claycoloured stools, in most instances, is the in-ability of the blood to furnish an adequate supply of the healthy bile; consequently, to stimulate the liver to secrete an increased quantity under these circumstances, is to imSTO STO

health, permanently and beneficially. that an occasional dose of grey powder may not be useful, but it is not the remedy. In adult tife, the stools become clay-coloured, or chalky, from a different cause or causes, the most usual being obstruction to the flow of bile (see Jaundice), but also from deficient secretion consequent upon disease of the liver, such as occurs in drunkards. The stools may vary in consistence, being either too hard or too liquid; the former is the case in persons of costive habit, in whom the fæcal contents pass so slowly through the bowels, that their liquid components are too much absorbed (see Constipation). In the latter case, the too liquid condition of the motions is associated, generally, with tendency to diarrhoea (see Diarrhoea). The form of the motions may, by its peculiarity, convey important information: thus, in an enlarged state of the "prostate" gland at the neck of the male bladder, they assume a flattened form, or they may be diminished in size by narrowing of the gut (see Stricture). The general bulk of the stools must of course depend much upon the amount and quality of the food; inattention to this fact sometimes misleads. It is not uncommon for persons to imagine that, so that the bowels are regularly moved once a day, they must be in a perfectly free state, forgetting, that though they may discharge a portion of their contents, they do not necessarily discharge all; and such is really the case. In old people especially, enormous accumulations of fæcal matter are apt to take place, whilst the person is under the impression that, because there is a daily stool, the bowels are periodically fully relieved. On the other hand, again, the popular impression seems to be that the bowels fulfil no other office than that of a passage for the food refuse. This fallacy has already been alluded to under articles Alimentary Canal-Digestion, &c.

Various articles of food, such as the seeds and skins of fruits, will, as mentioned above, affect the appearance of the stools, and medicines do so more especially; iron, in particular, forms an inky black with the colouring matter of the bile, and as persons are often unnecessarily alarmed at the appearance, when iron is pre-scribed, the circumstance should be made known. Rhubarb, senna, &c., in some degree impart their colour to the stools. Mercurials modify them, causing an olive or deep-green appearance, which may be kept up for a length of time, if mercurials are too continuously given. Persons are thus deceived at times, and under the idea that the motions do not become healthy, go on purging with the mercurials, which are themselves the cause of the unhealthy appearance. Other purgatives may have the same effect in a lesser degree. In unhealthy states of the system, and especi-

be, a little wine or malt liquor, is much more | much more offensive than in health. When such tikely to bring the motions to the colour of is the case, the bowels generally require purg-Not ing. The stools may contain blood. If this comes from the stomach, or high up in the intestinal canal, it is usually black and pitchy in appearance, and often highly offensive; stools of this kind often occur after severe bleeding at the nose when the blood has been swallowed. The blood may be fresh and clotted, and either dark or florid (see Piles). In some cases the stools contain large quantities of mucus, simple or gelatinous-looking, or they contain matter. In all such cases the motions should be kept for inspection, and a medical man sent for as soon as possible. In Asiatic Cholera, and sometimes in its British simulator, the stools resemble thin gruel or "rice-water." Straining at stool may arise simply from costiveness, and therefore is probably habitual; it is, moreover, one of the chief evils of costiveness, for not only is it apt to induce rupture in the predisposed, but, in the aged, it may bring on head attacks. Straining, or, as it is called medically, "tenesmus," occurs as a consequence of an inflamed and swollen condition of the lining membrane of the rectum (see Rectum), such as occurs in diarrhœa, &c.; there is the sensation as if the bowel was still unrelieved, and constant instinctive efforts are made to free it; they only increase the evil, and should, by an effort of the will, be desisted from, if possible. In children, straining and sitting too long when the bowels are evacuated may cause falling down of the bowel. The custom should be corrected. - See Prolapsus-Rectum.

STOVES, as distinguished from open fire places, are less agreeable and wholesome on account of the dry atmosphere they cause, and the unpleasant odour which is apt to arise when the iron plates of which they are constructed become over-heated. As a rule they are defective ventilators, and ought not to be used in preference to open fire grates in sleep-ing or sitting rooms. In halls, in churches, and in public buildings generally, close stoves are much employed on account of their slow combustion, and the large amount of heat they give off at a comparatively small cost for fuel. One of the best of the close stoves is that known as the "calorigen," which is made to burn either gas or coke. George's gas calorigen (fig. 205) consists of a cylinder, the interior of which is occupied by a coil of iron pipe (D) communicating at one end (G) with the external air, while the other extremity (H opens into the apartment, into which it conveys a con-tinuous stream of warm air. The products of combustion are carried away by the chimney, or by a channel communicating directly with the external air. The slow combustion calorigen, which burns fuel instead of gas, is constructed with a fresh air chamber corresponding in its action to the tubular arrangement of ally in some febrile affections, the stools become the gas-stove and the heat is increased and

retained by the fuel chamber being lined with fireclay. The slow combustion calorigen is intended to burn anthracite coal or coke, and its promoters maintain that the fuel will keep

strawberry—This delicious fruit must be classed with the most wholesome productions of the vegetable kingdom. It is recorded of Fontenelle that he attributed his longevity to them, in consequence of their having regularly cooled a fever which he had every spring; and that he used to say, "If I can but reach the season of strawberries!" Boerhaave looked upon their continual use as one of the principal remedies in cases of obstruction and viscidity, and in putrid disorders. Hoffman furnished instances of obstinate disorders cured by them, even consumption; and Linnæus says, that by eating plentifully of them he kept himself free from gout. They are good even for the teeth.

STYPTICS are applications, usually of an astringent character, which possess the power of arresting hæmorrhage. The remedies classed under astringents may all be used as styptics. but many of them are not generally had recourse to as such—that is, as external arresters of bleeding: it is to these that the term styptic is applied in this article.

A most effective styptic solution, and one which causes no pain, is made by dissolving pure tannin in its own weight of water. The solution should be clear, dark brown, and of treacly consistency. It may be used freely to a bleeding wound.

Oak-bark decoction, and gall-nuts in powder or infusion, which owe their efficacy to the tannin they contain, are used as external styptics, and "Ruspini's Styptic," formerly much in vogue, is said to be a solution of tannin in spirit (see Oak). In addition to these, matico and turpentine are styptics derived from the vegetable kingdom; also the agaric fungus popularly known as the "fuz-ball," which is frequently applied to bleeding wounds, and with apparent benefit. From the mineral kingdom many styptic applications may be derived, such as the salts of iron, especially the perchloride, the sulphates of copper and zinc, the acetate of lead, and the nitrate of silver. Cold, the actual cautery, or red hot iron, &c., are all styptic applications. See the various articles.

SUDORIFIC—a promoter of perspiration

or diaphoretic.—See Diaphoretic.

SUFFOCATION is the term usually applied to the condition in which air is prevented from entering the lungs by agents which do not compress the windpipe, as they do in hanging or strangulation. The distincdo in hanging or strangulation. The distinction is, that in the latter case the vessels of the neck by being compressed offer an obstruction to the flow and return of the blood from the brain, and at the same time the free exchange of carbonic acid for oxygen in the lungs is partly or wholly suspended. To both conditions the term "asphyxia" is applied, death being caused by a failure of the heart to propel blood through the lungs, which become engorged with venous blood from the want of their accustomed stimulus. From this cause the respiration is suspended, and the heart's action ceases; at the same time the skin becomes pale and anæmic, except in the more vascular parts, such as the face and lips, and extremities of the fingers, which become blue from the venous congestion. In all cases of apparent death from suffocation, it is imperative that measures of restoration should be attempted, and persevered in for some considerable time; the most important of these is artificial respiration, which should be carried out in the manner recommended under the article Drowning.

Suffocation is the result of such accidents as immersion in an atmosphere of carbonic acid gas or "choke damp," of drowning, of

SUG

SUF

or windpipe, of spasm (see Larynx, &c.). As these causes of the accident are all treated of respectively, it is unnecessary to enlarge upon them here.

It is requisite, however, by way of caution, to notice some causes of accidental suffocation,

which are sometimes fatal.

People who eat greedily, or who, as in the aged, are unable to chew their food properly, are sometimes suffocated (see Gullet) the accident, too, has sometimes followed vomiting in intoxication. A curious case of the kind is recorded in which a man, who, after vomiting, was put to bed drunk, was shortly after found dead-suffocation having been caused by a small piece of potato skin, so fixed over the opening of the larynx as perfectly to stop the passage of air. In children, a small body like a pea or cherry stone, accidentally drawn into the air-passages, has caused suffocation; and, very recently, a case was recorded in which a young man was killed by being forcibly pushed into a sack containing bran. bran drawn into the windpipe caused suf-

Infants may be suffocated, oftener perhaps than comes to light, by the very reprehensible practice followed by some ignorant nurses, of giving them a bag of wash-leather, or cloth, filled with sugar, to suck, in order to keep them quiet; if this happens to get too far into the mouth it will certainly suffocate. Death by suffocation in infants "overlaid," by heavysleeping nurses, is far from being a rare occurrence; and, indeed, it may happen simply from too great an accumulation of clothes over the mouth and nose.

Other causes might be cited—the above are perhaps sufficient to excite caution.

Refer to—Death—Hanging—Inquest.

SUFFUSION is a medical term usually applied to the eyes, when they are blood-shot

SUGAR.—This important article of food is for the most part a product of the vegetable kingdom, but not entirely so, for it occurs in milk, and in eggs in small quantity, and is also produced by the animal body under con-

ditions to be hereafter noticed.

Sugar is formed principally of two distinct varieties,-cane, or ordinary sugar, and sugar of fruits, or grape sugar. Both are composed of the elements, carbon, oxygen, and hydrogen, but differ somewhat in the proportions in which these are combined. In addition to the above sugars, Liebig enumerates a third, a non-crystallisable variety; and milk or manna sugar-also differing from them slightly in composition. Cane, or ordinary sugar, is produced by the sugar maple, by the birch, by beet-root, carrots, &c.; but its chief source is the sugar-cane, from which it is most easily

foreign bodies becoming lodged in the gullet | the expressed juice, after undergoing certain operations of heating, is left to crystallise, the dark uncrystallisable portion known as treacle or molasses being permitted to drain off. The crystallised sugar which remains is the brown or Muscovada sugar of commerce. As may be expected, it contains many impurities; moreover, the treacle which drains from it is rather the result of bad preparation, especially in the application of heat, than a necessary product. It is, in fact, grape sugar, which has been formed from the cane sugar by the decomposing influence of heat. In order to produce the refined sugars of the shops, other processes of re-solution, filtration, and crystallisation, require to be gone through.

Cane and grape sugar differ from each other in some important particulars. The former is only produced naturally, "it is crystallisable," "and, when pure, not prone to deliquesce, or to alter when exposed to moisture or to a

moderate temperature."

Grape sugar is also a natural production, but can be formed by art from starch, dextrin, and even from cane sugar, by the action of weak acids (see Fermentation), it does not crystallise regularly, and the aggregations into which it forms are very prone to attract moisture. Pure cane sugar ought, therefore, to be crystalline and free from moisture; when it contains grape sugar, which it frequently seems to do, either by natural formation or by designed adulteration, it is liable to become clammy and moist. According to the investigations of the Lancet Sanitary Commission, from which much of the information contained in this article is derived, experiments show clearly that cane and grape sugars coexist in most, if not all, the colonial brown sugars, and even in some of the lump sugars, and that they even exist together in the cane itself. The amount of the admixture of grape sugar is important, not only from the tendency which it imparts to the whole to become moist (it is to be feared, however, that all the moisture in many of the sugars retailed is not attracted from the atmosphere), but because it possesses a much lower sweetening power, and is much more prone to fermentation than the cane sugar. The latter, when purified, is generally free from grape sugar, and from many of the other impurities with which the ordinary brown sugars are intermingledconsiderations which render the purchase of coarse sugars a very doubtful piece of economy.

The chief impurities found in brown sugars, as imported into this country, are portions of the cane and vegetable albumen, which imparts a strong tendency to fermentation, and also assists to nourish the sugar acarus or insect (fig. 206), which, as shown by Dr. Hassall, exists in greater or less proportion in nearly all the brown sugars sold to the public. This disgusting impurity in food is said to be so conand abundantly extracted. To effect this the siderable in size "that it is plainly visible to canes are crushed between heavy rollers, and the unaided sight." When present in sugar,

it may be detected by dissolving a couple of | ever, to mention, that Mr. Wynter Blyth, tea-spoonfuls of the sugar in a large wine-glassful of tepid water, the solution being permitted to remain at rest for an hour; "at the end of that time the animalcules will be found, some on the surface of the liquid, some adhering to the sides of the glass, and others at the bottom, mixed up with the copious and dark sediment, formed of fragments of cane, woody fibre, grit, dirt, and starch granules, which usually subside on the solution of even a small quantity of sugar in water." The idea has been suggested that the disease known as "grocers' itch," to which those who handle sugar much are liable, may be caused by this insect, which closely resembles the itch acarus in form. A minute species of fungus is also generally met with in the moist sugars.

The refined sugars sometimes retain traces of the albuminous matters, serum of blood or

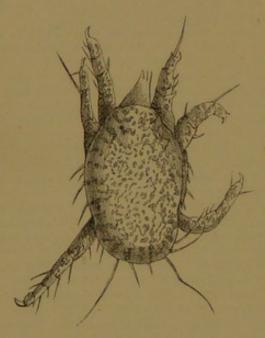

Fig. 206.

white of egg, &c., used in their purification, also traces of lime, lead, iron, &c., acquired in the According to the Lancet reports, an examination of fifteen samples of lump sugar gave the following results:-That in nine were fragments of cane, of sugar insects, or fungi, to be detected; that in three there were traces of grape sugar; in ten, of animal matter; and in all, of flour.

According to the same report, an examination of thirty-six samples of moist sugar showed -That the sugar insect was present in the whole of the samples, and in many of them in great numbers; that fungi were also present in all, and besides these, the fragments of cane, grit, &c., already mentioned. It is evident that pleasure in food, health, and economy, are more consulted by purchasing the refined than the moist sugars. It is but fair, how-

in his recent excellent work on Foods, states that, since the operation of the Sale of Food and Drugs Act, he is not aware of a single conviction having been obtained in England for selling sugar which had been adulterated, and that, according to his experience, the above series of impurities represents "rather the stereotyped list enumerated by various authors in different countries, showing more what is possible than what actually exists."

As an article of nutriment, sugar is of course the representative of the saccharine principles, which include starch, gum, &c.; the position which these principles hold, and the part they fulfil in the processes of nutrition generally, having been sufficiently entered into under the article Food, it is unnecessary to repeat them

With regard to the digestibility of sugar by different individuals there is considerable variation. Some persons cannot consume it, even in small quantity, without being disordered and suffering from acidity, whilst others seem actually to digest their food better when an amount of saccharine matter is mingled with it. In the West Indies, and other countries where sugar is cultivated, the inhabitants, the negroes especially, are said to improve in health and appearance during the sugar season, when they consume it plentifully; and, undoubtedly, a moderate proportion of this pleasant aliment is a wholesome article of nutriment for people generally, except under those peculiar states of constitution, or rather of disease, when the tendency of the assimilative powers generally is to form sugar even from dietetic principles which could scarcely be expected to yield it. This animal sugar has not only been detected in the blood, but in the stomach, after a person had been fed for days upon animal food alone. Moreover, it is now fully established that a substance akin to sugar is formed, naturally, in the liver. In medical practice sugar is used principally to cover the nauseous taste of drugs, and the British Pharmacopeeia admits not less than seventeen preparations of syrups, some of which as the syrup of poppies, senna, and the syrups of the phosphates and iodides of iron, are usually administered separately, while the greater number are employed to sweeten mixtures and draughts. Sugar is a powerful antiseptic. - See Diabetes.

Milk sugar, which differs from the sugars already noticed, "occurs in commerce in thick crystalline crusts, which are usually yellowish, yellowish-brown, or dirty, from want of care and cleanliness in its preparation;" when purified, however, it becomes very white and hard. Its sweetening power is weak, and it is capable of undergoing the vinous fermentation.

SUGAR OF LEAD .- See LEAD.

SUI SUI

SUICIDE. - SUICIDAL TENDENCY. - The | him to the commission of suicide is not asdistressing state of mind which seems to impel individuals to self-destruction has too exclusively been viewed in its metaphysical light alone, without reference to those states of bodily disorder which unquestionably induce great changes upon the views and feelings, particularly in persons naturally disposed to melancholy. The following observations of Dr. Forbes Winslow are most pertinent to the He says: "It is the prevalent opinion, even among persons otherwise well educated and intelligent, that this desire of self-destruction is, in the majority of cases, a mental act, unconnected with a disturbed condition of the bodily functions, and incurable by any process of medical treatment; that the mental depression which is so generally associated with the invisible tendency, is an affection of the mind per se; the physical organisation having no direct connexion with what is termed the spiritual impulse. This metaphysical view of the matter is fraught with much mischief, and, I have no doubt, has led to the sacrifice of many valuable lives. It is a matter of the highest moment that the public mind should be undeceived upon this point. Right views on this subject ought to be generally diffused. It is of consequence to establish the belief that the suicidal idea is almost generally connected with a morbid condition of the body, and is often the only existing evidence of such an affection; that it is, with a few exceptions, universally associated with physical disorder, disturbing the healthy balance of the understanding; and that this bodily affection, which is in nine cases out of ten the cause of mental irregularity, is easily curable by the judicious application of remedial means. The tendency of the spiritual or metaphysical view of the question is to create a distrust in remedial measures, and the poor man, who is struggling against an almost overwhelming desire to destroy himself, is induced to neglect entirely his lamentable condition, under the belief that he is literally placed beyond the reach of curative agents, and that the only remedy for his mental suffering is

"If a person in this unhappy state of mind is induced to believe that his mental despondency is but a consequence or effect of a disturbed bodily condition, influencing, either directly or indirectly, the natural and healthy operation of the brain and nervous system, and giving rise to perverted ideas, that his malady is curable, he may be induced to avail himself of the means which science has placed at the disposal of the physician, and thus be protected against his own insane impulses.

"Where no disease is suspected, no remedy will be sought. Tell a man who has attempted to destroy himself that he is perfectly sane, that his judgment is sound, that his will is

sociated with any deviation from corporeal health, and you inculcate ideas not only fallacious but most pernicious in their character and tendency. We might, with as much truth, tell a person playing with a lighted taper at the edge of a barrel of gunpowder that his life is not in jeopardy, as say to a person disposed to suicide that he is in the perfect enjoyment of health, and requires no moral or medical treatment. It may be laid down as an indisputable axiom, that in every case of this kind, bodily disease may, upon a careful examination, be detected. I never yet saw a case where a desire to commit suicide was present, in which there was not corporeal in-

disposition."

While it is of the highest importance that the connexion which exists between the tendency to suicide and derangements of the general health, or any condition of disease, should be well attended to, it would perhaps be dangerous to lead persons to the idea that all depended upon physical derangement; this there may be, perhaps is, in the majority of cases, at times giving rise to irresistible impulses, at least apparently irresistible, for how far they are so man cannot judge; but to base too much upon the bodily condition may hold out inducements to those who are afflicted with the suicidal tendency, to abandon that moral and religious control of their actions which is so powerful, and which in so many cases will overcome in the end. The subject of suicide is one which it is impossible to separate from religious considerations, when it is considered among Christian men; and if these men truly believe that God does assist those who look for his aid in the hour of trial and temptation, they cannot think that in such an hour as that, when one of His creatures contemplates the violent destruction of the life which He has given him, that God will not aid if His help is sought, and strengthen the combat of the higher powers of the mind against the lower principles; for suicide is selfish and cowardly. If an elevated religious and moral tone had nothing to do with controlling the propensity to crimes, and to that of suicide among the number, statistics would not furnish the evidence of the preponderance of these crimes amid people who notoriously cast aside the practical regulation of religion in their lives, individually or socially.

By these remarks the author does not intend in any way to weaken the force of the previous ones of Dr. Winslow, but to caution the reader, lest the consideration of the physical should obscure that of the spiritual. Nevertheless, it is probable, that, in the first instance, more benefit will be derived by treating the affection as a physical disorder. When an individual afflicted with a suicidal tendency can be thoroughly kept under surveillance in not perverted, that the impulse which urges | private, the effect of well directed medical

SUL

and safest plan is to commit the sufferer to a

well regulated asylum. - See Insanity.

The subject of human responsibility, where, overcome by the evil tendencies originating in physical derangement, it ceases to be responsibility, is perhaps one which man can never fathom, but it is one which ought to be upheld to the utmost in such conditions as a tendency to suicide; whilst giving every attention to the medical treatment of the physical condition, there should at the same time be given every encouragement to those who show the least tendency to this derangement, to keep, if they can, and as long as they can, the reins of reason. The mind can, and often will, overcome mental depression from physical causes, but it must be exerted. The reader is referred to some observations under article Habit. The tendency to suicide is found to be least in persons who are occupied out of doors. - See Insanity.

SULPHATES are salts in which the base, such as an alkali, or a metallic oxide, is united with sulphuric acid. - See Copper - Mag-

nesia - Zinc, dc.

SULPHUR belongs to the elementary It is found in large quantities in some volcanic countries, such as Sicily, from whence, hitherto, the chief supply has been obtained. It also occurs in the form of metallic sulphurates, such as those of iron, usually called pyrites, from which, in Sweden and other places, sulphur is procured. In the combination of sulphuric acid with different bases, such as lime, magnesia, &c., sulphur is again found, so that in one way or other it it one of the most abundant constituents of the globe. In the vegetable kingdom sulphur occurs, as in the mustard tribes, in the grains, &c.; in the animal kingdom it forms a constant element of the albuminous and fibrinous tissues,

and in the hair, saliva, bile, &c.

The pale "sulphur yellow" colour of sulphur, and its brittle crystalline texture, are sufficiently familiar in the form of stick or roll sulphur. The "flowers of sulphur" is made by "sublimation," that is by exposing crude sulphur to heat sufficient to cause it to rise in the form of vapour, the latter being condensed in a cool receptacle, when it takes the form of the well known "flowers of sulphur." Roll sulphur is now made by simply fusing the sublimed sulphur, and casting it in the form of sticks. In medical practice the flowers of sulphur is the preparation most in use—combined with lard in the proportion of one to four parts, it is the familiar remedy for itch and other skin diseases of a parasitic origin (see *Itch*). It is also used as a mild laxative in pregnancy, in cases of piles, and in most affections of the rectum. For the latter purposes it is advantageously mingled with three or four times its weight of cream of

creatment may be tried; otherwise, the best | The sulphur confection of the Pharmacopæia is a combination of four ounces of sublimed sulphur, one ounce of cream of tartar, and four fluid ounces of syrup of orange peel. One very serious objection to the use of sulphur is the abominable odour which it imparts to the person, particularly to the insensible perspira-tion. There is no doubt that it passes off by the skin in the form of sulphuretted hydrogen in considerable quantity, so freely, indeed, as to blacken silver which the individual taking it may happen to carry about with him.

The dose of sulphur as a laxative is, alone, two drachms; of the confection, two tea-spoonfuls; when mixed with cream of tartar or magnesia in powder, from half a drachm to a drachm. It is best given in a little milk.

SULPHURIC ACID, or OIL OF VITRIOL, belongs to the class of mineral acids. It is a compound of sulphur and oxygen gas, in the proportion of one of the former to three of the As usually met with, it contains a certain amount of water, but it may be obtained pure, and in the form of a crystalline solid, "glacial sulphuric acid." Sulphuric acid was formerly procured solely by distillation from the sulphate of iron, or green vitriol, and indeed is so yet in some places. It is now made in Britain on a large scale, by decomposing sulphur along with saltpetre in immense lead-lined chambers. As usually met with, sulphuric acid is a liquid of oily consistence-hence its name, oil of vitriol. It ought to be colourless, or nearly so, but frequently it has a brownish tinge from the presence of impurities. It is highly corrosive, destroying with great rapidity whatever textures, living or dead, it may happen to come in contact with. When mingled with water, a great development of latent heat takes place; in some proportions, indeed, so great as to raise the temperature of the mixture as high as 300° Fahr. After cooling, the bulk of the mixed fluids is considerably less than that which they occupied separately. For medicinal purposes, sulphuric acid is used diluted in the proportion of one part and a half of acid to fourteen and a half of water, and it is better for unprofessional persons to buy it thus prepared; indeed, unless absolutely required in a concentrated form for some special object, sulphuric acid should never be kept in a private house otherwise than diluted. Some lamentable poisonings have happened in consequence of neglect of this precaution. When concentrated sulphuric acid is mingled with water, the development of heat which occurs must be borne in mind, otherwise, the vessel, especially a glass one, may be cracked, and injury to clothes or person be the result. The mixture is best made by adding the acid to the water in small quantities at a time, and mixing each by agitation before more is added. Indeed, the water ought to be in a state of agitation when the tartar, or with its own weight of magnesia. acid is added, for if not, the extreme weight of

SUL SUL

the latter will carry it to the bottom of the | more used in England than it is at present: vessel, and there cause heat to be so strongly

developed as to crack it.

As a medicine, diluted sulphuric acid is extremely valuable. In relaxed states of the system it is one of our best tonics, given in doses of from ten to twenty drops in a large wine-glassful, or two ounces of water. In this way it preserves tone, and checks the perspirations in pulmonary consumption, and, when the case is suitable, improves both appetite and digestion. It also exerts considerable astringent properties, and is much in favour for checking mucous discharges of all kinds, especially from the bowels in cases of chronic diarrhea. Sulphuric acid is a powerful controller of internal hæmorrhage (see Abortion), it is also one of the commonest additions to gargles. Some persons find this medicine gripe a good deal, and if taken by nurses it is almost certain to disorder the infant. In other cases, however, ten drops added to small well-diluted doses of Epsom salts are serviceable. When sulphuric acid is taken medicinally, it ought, like the other mineral acids, to be sucked through a quill, or small glass tube, to prevent injury to the teeth, on which it acts powerfully; it is well to rinse the mouth with water containing a small proportion of soda immediately after taking the dose. In consequence of its employment for various household purposes-

Poisoning by Sulphuric Acid is not very uncommon, and if the acid be strong, is one of the most distressing accidents of this nature which can happen. The person is generally conscious of the description of poison which has been swallowed. According to the strength of the acid, there is intense burning pain in all the parts, from the mouth to the stomach, with which it has come in contact, and if it be of corrosive strength, these parts look white and shrivelled. There is also vomiting of shreddy and bloody mucus, great constitutional depression, and, probably, if the acid has been

strong, speedy death.

In such cases, the first thing to be done is to neutralise the action of the poison by alkaline and demulcent remedies. Magnesia, chalk, lime-water, potash, soda, soap-water, woodashes, milk, and oil, are all remedial; and in such a case, that which is first to be procured is the best; if there is power of choice, magnesia or chalk is generally preferable. In the absence of either of these antidotes, a portion of wall plaster, or mortar, rubbed up with milk or water, may be used. At the same time fluids must be given very copiously. When injury has resulted from the application of corrosive sulphuric acid externally, the best proceeding is to wash the parts freely with water alone, or with water containing an alkali, as soap-water does.

Aromatic Sulphuric Acid is a pleasant form of medicine, flavoured as it is with cinnamon and ginger, which might with advantage be the dose is from ten to twenty drops in a wine-

glassful of water.

Sulphuric Ether, now more generally known as ether, is procured by the action of sulphuric acid on alcohol, and by distillation. It is a perfectly colourless limpid fluid, of very light specific gravity, and very volatile: its odour. peculiar and penetrating, is usually called the ethereal odour. It is chiefly employed in medicine as a diffusible stimulant and antispasmodic, that is, it acts very rapidly and energetically as a stimulant when taken into the stomach, and on that account is peculiarly valuable in some diseases, such as angina pectoris, spasmodic affections, such as asthma and hysteria, attended with sudden violent symptoms; it is also a powerful restorer in the depressed conditions of the system, such as faintness, &c. For the above purposes ether is given in doses of twenty drops in water. A more convenient form, however, is the spirit of ether, which consists of one part of the ether mixed with two parts of alcohol; it acts in the same way as sulphuric ether-the dose about forty or fifty drops in water. The transient effect of ether renders it in many cases less valuable than sal volatile, or than spirits, such as brandy. Its antispasmodic power is increased by the addition of opium. When bottles containing this ether are opened at night, its highly inflammable character, even in liquid, but especially in vapour, ought to be borne in mind, and care taken that lighted candles are not too nearly approached. In giving ether, it is not to be forgotten that it floats on the top of the water, and thus, that if a bottle containing three or four doses of medicine, of which ether forms an ingredient, be not shaken before each dose is poured out, more than the proper proportion of ether is likely to be poured out first.

Ether, from its extreme volatility, evaporates rapidly in the ordinary atmosphere, and in doing so occasions a considerable amount of cold: as a spray, it is employed to produce local amesthesia by freezing, rendering absolutely painless small operations such as the opening of abscesses. Its most valuable property is its power of causing complete insensibility when inhaled; for this purpose it is used as an alternative to chloroform and other anæsthetics. The relative value of different anæsthetics is a much debated question. In America ether is almost universally preferred to chloroform, and in this country there is a profound impression in the minds of the leading surgeons that ether is attended with fewer fatal consequences than chloroform. A mixture of ether, chloroform, and spirits is perhaps the safer anæsthetic, although opinions are greatly divided on this very important matter. Inhalation of ether is a proceeding which should never be tampered w.th by unprofessional persons.

Sulphurous Acid, properly speaking, is a

SUN SUM

two parts of oxygen; but, as known in medicine, sulphurous acid is a solution of a definite proportion of the gas in water, the solution having a pungent sulphurous odour, and, unless kept in well-stoppered bottles, tending to get weaker by the giving off of the gas; it should therefore, if possible, always be used fresh. Sulphurous acid ranks as a disinfectant and deodorizer, and in its gaseous state is perhaps the best we possess. It is very destructive also of animal life, and a gaseous bath of sulphurous acid made by burning sulphur is recommended as a certain and speedy cure for itch; the solution is useful in other parasitic diseases, when mixed with an equal amount of glycerine. In the form of spray, sulphurous acid solution was specially introduced by Dr. Dewar, who also recommends its employment in a number of other ailments, internal and external.—See Disinfectants—Itch.

SUMBUL is a stimulant, anti-hysteric remedy, of considerable value. The tincture has a powerful, pungent, musky odour, and a bitter aromatic taste. When added to water, the mixture becomes milky in appearance. Dose, half a drachm to a drachm in water. This remedy was introduced into practice by

Dr. Granville, in 1850.

The author has administered sumbul in combination with opium, in cases of hysterical nervous excitement with sleeplessness, and has found it act extremely well in allaying the irritable condition of such nervous patients.

SUMMER.—See Seasons—Heat, &c.

SUNSTROKE.—Coup de Soleil, Insolation, and Heat Apoplexy, are all names given to what is best known in this country by the name of Sunstroke, an affection of the nervous system very fatal to the European soldier in tropical climates, and induced by protracted exposure to heat and exertion in a dry and suffocating atmosphere, together with anything which prevents the proper amount of rest and sleep being taken. It has been observed that people of intemperate habits are much more likely to be attacked than others, and to avoid the liability, it is of imperative importance that alcoholic drinks should be avoided, and others substituted more suitable to the climate, and better adapted in every way to further the moral and physical well-being of the young soldier. Those whose general health is not good may be said to be predisposed to the disease, and ought on no account to undertake a fatiguing journey in India, or any other tropical climate, without every precaution; that is to say, an ample supply of good water should be provided, the best tents should be used, frequent halts in shady places should be made, and an efficient worn over the head, to protect it from the rays of the sun. Cold bathing, and exercise in the cool of the evening, are good prevention. rays of the sun. Cold bathing, and exercise patient will bear it, the cold douche should in the cool of the evening, are good preventive be applied to the head, neck, and chest; if

gas, a compound of one part of sulphur and | measures. Flannel should be worn next the skin to prevent sudden chills, and the dress should be of a colour that does not readily absorb heat.

> The affection often comes on so insidiously, that it is very difficult to say at the out-set whether the patient is the subject of sun-stroke or not. Headache is common, but not always present, while there is almost always a certain amount of giddiness. The skin is hot and dry, and there is marked prostration of strength. The pulse is quick, and sometimes full, but is more frequently so small and feeble that it can scarcely be felt by the finger. The bowels are confined, and the urine so copious, that the patient has frequent calls to make water, while the thirst is excessive. After these symptoms have continued for some time, the breathing becomes rapid, the action of the heart tumultuous, and the patient may become suddenly, or, in some cases, gradually insensible. In this state the eyes are frequently bloodshot, with contracted pupils, the face is pallid, and the surface of the body very hot and dry. Convulsions not unfrequently occur about this period of the disease, the patient soon passing, however, into com-plete stupor, in which he dies. The approach of death is heralded by intermittent pulse, difficult and stertorous breathing, and, just before death, by dilatation of the contracted pupils. Patients who recover are apt to be troubled by some affection of the nervous system, either in the form of temporary paralysis, convulsions, or some form of insanity more or less severe.

The greatest variability exists as to the duration of the disease. In some cases, where numbers of our troops were attacked, death took place generally in two or three hours after the attack, while, in other cases, a longer

interval elapses.

An examination of the brain and nervous centres after death does not throw much light upon the nature of this affection, seeing that the condition of these parts has been found to be very different in cases affected by the same symptoms. Congestion of the membranes of the brain, or effusion of serum at the base of the brain, are the true morbid phenomena most frequently met with.

Cases of apparent sunstroke due to the same causes as the above, but which eventually recover, occur in most countries, but most frequently to Europeans in hot climates. The treatment to be adopted is similar to that recommended in the more serious forms of the

accident.

In the treatment of the disease it is to be remembered that, as the patients usually die

SWE SUP

act, these parts should be sponged and bathed with cold water and vinegar. The hair should at once be cut short, a blister applied to the nape of the neck, or blistering fluid pencilled over it. Mustard poultices should be applied to the calves of the legs, and an injection given, containing two table-spoonfuls of turpentine, with the same quantity of castor oil in a pint of gruel. Good strong tea given frequently, with brandy and ammonia, according to the state of depression, are the remedies on which most reliance is to be placed, and if the patient is unable to swallow, these may be

given by means of injections.

It is a curious fact that sunstroke is rare in mid ocean, though it occurs frequently in a narrow sea; it is rare also at great elevations, and this is probably to be accounted for by the fact, that although the effect of the sun's rays is greater in such situations than elsewhere, yet the temperature is not correspondingly high, nor is the atmosphere so suffocat-The occurrence of sunstroke has been ascribed, by Drs. Crawford and Barclay, to the effect of an atmosphere highly charged with electricity. The thermometer has been noted at 96° to 120° Fahr. in the shade, in the parts where sunstroke prevailed, such as Central India, Scinde, the Punjaub, Egypt, and the Coromandel Coast. Dr. Livingstone states that sunstroke is unknown in the interior of Africa.

Isolated cases occur in this country during the heat of summer, but they are generally met with in those who have been much exposed to depressing causes of other kinds. Intemperate persons, those who are recovering from illness, or those of a weak and excitable nervous temperament, are most likely to be

attacked.

SUPPER.—The last meal of the day is properly supper, and some of the modern dinners would more aptly fall under the former designation. Much has been said respecting the unwholesomeness of eating suppers — much depends on circumstances. Generally speaking, animal food once a day is sufficient for most; if, therefore, an individual for whom it is enough, after a sufficiently good meat dinner, adds a superfluous meat supper shortly before retiring to rest, there can be little wonder if he pays the penalty in sleep disturbed by dreams and nightmare, and by a furred tongue and unrefreshed waking in the morning. This is especially the case if the superfluity is indulged in after a dinner made in the latter part of the day. If dinner is early, if much exercise is taken between that and the evening meal, and if supper is not eaten at too late an hour, many persons can take with benefit a moderate proportion of animal food.

It certainly is better not to eat a meal heavy, either in quantity or quality, before a period of inactivity and sleep so prolonged as that of the night; but there is no doubt that much of the bad character of supper as a meal, has

arisen from its being too often one of superfluity. Those to whom suppers are most injurious are the plethoric, or such as suffer from head symptoms. head symptoms. Some persons, however, especially dyspeptic invalids, do themselves harm by abstaining from suppers of every kind, even after the principal meal has been taken early in the day. They do this under the idea that all suppers are bad, and suffer, in consequence, from uneasy sensations in the stomach during the night, and from a sense of exhaustion in the morning, both of which may be prevented by a moderate supper of light food, such as is found to agree best; many a dyspeptic will find his morning mea better digested after a light supper than without.

Refer to—Breakfast—Dinner— ood—Diet. SUPPOSITORY is a medicine in a solid form passed up into the rectum. In some cases this mode of administering remedies is very convenient, especially when the stomach cannot receive them readily. Generally, it is most suitable in painful diseases - such as those of the bladder, womb, and other parts, situated in the vicinity of the lower bowel. In such cases, the suppository may be made with an anodyne or an astringent. The suppositories introduced into the British Pharmacopœia are separately composed of tannic acid, mercury, morphia, lead and opium, belladonna, and carbolic acid, and are variously made up with oil of theobroma, lard, and wax, or with curd soap. A suppository may be introduced into the bowel on the point of the finger, both being well greased; the operation is, however, better and more conveniently done by the suppository tube made for the purpose. Glycerin suppositories are useful in Constipation, and

can be easily passed up by the patient himself. SUPPRESSION.—The cessation, or nondevelopment of an ordinary secretion, or ex-

cretion.

SUPPURATION .- The formation of pus, or matter. - See Inflammation - Pus - Abscess.

SURGEON AND SURGERY.—Literally, by the word surgeon is meant an individual who employs his hands in the treatment of diseases, and, by consequence, one whose practice is limited to the external treatment of external affections, and such as require manual interference for their removal. Practically, no such distinction can exist.

-Suffocation, &c.
SUTURE—in surgery, means a joining, by means of threads or stitches, of the edges of a wound .- See Wounds.

In anatomy, the term is applied to the junctions of the bones of the skull. -See Skull.

SWALLOWING.—See Alimentary Canal

Gullet—Throat, &c.
SWEAT, or Perspiration—is the fluid

thrown off from the blood, "excreted," through | occur, that unsymmetrical development, of the the agency of the skin, or rather of the glands contained within the texture of the skin. - See Skin.

Refer to-Diaphoretics.

SWEETMEATS.—See Confectionery. SWEET SPIRIT OF NITRE. - See NITROUS ÆTHER.

SWELLED LEG.—See LEG.

SWELLING .- Increase of size of different portions of the textures of the living body may arise from a variety of causes. The swelling may be either of a fluid or of a solid character. In the former case, it may be caused by increased accumulation or determination of blood in or to the part, the blood being still contained within the blood-vessels; more usually, however, fluid swelling is caused by blood or other fluid not contained within the vessels, but effused into the textures where the swelling occurs. Of this nature is the swelling which occurs after violence; it is, in fact, the result of the effusion of blood-inward bleeding-or of serum into the tissues. The formation of matter also causes swelling. Fluid swellings are in many cases of rapid formation; solid swellings, from their nature, are in general necessarily of slow increase. In rupture, of course, the presence of gas in the protruded bowel renders that a cause of swelling, though comparatively an unfrequent one. As the different forms of swelling are noticed under other articles, it is unnecessary to reiterate them here. - See Tumour.

SWINE-POX is a variety of chicken-pox, characterised by the globate form of its vesicles,

vulgarly termed "the hives."—See Chicken-pox. SPLINT FRAC-SWING TURED LEG.—See Fractures.

SWOON .- See FAINTING.

SYMMETRY .- The term, as applied to the human form, includes that proportionate adaptation of the various parts of the body to one another, which gives not only grace and beauty, but strength, and, it may be added, in some degree, health. The latter observation is especially applicable to the symmetrical development of the trunk of the body, which can scarcely be unsymmetrical, and still less, deformed, without the contained vital organs being injuriously impeded in their functions. Deformed persons suffer more than others from bad health, and if they are subjected to an attack of acute disease affecting the impeded organs, they are more liable to succumb. Thus an individual in whom spinal curvature, by distorting the ribs and trunk, injures the symmetrical development and proper capacity of the chest, is more liable to chronic affection of the lungs and heart, and such attacks as bronchitis, and the like, are more severely felt. Want of symmetry, or deformity of the limbs, is less important than when the trunk is affected, the importance varying, of course, with the nature of the case; it may, however, and does

lower limbs especially, leads ultimately to greater or less distortion of the trunk also. Moreover, in many cases, want of symmetry must be regarded as the sign of a constitution hereditarily weak, or as the result of sickliness in childhood.

The subject of symmetry is an extensive one, embracing, as it does, the theories of ideal beauty, and the standards of measurement proportional and otherwise; into these we need not enter here; but it may be adopted as a general rule, that the symmetrical development of a race or nation must in some degree be commensurate with their general sanitary condition, the means of obtaining proper nourishment, and their free exposure to light and air. Under article Light, it was stated that Humboldt has attributed the absence of deformity among the Caribs, Mexicans, Peruvians, &c., to the constant exposure of the body at large to strong light; and, under the same article, the effect of a diminished supply of light in giving a tendency to the production of deformed children, was also alluded to. Analogous effects will be found to follow, according to the fulfilment or not of the other sanitary conditions; there is no surer sign of a people advancing higher in the scale of comfortable subsistence than the improvement of their physical development and symmetry. reverse of this is seen in the degeneracy of some of the Irish in the more remote districts on the west coast, in the Indians of the Rocky Mountains, and among the hard-worked population of large towns, especially such as are employed in-doors. Although comparative symmetry is to be met with among many nations, and in the persons of individuals, absolute symmetry, in the sense of perfect balance and correspondence of the two halves of the body, is probably not to be found, and exact measurements go to prove that there always exists some disparity between the corresponding degrees of different sides.

Symmetry is not, however, confined to the actual development of healthy tissues; it extends to and influences many forms of disease, such as often occur in the symmetrical distortions, so to speak, of gout, rheumatism,

Refer to-Deformity-Spine, &c.

SYMPATHETIC NERVE .- See NER-VOUS SYSTEM.

SYMPATHY .- In man, probably in the higher animal tribes, there exists between certain different portions and organs of the same living body, a bond of connexion, or at least of relative action, through which excited or diseased action in the one is excited in the other, "sympathetically," as it is called, or by "sympathy." It is evident, however, that what are called sympathetic actions arise, apparently at least, in very different ways. Some which are classed as such are evidently

SYM SYM

the result of contiguity, others of reflex action (see Nervous System), or at least of nervous communication, others of derivative action .-See Derivative.

SYMPTOMS.—In a state of perfect health, all the functions of the living body are per-formed in regular series, and according to certain modes of action, which we recognise as those of health. When, however, these series or modes become deranged or altered, there arise certain signs, or, as they are generally called, "symptoms," which, as they vary according to the nature of the cause that produced them as effects, afford to the medical man a clue to the detection of the cause, more or less perfect, according to the state of his knowledge, experience, and means of investigation; they in fact furnish the means by which he forms his "diagnosis" in the first instance, and which guide his opinion as to the treatment and ultimate issue of the case.

There are certain symptoms, both general and special, which are too marked to escape detection; some, indeed, are forced upon the attention by the complaints of the sufferer, and others are too palpable not to attract the notice even of the unobservant. Beyond these plain and palpable symptoms of disease, however, which "he who runs may read," there are others which lie deeply hidden from ordinary eyes, which it requires all the advantages of knowledge and experience, of educated ear and eye, and of patient attention, to discover, and when discovered to read. There are many signs and characters brought to light in the explorations of the physician, both in the living and in the dead body which he may see, but cannot read correctly, if he can read them at all. Again, there are symptoms which one man can see as symptoms, but which another cannot, and therefore passes them by unheeded; and further, there are other symptoms which one man can not only see, but interpret, but of which another, if he sees them at all, can make no use. In this lies the difference, in one department of practical medicine at least, between the skilled and unskilled practitioner. It does not follow of necessity that the man who, from his knowledge of symptoms and of what they indicate, is most successful in the investigation of disease, is so likewise in its treatment, but the chances are greatly in his favour.

If many symptoms pass before the eyes even of the most skilful, which either cannot be seen, or, if they are seen, cannot be correctly interpreted, how superficial must that knowledge of disease be which unprofessional persons can gather from the comparatively few symptoms they are capable of observing or appreciating! How cautious, then, ought such persons to be when circumstances call for their management, temporary or permanent, of even the most trivial ailments! In observing and forming

ought to be-Do they indicate an acute attack ! have they supervened suddenly ? and if so, to what can the attack be traced? Has there been exposure to cold and wet, or to checked perspiration—those fruitful sources of inflammatory and rheumatic affections? Has there been exposure to contagion in any form, or to malaria of any kind; or is there any prevailing epidemic? Can any violence, at no very distant date, account for the attack? Careful consideration of the "history" of the affection will often throw much light upon its nature. Again, if the usual symptoms of fever indicate inflammatory affection, it is to be considered whether pain or uneasiness in any part, or dis-ordered function of any organ, indicate that the disease has localized itself. If inflammatory symptoms are absent, the spasmodic character of pain-(see Spasm)-or the nervous character of the general disorder, become questions for consideration. Should the symptoms of ailment be chronic, the same consideration of the history and of the hereditary tendencies ought to be entered into, and attention particularly directed to the fact of there having been progressive loss of flesh, habitual complaint of cold, unusual lassitude, alteration in the com-

plexion, difference in sleeping, &c.

By systematizing inquiries and observations, a much clearer idea will be gained of the state of an individual who is an object of care and solicitude, than by making them at random. Thus, beginning at the head, attention should be directed to any usual sensations complained of by the person, or any unusual manifestations apparent to others. These are pain, giddiness, affection of the senses, confusion of thought, or impairment of mental power; flushings, twitchings, drawing of the features to one side; disturbed sleep; moaning; grating of the teeth; sleeplessness, or too greatsomnolency. Passing downwards to the organs of respiration-alterations in the character of the voice; in the respiration, as to the frequency or otherwise; in the power of lying in any or every posture, are all matters for observations; also any habitual cough, and its When the digestive organs are character. affected, the times of their chief disorder, as connected with taking food, is an important symptom; whether the uneasiness comes on quickly after a meal, or not for some hours ; whether it is worse after long fasting, or the reverse; whether there is habitual vomiting, &c. With respect to the bowels, the nature of the motions or stools is to be inquired into, and especially the fact of thorough daily relief. In inquiry into the state of the urinary organs, the amount of the secretion, whether it contains albumen, or sugar, its nature as to colour, or its tendency to deposit sediments immediately after being passed, or when it becomes cool, are principal objects. If the calls are too frequent, it is to be noticed whether this deductions from symptoms, the first questions | depends on increased quantity or on diminu-

TAB SYN

tion, which causes irritation from greater concentration. In this way, by carefully and systematically considering a case, even an unprofessional person may acquire very considerable knowledge of its leading features, sufficient probably to enable him to refer to those articles in this work from which he will derive proper information; in many cases, sufficient to open the eyes to a condition of health that calls for the prompt submission to proper medical advice; and when this is determined on, the observation of symptoms, either in his own case or in that of another, such as a child, will enable an individual to furnish a medical man, even at a first interview, with such a history as will afford him much assistance in forming his opinion.

Refer to—Diagnosis, &c.

SYNCOPE.—A state of swoon or fainting.

-See Fainting.

SYNOVIA, or SYNOVIAL FLUID, is the fluid which is secreted within the joints by the lining or synovial membrane, for the purpose of lubricating the opposed cartilaginous surfaces of the bones, and facilitating their movements upon one another. It contains a considerable amount of albumen, and from its unctuous quality is known popularly as "joint-oil." When, from any cause, a joint becomes the seat of irritation, there is apt to be a greatly increased secretion of the synovial fluid. This takes place in chronic synovitis, or, as it is often called, "white swelling" of the knee .- See Knee

SYPHILIS, or the VENEREAL DISEASE, is disease contracted in consequence of impure connexion. The fearful constitutional consequences which may result from this affection,consequences, the fear of which may haunt the mind for years, which may taint the whole springs of health, and be transmitted to circulate in the young blood of innocent offspring, are indeed terrible considerations, too terrible not to render the disease one of those which must unhesitatingly be placed under medical care. In the meantime, if any delay must occur, the pustule sores which may be observable should be well touched with caustic, the diet should be reduced and deprived of stimulant, and the bowels acted upon by moderately active aperients; violent exercise being at the same time avoided.

Whatever the circumstances may be, once and for all the author would warn against any trust being placed in the specious advertisements in connexion with the disease in question, which are so perseveringly and disgustingly paraded before the public eye by quacks, who endeavour to fleece the silly dupes who resort to them, by first exciting their fears.

SYRINGE.—This well-known instrument is useful domestically for many purposes, and its employment is recommended in various articles in the present work. Generally speaking, the ordinary pewter syringes are procured

too small to be of much use. Instruments made of glass or vulcanite, capable of holding an ounce or more of fluid, will be found more serviceable.

Refer to-Ear.

SYRUP.—A saturated solution of sugar in water. A great variety of medicinal syrups are made, but many of them are comparatively little used. The ordinary simple syrup is made by dissolving, with the aid of gentle heat, five pounds of refined sugar in thirty ounces of water. Syrups made with unrefined sugar are much more liable to ferment than those made with it purified (see Sugar). A syrup should always, if possible, be kept in a situation with the temperature up to 555 Fahr.

SYSTOLE is the contractile action of the heart, by which the blood is expelled from the cavities. It is the reverse of diastole.—See Diastole—Heart, &c.

TABES -or TABES MESENTERICA - means a disease characterised by wasting or atrophy (see Atrophy). The term, however, is applied to a special diseased condition which causes atrophy, the essential nature of which is scrofulous or tuberculous affection of the "mesenteric glands" (see Digestion) through which the chyle or nutrient fluid, extracted from the digested food, passes on its way to the blood. The disease, in fact, may be called consumption in the belly; for, though differing in many respects from consumption in the lungs, there are many points of analogy between the two maladies.

Mesenteric tabes is a disease almost peculiar to the scrofulous constitution, whether hereditary or engendered, and it usually occurs previous to the completion of the twelfth year, most frequently previous to the ninth; some consider that children, nursed at the breast, are less liable to be affected by this form of scrofula, but the rule is by no means absolute.

Probably the first symptom which attracts attention in a child becoming the subject of tabes is the progressive emaciation, coincident with undiminished, and often greatly increased appetite, sometimes with depraved appetite, the child evincing a strong desire for such indi-gestible food as cheese more especially. Along with these symptoms there has generally been complaint at different periods, perhaps two or three times in the day, of pains in the belly, which probably were attributed to griping. The stools, if attention is or has been directed to them, are found to be unnatural, irregularly costive or relaxed, often frothy, and the colour, especially, much lighter than in health, apparently from deficiency of bile, the evacuations look clayey or chalky. If the disease has made some little advance, there may or may not be some amount of tenderness of the belly on pressure. There is usually fretfulness and irritability of temper, and tendency to flushing

TAN

smells heavy and disagreeable, at night. As time advances, the emaciation becomes more marked, and the attenuated limbs contrast strongly with the abdomen, which probably, but not always, becomes tumid; the features lose their plumpness, the skin of the face is wrinkled, and the whole countenance often approaches in appearance that of an aged person; the veins are prominently marked on the white skin, and with the latter the preternatural redness of the lips often strongly When the disease reaches an advanced stage, hectic fever is regularly established, and the patient dies exhausted, if not cut off previously by some acute attack of inflammation. The predisposing cause of this disease is, certainly, in the first place, the scrofulous constitution; its development, however, is greatly favoured by those deficient sanitary arrangements to which the poorer classes are exposed, especially the influence of damp and ill-ventilated rooms, combined with deficient food.

There is a prevailing popular idea that a naturally large or prominent belly is an indication of a tendency to the disease in question; this, however, does not appear to be the case, neither is the prominence of the abdomen always a marked symptom (unless, indeed, it be occasioned by flatulence), until the later stages of the disease, and then the enlarged glands can frequently be felt through the thinned walls of the abdomen, which, moreover, are covered with enlarged, often tortuous veins.

Mesenteric tabes is so fatal a disease, especially if it is allowed to make any progress before treatment is adopted, that its first symptoms cannot be too soon detected and attended to; and those who have under their care children who exhibit scrofulous tendencies (see Scrofula), ought to be alive to the possibility of its taking place. Should its occurrence be suspected, the safest and best plan will be to place the patient under proper medical care at once. Medicine, however, is not more requisite than strict attention to the sanitary surroundings, to the ventilation, dryness of the sleeping and other apartments, to exercise in the open air, to due clothing, with flannel next the skin, and to the food, which ought to be nourishing, and to consist of well-cooked fresh meat, mutton especially, at least once a day, or well made nourishing animal broth, nourishing puddings, &c., but with avoidance of all cheese, pastry, &c. A little port wine, or porter, may be useful in some cases, but of this a medical attendant can only safely judge. With regard to medicine, the paleness of the motions, suggesting the idea of deficient secretion of bile, often gives rise to undue perseverance in mercurial remedies. For remedies in this disease the reader is referred to article Scrofula; indeed the general treatment of that

in the evening, and to perspiration, which | required in the mesenteric affection that it is superfluous to repeat it, with exception of noticing the almost specific powers of cod-liver oil in many cases of this disease; the following may serve as illustration. A child eight months old was shown to the author, very reluctantly, by its mother, who, as well as her relatives generally, had abandoned all idea of its living beyond a few days. It was a complete specimen of the advanced stage of mesenteric disease; the limbs were shrunk till they resembled sticks covered with parchment, the features withered and old looking, the prominent belly was hard, knotty, and covered with enlarged veins, and, as if in constant pain, the infant screamed almost perpetually. With some persuasion the parents consented to try cod-liver oil given in tea-spoonful doses twice a day, and rubbed into the belly in the same quantity twice a day. Under this treatment the child at once began to improve, and in the course of three or four months had lost every appearance of disease. He is now a fine healthy boy. Similar treatment checked the disease in an early stage in a younger browner of the above patient.

TABES DORSALIS is a disease of the spinal cord, more commonly known as Locomotor Ataxy, characterised by progressive loss of control over the movements of the legs, with some loss of sensation, and not unfrequently some paroxysms of pain. Skilled medical ad-

vice is essential for its treatment.

Refer to Atrophy—Digestion—Scrofula, &c. TAMARINDS are produced by a tree which belongs to the leguminous or pea tribe, a native of India, &c., and also cultivated largely in the West Indies for the sake of the acid pulp of the pods, which resemble somewhat those of the common field bean. Tamarinds are brought to this country, either simply dried or preserved in sugar, in jars or casks. The appearance of the pods mingled with fibrous substance and seeds, and immersed in syrup, liquid or partly crystallized, is suffi-ciently well known. Preserved tamarinds are cooling and aperient, and a welcome addition to the sick-room dietary in many febrile diseases. They are most beneficially employed in the form of infusion made with hot water, and permitted to become cold. A pleasant aperient whey is made by boiling an ounce of tamarind pulp in a pint of milk. The acids of the tamarinds are chiefly the citric and

TANNIN and GALLIC ACID .- Tannin is the active astringent principle of the nut-gall.—See Gall—Nut.—When exposed to the atmosphere in a state of moisture, it appears to attract oxygen, and to be converted into gallic acid. Both tannin and gallic acid are powerful astringents, and are widely diffused as the astringent principle throughout the vegetable kingdom. The former is met with state of constitution is so similar to what is in the form of a yellowish powder, the latter

2 P

TEA

are soluble in water, and in solution are used externally for the same purposes as astringents generally; from half a drachm to a drachm in half a pint of water forming an astringent lotion. Tannin or gallic acid is generally given internally in the form of pill, in hæmorrhage and other similar affections, in doses of three to six grains every two or three hours if requisite. Lozenges and suppositories containing tannic acid are introduced into the British Pharmacopieia.

Pure tannin may be dissolved in its own weight of water by the aid of heat, and in this form is an admirable astringent. Strips of calico dipped in the solution may be well applied over a cut or wound, the dissolved tannin drying into a kind of varnish.

TAPEWORM, also called TENIA. - See

WORMS

TAPIOCA is a starchy substance, or fecula, like sago; it is procured from the root of a shrub, which is cultivated chiefly in the West Indies. The root which is known as the "bitter cassava," contains a juice possessed of highly narcotic poisonous qualities; this juice is thoroughly removed by washing, and the starch, or tapioca, dried in the form of grains, resembling, but two or three times the size of, the sago grain. Tapioca is used in sick-room cookery for the same purposes as arrow-root and sago. Dr Christison remarks of tapioca, "no amylaceous substance is so much relished by infants about the time of weaning; and in them it is less apt to become sour during digestion than any other farinaceous food, even arrow-root not excepted."

An imitation, "British tapioca," is made

from potatoes, and is very wholesome.

Refer to Fecula.

TAPPING, in medical practice, is the withdrawal of fluid which has collected in unnatural quantity in any of the natural cavities of the body. The operation can only

be performed by a medical man.

TAR and PITCH.—The well known black viscid substance, tar, is obtained from the wood chiefly of the Scotch fir, by the agency of heat. The process, which varies in detail according to the situation, is essentially what is called "distillation per descensum, that is to say, the wood being placed in a hollow of the ground, or in a pot, is kindled, and being covered up, is allowed to burn with a smothered combustion; by this means the tar is formed, and is collected by suitable arrangements at the bottom of the receptacle in which the process is carried on. For medical purposes tar has been used from the most ancient times, and its employment both as an external and internal stimulant is still strongly advocated. It possesses much the same properties as creasote and carbolic acid, and is often used in chest affections, especially nutrition. The tea plant is a native of China, in bronchitis and incipient consumption, where Japan, and Tonquin; and, until late years,

in fine, white, silky-looking crystals. Both | it appears to check the expectoration and cough, and to relieve the breathing. It is best given in the form of pills, containing each two or three grains of tar, and administered every three or four hours. Tar is often administered in the form of tar-water, which is best made by digesting-stirring occasionally-one ounce of tar in thirty-two ounces of water for seven or eight days, and then straining. The dose is half a pint twice a day mixed with milk. The vapour of tar has also been recommended, but has not been so generally employed. Tar is now chiefly used as an external application in some cases of skin disease, especially in eczema and psoriasis, and is best applied in the form of ointment composed of five ounces of tar with two ounces of yellow wax, melted together by heat. Pitch is the hard black brittle residue left after tar has been exposed to heat. It is little used. Pills made of pitch were formerly a popular remedy for bleeding piles, but they are now superseded by the preparations of tar. Packer's American tar soap is a specially good preparation.

Refer to Piles.

TARANTULA is a species of large spider, common in Southern Europe, the venomous bite of which produces effects similar to those of the scorpion sting. Many fabulous tales of the effect of the tarantula bite were formerly currently believed.

TARAXACUM.—See DANDELION.

TARTAR ON THE TEETH .- See

TARTAR EMETIC, or TARTARIZED

ANTIMONY. - See ANTIMONY.

TARTARIC ACID belongs to the class of vegetable acids. It is the characteristic acid of the grape, from which source it is procured. In the fruit it exists in combination with potash, as bitartrate of potash, or cream of tartar, the acid when prepared being separated from the alkali by chemical process. For an account of the mode in which cream of tartar is obtained, the reader is referred to article Potash.

Tartaric acid is met with both in crystal and powder, generally the latter. Its principal use is to form the acid ingredient for effervescing mixtures of various kinds-and for this purpose it is well adapted, wholesome, and cheap. It is also a good solvent for

quinine.

Refer to Effervescing. TASTE.—See TONGUE. TAXIS .- See RUPTURE.

TEA .- Few articles consumed by man as food require more careful consideration in every point of view than this important and widely used product of the vegetable kingdom; which, as we shall see, is not only a luxury, a cheering but not inebriating stimulant, but a valuable addition to the essentials of healthy TEA TEA

new source, and one which promises eventually

to be advantageous in every way.

The varieties of teas employed in commerce are very numerous; those most consumed in this country are the black teas, Congo, Souchong, Oolong, and Pekoe, the special characters of which are variously modified by the soil, mode of growth, and by the periods at which the leaves are cut. Green teas comprise not only the gunpowder and Hyson sorts, but are also prepared from the black teas by subjecting them to a process of facing or colouring by means of Prussian blue, turmeric, gypsum, and other deleterious substances, their natural colour really depending on the time occupied in drying the leaves, the green teas being dried much more rapidly than the black. Good tea, when infused, possesses an aroma and natural fragrance impossible to imitate; it should be neither harsh nor bitter to the taste, and the leaves should be free from sand and dust, and unbroken. The infusion ought to be made with soft, in preference to hard, water, and if the former cannot be had in its natural state, it ought to be prepared by boiling it beforehand with a few grains of carbonate of soda. Tea, like coffee and cocoa. owes its peculiar properties to the presence of the alkaloid, theine, and is further modified in action by an essential oil and an astringent principle. Good average black tea, as imported, contains the following ingredients in one hundred parts:-

Water, 8.0 Theine, 2.5 Tannin, 14.0 Essential oil. 0.4 Minor extractives, 15.0 Insoluble organic matter, 54.4 Mineral matter, 5.7

Tea is well known to be subject to numerous adulterations, either by the addition of old and damaged leaves, or by the mixture of the leaves of other plants with the genuine tea leaf, a composition known by the name of "lie tea." To these are sometimes added powdered catechu, gum, and starch, and other more or less deleterious ingredients, especially in the manufacture of green teas; these sophistica-tions, however, as a result of the Adulteration Acts, have been nearly driven from the market. Probably there is no substance, not strictly medical, which exerts so powerful an influence on the nervous system as teaespecially the green variety, of which some people cannot partake without experiencing the most disagreeable effects. Where individuals have a tendency to dyspepsia, the symptoms are apt to be aggravated by the use of tea. Many cases of hypochondriasis may be traced to its abuse, and most people have had

the supplies to this country were all brought by drinking tea before bed-time. Nevertheless, from China; its cultivation, however, in the province of Assam, in India, has opened up a most useful. When taken in moderation it as an article of diet, or as a beverage, tea is most useful. When taken in moderation it produces effects at once agreeable and beneficial, its action on the system being both stimulant and restorative, by gently accelerating the pulse and increasing to a moderate extent the action of the skin, and it is unattended by any subsequent symptoms of depression. Taken towards the close of a meal or shortly after it, tea certainly favours digestion, and removes the drowsiness which so often accompanies the process; and lastly, it appears to meet a want in the alimentary requirements of the system which no other beverage, except, perhaps, coffee,

is able to supply.

A writer on the effects of green tea on the system says :- "There are some females upon whom green tea produces nearly the same effect as digitalis; and it has been medicinally employed in the diseases for which that herb has so decidedly obtained a high reputation. Desbois of Rochfort has, by the use of it, cured many nervous diseases which have arisen from accelerated circulation. Dr. Percival had an idea that green tea possessed nearly the same power as does digitalis, of controlling and abating the action of the heart." "It is upon the nervous system that the effects of tea are chiefly manifested." chiefly manifested; green tea, especially, is distinguished by this property. It is said that a strong solution of it, applied to the sciatic nerve for half an hour has caused death. Introduced in only a small quantity beneath the abdominal integuments of a frog, it produced complete paralysis of the hind legs, lasting for some hours." "Administered as an injection to a dog, it caused a perfect paralysis of the bladder and intestinal sphincters, a partial loss of power in the hind legs, and a total loss in the tail." "A poultice of green tea leaves, applied over the human stomach, has caused sickness and vomiting; over the abdomen, colicky pains and purgings; over the heart, faintness and irregularity of pulsation: over the kidneys, diuresis." Were it requisite here, many more instances of the poisonous effects of this herb might be cited. True, these are chiefly the results of green tea, but in some, black tea will produce nearly similar symptoms. Where individuals have any tendency to dyspeptic affections, these are very apt to be aggravated by the use of tea, which occasions severe gastralgia; these cases are familiar to every medical man; they are frequently cured solely by enforcing the disuse of the beverage, which, indeed, ought to be done in all such cases.

Mr. Corfe, in his lectures on the Physiognomy of Diseases, mentions a case very closely imitating cancer of the stomach, which completely and rapidly recovered as soon as the tea was given up; and in the Lancet very many cases are recorded to the same effect. experience of the extreme wakefulness induced action of tea, in exciting mental phenomena,

TEE

the body. Most students are familiar with its power of clearing the mind, and facilitating its working; many, too, have experienced its baneful effect in preventing sleep and occasioning mental irritability. At times, however, the disorder of the faculties of the mind, under the influence of strong tea, amounts nearly to

The stimulant properties of tea are not so strongly exhibited when it is taken with a solid meal as when taken with a small quantity of light food. When taken in excess at any time, or too soon after a full meal, the warm liquid is apt to debilitate the stomach, and to interfere with the regular process of digestion. Notwithstanding, however, the evils resulting from the abuse of tea-drinking by some, or its deleterious effects upon a few peculiarly constituted individuals, there can be no doubt that the salubrity of the infusion to the general mass of the community is established on sufficient testimony to outweigh any argument founded on individual cases.

The moderate use of the beverage is of course alluded to. In cases where it evidently disagrees, it ought to be given up altogether; and it may be taken as a rule for most, that two cups of moderately strong tea, morning and evening, are sufficient, and not too much, for health. If this quantity is exceeded, not only is it apt to cause nervousness, but the amount of warm fluid debilitates the stomach.

Refer to—Breakfast—Coffee—Opium, &c.

TEARS. - The watery saline secretion named the tears is formed by the "lachrymal gland" (see Eye), which is situated in the outer and upper corner of the socket or orbit. secretion is continually passing over the forepart of the eye ball, keeping it clear, bright, and free from dirt, and facilitating the movements of the eyelids, any superfluity of moisture being taken up at the inner angle of the lids, and conveyed into the nose (see Eye). The increased secretion of tears is a remarkable instance of mental influence over the body, still more so, when it is reflected that infants do not shed tears in their crying. It would seem that mere crying from physical causes is not sufficient to cause increased secretion, and that some amount of intelligent mental emotion must be conjoined. - See Eye.

TEETH are hard substances placed generally at the entrance of the alimentary canal of animals, for the purpose of comminuting the food. True bony teeth are met with only in the higher or vertebrated classes of animals, and in the highest class, the mammalia, to which man himself belongs, they are found to be placed in single rows in each jaw. Even a superficial examination of the teeth of different animals makes evident how specially they are constructed with reference to the habits and food of the being whose purposes they subserve. There are the sharp-edged chisel-like divided vertically, as shown in the magnified

is equally remarkable with its influences upon | incisor teeth of the rabbit or hare; the sharppointed, conical canine teeth of the dog, and of other carnivora; the broad crushing molar or back-teeth of the graminivora and grain-feeding animals. In the case of man, who is calculated to subsist on a mixed diet, we find all the above forms of teeth, but in a modified degree. The teeth of the human adult are thirty-two in number, arranged in two arched rows, containing sixteen in each. The teeth in each of the arches correspond to one another, but those of the upper arch in most jaws overlap the lower. Fig. 207 represents the teeth of one half of the adult lower jaw. Of these—(1) marks the two incisors; (2) the canine teeth; (3) the two "bicuspid" or two-pointed or false molar teeth; and (4) the true molars, three in number; that is, eight teeth in all on one side of the

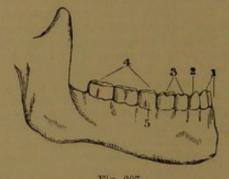

Fig. 207.

one jaw, giving, of course, sixteen for the single jaw, or thirty-two for both upper and lower jaws. The larger illustration (fig. 209) gives a better view of the separate teeth. It represents the teeth of one half of the upper and the corresponding half of the lower jaw, with their roots or fangs. The numbers beginning with (1, 2) the incisors, refer to the positions in which the teeth are set in the jaws. In the child, the number of the first temporary, or "milk teeth," is not so great as in the adult, by twelve. There are the four incisor, and two by twelve. canine teeth in each jaw, but the true molars (fig. 207—4), are entirely absent, their place being supplied by four temporary molar teeth, two on each side, which occupy the situation of the bicuspid teeth (fig. 207—2), in the adult. About the seventh year of age, when the shedding of the first teeth is commencing (but it may be later), the child cuts the first of the true or permanent molars. These teeth appear without direct reference to the shedding of the first set of teeth, as they do not occupy the site of any of the latter, but, so to speak, break new ground for themselves.

Every tooth is divided externally into a crown (fig. 210-1), and into a fang or root (3). At the point where the gum ceases the tooth is slightly contracted (2), and this, which marks the division between the two other portions, is called the neck of the tooth. When a tooth is

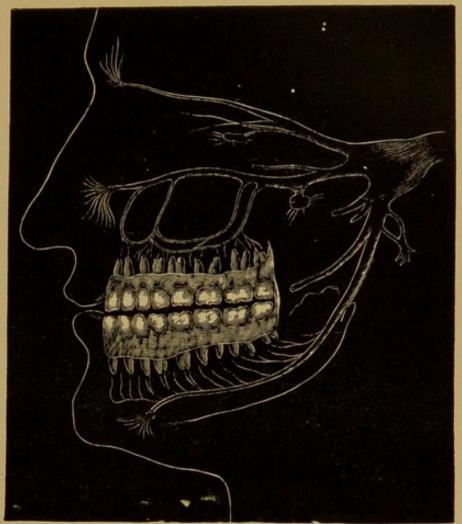

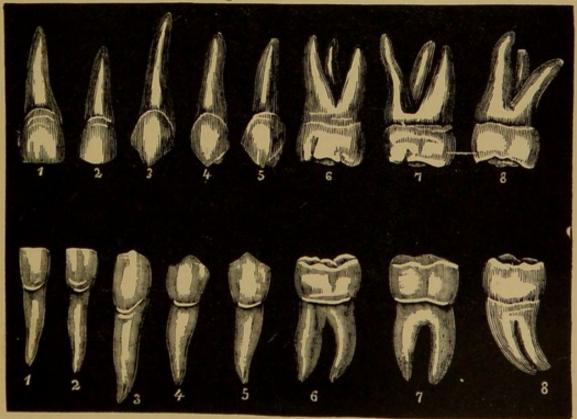

Fig. 208.-Trifacial Nerve.

ец. 209.

From The Teeth: How to preserve them and prevent their Decay, by S H Linn, M.D., D.D.S., Dentist to the Imperial Academy of St. Petersburg.

TEE TEE

section of an incisor tooth (fig. 210), there is | known to be occasioned by a diseased tooth, seen covering its exposed portion or crown, the "enamel" (4), which, thickest at the superior part, gradually thins off towards the neck, where it ceases. At this point, however, begins another substance; the "cementum" or "crusta" petrosa" (6), which gradually increases in thickness towards the extremity of the fang, where it leaves a perforation, through which

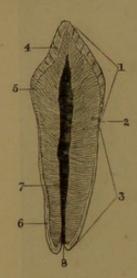

Fig. 210.

the vessels and nerve pass to the interior or pulp cavity (7), which occupies the centre of the tooth. Between this pulp cavity and the enamel on the crown, and between it and the outer bony casing or cementum on the fang, lies the tooth bone, dentine, or ivory (5), which constitutes the great bulk of the tooth.

Nerves of the Teeth. - The teeth derive their nerve supply from two great branches of that important sensory and motor nerve, termed the trifacial (fig. 208), which, originating in the substance of the brain, sends branches to the eye and to the upper and lower jaw, from which also filaments are furnished to the skin of the face, the ears, forehead, and scalp, to the muscles of mastication, and to the tongue. From the upper and lower maxillary branches, each tooth is furnished with a nerve filament, which enters at the roots of the separate fangs with the blood vessels through the dental canal. From its extensive sympathetic connexions with all parts of the head and face, irritation, due primarily to the teeth, is conveyed by the nerve to distant parts, causing much pain and inconvenience, without the origin of the evil being always Convulsions in young children discovered. are often due to the irritation of the nervous system from the process of teething; facial neuralgia, frontal headache, earache, and neuralgia of the scalp, may continue for a long time without the cause being discovered, in the absence of a close inspection of the state of the teeth. Some diseases which even partake of a constitutional character, such as debility, sleeplessness, and mental disturbance, have been

and relieved by its extraction.

Composition and Development of the Teeth .-Probably no structure in the animal body, not even the eye itself, evinces more striking evidence of wise design, than there is to be found in a completely developed tooth, still more when the processes of its development are traced, as they have been, from the first papilla or appearance of preparation for the future structure. These, indeed, are wonderful and beautiful, but how much more wonderful to find that before an infant has yet breathed the air of this world, the preparation is made in its jaws for the development of its future permanent teeth, not to be made apparent for eight or nine years after, when the enlargement of the bones permits this development and renders it neces-

The calcareous enamel of the teeth is composed almost entirely of earthy or mineral constituent, the animal matter not constituting more than two per cent. of the whole. It covers the entire exposed portion, or crown of the teeth (fig. 210). The enamel is not, as

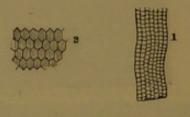

Fig. 211.

might be supposed, a homogeneous structure, but is composed of numbers of minute hexagonal fibres or rods, as shown when magnified (fig. 211-1), placed side by side; a transverse section of these fibres, presenting the hexagonal divisions (fig. 211-2). The diameter of these fibres is about the 4500 of an inch. They are not straight, but as represented, have a wavy appearance; their inner extremities rest in shallow depressions on the surface of the tooth-bone or ivory, their outer ends forming the surface of the crown of the tooth. By this arrangement of its structure, the enamel is evidently most perfectly adapted for sustaining the pressure, to which it must be liable, in the process of mastication. The "tooth-bone," "dentine" or ivory, which constitutes the great bulk of the tooth (fig. 210), and on which the enamel rests, is composed of numbers of branched tubes, which radiate from the central cavity. Through these tubes, the branches of which intercommunicate in all directions, the fluids of the tooth permeate; moreover, the firmness of their walls, and of the surrounding fibrous substance, and the radiating and waved course of the tubes give the entire mass of dentine or ivory the greatest possible power of resistance. The cementum, or crusta, which

TEE TEE

root of the tooth (fig. 210-6), resembles ordinary bone in structure. It is the enlargement of this bony crust which is sometimes found upon the fangs of teeth. The pulp (fig. 210-7) contained in the tooth cavity, is largely supplied both with blood-vessels and nerves, which enter at the perforation in the extremity of the fang

The separate sockets or "alveoli," into which the teeth are so firmly fitted, correspond to the shape and directions of the fangs, to which they are united by a somewhat elastic "periosteum," and by communicating blood-

vessels.

The bicuspid or false molar teeth frequently have a fang forked at the extremity, each division being perforated. The true molar teeth have two, three, and sometimes four fangs each (fig. 209).

In infancy, the period of teething, or the coming forward of the first set, the temporary or milk teeth, always occasions some amount of disturbance in the susceptible young con-

stitution. - See Childhood.

The order in which the teeth are successively developed varies considerably; the following table gives the average time, the teeth of the lower jaw generally appearing before the corresponding ones of the upper :-

## TEMPORARY TEETH.

7th month, two middle incisors.

two lateral incisors.

12th first molars.

18th canine.

24th last molars.

## PERMANENT TEETH.

61 year, first permanent molars (fig. 209-6, 6).

7th ,, two middle incisors (1, 1). 8th ,, two lateral incisors (2, 2).

9th ,, first bicuspids (4, 4).

10th second bicuspids (5, 5).

11th, 12th, canine (3, 3).

12th, 13th, second permanent molars (7, 7). 17th, 25th, third, or last permanent molars or "wisdom teeth" (8, 8).

The first teething in infancy is always somewhat critical (see Childhood), but even the second is not always free from irritant effects upon the constitution, and epileptic and other attacks have dated from this cause and

There are a few instances on record of a third

partial teething even in old age.

Decay of the Teeth. -The carelessness or neglect in the preservation of the teeth, which prevails among all classes, and especially among the lower orders, can result only from ignorance of the important purposes they subserve in the animal economy, and of how closely their perfection and efficiency are linked with

forms the thin bony covering of the fang or of a good set of teeth may make all the difference between a hale and prolonged old age, and premature decay of the powers of life (see Moreover, the disorder of the Digestion). stomach produced by the insufficient mastication and comminution of the food, which must be the cons quence of deficient teeth, tends still n ore to increase the evil; for since the teeth may, as nails and hair on the skin, be considered as developments from the mucous membrane which lines the digestive organs, they sympathise with, and suffer from, whatever affects that lining membrane; cousequently, there is no more certain cause of decay in teeth than indigestion, and particularly if the saliva becomes acid.

> There is no question, however, that although chronic indigestion is very liable to assist decay in teeth, the process takes place much more quickly, from any cause, in some persons, than it does in others. There certainly is hereditary tendency in this as in other peculiarities of constitution; for the members of one family preserve their teeth sound much longer than those of another, though equal care is bestowed on them. At the same time proper

> attention to the teeth will do much to preserve

a naturally deficient set, and vice versa.

The teeth being constantly moistened with the saliva, are continually liable to become encrusted with the animal matter and earthy salts contained in that fluid, forming what is popularly known as the "tartar" upon the teeth. This formation would accumulate much more rapidly than it does in those who neglect their teeth, were it not partially removed at each meal by the friction of the food in course of mastication; this is seen when persons, as in fevers and paralysis, lie long without food; the teeth become at times quite crusted over. The author met with a strong example of the kind in the case of a girl of bad constitution, in whom, from avoiding eating on one side of the mouth in consequence of a tender decayed tooth, an accumulation of tartar of considerable thickness entirely covered not only the decayed tooth itself, but those next it, requiring considerable force and chiselling to detach. It formed, in fact, a calcareous case over the tooth. Although partly removed by the food during mastication, the tartar cannot be so entirely, consequently it tends to accumulate around the necks of the teeth at the margin of the gum, and in time drives back, as it were, the gum, exposing the parts of the tooth which are not protected by the hard and resisting enamel, to the action of the influences which speedily induce decay. Besides the tartar, there has been observed to accumulate from neglect, especially between the teeth, a filiform fungoid-like growth. In no way is it possible to remove these continually forming incrustations but by the brush, or at least by some substitute for the brush, by which tolerably active health; there is no question that the possession | friction can be employed. Neither is it well

TEE TEE

to trust too much to dentifrices, or tooth | very hot. The use of the teeth to crack nuts, powders, the brush and plain water is amply sufficient for most purposes; a small addition of fine white soap is found to facilitate the cleaning of teeth in some cases, but never should rough or acid tooth-powders be used; they may, it is true, clean the teeth more quickly, but they do this at the expense of the enamel, which in the first instance is gradually worn away mechanically, and in the case of the acid, chemically dissolved. If a tooth-powder is perfectly impalpable, it is difficult to see how it can assist the cleaning of the teeth at all; and is, therefore, just as well dispensed with. A good dentifrice may be prepared by mixing-

Prepared chalk, . . 6 ounces.
Orris root, . . 1 ounce.
Cassia powder, . . ½ ounce.

When, however, the gums become spongy, and the teeth inclined to loosen, it may be well to use some astringent application for the purpose of strengthening the gums; tincture of camphor dropped into water is commonly used, but, although not fully proved, it has been thought to injure the integrity of the teeth themselves; it is, therefore, as well avoided, especially as a few drops of tincture of myrrh on the tooth-brush is equally efficacious, and is free from suspicion. The powder or tincture of rhatany-root may be used for the same purpose. The following is a tooth powder which might be useful to persons with weak spongy gums :-

Orris root, 3 ounces. Powdered cinchona bark, 2 ounces. Powdered Castile soap, . 1 ounce. Loaf sugar, 4 ounces. Gum myrrh (powdered), 1 ounce.

Prepared chalk, . . . . 18 ounces.
Rub well together. Or one of the "quinine tooth-powders," by which the bacteria which infest the teeth are destroyed. As a general rule, however, the use of a tolerably firm brush twice a day, or after each meal, and with water alone, is quite sufficient to preserve most teeth in purity and soundness. It is really surprising to what an extent cleaning the teeth is neglected even by persons in respectable stations in life, and among the majority of the lower classes it seems never to be thought of. Putting comfort, cleanliness, and refinement aside, on the score of health alone the habit ought to be practised, and among all classes ought to be taught to children. There is no doubt that where the food is simple, and health and digestion good, there is much less tendency to the accumulation of tartar about the teeth; but this immunity is certainly not enjoyed by the lower classes in Britain, who suffer greatly from decayed teeth. It has been thought that the hot food and fluids used by civilised man tend to promote the decay of the teeth, and probably they do, if the habit is acquired, as it is by some, of taking these a tooth is so utterly decayed that it cannot be

to bite hard substances, and the like, is apt to chip off the enamel, and thus to expose the tooth to certain decay. Some medicines have an undoubted tendency to injure the teeth, certainly mercury given to affect the gums does so, and this should always be a serious consideration with a medical man in using the drug to this extent, in the case of the young especially. The mineral acids act chemically, by dissolving the enamel; they ought, there-fore, always to be sucked through a quill or glass tube, and the mouth rinsed with water afterwards. Prussic acid given medicinally has been thought to injure the teeth; iron medicines discolour them if the teeth are not brushed after the dose. Under article Grape, the author has noticed a singular effect of the acid of that fruit in dissolving off the enamel. Another cause of decay is the lodgment of particles of food in the interstices between them; these the brush will remove, but the use of tooth-picks of any kind is most injurious.

Stopping the Teeth. - As the calcareous, almost crystalline, enamel is the great protection of the inner and more easily acted on structures of the tooth, its removal quickly gives a tendency to decay, which, once begun, tends to spread, unless means are used to stop This is best done by means of the "stopping" process with gold or other material, as practised by dentists. To be thoroughly done, stopping requires considerable care, the removal -scraping out-of the decayed portions of the tooth, &c., it therefore requires to be effected by the dentist, who should always be resorted to for the purpose, care being taken to ascertain that the stoppage is not-as has occurred-of such a metallic nature as will injure the constitution. As a temporary stopping, which any one may insert for himself, nothing answers better than a piece of gutta-percha, softened in water, and pressed well into the cavity, which it should fill: it will thus often retain its place for months. Care must be taken, however, that this or any other stopping does not press injuriously upon the nerve, otherwise severe suffering may ensue.

Toothache .- When, in the course of decay, the cavity of the tooth, which contains the nerve pulp, is opened into, toothache begins; the nerve becomes highly sensitive, probably inflamed, and not only is extreme pain excited by the slightest cause, a crumb lodging in the cavity, or a draught of hot or cold fluid, but the slightest jar upon any portion of the tooth is most acutely felt. The pain of toothache may continue with more or less severity and intermission for a long time, till either the sufferer is driven to the permanent cure of having the tooth extracted, or, as often happens,

TEE

too soon be submitted to; at the same time, it is worth while to suffer a little pain to save a tooth that is likely to do after-service, and that will bear stopping after the irritation of the nerve has subsided or been subdued. The aching of a decayed tooth is very often excited by cold, or by disorder of the digestive organs; when, therefore, the pain commences, the possibility of such causes should be investigated, and if they exist, they should be rectified (see Cold, Indigestion, &c.). If, however, after this has been done, the neuralgic irritation still continues, it may be advisable to give quinine, and also opium, as recommended under the article "Neuralgia:" counterirritation, in the form of blister or mustard plaster behind the ear, being also used. The agonising ache of the tooth itself requires to be quickly relieved, if possible, independent of the above remedies, which are to remove the tendency. The applications used to cure toothache would make a long list; one of the best is made by dissolving a drachm of gum mastic in chloroform, and adding to that half a drachm of pure carbolic acid; among the others, chloroform, creasote, and opium are the most useful. Even when tooth pain of a neuralgic character is associated with decay, the tincture of gelseminum will frequently relieve (see Neuralgia). Strong ammonia is also sometimes used with success; it probably acts partly by neutralising acid matters within the decaying tooth. The most effectual application which the author has ever used, is composed of creasote and strong solution of ammonia, of each one part, tincture of myrrh two parts. In some cases the ammonia and myrrh are effectual without the creasote. All these liquid applications are best introduced into the decayed tooth by means of a small pellet of cotton wool, soaked in them, and lightly laid in the cavity. If pressed in, its mechanical pressure on the nerve may counteract the good effects of the remedy, or even aggravate the pain. If the first use of an application does not relieve, the piece of cotton should be removed, and a fresh charged portion introduced; this is often successful. The applications which are most generally serviceable in toothache, are stimulants, which seem to act by destroying the sensibility of the nerve. This is now generally effected by dentists by means of a paste containing arsenic. It is sometimes difficult to find the opening into the pulp cavity of a tooth when small; not unfrequently it is situated at the neck of the tooth, where both enamel and cementum are thinnest.

The wisdom teeth, or last molars, are peculiarly susceptible of this species of decay. When the gums are much inflamed in toothache, much relief is sometimes given by lancing them freely around the tooth.

stopped, and is of no use, its removal cannot being merely a mechanical operation, certainly requires no great amount of knowledge, and is one performed in some villages still by the blacksmith or barber; some of these amateurs, by practice, tact, and strength of arm, perform it very well, though perhaps not so easily as the professed dentist, who uses improved instru-ments. The fact, however, is sufficient to show that any one, such as an emigrant, inclined to render himself useful, and perhaps make a little odd money, in an out-of-the-way place, may acquire the art. At the same time, perhaps, few would willingly trust themselves in the hands of an amateur, except from dire necessity; but as that necessity is not an uncommon one, the accomplishment of tooth drawing may be found not at all a useless one in some situations. It can scarcely be acquired properly, however, without a few practical lessons, which there can be little difficulty in obtaining, in this country at least. Various forms of forceps adapted to grasp each separate tooth are now employed by surgeons and dentists in tooth extraction, being preferred to the old fashioned instrument called the "key," on account of their less liability to injure the gums and jaw of the patient. Possibly an unprofessional person might find it necessary under certain circumstances to use either of these instruments, and it may be found advisable to add a few practical instructions as to their employment.

The key (fig. 212) is of the form represented,

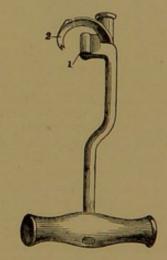

Fig. 212.

with the handle placed crosswise. The bolster (1) acts as a fulcrum; the claw (2) is fixed to the neck of the tooth, inside or outside, as may be most convenient for drawing, and the bolster made to press against the gum on the other side. The head of the patient being fixed by an assistant if the operation is on the lower jaw, the tooth is twisted out by the force of the leverage of the bolster against the gum or jaw. When the upper jaw is dealt with, it is most convenient to seat the patient on the Extraction of Teeth. -To extract a tooth, floor, or on a very low stool. The bolster

round, otherwise it bruises the gum unnecessarily. It is better with a gum-lancet to separate the gum from the tooth previously to drawing, otherwise the former may be torn.

Tooth forceps are much preferred to the key by dentists, and by medical practitioners generally, for the extraction of teeth. These are made by the chief instrument makers, with the claws varying in shape to fit the peculiarities of nearly every tooth of the upper as well as of the lower jaw. The pair figured represents the shape of the instrument commonly

Fig. 213.

used for molar teeth of the lower jaw, although they might also prove serviceable in extracting others. For the front teeth, both lower and upper, straight forceps, that is, forceps with the claws on a line with the handle of the instrument, are more generally used. Whatever forceps are obtained, they should be selected by some professional friend, and should not be so close or sharp as to risk cutting the tooth through. When used, one blade is to be fixed on the outer and the other on the inner side of the tooth, just within the gum margin, and the head being fixed, the tooth is drawn straight out of its socket by the force of traction, accompanied with a slight rotary and lateral motion.

It is impossible in the space of this work to enter as fully into this subject as might be; for those who desire more information, there are popular works published upon it at a moderate price. - See Gum Boil.

TEETOTALISM .- See INTOXICATION-STIMULANTS

TEMPER.—See Passion. TEMPERAMENT is a term which took its origin in the earlier stages of medical science, disease, seeing that it is in most instances, if it

should be padded by a piece of lint wrapped | when the constitution of the body was supposed to depend upon the proportional mixture or "tempering" of the four principal fluids or humours-the blood, the phlegm or lymph, the yellow, and the black bile. Hence, corresponding with these, there was the "sanguine," or blood temperament, the "phlegmatic" or "lymphathic," the "bilious" and the "atrabilious" or "melancholic." As these distinctions are applicable to certain recognised types of constitution they are atill retained with the constitution, they are still retained, with the addition of the "nervous" temperament. The sanguine temperament is usually distinguished by the ruddy complexion, blue eyes, and brown hair, and generally full large habit of body, with vigorous performance of the functions of life. The phlegmatic, sometimes called lymphatic temperament, is almost the reverse of the first. The functions of life are usually more feebly performed, the circulation is languid, the skin is pale, the hair light in colour. The choleric or bilious temperament is characterised by black often curling hair and beard, the latter being generally thick and strong; the eyes dark, the complexion ruddy though dark, and the circulation good. In the melancholic temperament the hair is black but straight, the skin is dark, but wants the red tinge of the true bilious; the circulation and the functions are slow and languid. The above temperaments are not unfrequently met with strongly defined in individuals, but in the majority they are mixed up with one another.

TENACULUM is a slender hook (fig. 214) to which a handle is attached, used by

Fig. 214.

surgeons for laying hold of and pulling forward a bleeding artery, so as to permit of its being secured. The instrument may be made to shut up into a handle or not, as convenient. It might be found useful in emigrant life.—See Artery-Instruments.

TENDERNESS, on pressure of any portion of the body, is a symptom which is always much regarded in the investigation of

TEN TES

inflammation. In making pressure, however, to ascertain the existence of tenderness, care must be taken, if possible, to bear upon the part examined with a sufficiently extended surface of the hand, and not to press too quickly or forcibly, otherwise the mere roughness of the examination mar cause pain, and

give the appearness of tenderness.

TENDO ACHILLIS is the remarkably strong tendon which connects the muscles of the calf of the leg with the heel. Any one may feel it in his own person. It is chiefly to be noticed here, on account of the not very uncommon accident of rupture, to which it is liable, particularly in heavy individuals. Perhaps, in making some unusual exertion, there is felt the sensation as of a violent blow upon the tendon, and if the person does not fall to the ground, he at once finds the power over the foot is lost. If the place is examined, the space left between the ruptured ends of the tendon may be distinctly felt. It is, of course, important that the injury to a part on which locomotion so greatly depends should be efficiently repaired; the case, therefore, should always, when possible, be treated by a medical man. The accident, however, is one liable to happen in out-of-the-way places; with a little care, its treatment may be efficiently managed even by an unprofessional person, at all events till skilled assistance is obtained. The principle of treatment is by relaxing the muscles of the calf, to permit the ruptured ends of the tendon to approach one another. To effect this, the palpable proceeding is to bend the knee and the foot as represented (fig. 215).

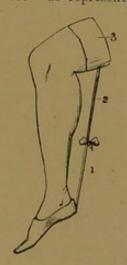

Fig 215.

To attain the position, it is sufficient to attach a strong cord or tape (1) to the heel of a slipper placed upon the foot; to attach a correspond-ing cord (2) to a band of some stout material, (3) stout calico will do, put round the lower part of the thigh; and this being done, to tie

is not in all, indicative of irritation or acute | be kept up for at least four or five weeks, at the end of which period gentle and gradual extension of the heel may be tried, but no attempt at walking should be made for a considerably longer period. Ultimately, if the case is properly treated, perfect recovery takes place. For some time after the above accident, it is advisable for the person to wear a high-heeled laced boot. Some apply a light bandage in addition to the apparatus described above

Refer to-Wounds.

TENDONS, popularly called leaders, are the strong fibrous extensions by means of which the muscles are attached to the bones. All tendons are liable to be divided by wound or by rupture; in these cases the nature of the accident is indicated by the loss of power over the limb or members. The treatment required is similar in principle to that for ruptured Achillis tendon—the relaxation of all the muscles which are connected with the injured part for a sufficient period to permit union.

TENT.—A piece of lint, sponge, or other material used for dilating openings, or for

keeping open wounds.

TEREBENE is a colourless volatile oil, derived from oil of turpentine by the action of heat and sulphuric acid. It is much used as an antiseptic dressing for wounds, many preferring it to carbolic acid on account of its pleasant pine-like odour. It may be applied in its pure state, but it is better to have it mixed with five or six times its quantity of olive oil. The preparation called "Sanitas," so extensively advertised, as a disinfecting agent, is an allied product to terebene.—See Sanitas.

TERTIAN.—See AGUE.

TESTICLES, the male organs, are liable to various affections. Inflammation is accompanied with severe pain and swelling; it requires the treatment of inflammation generally; leeching, fomentation, poultices, calomel, and Dover's powder, and aperients, with perfect rest in bed and low diet. Enlargement of the veins-varicocele-accumulation of fluid (see Hydrocele), and various chronic enlargements and diseases, occur in connexion with these glands, but for all a medical man's attendance is absolutely necessary. In the meantime, if the symptoms are urgent and painful, perfect rest in bed, avoidance of all stimuli, and attention to the state of the bowels, are the best measures. If circumstances prevent absolute rest, support should be given by a bag-truss the two cords together, so as to preserve the or suspender, or by some such contrivance as requisite amount of the flexure, which must that recommended in article Prolapsus.

THERAPEUTICS is the art and science of the application of remedies for the cure of disease. - See Medicine, and Medicine, Practice

THERMOMETER, or MEASURER OF HEAT.—The principle upon which this instrument depends is the expansion or contraction of a fluid according to the increase or diminution of sensible heat. The fluid used is sometimes spirit, but more generally it is mercury, on account of the equable manner in which this fluid metal alters its volume

with change of temperature. For the purposes of the measurement of heat, a thermometer is constructed by enclosing the mercury, or spirit, in a perfectly closed or hermetically sealed glass tube, with a bulb or expansion at one end; to this tube a regularly marked or graduated scale is attached, which indicates the changes undergone by the mercury within the tube in accordance with the changes in temperature. These scales may be, and are, differently graduated; it is here sufficient to notice the scale of "Fahrenheit," which is universally used in this country. In the Fahrenheit scale, or thermometer, the zero or starting point, or 0°, is placed 32 degrees below the temperature at which water freezes; consequently the freezing point of water is placed at 32°. Between this and the boiling point of water there are 180°, the latter, consequently, is marked on the scale 212°. Between these points there are other temperatures recognised, and usually marked on most thermometers; they are "temperate" at 55° "summer-heat" about 76°; animal or "blood-heat," 98°:4; and "hotbath" about 105°. A thermometer is an instrument which ought now, considering its low price, to be found in every house. For prac-tical purposes, such as ascertaining the temperature of baths, &c., it is best to have the tube fixed to a

five inches long, with a break in the column thorn, which is the most conspicuous part of

of mercury to allow a portion to remain when the thermometer is removed from the body, and with a contraction in the stem to prevent the registering portion of mercury from descending into the bulb. They are usually graduated from 90 to 112 degrees Fahr., and are made delicate enough to indicate tenths of a degree. It is customary, when using the instrument, to place it either in the armpit or in the mouth, and to allow the bulb to rest there for a few minutes, or till the observation can be taken with accuracy. The normal temperature of the blood is 98°4, while in fevers and in other inflammatory states, it may rise to 106°, or even higher. In the collapse stage of or even higher. cholera the body temperature diminishes, and has been registered as low as 82°, and in one case 73°. The accompanying illustration gives a view of Casella's clinical thermometer, with a patent arrangement for setting the index, and preventing it from being disarranged after an observation is taken. The arrangement is effected by means of a contraction below an expansion of the bore of the tube. The index C expands on reaching the chamber B, nearly filling the space, while by aid of the contraction below, the index is prevented from being lost in the mercury of the bulb.

Refer to Bath-Bed-room, &c.

THIGH .- The portion of the body which extends from the hip to the knee is composed principally of a mass of fleshy powerful muscles. The fold of the groin, at the junction of the thigh with the trunk, is one of the most important regions of the body in a surgical point of view, for close to it is the most usual seat of rupture (see Rupture); and at this point, towards the lower end, the large vessels which pass to and from the lower ex-Wounds of tremity lie very superficially. the groin are, therefore, particularly dangerous, and if the main artery is injured, life is placed in the most immediate peril (see Artery). A little below the groin, the vessel becomes more deeply imbedded in the muscles, and ultimately passes round the inner side of the thigh bone to reach the ham. The thigh bones (see Skeleton, fig. 190) are the longest bones of the body; from their ball and socket-joint at the hip they incline inwards towards one another at the knees. This inclination is more especially marked in the female, in consequence of the greater width of the pelvic bones.

body. For further information the reader is referred to articles Cut-Throat-Digestion-Gullet, which includes choking-Larynx-Laryngoscope — Mouth — Neck — Palate — Sore Throat—Tongue—Tonsils.

THROMBUS .- A clot of coagulated blood filling up the interior of a vein or artery, or occurring within the auricles or ventricles of the heart.

THRUSH.—See APHTHA.

THYMOL is obtained by distillation from oil of thyme, the distilled product being afterwards treated with a solution of soda, and the thymol set free by hydrochloric acid. Thymol is a crystalline substance of a strong aromatic odour, sparingly soluble in water, but readily dissolved in alcohol or ether. It is an excellent substitute for carbolic acid, and may be employed for all purposes for which the former agent has been so extensively used, possessing at the same time the advantage of an agreeable odour, and of not irritating the skin, or corroding instruments. For surgical dressings the following solution is recommended :- one part of thymol, ten of alcohol, twenty of glycerine, with 1000 parts of water. As a ready antiseptic agent, a spirit of thymol, made with an ounce of thymol dissolved in three ounces of alcohol, may be kept in the sick room. A table-spoonful of the spirit added to half a gallon of water makes an excellent and agreeable wash for the hands, face, and hair, after exposure to infection.—See Disinfectants.

THYMUS GLAND - a glandular body situated behind the upper portion of the breast-bone; it is larger at birth, and during the first year of infancy, than at any subsequent period

TIC DOULOUREUX .- See NEURALGIA. TIGHT LACING. - See EDUCATION.

TIN TOB

TINCTURES are solutions of medicinal | tion, in quantity certainly sufficient to injure. substances in alcoholic spirit, either rectified or proof. Rectified spirit, which consists of eight parts of alcohol to one of water, ought to have a specific gravity of 838°. Proof spirit, which consists of five parts of rectified spirit to three of water, ought to have a specific gravity of 920°. The above different strengths are employed according to the solubility in spirit of the active principles of the drug from which the tincture is made. Some drugs, such as camphor, are entirely dissolved in rectified spirit. The general directions for making tinctures are, that the drug, if it is in solid substance, should be divided into small fragments, or into coarse or fine powder, as the case may be; it is then to be macerated in the spirit in a closed bottle for a certain period-generally from seven days to a fortnight, and after that strained through a cloth, or filtered through paper, or both (see Filter). During the maceration, the bottle is to be frequently shaken, and when the straining takes place, the solid is to be freed from the fluid as thoroughly as possible by pressure in a cloth. This may be done by hand, but much more effectually by means of a "tincture press" made for the purpose. Indeed, some substances, such as squill, cannot be at all properly exhausted without the aid of a press. Many tinctures are made by the process of percolation, that is, by transferring the ingredients for maceration to a percolator, and when the fluid ceases to pass through the percolating filter, adding the portion of spirit reserved for the purpose, from the first step of the process; afterwards subjecting the contents of the percolator to pressure, filtering the products and mixing the liquids.

As medical preparations, tinctures possess many special advantages, not the least being their keeping properties; moreover, the form of tincture often facilitates the use of a drug in a state of solubility, and therefore of activity, which could not be attained in any other way. Except in those cases, when the stimulant action of the spirit is desirable, tinctures are best adapted as vehicles for medicines which act in small doses; if the action required from medicine be not stimulant, or rather the reverse, the form of tincture cannot be employed with advantage, that is, if such a dose is required that the stimulant properties of the spirit will be sensibly manifested. For instance, although rhubarb is an aperient medicine, which may safely be given alone, even when fever exists, it would be very injurious under such circumstances to give it for its aperient action in the form of tincture, in which case the dose must be from half an ounce to an ounce or more. Even in the case of the comparatively mild antimonial wine, the author has frequently had to point out the injury which may result from dosing children suffering from inflammatory attacks, or head affection, with this prepara-

Of course, when tinctures, such as those of rhubarb, ginger, orange peel, &c., are avowedly stimulant, and given for stimulant purposes, the presence of the spirit is rather an assistance than otherwise, but the rule should be borne in mind, that unless stimulant action is required, or at least admissible, a medicine ought never to be given in tincture, if the dose which must be administered involves an amount of spirit which will be felt by the system.

The list of tinctures is a very long one; the following will be found most useful for domestic

use:-

Tincture of Arnica. Calumba. Camphor. Cardamoms, compound. Catechu. Ginger. Henbane. Perchloride of Iron. Lavender, compound. Myrrh. Opium or Laudanum. Opium, ammoniated. Orange Peel. Rhubarb. Squill.

To the individual articles the reader is referred: in a few, directions for preparing the tincture are given; but, generally speaking, it is both more convenient and economical for domestic purpose to purchase the tinctures

ready prepared.

TOAD.—The poisonous properties of this reptile have at times been doubted, but it seems well ascertained that the follicles of the skin do contain an extremely acrid fluid, capable of acting on the body like the poison of the wasp, or of snakes. - See Wounds, Poisoned-Stings.

TOASTED BREAD, if not cut too thick, and if toasted slowly, is probably somewhat more digestible than simple bread—it is more thoroughly cooked. Toast, when soaked with melted butter, is one of the most unwholesome and irritating articles of diet that an invalid can take.

TOAST WATER .- See COOKERY FOR

THE SICK.

TOBACCO.—This article, a luxury, a drug, or a poison, is the leaf of the Nicotiana tabacum, a native of America, both Northern and Southern, but now cultivated extensively throughout the world, and even capable of being so in the climate of Britain. The leaf is large and oval shaped. Very many kinds of tobacco are met with; the Virginia, which is one of the strongest, is used in medical practice in the form of infusion, but is no remedy for domestic employment. Tobacco, however, re-quires consideration on account of its too widely TOB TOB

mode in which it is taken into the body. Applied locally, as in the familiar form of snuff, it acts as a powerful irritant; taken into the stomach, or injected into the bowels-as it sometimes is by medical men-in the form of infusion, it depresses powerfully the action of the heart, causing fluttering, and a sense of sinking about that vital organ, with deadly faintness, and a tendency to relaxation of the bowels. and if the dose be large, death. Taken into the system by the lungs, in the form of smoke, for the first time, its narcotic rather than its sedative action is exhibited; it acts upon the brain, causing giddiness, inclination to vomit, &c., and at the same time it de-presses. The effects of tobacco, especially as it is usually employed, vary of course according to the strength and nature of the variety used, and also according to the original constitution and acquired habits of the individual. Few, perhaps, if any, there are, who on first commencing the use of tobacco, escape unpleasant effects from its narcotic and sedative properties, and some individuals never lose their susceptibility to be affected thereby, others become so far habituated to the use of the drug, that these effects are not developed, and others seem to become capable of deriving peculiar restorative influences from its use, experiencing, especially under conditions of exhaustion or irritability, a mixture of stimulant and sedative action which is described as peculiarly grateful.

A drug which is capable of acting so powerfully upon the system as tobacco, cannot, certainly, be habitually made use of without its influencing the functions of the body more or less; much more, probably, in some than in others, but to a considerable extent in all. Opinions vary greatly as to the actual influence which tobacco, when habitually used, exerts upon the constitution; this may perhaps be accounted for by the fact that some, from whom the opinions have proceeded, have them-selves been lovers of the "weed," and naturally prejudiced in its favour; few, however, are found to defend it as entirely innocuous, and medical men generally are agreed that, in some constitutions at least, it is highly injurious. those of the melancholic temperament it seems

to exert peculiarly injurious effects.

When the habit of "snuffing" causes injury, it is more usually to the digestive organs, and in some persons it certainly gives rise to dyspepsia: indeed, according to Dr. Prout, it may occasion malignant disease of the stomach and liver. Chewing tobacco acts as an excitant upon the salivary glands; if the saliva is swallowed, the narcotic properties of the drug

are called into action.

The most obvious injury which is apt to result from smoking, more or less, according to the extent in which it is indulged, is disorder

apon the human system vary according to the | quently accompanied with depression of spirits, and at times with extreme nervous irritability, the latter being more especially manifested in an inveterate smoker, if, from illness or any cause, his habitual indulgence is interfered Very recently, the author saw this well exemplified in the case of a strong countryman, a constant smoker, but otherwise not intemperate. He was attacked with fever; in the course of a few days, in consequence, apparently, of the interrupted use of the tobacco. for by no other reason could they be accounted for, nervous symptoms set in with extreme violence, threatening a speedy fatal termination, and requiring the continual use of opium to keep them in any way under control. In many persons addicted to smoking, especially in those who naturally possess the "melancholic" complexion, the skin seems to acquire a darker, and somewhat of a greenish hue. According to Dr. Prout, a tendency to urinary disorderoxaluria-is excited. The local injury caused by tobacco smoking is well ascertained; the bad effects, doubtless, are partly due to the heat of the process. Under article Lip, the occurrence of cancer in those who habitually smoke from a short pipe was noticed; the injury to the teeth from smoking, and especially their discoloration, is notorious, and, further, we have the valuable authority of Dr. Green of New York, to prove that disease of the throat and air passages is apt to follow indulgence in this useless petty vice. He remarks: "As an exciting cause, the use of tobacco, in my experience, has proved a powerful agent in the production of follicular disease of the throat. Acting as a stimulant directly and constantly upon the mucous follicles of the fauces and throat, and greatly increasing, as it does, the secretion of these glands, its employment, as we should conclude, à priori, must have a direct tendency to develop the disease, especially if a predisposition to the affection exists; hence it has occurred to me to notice that of a great number of cases of throat-evil, which during the last year or two have come under my observation, a large proportion of them have taken place in individuals who had been, or were at the time, in the habitual use of tobacco. My attention has been called more particularly to this subject from having noticed, several years ago, some observations on the use of tobacco, in laryngeal and bronchial affections, by an eminent surgeon of this city. After having alluded to the almost universal use of tobacco in the countries of northern Europe, he observes: 'In one very fatal and distressing form of disease, to wit, laryngeal phthisis and bronchitis, among public speakers, the fact is very clearly established, that the moderate habit of smoking, by the drain it accomplishes, and its anodyne qualities, has been eminently useful, at least as a preventive of that peculiar malady the extent in which it is indulged, is disorder so frequent in the United States, especially and irritation of the digestive organs, fre- among the clergy.' From this opinion of my

603

TON TOE

compelled to differ entirely, by the statistical facts which I have obtained on this subject. Not only has the use of tobacco, in any and all its forms, proved to my experience an exciting cause of larvngeal disease, but where its employment has been persisted in during the treatment of any case, I have found it impossible to restore such to perfect health.'

Enough, perhaps, has now been said to convince that, although the use of tobacco may be indulged in by some, perhaps by many, and to a considerable extent, without very evident injury, there is a large proportion of constitutions in which it is almost a direct poison, sapping the whole foundations of health. The wide extension of the use of tobacco by man since its introduction from the "new world," in the middle of the sixteenth century, is one of the most singular facts of human history; for it is to all, perhaps, at first, a nauseous, acrid, disagreeable drug, which causes uncomfortable sensations in whatever form it is used.

The objections to smoking tobacco as a mere habit do not, of course, extend to its employment as a remedy in disease, particularly of an asthmatic character, in which some persons derive the greatest benefit from its moderate use.

In any case in which the use of tobacco has produced the symptoms described at the commencement of this article in alarming degree, general treatment, somewhat similar to that pointed out under article Belladonna, may be employed.—See Smoking.

TOES .- See Bunion - Corn-Fracture,

TOLU.—See Balsam.

TONGUE.—The organ of speech and taste (fig. 219) is composed of muscular fibres running

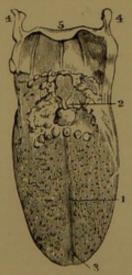

Fig. 219.

through it in different directions, mingled with a considerable amount of cellular and fatty matter, it is abundantly supplied with vessels | man, in case it should be necessary to excise a

distingushed countryman and friend, I am | and nerves. The tongue is divided in the centre by a depressed line, the "raphe" (fig. 219 It is covered by a dense mucous membrane, continuous with that of the mouth, on which are numerous "papille," small towards the tip, but becoming much enlarged (fig. 219-2) towards the back part of the tongue. At the tip, underneath, the tongue, as any one may see in his own person, is confined by a bridle or tie, or "frænum;" at its root, the tongue is con-nected with a curved bone, the "hyoid," the extremities of which are represented (4, 4); between these also, at the root, is the "epiglottis" (5). - See Throat - Larynx - Skeleton.

It is superfluous here to dwell upon the wellknown facility of motion and acute sensation by which the tongue is enabled to perform its well-known functions of speech (see Speech). Taste may be regarded as similar in kind to the sense of touch, but as more exalted in degree: some amount of solubility in the substance placed in the mouth appears requisite for its development. Taste, like other sensations, is liable to alteration and perversion in

disordered states of the system.

In a medical point of view, the tongue has to be regarded both with reference to its own disorders, and to the indications it affords of disorder in other parts of the system. The tongue is liable to inflammation, although cases of it are rare. When it occurs, the most prominent symptom, in addition to the constitutional affection, is the enormous swelling, which causes the organ to protrude from the mouth, and at the same time threatens suffocation; it is therefore, a very serious affection, and one which requires the immediate attention of a medical man. The remedial measure which gives most relief is to make two free longitudinal incisions down each side of the tongue; these, of course, admit of copious bleeding, but as the tongue diminishes in size, the cuts and the flow of blood also diminish. The remedy is one which might be practised by an unprofessional person in a case of urgent necessity; at least it would be better to do it, even at some risk, than to permit an individual to die of suffocation whilst medical assistance was being procured. Ulceration of the tongue may occur as a symptom of digestive disorder, as a consequence of mercurial salivation, or from local causes, such as the presence of decayed teeth, especially with ragged or sharp edges (see Aphtha-Indigestion-Mercury, &c.). Of course, when teeth stumps are the exciting cause, they should at once be removed. In many cases of ulceration, the local treatment recommended under Aphtha may be pursued with advantage.

Cancer of the tongue is one of the most distressing maladies to which humanity is liable; it may in some cases be removed with advantage by operation; at all events, any persistent sore upon the organ should be submitted without delay to the examination of a medical portion, which is only successful when performed at an early stage of the growth. For the affection known as Tongue-tie, see Child-

hood-Speech.

As all are aware, the condition and appearance of the tongue are indications almost always consulted by a medical man in investigating a case of disease, and most valuable guides they are at times, when experience and observation have given the power of reading them aright. When the appearances of the tongue, however, are admitted as evidence, consideration must always be given to the natural state of the organ in the individual, for some never have a clean tongue, whilst in others it scarcely becomes furred, even when considerable disorder is going on in the system. In chronic disorders, especially of the digestive organs, the most valuable indications are often afforded by the tongue, immediately after the night's sleep, before food has been taken. Persons who sleep with their mouths open generally have a dry tongue in consequence, but in most persons in health, the mouth should be pleasantly moist on awakening in the morning; if it is the reverse, if the tongue is dry, or clammy, or viscid, and covered with fur, there is usually disorder of the digestive organs, permanent or temporary, from some indiscretion in food, and especially in the use of stimulants. In feverish conditions of the system generally, the tongue is liable to become dry. The appearance of the fur on the tongue varies greatly; it may be thick and dirty white, as it is in stomach and febrile disorders, and especially in sore throat; it may be a thin creamy looking white, as in inflammatory disease within the abdomen; or it may be yellow, as in biliary disorder. It may be patchy, as in scarlatina; or, the centre and sides of the tongue being preternaturally red, as in some forms of intestinal irritation, may contrast with the white fur in other parts. Further, the tongue may be morbidly clean and red also in intestinal irritation and in hæmorrhage; in the former case, perhaps, feeling sore as if scalded; or the papillæ may be elongated as in scarlatina. Again, partaking of the general anæmic condition of the system, the tongue may be pale, when it is also usually broad and flat, indicating general want of tone and flaccidity of fibre. motions of the tongue, moreover, when it is protruded, give a clue to the state of the nervous system especially; thus, in paralysis of one side of the body, it is protruded towards the paralysed side; in delirium tremens and nervous affections it is tremulous; in the low stages of fever it perhaps cannot be protruded

Such are a few indications afforded by the tongue. As the appearances in each particular disease are adverted to under the individual articles, it is unnecessary to pursue the subject here.

TONICS are remedies which improve the health, muscular tone, or vigour of the system; many medicines, properly so called, possess this power, and are therefore classed as tonics; but other means of health, both mental and physical,

are included in the category.

When an individual is in good health, the muscular fibre throughout the body, both voluntary and involuntary, possesses a certain amount of tone, or tonicity, the flesh feels firm, and the actions performed in obedience to the will are effected regularly and decidedly. When, on the other hand, the health becomes impaired, the muscles and fibres generally become "flabby and incapable of continued exertion, but are sometimes irritable, with the tremulousness of debility." These changes in tone are most strikingly manifested in children, in whom they take place with great rapidity; every mother or nurse is practically aware of the fact, and judges greatly and rightly of the health of her young charges by the firmness of the flesh. The connexion between a state of proper tone or the reverse, with the actual physical condition of the muscular fibre, may be "demonstrated by detaching a muscle from the bodies of two animals in these opposite conditions, and ascertaining its strength by appending weights to it; the muscle taken from the healthy animal, or that in a state of tone, will sustain a much greater weight than that which is in the opposite state." Tonics, therefore, are remedies which tend to correct the want of the tone above described by exciting the reverse or tonic condition. In this way food of particular kinds may be regarded as tonic. The "condition" of the horse, as all know, is a state in which the muscular power and endurance is augmented to a high pitch by means of the stimulant power of dry corn food, in contrast to the comparatively weak muscular tone which can be obtained from green food.

Indeed, if the word tonic be taken in its widest sense, it would include a vast number of agents; medically, however, it is used more

restrictedly.

The medicinal tonics may be classed as— Tonics which act directly by influencing the stomach, and increasing its digestive powers.

Tonics which act indirectly, by passing into, and exerting their influence through the

blood.

The first, or stomachic tonics, are chiefly the vegetable bitters; of these the most important, at least in a domestic point of view, are—

Calumba. Hops.
Chamomile. Quassia.
Cinchona Bark. Salicine.
Gentian.

To which are to be added the mineral acids. The second, or indirect tonics, including nervine and vascular tonics, comprise iron in its various preparations animal and vascular ble sile.

and arsenical salts, to which, perhaps, may be added the vegetable acids.

The non-medicinal tonics are-

Cold in its various forms and applications.

Exercise and fresh air.

Mental emotions of a pleasing and stimulat-

ing character.

From the above, it may be seen that the action of a tonic is of a stimulant or excitant character; it is, however, distinguished by its permanency, in contradistinction to the transient action of stimulants proper. In order, therefore, to insure the proper action of a tonic, it is requisite to administer it in small doses, which do not cause appreciable stimulation, and at short intervals, once, twice, or three times, according to circumstances, in the twenty-four hours. At the same time, there is a limit to the use of tonics; some, such as iron, if too long continued, are apt to occasion un-comfortable sensations in the head and elsewhere, and bitter tonics, if given regularly for a length of time, at last tend rather to weaken than to strengthen the digestive powers. On this account, it is to be feared that the now fashionable "bitter beer," although a most excellent beverage and tonic in some states of the system, may, if taken too continuously, tend rather to mischief than benefit. As the employment of tonics in different affections and states of the body is entered into in the individual articles, it is unnecessary to pursue the subject further here. - Refer to - Excitants -Stimulants

TONSILS are the almond-shaped bodies situated on each side of the "fauces" (see *Throat*), and between the folds or "pillars" of the soft palate (see *Palate*). They are glands

which secrete a mucous fluid.

The tonsils are liable to inflammation, constituting "sore throat," or quinsy (see Sore Throat). They may also be the seat of ulcerations, and often become enlarged. In the former case - ulceration - astringent gargles may be used, and any disorder of the general health attended to. Enlargement of the tonsils is a very common affection, particularly in scrofulous constitutions, and may come on very early in life. When considerable, it may occasion some difficulty in swallowing, and always gives rise to thickness of speech; the subjects of it, too, are more than usually subject to attacks of sore throat or quinsy. When the enlargement is great, and causes much inconvenience, it is remedied by the simple and not very painful operation of slicing off the most prominent portion of each gland; this, of course, must be done by a surgeon. When, however, the operation is not required, or is objected to, much may be done to reduce the size of the glands, by the use of astringent gargles (see Garg'es) or pigments such as glycerine of tannic acid, and by attention to any deficiency in the general health.— See Scrotula—Sore Throat—Debility, &c.

TOOTH-ACHE .- See TEETH.

TORMENTIL, or TORMENTILLA OFFI-CINALIS, is a plant native to Britain, and common on moor ground or hill pastures. It bears a small yellow flower, with four, rarely five, petals, and the stems are straggling. The root of the tormentil is so powerfully astringent that it is used in various places for tanning, and the same property gives it active remedial powers, which have been, perhaps, too much overlooked. There is no reason why tormentil should not be used in place of more expensive and further fetched astringents. The root, which is the part used, is short, and thick for the size of the plant; dark brown externally, and reddish within. When powdered, it is given in from half drachm to drachm doses. The decoction is made by boiling two ounces of the bruised root in thirty ounces of water, till it is reduced one-third, and straining. dose of the decoction is an ounce and a half. It may also be used as an astringent gargle or lotion. Tormentil root, as an officinal remedy, has been expunged from the British Pharma-

TORPOR.—See DEBILITY, &c.

TORQUAY-One of the best known, and probably the most beautiful, of the southern health resorts of Britain, presents many, it may be said unequalled, advantages. Although Torbay has a south-eastern aspect, the town faces for the most part due south, being protected from the north and east by limestone hills of greater or less elevation up to 450 feet; the hills being intersected by "combes" or valleys, sloping down to the sea in diverse directions, and both hills and valleys being profusely clothed with shrubs and trees, mostly evergreen, the winter shelter is very complete. Torquay, of course, being in Devonshire, has a considerable rain-fall; in flat and heavy soiled localities a great drawback, but in a place situated like Torquay a decided advantage. It is not the rain that falls, but the wet that remains, which is injurious; in Torquay it cannot remain, indeed the combination of slope and limestone subsoil carries off the water almost too quickly. Falling rain washes the air, the roads, and the drains, and adds greatly to the salubrity of a town, especially when the main drainage is in the perfect condition in which it is in Torquay, where, in the absence of rain, the water supply is abundant, few towns enjoying a freer and purer supply than Torquay, which obtains its water from the granite hills of Dartmoor, where no contaminations can reach it, and where mineral ingredients cannot impair its natural softness. which equals that of the Loch Katrine water supplied to Glasgow.

We have here, then, a combination which tends to make a Health Resort as complete as possible—a southern aspect, variety of elevation, dry subsoil, a sufficient rainfall to keep all, air included, well washed and purified; a perfect

TOT

of pure fresh water; whilst to these must be added the sea, not merely forming, but almost surrounding, the peninsula upon which Torquay is situated. One more advantage (and that not a light one for invalids): there is the great natural beauty, not surrounding only, but interweaving this town of villas, and the ever varying aspects of the country around, embracing sea-coast, cliffs, inland pasture, wood and orchard, gradually rising into the heathy uplands, wild moors, and rugged "Tors" of Dartmoor. As a winter health resort, Torquay has long since made its reputation, and has maintained it, spite of the rivalry of less favoured spots. As a summer resort, it has of late come more into notice, and deservedly so. When Torquay consisted only of a few villas and terraces under the cliffs, it was said to be a "hot place in summer," but now that it has spread itself far and wide over the foliaged hills, it is as cool as, perhaps cooler in summer than, most southern places; the sea breeze which is ever passing over the Torquay peninsula keeps down the general temperature to a very moderate level in summer, and in winter the same cause has the very opposite effect of raising the temperature above the inland level. In summer the sea is cooler than the air; in winter, on the south coast at all events, it is

Of course neither Torquay nor any southern health resort can boast of the continued winter sunshine of the shores of the Mediterranean; but offering many climatic advantages, it can also supply the requirements of a well-ordered, beautiful English town, with the comforts and amenities of English home life, within reach of friends and all that is therein implied.

The merits of Torquay as a winter residence for invalids generally, and especially for those suffering from chest affections, are too well known to require comment here; how far they are to be taken advantage of depends greatly upon the medical adviser at home and his knowledge of the subject.

TOTAL ABSTINENCE.—See STIMU-

TOURNIQUET — from the French, to turn, is an instrument (fig. 220) used by surgeons to stop the flow of blood in a limb during operations, or after accidents. For the latter purpose, the tourniquet might be found of great service in out-of-the-way places, and might well form an addition to the outfit of the emigrant. The instrument consists, essentially, of an upper and lower plate (1 and 2), which can be separated from each other by means of a strong screw (3). Connected with the plates are rollers (4, 4), and through these rollers is run a strong band of webbing or other material (5), with a buckle (6) at one end, and a movable pad (7). When the tourniquet is applied, the band (5) is buckled round the limb, and the pad (7) is so adjusted as to press

system of main-drainage, and an ample supply of pure fresh water; whilst to these must be added the sea, not merely forming, but almost surrounding, the peninsula upon which Torquay is situated. One more advantage (and that not a light one for invalids): there is the great natural beauty, not surrounding only, but interweaving this town of villas, and the ever varying aspects of the country around, em-

The above remarks will probably make evident the invaluable assistance which may be derived from the tourniquet, in cases of wound or accident; as, however, the instrument may

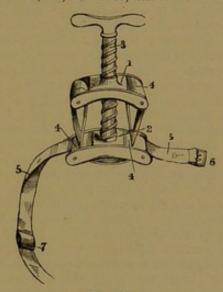

Fig. 220.

not be always forthcoming, it is to be borne in mind that its principle of application is pressure on the course of a bleeding vessel, by means of a pad secured by a band round the limb, which can be tightened or relaxed at pleasure, and that these effects may be brought to bear by means of a pad of the first convenient material at hand, a folded stocking will do, a pocket-handkerchief tied round the limb, and a short stick to tighten the latter by twisting.

Refer to—Artery—Arterial Homorrhage— Emergencies.

TOUS-LES-MOIS. — A substitute for arrow-root, now imported into this country from the West Indies, where it is said to be equally esteemed with the latter for dietetic purposes. The starch granules (see Fecula) are considerably larger than those of arrow-root.

TOW is a valuable appliance in the sick-room, and may be used as a substitute for cotton wool in padding splints and in bathing wounds. When spread out to the required size, it forms an excellent support, instead of rag or lint, for the basis of a poultice, the outer edges of the tow being rolled round with the fingers to form a border, to prevent the material of the poultice from escaping or slipping. Carbolised tow and finely carded oakum are the best appliances for soaking up-offensive matters from wounds.

TOW TRA

TOWN .- See Houses, Life, and the various articles referred to under Sanitation.

TOXICOLOGY—the study of poisons. See Poisons.

TRACHEA.—The windpipe. See Lungs. TRAGACANTH GUM. - See GUM.

TRAINING is a system which has been practised, both in ancient and modern times, for bringing the animal body up to as high a pitch of health, tone, and muscular power as possible. If the ulterior purposes for which training is practised in these days are neither desirable nor elevated, the system itself and the effects of it are worthy of attention as bearing upon the subject of health and development. Of course, those in whom great muscular power is desired as the result of training, must possess at first some amount of constitutional vigour, good assimilative powers, and be free from disease, or even disorder of a temporary nature; if the latter should exist, it must be removed by medicine or otherwise.

The body being in good health, the object in training must be to get as much food as possible containing albuminous principles, well assimilated (see Food); that is to say, although saccharine and starchy substances must be taken in sufficient proportion to maintain health, it is upon the animal muscular fibre, that of beef or mutton especially, and also upon the dry farinacea, such as bread, on which reliance must be placed to supply the albuminous or plastic elements of muscular development and power. Animal food, therefore—beef and mutton especially, as being most easily digested, -must be freely allowed, and must, moreover, be well digested. In order to insure proper assimilation and health, coincident with the consumption of a large allowance of animal food, abundant exercise is absolutely requisite. This, it is true, must exhaust a greater amount of muscular tissue than if the individual kept at rest; but by the stimulus it imparts to all the functions, and to those of digestion and circulation in particular, it seems to confer the power of assimilating strong nourishment in greater proportion than is requisite to repair the loss by the waste arising from increased muscular movement. Thus there are the two first principles of training, the healthy assimilation of abundant strong nourishment — lean animal food—and the working up, so to speak, of that nourishment into the system by the aid of regular exercise, not carried to that stage of excess in which the stomach and other assimilative organs partake of the exhaustion, and fail in their functions. In order, however, that the assimilative processes may work to full advantage, the other functions must be in healthy working order: the capacity of the lungs should be good where great strength is required, and the air drawn in pure and dry; the skin should be clear of all impediments to its important fulfilments; sleep should be although it is well, if possible, to avoid mak-sufficient to thoroughly recruit the frame (see ing any connection with a drain which is not

Sleep), and should be taken on a tolerably hard bed, with light covering, which will not tend to cause perspiration, or to relax. Much fluid is to be avoided; and if stimulants are taken, table beer is perhaps the best; wine mingled with water, next; but spirits never. As above stated, where muscular development is the object, animal food, with bread, must be the staple; vegetables being used only in sufficient quantity to preserve health; but all puddings, pastry, or soft food of any kind, are incompatible with the end in view.

In fact, training, being the endeavour to bring the physical power and endurance up to the highest possible pitch, is a system of hygiene, from which all may derive information respecting the management and improvement of health, without their object being

the cultivation of brute force.

It must not, however, be imagined that it is laid down as a principle, that animal food in large quantity, or even at all, is absolutely requisite for the development of great muscular power; this experience tells us it is not. Some of the most powerful and hardy nations of old subsisted solely on vegetable food, and many modern tribes, noted for strength and endurance, do so. These facts, and many others which might be cited, prove that great muscular power is quite compatible with a vegetable diet, if combined with habitual muscular exertion. There can be no question, however, that by means of animal food the system may be more quickly worked up to a state of high tone and condition, but for temporary purposes only; the state is one, in fact, of artificial excitement, and cannot be maintained for any great length of time. It is now generally understood that many of the fanciful restrictions as to diet among trainers are quite unnecessary, and that common sense, after all, is the best guide as to the quantity and quality of the food and exercise which ought to be taken to bring the body into the athletic condition.

Refer to-Food-Dietaries, &c.

TRANCE.—Catalepsy.—See Catalepsy. TRAPS .- The function of traps has already been mentioned under the section devoted to Drainage. There are certain conditions with which all traps must comply in order to be effective. They should be self-cleansing, otherwise solid matter will collect in them which will soon begin to decompose and give rise to a nuisance. To avoid this it is essential that they should be quite free from angles, projections, or cavities. The water-seal must also be of sufficient depth, 14 inches being the least which is compatible with safety. Again, as it is the water in a trap which constitutes the seal, in the case of drains which are only in use at intervals it is necessary to guard against the lowering of the water from evaporation by replenishing it from time to time,

likely to be regularly in use. A bend in a pipe, sufficient to form a syphon, gives the best example of a trap when made of lead (as represented in fig. 221), with a cap and screw attached to it for unstopping or cleansing. It is most useful for sink-wastes, &c., and has superseded the old and objectionable bell trap.

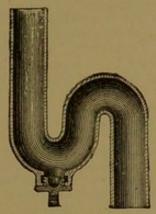

Fig. 221.

Traps are very liable to become unsealed by syphon action, particularly when more than one trap is connected with a waste-pipe, an arrangement which is frequently met with in the case of baths and lavatory basins, or where a series of lavatory basins are connected with one waste pipe. To avoid this danger it is necessary to connect an air-pipe with the top of the trap beyond the water-seal, as is shown in the drawing (fig. 222, AA).

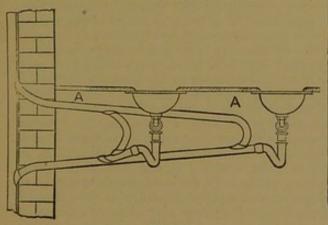

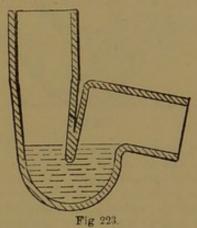

Fig. 222.

Pressure of foul gas within the drain is not an uncommon cause of foul smells being given off from traps by the water-seal being forced—a risk which can be guarded against by the proper ventilation of drains and sewers. Foul gases may also be absorbed by the surface of the water on the far side of the trap, and be given off from the surface of the water on the house side.

An improved syphon trap (fig. 223), called the anti-D-trap, as it is designed to take the place of the highly objectionable D-trap, which invariably used to be fixed in connection with water-closets, has been introduced comparatively recently by Mr. Hellyer, of the firm of Dent & Hellyer, Newcastle Street, Strand, and is designed to meet all the conditions already mentioned. It will be noticed that the diameter of the throat or bend is smaller than that of the mouth and out-go, and that the latter, in place of being round in shape, is square. Both these peculiarities tend to diminish the risk of syphonage, besides which the narrowing of the throat facilitates the displacement of the contents, in other words, improves the self-cleansing property, a requirement which in the case of water-closets especially is all important.

Dean's traps are excellent examples of open air traps available for any purpose except the passage of soil, and for any situation. The trap (fig. 224), which is in most use, consists

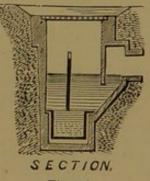

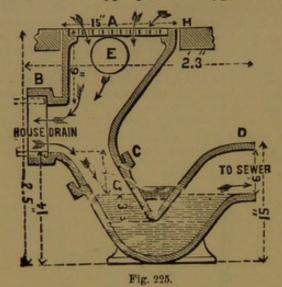

Fig. 224.

of a round or square trough covered with a grating for the admission of waste and surface water, and half way up the side of the tank is an exit opening communicating with the drain.

As an example of a trap fitted alike for house drains or sewers, and available for waste water or soil, that suggested by Mr. Hellyer is among the best and most used. It is made of stone-ware in different sizes (fig. 225), and consists of an interceptor C, D, shaped like the letter V, with a water dip of not less than 3 inches, to check any reflux of gas from the sewer. In the size represented, the calibre of the tube is six inches, but smaller and larger sizes are made to suit special requirements. The soil or waste water from the house drain B, falls with

and displaces it with a comparatively small flush, while the upper part of the syphon, or air

chamber, is made large to allow of free ventilation, and to afford a ready ingress to the currents of surface water. The circular opening E is intended for the reception of any other rain or waste pipe, which it might be thought desirable to empty into the syphon. Besides the hydraulic traps, there is also

the flap or hinge trap, which consists of a circular iron plate suspended over the mouth of the drain; this is only suitable for fixing at the outlet of a sewer into which sewage is likely to backpound, as, for example, when it

discharges into the sea.

Cautions ! — One word of caution — as all drain traps have a tendency to obstruct the flow of sewage, discretion must be exercised in making use of them. It is a popular fallacy to suppose that traps will correct all drainage evils, and that wherever a smell is experienced they are the necessary remedy. Again, as a rule, too little attention is paid to the ventilation of drains, and their disconnection from houses, and it is a common mistake on the part of inexperienced plumbers to suppose that the disconnection of a house waste-pipe from the drain by means of a gully trap does away with the necessity of trapping the waste-pipe All waste-pipes should be trapped itself. within the house as well as disconnected from the drain without.

It is a common practice to introduce a trap at the point where the soil-pipe joins the drain, but this is not the proper position for it. It should be introduced at the furthest point in the course of the drain before it joins the sewer or cesspool, as the case may be. When it is placed near to the house, any smell which may issue from the air-opening of the trap when the closet is used may enter the house through open windows. Besides, by introducing a trap in the course of a drain

considerable force on the water in the trup G, near to the house, the soil-pipe ventilator and displaces it with a comparatively small cannot then serve the useful purpose of a drain ventilator.

> TRAVELLING is both an excitant and a tonic, and, as a remedial measure, in some cases, offers advantages by no other mode attainable (see *Recreation*). Most persons, when undergoing continued travelling, suffer from slight irritable feverishness of the system, particularly if the usual rest be interfered with; the effects of this are best counteracted by spare diet and avoidance of stimulants. Animal food, if taker at all, should be so sparingly, and the best restorative, except, of course, in real debility, when wine is required, is a cup of tea or coffee. A warm bath at about 920 is an excellent soother of the system after travelling.

TREMOR, or TREMBLING, is a symptom and accompaniment of nervous debility and exhaustion, as exemplified in those who exhaust the system by the abuse of ardent spirits. In some diseases, such as fever, the occurrence of tremor is a grave symptom, indicative of

giving way of the vital power.

Refer to-Nervous Disease-Delirium Tre-

TREPHINE .- A circular saw used by surgeons for removing portions of the skull.

TRICHINIASIS.—This disease, which has excited much attention and alarm, derives its name and origin from the presence of a minute worm, the Trichina spiralis, in the flesh

of certain animals used as human food, particularly in that of the pig. There is no doubt that cases of poisoning have frequently occurred from this cause before the true nature of the malady was discovered, and there is reason to fear that the disease may still occasionally arise among persons who have incautiously indulged in pork or smoked sausages which have not undergone a cooking process sufficient to destroy the vitality of the parasite. The disease usually sets in a few days after eating the infected meat, with loss of appetite, nausea, and general prostration, followed by fever, with pains in the limbs, swelling of the face, and copious perspiration. In the worst class of cases, these symptoms are supplemented with vomiting and persistent diarrhœa, and some of the most alarming signs of typhoid fever, with which disease it has no doubt been often confounded. Trichiniasis, though at all times to be dreaded, is not necessarily a fatal complaint, as the minute worms, after finding their way into the fleshy parts, their natural habitat, become encapsuled or embedded in the muscle and remain quietly at rest, causing little or no further disturbance. Numerous remedies have been suggested for the disease, the most feasible being the attempt to remove the trichinæ from the bowels by active purgation; but on the first alarm or suspicion of the disease the case, or cases, should be at once submitted to the advice

of a medical man. Considering the gravity of the distemper, and

TRO TRI

portant question as to what steps should be taken to prevent its occurrence among the population. In the first place, it is obviously necessary to guard against the feeding of pigs, which are notoriously foul feeders, with flesh or offal of any kind which has not been boiled; and in the second, it is equally imperative that the greatest care be exercised in the cooking of meat, especially of pork, so as to destroy all vitality in the parasite, should it happen to be present. Salting, smoking, or toasting are not sufficient for this purpose; it is essential that every particle of the meat should be subjected to a temperature not less than 212°, the temperature of boiling water.

Many deplorable accidents, almost approaching epidemics in the extent of their virulence, have arisen from the cause in question. It is related that in the year 1863, in a small town in the Hartz Mountains, on some festive occasion, 103 persons dined on sausage meat unwittingly derived from a trichinous pig, and within a month 20 died, while the remainder suffered more or less from the same cause. From America we have more recently had accounts of a similar character, and it is now pretty well understood that numerous anomalous fevers described by the older writers long before the true character of the parasite was established might have been directly traced to

its ravages.

It will appear, from what has been already said, that this is a matter which not only sanitary authorities but the public generally, and, in fact, each private individual for himself, should guard against, seeing that we do not know how soon accidents might take place. No subject of the present day, per-haps, has assumed a greater importance than the occurrence of the parastic diseases; and we may confidently hope that our knowledge of the causes, and of the means of cure, and still better, of prevention, will be every day increased.

The small white specks formed by the capsules of trichinæ disappear at once when they are touched with dilute hydrochloric acid. This is a very simple test. Trichinæ which are not in their little shell-like capsules can only be seen by the microscope. An instrument should be used which magnifies fifty diameters. The part of the muscle next

Fig. 226.

the tendon is said to be most often inhabited by the trichinæ.

The annexed illustration (fig. 226) from

its insidious origin, it becomes even a more im- | the trichina lying coiled up in his cyst in the muscle; and the next (fig. 227) shows him partially uncoiled, removed from the cyst, and further magnified :-

> The trichina was first minutely described by Professor Owen in 1835, although it had

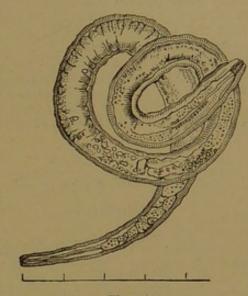

Fig. 227.

been previously noticed by others, especially by Mr. Hilton and Dr. Hodgkin of Guy's Hospital. Perhaps the best description of the worm is given by Dr. Cobbold in his work on

Helminthology.

TROCAR is an instrument used for piercing cavities of the body, such as the abdomen or chest, for the purpose of giving exit to fluid. The trocar is usually so fitted inside a metallic tube or "canula," that when it pierces the body, it carries the latter along with it; the trocar being then withdrawn from the tube,

leaves a clear passage for the fluid.

TROCHES—LOZENGES.—See LOZENGE. TROPICS AND TROPICAL DIS. EASES.—As might be expected, the forms and types of disease which occur in hot, tropical climates are frequently very different from those which are met with in this and other temperate regions. Under articles Acclimation, Bile, Cholera, Dysentery, Fever, Heat, Liver, &c., the reader will find information illustrative of the effects of a residence in a warm connate upon the system; a special article in the Appendix deals systematically with the subject. The author would strongly advise all individuals about to proceed to a warm climate to consult some medical man of repute, who (and there are many such to be met with), from practical experience and residence in such climates, are competent to advise upon the subject, and to point out, in writing if required, the peculiar causes and symptoms of disease to be guarded against and attended to. Beri-Beri is an obscure and very fatal disease common to the Tropics, though practically Dr. Aitken's "Practice of Medicine," shows unknown in this country. It exists also in

TRU TRU

China and Japan, and is endemic in some parts | the walls of a large cavity, in which the organs of India, especially in the provinces lying to the west of the Bay of Bengal. The disease is entirely constitutional, and is attended with stiffness and numbness of the limbs, and sometimes with paralysis of the lower extremities. Like many other tropical diseases in India, it is most common at the close of the wet season, and when the alternations between day and night temperature are greatest.

TRUNK. - This name is given to the large mass of the body to distinguish it anatomically from the head and neck and the limbs. The are lodged the alimentary or blood-producing spine, ribs, and pelvis form a bony casement, organs, the spleen, kidneys, and other urinary

of nutrition are situated. This cavity above its middle part is divided into two, by means of a septum or partition of muscular substance called the diaphragm, which forms the floor of the thorax or upper cavity, and the roof of the the lower or abdomen (fig. 228). The chest, or thorax, contains the lungs and heart with large blood-vessels, is conical in shape, from which circumstance it is often likened to a beehive, and its contents occupy the internal area to the fullest extent. In the abdominal cavity which, with the aid of the soft parts, constitutes organs, as well as the organs of development.

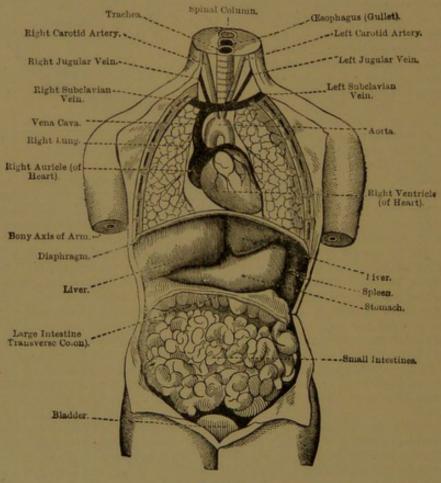

Fig. 228.

In addition to these, and common to both | mediate vicinity, and on either side, are the cavities, are the sympathetic ganglia of the nervous system, and piercing the diaphragm downwards are the esophagus and the aorta, and from below upwards the large vein which returns the blood from the lower parts of the body to the heart (inferior vena cava) and the thoracic duct. The accompanying figure (228) presents a front view of the organs of the trunk nearly in their normal position. The section at the neck where the latter joins the trunk shows the relative position of the three canals formed by of the diaphragm in the manner represented in the spinal column, the cesophagus or gullet, the figure, with the lungs on either side filland the trachea or windpipe. In their im- ing the cavity. The chest cavity being air-

large blood-vessels, comprising the right and left carotid arteries and arteria innominata, which carry the blood from the aorta to supply the head also the returning veins, the right and left jugular, which conduct the blood back to the heart by the subclavian veins and superior vena cava. If the chest were laid open, the heart would be found lying immediately under the breast bone and ribs, the lower part or apex resting on the curve TRU TUR

of the muscles between the ribs, and engaged in the act of respiration, increase and diminish its capacity, to permit first, the pressure of the outside air to inflate the lungs, in the act of inspiration, and afterwards by an equivalent pressure from within, to cause the lungs to contract in the process of expiration, an equilibrium between the outside and inside pressure being established in each instance. average amount of air inspired and expelled in each act of respiration is calculated at 20 cubic inches, and what is termed the vital capacity of the lungs, that is to say, when the organs are fully distended, the amount of air which can be expelled by forced expiration is usually estimated at from 200 to 250 cubic inches, tall men and women having a greater capacity than those of smaller stature. In forced inspiration, or indeed under ordinary circumstances, the diaphragm contracts and descends more into the abdominal cavity, pressing down the liver and stomach, and pushing forward these organs; while in the act of expiration it returns to its natural curved position. - See Chest—Respiration.

The larger cavity of the trunk contains in its upper part the liver, which extends from the right to the left side, the stomach resting its cardiac or left end against the convex side of the spleen and the small and large intestines, which occupy the greater part of the cavity in front. The other organs, with the exception of the bladder, are too deep-seated to be shown in the diagram. - See Abdomen-Alimentary Canal-Digestion.

TRUSS .- See RUPTURE.

TUBERCLE.—See SCROFULA.

TUMOUR-a swelling of any kind in the widest sense of the word, but the term is usually restricted to a permanent swelling. Tumours are met with in every situation in the body, and differ greatly in their characters and tendencies. Of these, it would be perfectly impossible for inexperienced and unprofessional persons to judge; as an invariable rule, therefore, whenever a tumour is discovered to exist, it should be submitted to the examination of a medical man without delay, and all rubbings and the like avoided; they are not likely to do good, and may do much harm by irritating, and thereby causing increased growth. Tumours are dangerous from their nature, or from their situation. In some parts of the body, simple unmalignant tumours may attain a very large -an enormous-size, without threatening life, or, indeed, causing inconvenience, except from their bulk. Rapid and great increase of bulk is most usual in tumours which are pendant. Of all tumours, those of a malignant or cancerous nature are most dreaded, and generally cause the most pain. - See Cancer.

A tumour, however, may give rise to many painful symptoms, particularly if its growth

tight, the alternate contraction and relaxation | parts around it, or of the nerves which pass over it; this often occurs in tumours in the neck.

> If, after a tumour has been discovered, any delay must necessarily arise before it can be examined by a medical man, and if it exhibits signs of irritation or inflammation, the best remedies are perfect rest, low diet free from stimulants, the regulation of the bowels, and the application of cloths wet with cold or tepid water, or, if need be, a few leeches. If a tumour is inconvenient from its weight, it should be supported.

Refer to—Cancer—Cyst—Swelling, &c.
TUNBRIDGE WELLS "is one of the most agreeable summer retreats in England." "But it is in the absence of humidity, as deduced from hydrometric observations, the rain gauge, &c., that the climate of Tunbridge Wells surpasses that of most places;" "its true distinctive character and pre-eminence 'consisting' in the momentous element of atmospheric dryness." "The nature and medicinal qualities of the Tunbridge Wells mineral spring are well calculated to aid this very salubrious property of the air, as it holds iron in solution in its purest and simplest state of combination, that of a carbonate, with very little foreign ingredient, and with a sufficient quantity of carbonic gas to render it a grateful and wholesome stimulant to the stomach. The water from this spring proves highly beneficial in all cases of simple debility, and in such debility as is complicated with sluggish movements in the glandular system, where no inflammatory action or serious obstructions exist."

"People troubled with any fulness about the head should avoid Tunbridge or its wells."-See Health Resorts.

Refer to-Chalybeates-Iron, &c.

TURN OF LIFE.—See MENSTRUATION.

TURNIP .- The turnip belongs to the cruciferous plants, or mustard tribes. It is nutritious, combining one part of flesh-forming element to eight parts of carbonaceous or heat givers reckoned as starch; these, however, are combined with from 90 to 96 per cent. of water. The turnip is somewhat faxative and diuretic; it is, however, liable to disagree and cause flatulence in persons of weak digestion. A turnip poultice is sometimes used, but is disagreeable from its smell.

TURPENTINE-of various kinds, is an exudation, chiefly from different species of pines. Common turpentine is the fluid resinous exudation from the Pinus sylvestris, or be rapid, simply from the stretching of the Scotch fir, and others of the pine tribe. From

ULC TUR

turpentine, as it is often called, is obtained by distillation, the dry substance which remains constituting resin (see Resin). Oil or spirits of turpentine is a valuable remedy, either externally or internally. In the former case, if applied to the skin, by means of cloths soaked in it, it is a powerful counter-irritant, acting like mustard, and sometimes even blistering. It is often employed for purposes of counterirritation in inflammatory diseases of the abdomen, sprinkled on hot fomentation cloths. Turpentine may be warmed, by placing the pot or bottle containing the turpentine in hot water. In rheumatic affections, lumbago, sciatica, and chronic inflammations, turpentine is a valuable addition to liniments. One part to two of the ordinary soap liniment may be used, or the turpentine liniment of the Pharmacopœia, which is composed of sixteen parts of oil of turpentine, one of camphor, and two of composed of turpentine, camphor, and acetic acid, which is supposed to be analagous to St. John Long's Liniment, at one time in high favour as a remedy for diseases of the joints.

Internally, in small doses, turpentine acts chiefly upon the kidneys, increasing the flow of urine considerably, and giving it at the same time the odour of sweet violets. In larger doses, turpentine acts as a purgative, and has chiefly been used in this way in half-ounce doses, combined with an equal portion of castor oil, to destroy and carry off worms in the intestinal canal (see Worms). As an internal remedy in rheumatic cases, turpentine often proves of much service, in fifteen-drop doses given twice or three times a day in milk. It may also be given in similar doses in cases of hæmorrhage, as from the bowels, or in pur-

pura. - See Purpura.

When a large dose of turpentine is taken internally, it is apt to cause sickness, with a feeling of giddiness resembling intoxication; after this it usually purges freely, especially if combined with another purgative, such as castor oil. If the purgative action of turpentine is not freely developed, it will, in some persons, affect the kidneys severely, causing symptoms of strangury, similar to those which occasionally follow a blister, and to be alleviated in the same way .- See Blister.

Various methods of taking oil of turpentine are recommended, one of the most usual being that of emulsion, made with the yolk of one egg for every two drachms of the oil, and distilled or soft water. The author generally gives it, and finds it well taken in milk, the oil being added to the milk just before it is swallowed. It may also be given to conceal

the taste in capsules of gelatine.

As an addition to enemas in stoppage of the bowels, in worms, in hæmorrhage, and in mucous discharges, turpentine is frequently used in the proportion of from half an ounce to oftener than upon the right: they are, moreover,

this the volatile oil of turpentine, or spirits of | an ounce and a half to the pint of gruel or barley-water. After turpentine has been used in an enema syringe, the latter should be well cleansed by warm soap water being passed through it.

Refer to—Enema—Terebene.

TYMPANITES is unusual distension of the stomach and intestines with gas. This is apt to occur in fever and in acute inflammation within the abdomen. In such cases it is a symptom which must often be seriously regarded. Tympanites, however, sometimes occurs as a chronic affection. In any case, it may proceed to a great extent, distending enormously the whole abdomen and impeding the breathing. Injections of assafætida, rue turpentine, or other stimulant aromatics give relief; and aromatics, sal volatile, tincture of cardamoms, &c., are often given internally, but many cases derive more benefit from the mineral acids.

TYMPANUM. - See EAR.

TYPE OF A DISEASE is the combination of characteristic and prominent symptoms which marks all the cases of a prevailing

disease, such as fever, &c.

TYPHOID.—See Enterio Fever. TYPHUS .- See FEVER.

ULCER AND ULCERATION .- An ulcer is a sore which discharges matter, and which arises from loss of substance, or separation of continuity in any of the living structures. When a wound, instead of healing up at once by the first intention, remains open, discharges healthy pus or matter, and presents upon the surface small red points or granulations, it is a specimen of a healthy ulcer, or one tending to heal. But though some ulcers, whether healthy or the reverse, may be the result of external violence or wound, in others the cause is more obscure, occasionally it is due to prolonged irritation as that caused by the sharp edge of a tooth, or a nail in a shoe, or large veins, in others it follows a little pustule which may arise in the skin, and into which dirt may have been rubbed. Many others arise from constitutional diseases, such as scrofula, and in some a feeble circulation determines the formation of the sore. Ulceration may occur both within and on the surface of the body; under article Bone, caries was described as an ulceration of bone. Ulcers also occur in the mouth and throat, and, indeed, on any portion of the membrane lining either the respiratory or digestive passages. Respecting these forms of ulceration, whatever is requisite has been entered into in other articles; in this place, external ulceration of the skin is only treated of.

Ulcers may occur on any portion of the surface, but their most frequent site, out of ail proportion, is upon the legs, and upon the left ULC ULC

much more common in the aged than in the young. In the majority of these ulcers, large veins will be found in the surrounding skin, and to their existence the ulcer is due; these alcers exist in the lower half of the leg, where the irritation from the large veins is greatest. Under normal circumstances the valves which the veins contain distribute the pressure of the column of blood upon the venous walls. In some people, either from prolonged standing, from too tight gartering, from habitual constipation, or from a predisposition, the veins become dilated or "varicose," the valves are now un-able to close, and so the pressure is felt chiefly in the lower part of the vein: at the same time the dilated vein irritates the tissues around, producing there a thickening, which can always be felt, the vein appearing to run in a gutter (see Veins). In this condition of the veins there exists the commonest cause of ulcer: the blood in the large vessels being retarded, reacts upon the circulation in the smaller, or "capillary" branches, and sooner or later ulceration is the result. This ulceration may arise spontaneously, without obvious cause, but very often it is determined by some slight injury; a scratch, a bruise, or an abrasion causes slight inflammation, and gives the first start to the ulcerative process, which extends with greater or less rapidity, according to circumstances, and gives rise to ulcers presenting very different appearances. Into the minutiæ of these appearances it would be useless to enter here; some ulcers present an angry inflamed appearance, with a blush of inflammation extending for a considerable distance around; some are surrounded with hard swelling without much apparent inflammation; and the sore appears to lie deep, surrounded by thick edges. In some the surface of the sore seems glazed and smooth, in others the granulations are large, prominent, and pale, constituting what is called proud flesh. Some of the sores are but little felt, others are intensely painful and irritable. Although it has been said that a large proportion of ulcers depend upon a "varicose" condition of the veins, all do not; many are occasioned by constitutional or other causes. Indeed, the existence and appearance of an ulcer will often afford to a medical man a good index to the state of the system generally.

There are cases of ulceration which require all the skill and patience which a medical man can bring to bear upon their treatment, and where an ulcer is continued, and appears to extend, it should always be placed under proper medical superintendence. There are, how-ever, certain general rules of management which may be adopted with advantage by unprofessional persons, either in their own persons or on those of others.

The great requisite in the treatment of ulcers of the lower extremity is rest, and rest limb (fig. 229-1) are applied piece by piece,

become properly balanced. It is often surprising how quickly, under this proceeding alone, and without other treatment, the swelling around an ulcer subsides, and the sore itself alters to a more healthy character. Indeed, there are cases which only require rest to get well. In many cases, however, especially of old standing, further treatment is requisite. If there is angry-looking inflammation and a foul sore, the one has to be subdued and the other cleansed, in the first instance by poultices continued for two or three days, after which, water dressing (see Dressing) may be substituted, and if the ulcer improves under its use, continued till the cure is complete; it may be necessary, however, if the surface of the ulcer appears pale, and the granulations large and flabby, to substitute for the water, an astringent lotion of lead, zinc, tincture of myrrh, or to touch the surface of the sore lightly with lunar caustic, or sulphate of copper (bluestone). These liquid dressings of water or lotion are far preferable in every way to ointments. It is desirable, even while the patient is confined to bed, to support the limb and retain the dressings by means of a roller bandage applied from the toes upwards, and this is especially requisite if, or when, the rest of the recumbent posture is abandoned. In many cases of ulcer, however, it occurs that rest cannot possibly be taken; in such, the treatment by strapping with plaster, and by the use of a supporting well applied bandage, offers the most benefit, and best chance of cure; even in these cases, however, it is desirable, if possible, to procure the subsidence of the inflammation and swelling by a few days' rest. When strapping is used, the leg ought in the first instance to be well washed, and the hairs shaved off; a roller bandage (see Bandage, fig. 16—C) is then to be applied from the toes to a little below the sore; strips of plaster rather more than an inch broad, and long enough to go once and a third round the

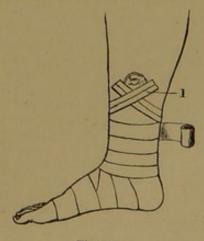

Fig. 229.

in bed, or at least in the horizontal posture, so each one overlapping slightly the preceding, that the circulation of the affected limb may from an inch below to an inch above the sore.

URI

The mode of application is this—the strip being | is a point, however, which ought to be reguheated, its centre is applied to the side of the limb opposite the sore, and the ends are brought round to overlap as represented, care being taken in the application of both strapping and bandage that they lie evenly, so as to afford equable and sufficient support to the limb, and especially to the veins. The heating may be effected quickly and easily by simply passing the slip of plaster through a basin of hot water, holding one end in each hand. With such a dressing as the above, an individual may be permitted to take a considerable amount of exercise. The dressing will require changing every two, three, or four days, according to circumstances; if the discharge is very profuse, it is well to cut a piece out of the plaster directly over the sore. Diachylon plaster is commonly used for strapping, but for irritable skins soap plaster is preferable; in some cases even this cannot be borne. A new bandage has been invented for ulcer of the leg, and called after its originator "Martin's." It is made of finely perforated india rubber, and with it the leg and foot are bandaged to the knee, the ulcer being covered by the bandage only. At night it is removed and placed in cold water. With this support, many people are enabled to perform their daily duties, the ulcer either remaining stationary or healing. These bandages are sold by instrument makers and chemists. Of course the rules as to position, support, and rest, apply more especially to ulcers situated on the lower extremities. When large, the healing process may be hastened by "grafting" (see Wounds). Various lotions are employed for the relief and cure of ulcers. None answer better, on the whole, than the carbolic lotion, in the proportion of one of acid to forty of water. Carbolic oil forms the best application for those large ulcers of the leg, where the person must move about. The proportion is one in ten. When the pain is severe, the lead and opium lotion will often relieve; and when the ulcer is inflamed, or is rapidly increasing, the recumbent position should at once be assumed, and a poultice applied to remove all the foul material, after which any of the dressings named may be used, When an ulcer seems to depend upon enlargement of the veins leading towards it, it is necessary, by means of a small pad of folded cloth applied over the portion of the vein nearest the ulcer, to relieve the blood pressure, the pad being secured by a strip of plaster partly encircling the limb or leg. When an ulcer appears to depend on any particular de-rangement of the general health, the latter should be attended to, the bowels especially must be kept unloaded, the contrary condition tending greatly to cause and keep up the varicose condition of the veins. In the aged, in whom the functions and circulation generally are torpid, much benefit often results which, although it is constituted of elements from the use of moderate doses of opium, this filtered off from the blood, to the purification

lated by a medical man.

In some cases, in which an ulcer has been in existence so long that it has become as it were an established excretory outlet for the system, it cannot be healed up without danger of some other disease, such as apoplexy, &c., supervening. As circumstances may, however, render the healing of even an old sore both safe and desirable, a medical man should be consulted. Serious accidents occasionally occur in consequence of an ulcer on the leg opening into one of the veins; when this occurs, a large, or even fatal quantity of blood may be lost in a short time, unless the individual, or some other person, has sense enough to elevate the limb and apply pressure on the vein (see  $H\alpha$ morrhage-Veins, &c.). In dressing ulcers, the mistake is often committed of being too assiduous in cleansing their surface, washing off the pus or matter which lies upon it, and which in some measure is a protection against irritation. This should not be done. The pain of an ulcer underneath either bandage, or plaster and bandage, may often be alleviated by simply soaking the dressings with cold or tepid water, without removing them.

bed—Childhood—Rupture, &c.
URETER.—The tube which conveys the urine from the kidney into the bladder. - See

URETHRA is the passage for the urine from the bladder (see Bladder). This passage is liable to be affected in various ways, especially in males; sometimes it is injured by violence, at others, small stones or calculi are apt to be impacted in it, and cause much suffering (see Urine). The most frequent affection, however, of the urethra is stricture, or diminution of its calibre. This painful disorder in males generally takes it origin from diseases contracted in the irregularities of early life, especially, but may continue to afflict, or punish, even in old age. Stricture is, of course, of every degree, but sometimes proceeds so far as to occasion complete impediment to the discharge of urine, causing much distress and suffering, and requiring the instrumental interference of the surgeon (see Catheter). If there is any necessary delay in procuring assistance, the measures recommended in article Bladder, Stoppage of Urine, will give relief in the meanwhile. In this disease, as well as in others which affect the urinary organs, it is again repeated-avoid the quacks.

URINE .- This most important excretion is purely an excretion; that is to say, it does not, after its formation, fulfil any purpose connected with the living system before it is thrown out of the body; in this respect, it differs from such an excretion as the bile,

ant ends in the digestive processes.

The minute structural arrangements in the kidney, whereby the separation of the urine from the blood is affected, have already been sufficiently entered into: to article Kidney the reader is referred.

The urine being separated or excreted solely from the blood, and being thrown out without serving any purpose in the living economy, must, by simple reasoning, be supposed to contain ingredients from which the body ought necessarily to be freed, and which could not be retained without injury; such proves to be the case, for complete suppression of the fluid cannot continue above a few days without symptoms or narcotic poisoning being developed, and death ensuing if the function be not restored. Urine consists of water holding in solution certain animal principles, and a proportion of saline constituents. The principal and most characteristic ingredient of the urine, however, is its urea, a substance which acts as a base to, or combines with acids; it is the retention of this compound in the blood which causes the symptoms of narcotic poisoning already alluded to, when the urinary excretion is suppressed. Above half an ounce, on the average, of urea is excreted in the urine of an adult in the twenty-four hours; but in some cases, when rapid emaciation goes on, the proportion is greater, the urea being in fact a product formed from the used-up tissues of the body. in importance to the urea of the urine is its peculiar acid, generally known as uric or lithic acid. It is this acid which, when in excess, constitutes the yellow or red crystalline gravel, or "sand," which is so frequent in many persons. This acid exists partly in combination with ammonia, forming what is known as the "lithate," or "urate of ammonia."

In addition to these two principal and characteristic constituents, urine contains various animal and colouring matters, also hydrochloric, sulphuric, and phosphoric acids, in combination with lime, magnesia, and soda, all these being derived from the blood. Further, there is always mixed with the urine a certain pro-portion of "mucus" derived from the bladder and urinary passages. Moreover, other ingredients not natural to it, are apt to be intruded into this fluid, such as the albumen of the blood, or blood itself, pus or matter, oxalic acid, &c. The average quantity of urine secreted by the kidneys of a healthy man in the twenty hours is from forty to fifty ounces, containing from seven hundred to a thousand grains of solid matter. Both fluid and solid matters, as already stated, are derived solely from the blood; not, however, we have every reason to believe, from the healthy constituents of the blood, but from those which have become "effete," which, having served their

of the vital fluid, yet certainly fulfils import- | the current of the circulation, probably for the sole purpose of being brought under the power of the excreting organs. Not only, however, do the kidneys separate the used up materials which have formed part of the organ-ised frame, they also lay hold of, so to speak, and throw out from the blood, many ill-digested and useless matters which have been derived from the food.

From the above account of the sources of the urine constituents, it cannot excite surprise to find the fluid varying, as all know it does, at different times. Even within the limits of health, the variations are regular, almost periodic. Thus, after a fluid meal, such as breakfast, or after much fluid has been taken, the kidneys secrete largely, the urine is plentiful, but generally pale in colour—it is the urine from fluids. Again, after a solid meal, such as dinner, the urine is less abundant, it is darker in colour, and probably has the odour of some ingredient of the previous meal—this is the urine of solids. Lastly, if no heavy meal has been taken just before retiring to rest, the urine is probably a mean between that of the fluids and that of the solids—it is the urine of the blood-and, being less likely to be influenced either by solids or fluids which have been taken into the system, affords the best index, as far as the urine is concerned, of the bodily condition. This is the reason why the "morning urine" is so often examined, in preference to that passed during other periods of the twenty-four hours. Although exposed to the above sources of variation, urine, if perfectly healthy, ought to be transparent, not only when passed, but when it becomes cool, a just perceptible cloud, composed of healthy mucus, being only visible at the bottom of the vessel; the colour ought not to be too dark, and the fluid should be acid when examined by means of litmus. The specific gravity ought not to vary greatly from the healthy average of 1.018—that is to say, for any length of time, or except from some obvious cause. In hot weather, in this climate, and in hot climates generally, when the action of the skin is so much increased, it of course leaves less fluid to be drained from the blood by the kidneys, and as the solids to be carried off by these glands still remain the same, or nearly so, the specific gravity of the smaller amount of fluid must be proportionally increased; here we have an obvious cause for the change, no less obvious than that which gives a large quantity of pale urine of low gravity if an individual indulges in fluids. Further, we know that nervous individuals of both sexes, and especially hysterical females, will occasionally secrete very large quantities of colourless urine. Such variations, therefore, cannot be considered to be the result of disease, but when permanent increase or diminution of the quantity of urine (see Diabetes-Dropsy-Bright's purpose in the economy, have been taken into Disease) occurs, without being accounted for,

URI

and especially if symptoms of constitutional | and indeed the white sediments generally, are disorder or debility, or of dropsy, show themselves, a medical man should at once be con-

sulted.

Uric Acid-Gravel.-Perhaps the most common change to which the urine is liable, is excess of its usual constituents, the lithic or uric acid. That is, in such excess, that instead of remaining dissolved, as in healthy urine, it becomes "precipitated;" in other words, there is so much of it that the urine cannot hold it dissolved. Thus, uric acid may exist uncombined, in which case it is deposited in the form of crystalline sand, of a yellow or red hue; very commonly, however, it exists in the combination with ammonia, as a "urate of ammonia," in which case it does not crystallise, but takes the form of a cloudy precipitate. This urate of ammonia forms the fawn-coloured sediment, with which most are familiar, as a consequence of a chill or of a common cold; it also assumes a pink, sometimes a deep red or purple hue, especially in affections of the liver; indeed, whatever colouring matter exists in the urine, the urate seems to attract it strongly. Urate of ammonia is extremely soluble in warm water or urine, and much less so in cold, so that, although when the urine is passed, it may contain it abundantly, the secretion is perfectly transparent, and it is only as it cools, and can no longer hold the urate in solution, that the latter becomes visible. This excess of lithic acid, alone or combined, in the urine, may arise from a variety of causes. One of the most frequent temporary causes of excess is suppressed perspiration. The skin is constantly excreting acid-lactic acid-along with the perspiration, so that when the latter is checked, the acid is thrown back upon the system. Here, the wonderful power by which one organ "compensates" for the deficiencies of another is brought into action: the kidneys assume in some measure the office of the temporarily disordered skin, and cast out the acid, not as lactic, but as uric acid, from the system. Another frequent cause of excess of uric acid is the introduction of injurious-probably often lactic-acid into the system, in food or drinks. The malt liquors, especially when in the least "hard," or old and acid, are most fertile sources of uric acid, from which brewery men and labourers, who often drink largely of old and acid beer, are extremely apt to suffer. - See Beer. A third source of uric acid, or red or pink gravel, is disorder of the digestive organs, especially if too full a diet of animal food be indulged in. There are other causes of uric acid excess, such as extra fatigue, especially if it gives rise to feverishness, &c. Moreover, uric acid may exist in excess in the blood, and yet may not be manifested in the urine; such is the case in gout. - See Gout.

The white sand or gravel is by no means so common as the red, and is usually connected with an alkaline condition of the urine; it, tractable malady than the opposite acid state.

more usually met with in the aged, and in states of debility. Oxalic acid occurs frequently in the urine of dysperitic persons, but may be occasioned by food which contains the acid naturally, such as rhubarb. Its presence cannot be detected without the aid of the microscope. Albumen in the urine has been already alluded to .- See Bright's Disease. Blood may occur in the urine in small quantity, giving the fluid merely a dark smoky tinge, or it may be discharged in larger quantity resembling nearly pure blood. In some cases, matter and thick glairy mucus are discharged with the urine. In pregnancy, occasionally, a thin creamy like scum forms on the urine, if it be allowed to stand for a day or two. Deviations from the healthy character of the urine are important, first, as indicative of deranged states of the system, and, second, from their own local effects. Some individuals are much more liable to have the urine disordered than others but in none can the condition be permitted to continue without risk, nor ought it to be without the cause being investigated. Such temporary disorders as that produced by cold, are in themselves comparatively unimportant, and the best remedy is to restore the functions of the skin, by warm baths, diaphoretics, &c.

When red, or pink, or fawn-coloured gravel appears to be permanent, and to be connected with derangement of the digestive organs, the symptoms should not be neglected. If food has been taken at all in excess, it should be reduced, and the allowance of animal food especially, moderated, malt liquor of every kind being sedulously avoided. If stimulants are necessary, a little sound sherry, or brandy, or gin with water, are the best. Exercise should be taken freely, but not so as to exhaust; the skin should be well cared for by frequent ablution. As regards medicine, the alkalies at once naturally suggest themselves as remedies, and most valuable they are. - See Potash-Soda. They quickly cause the acid to disappear, and were the disappearance of the acid all that is required, they alone might suffice; but the cause of the gravel, especially of the pink variety, is generally some derangement of the digestive processes, which must be recti-fied, if permanent amendment is desired. On this account, quite the safest plan is to consult a medical man on the subject, but if this is not done, along with the alkalies, some one of the tonic bitters should be combined; in fact, the digestive organs should be attended to as recommended in article Indigestion.

One caution is here requisite. Persons who have been the subject of red gravel, are very apt to continue too long the use of alkaline remedies, and thus seriously to injure the constitution and the digestive powers, and in the end to induce a permanent alkaline condition of the urine, which is a more serious and in-

The presence of white gravel is often so indicative of serious disease, that as soon as its presence is suspected, a medical man ought to be consulted. The tendency to its formation is frequently difficult to remove. One of the best remedies in alkaline urine is the nitro-hydrochloric acid; it is likewise a most valuable remedy in the oxalic acid urine. Oxalic acid is itself very soluble, but occurs in urine in a comparatively insoluble form, in combination with lime, in the shape, as seen under the microscope, of beautiful eight-sided crystals. This form of gravel is far from being uncommon, but, when abundant and persistent, it is often associated with hypochondriac indigestion in the melancholic temperament. Whatever the form of the gravel, the skin and the digestive organs require especial attention. It is always desirable to keep the flow of urine free, and for this purpose sweet nitre, or infusion of broom or dandelion are well adapted. Many find gin, used in moderation, of much service. however, the symptoms of gravel are constant, a medical man ought to be consulted, for it is not solely the immediate inconvenience which is to be obviated, but the liability of the gravel, whatever its nature, to accumulate, either in kidney or bladder, in which case the result is either a most painful attack, a "fit of the gravel," or the formation of "stone."

"A fit of the gravel" is caused by a small gravelly concretion, or stone, passing either from the kidney down the ureter into the

bladder, or through the passage—the urethra—from the bladder; in either case giving rise to intense suffering. When the passage is from the kidney to the bladder, the pain often comes on suddenly, is felt chiefly in the groins and down the thighs, sometimes occasioning cramp; it remits, and if pressure be made deep in the groin, there is tenderness. The symptoms of the passage of a small stone from the bladder, are somewhat similar, varied of course by situation; there is often sickness and vomiting. In such cases, the best means of relief, till a medical man sees the case, are the warm bath, hip or general, and hot applications generally. Opiates in tolerably large doses, equal to twenty or thirty drops of the tincture, are required at intervals to allay pain, given either by the mouth, or in warm enemas of tolerable bulk, which give relief by acting as an internal fomentation. Copious draughts of demulcent drinks, barley-water, and the like, are advisable. Sweet nitre may be given, and if the acid is known to be red habitually, the alkalies will be useful. Solution of potash, in twenty drop doses, is perhaps the best. Should great tenderness at the seat of pain come on, leeches may be required, but the above measures will suffice to give much relief, till the case is visited by a medical man.

Stone, that is, a concretion of gravel so large

that of the bladder. This affection is more common either before puberty or after middle

When a stone forms in the kidney, it gives rise to a constant sense of uneasiness, or of pain, in the back and loins, extending down These uneasy sensations are always aggravated by motion, especially that of riding, either on horseback or in a carriage, and after such exercise the urine is apt to be tinged more or less with blood, or to contain small blood-clots. When the pain is severe, sickness may be produced. The stone in the kidney may continue without change of situation, and with but little enlargement, for an indefinite time, but if it descends into the ureter, it then gives rise to the painful symptoms, a fit of the gravel, above described. When a stone has descended into the bladder, the symptoms it occasions are in some respects similar to those caused by one lodged in the kidney, but are more severe. The calls to empty the bladder are increased in frequency, the attempt causes pain more or less, and the stream of urine is apt to be suddenly checked, probably by the stone falling against the opening. In such cases, if long continued, the urine is apt to become loaded with thick mucus, or with pus or matter. The suspicion of such a malady as stone ought at once to be the signal for the case being properly examined. In the meanwhile, as little movement as possible should be made; demulcents (see Demulcents) taken freely will be found useful, and if there is much pain, it may be soothed by opiates, given either by the mouth, or in the form of injection.

Incontinence of urine in the aged, stoppage of the urine and strangury, are sufficiently entered into in article Bladder, to which the reader is referred.

Incontinence of urine in the young, wetting the bed, is frequently a most annoying habit, and one, moreover, which is often not to be overcome without much difficulty; it may even continue up to the time of puberty, or beyond it. Various methods of treatment are employed -nitrate of potash (saltpetre), given for some time to the amount of half a drachm in the twenty-four hours, to a child of seven or eight years of age, is said to be sometimes successful. The quantity may be given in three doses of ten grains each, dissolved in barley-water. Benzoic acid, in six grain doses, in the form of pill, given twice a day, is used by some; the author has found the tincture of muriate of iron, "tincture of steel," answer well, in doses of ten drops, twice or thrice a day, in conjunction with which cod liver oil may be employed with advantage. This remedy is peculiarly adapted for weakly children; another remedy recently introduced and found often successful is the tincture of Belladonna, from five to ten that it cannot pass by the natural outlets, may drops in water three times a day. In all such form either in the cavity of the kidney, or in cases, it is extremely important that, without UTE VAC

The quantity of fluid permitted should be kept at a medium, but the amount taken in the afternoon and evening must be curtailed as much as possible. In addition to the above remedies, either the cold douche to the lower part of the back, or the cold hip bath at night or in the morning, whichever is found most beneficial, may be employed. It is of importance that the child should be waked once in the night to pass its water.

Dribbling of urine, either in the aged or in those confined to bed by some continued and exhausting diseases, is a not unfrequent occurrence, which occasions much discomfort both to the patient and others, in consequence of the offensive ammoniacal odour. This is in most instances due to an over-distended and insensitive bladder, from which the urine overflows instead of being properly expelled at intervals. Medical aid should be sought, and the bladder emptied once or twice daily by means of a clean and aseptic catheter.

Refer to—Bladder—Oxaluria—Urethra, &c.

UTERUS .- See WOMB. UVA URSI.—Bearberry is a low creeping shrub, which grows in rocky heath ground throughout Northern Europe, including Britain. Its leaves, which are used in medicine for their astringent properties, are deep green in colour, and somewhat resemble those of the box, but are thicker and more leathery. As an astringent, particularly in urinary affections, the uva ursi might be advantageously used in localities where it is found. The dose of the dried powdered leaves is from ten to forty grains. The infusion is the only preparation entered in the Pharmacopæia, and is made by infusing an ounce of the leaves in a pint of boiling water. Dose from one to two ounces.

UVULA .- See PALATE-THROAT, &c.

VACCINATION. — The name of Dr. Jenner, who discovered this inestimable boon, and introduced the practice of vaccination—as the inoculation of cow-pox matter is termed, must be known to all. His attention was first directed to the subject from the known circumstance, that when the cow-pox had prevailed among the cows of a particular district or farm, many of those connected with the management of the animals likewise became affected with the disease, and in consequence a certain number were protected against small-pox. The value of this circumstance seemed at first to be materially impaired by the fact that the protection was neither universal nor certain, until the investigations of Dr. Jenner made it clear that the protection or nonprotection depended upon the stage which the disease had attained in the animal at the time it was contracted by the human attendant; that is to say, if the vaccine disease advanced into the stage of maturation, or that in which the amongst the unvaccinated, amongst those

being purged, the bowels should be kept lax. | contents of the vesicle, which forms its out-The quantity of fluid permitted should be kept | ward manifestation, had become converted from a limpid-looking fluid into matter, although sores were produced upon the hands of the milkers, that certain protection was not afforded which ensued when the sores were produced by the fluid from the vesicle in an earlier stage.

Following up his investigations, Dr. Jenner clearly demonstrated, that when the human subject was properly inoculated with virus taken from the cow-pox vesicle, at the proper stage of its progress, and when, in consequence of that inoculation, the disease was regularly produced, and went through its proper stages, both locally and constitutionally, the individual thus affected was thenceforth all but certainly protected from the contagion of small-pox. These inferences have been the subject of much discussion, and in the interval between Jenner's discovery and the present time, extending as it does over a period of a century, much new light has been thrown on the matter, modifying to some extent Jenner's conclusions, but confirmatory of the blessings which the practice of vaccination has conferred on humanity. A thorough appreciation of the protective influence of vaccination was, however, long in taking root in this country, and it was not till the year 1853 that a Vaccination Act was passed by the legislature, rendering vaccination compulsory among the infant population. For some years, on account of the unsatisfactory working of this act, much disappointment was felt as to its feeble influence in checking the mortality from small-pox, and the Privy Council was forced by subsequent enactments to enforce compliance with its provisions. From the very full inquiries made at the time, at the instance of the Board of Health, it was clearly demonstrated that the protection afforded by vaccination diminished the mortality of the disease in direct proportion to the efficiency of the means adopted in carrying it out. The following figures, tabulated by Mr. Simon, were the result of an investigation into the history of not less than 6000 persons, who had contracted small-pox after vaccination, and are compared with the mortality among others who had not been vaccinated. The cases are classified in the order of their vaccinationmarks, and the numbers refer to the proportion of deaths in every hundred attacked with the disease.

Stated to have been vaccinated, but without cicatrix, Having but one cicatrix, Having two cicatrices, 13 Having three cicatrices, Having four or more cicatrices, -Unvaccinated cases,

These statistics are confirmed by others from numerous sources, and it may be laid down as a rule, that while the mortality in small-pox

sufficiently protected by vaccination it does instructions issued to public vaccinators not amount to more than one per cent. It is frequently argued that the protecting power of the vaccine virus is impaired by transmission, and that it is limited to a shorter period of the life-time of an individual than the period during which it was orginally supposed to grant immunity. Our leading authorities in vaccination are of opinion that the lymph is not deteriorated by transmission from one generation to another, but there can be no doubt that even what is recognised as efficient vaccination does not always insure a lifelong immunity from small-pox, and the remedy which we have always in our power to employ is found in re-vaccination, a practice which has become pretty general of late years among nearly all classes. Its importance is recognised by the Government among soldiers and sailors, and by local authorities in colleges and public schools. About twelve is the best age for revaccination, and as it is not attended with any hazard, it may be renewed a third time, especially to allay fears on the approach, or during the progress, of an epidemic of small-pox.

With regard to infant, or what is often termed primary vaccination, the law requires that ever child born should have the operation performed within six months of the birth. the infant is in ordinary health it ought to be done while it is a month or six weeks old. Of late years the Vaccination Act has not been so diligently enforced in England as formerly, and the Government appointed a Commission some years ago to enquire into the whole question. Having sat for several years, the Commission reported strongly in favour of vaccination as a preventive of small-pox and made certain recommendations, upon some of which the Vaccination Act of 1897 was framed. This Act, which in the first instance came far short of the expectations of the medical profession, was mutilated still further by Parliament by the introduction of the celebrated conscience clause, which enables parents and guardians to obtain exemption rom the Act on making a statutory declaration. The new Act provides for the use of calf lymph, mixed with glycerine, as a substitute for arm-to-arm vaccination, the glycerine having the effect not only of preserving the lymph but also of rendering it more safe from the point of view of specific inflammatory ailments following the operation. The Act also provides for the vaccination of children at their own homes instead of at vaccination stations.

Requisites for Vaccination .- It is but right that the public should be well advised on this point, for it is one on which much misconception has prevailed (and will continue to do so) among the ignorant. Three factors are requisite for the success of this important operation: (1) the infant should be in tolerably

require them to make four or five separate punctures, so as to produce an equal number of good-sized vesicles; or a similar result may be arrived at by inserting the lymph through a series of scratches, made on a limited portion The part of the body on which of skin. vaccination is usually performed is the outside of the arm, half-way between the shoulder and the elbow, a point not of much importance in males, but to be attended to in females, who sometimes wear low dresses, and who will not thank the doctor for a scar on a visible part. In choosing the arm in a child, it should be done with reference to that on which the nurse or mother habitually nurses it, attention to this point may save the child much uneasiness, and even prevent failure of the operation by the vesicles being rubbed or broken. under special circumstances a non-professional person may be so situated as to be obliged to perform the operation himself, we may summarise the directions for its performance from the Fourth Report on Public Health. The part of the arm to be operated on should be grasped with the left hand, and the skin should be drawn tight enough between the fingers and thumb to facilitate the introduction of the point of the lancet with the other hand, and four punctures should be made about half an inch distant from each other for each intended vesicle. The punctures should penetrate the cuticle in an oblique direction, and should not be deep enough to impinge on the true skin. The lancet employed should be charged with lymph taken from a calf or a child on the eighth day after vaccination, never from a re-vaccinated child or adult, as it is now pretty well understood that lymph taken from the vesicles of re-vaccinated persons is less certain to produce satisfactory results. The lancet should be allowed to remain in the punctures for several seconds, and in the course of its removal the site of puncture is to be com-pressed with the flat side of the instrument, partly to prevent bleeding, and partly to detach any lymph which may still adhere near the point of the lancet. Equally serviceable is the process adopted by many vaccinators of introducing the lymph by scratching the skin with a clean lancet, and afterwards charging it with lymph, and inserting the virus over the scratched surface, care being taken that the scratches are not deep enough to cause bleeding. Sometimes simple abrasion of the cuticle is had recourse to. This is managed bleeding. by means of a scraper or knife over a limited area of skin, about half a square inch in extent. and the wet lymph is smeared over the abraded surface. Any of these processes will suffice, so long as the virus is brought into contact good health; (2) the lymph employed ought to be of good quality; and (3) the operation make a child cry, and without unnecessary bleeding, though it is requisite that a small

VAL

Numerous instruments are made for the purpose of vaccination, but none answer so well as the ordinary lancet used also for bleeding. Of course any thing that will abrade or punc-ture the skin in the manner described above will do; a large needle will answer the purpose if nothing better is at hand, but a lancet is

always preferable.

It calf lymph is not used, what is termed 'arm-to-arm" vaccination, that is to say the immediate transference of lymph from the mature vesicle of a child recently vaccinated, to one about to undergo the process, is to be preferred, but this may not always be convenient, and it is frequently necessary to employ lymph for the purpose of vaccination which has been preserved on ivory points, between pieces of glass, or in its liquid form of thin capillary tubes sealed at both ends, the latter form being infinitely the best. When intended to be used, the ends of the tube are snipped off with the fingers, and its content blown with the mouth on the point of the lancet.

By the end of the second, or in regular one. the course of the third day, small spots appear, slightly elevated and inflamed, over the site of the punctures or scratches, and on the fourth day they become redder and more perceptible. On the fifth day, each pimple is surmounted with a vesicle which continues enlarging till the eighth day, when it is fully developed and distended with clear lymph. At the same time, the skin surrounding the vesicles becomes gradually swollen and greatly inflamed, causing a rose-coloured ring or areola round the part, giving the whole a fancied resemblance to "the pearl on the top of the rose." By the tenth day, the vesicles change colour, becoming darker and more opaque, while the signs of inflammation in the skin are still more marked. After this time, the areola or red circle begins to fade, the vesicles become still darker in colour, are drier, and begin to shrivel, and finally assume the forms of chocolate-brown coloured scabs, with a tendency to become detached and fall off, which they usually do from the twenty-first to the twenty-fifth day from the commencement of the process, leaving behind cicatrices upon the arm, which permanently mark the person, and are afterwards recognised as signs of successful vaccination. It occasionally happens that the process does not follow the above regular steps; four, five, or six days may elapse before the pimples are perceptible, and it may be the tenth or eleventh day before the vesicles are fully formed; while, on the other hand, the maturation may advance so quickly as to be well over by the seventh of this work. day. In a weakly child, the process is liable to be delayed, and in a strong child to be officinalis, or common valerian, is one of the hastened, but it observes no general law. The most useful and generally used remedies in

quantity of exuded serum from the blood constitutional symptoms also vary in different should mingle with the vaccine matter. children, but are generally most marked about the eighth day, the child continuing fretful and feverish for three or four days, and without this evidence of bodily disturbance the protection afforded by the process cannot be calculated as completely satisfactory.

The management during the progress of the vaccine disease is very simple, the principal point being the protection of the vesicles from injury, either by rubbing or by the dress. A piece of soft linen should be placed upon them on the fifth day, or what is better, some cotton wool kept in its place by a turn of a bandage. If the inflammation of the arm is severe, as sometimes happens, a cold poultice of bread and water should be applied. A little goulard water will allay the after-irritation, if troublesome. A dose of some simple aperient, castor oil or senna, should be given on the tenth or eleventh day, and repeated once or twice afterwards. Care should be taken that the scabs are not forcibly detached, otherwise a sore, sometimes difficult to heal, may be the consequence. Sometimes this will happen in spite of all precaution, in children of a scrofulous As a rule, the process of vaccination is a habit, and a troublesome ulcer form. This is best treated by dusting well once or twice daily with a powder made of equal parts of boracic acid and oxide of zinc; or it may be dressed with an astrigen: lotion composed of two grains of sulphate of zinc to an ounce of water.

Occasionally, an eruption of vaccine vesicles comes out all over the body; it is of no importance, and the treatment is the same.

Lymph taken direct from vaccinated calves and diluted with glycerine, which acts as a preservative and purifying agent, has recently been largely used as a substitute for lymph derived from a child's arm. It is equally effective as a prophylactic against small-pox; and meets the objections of those who feared contamina-

tion from human lymph.

Vaccine Treatment.—Of recent years, as a result of bacteriological research, vaccines prepared in different ways from cultures of noxious bacteria have been employed both for the prevention and the cure of the diseases associated with these bacteria. The most valuable of the diseases able of these have been prepared from the microorganism of tubercle, and have been used under the name of Tuberculin in various forms of tubercular disease, including phthisis. The prepared vaccine is usually injected subcutaneously at intervals determined by observations of the results attained (see Opsonins). Among others which have been used with some success may be mentioned anti-cholera and anti-plague vaccines. Much technical skill is required in their preparation; and the indications for their use lie altogether beyond the scope

VALERIAN .- The root of the Valeriana

hysteria, and in spasmodic attacks generally. This plant grows commonly in Britain, usually about moist hedge-bottoms, woods, &c., showing its heads of lilac-coloured flowers in the month of August. The root, which has a powerful peculiar odour, consists of a number of rootlets, about the thickness of a crowquill, which proceed from a central stock. Valerian is given internally in various forms, but the preparation generally employed is the ammoniated tincture, in drachm or drachm and half doses, in an ounce and a half of water; this preparation ought to be purchased ready-made. The common tincture, of which the dose is the same as the above, is made by macerating five ounces of the bruised root in two pints of proof spirit. The dose of the powdered root is half a drachm.

Combinations of valerianic acid with zinc, quinine, &c., are now much prescribed in functional disturbances of the nervous system.

VALETUDINARIAN—one who is the subject of frequent illness, and is constantly in search of health.

VALVES .- These mechanical agents are found connected with the circulating system. Refer to-Heart-Veins.

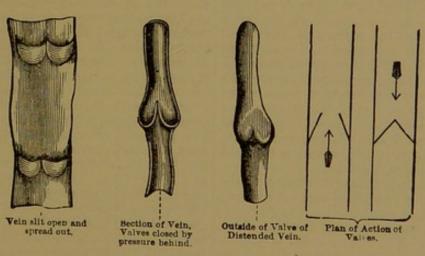

VAPOUR BATH .- See BATH. VARIOLA, SMALL-POX. - See SMALL-

VEAL, like young meats generally, is not so digestible as the flesh of the adult animal, but it is rendered more injurious to persons of weak digestion by the conventional modes of cooking with melted butter, &c. The objection to veal, as invalid diet, does not extend to the broth made from it, which is often peculiarly adapted to the requirements of convalescence and illness, from the amount of gelatine it contains. The knuckle of yeal stewed so as to be very tender affords food which agrees remarkably well with weak, and especially with irritable stomachs.

VEGETABLES.—See FOOD—GRAINS—

and articles on individual vegetables.

VEINS. - The veins are the vessels or membranous canals through which the blood is conducted back to the heart (see Circulation) after it has passed through the capillary vessels, and been brought into intimate contact with the tissues of the body. Whilst passing through the capillaries, the blood undergoes the change from arterial or red blood to venous or black, or rather dark purple blood;

its mode of progression is at the same time | between the two sets of vessels principally altered; instead of the forcible, intermittent, propulsion which attended its passage through the arteries, it moves through the veins more equably, and without pulsation, except occasionally in the large veins of the neck. Its progress, however, is accelerated by mus-cular movements. Moreover, as the aggregate calibre of the branches of the veins distributed throughout the body is considerably greater than that of the large trunks into which the blood is collected as it approaches the heart, the current of the venous blood must be accelerated as it enters these large vessels. Like the arteries, the veins have three coats,

exists, the middle coat of the vein wanting the elastic fibre of the artery; consequently, when veins are emptied of their blood they become flat and collapsed, whereas arteries preserve their cylindrical form. A further difference exists in the interior of the two vessels-the veins, particularly of the extremities, are furnished with valves, distributed at intervals. These valves (fig. 230) are so arranged, that whilst they permit the free flow of the blood towards the heart, they do not permit its retrocedence. A moment's reflection will make evident how greatly this valvular arrangement must assist the, for the most part upward, an external or protective, an inner or lining, carrent of the blood in its return towards the and a middle or fibrous coat. It is in the latter heart; how great the inconvenience attendant that the principal difference as to thickness upon its impaired efficiency will be shown

VEN

presently. The illustration shows the peculiar | distensive force upon the vessels, and upon formation and plan of action of the valves of the veins. They resemble in appearance somewhat the valves of the large arteries nearest the heart, and consist of pouches or semilunar folds of the inner and middle coats of the

The veins generally are divided into those which lie deep and accompany the arteries, and into the superficial veins. The most important of the latter, so far as a work like the present is concerned, are the external jugular veins of the neck, generally so evident in thin people, the veins at the bend of the arm (see Blood-letting), the veins of the lower extremity, and those of the rectum (the hæmorrhoidal veins); moreover, in addition to the veins properly so called, there are the venous sinuses (see Sinus). When a vein is wounded, either by accident or design, the blood flows from it in a continuous stream, with much less force than from an artery, and dark in colour; moreover, the bleeding from a vein is generally more easily arrested than it is from the elastic, muscular, arterial tube, assisted by the pulsation of the heart; comparatively slight pressure by a pad, or otherwise, being sufficient to restrain the flow from the former (see Hamorrhage). A wounded vein generally heals quickly, and the current of the blood through it is uninterrupted. In order to arrest the flow of blood through an artery, it is necessary to make pressure between the bleeding point and the heart, or trunk of the body; in the case of a vein, the reverse must be done. In almost all cases, however, in which it is desired to stop bleeding from a vein, pressure directly over the wound is the best remedy.—See Ulcer—Varicose.

Veins are liable to inflammation from wounds, from inflammation extending from the adjacent parts, &c. This is a most dangerous affection, and frequently resists the best directed efforts of medical skill. The affected vessel is painful, feels hard, and the skin covering it, and the parts around, are red and inflamed; there is much constitutional fever, which tends quickly to a low or typhoid form. The most that could be done by an unprofessional person in such a case would be to use repeated fomentations to the inflamed parts, and to administer from quarter to half grain doses of opium with two grain doses of calomel, every three, four, or five hours, according to circumstances, until

the arrival of a medical man.

"Varicose" Veins .- A "varicose" condition of the veins is chiefly met with on the lower extremities. The affection consists, essentially, in the veins becoming elongated, so as to permit of their assuming a tortuous knotted condition, while they are at the same time enlarged. The state is usually associated with obliteration or deficiency, more or less, of the valves within air contained in enclosed spaces. The obthe veins, so that the weight of the entire ject is to provide, in the first place, for superincumbent column of blood bears with the escape or withdrawal of air which has

those parts of them which are most dependent. The most frequent causes of the varicose veins are such as cause impediment to the upward flow of the blood through the large veins of the abdomen. In this way, pregnancy, if frequent, is a most common exciter of the condition, habitual costiveness, diseases of the liver, tumours of any kind within the abdomen, act in a similar manner. The truss worn on account of rupture, or garters too tightly tied, likewise excite the varicose condition, which is usually more common in persons whose occupations require much standing, especially if they are of tall stature. The inconveniences which ultimately result from a varicose condition of the veins of the leg have been sufficiently pointed out under article *Ulcer*. The causes of it, which have been just alluded to, naturally suggest the best means of allevia-tion and cure, that is, the removal as far as possible of all interruptions to the upward flow of the blood, and the horizontal posture of the body or limb. As these conditions, however, cannot in all probability be perfectly carried out, it is desirable that in all cases of varix the veins and limbs generally should be supported by some one of the forms of elastic stocking; these can now be obtained at so moderate a price, that none need be without their valuable aid. It is often surprising how immediately the use of well applied mechanical support, such as the elastic stocking affords, removes the uneasy and painful sensations connected with the condition of the veins in question. Some individuals cannot, however, wear an elastic stocking of any kind; for such cases, an elastic india rubber bandage fixed to the foot by a stirrup, and wound spirally round the limb, has been successfully employed. Spaces of about three inches being left between the spirals, each time the band crosses the vein, it acts like a valve. Other methods of curing varicose veins, such as tying and cutting outsmall portions of the veins under carbolic spray, are had recourse to by surgeons, but as long as sufficient comfort and relief can be obtained by the use of elastic supports, these methods are perhaps better avoided.

VENEREAL.—See Syphilis. VENESECTION.—See Blood-Letting. VENISON. - The flesh of the deer, like that of other wild or hunted animals, is particularly digestible, and is probably rendered more so by the custom of long keeping. In Dr. Beaumont's table of the digestibility of various articles of food, "venison-steak" is noted as taking but one hour and thirty-five minutes for digestion; beef-steak being noted in the same table as requiring three hours.

VENTILATION AND WARM-ING.-Ventilation is the renewal of the

624

become deteriorated from any cause, such as animal respiration; and in the second, to supply the place of the deteriorated air withdrawn by that which is fresh and pure. Under the head of ventilation, moreover, the heating and cooling of air may perhaps be included. Under such articles as Air, Aëration, Blood, Lungs, and Respiration, the requirements of the animal constitution, which render a regular supply of pure air necessary for health, have been sufficiently entered into, and need not be repeated; and under article Bed-room, information on the subject itself will be found—to these the reader is referred. The entire surface of earth is subject to a vast system of ventilation, effected by means of the currents of air, or winds, which are continually passing over it, especially by those which, like the trade, and other winds, blow continuously in one

direction for months together. In some respect, ventilation is the necessity of a nation living in a variable and cool climate, and of a people who have attained proficiency in architecture, and particularly in domestic In hot climates, where the architecture. breezes from without are rather courted than shunned at all times, ventilation, except in the way of cooling, is uncalled for as a systematic arrangement. In the ruder ages of our own country, when shuttered instead of glazed windows prevailed, and when buildings and fittings generally were defective, ventilation was abundantly, though unintentionally, provided for, and especially as long as the wide lofty chimney-place remained (see Chimney). But at length, when the art of building attained greater perfection, when doors and windows were made to fit tight and well, the ventilation was interfered with by the very perfection of the work, and as practical scientific knowledge of sanitary matters was but little diffused or cultivated, we have the fact of a community suffering evil in consequence of an art being more rapidly advanced than the practical science which ought necessarily to accompany it. Now, however, not only are scientific and professional men well aware of the necessity for providing proper ventilation of all enclosed places occupied by man or animals, but most educated people, generally, are alive to the fact, and have some idea, at least, of the principles on which the necessity is based. cannot return to the old unintentional ventilation of badly built dwellings, and old-fashioned chimneys, consequently, the desideratum has been to find those systems of ventilation which shall combine efficiency with comfort and economy, and which in many instances can be most easily adapted to buildings already constructed, without reference to any plan of ventilation at all.

The methods employed are very numerous, and for convenience of description may be which are best suited for public halls and large buildings where people are in the habit of con-

gregating.

Ventilation of Dwelling Houses. - A dwelling house, whether small or large, ought at all times to contain within itself sufficient provision for keeping up a continuous change in its atmosphere. The first desideratum is a ready means of ventilating the staircase, which may be regarded as a central shaft, communicating with the habitable apartments, up which both fresh and vitiated air make their way, but as vitiated air is also, as a rule, heated air, it ascends more rapidly, and unless suitable means are provided for its escape at the top of the shaft, by an open window or skylight, it is liable to accumulate and permeate the rooms, especially on the upper floors. For the renewal of the air in the rooms, no system suggested or employed has been found so serviceable in obtaining good natural ventilation as the properly constructed window and fire-place. In mild climates and in fine summer weather, open doors and windows are at once the readiest and best means of renewing the air of dwellings; but in cold weather considerable difficulty is experienced in opening windows on account of the draughts. Cold air, by virtue of its greater specific gravity, dis-places deteriorated air as it enters a room, and on this account it is of importance that its point of entrance should be considerably above the heads of the occupants, to cause more perfect diffusion. This is practically done by lowering the upper sash of the window in preference to raising the lower, and can be effected to a greater or less extent in all but the coldest weather, without producing inconvenience save to some sensitive individuals, whose sensations may be considered, and possibly relieved, by some means of directing the current of incoming air upwards before it enters the room. The insertion of "louvre" panes in the window will, in such cases, obviate the necessity of opening it at all, but a board fitted to the upper part of the window, and so contrived as to form an angle when the sash is lowered, will divert the current upwards to the ceiling before it mingles with the air of the room. A simple plan of diverting the incoming aircurrent, applicable to any window, and within the reach of every one, was long ago suggested by Mr. Hinckes Bird; but it is far from being generally adopted. In place of admitting the air directly by the lower or upper sash, Mr. Bird recommends that it should enter alone by the space between the sashes which must always be open when the lower sash is raised, and that a block of wood, corresponding in size to the lower part of the sash frame, should be placed underneath it to exclude the usual current from this, the ordinary inlet. By such an divided into (1) such as are applicable for the primary construction of all windows could ordinary dwelling houses, and (2) to those easily be rendered permanent), the air, instead arrangement (which by a little ingenuity in

VEN VEN

of being directed forwards and downwards, as | the admission of air, and it is self-evident that is usually the case, is directed upwards, and has its current broken in transmission by the

top bar of the lower sash.

To supplement the action of the windows (for they can hardly be said to form a substi-tute for them), are the numerous contriv-ances employed to admit air through openings in the walls by means of gratings, tubes, valves, and perforated bricks. In all these cases it is usual to make provision against down draughts by first dividing the currents at the external openings, and afterwards by diverting them upwards as they enter What is known as the "Sherringham valve" is among the best apparatus of this kind. It consists of an iron box let into the wall near the ceiling with a hinged door in front, and with cheeks which form, when the ventilator is in action, a kind of hopper-mouthed opening with the mouth facing the ceiling. By means of a string and pulley, delicately adjusted inside the ventilator, it may be easily closed or opened to any extent, from the floor, and will remain in a fixed posi-tion until it is interfered with. A plan of tubular ventilation, often spoken of as "Tobin's" system, has numerous advocates, and is frequently found advantageous when the windows are at fault. This consists in the admission of air through gratings in the external walls communicating with horizontal shafts placed under the floor, and terminating in upright tubes about five or six feet in height inside the room, and usually placed along the walls. These may be put out of action by shutting up their inlet openings, and when in use dust and dirt may be prevented from entering the room by protecting the mouths of the flues with wire gauze or similar material. Jennings' air-brick system of ventilation has the advantage (and, in some respects, the disadvantage) of being permanent in its action, and is certainly beyond the reach of interference by meddlesome employés. The air is introduced through a brick opening in the external wall (fig. 231), first into

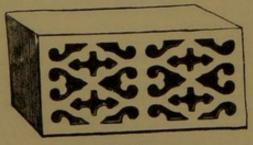

Fig. 231

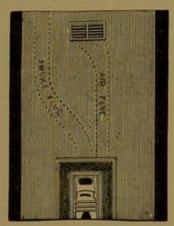

a chamber inside the wall, and afterwards it ascends through another series of perforated bricks in a sloping direction towards the ceiling. The arrangement answers well in barracks and dormitories, and has been introduced into the construction of many private houses.

the problem how to ventilate cannot be solved unless we have equal facilities for aiding the escape of air which has become vitiated and It is true that unfitted for respiration. counter currents may be established inside a dwelling by freely opening the windows until the temperature of the air inside is reduced to a level with that outside, but efficient ventilation requires warmth with the renewal of the air, and how to obtain this warmth in an equable and agreeable manner is the main difficulty to be encountered. In ordinary dwelling houses, the necessary degree of warmth is furnished by the coal fire; in large buildings by hot air from closed stoves, hot water pipes, and open fire places, while the chimney flues, which are continually absorbing more of the heat, act as extraction shafts for the removal of the air which has already served its purpose. Under ordinary circum-stances the coal fire is alone used in dwelling houses for obtaining this exchange of air, but as the extraction force of the fire and chimney is mainly exerted on that part of the room in front of and adjoining it, it follows that the upper strata of air become more and more charged with the products of respiration, this condition being greatly favoured by the combustion of gas in the room, which often renders the apartment unfitted for occupation. Various remedies are employed to meet this inconvenience, among the most obvious of which are ventilating openings in the ceilings, communi-cating with horizontal shafts which have their outlet in the chimney, or by vertical shafts which carry the products of combustion upwards through the separate floors to make their escape through the roof. A simpler method of carrying away the vitiated air is furnished by Arnott's valve, or rather by a modification of it, as the original balance valve invented by Arnott is now nearly superseded by simple gratings fixed in the wall near the ceiling above the fire-place, and communicating directly with the chimney, the smoke being excluded from entering the apartment through the channel by means of a movable diaphragm of oil silk or tale, which acts as a valve inside the grating. To economise heat, as well as to assist ventilation, many ingenious grates have been constructed, furnished with an air-chamber at the back, and communicating through a channel with the outside, in which chamber the air, after being warmed, is led through separate channels into the room. The best of these contrivances is that known as the Galton stove, which has been so much employed in barracks and hospitals, and a front elevation of which is given below (fig. 232). The grate in this instance is ingeniously contrived so as to economise fuel and consume smoke, as well as to utilise the warm air from the warm airchamber at the back of the grate, which passes What we have already said applies only to by a channel almost directly upwards to the

VEN VEN

ment, while the smoke is carried away by means of an iron tube into the chimney.

While, however, every care is taken to renew the air in the interior of dwelling houses, the measure will be a useless one unless the air introduced from without is itself pure. In this way the system of ventilation becomes more or less connected with the local sanitary arrangements, especially with the drainage

both inside and outside of the house, and indeed with whatever tends to render the atmosphere unwholesome. Whatever the condition of the outside air, it is of the utmost importance that that admitted for purposes of ventilation ought not to be taken from too near the level of the soil, for not only is it liable to be more damp, but also to be impregnated with any malarious agencies which may possibly exist

there.—See Aguc.

Ventilation of Public Buildings.-For the ventilation of large buildings an infinite variety of appliances have been employed to secure a constant supply of fresh air at an equable and agreeable temperature. Windows on both sides, though scarcely applicable to an ordinary room, are almost a necessity in connexion with a large assembly hall or hospital ward, to enable the air to pass readily from one side to the other, according to the direction of the wind's current; but it is only in certain conditions of the weather and during summer that it is possible to obtain this desideratum. As a step towards it, and provided the place to be ventilated is either a one-floor building or an apartment on the upper floor, advantage is often taken of the natural tendency of vitiated, which is also heated air, to ascend, and then to further its exit through the roof of the building. For this purpose what is termed "ridge" ventilation is often employed; that is, the highest point or angle formed by the two sloping sides of the roof is detached from the rest, and the foul air from the interior makes its escape through the louvres or lattice work, inserted between the two parts. More frequently, recourse is had to round or square ventilators placed at intervals apart along the

aperture, and from thence flows into the apart- | roof. These are often made movable, and surmounted with cowls and wind-guards, to aid the aspiratory force of the external air; but if cowls are employed, they had better be fixed and motionless. It is no uncommon practice to place a circular row or series of gas burners, called sunlights, in the mouths of tubes communicating with these ventilators, for the lighting of halls and churches, thus carrying away the products of combustion at once, and greatly aiding the ventilation of the buildings. A similar method of removing the heated air from gaslights is sometimes had recourse to in private houses, the lights in this case being enclosed in a globe attached to a tube fixed to the ceiling, and communicating with a channel between the joists, ultimately terminating in the open air; but the plan, in consequence of occasional accidents, has not met with general acceptance.

The interchange of air currents by means of ventilators is facilitated in large rooms, occasionally occupied by great numbers, where advantage is taken of the greater or less specific gravity of the external and internal current, to promote their natural flow by some mechanical contrivance. Thus a cylindrical ventilator with a semi-detached cover placed

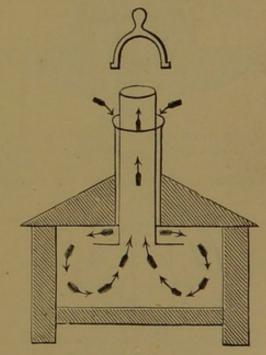

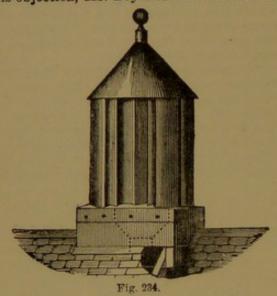

Fig. 233.

on the roof of a building, and communicating with a room to be ventilated underneath, can be made doubly serviceable (that is, for the escape of vitiated and the admission of fresh air) by dividing the external and internal currents, which must otherwise necessarily come into antagonism. This may be done in various ways, but best, perhaps, by means of the double-tube ventilator originated by M'Kinnell (fig. 233). This apparatus consists, as shown in the drawing, of two cylinders placed

VEN VEN

one within the other; the inner tube, which is made considerably taller than the other, forms the outlet; while the outer tube, which has a sectional area equal to the inner, is provided with a flange at its base, to direct the fresh air current towards the ceiling, from which it gradually descends into the apartment. For the most part double-action ventilators answer their object well, but it often happens that their action is seriously deranged by various eccentric causes, such as open doors or windows or by fires in the apartment, which have sometimes the effect of reversing the outlet-action, and of flooding the apartment with cold air from above. To obviate this objection, Mr. Boyle of Holborn Viaduct

has designed an apparatus mainly for the extraction of vitiated air, which has been received with much favour by most sanitary authorities, and is adapted for churches,

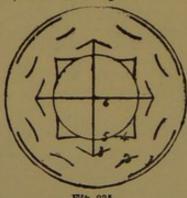

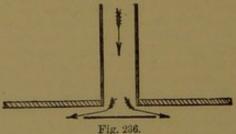

Fig. 235.

schools, and other public buildings into which it has been extensively introduced. Mr. Boyle has given the name of the "Seif-acting airpump ventilator" to his invention, which consists of four sections, each acting independently and designed to meet the ever-varying directions of the wind. The annexed illustrations (figs. 234 and 235), give explanatory views of the construction of the ventilator.

The sectional drawing (fig. 235)--(1) represents a curved plate or guard to concentrate the current, and prevent the wind blowing through the slits opposite; (2) a smaller curved plate to take pressure off the vertical slits communicating with the internal chamber, and to prevent down-draughts. external air impinging on the diaphragm (3) is deflected on the central radial plate (4), establishing an induced current, and in its passage drawing the air from the vertical chamber, and expelling it at the opposite The heated air from the apartment passes upwards through the shaft communicating with the ventilator, and thus the apparatus secures a continuous exhausting force. (6) represents the partitions which separate the four chambers of the ventilator, and which prevent the outside air from being drawn through the slits upon which the wind is not directly acting. From the fact of there being no down-draught to contend with, and the extraction force operating a long way from the occupants of the apartment, in all conditions of weather, and irrespective of adverse currents of wind, there can be small doubt of the efficiency of this contrivance, so long as other means are at work to introduce fresh air into the building so ventilated. Ceiling outlet openings should invariably be connected with an air-tight shaft, which should pass through the roof and terminate in a cowl of this Even with this arrangement, description. down-draught will occasionally occur, and to overcome the effect of this it is well to fix a circular disc under the opening, and of larger diameter than it, within a few inches of the ceiling, as is represented in the sketch (fig. 236).

A common practice, and one which is to be condemned, is to cover outlet openings with wire-gauze or perforated zinc, with the view of checking down-draught. It is true this plan may have the effect of correcting the evil, but it can only do so by permanently interfering with the extracting power of the shaft on account of the diminution of its calibre.

In most public buildings it is now found necessary to supplement the natural ventilation by numerous mechanical expedients, with the object of introducing fresh and warm air, (with or without ordinary fire-places), or of withdrawing the vitiated air by means of shafts heated by coils of steam or hot-water pipes, or in combining both systems together. Occasionally pumps and fanners, worked by

628

steam machinery, are employed for the double purpose of admission and extraction of the air; but although this method of ventilation has many advocates, its trials have not, in all

cases, been particularly successful.

To discuss the various appliances for mechan-ical ventilation would hardly serve any useful purpose in such a book as this, and the subject at present has not been sufficiently investigated to warrant any definite opinion being expressed regarding it. In some instances, particularly in factories, its introduction has proved successful, but experts still differ very much in opinion regarding its general application. The question is often asked, "What is the best system of ventilation?" The reply must be the same as in the case of sewage disposal: "it depends entirely upon the circumstances of the case." That which will answer the purpose for private rooms will fail utterly in the case of large public rooms and theatres, which are habitually overcrowded, and, for this reason, require a more frequent change of atmosphere than is attainable, without causing draughts, by the simple process of natural ventilation, upon which we have to depend as a rule in most houses.

Warming. - It is impossible to discuss the subject of ventilation without dealing at

passes over the heated pipes, and enters the room fresh and warm without giving rise to the feeling of draught which is experienced from so many inlet ventilators. There is no simple plan of ventilation and warming so effective and healthy as a combination of this method with open fireplaces, provided the extracting power of the open fire is made fully available by introducing a mica-flap ventilator into the flue near the ceiling, as is described on page 626. With such a system of ventilation, however, it is desirable to provide other inlets which may be made use of at times when the hot-water pipes are not in action, or in conjunction with the hot-air inlets at any time when the room may be overcrowded; the inlets themselves are too near the floor level to allow of their being left open when the pipes are not heated.

The pipes employed in heating by hot water may be large or small in diameter. In the former case they are of cast iron, 4 inches in diameter, and, the circulation not being conducted under pressure, the temperature attained by the pipes rarely exceeds 200° F. Twelve feet of such piping for every 1,000 cubic feet of air-space will maintain the temperature of a room in cold weather at about 50° F. A circulating boiler connected with a

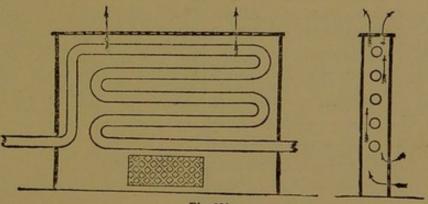

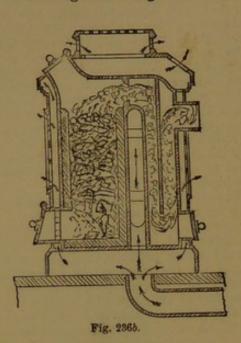

Fig. 286a.

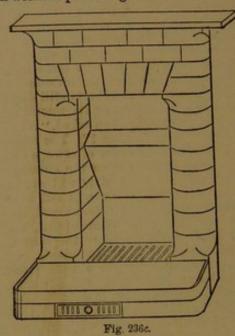

the same time with the system of warming now in use. When hot-water pipes were first made use of in houses for this purpose, ventilation suffered greatly in consequence, for, the extracting power of the open fireplace, which is by far the most effective available means of house ventilation, was then lost, and the resulting stuffiness was intensified by the dryness of the air, which heating by hot-water pipes and stoves gives rise to. Now, however, the objection on the ground of ventilation has been overcome both in the case of hot water heating and stoves. In the former case this has been accomplished by arranging the pipes in the form of coils enclosed in a casing which has an opening at the top into the room, and another at the bottom communicating with the outside air. The result of this arrangement is that the fresh air which

stove is necessary in this case, and a vent pipe must be connected to the highest point of the circuit and carried to the outside to allow of the escape of air or steam. In the system of warming by small pipes (Perkins), wrought-iron pipes with an internal diameter of 3 inch only, and an external diameter of 15 inch are used. In this case no escape pipe is provided, and the pipes are not con-nected with a boiler, but are simply coiled within the furnace, the length of coil being regulated by the length of circuit travelled, the usual proportion within the furnace being one-tenth of that outside. It is necessary to fix a series of tubes at the top of the circuit, of larger diameter than the pipes themselves, and filled only half full with water, the rest of the space being occupied with air to allow of expansion. It is possible with this system. enters at the lower opening is warmed as it to obtain a pipe temperature of over 300° F.

The diagram (fig. 236a) represents, in section, the ventilating arrangement described above applied to this form of heating. It is essential that every portion of the air inlet and the coil it contains should be easily accessible to allow of thorough cleansing from time to

which the chimney is the means of producing, is almost entirely abolished, and the air of the room, which is usually a bedroom, becomes horribly foul in consequence. Of course it is quite inadmissible to fix a gas stove in a room without providing means for the removal

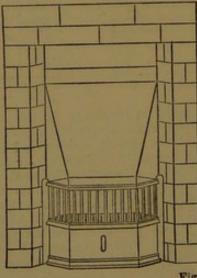

time, and particularly after the summer | months when the apparatus has not been in use for a long period.

Gas Stoves have become very popular lately, and provided they are properly fixed, there is no objection to their use. The practice too often followed by gasfitters, however, is to

of the gas fumes, but even this is not infrequently done. Gas stoves are now made which provide for the introduction of fresh air from the outside, in addition to the removal of the gas fumes, the cold air being warmed in a tube which passes up within the chamber in which the gas is burning, and

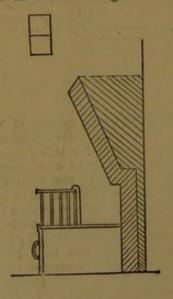

Fig. 286d.

cover over the ordinary fireplace with sheet | opens at the top end into the room. In priniron, in front of which the stove is placed, and through which the gas fumes are conducted to the chimney by a pipe 2 or 3 inches in diameter. The result of such an arrangement is, that at times when the stove is not actually in use, the natural ventilation purpose well. As in heating by hot-water

629a

ciple, such a stove corresponds with the one shown on page 578 (fig. 205).

Stoves are often used for warming the halls and passages of houses, churches, and schools, and with certain provisos, they answer the

pipes, the air of stove-heated rooms becomes dryer than is consistent either with health or comfort, and measures should be taken to obviate this. The simplest plan, and one which answers the purpose very well, is to place a vessel containing water on the top of the stove sufficiently near to insure its gradual evaporation. Such an arrangement may be concealed from view by placing over the vessel

an open iron-work cover.

Another objection to stoves is the risk that the floating particles in the air may be singed by coming in contact with the stove should it be superheated, and give rise to an unpleasant smell. A more serious risk than this, however, arising from the stove becoming red hot, as it frequently does, is the formation of a very poisonous gas (carbonic oxide) which either passes from the interior of the stove through the pores of the heated metal, or is generated from the air in contact with the outside. In either case, a remarkably small amount of this gas in the air of a room will give rise to headache and lassitude among the occupants, if not to more serious consequences. Both the above faults may be avoided by lining the interior of the stove with firebrick, and no stove that is not so lined should be fixed.

Very excellent stoves are now made that provide for the introduction of fresh air from the outside, which is warmed by passing upwards through chambers in the stove before it penetrates into the room. The drawing (fig. 236b) shows, in section, one of Musgrave's stoves which is constructed on this principle.

Open Fireplaces. - Although, as already stated, open fireplaces are excellent aids to ventilation, their construction is frequently such that great loss of heat, and, consequently, extravagance in the consumption of fuel is occasioned. The chief causes of this are:-(1) The grate is placed so far back under the flue opening. (2) The flue passes backwards and upwards from immediately behind the grate. (3) The back and sides of the grate are constructed of iron, and there is a large space behind, which causes loss of heat by radiation. (4) The front and bottom bars are constructed so wide-apart, that the coal falls through in unconsumed pieces, and as the grate is open from below as well as in front, combustion is needlessly rapid.

Fig. 236d shows, in plan and in section, an excellent fireplace, designed by Mr. Pridgin Teale of Leeds, in which the above faults are

reduced to a minimum.

The overhanging projection at the back which is built of fire-brick, as are the sides of the grate, radiates the heat down upon the fire and on the hearth, and so aids in the combustion of the smoke and prevents so much loss of heat up the chimney. An ash tray is also introduced which prevents the air from entering underneath the fire.

Mr. Lionel Teale has constructed a grate on similar principles, except that the fire is sunk below the level of the hearth, which is raised 5 inches above the floor level; it is entirely composed of fire-brick with the exception of bars at the bottom. The air for combustion in this case enters under the fire, by an opening in front of the hearth, from which opening the ash tray is removed. A glance at the drawing (fig. 236c) will make this clear. This fireplace gives off a great deal of heat and the combustion is slow, consequently it is a very

economical arrangement.

Ventilation and Health.—In a brief sketch like the foregoing it would be useless to attempt more than an outline of the principles of a subject so extensive as ventilation, but its importance from a health point of view cannot be over-estimated. Statistics prove conclusively the injury to health which results from impure air. For example, the mortality in districts containing a large proportion of "back-to-back" houses is very much greater than that of similar districts, inhabited by the same class of people, where the houses have back doors and windows which permit of a through current of air. - See Air - Smoke-Abatement.

VENTRICLE. — See CIRCULATION —

HEART.

VERDIGRIS is an acetate of copper. It is prepared chiefly in the wine countries by acting upon plates of copper, by means of the husks and other refuse of the grape, which are made to undergo the acetous fermentation. Poisoning by verdigris sometimes occurs: it is to be treated in a similar manner to that from the sulphate of copper or blue vitriol. -See

VERTEBRA.—See SPINE. VERTIGO.—See GIDDINESS.

VESICATION .- Blistering. - See Blis-

VESICLE—a little blister, or elevation of the epidermis or scarf-skin, by clear fluid. In the first stage the cow-pock is in the state of a vesicle, but in the later stages, when the clear fluid becomes turbid, like matter, it becomes a pustule.

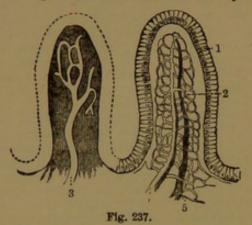

Refer to -Skin-Vaccination, &c.

VICARIOUS ACTION is action set up in one part of the body as a substitute for a similar action in another. It occurs chiefly in connexion with menstruation. - See Menstruation.

VILLI are minute, hair-like processes confined exclusively to the small intestine, and giving to their inner surface an appearance something like velvet pile (fig. 237). villus is invested with an epithelial covering (1), which rests on a basement membrane, and is supplied with arteries, veins, and capillaries forming a dense net work (2). In the centre of each, entering at the base, is a single lacteal or lymphatic vessel, which terminates at the tip

VIN VIN

with a closed end (3). The lacteal vessels, which | they act on many metals with which they may form the great feeders of the lymphatic system of the bowels, absorb chiefly the fatty portion of the chyle formed in the intestines, and conduct it through the glands of the mesentery to the chyle receptacle, from which it is conveyed by

the thoracic duct direct into the venous circulation. The blood-vessels of the villi, consisting of a small artery (4) and vein (5), with their network of capillaries, act in a similar way to the lacteal radicles, but are less restricted in the material of the food they absorb, abstracting everything from the chyle, provided it is soluble, and in a state of subdivision minute enough to pass through their walls. -See Ab-

sorption—Digestion—Intestines.
VINEGAR OR ACETIC ACID.-Acetic acid is the volatile acid principle which, diluted with water, constitutes vinegar. The acetic acid itself may be got very strong and concentrated by various chemical processes; it is also obtained of considerable strength by the destructive distillation of wood; when thus procured, it is named pyroligneous acid, or wood-vinegar. The diluted acetic acid of the Pharmacopœia is composed of one part of acetic acid to seven parts of water. Vinegar is a solution of acetic acid in water; it is of variable strength, and contains colouring matter, and usually, also, spirituous and ethereal principles. It is prepared from wine, malt, sugar, cider, and from various vegetable substances; and also, as stated above, from wood. Except in the case of the last, it is produced by the acetous fermentation, which is carried on under a temperature approaching 80° Fahr.

The wine vinegars, or French vinegars, are made chiefly from the lighter wines by a careful process of fermentation. They are usually better and stronger than those of British manufacture, and more free from adulteration. British vinegars made from malt, sugar, &c., generally want the aroma of the French; most of them contain sulphuric acid, in the proportion of one thousandth part, as permitted by law, but sometimes in much larger quantity. Vinegars are also liable to contain metallic impurities, owing to the readiness with which | corked.

come in contact in process of manufacture. These impurities are got rid of by the process of distillation, consequently a distilled vinegar, or acetic acid, is always used for medicinal purposes. The addition of sulphuric acid to malt vinegar is permitted, to counteract a tendency which it might have to pass into the putrefactive fermentation. The colour of the brown vinegars is occasionally imparted by burnt sugar. According to investigations it appears that the chief adulteration of vinegar is by sulphuric acid in excess of the legal quantity; tartaric acid, pyroligneous acid, and some metallic impurities are occasionally found in it, and are derived from the vessels in which

it is prepared and kept.

The domestic manufacture of vinegar is so simple, that those who wish it can easily render themselves independent of the manufacturer, and, indeed, many housekeepers do manufacture their own. It is not uncommon, at least in some parts of the country, to see standing near the fire a large brown jar, tied over with a porous cloth, in which the process of vinegar making is carried on by means of the vinegar plant, as it is called. Of this plant, which is in the form of a large, flat, leathery fungus, found on decaying bodies and in liquids undergoing the acetous fermentation, a correspondent in the Lancet gives the following account and mode of using:-" Put the plant—a young one—in an earthen jar, add to it half a pound of the coarsest moist sugar, and half a pound of treacle, with five pints of milk-warm water; cover it lightly over, so as to keep out the dust, but not the air, and then put it in a moderately warm place; there let it remain seven weeks, not disturbing it more than you can help. At the end of that time, pour off what is now the clear vinegar, and keep it in well-corked bottles for use. Again add to the plant the same quantity of water, sugar, and treacle, as before. At the end of the second seven weeks the plant will have become like two thick pancakes, and they may be easily divided, care being taken not to tear the old or new plant. If the plant is exposed to the cold, or kept too long out of the liquid, it will become black and die." Another receipt is given in the Lancet as follows:— "For every gallon of hot water, take eighteen ounces of sugar, and when the syrup has cooled to 75°, add four per cent. by measure of yeast. When the vinous fermentation is pretty well advanced, in the course of two or three days, rack off the clear wash from the lees into a proper cask, and add one ounce of winestone, and one of crushed raisins, for every gallon of water. Expose it in a proper manner, and for a proper time, to the acetifying process, and then rack off the vinegar, and fine it upon beech chips." It should be afterwards put into bottles, which are to be well

quires to be considered both in a medicinal

and in a dietetic point of view.

The strong acetic acid and especially the concentrated preparation known as the glacial acid, is a powerful irritant, causing redness, and if long applied, blistering of the skin. It is also used as an external application to warts, and corns, which it often quickly removes, acting as a solvent of their albuminous and When the strong gelatinous constituents. acetic acid is employed as a solvent for aromatic essential oils, it constitutes the aromatic vinegar, or, as it was formerly called, "thieves' vinegar." This preparation derived its name and its reputation as an antidote to contagious emanations, from its first having been used in the time of the plague, by those who wished to plunder the houses or persons of the dead or dying without risk. If they escaped, it was probably from the confidence inspired by the possession of such a supposed protectionfor vinegar, of any kind, can afford no real protection against contagion, that is, it can exert no chemically destructive effect over the contagious emanations in the way that chlorine does. Nevertheless, vinegar, plain or aromatic, either sprinkled about, or burned in a sick room, is often agreeable and refreshing; only, its use should not be permitted to supersede more essential purifications. Vinegar, diluted with water, in the proportion of one or two table-spoonfuls to the half pint, is used for sponging the skin in febrile diseases. It is also a good addition to gargles in sore throat. Before the more powerful astringent gargles are used, one-sixth part of vinegar may be added with advantage to the warm gruel or water gargle. It assists the separation of the tough mucus, which is apt to cling about the throat in such cases.

As an internal remedy, vinegar is but little used alone, it is, however, employed as a solvent of a few medicinal substances (see Squill). As a dietetic condiment vinegar is unquestionably useful and wholesome, more so, however, to some persons than to others. It is generally considered, in common with other vegetable acids, to promote the digestion of oily food, and probably there is something instinctive in its frequent addition to such aliment. But if, in moderate proportions, vinegar assists digestion, taken immoderately it is very injurious, destroying the digestive powers, and even inducing actual disease of the stomach. It is from this injurious effect upon the digestion that vinegar has acquired the reputation for reducing corpulency, which occasionally tempts foolish people to have recourse to it for this pupose - the practice cannot be too strongly condemned.

VIOLET .- The flowers of the common

The action of vinegar upon the system re- | said to be slightly laxative. The root of the sweet violet possesses gentle emetic powers, similar to those of ipecacuanha. The two roots have some resemblance in form.

VIPER.—See Wounds, Poisoned.

VISION is the power of taking cognizance of the size, colour, position, &c., of objects, external to the body, by means of rays of light, which are received upon a nervous expansion, capable of conveying the impressions received by it to the sentient being. In the lowest tribes of animals, the organs of vision, or eyes, are of comparatively simple construction, but the same organs in man are most exquisitely elaborate. Under article Eye, this structure has already been entered into as far as space permitted. Fig. 238 represents a diagram,

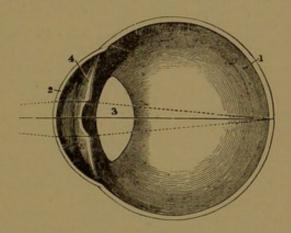

Fig. 238.

not a picture, of the section of the human eye, illustrating the parts essential to vision—first. a dark chamber (1) lined by the nervous retina, and glazed anteriorly by the glass or cornea (2). The rays passing through the cornea, and striking upon the nervous retina, would probably be sufficient to convey to the mind an impression of light and shade, and, perhaps, a general, though confused idea of external objects, but to confer the perfect accurate vision we enjoy, other arrangements are necessary; consequently, we find the lens (3) suspended, as it were, in front of an exquisitely transparent jelly, which fills the

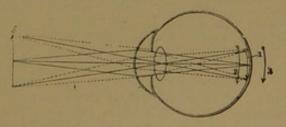

Fig. 239.

cavity (1), and the space between the lens and the cornea filled with transparent fluid. The result is, that the rays proceeding from exsweet violet are employed to impart their ternal objects, in their passage through these colour and fragrance to a syrup, which is often various transparent substances, become so given to children for colds and coughs. It is collected and arranged (fig. 239) that by the

VIS VIS

sensitive nervous retina, they form in it exact miniature pictures of external objects, the picture, however, being placed upside down. This, perhaps, will be better understood by tracing the direction of the rays proceeding from the object (5) to the reversed image of it formed at the back of the eye (1). In addition to these arrangements for collecting and arranging the rays, there is superadded the iris (fig. 238-4; see Eye), in the centre of which is the aperture of the pupil, through which all the rays pass; and as the iris has the power of diminishing or enlarging this aperture, it acts. as a regulator of the amount of light admitted into the interior of the eye. How it is, that, although images are formed in the retina in a reversed position, we see them correctly, is not at present satisfactorily explained.

The refractive power of the eye-i.e., its power to bring to a focus on the retina rays of light falling on the pupil—depends on the strength of the lens, and upon the refractive power of the cornea, and the aqueous and vitreous fluids in front of and behind the lens respectively. But as the lens is the principal refractive agent it is usual to speak of it as representing the whole refractive power of the eye. The shorter the eye is from front to back the stronger the refraction must be to bring rays to

a focus on the retina, and vice versa.

In a perfectly normal eye images of objects at considerable distances are exactly focussed on th retina without any muscular action. If objects within a distance of a few feet are to be focussed distinctly, the lens requires to be increased in strength by the action of a small muscle which surrounds it, known as the ciliary muscle. The action of this muscle is involuntary, and as a rule unperceived, but if it is taxed unduly by, for instance, trying to read at a distance of only three or four inches, a distinct sense of effort and strain is experienced.

Departures from the normal eye are not infrequent; of these the first condition is called "long sight," and is due to the fact that the eye is too short, the focus of light falling behind the retina; in the second the eye is too long, so that the focus in front of the retina; this is called "short sight." Spectacles with convex glasses remedy the defect in long sight, or hypermetropia, and spectacles fitted with concave sight." glasses are needed for short sight, or myopia. Both these conditions occur in young people, but in Britain long sight is the more common. Many symptoms, apparently unconnected with vision or the eye, arise from this peculiarity, such as headache, peculiar spasm of the muscles of the eye on attempting to read, &c. It is also a frequent cause of squint. When people advance in life, the lens of the eye becomes harder and loses its elasticity, so that it is no longer capable of being altered in shape by the action of the muscle within the eye. —may be vanquished by the power of disease, It is by the action of this muscle that the lens and at last is vanquished by the power of

time they reach the back of the eye, or the | is rendered more or less convex, enabling us to see both near and distant objects. When by age this power is lost, the ability to see near objects is also lost, and convex glasses are necessary to compensate the flatness of the lens, while vision for distant objects remains good. Another peculiar anomaly of refraction is called "astigmatism." In this condition, the vertical and horizontal planes of the cornea do not correspond in curve, hence while upright lines may be distinctly seen, horizontal ones are misty or invisible, or the reverse maintains. This deformity of vision is only to be remedied by spectacles of a suitable construction.

Vision may be interfered with by causes which obstruct the access of light to the nervous expansion or retina, or by those con-nected with the retina itself, or with its nervous communications in the brain (see Amaurosis — Brain). In the former case, "specks," or opacities on the cornea, opacities of the lens, constituting "cataract" (see Cataract) inflammation, acute or chronic, may be the obstructing causes. But, whatever the case, or whatever the probable cause, when so delicate and valuable an organ as the eye is concerned, no time should be lost in submitting it to proper medical examination. For further information, see Amaurosis-Cataract-Eye.

VIS MEDICATRIX NATURÆ, TEN-DENCY TO HEALTH, NATURAL POWERS OF RECOVERY, OR OF HEALING, are all phrases expressive of the same thing: of that power or tendency implanted in a living, organised body by its Creator, to restore to a state of order whatever portion of its living organisation may, by circumstances, have been thrown into disorder. By disorder, is here meant either what medical men call "organic disease," that is, change of structure palpable or appreciable; or what they call "functional disease, or "functional disorder," in which the functions of a part only are affected, or in which, if structure is altered, our means of investigation are not sufficient to enable us to detect the change, and we can only judge of the dis-

ease by its functional symptoms.

The existence of a power tending to health, of a vis medicatrix naturæ, has been recognised from the earliest times; but in what that power consists, medical men have never explained; it is, probably, connected with that principle of life which all created things derive from Him who made them. Without it the efforts of the physician or surgeon would be futile. The ends of the fractured bone might be placed in apposition, the edges of the wound drawn together, but in the absence of the vis medicatrix they would remain so only so long as retained in place by art, however long the artificial restraints might be applied. True it is that the natural tendency to cure may be much weakened-may be almost apparently absent

632

cannot know till we explain what that is which we call "vis medicatrix." Nay, further, till we explain the why and wherefore of disease, why each and all possess certain tendencies to disease, which may, sooner or later, according as they are favoured or not by circumstances, show themselves, and overcome the natural tendencies to health and order in our material systems. These things are connected with the deeper arcana of our being. In this place the question requires more practical consideration. Notwithstanding the recognition of the "vis medicatrix" from the earliest times, it has too often been lost sight of in the treatment of disease and injury, especially in former years; physicians and surgeons acted as if they were the real powers for restoring health, instead of only being the assistants of those powers, and in this way arose an artificial, officious system of medicine, and a meddlesome surgery, from which the worst results ensued. The natural powers instead of being assisted were thwarted, and embarrassed or weakened; if they did ultimately succeed in throwing off the disease, or in repairing the injury, it only served to prove what the natural powers could do even under such circumstances. In times gone by a gun-shot wound was treated with scalding oils, scarified and cauterised; it is now more simply and successfully conducted to cure by the use of water alone (see Dressing). simple wounds, balsams and spirits of various kinds were applied, which now under the plain water-dressing quickly and painlessly get well; but even now, so strongly is the idea of the healing power of plasters entertained by the popular mind, that the cure of a wound is attributed directly to these applications, which only fulfil the mechanical end of holding its edges together, that is, of putting the injured parts in such a position that the natural powers of healing can be exerted.

Formerly, small-pox, fever, and such diseases, were treated by stimulants within, and by the stimulant action of heat without, in the form of hot rooms, closed curtains, and loads of bed-clothes; and, as the reverse of this, it is not long since the natural powers that would cure if they were permitted, were weakened by indiscriminate bleeding. Even now, numbers in this country do not think it possible to get rid of any disease without

By these observations, it is not meant to weaken the confidence of any in the curative or salutary powers of medicines, which are true and real blessings; but it is intended to point out how, by losing sight too much of the natural implanted power of resisting and throwing off disease possessed by the living body, injurious systems of officious meddling prevailed. Indeed, it may be that at present the current has set too strongly the other way, and many are too much inclined to be alto-

death; out why and how this is, we know not, | gether sceptical as to the curative powers of medicine. This, it need scarcely be said, is an extreme, equally vicious with the other, which trusted all to it alone. We know that the vis medicatrix naturæ, the natural tendency to health, is strong, and will often prevail even in the most adverse circumstances; but we also know that it is often weak, that it fails to overcome, or that, whilst it is fighting the battle, its resources, its "commissariat," to speak, fail. In such cases we know that assistance must be given from without by those means, or agents, which He who gave the one power within the body, has endowed with powers capable of assisting that power, of

aiding it in the combat.

Nothing, perhaps, makes the above remarks more obvious than the circumstances which occur in cases of fever. This disease is generally admitted to be a continued state of disordered action in the system, in which-although at times the powers seem to be completely overwhelmedthe tendency is in a large number of cases to run a certain course, ending in recovery, or in the victory of the tendency to health over the acting causes of disorder. None, perhaps, are bold enough to profess to cure a fever-to profess to remove the disease by active treatment, either directly medicinal, or otherwise; and the man who attempts it will probably do so at the peril of his patient. The wise ph sician is content to leave to the vis medicatrix the removal of the disturbance, for which he can offer neither rational explanation nor method of direct cure. But if, in eschewing all active interference, he defers to the power within, in rendering his assistance to that power, he fulfils a most important, a necessary office, and often assists to save a life which the unassisted powers of the body must have lost.

The office of the physician in such a case is to preserve those outward conditions of health, which it is every man's duty to provide for himself when he has health and strength to do so, albeit these conditions now require nice management. The blood of the fever patient is disordered-poisoned. The office of the physician must be, by seeing that his patient draws pure air into his lungs, to facilitate the purification of the vital fluid: the exhalations of the body by the skin and lungs are depraved; he must see that, by the removal of these, and of all things which can absorb and retain them, the diseased action is not assisted: the excretions from the bowels are depraved, offensive, morbid; the due evacuation of these must be attended to: the natural appetite and power of digestion is all but annihilated, but a process is going on within which is consuming, burning up the framework, and may come to bear upon the vital tissues; to prevent this the medical man must support strength by nourishing fluids, which pass easily, and with little digestive effort, into the circulation; and if the disease goes on, if the

"vis medicatrix" is still combating, and | requires but a little time longer; if, then, all the available supplies for carrying on the ordinary processes of vital warmth, &c., are exhausted, he must, with wine or brandy-alcoholic fuel -keep, almost artificially, the machinery at work. In such offices as the above, and many more, surely there is abundant room for the skill, the judgment, the interference, of a medical man, without his attempting to take into his own hands the office of that power which he cannot supersede, but which he may greatly thwart. In such a disease as fever, it is true, medicine, although often, or rather always, requisite, is not so to the same extent that it is in other diseases; but even in others, in which, such as neuralgia, we can often directly trace the removal of the disorder to the administration of the remedy, we can only look upon the power of the latter as the assistant to the natural tendency to cure. There are, it is certain, some diseases, such as cancer, which resist not only all efforts for their removal from within, but all the assistance we can give by remedy. Why it is so, we cannot tell; that they are thus "incurable," is probably because we are ignorant of the remedy which might give the assistance to the natural tendency to health, which would enable it to overcome the disease, just as there are certain obstinate ulcers, or affections of the skin, which resist many modes of treatment, and at last yield under the influence of a particular remedy, but yet to the remedy can only be ascribed the power of assisting.

The present subject has been dwelt upon, because, as already observed, from the extreme which at one time existed, of trusting all, or, to say the least, too much to medicines, drugs, &c., there certainly has been a tendency in many to discard these altogether, and to trust entirely to the powers, the "vis medicatrix naturæ." As in most other things, in the medium will be found the best course; and he probably will treat disease most successfully who endeavours, by strict attention to the sanitary surroundings of the patient, to put the natural powers of resisting and casting off disease in as favourable a position as possible; who trusts those powers, but yet watches their operations, and who is prepared, with full confidence in the efficacy of medicines, to use them decidedly and actively when rational ground

for doing so appears.

There has been, undoubtedly, far too much trusting to drugs alone, and far too great neglect of the general principles of health, in the treatment of disease, but it is folly on that account to attempt to cast aside medicines altogether. If the Author of all things im-planted in the living animal body a "vis medicatrix," He also endowed other substances with the capability of assisting that power. We can see how the neglect of the first was an error; surely to ignore the last must be so too.

VITRIOL .- See SULPHURIC ACID and

VOICE, or VOCAL SOUND, produced in the larynx (see Lungs), is the endowment of animals generally, and differs from speech, possessed by man alone, the latter, physically speaking, depending upon the formation and action of the parts about the mouth. Crying, singing, and the sound of speech all depend upon the action of the larynx, which partakes of the characters of both a wind and of a stringed instrument. In some diseases the alteration in the voice is very characteristic. In Asiatic cholera it acquires a very peculiar pitch; in consumption it is often of a remarkable hollow character; in some forms of disease it may be almost lost. In cases of aneurismal and other tumours pressing on the nerves which go to supply the mechanism of the voice, a remarkable alteration of intonation takes place, sometimes accompanied by peculiar changes in the sounds of the cough, very familiar to the physician. - See Aphonia-Cryof Children-Reading Aloud-Laryngoscope, &c.

VOMITING is the action of discharging the contents of the stomach through the gullet and mouth by muscular effort, or rather by a combination of muscular efforts. Formerly, it was imagined that vomiting depended upon "convulsive" action of the stomach alone; after that it was thought that the stomach was passive in the act, and that the pressure of the muscles of the abdomen, thrown into violent action, was the sole cause. It is now well ascertained that both these agencies are called into play when vomiting occurs; that the stomach does, by the action of its muscular fibres, assist in the expulsion of its contents, but that its efforts are greatly aided by the muscles of the abdomen, including the diaphragm (see *Diaphragm*). Every one is conscious, that previous to the act of vomiting, a deep inspiration is taken; by this the diaphragm is forced downwards towards the cavity of the abdomen, and being there fixed, or rendered tense, by the contraction of its own fibres, it offers a fixed point of resistance, against which the stomach can be pressed by the contraction of the muscles in the forepart of the abdomen. At the moment that this almost convulsive pressure is exerted on the stomach, and by the stomach on its contents, the muscular fibres at the "cardiac" junction of the stomach with the gullet (see Stomach) are relaxed, so as to permit of the passage upwards of the matters contained in its cavity, whilst, at the same time, the glottis is closed, so as to protect the larynx and air passages, as in swallowing.

Vomiting is requently preceded by nausea (see Nausea), but not always; probably it is not so in the vomiting of infants, which overfill their stomachs, for nausea is a sensation which causes uneasiness and distress, and yet the little creatures generally look remarkably

happy whilst they relieve their stomachs of a stop to it. For this purpose the remedies the overload. Again, some persons, especially dyspeptics, possess the power of vomiting at will, and can, without any feeling of nausea, discharge the contents of the stomach; neither is there much, if any, feeling of nausea connected with the vomiting which sometimes follows coughing, sobbing, and over-eating.

The causes of vomiting are very numerous. It may depend on local irritation of the stomach by bile, mucus, &c., or by indigestible food, by medicine, or by poison; it may be excited by the mechanical efforts, and probably through the intimate nervous communications in cough, hiccup, sobbing, laughing, &c.; it is often sympathetic with and symptomatic of disease or accident in distant parts, or of excited action in distant organs, as in the case of the womb in pregnancy, or in sea-sickness. Irritating or tickling the throat likewise causes vomiting. In some persons, disagreeable or peculiar tastes, smells, and even sights and sounds, will give rise to vomiting; mental emotion will produce it, and certain drugs, such as tartar emetic, give rise to it if injected into the blood. At the onset of acute disease, vomiting is a common symptom. When a person becomes affected with vomiting, it is of course well to keep these various causes in mind; for though, in the majority of instances, perhaps, vomiting depends upon disorder in the stomach itself, it must evidently be of much consequence to recognise it as symptomatic of disease, which is often of a serious character.

When vomiting has been preceded by symptoms of indigestion, or when it is of a bilious character, accompanied with furred tongue, &c., the probability is that it depends upon the presence of bile or other matters. In such cases, if the natural process of relief appears inclined to be sufficiently energetic, it will be enough to assist by drinks of tepid water or gruel, or of chamomile tea; if the action is not sufficient, an emetic (see Emetics) may be given to fulfil the natural indications. These attacks of spontaneous vomiting from disorder of the digestive organs are frequently accompanied with diarrhoea; but when this does not occur, it is generally advisable to give aperient medicine in some form, and as the stomach often remains unsettled, nothing seems sooner to restore it than a few effervescing draughts, either simple, or containing a tonic bitter .-See Indigestion.

Vomiting, however, may continue from simple irritability of system or stomach, after the irritation in the latter organ has been removed; when it does, means for allaying that irritability must be resorted to, similar to those employed when the vomiting is the result of sympathy, as it is in pregnancy, &c. In any case, obstinate vomiting is so distressing a symptom, and one so injurious to some

recommended are very numerous.

If there is offending matter in the stomach, which is the cause of the vomiting, it is of course useless to attempt to stop the latter till the former has been removed, as adverted to

As general remedies in vomiting, effervescing draughts are the most safely usable by an unprofessional person; also alkalies, or magnesia, if there is acidity; and with these it is advis-able, at times, to combine a stimulant, sal volatile, or if calcined magnesia is used, a little sherry. Small fragments of ice allowed to melt gradually in the mouth will frequently allay the irritation of the stomach. Diluted hydrocyanic acid in five minim doses, every two or three hours till the vomiting ceases, is a favourite remedy. Opium, chiefly in the form of hydrochlorate of morphia solution, may be given in doses of from ten to twenty minims, or may be combined in less proportion with from ten to twenty grains of subnitrate of bismuth. The fermented preparation of milk called Koumiss will often remain on the stomach while other foods, including fresh milk, are rejected. The writer has often treated successfully the obstinate vomiting of pregnancy by one minim doses of ipecacuanha wine, given every hour in a tea-spoonful of water. In other cases, two minim doses of tincture of nux vomica in a drachm of water may succeed. Besides internal remedies, assistance may be derived from external applications, such as three or four leeches to the pit of the stomach, if there is much tenderness, or a mustard plaster or blister; position, too, whether recumbent or not, may make considerable difference. It may be well not entirely to neglect the indication of appetite, or of any unusual craving for food of a particular kind; its gratification may stop the symptom. When vomiting comes on without obvious cause, and when it continues to recur, a medical man should be seen at once, for it may be symptomatic of serious disease. If, without obvious reason, it happens shortly after a meal, and especially if more than one person is affected, the possibility of poison is not to be forgotten.

SLEEP, &C.

WALKING is the natural exercise of man, and for the strong and healthy it is the best. Even in the case of the debilitated and of the aged, it should not be neglected: no other mode of exertion diffuses the blood and accelerates its circulation so thoroughly throughout the body. The principal caution patients, that it is desirable at all times to put required for such persons is not to continue

WAT WAL

are not unfrequently injured and weakened in constitution by their daily exercise being a walk, too often carried to fatigue, especially in summer. When attainable, a playground in which rest and exercise can be taken alternately, and at will, is much preferable to the former. Any unusual peculiarity in walking, especially in children or young people, should not be permitted to pass unnoticed; it may be the first indication of spine or hip disease.

WALLS AND WALL-PAPERS .- The principal object, on the score of health, tobe regarded in the external walls of dwellings is, that they shall be sufficiently thick for warmth, and not of such porous material as will too readily absorb or give out moisture. Some kinds of stone and badly-made bricks do this, and render dwellings unwholesome. The defect of outer-walls, either as regards material or thickness, may be considerably ameliorated by lathing and plastering within. In covering the inner walls of houses either with paint or paper, too little regard, perhaps, has hitherto been paid to the effect of the materials which are used on health. In another part of this work, it was stated that colours containing lead and arsenic have been found to affect injuriously the occupants of rooms to the walls of which they have been used. Moreover, as light exerts so strong an influence upon health, it is not unlikely that wall colours, especially in the variation from light to dark, may be found to do the same.

Wall papers are of course liable to the same objections, and also to another connected with the size, by means of which they are attached. This will be best illustrated by the following "Hints on Paperhanging," from a popular

periodical.

"Many a fever has been caused by the horrible nuisance of corrupt size used in paper hanging in bed-rooms. The nausea which the sleeper is aware of on waking in the morning, in such a case, should be a warning needing no repetition. Down should come the whole paper, at any cost or inconvenience; for it is an evil which allows of no tampering. The careless decorator will say that time will set all right, that the smell will go off, that airing the room well in the day, and burning some pungent thing or other at night, in the meantime will do very well; it will not do very well; for health, and even life, may be lost in the interval. It is not worth while to have one's stomach impaired for life, or one's paragraph about the calculations. nerves shattered, for the sake of the cost and trouble of papering a room, or a whole house, if necessary. The smell is not the grievance, but the token of the grievance. The grievance is animal putridity, with which we are shut up, when this smell is perceptible in our Down should come the paper; of every particle of its last covering. It is by weight. Chemists demonstrate the gaseous chambers.

their exercise till exhaustion occurs. Children | astonishing that so lazy a practice as that of putting a new paper over an old one should exist to the extent it does. Now and then an incident occurs which shows the effect of such Not long ago, a handabsurd carelessness. some house in London became intolerable to a succession of residents, who could not endure a mysterious bad smell which pervaded it when shut up from the outer air. Consultations were held about drains, and all the particulars that could be thought of, and all in vain. last a clever young man, who examined the house from top to bottom, fixed his suspicions on a certain room, where he inserted a small slip of glass in the wall. It was presently covered, and that repeatedly, with a sort of putrid dew. The paper was torn down, and behind it was found a mass of old papers, an inch thick, stuck together with their layers of size, and exhibiting a spectacle which we will not sicken our readers by describing.

WALNUTS are about as wholesome and unwholesome as nuts generally. The infusion of walnut-tree leaves has been highly extolled as a remedy in scrofula, but that such is the case we have no sufficient evidence. tincture from the leaf of the walnut given in tea-spoonful doses will often check vomiting.

WARM FLUIDS. - See DILUENTS -

HEAT, &C.

WARTS are enlargements of the papillae of the true skin, and thickening of the covering epidermis or scarf skin. They are most usual in children, up to a little beyond puberty, and generally occur on the hands, sometimes on the face. In the latter situation, they are better not interfered with. When situated on the hands, they often disappear of themselves; when their removal is desired, strong acetic acid, applied every two or three days, is quite the best remedy; caustic, however, or tying, or cutting them off, are measures also resorted to. When a wart on the face, especially in those advanced in life, appears inclined to become ulcerated, or irritated, it ought to be shown to a medical man. It may require removal, to prevent it from degenerating into cancer.

WATER.-This apparently simple fluid, considered by the ancients as one of the elementary or simple bodies, is composed of the two gases, oxygen and hydrogen, in a state of chemical combination, in the proportion of eight parts of the former to one of the latter,

WAT WAT

decompose the fluid by means of electricity, and collect the two gases separately, or they form it by causing the two gases to unite in proper proportion. Indeed, the formation of water by the union of the gases may be witnessed by any one in the moisture evolved inside a gas lamp, in consequence of the union of the burning hydrogen with the oxygen of

the atmosphere.

Water, when perfectly pure, is transparent and colourless, without taste or smell. It freezes at 32°, and boils at 212° Fahr. however, impossible, perhaps, to procure perfectly pure water, except by the process of artificial distillation; even rain water, which is the purest natural water, although collected at a distance from human habitations, is found to contain traces of ammonia, and sometimes of nitric acid; if collected near dwellings, it is of course liable to contract much greater impurity. Nevertheless, rain water, being the product of natural distilla-tion, that is, having passed into the atmo-sphere in the form of vapour before its descent as rain or snow, is free from the saline and other impregnations which it necessarily possesses as soon as it has come in contact with the earth.

It is reckoned that a healthy man requires, for his daily consumption, from sixty to seventy ounces of water, about one third of which he obtains from his solid food, and the remainder from tea, coffee, and other beverages (including water), which he is in the habit of consuming. There is no nourishment in the ordinary sense of the word in water, but as the human body is made up in the proportion of from two-thirds to three-fourths water, it is even more necessary for our existence than solid food; a man may live for weeks on water alone, but he would die in a few days if totally deprived of it, and the sensation of thirst is far more terrible to bear than that of hunger. fluids which are constantly ebbing and flowing through the various organs of the body, and undergoing changes of a chemical and mechanical nature, in the processes of secretion and absorption, must make their exit in time in the solid, liquid, or gaseous state. It is calculated by the best observers that rather more than a pound of fluid is exhaled daily from the lungs, one pound and three quarters from the skin, and not less than two pounds and a half from the kidneys; so that altogether, the estimated excretion of water daily from the system is over five pounds, which has to be returned, in the process of repair, in as pure a condition as it is possible to obtain it. The water in our food, in our tea, and in our beer (if we indulge in the latter), has undergone changes in the preparation which, in all probability, deprive it of any deleterious influence the water may have possessed in the first in-

composition of water in two ways: they either | ready means of destroying any germs of organic life that may exist in the water, though such may not have been patent to the senses. Hence, when any suspicion exists as regards impurities in water, it is a wise precaution to have it boiled before using it in any form, apart from filtration, which for the most part only removes mechanical impurities. Water, however, which has been boiled, is flat and mawkish, and few partake of it unless compelled by sheer neces-The best kinds of water for drinking purposes are those which are clear, transparent, and well aerated, which sparkle in the vessel into which they are poured, and which are without taste or smell. As a rule, water contaminated with animal or vegetable matter has an unpleasant odour and also taste, and is often turbid, although this is not always the case, while some of the clearest waters are quite unfitted to drink. On the other hand, turbid water may be perfectly pure, when it owes its turbidity to the sands through which it passes; but in most cases it must be regarded with suspicion, especially when it proceeds from shallow wells in the neighbourhood of houses.

> With the exception of the air, no necessity of man's living existence, perhaps, exercises more powerful and direct influence for good or evil than the water he imbibes; indirectly, also, it affects his moral condition, whether considered as a beverage, or according to its economic uses. Notwithstanding, however, the acknowledged utility in every way of a free supply of pure water, it must be considered not only an anomaly, but a disgrace to the boasted civilisation of the latter part of the nineteenth century, that so little attention has been given to supplying most of our large towns with this necessary of healthful existence, physical and moral. In their provision for water, the ancients far, very far, surpassed the moderns, as the remains of their magnificent aqueducts testify, and b stowed great care and expense on the means of procuring it pure.

Rain Water .- As stated above, rain or snow furnishes water freer from impurities than that procured from any other source; the absence of all saline impregnations especially renders such water peculiarly well adapted for cleansing purposes; it dissolves soap easily and readily, not curdling it as the hard waters do. Rain water is seldom used for drinking, on account of its vapid taste; but from its softness and freedom from impurities, more especially in country districts, it can be usefully employed in cooking, tea making, and for other domestic pur-In the case of an epidemic of any kind, and when the ordinary water supply may be suspected to be at fault, it is often advisable to have recourse to rain water only, but it should be remembered that rain water in or near towns is always largely contaminated with the impurities in the air, and should be stance; as in the process of boiling, we have a avoided for drinking and cooking purposes.

WAT WAT

Rain water which has descended upon, and | entered the earth, becomes, as stated above, impregnated with impurities of various kinds; these vary according to circumstances; they are classed as mineral or saline, and as vegetable or animal impurities. There may also be impurities which are wholly dissolved in the fluid, and others which are merely mechanically suspended; the latter are capable of being completely separated by filtration, the former are

"Hard" and "Soft" Waters .- The most important and generally abundant saline impurity in water is the carbonate of lime, from which hard water chiefly derives its character; besides this salt there are often to be found in smaller quantity sulphate and nitrate of lime, common salt as well as salts of magnesia and iron; the latter impurity, however, is not very common, except in mineral springs. The degree of hardness of any water is indicated with reasonable accuracy by the amount of soap re-

quired to form a lather with it.

The earthy salts, that is, those of lime and magnesia (and especially lime), are the chief sources of hardness in water; excess of carbonic acid and the presence of iron are occasional causes not often met with. Filtering such water does not in any way modify its When the hardness of water arises from excess of carbonic acid, exposure to the air in great measure removes the inconvenience, and also does so slightly in water rendered hard by the presence of the carbonates of lime or magnesia; such waters, however, are softened in some degree by long boiling, which causes the separation of the salt of lime or magnesia, in the form of an insoluble carbonate; this is in fact the chief constituent of the crust or "fur" which forms inside boilers, kettles, and sauce pans, in districts where the water is hard. Waters are consequently water is hard. divided into "hard" and "soft" in proportion to the amount of mineral ingredients they contain, and although soft water is preferable to hard for most domestic purposes, it does not follow that hard water is of itself injurious. The differences in the two waters depend on the nature and character of the soil through which they percolate. Small quantities of hard water can be successfully made soft by distillation; boiling also greatly reduces the hardness by causing precipitation of the carbonate of lime held in solution by carbonic acid. No process is practicable for completely removing the hardness on a large scale; but it can be much reduced.
The process, which is known as "Clarke's"
(having been patented by Dr. Clarke of Aberdeen) is a very interesting one, showing how an excess of the mineral impurity added to the water relieves it of its objectionable character. The carbonate of lime, which is the cause of the hardness, is soluble in the carbonic acid contained in the water, and when quicklime is added to the latter, the acid is no longer capable ally impure or contaminated from accidental

of retaining it in solution, but combining with the excess of lime, deposits it in the form of chalk in the bottom of the tank. It may be remarked that hard waters are far more frequent either from surface springs or sunk-wells; and that certain springs, especially from the surface of hilly or undulating countries, are often extremely soft, such springs being in fact supplied by surface water—that is water which has only percolated through the upper strata, and has not passed through those which furnish the deeper springs with their saline, lime, and magnesia impregnations.

River Waters are softer than surface or deep well waters, but still hard, and if the rivers have villages or towns on their banks, they are liable to be contaminated with sewage

impurities.

Lake Waters, especially those from among the mountains, are very soft and pure, and, whenever practicable, large towns should be supplied with water from this source.

Artesian Well Water, that is to say water obtained by boring to a great depth through clay or other impervious strata to the chalk or water-bearing rocks, may be either soft or hard, and can always be depended on for its purity.

For purposes of drinking and cooking, and especially the former, the importance to a population of a due supply of good pure water cannot be over-estimated. If the water is impure, it either injures the health or drives people to take it in combination, too often with spirits, or under other forms, and thus engenders habits of drinking. It is, indeed, not improbable, that many of the artificial drinks have been resorted to solely as substitutes for bad water. In the choice or appreciation of a drinking-water, people will, perhaps be greatly guided in their judgment as to pleasantness by the nature of that to which they have been accustomed. As a general rule, however, most people prefer a water which contains a slight amount of mineral ingredient. At the same time, those who have habitually drunk even very hard water do not at first relish that of a softer character. Water which has been drawn for some time becomes, as all know, unpleasant and vapid; this is often accounted for by the loss of carbonic acid, or air, which most waters contain naturally. Another, and probably more powerful cause of the acquired unpleasantness than either of the above, is the facility with which water attracts atmospheric impurities and exhalations, and there are generally sufficient of these to be met with.

Water Supply in Towns .- In large towns especially, where diseases spread rapidly from an impure or deficient supply, it is the duty of the municipal authorities to take every pre-caution against the numerous dangers which the experience of recent years has shown to be associated with drinking water either origin-

and unseen sources. In towns, the necessary arrangements for distribution are usually in the hands of the water companies, who calculate roughly the wants of the community by apportioning to each member as many gallons of water per day as their sources of supply will permit, keeping in view in the calculation a suitable provision for town requirements, such as watering of streets, extinguishing fires, and other purposes. From the inquiries made by the Rivers Poliution Commission, the average amounts vary greatly, ranging from a minimum of 4 gallons per head in one town to a daily maximum of 140 gallons in another. Professor Rankine considers that an allowance of 10 gallons per head daily for the domestic requirements of each member of the community should be the rule with all water companies, and that 10 gallons more should be supplied for town and trade use in non-manufacturing towns, while an extra 10 gallons, making in all 30 gallons per head, should be furnished to manufacturing populations. The accompanying table, taken from Parkes' Hygiene (edition by Dr. De Chaumont) gives the estimated by Dr. De Chaumont), gives the estimated amounts supplied to each head of the population by various water companies in their respective districts and towns:-

There are two ways by which water companies convey their supply to houses, named respectively constant and intermittent, the terms sufficiently explaining the mode of distribution in each case; of the two methods there can be no doubt—notwithstanding the liability to a certain waste of the commodity—that the "constant" plan of water supply is preferable to the other, inasmuch as the water being constantly at high pressure in the pipes, there is little danger of the supply running short, or of its being contaminated in cisterns, since these are in a measure dispensed with. It is always advisable, however, in either case, to have small reservoirs in direct

connexion with the water-closets, the best forms of which are known usually by the name of "water waste preventers," and which supply usually two gallons of water and no more each time the closet basin is flushed. It is of importance, moreover, as Dr. Corfield has pointed out, that the water-closets should not be supplied directly from the main, as it happens occasionally from some unavoidable cause, that the constant service is suspended, and the house is served for a time on the intermittent system, in which case foul matters may get into the pipes, either from the soil through leaky joints or from the basins of the closets.

To ensure health and cleanliness it is most important that water should be laid on, not only in every house, but in every occupied floor of the house, and it should also be borne in mind that surplus water is not wasted so long as it fulfils the useful purpose of helping to flush the drains.

Impurities in Water .- A small amount of mineral ingredient may not be, and probably is not, injurious; but water containing any great amount cannot be regularly consumed without risk to health, although more to some constitutions than to others. It is tolerably certain that the origin of bronchocele or goitre is connected with the presence of magnesium salts in the waters of the districts in which the disease prevails; and, in all probability, certain hard waters are responsible for some urinary diseases. Bad as hard waters may be, however, those impregnated with organic matter, especially of animal origin, are beyond comparison worse, and are fertile sources of disease. Indeed, there is every evidence to show that organic matter in itself is capable of causing illness, but its presence is important chiefly because it is indication of a risk that the water may become specifically contaminated with the germs of disease (see Enteric Fever and Cholera). Dysentery, diarrhœa, and ague, are other diseases which have often originated from drinking bad, especially marsh, water. It ought also to be remembered that though the water may be good when drawn, if it be preserved in bad receptacles, such as butts, the wood of which is decayed, in cisterns lined with lead, on which the water acts (see Lead), or where it is exposed to contract impurities from the atmosphere, a really wholesome fluid may be converted into an unwholesome or even poisonous one.

Microscopical Appearances of Water.— Under the microscope, water will be seen to contain (in a greater or less degree, according to its purity) various forms of animal and vegetable life, the leading types of which are figured in the accompanying plate (fig. 240), which contains a representation of the following common species:—

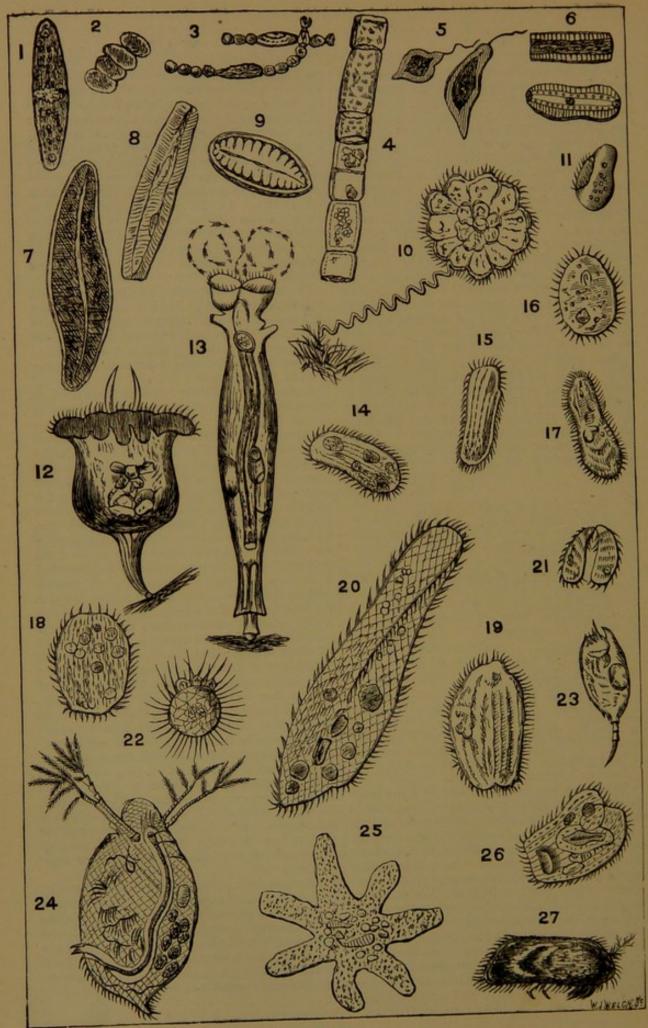

Fig. 240.

Closterium. Semidesmus obtusus. Spores of a fungus. Conferva floccosa. Englena viridia

Diatom vulgare, Pleurosigma angulatum. Navicula viridis. Surirella spiendida.
 Colony of vorticella.
 Cyclidium glaucoma.

12. Brachionus. 13. Rotifer vulgaris. Oxytricha lingua.
 Pellionella.

No. 16. Glaucoma scintillans. 17. Glaucoma Gibba. 18. Leucophrys striata 19. Paramæcium aurelia. 20. Paramæcium tum. 21. Paramæcium chrysalis. 22. Actinophrys sol (budding). 23. Monura dulcia. 24. Daphnia, 25. Amoeba. 26. Chilode 27. Cypris. Chiloden.

Of these microscopical appearances, Mr. Blyth says: "Confervoid growths, algæ, and desmids (Nos. 1, 2, 4, 5, 6, 7, and 8, fig. 240) are met with in running streams of great purity; and if these are the only structures met with, a water should not be condemned; but, in my experience, when such forms have been numerous, infusorial life is also present. On the other hand, ciliated forms (such as Nos. 14, 15, 16, 17, 18, 19, 20, 21, and 23, fig. 240) are, as a rule, indicative of sewage contamination; it is, indeed, said that waters containing paramæcium are even injurious to animals. Cotton tibres, epithelium, potato, starch, hairs, and similar structures, although they may be harmless in themselves, are evidences that the water is susceptible of human contamination. Fungi and much decaying vegetable matter are always suspicious.

"With regard to the interpretation which should be put upon microscopic results, the fewer living forms met with, as before said, the purer the water."—Hygiène and Public Health (A Dictionary of).

Water as a Beverage.—It is perhaps going too far to say that man should never drink anything but the natural beverage provided for him; that it is the only wholesome regular drink of healthy men is certain, but to contend that it never should be varied is inconsistent with the law, which seems so general, that change within certain limits is more beneficial than unvarying uniformity. Moreover, if water be the most abundant natural beverage, milk and vegetable juices furnish others in great abundance, and there can be no question that tea and coffee are providential provisions for man's health and comfort (refer to Tea, Stimulants, &c.). At whatever other times water is drunk, and in whatever proportion to other beverages, it is never more beneficial to the majority of people than on first rising in the morning; then a draught of pure fresh drawn water is a most admirable persistent tonic, which may be continued a life through; it has, too, the advantage of stimulating the bowels, and assists to keep them open. Some few persons of weak digestive and nervous power cannot take a large draught, though they may a small one. Another most wholesome period for a good draught of water, with persons of tolerably good nervous power,

mit the error of drinking water too largely with their meals. This acts injuriously by washing down the food insufficiently masticated, by giving a sort of artificial appetite, so that more than enough is consumed, and it injures digestion by lowering the temperature of the stomach. Too large a draught of cold water when the body is heated, especially if exhausted, it is well known, is apt to prove serious, perhaps fatal (see Shock). In disease, both as an external application (see Ablution, Affusion, &c.) and as an internal remedy, water is most valuable; and, indeed, in febrile diseases attended with much thirst, it may be allowed largely with the greatest benefit. Moreover, pure cold water is generally preferred, at least for a time, to all the artificial drinks. There is among the poor, and even among others, an unaccountable prejudice against allowing the sick to drink cold water. There need be no fear when it is craved by feverish thirst, indeed few febrifuges excel it as a remedy.

In recent years much confidence has been established in filtration on a large scale as conducted by water companies. The absence of very frequent outbreaks of such diseases as enteric fever among communities supplied by river water from a stream which, above the intake, has received the sewage of a large population, points to the conclusion that the poison, the bacterial nature of which has now been pretty conclusively proved, is arrested by the process. Were this not the case one would expect that widespread epidemics would constantly occur whenever cases of enteric fever existed in the community up stream. Quite recently, during the epidemic of cholera at Hamburg, Prof. Koch demonstrated that the almost complete absence of the disease in one part of the town, while it was so fatally prevalent in another, was to be accounted for by the fact that although both parts were supplied with sewage polluted river water, the water was supplied to the infected part in an unfiltered state, whereas in the case of the district free from cholera the supply was passed through a sand filter. It is not a very consoling thought to know that large populations have to depend upon a few inches of sand to protect them from enteric fever or cholera; but, so long as water-supplies are derived from sewage-polluted streams, it is some satisfaction to learn that the measures adopted to purify them are attended with success.

WATER BEDS AND CUSHIONS.

See BED-INDIA RUBBER.

WATER-BRASH - PYROSIS - is a disorder characterised by occasional vomiting of clear fluid, either sourish or tasteless, from the stomach. It is a frequent accompaniment of chronic indigestion, and those who live is just before dinner. Many, however, com- much on innutritive vegetable food are peculiarly liable to it. Before the fluid is brought up there is often pain, more or less severe, experienced at the pit of the stomach. Improved diet, and the treatment of indigestion generally, are the most suitable measures. One of the best remedies for this distressing affection is the subnitrate of bismuth, of which twelve grains may be taken twice a day, along with five grains of aromatic powder, well mixed in a little milk. Under article Saliva, an affection which is generally confounded with water-brash is alluded to.

Refer to -Indigestion.

WATER-CLOSETS .- On account of the dangers which have been proved to be associated with the introduction of water-closets, and which have been especially brought under public notice during the last few years, a variety of different closets have been patented and introduced into public institutions as well as into private houses; some entirely on new principles, while others are simply modifications of those which have been a long time in use. The main object aimed at is (1) to secure a basin and trap that will prove efficient in intercepting sewer emanations, (2) that will nor readily foul of themselves, and (3) to obtain a sufficient flush of water to rinse the basin and syphon without unnecessary waste. It is doubtful whether many of the new contrivances referred to surpass in efficiency the ordinary hopper basin (fig. 241), either jointed

40, or continuous with, a syphon of the same stoneware, in which a stratum of water must always remain until removed by flushing. This is the cheapest form of water-closet, and consequently it is most used in the houses of the

The "pan" or "container" closet is not a very costly apparatus, and on this account, notwithstanding its very objectionable character, it is still sometimes employed. In this closet (fig. 242), the narrow end of the basin M projects into a copper pan or saucer, which retains a considerable quantity of water when out of use, by means of which the basin is sealed from communication with the iron

box receiver underneath. The pan O (which is in immediate communication by a hinge joint with the pull-up mechanism is upset each time the former is brought into action, and its contents precipitated into the receiver N, and thence to a leaden trap continuous with the

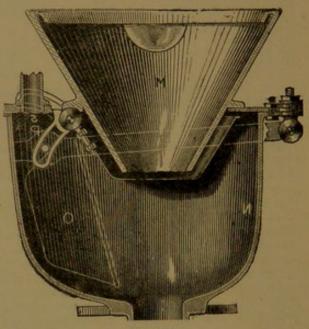

Fig. 242.

soil pipe. The objections to the pan closet are the difficulties experienced in keeping the syphon (or whatever trap is used) free from foul air, which is all the more liable to collect there on account of the iron receiver and the under surface of the pan becoming, in course of time, encrusted with dirt, from which filthy odours are given off each time the closet is used.

The vortex closet (fig. 243), which is an adaptation of the hopper closet, is a much

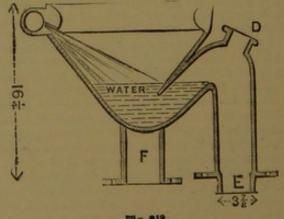

Fig. 248.

improved form, and belongs to the class which is known as the "wash-down," in contradistinction to the "wash-out" (fig. 244). The "wash out" closet was first introduced by Mr. Hellyer as an improvement upon the hopperform of closet, but it is now unhesitatingly and

WAT

deservedly condemned by him. Unfortunately, it has been manufactured in large numbers and fixed in many houses, with the result that large numbers have since been removed in consequence of the nuisance which invariably arises from all closets of this pattern unless an unlimited water flush, more than any water company would sanction, is pro-

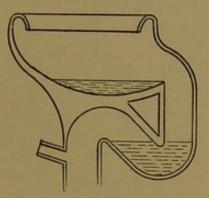

Fig. 244.

vided. Comparing this closet with the "washdown" closet (fig. 243), the explanation of the following defects in the former will be understood. By introducing the shallow container above the trap, which is intended to prevent, and which, no doubt, does prevent to some extent, the fouling of the basin, the flushing effect of the water is greatly impaired, and, in consequence, the trap is seldom, if ever, emptied of its contents. The result of this is that the mixture of urine and fæcal matter, which remains in the trap after the imperfect flush, leads to a deposit being formed on the sides which soon begins to decompose, and each time the closet is used a certain area of this deposit is exposed and foul odours are given off. In addition to this, the splashing of the flush against that part of the closet immediately above the trap causes portions of fæcal matter to be deposited on the sides, in a position beyond convenient reach for cleansing. In time this causes the glaze to crack, and so, by converting what ought to be a non-porous into a porous surface, the mischief is added to. The effect of both these faults is to produce a condition of things which is hardly less objectionable than the nuisance met with in the case of the old pan closet.

The "wash-down" closet on the other hand, if it is designed on proper principles, is free from these objections, as in most cases a twogallon flush will suffice to empty the trap; at the same time a three-gallon flush is to be preferred; but, unfortunately, as a rule, the regulations of the water companies will not

allow of this amount.

A good valve-closet, such as is shown in the drawing (fig. 245), is undoubtedly the most satisfactory form of closet, provided expense is no object. It consists of an earthenware enamelled basin, A, which is kept about two-

the outlet. The water flush is connected with the rim of the basin, which is turned inwards upon itself, C, so that the discharge passes all over the surface, in place of being distributed over one side only, as is the case with the fan spreader. By means of a "pull," the valve is depressed within the box, D, which is connected with the basin above and with the soil-pipe trap below, and thus the water and the contents of the basin are discharged through an opening 3 inches in diameter into the soil-pipe. The valve-box, which ought to be made of cast iron enamelled in the inside, is connected with the trap by means of a short conducting pipe, E. An overflow, F, connects the basin (above the water level) with the valve-box below. This is accomplished by means of a lead pipe with a properly con-

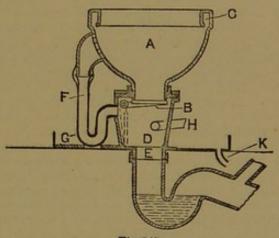

Fig. 245.

structed syphon trap, G. It is also important to ventilate the valve-box by a pipe, H, which should be carried through the wall, where it may be cut short. This vent does away with the danger of the syphon-trap of the closet overflow being unsealed by the rush of water when the closet is in action. Upon the floor under the closet, a safe or tray should be fixed to prevent injury to the floor or to the ceiling below (if the water-closet is on an upper floor), in the event of the overflow of the basin being stopped, and the supply valve becoming defective, or any other accidental circumstance that might cause leakage. An overflow, K, from this safe should be carried through the wall, where it should be cut short. The plumbing work connected with the fixing of all closets is of the utmost importance, as the best appliances may be rendered faulty by a careless workman. To go into detail in describing such work would occupy too much space, but a few of the more important points may shortly be mentioned.

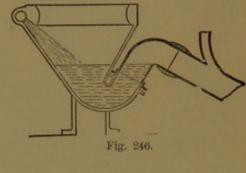

Soil-Pipes. - Drawn lead soil-pipes with properly "wiped" joints are by far the best. In most old houses seamed lead pipes will be found, and it is the rule to find them riddled with holes along the seam. Very often such thirds full of water by means of a valve, B, at | pipes are built into a wall, and their presence

thoroughly saturated with sewage. For eco- ware trap below the level of the water, so nomical reasons, iron pipes are now often used, that if any fault should occur, it will imand, as a rule, ordinary rain-pipes with putty | mediately be noticed, owing to leakage takjoints are made to answer the purpose. The ing place. In the case of a closet on the only iron pipe which is admissible for this ground floor, the best form of joint is that purpose is one which is strong enough to shown in the drawing (fig. 246a), the out-go allow of proper caulked lead joints being made, hence a water main pipe is necessary, and it should be protected from rust by Angus Smith's varnish. Glass enamelled iron soilpipes are now made, and they seem to answer very well, and are much cheaper than lead, at the same time, if cost is not a consideration, drawn lead pipes are to be preferred to any

Soil-Pipe Connections .- The connection of the closet with the soil-pipe, and of the soilpipe with the drain, are matters of considerable importance. In the case of closets with lead out-goes, no difficulty need be experienced, as the union is made by means of a wiped Until recently considerable difficulty was experienced in properly connecting an earthenware out-go with a lead soil-pipe. Some plumbers were satisfied with simply making a putty joint, but it is obvious that this was highly unsafe. Various patent joints were then introduced, most of them consisting of a rubber ring placed between a flanged outgo from the closet, and a similar flange made by tufting back the lead soil-pipe connection, the whole being screwed up by means of clamps. Such a joint answered very well for a time, but, rubber being liable to perish, sooner or later it became defective, and leakage occurred. This difficulty has now been completely got over by a joint which was first brought out by Doulton & Co., called the metallo-keramic joint, an arrangement by which a lead out-go is firmly connected to the pottery, thus allowing of a wiped joint connection with the soil-pipe. Although Doulton & Co. were the first firm who made such a joint, several other firms have since brought out similar joints with lead out-goes fastened to the earthenware practically in the same way, so that no difficulty need now be experienced in obtaining a satisfactory wash-down closet for fixing to lead soil

In some cases it may be thought desirable to fix closets in such a way that in the event of damage to the earthenware, which not infrequently happens in asylums, the apparatus may be replaced without disturbing the soilpipe connection. The flanged joint with the rubber ring would answer this purpose, but, as pointed out, it is not a reliable joint, and there is no necessity now to make use of it. A far better joint has been introduced by Dent & Hellyer which meets this requirement, and allows of a "wiped soldered" connection with the soil-pipe being made. This arrangement is represented in section in the arrangement is represented in section in the drain, a sound joint may be made by an arrangement in the drain, a sound joint may be made by an arrangement shown in the drawing (for 246b). drawing (fig. 246). It will be noticed that arrangement shown in the drawing (fig. 246b).

is not discovered until the wall has become the lead out-go is bolted on to the earthen-

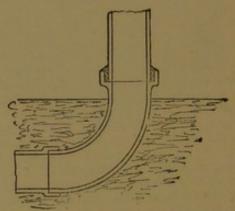

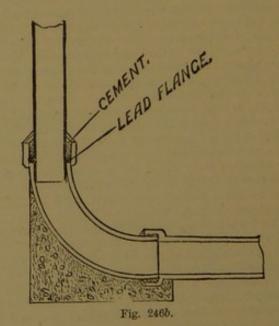

Fig. 246a

from the closet being connected with the drain direct, above the floor level, by means

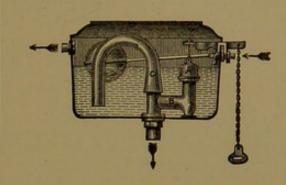

It will be noticed that the soil-pipe is prolonged for a little distance into the drain-pipe, and it has a lead flange attached to it which rests on the floor of the socket, the joint being made with cement. The drain-pipe which receives the soil-pipe should rest on a solid foundation of concrete.

Ventilation of Soil-Pipe.-In all cases the soil-pipe should be outside the house, it should be ventilated by being carried, full bore and without angles, above the eaves of the house, where it should terminate at a safe distance away from any windows or chimneys. The small opening which exists in most closets at the top and far side of the trap is often supposed by ignorant workmen to be intended to act as a soil-pipe ventilator, but this is not the case. The object of this opening is to allow of an air-pipe being connected for the purpose of preventing the risk of syphonage, a point which has already received notice under the remarks upon Traps.

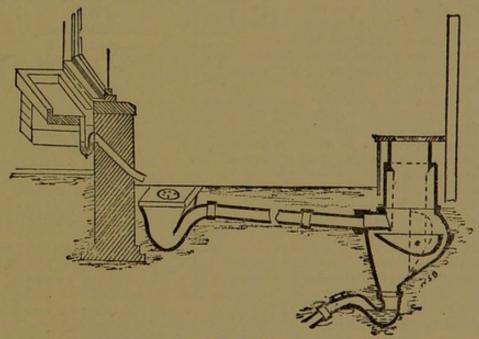

Water-flush.—The danger of connecting a general supply cistern with a closet apparatus

Water, where it is pointed out that a special cistern should be fixed for the closet, called a "water waste prevention."

One of the simplest forms of the apparatus is known as Purnell's, an engraving of which is attached (fig. 246c). Its action may be described as follows:-

As soon as the valve A is opened by a pull of the handle of the chain, the water flows through direct has been referred to in the article on | connexion B into the discharge pipe, causing

a partial vacuum, and the water rushing to fill up the vacuum starts the syphon C; when once the syphon is set in action, it will continue running until the whole contents of the cistern have been discharged.

Slop-Closets.—The above drawing (fig. 246d) represents, in section, a slop-closet, to which reference is made in the section on privies. There are various makers of these appliances, but the principle is the same in all, namelythe utilization of the slop-water of the house as an automatic flush for an out-door closet. It will be seen that the sink waste discharges in the usual way on to a gully trap outside;

direct into the main drain, it is carried to the closet, where it is made to discharge into a vessel which is suspended on pivots and is so balanced that when full it discharges into a trap below, which carries it to the main drain. Over the "tipper," which holds three gallons, the closet seat is fixed, and the excreta and urine drop into it, to be carried away with a good flush each time the vessel tips over, that is as soon as it has been filled with house slop-This appliance can be fixed under ordinary conditions - drain connections included - at a cost of about £4, and, as a substitute for the objectionable privy, it canbut in place of the drain from this trap going | not be too highly spoken of. by all sanitarians; but, in judging of their may be fed, and is not, as usually has been merits, it must be remembered that they are imagined, formed from the pollen or flowerintended as substitutes for universally condust. When first formed it is said to be quite

WATER DRESSING.—See Dressing. WATER IN THE CHEST is the effusion or throwing out of the watery or serous portion of the blood into the cavity of the pleura between the lungs (see Lungs) and ribs. Such an occurrence may be the effect of two different causes; the most usual, especially when the water forms rapidly, being inflammation of the pleural covering of the lungs, or pleurisy (see Inflammation). In this case the effusion of fluid is usually confined to one side of the chest.

Water in the chest, however, especially in the aged, may be caused by affection of the heart or lungs, and obstructed circulation, in which case it often occurs on both sides, and and the age of the child. If the mother be in

these closets (Duckett's, for example) have is accompanied with other dropsical symptome The difficulty of breathing, aggravated or relieved by particular positions The question of slop-closets has been speci- of the body. When the effusion is large, it Board, and the following are some of the fluid in the cavity, slight shaking of the body conclusions he arrived at:—

fluid in the cavity, slight shaking of the body causes a very audible splashing sound. These symptoms, however, more generally follow as a complication of pleurisy.

It is not likely that an unprofessional percon could detect the presence of water in the chest; suspicion of such being the case should at once cause proper medical assistance to be sought; in the meantime, the palliative remedies recommended under Dropsy may be resorted to, and if the breathing is very distressing, and the patient not very debilitated, a large blister may be applied over the chest,

WATER, MINERAL. — A mineral water is one which differs from the fluid as it usually flows from the earth, in possessing, naturally, sensible taste or smell, or a higher

temperature than ordinary.

Mineral waters are usually divided into and Hot. The principal mineral springs in Britain are adverted to under separate articles in the present work; those who desire more information will find it in the useful publications of Mr. Lee on the watering places, baths, &c., of both this country and the Continent.— See Chalybeate—Health Resorts.

WAX is a secretion of the bee, formed from Slop-closets are not looked upon with favour the sugar which it collects, or with which it demned appliances and for outdoor purposes white, becoming yellow from contact with the honey. In this yellow condition it is, when the combs are melted together, the common bees' wax of the shops. It is, however, purified and bleached for medicinal purposes, and is then generally met with in the form of round white cakes. Wax is used in medicine in the formation of, and for giving consistence to, plasters, ointments, and suppositories. It is also employed in the preparation of the gauze used for antiseptic dressings, and occasionally alone as well dressing, when it is sionally alone as wax dressing, when it is thought desirable to exclude the atmosphere from the surface of a wound.

WEANING. - The weaning of infants must depend upon two considerations, the condition and health of the mother or nurse,

WHI WEA

nurse her infant, with benefit either to herself or it, weaning of course must take place at once; but in the generality of cases, the pro-per time is about the ninth or tenth month, when the first four teeth have appeared. Indeed, the development of the teeth may be taken as the signal that other food is required; if, therefore, their appearance is delayed, suckling may in most instances be prolonged, for the reason that the late appearance of the teeth is frequently associated with delicacy of constitution, and then it is desirable for the child to be kept longer at the breast.

Previous to weaning, the child should be gradually accustomed to other food. It is desirable for weaning to take place in fine weather, when the infant can be carried a good deal out of doors. Should disorder of the bowels or other symptoms of illness arise, it must be managed as recommended under article Childhood, to which the reader is referred.

WEIGHTS AND SCALES are most necessary adjuncts to the domestic laboratory. In the British Pharmacopæia, the old system of apothecaries' weight has been abolished, and the avoirdupois pound and ounce adopted, the troy grain weight being retained as a convenient unit. The following table illustrates the division of weights now sanctioned.

1 grain, gr. i. 1 ounce, oz. i

437.5 grains. 1 pound, lb. i=16 oz. =7000 grains.

By this arrangement the old scruple and drachm weights, which represented respectively twenty and sixty grains, are abandoned; but it is still optional with medical men to use the symbols 9 and 3 for scruple and drachm, should it be found conducive to accuracy and convenience.

The ounce weight itself is known by the symbol, 3; the additional mark thus, 3i, stands for one oz., and 3 ij for two ozs.; so with grains, it is gr. i, gr. ij, or gr. iii, as the case may be. The weights themselves are always made of brass, the grains in thin plates stamped with as many dots as they weigh grains, the heavier weights with the characters of each: weights, however, are also made, the grains with the numbers in figures, and the others with both figures and the name legibly stamped upon them. Unprofessional persons, who may forget, or who may become confused with the characters, will find it more advantageous to provide themselves with weights of the latter kind.

such a condition of health that the cannot | convenient small size, care being taken to ascertain that they weigh true. After these scales have been used, they should always be well wiped, otherwise they are apt to become corroded. On account of this tendency, the scale "pans" are sometimes made of glass, and also of the metal platinum; but the former are of course liable to get broken, and the latter are very expensive. Neither are requisite; the brass are perfectly sufficient, with the most ordinary care. - See Pharmacopaia.

WHITES, called by medical men Leu-This extremely common corrhæa. troublesome female discharge may occur in a variety of constitutional conditions and circumstances, but more generally it is associated with general debility, and almost certainly so, if it has continued profuse for any length of time. For the latter reason, it ought not, as too often is the case, to be neglected, for not only may the constitution, the general health and strength, be fatally injured by it, but a comparatively mild and easily removable affection may be converted into one of an inveterate and serious character.

The importance of these remarks may be imagined, when it is stated that Dr. Ashwell, one of the highest authorities on these subjects, says: "Of all the diseases peculiar to the sex, there is none so common. Few married women, particularly if they are mothers, escape its attacks." By the same authority, the varieties of the affection are divided into the mild, acute form, accompanied with more or less inflammatory action; the chronic and inveterate or habitually established leucorrhea; and the variety symptomatic of other diseases, as of the womb, &c.

An acute or inflammatory form of "whites" may arise in those who are in tolerable health, the symptoms being so mild that they are either unattended to, or are quickly removed by rest in every sense of the word, local and general, by cleanliness, and by such antiphlogistic means as reduced diet and gentle aperients, especially mild salines, with perhaps one or two doses of grey powder, at bedtime.

In those of plethoric habit, especially in the middle periods of life, the inflammatory symptoms may be of greater severity, requiring the above treatment to be more vigorously carried out, and combined with fomentation, hip-The scales employed for dispensing medicine baths, and leeches; at the same time, in such are generally of brass, and should be of a cases, whether mild or severe, it will be advis baths, and leeches; at the same time, in such WHI WHI

parts by the use of tepid water and a syringe. When any inflammatory symptoms have disappeared, some astringent wash may be substituted for the simple water, and used either cold or tepid, whichever appears to be most beneficial. Some of the forms of lead lotion (see Lead) answer well; or one made with five or six grains of sulphate of zinc to the ounce of water; or an alum wash in similar proportions to the last, or decoction of oak bark, or of green tea; in short, any mild astringent. In cases requiring a more powerful astringent, a lotion of one drachm of tannin with one drachm of powdered alum to the pint of water answers well. It must be remembered, however, that in all cases, the strictest cleanliness is absolutely requisite, both as prevention and cure. Indeed, the neglect of this is one of the most frequent causes of the disease. When whites occur in a weak individual, they may, being unaccompanied with any inflammatory action, require the use of astringents from the first, with tonics, mineral acid, quinine, and iron, with good diet and wine, or malt liquor, probably also tepid or cold salt water hip-baths. The bowels in all cases require strict attention, and should be regulated by castor oil, rhubarb, and magnesia, or by tepid enemata of salt and In tolerably strong habits, small doses of Epsom salts, in combination with sulphuric acid, answer extremely well. Due attention should of course be given to exercise, and rest at night must be taken upon a hard bed.

In the milder attacks of leucorrhoa, a little well applied domestic management will often be sufficient to remove the symptoms, but when these become in the least urgent, a medical man ought to be consulted, before the disease becomes habitually local. To allow of its continuance, from motives of mistaken delicacy, or from carelessness, is a serious, it may be a fatal mistake; for, as stated above, its continuance gradually undermines the powers of the constitution, and dropsy, consumption, and other diseases of debility, may be origin-

ated in consequence.

Moreover, when family is desired, the wish is not so likely to be accomplished as long as the discharge continues, and miscarriage is more liable to occur. The ordinary function of menstruation, moreover, is apt to become deranged.—See Menstruation.

As a further reason for submitting continued or severe cases of the affection in question to the care of medical men, is the fact of the white discharge being at times symptomatic of disease connected with the womb. Sometimes, however, it is the result of irritations in the bowels, caused by accumulations in them, and sometimes by worms. To sum up, it should be remembered, that the disease is often the result of neglect, and want of sufficient cleanliness; that it may occur in a form more or less inflammatory, when it requires soothing house with lime sufficient to whitewash once,

able both to cleanse and soothe the internal | remedies ; that after the inflammatory stage, and often without it, especially in the debilitated, it requires astringent and tonic treat-ment, rather than relaxing; that if neglected, it is liable to become an obstinate disorder, and, by its continuance, seriously to injure the constitution, and that it may be symptomatic. Lastly, that in all but the mildest cases, the nature of the disease requires proper medical treatment, and perfect rest in every sense. This article cannot be concluded without the fact being alluded to, that the occurrence of the disease in its aggravated form, and the occasional consequences it then gives rise to, have been the means of raising unfounded suspicions of moral impurity, and of creating discord where it ought not to exist. Never ought such ideas to be entertained for one moment in the mind, still less given in words, except when based upon the careful examination and opinion of more than one medical

Refer to-Menstruation.

WHITE-SWELLING .- See KNEE.

WHITEWASHING by means of lime is one of the most powerful means of general household purification which it is possible to employ, especially on the large scale on which such purification is often required in the dwellings of the poorer classes, particularly in towns. Lime absorbs powerfully the carbonic acid from the atmosphere, and in this, and probably in other ways, tends greatly to remove the most fertile sources of disease.

The effect of whitewashing with lime in this way could not be more strikingly shown than it was in one of the epidemics of fever in Edinburgh. According to Mr. Ramsay's Report to the Commissioners of Police, "The business of whitewashing was commenced on the 14th of September, and continued to the 30th of October, and less extensively up to the 14th of December," during which period, he states there were washed—

"690 staircases,

1531 passages,

2120 apartments, exclusive of

1212 places cleaned previous to that date, making a total of 5553 different places, at a total expense of £77." Mr. Ramsay further states, "The effect of these limewashings on the epidemic has been matter of great interest to myself; and I have watched with the most anxious care to ascertain whether any new cases of fever occurred in dwellings previously subjected to purification; and I have pleasure in saying, that out of a great number of cases reported to me, with two exceptions, the whole turned out to be cases of relapse.'

Beyond these Mr. Ramsay failed to discover any other cases. The above is strong evidence. It might render it a question for boards of

WIN

if not twice a year, might not be real economy, and diminish poor-rates as well as disease. Moreover, it has been pointed out that free light, and light-coloured walls, tend to pro-mote health; in this way, the white colour of lime-wash must be an additional counteragent to causes of disease.

Refer to—Houses—Light—Walls.
WHITLOW is abscess of a finger or thumb, which in this situation is rendered extremely distressing, and even serious, as regards the use of the member, in consequence of the matter being generally confined by the firm skin, and subjacent firm fasciæ or fibrous membranes which are connected with the tendons, by means of which the fingers are moved. The matter often has great difficulty in reaching the surface, and of being dis-charged, and probably lies near the bone. The consequence of all this, especially if the inflammation is very acute, is to give rise to disease of the bone, or to mortification of the finger generally; in either case, the member is rendered worse than useless, or requires amputa-Whitlows are certainly more common in those who employ their hands in hard labour, also in cooks and individuals who are exposed to wounds from bones and splinters.

The symptoms are deep-seated throbbing pain in the affected member, which continues increasing till it becomes almost intolerable, the finger feels "ready to burst," and if examined, the skin is found tense and hard, and more or less inflamed. If nothing be done to remedy this state of things, the symptoms increase, the whole arm is affected, is more or less swollen and inflamed, especially in the course of the absorbent vessels (see Absorbent), and the glands in the arm-pit are swollen and At last the matter finds exit somewhere by the skin being ulcerated, not unfrequently about the nail When this happens, there is relief to the severe symptoms, but probably so much mischief has been done to the member that the results above described -mortification or death of the bone and the finger-occur, and it is lost. To prevent such a serious consequence, it is needless to say that active measures should at once be resorted to, and the case seen by a medical man as soon as possible.

On the first symptoms of whitlow occurring, however, the disease may in some cases be arrested at once, by thoroughly rubbing over the whole of the affected member with lunar caustic, and the most efficient way of doing this is to use a solution of nitrate of silver, or lunar caustic, in the proportion of five grains to the drachm of pure nitrous ether. proceeding, however, must be resorted to at once, and accompanied with a dose or two of a saline aperient. It must be confessed, too, it is more efficacious in those the skin of whose

Quite the most efficacious proceeding in whit low, when there is evidence of matter having formed (see Inflammation, Pus), is to lay open the finger down to the bone, by means of a lancet or knife; this proceeding, of course, ought to be done by a medical man if possible, but, under circumstances, it might be resorted to by an unprofessional person. It is certainly attended with great momentary pain, but gives otherwise very great relief, and often saves a finger; after it is done, the ordinary treatment of abscess, poultice and water dressing, will be requisite. When from timidity on the part of a patient-although chloroform might certainly be used-or other cause, a whitlow is not opened early, the only proceeding is to poultice assiduously till the matter finds vent, to support the hand and arm in a sling, to regulate the bowels, and to soothe the excessive suffering by opiates. After the matter is discharged, poultice for a short time, followed by water dressing, will be most suitable if the finger is saved. In some of these cases, the simple poultice or water requires shortly to be exchanged for a more stimulating and astringent application. None answers better than carbolic oil.

WINE, strictly speaking, is a fermented juice of the grape alone. It, or rather sherry wine only, is used medicinally to form a vinous tincture, or "wine" of various drugs. The most commonly used preparations are the wines of aloes, of antimony, of colchicum, of ipecacuanha, of iron, and of opium (see articles). Orange wine, which is made by the fermentation of a saccharine solution to which the fresh peel of the bitter orange has been added, is employed in the preparation of wine of citrate of iron, and also in the wine of quinine. For the dietetic properties and uses of wines the reader is referred to Stimulants.

The most important constituents in wine are alcohol, sugar, numerous acids, among which tartaric acid predominates, and colouring matter, due to the presence of tannin, which imparts an astringency to ports and clarets, rarely to be found in white wines. The peculiar bouquet or aroma characteristic of various wines, and to the same wines at separate stages of their growth, arises from the combined action of the ethyl of the alcohol with the acetic and other free acids contained in the wine, giving it a value in the eyes of connoisseurs probably beyond any medicinal or dietetic virtue the wine possesses, but still indicative of its genuine character. The relaxation of the duties on wines, especially on the light wines of France, Germany, and Hungary, has considerably increased the consumption of these liquors in Britain, but not fingers has not been hardened by labour, and by any means to the extent anticipated, so in whom the disease is generally least severe. difficult is it to alter the acquired habits of the

648

people, whose tastes for malt liquors and pre- | tastes like treacle. This is turned into a cask ference for port and sherry, as well as probably the influence of our northern climate, all militate against their general adoption.

Although we are indebted to Mr. Gladstone for the reduction in the rate of duty on wine, still the fact remains that our old-fashioned wines, port and sherry, are very expensive, and the terms upon which they are exported from Spain and Portugal are practically as high as ever, while the ravages of the phy-loxera or wine disease have nearly driven them from the market. It is impossible to obtain these wines of a genuine quality, except at a very high price, and it is well known to those who are instructed on such subjects, that the miserable compounds often sold in this country under the name of port and sherry are advertised at a figure far below that at which they can be bought pure and genuine in their native country. The fact is, that the majority of these are "Hamburg Ports and Sherries," that is wines, or rather compounds or mixtures (for they do not deserve the name of wines), adulterated to a large extent with potato or malt spirit. Very little of this socalled port wine, which is consumed in the United Kingdom, is imported from any winegrowing country; it is merely a compound made up largely of alcohol, to suit the taste of the British consumer, coloured with a preparation of elder berries, and a small amount of grape juice, but perfectly innocent of the genuine qualities of the juice of the grape of Oporto. Other red wines, grown chiefly in the south of France and in Spain, and though not of themselves injurious, are doctored in a similar way. Thus to render wines less acid, sugar and tartrate of potash are added, with coarse brandy to preserve and fortify them. The port wines sold in the shops are said to be mostly of this character. Sherry (the socalled) is made up of various kinds of wines, so mixed, and incorporated, and evaporated, to increase their strength, that their original flavour is quite lost. Brandy or spirit is largely added; a proper colour is obtained by means of burnt sugar, and finally, a compound, fiery and heady enough to suit the English market and the English taste, is produced. Mr. Shaw, in his work on Wine, the Vine, and the Cellar, thus speaks of the way in which

spirit is added to sherry in Spain:—
"One can no more drink, in Spain, the sherry usually consumed in England, than they can, in Oporto, the usual English port. About six gallons of spirits are put into a butt of sherry after fermentation, and generally about four gallons more previous to its being shipped. It is almost quite pale at first. The very dark brown is made at St. Lucar in the following manner:—Twenty or thirty gallons of must (unfermented juice) are put into an earthen vessel, and heated until not more than a fifth part remains, when it looks and should be as parts of a whole, and not as in-

containing more must, which causes it to ferment, and the result is a very full luscious wine, which if originally good, becomes after many years invaluable for g ving softness, richness, and colour to others. Large quantities of this product, when new, are used to colour, and to cover the harsh thinness of poor qualities. It is for this reason that it is called 'the Doctor;' and many a butt that comes to England to be sold as 'curious old brown' at an immense price, has to thank the old boiled mosto stocks for its character.'

Now, the above description may appear very bad to those who flatter themselves that they have been in the habit of drinking pure sherry, but it must be remembered that much of the so-called sherry has no sherry in its composition at all, and is merely spirits altered and flavoured, so as to give it a resemblance to what is so universally used in England under the name.

The consequence of drinking wine into which this large quantity of alcohol enters is marked indisposition and depression, "reaction" next day, if any quantity be consumed. Such wines, even the best of them, must be looked upon as liqueurs, and they are practically used as such. Wine is not meant to be sipped but to be drunk, and it is needless to remark that should the wines above described be "drunk, in the true sense of the word, the result would be, with most persons, subsequent headache, depression, and indigestion. This result would not follow indulgence in a similar quantity of pure wine, the action of which is to restore to comfort, cheerfulness, and activity of body and mind those who are worn out by bodily or mental toil, as well as to promote appetite and digestion.

Dr. Druitt, of London, has published an admirable treatise (the substance of which appeared originally in the columns of the Medical Times and Gazette) upon the cheap wines of France, Greece, and Hungary. We confidently recommend this little work to all those who wish to think independently upon the subject, to escape from the thraldom of custom, prejudice, and acquired taste, to find out for themselves how to tell good wine, and to contrast the advantages offered by cheap pure wines over those which are adulterated and expensive.

Dr. Druitt gives, amongst others, two simple and practical tests to be employed in the tasting of wine, even by those who are neither wine merchants nor professional connoisseurs. He says :-

"In the first place, in drinking a good large sip of the wine, does it prima facie strike us as being one liquid, or a compound of many ! Wine should have an absolute unity; it should taste as one whole. True we may distinguish various properties on reflection, but they

WIN WIN

dependent units mixed together. wine resembles a black draught; here a something sweet meets one part of our gustatory organs, there something sour, there something fruity, or bitter, or hot, or harsh, just as if half a dozen ill-blended liquids came out of

"2. Wine should have a certain generosity of taste; unless spirit could be extracted by distillation, it would not be wine; but there should be no smell nor taste of added and illcombined spirits, nor that heat about the

throat which they cause.'

Dr Druitt strongly advocates the use of well selected, cheap, pure wines, such as those of Greece and Hungary, not only as restorative, but as tonic beverages. He also advises that they should be given to weakly and delicate children, and to children who require stimulating treatment during the course of acute disease, in preference to port and sherry. An

able writer in a popular periodical in reviewing
Dr. Druitt's book, says:—

"It need hardly be said that the cheap
wines now coming into common use are not cheap by reason of inferiority. They are actually superior, not only as pure wines, but for intrinsic commercial worth of material, to many ports and sherries sold at twice their We export raw spirit to reimport a considerable part of it from Portugal and Hamburg as port and other wine. A fifth part of even a good hottle of port consists of proof spirit, costing at the rate of about threefarthings a bottle; for the Portuguese buy the spirit they send back to us at the rate of two shillings the proof gallon, taking in one year a million and a half of gallons of spirits, and sending us back three and a half million gallons of their wine. In all pure wines the natural proportion of proof spirit is usually from eighteen to twenty-two per cent.; many contain eighteen; some reach twenty-five or even twenty-seven; and, in rare cases, the proportion of proof spirit may even be thirty per cent. Port wine that has not been brandied for the English market contains twenty-three and a half per cent. Port wine, as we get it, contains thirty-five or even forty-five per cent. of spirit, that will only blend in flavour with the natural wine after the costly process of long keeping, although one of its uses is to throw down the fermentable extractive, and give to the wine at once the appearance, with-out the flavour, of 'tawny old port.' This sort of old port is usually said to have been long in wood, lest people should look too curiously at the cork, or seek in the bottle for the crust of tartaric acid which is deposited in course of time, and leaves the wine mellower for its absence. Since the vine disease, really good ports and sherries have almost doubled in price; and at prices below five, six, or seven

But bad | France, Hungary, Austria, or Greece, of which a choice quality is to be had for half the

"For poor hard-working people who lead in-door lives, -teachers, milliners, dressmakers, -to whom even good beer (the best cheap drink for healthy folks who take active outdoor exercise) is indigestible, there is food and medicine in a small dose of light pure wine. The white nervous tongue of the sickly dressmaker, who thirsts for tea that weakens further the deficient appetite, if she took in place of tea a little cheap pure Bordeaux wine, with an equal quantity of water, would recover healthy colour as her stomach regained tone and appetite, and her blood flowed in healthier current. It would be well for the town child between seven and ten years old, who flags in appetite, and is dainty with his meat, as children are allowed to flag in nurseries from which no comfort need be excluded, if the doctor's order answered to Dr. Druitt's suggestion in such case, 'Give some kind of light, clean-tasting, sub-acid wine-Rhine, Bordeaux, Chablis, or some of the clean, dry wine of Greece and Hungary; let this be sipped freely at dinner, and then look to your mutton.'

It is, perhaps, fair to state that the author is assured by wine merchants that there is a large quantity of inferior port wine brought from districts, both in Spain and Portugal, where the higher class wines cannot be made, and that this port, a mixture of several red wines to which a certain amount of wine from Oporto is added, constitutes a considerable proportion of the cheap wine now largely used in hospitals, and in poor-law districts. It certainly seems to answer the purpose for which it is given in ordinary cases, and it is undoubtedly superior to much of the wine sold as genuine Oporto port at the usual high prices. The faith reposed by the poor in the virtues of "Real Port," will for long make it difficult to satisfy them with lighter wines, such as those of France, Germany, and Hun-A good and wholesome red wine now largely used in hospitals and places for the sick, as well as in private families, is obtained from Spain even at a much cheaper price than the factitious ports. It is sold as Tarragona and Catalan, from the names of the districts whence

it is obtained.

It is not contended that port and sherry wines are not to be obtained pure, but those who desire to indulge in them must be prepared to pay a price which is far beyond the means of the masses of the population.

One of the great advantages of the Greek and Hungarian wines is, that they can be taken with benefit by those whose sedentary occupations and want of exercise prohibit them from the use of beer, while their cheapshillings a bottle they are factitious wines, incomparably worse than many a pure wine of the reach of those who cannot afford to drink ness (the price of the Greek wines ranging from

WOM WIN

first-class port and sherry, even if they could get them for money. The Greek and Hungarian wines are even now cheaper than most of the inferior growths of the French and Rhenish wines, and, of course, if they become as generally used as they deserve to be, the price would be much lower still. The talented and well-known authoress, Frederika Bremer, in her work upon Greece and its Greeks, thus describes the island of Santorin and its

"I have visited a great wine cellar excavated within the mountain, and have there tasted sixteen or eighteen different sorts of wine, all prepared from the grapes of Santorin. I was most pleased with the 'wine of Bacchus,' with the taste of nectar and colour of liquid gold; so also the 'wine of Night' (St. Elie), which is colourless, and has obtained that name from the fact of the vintage taking place during the night, and from the grapes being hidden under the leaves of the vine, and not exposed to the influence of the sun, by which means the wine is not coloured by it. It has en agreeable acid flavour, like Rhine wine, only milder. The entire island is a vineyard, and the productiveness of its volcanic soil for wine has attracted thither a population which is now too large for the resources of the island. . . .

"We ate a cheerful dinner at the Dimarch's, with compliments and toasts, which were drunk in nine different kinds of wine-Bacchus wine, Santo Wine, Night wine, Callista wine, and other kinds, —all good, but the wine of Bacchus, nevertheless, the best. . . . There we found sent down for we appropriate the state of the stat we found sent down for us a superabundance of good things,—grapes, apricots, figs, and large bottles of Callista wine, sweet, red, and thick, almost like a liqueur, and which is especially refreshing when mixed with water."

When one first essays a trial of the Greek and Hungarian wines, the puzzle is in the embarras de richesses which to select, and for those who really wish to test them fairly, the better plan is to get a number of the different kinds and go over them fairly in the way of ordinary drinking, keeping notes. Those who do so will not find that it is always the most expensive that are the pleasantest. If personal experience might go for anything, the writer would certainly agree with what Miss Bremer says regarding the "St. Elie," or wine of Night—resembling a very light dry sherry, it seems a pure drinking and most wholesome wine; in strength and body, between the sherry and the light wines of France and the Rhine. The Thera is a wine of somewhat similar character, but with more peculiarity of flavour, and therefore not so readily taken into favour by those unaccustomed to it. same remark applies to Santorin, a red wine approaching Burgundy. The red Hymet, also of a Burgundy character, is liked by most.

Another red wine, but more of a claret, the

Alderberger Ofner, is well adapted for ordinary drinking, and Red Keffesia may be put in the same category. It is said to be much liked by, and found of service to, consumptive patients. Of the white wines, the White Hymet, White Keffesia, Patras, and Hungarian Chablis are all good. It would, of course, be out of place here to go over the whole long list of Greek, Hungarian, and other wines, and those who desire more information will find it either in Dr. Druitt's Report on Cheap Wine, or in a small pamphlet published by Mr. Denman of Piccadilly. The author has mentioned only those of which he can speak from personal trial, and having recommended them somewhat largely, knows that they agree well with the majority of people. He quite coincides with Dr. Druitt in the opinion that, when these wines come to be better known, they will form no inconsiderable amount of the wine consumed in Britain. In some ways, and for some persons, in the colder months of the year, they seem preferable to the lighter, and certainly more acid wines of France. - See Stimulants.

WISDOM-TOOTH.—See Teeth.

WOMB-in medical language, the Uterus. This most important organ is, in its ordinary condition, situated in the cavity of the pelvis, but when distended, as in pregnancy, it rises into the cavity of the abdomen.—See Abdomen. Somewhat triangular in form, it is covered by the general lining membrane of the abdomen and pelvis, the peritoneum, and is held in its place by various ligaments. The affections of the womb may be considered as those which are connected with the state of pregnancy (see Pregnancy), and those which are not. In the latter case it is liable, though rarely, to be the seat of inflammation, the affection being characterised by the usual symptoms of inflammation, local and constitutional, and requiring the same management as inflammatory affection -peritonitis-of the bowels generally. Congestion of blood, enlargements, tumour, and polypus,—diseases of its neck, including cancer, &c.,—are among the affections to which the womb is liable. It is also exposed to displacements, dislocations, as it were, from before backwards, or the reverse; and likewise to coming or "falling" down, or, as it is called, "prolapsus." The latter occurrence is the most usual after the time of child-bearing is past, in women who have borne large families, and especially in those who have neglected themselves after confinement, by getting up too soon: it is therefore a frequent complaint among the lower orders, who are in a measure forced to neglect themselves under the circumstances. The falling, or prolapsus, of the womb is permitted by general laxity of the parts, but especially of the ligaments which ought to retain the organ in place: it is further aggravated by the congested and enlarged state of the organ which thence results. Such a state of matters cannot be too soon rectified, and by all means

medical man, who will recommend one or other of the various instruments contrived for such cases, as may appear most suitable. In the meanwhile, rest in the horizontal posture, and general soothing treatment, are the best palliatives; and if, in the meantime, circumstances render it impossible for the individual to remain quiet, comfort will be derived from the use of such a bandage as represented in article Prolapsus. The other displacements of the womb, backwards or forwards, are more usual in its enlarged condition; in pregnancy especially, the former is often the result of permitting the bladder to become unduly distended, so that by its weight it presses the womb out of place, and into such a position that it cannot easily recover itself. In these, and indeed in all affections of this organ, the assistance of a medical man cannot be too soon procured; domestic treatment can do little or nothing for their permanent relief, although it may, if properly directed, palliate considerably the more urgent symptoms. The affections of the womb may of course develop with greater or less rapidity; some are sudden in their onset, and urgent in their symptoms; others arise almost imperceptibly, and go on slowly. In most cases, however, there is sense of uneasiness and dragging, weight about the parts, perhaps and dragging weight about the parts, perhaps actual pain of more or less severity; the functions of the bladder may be interfered with, and difficulty of micturition occasioned; or difficulty or pain be experienced in emptying the bowels. Under some circumstances, discharges of blood or matter may take place.— See Menstruation, Whites, &c. The constitution may more or less sympathise, and irritable fever arise, or obstinate vomiting, or dyspepsia. with excessive nervous irritability and hysteria. Under circumstances, when symptoms like the above, or others suspected to be in connexion with the womb, show themselves, an individual can scarcely err in assuming, if possible, entirely the horizontal posture; if there is much pain, and especially any symptoms of feverishness, fomentations to the lower bowels, perhaps leeches may be used; and when the suffering is great, opium given by the mouth or by the skin hypodermically; at the same time, the strictest attention must be paid to the due action of the bowels by means of castor oil, senna, &c., or in full habits by salines, perhaps preceded by moderate doses of blue pill, but all preparations containing aloes must be sedulously avoided. Injections of cold, tepid, or warm water simply, or rendered more aperient by the addition of medicines, are often useful. The diet must be regulated according to the habit and constitution of the patient; if this be full, a reduction, especially in stimulants may safely be made; but if the habit be moderate, the diet may be kept so too. In the weakly and debilitated, it may require to be increased, especially if there is any drain, such | children, to all appearance well, are so infested,

ought to be placed under the management of a | as discharge of blood, &c., going on. - See Abortion - Menstruation - Whites, &c. above are palliative measures, which may be safely resorted to under most circumstances; they are, however, palliative only. curative means can only be carried out by a medical man, under whose care all affections of this organ, so closely connected with female health, happiness, and well-being, should be placed without delay - without waiting for serious symptoms to arise. Moreover, it should be remembered that there are states of impaired health, of a dyspeptic and nervous character especially, dependent on uterine derangement, which in itself gives no marked

In some affections of the womb it becomes absolutely necessary for a medical man to resort to means of examination, which, though they cannot fail to be highly repugnant to the feelings, no woman of truly delicate and pure mind would object to, when it has been fully explained to her, by a professional attendant in whom her confidence is placed, that such examination is positively required. It may be that the zeal of some has led them to disregard, perhaps too much, the feelings of patients suffering from these peculiar diseases, and to be too ready to avail themselves of all means

of investigation, but these are the exceptions.

WOMAN.—See Child-birth—Education—
Menstruation—Pregnancy—Whites, &c. WOOD-SORREL .- See OXALIC ACID.

WOOL and WOOLLEN CLOTHING.

See CLOTHING. WORMS. - There are various parasitic animals and plants which infest the human body; some, such as the acari, pediculi, and fungi, occupying the external surfaces only, whilst others, called by medical men "entozoa, are developed and live in the interior of the body. Of these the commonest and best known are the five species of "worms" which infest the alimentary canal. They are the common round worm; the thread, or maw, or chestworm; the long thread-worm; the common

tape-worm, and the broad tape-worm. The common round worm of the intestines was for long confounded with the common earth-worm, although it is difficult to imagine how it could be. It is firmer in substance, and much more acutely pointed at both ende than the latter, of a paler yellowish-pink, and more transparent. Its length varies from a few inches to a foot. This worm is more common during the early periods of life, and exists in many children without giving rise to any apparent disorder, unless it is developed in great numbers; very frequently, perhaps, after a dose of aperient medicine, a round worm is passed from the bowels by a child in whom such a parasite was not suspected to The occurrence not uncommonly causes exist. much needless alarm; a very large number of

WOR WOR

there are more. At the same time, the occurrence should always give rise to investigation, and to the employment of remedies calculated to remove any more of the animals which may exist. The usual site of these round worms is in the small intestines, but occasionally they find their way into the stomach, and are vomited or got rid of by the mouth—most commonly they pass off by the bowels.

The thread, or maw, or chest-worms, are familiar to most persons; they resemble long maggots, or bits of white thread, and are very lively in their movements when first expelled. These worms usually infest the lowest bowel, or rectum, in which they often exist in im-mense numbers, passing off with every evacuation, either separate, or rolled in masses; they also creep from the bowels; they are found too, occasionally, in the upper part of the alimentary canal; hence the name of chest-worm popularly given. In this case the worm is coughed or "hawked" up. The thread-worm is most commonly met with in children, but also occurs in adults, especially such as are weak and unhealthy. The long thread-worm does not occur in the immense numbers of the smaller variety, but seems to exist in most persons without causing much inconvenience. The tape-worms are quite the most formidable, and produce the most serious consequences of any of the intestinal parasites. The broad tape-worm occurs chiefly on the continent; the common tape-worm (fig. 247), which is usually

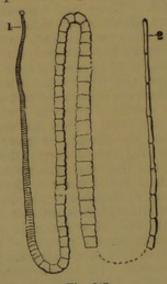

Fig. 247.

met with in this country, grows to many feet in length, extending, indeed, at times, almost throughout the entire length of the intestines. It is, as represented, flat and jointed, the edges of the joints being somewhat waved. At the head (1), it becomes much tapered, but, downwards, increases in breadth, sometimes to as much as half an inch or more, again tapering off towards the tail. In colour it is a dirty white. Generally, one worm only exists | favours their existence.

and the excretion of one worm is no proof that | in the bowels at a time, but sometimes there

The symptoms caused by the different species of worms are in some respects similar: they are, more or less emaciation, although the appetite is good, unhealthy hue and pallor of the skin, furred tongue, and unpleasant breath, and frequent griping pains in the bowels, which are irregular, the chief characteristic of the evacuations being increased secretion of mucus, with perhaps an inclination to sliminess. Itching and picking of the nose in children is often set down as indicative of the presence of worms, but it is also a symptom of intestinal irritation from other causes; it cannot, therefore, be considered as conclusive. Indeed, it is a question, whether any symptom, except the appearance of worms in the evacuations, can be considered positive. The appetite is apt to be capricious, and there are symptoms of general digestive disorder. Some patients complain of feeling the movements, but except in the case of tape-worm, this is probably imaginary. Perhaps some of the most important effects produced by worms are those which result in irritation of the nervous system. Children more particularly exhibit them. They grate their teeth at night, talk in sleep, or wake up screaming; they are irritable and fretful. In other cases, various convulsive or spasmodic affections, such as St. Vitus' Dance, squinting, stammering, obstinate cough, and many others, have been distinctly traced to the presence of worms. The thread-worm, in addition to constitutional irritation, causes much inconvenience from the constant, and sometimes intolerable itching it gives rise to, about the fundament. The tape-worm seems to cause more uneasiness in the bowels than the other varieties, and its occurrence is certainly characterised by more emaciation and general debility.

The origin of worms in the intestinal canal is explained by the fact that their ova are introduced from without by drinking contaminated water, or by eating fruits and salads containing them in an embryonic condition. A cachectic and debilitated state of the constitution in youth and childhood favours their development. Tape-worms are now well ascertained to be developed from what is called "measly pork," especially if it is eaten underdone. Dr. Spencer Cobbold also, in his elaborate work upon Entozoa, makes the statement, that one form of tape-worm is developed from germs existing in the flesh of veal and beef, and that this form is perhaps even commoner than that which owes its origin to diseased pork. The grand practical rule to be learnt is, to eat no sort of meat which is

imperfectly cooked. To get rid of worms, two modes of treatment are necessary, the one to destroy the offenders and get rid of them from the bowels, and the other to correct the debility which usually

WOU WOR

For the round worm, the best purgatives for children are calomel and scammony, or calomel and jalap, given at intervals of a few days, so as to purge briskly, the tonic-and some preparation of iron is generally the best-being given in the intervals. But if this treatment is not successful, santonin, in doses of five grains for an adult and two grains for a child, is an infallible remedy. It should be mixed with sugar, and taken fasting in a little milk twice a day, until four or six powders are administered. As the santonin has no purgative action, castor oil should be administered after or along with it. Some patients see things green while taking santonin, and the urine is coloured citron-yellow. Both these effects, however, speedily pass away and need cause no alarm. At the same time, the diet should be strengthening, well seasoned with salt, and ought to include a due proportion of fresh animal food. In the case of the thread-worms, the same general treatment is advantageous; but as they chiefly inhabit the lower bowels, their removal is much facilitated by the use of injections, either of salt water, or of infusion of quassia, or of turpentine; the latter being more applicable in the case of adults.

For the cure of tape-worm many remedies, and especially turpentine, have been used, but now they may safely be said to be reduced to two-the kousso and the fern, to the articles on which the reader is referred. - See also

Pomegranate.

WORMWOOD. - This common plant, known by its many cut leaves, silky on the under sides, and by its strong odour, is not much used in medicine at the present time, although it is a good aromatic bitter and tonic. The tops should be collected early in August, and dried. Half an ounce may be infused in a pint of water, and of this a tea-cupful taken twice a day.—See Absynth—Santonin.

WOUNDS are separations of the substance or tissues of the body, effected by violence. They may, as all are aware, be occasioned by a variety of causes; according to these causes, therefore, they are usually classified by surgeons into simple cuts, or simple incised wounds; into bruised and lacerated wounds; punctured wounds; poisoned, and gunshot wounds; the treatment of each variety being in some degree different, although there are certain general principles which must be observed in the management of all; these ought to be impressed upon the mind of those who may be called upon to direct the management of such accidents, and no kind of medical or surgical knowledge, perhaps, is likely to prove more useful to unprofessional persons in out-of-theway places.

The first circumstance, generally, which calls for attention, as the consequence of a wound, is the effusion of blood, but none of the consequences, perhaps, exhibit greater variation. Sometimes an extensive injury may be inflicted,

even the arm torn off at the shoulder, and yet the loss of blood be extremely small; on the other hand, a puncture with a penknife, if it penetrates an artery, may be sufficient to place life in the greatest immediate jeopardy; as a general rule, probably, putting the opening of large vessels out of the question, a greater amount of blood is lost after simple cuts than after any other description of wound. laceration, or bruising, takes place, there is usually, by stretching or otherwise of the coats of the arteries, a sufficient amount of mechanical impediment caused, to modify greatly, if not wholly, to prevent any hæmorrhage. As, under articles Artery and Hæmorrhage, the various modes of arresting the effusion of blood have been fully entered into, it is unnecessary to reiterate them here. wound is small, the best method of treatment is to tie it up at once with a piece of linen rag; this is usually sufficient at once to stop the bleeding, particularly if rest and position (see Position) are attended to; the small quantity of blood which may exude, quickly dries upon the wound, and forms a sort of glue, which effectually excludes the air. Friar's balsam is largely used amongst sailors for this purpose. As no better dressings can be used, either the one or the other may be left on till the cut is well; in some cases, before using the dressing, it may be advisable to draw the edges, of even a small cut, together, by means of adhesive plaster or material of some kind (see Plaster). Although linen rag is mentioned in the above directions, of course, should it not be at hand, soft calico may be used, or other soft material.

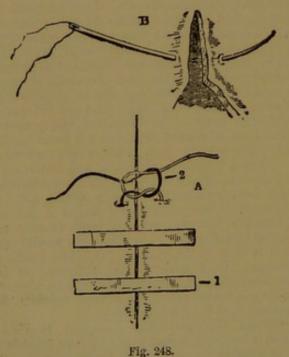

When a wound is extensive, and the bleeding profuse, it will not do to bind it up in this way, first, because it probably would not be sufficient to arrest the flow, and if it did so ultimately, it would retain a large amount of clotted blood, either in or about the wound, in such a way as to interfere with the healing process. In a large wound, therefore, it is necessary that the bleeding should be almost entirely arrested (see Hæmorrhage) before it is dressed, that is, closed up, &c.

Incised Wounds .- The first end in view when a wound is dressed, is to get as much of it as possible to heal by the "first intention," or by "adhesive inflammation" (see Adhesion); that is, to get the several parts to adhere at once without formation of matter, and thus with as little pain and trouble as possible. When the wound is a simple cut, such as that made by the surgeon's knife, this desirable termination may be expected, and often realised; even the extensive surfaces exposed in amputation of the thigh will heal in this way almost entirely; to attain the end, however, in many wounds, considerable care is requisite. In the first place, the wound must not be closed so soon as that a clot of blood will form between the exposed surfaces; if it does, unless extremely thin, it will prevent union. In the

654

WOU WOU

surfaces must be placed in as accurate a position as possible, and must be thus held to-gether till the process is complete. To effect and maintain this apposition or contact various agencies are employed, and of these position is not the least important (see Position); that is, the placing of the parts so that the surfaces of the wound may, as far as possible, fall into contact, and that when other dressings are applied, there may be no dragging to get things to meet. Thus in a wound of the fore part of the neck, it is requisite to fasten the head so as to prevent its being thrown back (see Cut Throat). At the same time, position must be regulated with a view to prevent hemorrhage. The wounded parts being properly placed, the next object is to draw the surfaces into as close apposition as possible; in some cases, this is sufficiently well done by means of strips of adhesive plaster (fig. 248 A-1) placed at such intervals as will permit discharge of matter, should any form. Frequently, however, from the nature, site, or

extent of the wound, plaster is not sufficient to keep the edges together, or to counteract the natural resilient tendency of the skin to retract when severed. In such instances, stitches, or, as they are called by medical men, "sutures," are employed. These consist of a piece of sufficiently stout silk or fine silver wire passed through the thickness of the true skin (fig. 248—2), at about the distance of a line from each of the severed edges. The line from each of the severed edges. thread is passed by means of a curved surgical needle (fig. 248—B), and the two ends being tied as represented, bring the edges together, and retain them most effectually in contact; that is, provided the stitch is not made use of to | duced, and there has been much contusion and

second place, when the wound is closed, its | drag parts into place; this it should never do. If there is a continued strain upon the sutures, not only do they cause much pain, but they quickly cause ulceration, which, by detaching, renders them perfectly useless. The surfaces of a wound having been brought into contact, a piece of thin linen soaked in water should be placed over it, and, if possible, a lightly applied bandage. This not only keeps the dressing in place, and assists to exclude air, but gives support, which is always serviceable, and often, in large wounds, absolutely necessary. The bandage may be kept wet with cold or tepid water, as most agreeable to the feelings of the patient When a wound progresses well towards recovery, when there is no appearance of discharge, or so little, that it is neither inconvenient nor offensive, there should be no meddling; the less the processes of reparation are disturbed the better, and in some cases a week may be allowed to elapse before the dressings are disturbed; they may of course require it before, especially in warm weather (see *Dressing*). It ought to be remembered that in the membered, that in the treatment of all wounds, it is important to exclude the action of the air as far as possible, and it should be taken as an aphorism, that rest, simplicity, and cleanliness are the great promoters of healing; the last is best attained by the use of water alone.

Lacerated and Contused Wounds.—The above observations have been directed specially to simple incised wounds; when laceration or contusion accompanies the injury, the principle must be to get the wound as much into the condition of a simple incision as possible. To do this, the wound having been thoroughly cleansed from dirt, grit, &c., by means of a soft sponge and water, and any foreign body which can be easily reached, removed, all parts not absolutely detached from the body are to be placed as nearly as possible in the natural position, stitches and plasters being used to retain them, and free exit left for the discharge of matter; over these there must be applied either carbolic oil or water-dressing, and a bandage may be necessary or not, according to

circumstances.

In cleansing wounds, a solution of carbolic acid, of the strength of one part in forty of water, is the most efficient lotion. All the crevices and irregularities must be carefully washed out, and all dirt removed. The plan of at once using a spray, when it can be obtained, containing the carbolic acid, and covering the wound with a gauze saturated with the same material, has, since its introduction by Professor Lister, been largely adopted, and with the best results. If decomposition can be appropriate to the control of position can be prevented in a wound, its rapid union is almost secured, and this the antiseptic system effects in a wound made during an operation performed under a spray. When, however, much foreign material has been intro-

WOU

antiseptic, and hence in such cases even the above precautions will not always prevent a dangerous amount of decomposition. - See Carbolic Acid.

Lacerated and contused wounds are always followed by more or less inflammation, with discharge of matter, and frequently by mortification of some of the injured parts. Often in different portions of the same wound may be seen simple adhesion, suppuration, and mortification going on at the same time. In con-sequence of these changes, the dressings of lacerated wounds require frequent renewal, the greatest cleanliness being observed. the course of a few days, after the infliction of the injury, if any parts are killed, or mortify, it is indicated by their assuming the characteristic appearance (see Mortification). The wound in such cases is to be managed-modified, of course, by circumstances-as directed in the above article. Such wounds, whether portions of the tissues have mortified or not, ultimately, if they do well, assume the characters of ulcers tending to heal, and require similar treatment.—See Ulcer.

The patient must always be carefully watched for the first four or five days after a serious wound, as it is during this period that serious complications are most liable to arise. At the first sign of feverishness indicated by loss of appetite, furred tongue, quick pulse, and headache, the wound must be examined, and if there be swelling and tenderness with redness, it is best at once to remove sutures, lay open the wound, and thoroughly cleanse it. At the same time, the bowels must be freely opened and the patient's strength kept

Punctured Wounds.—Punctured wounds are often more dangerous and troublesome to heal than their appearance would lead one to Their danger is, of course, commensurate with the importance of the parts wounded; on this account such cases should always be seen by a medical man. Generally, a simple poultice or water-dressing is the most appropriate application. Rest, too, should always be observed, and low diet, at least till proper advice has been procured. A wound from a barbed instrument, such as a fishinghook, may be referred to the class of punctured wounds. The best mode of extraction is to cut off the dressing of the hook, if there be any, and to push entirely through by the shank.

Gun-shot Wounds .- Gun-shot wounds partake more or less of the nature of lacerations and contusions. When small shots have entered beneath the skin, any that can be very easily detached may be, but it is well not to be too assiduous on this point. In such cases, perhaps the best thing that can be done, till a surgeon is procured, is to use means to check bleeding, to place the sufferer in as easy and

laceration, it is not easy to render the wound | poultice or water-dressing to the wound, and to counteract shock (see Shock) by the cautious administration of stimulants. Either in this case, or in that of any other wound, if there is much shock to the system, it must be counteracted, and, at the same time, if circulation in the wounded member is interfered with, means must be used to preserve sufficient natural

> Poisoned Wounds .- Poisoned wounds are wounds in which the division of the tissues, or even the abrasion of the outer skin, is accompanied with the insertion of poison of some kind, whether that of a gnat or of a wasp, of a rabid dog or of a snake. The wound in itself is generally trifling, perhaps not more than a scratch, but its character depends upon the nature of the poison inserted; a slight momentary pain or itching may be the greatest inconvenience, or speedy death may follow, or the poison may take days or weeks to develop, as it does in inoculated small-pox or hydrophobia. When an individual suffers from a wound, known or believed to be poisonous, immediate steps should be taken to prevent, if possible, the poison being absorbed into the system. The steps to be taken are sufficiently detailed in article Hydrophobia, and the minor applications to the bites of gnats, &c., will be found under Stings. The most serious poisoned wounds inflicted are those of the serpent tribe; they are not only quickly followed by extreme cold swelling of the limb, but by great or fatal depression of the system generally. The latter consequence has been painfully illustrated by repeated instances of death amongst the keepers of Zoological Gardens, from the bite of the cobra di capello, or poisonous hooded snake of India. In addition to the local treatment of the wound (see Hydrophobia), continued friction with some oily material appears to be most generally useful, whilst, at the same time, stimulants are freely given internally to counteract the depression. Of course, any stimulant first attainable should be used, but ammonia appears to be most highly recommended. A tea-spoonful of sal volatile may be given every five or ten minutes in a wineglassful of water, till reaction is thoroughly established.

Such cases as the above are not common in England; they sometimes, however, do occur in consequence of the bite of the adder or viper, the only species of poisonous snake common to this country. The common "ringed snake" is harmless; it has a yellow spot on each side of the neck; whereas the adder is of a dirty yellow colour throughout, marked with black spots, and the belly black. Poisoned wounds, such as those sometimes received in dissection by medical men, or by cooks, and others who have to handle dead animal substances, are apt to give rise to symptoms resembling whitlow, and require similar treatment (see Whitlow). advantageous a position as possible, to apply They may, however, place life in much jeo-

pardy by the constitutional affection they give | six grains twice or three times daily, in the rise to, and by causing the formation of abscesses in various parts of the body. Such, and indeed any severe, cases of poisoned wound ought to be put under medical care without

Refer to-Ammonia-Emergencies-Hæmor-

rhage—Lock-jaw—Scalp—Ulcers.

WRISTDROP.—See DROPPED WRIST. WRY NECK .- This well-known deformity is caused by the rigid contraction of a powerful muscle, the sterno-mastoid, on one side of the neck. It may be either congenital or acquired, and may be sometimes remedied, if not cured, by the person afflicted wearing an apparatus made by the instrument maker, by which gradual extension is kept up upon the muscle until it resumes its natural condition. Obstinate cases require division of the muscle by the surgeon.

YAWNING.—See GAPING.

YAWS .- A peculiar tropical disease, accompanied with a skin eruption. The advice given under Tropical Diseases applies also to this affection.

YEAST.—See FEVER—POULTICE—DIA-BETES

YELLOW FEVER. —See FEVER.

YEW-BERRIES.—The beautiful berries of the yew tree occasionally tempt children to eat them, and the leaves have been given ignorantly as medicine. Both are extremely poisonous. A child has died within four hours after eating a quantity of the berries. The symptoms appear in some degree to resemble those of poisoning by belladonna, and treatment similar to that recommended in such cases should be adopted. It is thought that the poison resides chiefly in the seeds of the berry.

ZINC .- This now well-known metal yields some useful medicinal preparations. Of these the principal are the oxide, the sulphate, and the chloride. The metal itself, which is of a pale bluish colour, was some years ago introduced in the manufacture of cooking apparatus, and especially of dairy utensils, but seems to have been abandoned as unsuitable (see Cream). The oxide of zinc is a white, tasteless, rather light powder. It is used externally in the form of ointment in various skin affections, especially where there is excoriation or slight ulceration, the proportion being eighty grains of the oxide to an ounce of benzoated lard.

form of pill.

The sulphate of zinc, or white vitriol, is a most useful preparation. It is sold in the form of small white crystals, somewhat resembling those of Epsom salts. It has a strong metallic, very unpleasant, styptic taste. As an external astringent application it is used in solution, and forms one of the most serviceable collyria or eye-lotions, in the strength of from one to four grains to the ounce of distilled or rain-water. When used to ulcers, the strength may be increased to double. Its principal internal use is as a tonic for spasmodic diseases of the nervous system, as epilepsy and hysteria, and its action as an emetic is admirably calculated, from the rapidity with which it causes vomiting, to empty the stomach in cases of poisoning by opium or other narcotic drugs. The dose, as an emetic, is from fifteen to twenty grains, in a wine-glassful of water; as a tonic, from one to two grains in pill or powder. The salts of zinc are said to have themselves proved poisonous, but very rarely so; moreover, by the rapidity with which they cause vomiting, they must in great measure prove their own antidotes. In such cases, the treatment should be similar to that for poisoning by blue vitriol. -See Copper.

Chloride of zinc is chiefly used as an external caustic, and also as a disinfecting agent. The pharmacopæial solution is powerfully corrosive, and many cases of poisoning have occurred by mistaking it for other medicine employed in the sick-room. Chloride of zinc is the main disinfecting agent in Sir W. Burnett's well-known fluid. The carbonate and the acetate of zinc have properties somewhat similar to the oxide and the sulphate, but they

are much less employed.

A combination of sulphate of zinc with valerianate of soda forms the valerianate of zinc, a remedy used as a nervine tonic, and serviceable in numerous neuralgic affections, particularly nervous headache. The dose is from one to four grains in the form of pill,

taken two or three times daily.

ZYMOTIC is a term of doubtful signification recently introduced into medical science, and is probably familiar to most from its occurrence in the regularly published reports of the Registrar General. The term includes the various epidemic, endemic, and contagious diseases, such as fever, small-pox, &c., which originate, or are supposed to originate, from a morbid poison being introduced into, and gradually extending itself throughout, the system. The process is likened to that of fer-Internally, it is used principally in spasmodic diseases, such as epilepsy, and St. Vitus' mentation, and the term is derived from the Dance. In the latter disease the author has used it successfully. The dose is from two to mentation—Germs of Disease.

# ON THE MANAGEMENT

OF THE

# SICK-ROOM.

BY W. ANDERSON, M.D., L.R.C.S., EDINBURGH.

It is very much to be regretted that so much ignorance prevails in this country respecting the domestic management of the sick-room, and that this ignorance is chiefly displayed by those whose duty it is to watch over the sick-bed, and to carry out the directions of the medical adviser. It is believed by many people that, like the poet, the nurse must be born, not made, but this is only partially true, and every day experience is teaching us that much can be done towards the training of efficient nurses for the use of private families who may require their services, and for our great public hospitals and charities. No doubt there are certain qualities of mind and disposition, without being possessed of which no woman will ever become a nurse, in the best sense of the word; but, on the other hand, there are many women who may be made excellent nurses, and yet who would never become such without proper, simple, preliminary training. It is extremely difficult to put down the details of that training in black and white, and it is not too much to say that the training, to bear any good fruits at all, must be essentially a practical one, that is to say, that, in our opinion, every woman who aspires to be a first-rate nurse should either be taught under a skilful teacher, or should cheerfully apprentice herself for a short time to some institution, where good nursing and all its concomitants are systematically taught. If it be asked what inducement there is to make any one undergo so much arduous and, perhaps, repulsive labour, we can only reply, that we have been frequently the witnesses of the heart-rending sorrow exhibited by a wife, a mother, or a sister, who have found too late, when the melancholy occasion required it, that they were unable to undertake those duties which were required of them, and from very ignorance, were obliged to hand them over, it may be, to a cold, perhaps cruel, and mercenary hireling. Sanitary knowledge, and especially this department of it, is making immense strides, and acquiring fresh importance every day; and it is matter of congratulation to all classes of the community that institutions, having for their object the training of skilful nurses, are becoming more frequent in all parts of the country.

CHOICE OF A SICK-ROOM.—With regard to the sick-room itself, it seems scarcely necessary to say that, when a choice can be made, it should always be large, lofty, quiet, and well ventilated; and these remarks apply all the more forcibly to those cases in which the patient is suffering from contagious disease of any kind—more especially from typhus fever, small-pox, scarlet fever, or from any injury which is complicated by having a large discharging surface, or which may be foul, putrid, or even gangrenous. In the dwellings of the poor, these ends cannot always be attained; and moreover, it is sometimes desirable not to remove a patient from the room in which be may happen to be at the time of his illness, or which may be most convenient for him in the case of accident. If the patient must be, then, in a small

room, this great disadvantage must be compensated for by attending, in every possible way, to the ventilation, both for the sake of the patient himself, for those who are in attendance upon him, for those who may come and go, and for those who live in the immediate neighbourhood; because such small rooms, when ill ventilated, become the foci from which disease spreads upon all sides, and, in various ways, may eventually lay hold upon all classes of the community. The poor in many places have a great objection to open windows; but it may be asserted that there is no danger whatever in opening the windows, if only care be taken to avoid draughts, and the occurrence of a chill upon the patient's surface. The following passage, quoted from the Lectures on the Eruptive Fevers, by Dr. George Gregory of London, shows the difference of practice which has taken place in this respect, as compared with that of former times:-" What think you," he says, "of a prince of the blood royal of England (John, the son of Edward the Second) being treated for small-pox by being put into a bed surrounded with red hangings, covered with red blankets and a red counterpane, gargling his throat with mulberry wine, and sucking the red juice of pomegranates? Yet this was the boasted prescription of John of Gaddesden, who took no small credit to himself for bringing his royal patient safely through the disease." Nowadays, of course, we think it very absurd to treat patients with infectious diseases in beds with any curtains at all. We never dream of increasing the temperature of the room, as was formerly done; we do not insist upon the patient being covered with any more blankets than he chooses; and we certainly are not so cruel or so blind as to refuse abundance of cooling drinks to the parched lips suffering from the maddening thirst of fever. The ventilation is, and has always been, a difficult question. In plain English, how are we to ventilate a room without causing draughts which may chill the patient, and cause him to take cold, or which may even light up inflammation of the lungs, bronchitis, or some other evil, in those who are already weakened by disease? Are we to ventilate by means of the window or windows, by artificial ventilators, or by the door and chimney? All experience teaches us that every sick-room should have an open chimney, and further, that ventilation can be only properly effected by open windows. Some open them from the top, some from the bottom, and some both at top and bottom, allowing the air to escape at one opening and to enter at the other. Now, this appears a very simple matter, and yet surprising how difficult it is to properly ventilate a room, and still more a ward, in this way, without the patients' complaining of draughts and chills. Again, many persons, especially in the lower ranks of life, are accustomed every night in their lives to sleep in such close ill-ventilated rooms, surrounded, it may be, by their numerous families, and perhaps a few lodgers into the bargain, so that it is not to be wondered at if they very soon catch cold when suddenly treated for the first time, according to the modern and enlightened notions-so warmly advocated by Miss Nightingale-as to open windows and fresh air. The writer has found, after many trials, that the least injurious way of admitting fresh air to a room, by the ordinary window sash, is to open it from the bottom to the height of a few inches, more or less, according to the state of the wind, weather, &c. A wooden board is then to be placed against the lower part of the window, to prevent the wind blowing directly into the apartment, and in this way, the current of air is directed upward, and diffused over the entire surface of the room. All the devices at present in use for artificial ventilation are more or less defective and imperfect, and have generally to be abandoned for the simpler sort of expedients alluded to. The chimney board or soot board should never be put up, because, of course, when the window is closed, the room is almost entirely dependent on the chimney for ventilation. In cases where an open window in the room cannot be borne, it is often desirable to ventilate the room by means of air transmitted through an open window in the adjoining room or in the staircase, and here an open chimney is more than ever desirable.

In Miss Nightingale's Notes on Nursing, the following excellent practical advice is given as to ventilation:—

"Always air your room from the outside air if possible. Windows are made to open; doors are made to shut—a truth which seems extremely difficult of apprehension. I

have seen a careful nurse airing her patient's room through the door near to which were two gaslights, a kitchen, a corridor, the composition of the atmosphere in which consisted of gas, paint, foul air, never changed, full of effluvia, including a current of sewer air from an ill-placed sink, ascending in a continual stream by a well-staircase, and discharging themselves constantly into the patient's room. The window of the said room, if opened, was all that was desirable to air it. Every room must be aired from without—every passage from without; but the fewer passages there are in an hospital the better.

"In laying down the principle that the first object of the nurse must be to keep the air breathed by her patient as pure as the air without, it must not be forgotten that everything in the room which can give off effluvia, besides the patient, evaporates itself into his air, and it follows that there ought to be nothing in the room excepting himself which can give off effluvia or moisture. Out of all damp towels, &c., which become dry in the room, the damp, of course, goes into the patient's air; yet this, 'of course,' seems as little thought of as if it were an obsolete fiction. How very seldom you see a nurse who acknowledges, by her practice, that nothing at all ought to be aired in the patient's room, that nothing at all ought to be cooked at the patient's fire! Indeed the arrangements often make this rule impossible to observe."

TEMPERATURE OF THE SICK-ROOM .- In many diseases of the chest, as for instance, inflammation of the lungs, the temperature of the room requires to be particularly attended to, because cold air not only increases the discomfort of the patient, but makes the cough worse, and aggravates the disease. Now it is not safe to trust to our own feelings as a guide by which the temperature of a sick-room can be regulated: therefore, a thermometer placed at a distance from the fire ought to be frequently consulted, and the temperature should be kept up to at least 60 degrees Fahrenheit. But whilst the room is kept warm, the bedclothing of the patient must be regulated accordingly (and this requires particular attention in the case of children), since it would be extremely injudicious both to keep the room warm and to heap blankets upon the patient. Common sense will teach one that, in those diseases in which it is necessary that the patient should breath a warm atmosphere, a cold room with abundance of bed-clothes would be hurtful, but that a warm air and a comparatively light covering to the bed, are what is required. However warm the room may be, or appear to be, the patient should always have a loose, warm dressing-gown at hand, to be put on when he leaves his bed, so that perspiration may not be suddenly checked. It will thus be seen that attention requires to be paid, first, to the temperature of the air of the room, and secondly, to maintaining the temperature of the body by appropriate clothing. As a general rule, it must be remembered that infants and old persons require much more artificial external warmth than adults, especially when sick. New-born children are said to require a temperature of from 65 to 70 degrees Fahrenheit, and old people (with few exceptions) are said to require a still higher amount. Healthy, well-clad, and well-fed adults will bear a degree of cold five or ten degrees lower without any inconvenience: while some people seem to have an extraordinary power of adapting themselves to different temperatures. It is probable that, in some acute diseases of a febrile character attended by great heat of skin, alow temperature, with a current of cooling air passing over the body, is of decided advantage; and this would seem to be proved by the fact that cases of fever treated in tents during great epidemics have generally done well. Most medical men seem to be agreed that in convalescence from all kinds of diseases there is great susceptibility to, and intolerance of cold, so that it is often desirable to keep a convalescent at a higher temperature than when he was the subject of acute disease.

As to the different methods of heating the sick-room, there can be no doubt that the common radiant grate with an open chimney is by far the best and healthiest.

The influence exerted upon the condition of a patient by the temperature of his room is well illustrated by the fact, that patients have been brought from a condition of raving and delirium into a calm and collected state, merely by the doctor's ordering the temperature of the 660

room to be low-red five or ten degrees; while, on the other hand, violent fits of coughing, with difficulty of breathing, have been at once relieved by reversing the order.

The air of the sick room, generally, should not be too dry; but in some special instances it is desirable that the patient should breathe a warm and moist atmosphere. This may be done very simply in a variety of ways. Perhaps the simplest of all is to allow the steam of a common kettle to diffuse itself throughout the room, or the common urn used for keeping boiling water for the tea-table may be employed. Stoves are very objectionable for the sick-room; but where they are used, special attention must be paid to keep the atmosphere moist.—See Bronchitis Kettles.

FURNITURE OF THE SICK-ROOM .- It may not be out of place to say one word as to the furniture of the sick-room. It has been already said that the bed should not be surrounded by curtains; the old-fashioned four-poster, with the curtains drawn, is the very worst sort of bed for a case of fever, or infectious disease of any kind. French beds, without curtains, are to be met with in most houses, and are in many ways suitable, but iron bedsteads are probably best of all. It is also a point of great importance that the bed should not be too high, nor too wide, otherwise it is quite impossible for the nurse to perform those many offices which a sick-room requires. As a rule, hospital patients are better off in this respect than patients in private houses. Miss Nightingale recommends "Iron bedsteads, with rheocline springs which are permeable by the air up to the very mattress (no valance, of course), the mattress to be a thin hair one, the bed to be not above three and a half feet wide. If the patient be entirely confined to his bed, there should be two such bedsteads, each bed to be 'made' with mattress, sheets, blankets, &c., complete-the patient to pass twelve hours in each bed, and on no account to carry his sheets with him; the whole of the bedding to be hung up to air for each intermediate twelve hours. Of course, there are many cases where this cannot be done at all-many more where only an approach to it can be made. I am indicating the ideal of nursing, of what I have actually had done, but about the kind of bedstead there can be no doubt, whether there be one or two provided."

Thick coverlets of a close texture ought never to be used, because they retain the excretions of the patient. The bed-clothes ought to be frequently changed and aired. Water beds are invaluable for particular cases. In cases of long or confirmed illness, in which the patient is confined constantly to bed, a bed constructed upon high and noiseless wheels, which can be moved easily from room to room, has been found a great luxury in relieving the tedium of illness.

The reader is referred to the article Bed, for an account of the various beds and bed-lifts, for invalids, which are most to be recommended.

One simple article of furniture which has been found of great use in the sick-room is a table so constructed that the leaf comes over the bed of the patient. He is thus enabled, on being propped up with an additional pillow or two, to take his meals with great comfort, and in an easy position, instead of in the usual awkward and constrained manner when it is attempted to take food from the bed-side.

Another of the most necessary and important articles is a night chair or commode. Great improvements have been made in the construction of these; and perhaps it is only necessary to mention that the lid should be of procelain, not wooden, and that there should be no seat or cushion above the lid which can retain the noxious exhalation from the pan below. Those made with a seat to the back, and supports to the arms, are decidedly the best, because patients requiring to use the night-chair are often in a state of the greatest debility, so much so that they dread getting up to it, and require to be supported while there.

A bed-pan, or, still better, a couple of bed-pans, ought to be always in readiness. The best are those made of strong porcelain of a shovel shape, and as simple as possible in construction. It is well to know that in an emergency, or where a bed-pan cannot be readily obtained, a common deep plate answers the purpose admirably; and, in point of fact, this can be used by some persons who cannot make use of the ordinary bed-pan.—See Bed-room.

661

On this subject Miss Nightingale, in the work already quoted, gives the following plain and excellent directions:—

"Of the fatal effects of the effluvia from the excreta, it would seem unnecessary to speak, were they not so constantly neglected. Concealing the utensils behind the valance to the bed seems all the precaution which is thought necessary for safety in private nursing. Did you but think for one moment of the atmosphere under that bed, the saturation of the under side of the mattress with the warm evaporations, you would be startled and frightened too!

"The use of any chamber utensil without a lid should be utterly abolished, whether among sick or well. But never should the possession of this indispensable lid confirm you in the abominable practice of letting the chamber utensil remain in a patient's room unemptied except once in the twenty-four hours—i.e., when the bed is made—yet, impossible as it may appear, I have known the best and most attentive nurses guilty of this; ay, and have known, too, a patient afflicted with severe diarrhea for ten days, and the nurse (a very good one) not know of it, because the chamber utensil (one with a lid) was emptied only once in the twenty-four hours, and that by the housemaid, who came in and made the patient's bed every evening. As well might you have a sewer under the room, or think that in a water-closet the plug need be pulled up but once a day. Also, take care that your lid, as well as your utensil, be always thoroughly rinsed.

"You can easily convince yourself of the necessity of this absolute rule, by taking one with a lid, and examining the under side of that lid. It will be found always covered, whenever the utensil is not emptied, by condensed offensive moisture. Where can that go when there is no lid?

"Earthenware, and, if there is any wood, highly polished and varnished wood, are the only materials fit for patients' utensils. The very lid of the old abominable close stool is enough to breed a pestilence. It becomes saturated with offensive matter, which scouring is only wanted to bring out. I prefer an earthenware lid, as being always cleaner; but there are various good new-fashioned arrangements.

"A slop-pail should never be brought into a sick-room. It should be a rule invariable—rather more important in the private house than elsewhere—that the utensil should be carried directly to the water-closet, emptied there, rinsed there, and brought back. There should always be water and a cock in every water-closet for rinsing. But even if there is not, you must carry water there to rinse with. I have actually seen, in the private sick-room, the utensils emptied into the footpan, and put back unrinsed under the bed. I can hardly say which is most abominable—whether to do this, or to rinse the utensil in the sick-room. In the best hospitals, it is now a rule that no slop-pail shall ever be brought into the wards, but that the utensils shall be carried direct to be emptied and rinsed at the proper place. I would it were so in the private house."

Spitting pots should always be used, since nothing is more inconvenient than to raise a heavy chamber pot for the purpose of spitting into it, and yet it will scarcely be believed that, even amongst patients of the better class, spitting pots are very seldom used, until they are ordered by the doctor. They should be light, and made of white porcelain, so that the medical man may at once ascertain the nature of the expectoration; and, in order still further to facilitate this, no matches, pieces of paper, or fragments of orange peel, &c., should be put into them.

A medicine glass and medicine spoon will be found useful.

A tin stomach warmer, or one made of india rubber, should be always at hand, so that warmth may be applied to any part of the patient's body at the shortest possible notice.

When it is necessary to provide for the dressing of a sore, the following articles should always be kept in readiness, upon a small table appropriated to them, and to them alone, with the exception of the lotion or ointment, or other appliance, which may be used or ordered by the surgeon:—A couple of small basins, a small quantity of tow or cotton wool to bathe the sore, a quantity of clean linen rags cut into appropriate pieces, or of lint, a few bandages, some

ofled-silk, or gutta-percha tissue, and some strapping or sticking plaster. These are articles which are being constantly wanted, and it is very provoking for the medical man to be obliged to send all over the house, first for the one, and then for the other, instead of having them all ready to his hand.

It seems almost superfluous to mention that an abundant supply both of hot and cold water ought always to be provided.

ATTENDANCE TO PATIENT.—How to wash, sponge, bathe, or otherwise clear the patient.

It is well known to experienced medical men and nurses, that patients are more grateful for being properly attended to in this way than perhaps any other, and it can be easily understood how great is the feeling of relief and comfort experienced by a patient, who has had removed from him the noxious and irritating excretions and exhalations of his body. The first point to attend to is, how sufficiently to cleanse the patient without exposing him to a chill of the surface. A skilful nurse, even in a very bad case, can easily manage this without much trouble either to herself or to the patient. When it is desirable thoroughly to cleanse the skin, and at the same time to avoid all chance of chill, it will be necessary that the nurse should use a small basin, with moderately hot water, a piece of soft flannel or a sponge, with plenty of soap. Only a small portion, or a single limb, or part of a limb, is to be washed at one time. The operation is to be quickly performed, the part speedily dried with a soft warm towel, and replaced within the bed-clothes. Care should be taken to have everything in readiness, and at hand, so that all may be speedily accomplished, and the patient not fatigued or chilled by having to wait until the different articles are obtained. It is astonishing how very easily the patient may be kept clean by a little common-sense management in this way.

sponge the body over with tepid or cold water, in order to reduce its temperature, and allay irritation. Now, this requires to be very skilfully done, in order to have a good effect; a large soft sponge, or two or three small ones, just moistened sufficiently to prevent dripping, should be passed quickly over the surface of the body, which should be quickly dried. If the patient is then able to bear it, his night dress should be removed, and he should be laid upon a blanket on a sofa or bed, close to his own bed; the sponging should be rapidly and efficiently performed, and a clean night shirt put on, and he should then be removed to his own bed, where he will experience a feeling of the greatest comfort and relief. This process may be repeated several times with benefit, where there is fever and heat of skin.

Sponging the body with vinegar and water has been found of decided value in checking the exhausting perspiration so distressing and so commonly met with in the course of consumption, and other chronic diseases. The sponging should be quickly done, especially over the chest, neck, arm-pits, and face, and between the shoulders, and the parts should be quickly and briskly dried with a soft absorbent towel. In certain cases of consumption, and in persons generally with delicate chests, great benefit is sometimes to be derived from sponging the chest, night and morning, with salt and water. A handful of salt should be used to a basin of water, the upper part of the chest and the arm-pits should be well sponged, and the drying performed quickly, as before. If the process is properly and efficiently performed, no fear need be entertained of catching cold, even by the most delicate, either in summer or winter; in fact, it is one of the best preventives of cold that we are acquainted with.

THE BATH.—The bath is a very useful piece of furniture for the sick-room, and the reader is referred to the different articles under this head, in the body of the work, for useful information on the subject. When it is desired to administer a bath to a patient who is confined to bed, the bath ought to be brought alongside of the bed, so that the patient may be moved into it and out of it as quickly as possible. This is particularly requisite in cases where it is 663

desired to make use of the relaxing and sedative effect of a warm bath to relieve stoppage of the water or strangulation of the bowels, in rupture, or where it is desirable, as it sometimes is, to administer an injection in the warm bath, in some cases of stoppage of the bowels.

The shower bath must be taken by sick people with great caution, and scarcely comes under the head of the sick-room furniture. It is, however, one of the best means we possess, as a bracing tonic in certain cases of disease, and especially in the nervous affections of children. A conical cap, such as that recommended by Dr. Jephson of Leamington, should be worn, when it is not desired to wet the hair of the head. The water may be used tepid, if cold water produces too much shock, or the hand shower bath will be found a useful and convenient modification, especially for children. Many persons are not aware of the extremely pleasing effect produced by a sudden cold shower bath immediately after a warm plunge bath; in fact, it seems to do away with the relaxing effect of the latter, and to favour agreeable reaction of the skin.

THE HIP BATH.—This form of bath is perhaps, of all others, most generally used in private families and in the sick-room, as it is so convenient, and can be so readily applied. A cold hip bath should not be taken by females at the time of the monthly change, but may be freely used by the strong and robust, and is an excellent strengthening tonic, especially to the organs contained within the pelvis. The warm hip bath, either simple, or with the addition of a handful of mustard, is one of the best agents with which we are acquainted for the stimulation of the womb to activity. In addition to, and after its use, the back may be bathed with mustard and water, soaked in a large sponge, and a mustard plaster, about twelve inches long by four or five broad, should be applied to the lower part of the back. A combination of these means seldom fails to rouse into action the dormant functions of the womb in simple cases.

THE FOOT BATH .- Like the above, the foot bath may be used either with simple water, or medicated with mustard, or otherwise, as directed by medical advice. The following illustrations may be given as examples of these cases, in which it is desirable that it should be employed. It not unfrequently happens that the poison of gout, lurking in the system, gives rise to serious, and it may be, fatal affections of important internal organs. A strongly medicated hot foot bath will frequently serve in such cases to determine the poison to the toe, or some of the small joints of the foot, with immediate relief to the patient, and freedom from danger. A patient who has been delirious for days, owing to the presence of the gouty poison in undue quantity in the blood, irritating his brain, has been thus quickly, and, as it seemed, wonderfully relieved. Again, a patient suffering from some disease of the chest, with congestion of the lungs, and great difficulty of breathing, has been often speedily relieved, so as to fall into a gentle sleep, merely from having his feet and hands plunged into very hot mustard and water, by which simple means a large quantity of blood is drawn to the extremities, and the overloaded and labouring internal organ lightened of its load, and enabled to perform its function in peace. In cases of convulsions in children, when a warm bath is ordered, the effect of it may be very much enhanced by adding a little mustard to the water, and if necessary, applying cold to the head, while the patient is in the bath.

THE NITRO-MURIATIC ACID BATH.—This is useful in cases of torpidity or inactivity of the function of the liver. Nitro-muriatic acid itself is frequently prescribed to be taken internally in such cases, and more especially of late years it has been very much ordered in the form of bath, as follows:—

Take of nitric acid one fluid ounce and a half; hydrochloric acid, three fluid ounces; warm water, from ten to twenty gallons, and mix. It should be prepared in a wooden or stoneware bath, because the acids act upon metallic substances, and the patient should remain in it from ten to twenty minutes. If the bath cannot be borne, the patient may sponge the different parts of the body with a solution of the acids, according to the strength above indicated.

664

SALT-WATER, OR SEA-WATER BATH.—This is found to be an admirable substitute for sea bathing, and exercises a powerful stimulative action upon the glands of the skin.

Take of bay salt, or sea salt, half a pound, sulphate of magnesia or epsom salts, two ounces, solution of chloride of lime, one ounce; water, from twenty to forty gallons; this forms an excellent artificial imitation of sea water, and can be very readily and cheaply obtained. In cases of debility or chronic rheumatic affection of the joints accompanied with debility, tepid water may be used with the above ingredients, either as a plunge, or as sponge bath, and the body, over all its surface, should be briskly rubbed with a coarse towel, hair glove, or flesh brush. Where there is a predisposition to consumption, or other manifestations of the scrofulous constitution, great benefit has been found to result from the use of the above, a stimulating effect of the salt water upon the delicate chest being very remarkable.

THE ALKALINE BATH.—This is generally prescribed for persons of rheumatic or gouty constitution, and may be made very simply by adding about a pound of carbonate of soda to twenty or thirty gallons of water.

One ounce of carbonate of soda, with one ounce of laudanum, to a quart of hot water, closely resembles the well-known Fuller's lotion. Folded lint or flannel dipped in this lotion may be applied to very painful rheumatic joints, oiled silk being placed over the limbs to keep them moist. In this way great relief is often obtained from severe, dull, aching pain. Carbonate of potash may be substituted for carbonate of soda, especially in gouty cases.

Some diseases of the skin, though not dangerous in themselves, are occasionally attended with so much irritation as to render the life of the patient a burden to him, and relief to this itching sometimes follows the use of a sulphur or other medicated bath, which will be prescribed by the medical attendant. The effect of a sulphur bath is most easily obtained by adding three or four ounces of sulphurated potash to about thirty gallons of water. This bath is frequently used as a cure for itch. The smell of sulphuretted hydrogen, which arises during its use, is very unpleasant to some people.

Itching of the skin is very frequently allayed by a creasote bath. For this purpose one or two tea-spoonfuls of creasote mixed up with a little mucilage or glycerine may be added to the ordinary warm bath. It would be needless to indicate the numerous forms of medicated baths which have each their favourite advocates amongst medical men; and, as a rule, none should be used without the sanction of the medical adviser.

THE PORTABLE VAPOUR AND HOT AIR BATH.—The hot air or vapour bath is of great use in the treatment of gouty, rheumatic, and neuralgic affections, some forms of dropsy, and of skin disease, and in every disease in which increased action of the skin is likely to be of service. It can be used by a person in bed, or on a chair, and also to the whole or any part of the body, with equal facility; it may also be fitted with a perforated tray for herbs, drugs, &c., when medicated vapour is required. It can be obtained of all surgical instrument makers, chemists, and tinsmiths. See Baths.

BATHS FOR INFANTS.—It is scarcely possible to pay too much attention to cleanliness in the care of infants, and any neglect on this head is generally followed by disordered health, and sometimes by peculiarly obstinate irritation and disease of the skin itself. In cold weather, the water used for washing infants should never be quite cold, because there is a tendency to congestion of internal organs if the surface is too much chilled without reaction, and, for the same reason, a child, when being washed, and still more being dried after washing, should never be exposed to a draught or current of cold air. For newly born and young infants, very fine soft flannel, or fine Turkey sponge, should be used with soap. The practice, which obtains amongst some old-fashioned nurses, of rubbing the child's skin over with spirit, after a bath, to produce reaction, is a highly reprehensible one, inasmuch as the stimulus is too artificial to be of any benefit.

665

HOW TO GIVE A CHILD A WARM BATH .- A warm bath is very often ordered by medical men as a remedial agent for children suffering from disease of the lungs, or other internal organs; but it must be manifest that, if the child is unnecessarily frightened, and exhausts himself by crying and struggling violently, owing to alarm at the preparations which are being made for what appears to him a frightful process, more harm than good will be done. The following piece of advice, therefore, to mothers and nurses, it is hoped, will be followed on all such occasions. First, prepare the bath out of the room, and out of the child's sight, so that he may not see it prepared in the room, and steaming frightfully as it seems to him. Secondly, after it is prepared, cover it over with a large flannel cloth, or with a suitable blanket, so as to hide the steam, and so prepared, bring it into the bed-room. If the child is very prone to alarm, and especially if this has been favoured by his having been roughly bathed by his nurse on former occasions, it will be well to place him on the flannel cloth, and let him down gently into the water. A floating ball, of a pretty colour, or a cork with coloured feathers, may be given him to play with in the bath, and in this way, what is often made an object of terror, and is the means of doing injury instead of good, may be converted into a source of real pleasure to children, so much so, that when this plan is adopted, in the writer's experience, they are more apt to cry at being taken out than at being put into the bath.

The temperature of the water used for a child's bath should be from 96 to 98 degrees Fahrenheit, at all events for the first five weeks of its life; but as it grows older, the temperature may be diminished until it is comfortably tepid; and if the infant is moderately strong, cold water may be used in summer, with the precaution that the body must not be left immersed in cold water for any length of time. After washing and bathing, the child should be thoroughly dried; and if the child is very fat, the creases of the skin may be dusted over with a little unscented hair powder, or with simple powdered starch, contained in a cushioned bag. Soap should be used with caution to the delicate skin of an infant, and if there is any abrasion or eruption, to such parts thin starch solution may be employed instead, or tepid water may be simply drained over them.

The parts requiring especial attention as to cleanliness are the thighs and groins, the creases in the neck, the bends of the arms, the hands, the hips, and behind the ears. If there is vomiting, or much discharge of saliva from teething, the lips, chin, and neck ought to be very carefully washed. Want of attention to these little particulars is almost certain to be followed by some troublesome eruption of the skin.

In conclusion, the whole process of washing and bathing an infant should be carried through expeditiously, and should be made a matter of recreation and healthful amusement, and a source of real pleasure, instead of a painful and irritating ordeal, without benefit to the health, and to the direct injury of the temper and disposition of the child.

THE DOUCHE, HOT AND COLD.—It is sometimes necessary, in order to relieve the painful and troublesome affections of the joints and other parts, so common in chronic rheumatism and allied diseases, to employ what is called the hot douche, or the hot douche bath: that is, to apply a continuous stream of hot water to the affected parts, either alone or accompanied by friction and percussion. The simplest and readiest method of effecting this is for the operator to stand upon a table or chair, armed with a jug or tea kettle, from which he allows a stream of water to fall upon the affected part, while, at the same time, an attendant keeps up percussion by means of an india rubber bottle, stuffed with wool, or some soft substance, attached to a handle of cane—any other material will do equally well instead of india rubber for this sort of bath, so much used on the continent, at some of the most fashionable watering-places. A very high temperature (150 degrees Fahr.) can be easily borne; and where desirable, as for instance, to an enlarged, painful, and stiffened joint, the process may be continued for half an hour at a time.

THE COLD DOUCHE.—This is applied in exactly the same way as the other, with modi-

fications, and without the percussion being required in some affections of the joints, &c., in which it may be ordered by a medical man. It will be desirable to use a strong stream of water, and to pour it from a good height; but when it is wished merely to apply cold to the head, as, for instance, in fever, or disease of the brain, or in the case of severe wounds of the scalp, a gentle stream of cold water only should be made to trickle over the patient's head. This may readily be effected by means of a worsted thread (or several threads) dipped in a vessel arranged at a proper height. The patient's head and shoulders should be laid upon a water-proof cloth, so disposed as to allow of the water flowing from it to a vessel placed at the foot of the bed.

OTHER METHODS OF APPLYING COLD TO THE HEAD.—Besides the abovementioned excellent method, cold may be applied to the head by means of evaporating lotions,
or by rags dipped in iced water, or by pounded ice in waterproof bags especially made for the
purpose. Even skilful nurses, or what are at all events called skilful nurses, require to be constantly superintended, else they do more harm than good in this particular. For instance,
they will take a large cloth dipped in cold water, fold it, apply it to the patient's head, and
leave it there for an indefinite time, not knowing that it very soon becomes hot, and acts like
a poultice, so that they are, in fact, applying heat instead of cold to the sufferer's head; perhaps,
too, the patient is unconscious, and unable to communicate his feelings to those around him.
In order properly to apply either cold iced water or evaporating lotions to the head, a simple
layer only of thin muslin or linen should be used, so as to allow of free evaporation, and this
may be frequently changed, or it may be wetted without being removed from the head at all
by squeezing a sponge or rag dipped in the lotion upon it.

The following may be recommended as a cooling, evaporating lotion for the head to be used in fevers, inflammation of the brain, injuries to the head, &c. :—

Take of solution of acetate of ammonia three ounces, rectified spirit, two ounces, rose water, seven ounces. Mix. Or simple vinegar and water, or spirit of wine and water may be used; or a lotion made of sal ammoniac and nitre, of each, two ounces; water, 16 ounces.

TO APPLY ICE TO THE HEAD.—The ice should be pounded and placed in one of the india rubber pillows which are made for the purpose. When all the ice is melted, it should at once be renewed, as the water soon gets very hot.

N.B.—It is to be remembered that the long and continuous application of intense cold to the head may be followed by great depression of the vital power, and dangerous results, so that it should be done under the eye of a medical man.

Should the patient complain of the weight of the ice bag or bladder on the head, a string may be passed from it to the rail of the bed post or to the ceiling, and brought down as over a pulley, and tied so as to support part of the weight.

FOMENTATION.—It is very difficult to get people to believe in the efficacy—which, however, is very wonderful—of simple hot fomentations, so that, in different parts of the country, different materials are used for fomenting, according to popular prejudice in their favour. Camomile flowers, poppy heads, marsh-mallow roots, and various other substances with sedative properties, are in common use. The lead and opium lotion, made by dissolving two drachms each of tincture of opium and solution of acetate of lead in a pint of water, is an excellent lotion to use in cases where it is wished to apply soothing and drying hot fomentation to an inflamed part. Three or four poppy heads, with a couple of handfuls of camomile flowers, may be boiled in water, and the liquor used for fomenting. This is a very favourite form of fomentation with the lower classes in several parts of England. We consider the old-fashioned poppy-head fomentation of so much importance that we must give particular directions as to how it must be applied. Four ounces of poppy heads are to be broken up and put into a vessel, into which four pints of boiling water should be poured upon them. The whole is to

be boiled for fifteen minutes, and the liquor then strained off.—See Fomentation—Bran-Heat.

**POULTICES.**—Poultices are useful as fomentations, in cleansing and promoting the discharge from sores, and also, when disinfectants or deodorising substances are added to them, they are serviceable in removing foul and putrid emanations. It will be seen that we have now a much greater number of substances than formerly for application to foul and gangrenous sores, with a view to destroying their noxious emanations; and it is to be desired that one or other of them should always be made use of to destroy bad smells in a sick-room, as a patient, and his attendants likewise, are sure to suffer in health unless this is attended to.

The principal points to attend to in making a poultice are, first, to crumble the substance of which it is to be made sufficiently, so that there shall be no lumps or irregularities; secondly, to make them neatly and light, and to fold in the edges of the cloth upon which they are spread, so that they shall not mess the patient by escaping from under the poultice cloth.—See *Poultice*.

men, and the direction is left with the nurse, or printed upon the bottle, "to be rubbed into the affected part;" but the kind of rubbing will, of course, necessarily vary with the nature of the case. For instance, when there is excessive pain and tenderness of the part, the liniment is not to be rubbed into, but simply to be gently applied over the part, either with the hand, or with a soft piece of lint, or, better still, by means of a camel's hair brush. But, on the other hand, what are called stimulating and counter-irritant liniments, are often prescribed; and by means of these it is frequently thought to disperse, remove, or cause absorption of chronic swellings of various kinds, as well as to allay pain in parts where there is no real tenderness on pressure. Now these liniments require to be applied in an entirely different manner—that is, they require to be briskly rubbed in by the hand warmed before the fire, or with a flannel glove. In such cases the medicina mechanica comes forcibly into play, and is often of as much service as the drug employed in the liniment.

Ointments are sometimes ordered to be rubbed into different parts of the body. Here again the method followed must be according to the effect it is desired to produce. For example, a very powerful ointment, containing aconite or atropia, is frequently ordered, to allay the severe pain of neuralgia; and ointments are sometimes ordered to promote the absorption of inflamed glands, where there is still a certain amount of pain and tenderness. In such cases the ointment must be applied gently, else it will only aggravate the affection which it was intended to relieve; but, on the other hand, ointments which are prescribed—such as tartar emetic ointment—to bring out an eruption on the skin, or mercurial ointment, with a view to its absorption into the system, should be vigorously rubbed into the parts indicated by the medical adviser.

Ointments should always be kept in a cool place, else, if the lard becomes rancid, serious irritation may result in the case of skin diseases, for which they are prescribed.

One word more as to the rubbing in of ointments in skin diseases. For example, in bad cases of the itch, great harm is done sometimes by rubbing in the ointment equally over all parts of the surface. It so happens that in certain parts of the body, from the great irritation of the disease, ulceration, and even sloughing, sometimes takes place; and it is very cruel and thoughtless (though it is constantly done) to rub in, it may be, an irritating ointment over parts which ought, on the contrary, to be protected by some soothing application. Such places should be either covered by poultices, by water dressing, by fresh lard, or by some simple mollifying ointment; while the other parts of the surface may be freely rubbed over with the original ointment which was prescribed.

RUBBING WITH THE FLESH BRUSH, HAIR GLOVE, &c.—These methods are principally to be used as hygienic means, and scarcely come under the head of sick-room 668

management. They are often, however, powerful adjuncts in the treatment of disease, and are useful for promoting reaction of the skin, after the use of baths, liniments, &c. Several new instruments of this kind, both for cleansing and stimulating the skin, have been introduced, since the ready application of the different forms of india rubber manufacture to the production of this sort of article has been understood.

HOW TO APPLY MUSTARD POULTICES OR SINAPISMS.—The acrimony or power of yellow mustard may be increased, if desirable, by making the mustard up into a paste with vinegar instead of water. Few persons can bear a well-made mustard poultice much longer than from fifteen to twenty minutes, in the course of which time it will probably have acted sufficiently. Pure mustard should never be applied to the delicate skin of infants, who are much more easily acted upon by it than adults. For them equal parts of bread crumbs, flour, or oatmeal should always be used, and the mustard poultice should only be kept on until a red blush appears.

After a mustard poultice is removed, the part should always be dressed with some fresh lard, spread cold upon a linen rag, or a sheet of fine cotton wool may be placed over it Nothing can be more soothing and agreeable to the feelings of the patient than this.

Mustard leaf promises almost entirely to supersede the use of the mustard poultice. It certainly has the advantage of being light, extremely easy of application, and free from the objectionable clammy feeling which accompanies the first few minutes after a mustard poultice has been applied.

N.B.—When mustard poultices are ordered to be applied to the calves of the legs, nape of the neck, or other part of a patient who is insensible, care should be taken to remove them in due time, because it has happened in the experience of medical men, under such circumstances, that in the confusion and hurry of the time, the poultices have been left on until they have produced ugly sores and sloughs, from the effects of which the patient could with difficulty be rallied.

HOW TO APPLY HOT BOTTLES.—It is often of great importance that hot bottles should be very quickly applied to the hands and feet, and to the sides. In certain cases life itself may depend upon the quickness with which this is accomplished.

When a patient, after an operation, or in the course of an acute disease, is seized with what is technically called rigor or shivering, hot bottles should at once be applied, in order, if possible, to check it. The ordinary old-fashioned stone foot-bottles, when enveloped in flannel, retain the heat for a considerable time. Their use, however, is sometimes superseded by bottles of india rubber, which are lighter, and much more easily managed. Hot bricks enveloped in flannel, or the plates from the oven of an ordinary kitchen grate, may be substituted for hot bottles. Bottles made of tin are sometimes used for applying heat in the same way as the stone bottles, and sometimes also they are used in the form of what are called stomach plates, to apply heat to the bowels or chest. They possess the advantage, after a hot fomentation, of being able to retain their heat longer, while they do not wet the patient's bed or clothes; but, on the other hand, there is an undoubted advantage in warm and moist applications, which the tin plate does not possess. An admirable substitute for the tin plates is the india rubber stomach cushion, which can be used for such a variety of purposes, and which is certainly one of the greatest improvements amongst the many additions which late years have made to the appliances of the sick room. Bags of hot salt, or of hot bran, are often used instead of hot bottles. The salt or bran is to be heated in the oven, and enclosed in a flannel bag previously warmed. This will be found to retain the heat for a long time.

A very good method of applying hot bottles, in order to check rigors which accompany febrile attacks, with dryness of the skin, and cold shivering, till the teeth "chatter in the head," is as follows:—Several ordinary black bottles are to be filled with hot water, and put into the inside of woollen socks or stockings, which have been previously wrung out of hot

water. These (two on each side) are to be placed alongside the patient, the bed clothes being protected by a dry flannel cloth. In a very short time the shivering will be checked, and the patient will be found bedewed with gentle perspiration.

HOW TO APPLY COLD WATER TO WOUNDS BY MEANS OF IRRIGA-TION .- Surgeons are now almost unanimously agreed in discarding the old, cumbersome dressings, plasters, ointments, bandages, &c., with which wounds and stumps used to be loaded. A practice now prevails of much greater simplicity, and even to the stump of an amputated limb, it is not thought needful to apply anything whatever, but only to lay it in a comfortable position, so as to relax the muscles, perhaps upon a water pillow, and to apply along the line of the wound nothing but a strip of wetted lint or linen, which, for some days, requires to be kept constantly moist. Ragged, torn, and bruised wounds, such as the shattering of the hand or foot by gun-shot accident, or a crush from machinery, whether they require partial amputation or not, are found to be treated most efficiently and simply by the process of irrigation, a process which every medical man, if he wishes to employ it, will direct to be followed out according to an idea of his own. At the same time it will be well that the attendants of the sick-room should be acquainted with, and know how to set in operation, this most excellent method of keeping wounds clean and moist.

If the bed be a four-poster, or a French bed, with a canopy, a vessel containing cold water may be slung from the top of the bed in such a position as to hang over the wound. But if the bed be an iron one without any canopy, it will be necessary either to fix a pole in the wall, or to have an apparatus or support for the vessel in the form of a gallows, the transverse limb of which, reaching over the bed, must have the vessel suspending from it. A few worsted threads are to be placed in the vessel containing cold water and allowed to hang over the wound, till their ends almost touch it. The water will run down the worsted and trickle drop by drop gently but continuously upon the surface of the wound. Nothing can be more soothing and gratifying to the feelings of the patient, or more likely to subdue the pain, heat, redness, and swelling which accompany inflammation. The wounded limb must be placed upon a mackintosh cloth, which can be so arranged that the water should drop from it over the edge of the bed, where it can be caught by a vessel placed for the purpose. If it be desired to have a large number of drops, the ends of the worsted may be kept separate by being passed through perforated cardboard.

Another method still more simple is to suspend an ordinary funnel or tin dish, by means of a piece of string, either to the bed, to a hook in the ceiling, or to such an apparatus as described above. A cork, fitting loosely, may be placed in it, so as to allow the water to escape only drop by drop, or it may be allowed to escape in a gentle stream, if the cork be fitted still more loosely.

Either of the above methods may be applied to wounds of the nature indicated above, to certain cases of compound fractures of the limbs, and, in fact, to cases generally in which it is desired to apply the simplest of all dressings, viz., lint or linen soaked in water and laid loosely over, merely to protect the wound from external influences, to keep it cool and moist, to favour the escape of discharges, and, "to give nature a chance" to effect the healing process.

EXPOSURE TO AIR, LIGHT, &c .- As it is very necessary that the sick-room, being the room in which the patient has to spend wearisome days, and still more wearisome nights, should be exposed as much as possible to a plentiful supply of fresh air, and to light, it is obviously of importance that a good aspect should be chosen. All creatures, whether animal or vegetable, turn themselves joyfully to the light, and it may be roundly stated, that especially for growing children, light is almost as essential as fresh air. Plants which are not exposed to the light grow up blanched and deprived of their natural colour, and the same is the case with our miners, our artisans, and even our women and children who live in densely crowded alleys, or in underground cellars, and especially in the lower regions of some of those

old-fashioned houses, which, though at one time inhabited by the flower of the aristocracy, are now only distinguished for the squalor, filthiness, and wretchedness of their inhabitants.

When any member of a family is laid up with some serious disease which may possibly render it necessary that he should be confined to the sick-room for months, or it may be years, the best room in the house should, if possible, be placed at his disposal, seeing that so much of his time has to be spent within these four walls. In addition to light and air, a good view from the window is a great advantage.

Of course, it is well known that in many cases where there is great nervous excitement, in fevers, cerebral diseases, &c., as well as in many affections of the eye, light for a time must be partially if not entirely excluded. This can, however, always be readily done, by means of a blind of a green, or still better, of a slate colour, which can be pulled up or down at pleasure. For all chronic diseases, and indeed, it may be said, for almost all diseases, with the few exceptions above named, an abundant supply of light is of the first necessity. It is thought by some very careful observers of disease that our great national scourge of scrofula is probably as much engendered by want of light as by want of fresh air. Without light, the mind undergoes degeneration as well as the body, and the body itself soon becomes stunted or deformed, and easily falls a prey to disease. We have reason to be thankful that the houses which are now built to be inhabited by the rising generation, are not liable to such a monstrous piece of exaction and absurdity as the window tax, an imposition which was no less prejudicial to the health of the community than a disgrace to the memory of those who devised it.

QUIET .- How often does it happen that a doctor leaves his patient with the injunction that he is to be kept perfectly quiet, to which the patient assents, and the nurse promises obedience: and yet, no sooner is the doctor's back turned than the sick-room, instead of being sacred and unmolested, is made the scene for the reception of a levée, or for the transaction of all manner of domestic business. How often do troops of sympathising friends force their way into its precincts, and each in his turn require to know the nature of the disease, and of the treatment which is being carried on, relating, at the same time, their own wearisome experiences of what they fancy to be precisely similar cases, and contrasting and commenting freely upon the different plans pursued, with the effect, perhaps, of not only grievously fatiguing the patient, but of filling his mind with groundless anxiety and alarm. It is, or it ought to be, quite sufficient to prevent such intrusions merely to say, that all visitors are prohibited by the medical attendant. The writer is in the habit of leaving a written paper to be shown to visitors, But there are a great many other reasons why the patient is to be kept quiet and undisturbed. Everything connected with the arrangements for his comfort, where practicable, should be done outside the sick-room, so that he may not be annoyed by any arrangements of a noisy character which can be avoided. The very least sudden or unwonted noise may alarm and seriously injure a patient suffering from nervous disease, and any noise which suddenly wakes a patient out of sleep does him real harm. Possibly hours may have been spent, and powerful doses employed for the purpose of lulling a patient to sleep, a sleep on which, perhaps, his recovery may hang, when some thoughtless and indiscreet person may spoil all by suddenly awaking him. A patient once roused from this kind of sleep, sometimes awakes excited, frightened, almost terror-stricken, and is sent to sleep again with much greater difficulty than if he had never been asleep at all.

It is not the absolute loudness of a noise which is injurious, but there are some noises which are exceedingly irritating, especially to the excitable ears of a sick person. Such are all rustling of dresses, whisperings, shakings, rattlings, jarrings of all kinds, the creakings of doors or of shoes, and the rattling of windows; the jarring tread of people overhead, or running up and down stairs, is frequently a source of great irritation to the sick man, who will tell you that he feels every step go through him. Patients suffering from an acute attack of gout have been thrown into an agony of pain by the tread of some one hastily crossing the room. As a rule,

children are not so easily disturbed by noises as adults; and it is astonishing how very young children will sometimes sleep in the midst of noises all around and about them.

It is an axiom insisted upon by all writers on the subject of nursing, that no attendant upon the sick should ever wear a rustling silk dress. The gown should be of a soft limp material, and, if we may venture to allude to the subject, we may say that crinoline is nowhere more out of place than in the sick-room.

READING ALOUD TO PATIENTS.—To some this is torture, while to others it is pleasant and soothing. Some will say, "Read me to sleep," and will actually soon drop off into a doze after the first few pages of some sufficiently uninteresting work has been read to them. It must be admitted, as a rule, that most people read very badly, and that conversation is more adapted for the sick, because the tone of the voice is more natural and pleasing when talking than when reading and reciting.

Care should be exercised in reading stories to sick children, especially to those of a nervous excitable temperament, for they often become interested in the story, and will beg it to be continued, little dreaming of the after effect upon their minds. The consequence is, that at night the scenes of the story are repeated, with the most grotesque variations, making a sort of night-mare or night-terror, the effect of which is often to prevent sound sleep, and to exhaust the little patient's strength, besides seriously adding to the nervous symptoms which may be present.

rest for patients than proper method and system in arranging and carrying on all the petty details of sick-room management. As an instance of what is meant, it will be easily understood what a much better prospect of quiet rest a patient has who gets his meals and his medicine regularly, and all his little wants attended to at proper times, and whose wishes are anticipated, planned, and provided for, than one who is attended to by those who are stupid and incapable, who blunder through their work without any fixed plan or order, and who continually disturb the patient at the most unseasonable time, by asking him, What will you take now? &c.

THE NURSE RESPONSIBLE FOR THE CARRYING OUT OF DIRECTIONS, NOT THE PATIENT.—When full and proper directions are given by the medical man, and these, it may be observed, should always be received by one person, who should be responsible for their being carried out, they should be acted upon without the patient having the trouble of thinking for himself about them. Nothing wearies and exhausts a patient more than having to think. He should be freed from all responsibility. He should be allowed to have nothing weighty on his mind. He should not be burdened with the fear of forgetting anything, and should have the comfortable sensation of having resigned the management of his case into other hands, in which he is to be, for the time, a mere passive agent. He should not be allowed to tax his memory by trying to remember the proper times for taking his medicine, or how it has acted; but should trust all these details to his attendant.

SHOULD THE PATIENT BE TOLD OF HIS DANGER?—A question here arises respecting which there is much difference of opinion, viz.:—When there is danger, should the patient be told of it? or is there any hazard in so doing? Now, it may be said that of late years there has been a considerable change in the practice of medical men with regard to this point, and much prejudice which formerly existed has been swept away, it is hoped, for ever. It is now pretty generally known that it rarely, if ever, does any harm to make a patient acquainted (in a proper manner, and at the proper time), with the nature of his case, and with the opinion of the medical advisers, as to the probable issue of it.

We are forced to admit that the contrary practice of former years originated, at all events, 672

in the desire to adopt this convenient excuse for the concealment of ignorance as to the real nature and probable termination of the disease. The ridiculous airs of profound learning and mystery assumed by medical men in old time has been well ridiculed and burlesqued by many writers, and by none so ably as by Molière in his Médecin Malgré lui, and the Malade Imaginaire.

Even now the strongest possible prejudice prevails in the public mind against telling a patient that he is the subject of heart disease. But provided that the communication be made with the view of instructing and guiding the patient in the treatment of his case, it will be found that, instead of doing harm, it may be the means of prolonging his life, and of increasing his comfort and happiness. The writer is, and has been, acquainted with many persons who have carried about with them a mortal disease which might put an end to their existence at any moment, and he cannot recall a single instance in which the patient was not the better for the knowledge of the facts of his case, or in which that knowledge was productive of any but the best results to both body and mind.

It is no doubt one of the most painful tasks that falls to the lot of the physician to pronounce that there is no hope, when such a verdict is evidently quite unlooked for, and when the patient, instead of expecting such melancholy tidings, is anticipating nothing but a speedy recovery. Young men and young women, it may be, in the prime of life, with a brilliant future apparently in store for them in this world, are sometimes found to be suffering from acute disease, which has come suddenly upon them, and which has already advanced so far as to leave no chance of life, while all the time no thought of real danger has as yet crossed the mind of one who, it may be, in a few days, or perhaps in a few hours, will be no more. Under such circumstances, when the physician has made up his mind as to the probable issue of the case, it is but fair, -it is only honest, when appealed to, -though with all due caution, to prepare the mind to receive tidings of the great change which is awaiting. Indeed, it is cruel to waste or to lose any unnecessary time, because long before death actually takes place the mind may be clouded, and the attention and faculties so engaged in the struggle against the great destroyer, that the mind loses its fine natural susceptibility to external impressions, and is utterly unable to deal with any subject, connected either with this world or with that which is to come. Here, as in every other relation in life, medical men, as well as the friends and relatives of patients, ought to follow the golden rule of doing unto others as they would be done by; and we think it would be generally agreed that no one would wish to be left in ignorance upon a matter of such momentous importance.

And here it may be said that, to the writer, it has often appeared needlessly cruel, and very unwise, studiously and mysteriously to conceal from children the fact that they are not likely to recover from a mortal disease. Surely it is a mistaken kindness, and one that argues little for the proper understanding which ought to exist between mother and child, to hear some parents, up to the moment of their child's death, assuring their child that it will soon be better. Any one who has seen the opposite course employed with children who have been sensibly brought up, will have been astonished at the very different effect upon their minds, and at the dignity, fortitude, and good feeling exhibited by many children at such times.

#### THE MANAGEMENT AND TREATMENT OF DELIRIOUS PATIENTS.

—The reader is referred to the articles Delirium, Delirium Tremens, Alcohol, Dipsomania, Intemperance, &c., for information as to the different kinds and treatment of delirium; but here it will be necessary to give a few general directions which may be of use in the sick-room. And first of all, it must be remembered that, in acute diseases, in fevers, after child-bed, &c., delirium, even of the most dangerous, violent, or suicidal nature, may develop itself so suddenly that the attendants may not be able, from want of sufficient warning, to prevent serious consequences. It will therefore be needful for those who have charge of the sick to carefully note and report symptoms which may arise in the course of the disease, such as wandering, incoherence, delusions upon any subject, or any outré act or speech which might

673

lead one to suspect the giving way of the mental powers. As a rule, when such symptoms have once manifested themselves, it is not safe for the patient to be left unwatched; and no article should be left within reach with which he might inflict an injury upon himself or others. Neglect of such precautions as these has, to the great grief and sorrow of all concerned, been followed by most serious consequences. Patients in whose family there has been no hereditary taint of insanity, and who themselves have never exhibited any trait of mental aberration, have, while the subjects of certain diseases, been known to get out of bed and throw themselves from the window. In the delirium of fever, patients, if unrestrained or unwatched, would oftentimes destroy themselves.

The cunning of maniacs and insane persons is proverbial; and while the "restraint system" is every day becoming more and more obnoxious in the eyes of medical men, it is much better that time and care should be expended in keeping a constant watch over patients who have exhibited a tendency to delirium, than that the slightest risk to life should be incurred.

In the treatment of all kinds of delirium, as in the treatment of the sick generally, patience, kindness, and firmness are the chief requisites on the part of the attendant; and where these are to be met with, cases will be very few and far between where anything like artificial restraint will need to be employed. No doubt it does sometimes occur that it is better the patient should be made to feel that he is overpowered, and that all his efforts to get loose are unavailing. Under such circumstances, restraint properly applied, without violence or disturbance of any kind, is in itself one of the very best means of quieting a furious patient, who will often drop quietly asleep after finding that his struggles lead to no result.

A careless attendant, when a patient is safely secured in the strait-jacket, or by other means, has been known to leave the patient for a length of time unwatched, thinking that now he is safe, and may shift for himself for a time. But this is very wrong; for the patient, especially if some of the apparatus alters its position in his struggles, may seriously injure himself, or may even, as has actually been the case, be found strangled.

In adjusting restraints upon the ankles, wrists, and other parts of the body, the greatest care should be taken not only to see that they are properly applied at the time, but to examine them repeatedly, in order to see that there is no chafing of the skin caused by the violent efforts to get free. Neglect of this precaution has been followed by the formation of deep sloughing sores, with other serious injury. Nothing is more foolish or reprehensible than when a patient is rambling in his talk in an incoherent manner, which may happen to be amusing to those who are standing by, to take up the thread of his wanderings, and encourage him to talk upon the subjects which, no doubt, are crossing and recrossing his brain in grotesque disorder. A kind, grave, firm and sensible nurse never appears to greater advantage than when dealing with a case of this kind, whereas one who reasons, talks, and attempts to argue with the patient upon his delusions, is sure to aggravate his disorder.

Sometimes, without the slightest assignable cause, patients suffering from delirium will be suddenly seized with the most violent aversion to, or dread of those who have been kindest, or are nearest and dearest to them. It is always best in such a case at once to remove the person from their sight, in which case the dislike or fear may very likely at the next visit be completely changed into sentiments of an opposite description. In the progress of disease, patients are much more liable to attacks of delirium at night, or during the early hours of the morning, and nurses cannot be too much cautioned as to the fact, since patients who have appeared to go quietly to sleep at their usual bed-time have, in the course of a few hours, suddenly awoke in a state of, for the time, raving madness.

No patients of this class require closer watching than those who are afflicted with suicidal melancholy. Such a one will often remain for days without saying a word to any one, and requires to be induced to perform the ordinary duties of life, to take his food, or even to change the posture which he has originally assumed. The despondency and depression of spirits are so intense, that, while they continue, the patient cannot be left with safety a moment, while he has the means of putting a termination to his existence. When he finds that he is closely

watched, and that it is impossible for him to carry out his determination, he will often, with a sinister cunning characteristic of his disease, throw aside his dull and morose manner, and assume a cheerful and contented deportment for days, or even weeks, in order to lull the suspicions of his friends. At the end of this time, however, when the vigilance of his attendants is relaxed, he will carry out the intention which he has probably premeditated and brooded over for a length of time, and will accomplish his own destruction in any way that may be in his power. Intending suicides will attempt to destroy themselves in various ways, even so as to baffle all the ordinary precautions. For instance, they will set fire to their clothing, they will attempt to strangle or hang themselves by every conceivable method, they will attempt to poison themselves with their medicine, or with anything else, and will even try to suffocate themselves by stuffing their clothes into their mouths, so as to prevent breathing.

One of the most embarrassing features in the management of insane or delirious patients is, that they sometimes absolutely refuse to swallow food of any kind. When this is the case, the attendant should be careful to tempt the patient with different articles of food; when this method fails, it will be necessary that the medical attendant should inject food into the stomach, by means of the stomach pump, such food being, of course, fluid, and of a highly nutritious description, such as different mixtures, containing milk thickened with farinaceous food, strong beef or mutton tea, milk, wine, brandy, cod-liver oil, &c. But it may happen that it may not be possible to secure the services of a medical man for this purpose, and at all times, in the case of a private patient treated at home, it is a very arduous and a troublesome process, that of feeding a patient three or four times a day, and one involving very frequent attendance on the part of the medical man. Therefore, in extreme cases, or where the services of the doctor cannot be procured, a long flexible tube might be passed through the nose, and down by the posterior nostrils, into the gullet. To the end of this a funnel is attached, and liquid food of the kind mentioned above being poured into the funnel will descend into the stomach, simply by force of gravitation. Failing this, nutritious enemata of the same kind as indicated above may be slowly injected three or four times a day, till other means can be adopted.

An attendant upon a delirious or insane patient should never make promises to him with out keeping them, should listen patiently to the story of his wrongs, grievances, and complaints, instead of treating them with contempt, and should, as a rule, never argue or reason with him, but as far as possible, even under the most severe provocation, preserve an equably kind, cheerful, and firm manner, by which means an influence will be acquired over all kinds of nervous patients, never to be gained by any amount of severity, punishment, violence, or restraint.

Presence of mind, and confidence in our own resources, exert a great moral influence over the insane, and have often been the means of rescuing an attendant from sudden peril in his intercourse with them, as well as of saving the unhappy creatures themselves from injury or destruction. The following anecdote well illustrates this:—

A patient in a high state of delirium eluded his keeper, and, running upstairs to the attics, escaped through a window opening upon the roof of the house. His keeper followed him out upon the slates, and upon seeing him, the maniac shouted, "Look here, I will make you jump down to the ground." With the utmost readiness and presence of mind the attendant replied, "Oh! any one could do that, but if you will come down with me, I will show you that I can jump up." The ruse, which certainly, under the awful circumstances, was quite justifiable, completely succeeded.

One other anecdote will suffice to illustrate the good effects of presence of mind in dealing with the insane. A medical friend of the writer's, the governor of an asylum, was once surprised alone, by a visit from a patient who had, for some entirely groundless reason, taken a great dislike to the doctor, and fancied that he was the cause of all his misfortunes. "Now," said the patient (who was an immensely powerful man), "I have caught you, and you will find resistance of no avail, for I have the strength of three men." To this the doctor, looking him steadily and unmovedly in the face, replied at once, with the greatest coolness, "There you

are mistaken, for I have lately had given me the strength of ten men, and if I chose I could double you up, and throw you out of the window." Immediately the current of the patient's thoughts was changed, and he began eagerly to inquire about the supposed miraculous gift of strength, and ever afterwards continued very much attached to his medical friend, whom he looked upon as the most remarkable man of the age.

There are few offices which require more good sense and delicacy of feeling than that of a nurse, because every nurse ought to be one who can be depended upon as "confidential." To her may be entrusted, either as a matter of necessity, or inadvertently, secrets which may involve the peace and comfort of families; and the qualities of such a nurse will be thoroughly tested in attending upon any cases of delirium, and mental disease generally. The greatest prudence and discretion will be necessary to avoid gossiping and talking, and it may be laid down as a rule, that any nurse who discloses what takes place in the sick-room, or who answers any questions respecting her patient or his friends to any except those who have a right to ask them, is quite unfit for her business. Truly, no one should venture upon undertaking the responsible duties of a nurse who is not prepared to carry them out in strict honesty of purpose, and who does not hope to be supported in them by a spirit of religious devotion.

It seems scarcely necessary to caution any young and inexperienced nurse against making the delusions and fancies, or the delirious freaks, of patients under certain circumstances, matter of amusement to herself or her friends. Surely it must be always a melancholy thing to contemplate a mind over which reason has lost its sway, and where the different faculties are permitted to run riot instead of properly controlling one another.

THE ADMINISTRATION OF FOOD AND MEDICINES.—For all information on this subject, the reader is referred to the articles Cookery for the Sick, Nurses, Medicines, &c., in the body of the work. It is very difficult to get inexperienced persons to pay attention to regularity in the giving of food to sick people, and also to study the hours at which food can be taken by the patient. The stomach of a sick man is so very delicate and capricious that it requires to be carefully observed as to these particulars.

The stomach is often so enfeebled by disease that it cannot even take liquid nourishment, except in the smallest quantity at a time, and at proper intervals. For example, how many patients will tell a medical man that they cannot take milk, that it always makes them worse, that it creates the bile or the phlegm, or something of that sort, whereas, the fact is, that there are very few, if any stomachs, that cannot bear milk, provided it be properly administered. It is not to be wondered at that a delicate stomach, during disease, should reject milk, if a large draught, say half a pint, or a pint, be taken all at once, and without any preparation. forget that the stomach requires to be educated, oftentimes, before it will bear even those sorts of food which are most likely to be of benefit. Many patients have been kept alive almost entirely upon milk who were well assured beforehand that they could not take it at all. But it should be given in small quantities at a time, and if there is much acidity a little soda or carrara water or lime water may be added to it, and in cases of great debility, a little rum or brandy. Patients who have been sick after taking milk, and who have seen that they have vomited the milk in a state of curd, often think this is conclusive evidence that milk must disagree with them, not knowing that milk must always undergo this change, by the acid of the gastric juice, before it can be digested or assimilated.

Some of these remarks apply also to beef tea, mutton tea, &c. A small quantity frequently administered, such as a tea-spoonful every half hour, will often be retained, when a large quantity, say a half-pint every two or three hours, would be rejected by the stomach. The doctor has very frequently to listen to the oft-repeated complaint, on the part of patients, that the nurse is always wanting them to take something, and that they can get no rest: and this is often very well founded, for a stupid nurse, without any system or method, generally contrives to be always tormenting the patient with something, whereas, by judicious arrangement of time, the patient could be got to take twice as many things with half the amount of fatigue.

676

In critical cases, life may depend upon the careful and punctual administration, not only of stimulants, but of nourishment, and it will be readily understood that, when the stomach is only capable of receiving a small amount at a short interval, if that interval be prolonged the opportunity of saving the patient may be lost.

In cases of sickness of old standing, perhaps connected with disease of the digestive organs, there is sometimes so great a repugnance to food of any kind, and so little power of appropriating it, that the patient, if left in the hands of an unskilful nurse, would certainly die of starvation. In order to prevent this, it will be the duty of those who have the superintendence of such matters to exercise all the ingenuity of which they are capable in preparing and cooking the patient's food; in giving it to him at those times when exhausted nature most requires itfor example, during the night or in the early morning, and in changing and varying the time of meals according to the state of the appetite or inclination of the patient. It may be repeated here that, both to avoid the danger of disgusting the patient and in order to keep the sick-room at all quiet and in a wholesome condition, no cooking must ever be done there, nor must any food be left about. It is too common to find a room littered about with half-consumed puddings, jellies, oranges, apples, grapes, &c., all of which should be kept out of the patient's sight, otherwise he will not relish them half so much when he is able to take them. It can scarcely be too much impressed upon the mind of a nurse, that she must plan and regulate the patient's diet according to system, and have everything prepared to carry out the proposed arrangements. It is the very refinement of cruelty to torture a patient with questions as to the arrangement of his diet, since nothing is more necessary than that the mind should be perfectly at rest, and free from all thought and responsibility on such subjects. Wherever practicable and desirable, it is a good rule to have written directions from the medical man as to the administration both of food and stimulants.

Attention should be paid to the quantity, or rather to the bulk, of food or drink which a patient may properly consume. Brandy and wine, when ordered to be taken with water, are sometimes so "drowned" that the enormous quantity of fluid dilutes unduly the gastric juice, and weakens the already enfeebled digestive power of the sufferer. Beef tea, broths, and farinaceous foods are also often made too thin or too bulky. In connection with this subject, let it be kept in mind that nothing disgusts a sick person more than to have large quantities of food put before him. When a little gruel is ordered, the nurse perhaps, instead of a cupful, brings a basinful, with the effect of thoroughly nauseating the patient by the sight of it.

By using the simple apparatus figured in article Bed-Room a cup of beef tea, or mutton tea, or something of the kind, may always be kept at hand warm, and it is wonderful how refreshing it proves to those who are wearied and exhausted by disease, and who lie awake in the early morning, ready to "sink through the bed," from sheer weakness. They will often go to sleep directly after having had warm and strengthening refreshment. Even a cup of tea or of coffee, at such times, will soothe and comfort a patient, and therefore, the means of procuring these readily should always be available.

Some people have the idea that calf-foot jelly is one of the most nutritious articles that can be given to a sick person; consequently it is, and has been in great favour in the sick-room, and has almost been looked to as a sovereign remedy in cases of desperate weakness. Others have gone so far as to state that it has no nutritive power whatever. The truth, however, lies as usual between the two extremes. Pure gelatine, if given alone without any other article of food, has no power to support life; but when given along with others it is a substance which helps to build up, and to supply the waste from the animal frame. Moreover, it is a convenient vehicle for wine and for nutritious articles of food. Sometimes, and in many diseases, it is agreeable to the patient, and easily taken, so that there is no reason whatever why this old favourite should be entirely banished from the sick-room, as suggested by some people.

ever is rejected for a time by the stomach. This occurs in disease of the organ, and in the course of other affections, after severe operations, &c. In such cases (generally of great extremity) it becomes necessary to nourish the body by means of fluids, introduced into and absorbed by the lower bowel. Beef tea, milk, brandy or wine, and other like substances, are given in this way. The great rule to attend to is not to give them quickly, otherwise they are sure not to be retained till any quantity is absorbed. They should be given slowly, and without causing any irritation. An ordinary enema tube of any kind may be used—the simpler the better. Difficulty of retention may be counteracted by the addition of five to ten drops of laudanum if admissible. Such injections too should always be small in bulk.

MEDICINES.—It need scarcely be said that the first duty of the nurse, as regards medicines, is to attend to the regularity with which they are given, seeing there are many remedies which, unless given according to system, do not present their characteristic action, and, consequently, the design of the physician is frustrated. In most diseases, however, sleep is of the utmost consequence, and, as a general rule, it may be said, a patient should never be aroused from slumber on account of his medicine, which may be given to him as soon as he awakes. Medicines are disagreeable at any time, but they are much more so when a person is roused from a refreshing sleep to have them administered.

As regards sedative or soothing draughts to be given at bed-time, one caution is necessary. Unless the patient is kept perfectly quiet, and nothing extraneous allowed to disturb him, the effect of the sedative draught will be to excite instead of to compose him, therefore it should never be given till all preparations for sleep are completed.

Medicine is generally given to produce some effect which can be observed by the senses, it is therefore of the first necessity that the nurse should mark this, and be able to communicate it to the medical attendant at his next visit. For instance, some medicines are given with a view to produce sleep or perspiration, or increased action of the bowels or kidneys, and the effects of prescribed remedies in these aspects must all be carefully noted by the nurse.

When medicines are ordered in drops, it is better to avoid the troublesome and uncertain process of dropping from the lip of the bottle; it is well known that fifty drops from one bottle may only equal in bulk thirty drops from another, therefore the drop-measure or minim-metre ought always to be used.

Many substances are employed to remove the nauseous taste of medicine, especially in the case of children, but, as a rule, sweet things, so generally given, are objectionable; and experience has proved that nothing is so effectual as a piece of dry biscuit or oatmeal cake.

Great trouble is often experienced in administering medicines to children, and where there is more than usual difficulty, the "medicinal spoon," recommended by Dr. Anthony Todd Thomson, may be employed.—See Bed Room: Requisites for the Sick.

It is astonishing how many people, even grown up people, have a difficulty in swallowing pills. Any one, however, can readily acquire the habit of practising with pills made of bread crumbs; and when it is considered how very desirable it sometimes is that medicines should be given in this form, it will be well that any one who suffers from the sort of nervous difficulty alluded to should endeavour to overcome it.

Effervescing mixtures are generally agreeable to the palate of the patient, and are besides often serviceable in allaying irritability of the stomach. Care should be taken to give them while they are actually in a state of effervescence, and not when the carbonic acid gas has evaporated, or, in other words, when they are flat. The powder of citric or tartaric acid, or the lime juice, if that be used, should, first of all, be put into the glass; then, when the patient is ready, the dose of the medicine should be poured over it, so that it may be taken while in a state of brisk effervescence.

When medicines are ordered containing chalk, magnesia, or insoluble powders, which by their gravity sink to the bottom of the phial, a label should accompany the bottle directing it to be shaken before each dose of the medicine is poured out. If this is not attended to all the active

ingredients accumulate at the bottom, the patient takes an almost inert mixture for, perhaps, a couple of days, and then gets an overdose at the last. This direction is no less to be attended to in the case of light medicines, lighter than the water in which they are mixed, and which float at the top of the bottle. For instance, prussic acid, which is often prescribed in medicinal doses, is apt to float at the top of any mixture containing it, and if the bottle be not properly shaken, as directed, the patient might get too large if not a poisonous dose all at once. Sulphuric ether is still more likely to float.

Any person of intelligence can easily understand that it is impossible to give all the directions necessary for the continued and proper administration of particular medicines upon the label of the bottle; and, therefore, we would caution nurses not to listen inattentively to the directions of the medical man, trusting that they will find it all written out for them there. As an example of what is meant, we may instance the case of a patient taking tartar emetic. The doctor may, perhaps, direct that it is to be discontinued, or to be given in a smaller dose if it causes sickness after the third or fourth dose, while he informs the nurse that he will not be surprised at its causing sickness at first, and trusts that it will be taken afterwards without that effect. He may warn the nurse that it may produce undue action of the bowels, in which case he may wish it stopped; or, he may explain to her the exact effect which he wishes to be produced, and may direct the remedy to be continued in a larger or smaller dose, and at a longer or shorter interval. Now it will be seen at a glance that it is impossible to convey all this upon the label of a bottle, and yet the successful issue of the case may depend upon the acumen of the nurse in appreciating, and her skill and faithfulness in carrying out the doctor's orders.

PECULIARITIES OF PATIENTS IN REGARD TO MEDICINES. — It is well-known that some patients are peculiarly affected by certain remedies, and it is highly desirable that any such idiosyncrasy should be reported to the physician, if it is known from former experience to exist. There are patients who cannot take certain remedies at all without experiencing peculiar effects quite foreign to the usual recognised action of the drug. For example, opium in some persons causes intolerable itching of the skin, or spasms of the stomach, or sleep-lessness; and ipecacuanha acts upon some persons in the same way as if they were affected with what is known as hay asthma or hay fever. Again, it not uncommonly happens that a remedy which ought to act, and which does generally act, say, upon the kidneys, shows a tendency in some persons to "run off" by the bowels, and so forth

INSPECTION OF THE EGESTA BY THE MEDICAL ATTENDANT.- In some cases it is not at all necessary for the physician to see the excretions of his patient, and it may be remarked, by the way, that some fussy people have most ridiculous notions on this subject, and seem as if they scarcely thought the doctor had earned his fee without examining the mysteries of the night stool on every visit. But, on the other hand, cases constantly do occur in medical practice, where it is absolutely necessary that the excretions should be inspected, and others where, in addition to this, their quantity must be noted from day to day. These details must not be looked upon by the attendants of the sick-room as in any way derogatory or offensive, because upon a proper performance of them may depend the issue of the case for life or death, inasmuch as without them it is quite impossible for the physician to have any idea of the effects of those powerful remedies which he is using to stop, to promote, to diminish, or to increase any one or more of the excretions of the body. Let us give an example of this: - In the well-known disease diabetes, powerful remedies are employed, and an entirely peculiar form of diet prescribed, in order to check, if possible, the enormous amount of urine containing sugar which is draining away the patient's strength day by day. It will be necessary, probably, to weigh the patient, so as to judge whether he is gaining or losing flesh; and, in addition to this, to note daily the amount of his excretions, part of which will be directed to be preserved, so as to be tested by the medical man. It is found that such

patients improve under one plan of treatment and retrograde under another; it will, therefore, be easily seen how important it is that these details should be so carried out that the progress of the case for better or worse may be determined. Another example—In all forms of dropsy, but especially in that depending upon Bright's disease of the kidneys, a daily note should be kept in a book or in a paper suspended by the bedside, of the amount of the patient's excretions; that is to say, at all events, of the quantity of the urine and of the number of the stools; for by this means the physician can see at a glance how his patient is being affected by the diuretic or purgative medicines which are given to remove the dropsy.

On daily noting the quantity of the urine in particular diseases, it will be necessary to remark, for the guidance of the physician, whether the patient has perspired profusely or has had diarrhoa, because without these careful observations the diminution in the quantity of urine, which will probably coincide with them, might be put down to the agency of remedies instead of the real cause.

# INSPECTION OF VOMITED MATTERS AND OF EXPECTORATION .-

It need scarcely be said that all vomited matters and everything which is spat up or "hawked up," should be preserved most carefully for inspection, instead of being thrown away, as is too commonly the case. No amount of description from a non-professional person can take the place of inspection, seeing it requires special training and education in order to observe these things to any purpose, and to be able to discover their exact nature.

None of the excretions are to be kept in the sick-room, but are to be preserved for inspection in a porcelain vessel, with a cover of the same material; either in the open air or in an outhouse; or, at all events, in another apartment, the windows of which should be kept open if possible. The importance of this rule will be admitted when it is reflected that in most contagious diseases the exhalations from the patient play the chief part in propagating the malady—and in the disease known as gastric, typhoid, or enteric fever, it is by the stools that the fever is communicated. When it will not interfere with the examination, a little of some disinfecting or deodorising fluid may be put in the bottom of the night-stool or bed-pan, or, at all events, they can be washed or rinsed out with it each time after being used.—See Disinfectants.

SYSTEM AND MANAGEMENT OF DETAILS .- It invariably happens that when the care of a sick person is undertaken without proper arrangements being made as to the economy of time and strength, there is a waste of both, and the attendants are knocked up and thoroughly unable to perform their duties, while the sick man is neglected, and everything goes wrong. It is not to be supposed that any nurse can remain with a patient and perform the duties required of her day after day, and night after night, without intermission. It is simply absurd to expect it, and yet how many people practically do so, or at all events, which is quite as bad, neglect making the proper arrangements for a change of attendants. hospital practice, of course, every provision is obliged to be made for this, and consequently there is a staff of day nurses, and night nurses, or, what is still better, those who are engaged throughout the day for a week at a time take a turn at the night work, and vice versa; but in private practice, when people engage a nurse, they seem to expect that if they require her services during an illness, she will be at her post night and day. Now, as we have said before, this is simply impossible, and therefore it will be necessary that the nurse must sleep or have leave to go to bed, either during the day, or during the night. In critical cases it is important that a person of experience should be with the sick during what are called the small hours, that is to say, early morning, because it is well known that at such times there is a liability to great depression of the vital power. With regard to a substitute, however, one point deserves special attention: it is absolutely necessary that when she goes upon duty, and undertakes to be responsible for the conduct of the case, she should receive instructions of the minutest kind upon all points as to medicine, food, &c., and not only so, but that she should

receive at the same time information as to all that has lately taken place, so that in the event of the medical man making a visit in the interval, she need not reply to any of his queries "I don't know,"—or, "the nurse never told me." The nurse should be particularly careful to give to her substitute the minutest information as to everything that has taken place since the last visit of the doctor, and when the substitute goes off duty again, she should in her turn report to the nurse everything that has occurred during her absence. In this way responsibility is not divided, and the doctor is enabled, as he is always entitled, to receive from one person, the person who is on duty at the time, full particulars as to the progress of the case. It is very aggravating when the doctor puts such a question as—Has he had any fits since I was here? that the nurse should reply, "Not when I was with him, sir," forgetting that it is the nurse's duty to know and to be able to report everything that has taken place.

Many cases come to a bad and unsuccessful issue through neglect of the golden rule that one person, and one only, should be responsible for the conduct of the sick-room. For instance, how will it be possible, if there are several people in a sick-room, to maintain quiet and order, unless one is in charge, and has authority to dictate as to the treatment of the patient, and to see that the orders of the doctor are carried out. It may be that one of the patient's friends, either not knowing, or, in his or her self-conceit, not approving of the directions of the medical man, may fancy that a patient who was ordered to be kept quiet would be the better of a little cheerful conversation, or that some new method of treatment might be entered upon. None but those accustomed to sickness can have any idea of the popular prejudices and fallacies with regard to it, or form the slightest notion of the confidence with which advice is tendered by those who are ignorant of the premises, and are utterly incompetent to give any opinion upon the question.

The absurdity of the nature of the advice and confidential communications which are daily tendered by the public to their sick friends, is aptly illustrated in a footnote to Miss Nightingale's Notes on Nursing. "I have heard a doctor condemned whose patient did not, alas! recover, because another doctor's patient, of a different sex, of a different age, recovered from a different disease, in a different place. Yes, this is really true. If people who make these comparisons did but know (only they do not care to know) the care and preciseness with which such comparisons require to be made (and are made) in order to be of any value whatever, they would spare their tongues. In comparing the deaths of one hospital with those of another, any statistics are justly considered valueless which do not give the ages, the sexes, and the diseases of all the cases. It does not seem necessary to mention this; it does not seem necessary to say that there can be no comparison between old men with dropsies and young women with consumptions, yet the cleverest men and the eleverest women are often heard making such comparisons, ignoring entirely sex, age, disease, place—in fact, all the conditions essential to the question. It is the merest gossip."

It will be granted that all such feeble counsellors and advisers should be rigorously excluded from the sick-room, and the person of authority over it will do well to keep them in remembrance, for they are a most intolerable nuisance to the sick man.

It seems scarcely necessary to say, that while strangers, gossips, and busy-bodies are kept strictly in check—it will often, also, be necessary in special cases to keep a watchful eye upon the admission of certain letters and newspapers (not to say telegrams and messages), which might contain intelligence often of an alarming or depressing nature. Bad news is always depressing, but especially so to the sick, who, when capable of being interested in conversation, should, if possible, be regaled only with topics of a light and cheerful description, and should be encouraged to look forward to the prospect of a happy future for themselves and for those in whom they take an interest.

FLOWERS IN THE SICK-ROOM.—There exists in the minds of many, a popular, though an ill-founded, prejudice against flowers in a house, the idea being that they exhale poisonous odours and are detrimental to health, but this is not the case; and although flowers

with a heavy sickly odour should never be admitted into a house at all, those of a brilliant and pleasing colour, either with or without agreeable odours, are always much appreciated by the sick. In some of our large and best conducted hospitals, flowers are regularly arranged in the wards. They are sent by railway by some of the country families in the neighbourhood from their conservatories, packed in tin boxes, and we feel quite sure that the liberal donors would be more than repaid if they could witness the joyful and eager looks of the pallid faces clustering around the newly arrived box and bestowing words and glances of heartfelt admiration upon its treasures as they are one by one drawn forth.

People who live a great deal in the country can scarcely form any idea of the instinctive longing for, and the intense pleasure felt at the sight of plants and flowers of almost any description, which is experienced by the weary and careworn artizan who spends every day of every year in the midst of our large manufacturing towns. Those who live constantly amongst and every moment of their lives breathe an atmosphere contaminated by dust, and smoke, and foul air, have the keenest delight at seeing and smelling a flower, which may recall to them some loved scene of their childhood, and may serve to awaken the highest and purest feelings, as well as help others to forget, for a time, the scene of their present weary toil. It has been found, then, that the patients in the large hospitals of our crowded towns have derived great benefit, both mental and bodily, from the introduction of flowers into the sick wards, and we feel sure that every medical man of experience will acknowledge that their presence in the sick-room, especially of a town patient suffering from a chronic disease, is, perhaps, one of the most valuable adjuvants to his treatment that he can possess. Flowers of a brilliant red colour have an exhilarating effect upon the mind of the patient, and should always have a preference given to them when there is a choice.

PICTURES AND PRINTS IN THE SICK-ROOM .- Several years ago, in some of the leading papers, the attention of the public was drawn to the fact, that the poor in our large hospitals were confined in the most cheerless wards or rooms, absolutely without any attempt at decoration; and it was suggested that private families might make a very acceptable donation to the governors of hospitals by presenting them with prints, pictures, &c .- chromolithographs, or those of a brilliant colour, being thought preferable. It was objected to this, mirabile dictu, even by some of the most eminent of the profession, that the presence of pictures in the wards was apt to suggest images to the mind of the sick man, which might, at certain seasons, serve as food for his delirious fancies. It has now been proved by experience, however, that this is not the case, and that a patient is much more likely to conjure up for himself, at a time of delirium, frightful images from the bare walls by which he is surrounded, than from any of the beautiful and interesting objects with which they may be clothed. We, therefore, strongly advocate pictures for the sick-room, and would decidedly give a preference to those with a pleasing and simple subject, and to such as represent familiar incidents in domestic and social Even for the poorest class of patients such may be most readily obtained at a trifling cost; as, for instance, the large chromo-lithographs published by the Illustrated London News and the Graphic. They may be either hung up as they are, or pasted upon a card board and varnished, or which is of course better though more expensive, framed and glazed.

During convalescence from illness, there is often a tendency in some patients to despondency and depression of spirits, accompanied by loss of appetite, and at such times when they are confined to the sick-room, and can't be allowed to go beyond its door, it is surprising how their recovery may be hastened, and their imprisonment rendered endurable, if not agreeable, by a little attention to the asthetics; not the least of which is to furnish them with nice books, pictures, flowers, &c.

For children, pictures are more especially necessary, not only on the walls, but they must have picture books which they can turn over leaf by leaf for themselves. This keeps them employed and amused, and is a great economy of the nurse's time and strength. The picture books should be made of calico, or some other material which cannot be easily torn, if they are to be given to young children.

682

THE WALLS OF THE SICK-ROOM.—Several points require special attention upon this head, in the choice of a sick-room. In the first place, green papers are to be avoided, as many of them contain arsenic in quite appreciable quantity, and the exhalations from them being breathed night and day by the patient, may give rise to poisonous symptoms. Secondly, papers which have been put on with bad size, or which have a nasty smell, are noxious in the extreme. A room, the walls of which are oil painted, and which can consequently be well dusted or washed, is perhaps the most suitable that can be found in a private house. In hospitals and large establishments, where the air is much polluted by emanations from the sick, the best walls are those which are made of glazed tiles, or of some material which will allow of their being well swilled or washed when the ward is cleaned.

CARPETS.—Were it not that it is desirable to keep the sick-room as quiet as possible, we should recommend that carpets should be altogether abolished from it, and that the floor should be a highly polished one, so that the dust and any impurities can be thoroughly removed from its surface. Such a floor does not, like a carpeted one, afford a nidus for the accumulation of morbid poisons, and is much more easily cleaned. But if the carpet is to be done away with, it is quite necessary that some matting either of india rubber or other material, be used upon those parts which the attendants must necessarily traverse, otherwise the noise is disagreeable. If neither carpet nor matting is used, list shoes or slippers must be worn by the attendants, and several large pairs kept outside the door to be worn over the boots of any one who comes in.

SCRUBBING OF THE FLOORS.—A great deal of discussion has lately taken place amongst medical men, as to the respective merits of scrubbing and dry rubbing, and some have gone so far as to state that hospital gangrene and other disastrous diseases have been originated and kept up by the emanations from a floor after being washed. Acting upon this idea in certain hospitals, no scrubbing of any part whatever has been allowed, except at certain periods of the year, when the patients were removed from the wards. The floors were ordered to be daily rubbed and polished after being swept, and it has been asserted that by the adoption of this plan the wards have been maintained in a healthier condition. At all events, it will be well to remember that a patient should, if possible, be removed from the sick-room while the floor is washed, since at such times the damp and unwholesome air is apt to be impregnated with peculiarly hurtful impurities.

COMMON OBSERVATIONS AND PRACTICAL EXPERIENCE .- To the observant man there is scarcely a study more interesting than that of the "human countenance," under all its varying aspects and conditions; and while we can generally form a pretty accurate estimate of the character of the individual from the study of the face, it is no less certain that the "physiognomy of disease" is a study, the importance of which is being more and more realised day by day, and one which will thoroughly reward not only medical men but also the attendant upon the sick-room. As an illustration of this, we may instance the remarkable fact, that if you take an intelligent physician into the sick ward of an hospital, and allow him to walk down the centre of the room and glance attentively and observingly at the countenances and attitudes of the different patients, while no doubt he will also listen to their breathing, and perhaps make numerous other little observations almost unconsciously to himself, of which you are ignorant, he will be able to form a tolerably accurate idea of the diseases from which they are suffering. It is not impossible, we will say, for a physician in this way to make what is called a correct "facial diagnosis" of the diseases of perhaps eighteen out of twenty patients. This shows how much is to be done by cultivating the faculty of observation with regard to the sick. One who has been taught to observe, in the best sense of the word, can tell almost at a glance whether his patient is better or worse, and reads with a wonderful certainty the happy signs of recovery, or the sad approach of death. 683

The sick-room attendant ought to be able, as the result of observation, to know when the patient is asleep or awake, in pain or at ease, when his breathing is oppressed and difficult, when he is low and faint and requiring nourishment or stimulus, when he wishes to be let alone, &c. These points are of even more importance as applied to the nursing of children, who are unable to make known their wants, or to describe their symptoms.—See Nurses for the Sick.

There is another kind of observation which one might call surgical observation, inasmuch as it is more to be exercised by surgeons or by surgical nurses, but which is a great advantage in the sick-room. For instance, one who has been taught this kind of observation knows at once, at a single glance, whether a wound is healing or not, whether it requires a cleansing poultice or a stimulating dressing, whether a fractured limb is lying in its proper position or not, &c. As to the observation of wounds, it is marvellous how experienced nurses, by keeping their eyes open, acquire a skill in the treatment of them, and know when and how to apply particular dressings so as greatly to expedite the healing process. An ignorant person, when no medical man is at hand, will go on applying substances to a sore which can never heal it, but only keep it open and make it worse, whereas a skilled and observant one can recognise and apply the appropriate remedy.

During convalescence, and throughout the progress of disease, relapses are oftentimes to be feared, and it is an important part of the duty of an intelligent observer of the sick-bed to note those appearances which indicate their probable appearance as well as to take every precaution

against them.

It is of the first importance that a nurse should accustom herself to accuracy of observation, so that when she has to make her report to the doctor she may not use vague and indefinite expressions, such as, the patient has slept "a good deal, sir, to-night," or, "his bowels have been open a many times;" but the answer ought to be expressed in figures, as, for instance, the patient has slept three, four, or six hours, as the case may be, or his bowels have been moved once, twice, four, six, or eight times. As near an approach as possible to the actual state of the fact must be reported, else nothing but confusion can ensue, since it is obvious that what one nurse might think a good night another might consider a bad one, and what will appear excessive to one nurse might be deemed nothing extraordinary by another. It will be needful to employ the same accuracy of speech, thought, and observation, as regards the eating and drinking of the patient, and it will not do to tell the doctor that he has a good appetite merely, since people's ideas as to a good appetite are apt to vary, and unless a doctor actually sees the dinner that is consumed by his patient he ought to be told, in cases where such particular inquiry is necessary, the exact quantity, or as near it as possible, of ounces of meat, or whatever it may be, that the patient is able to take.

It may be said here that the nurse must tax her own memory, and not that of the patient, with the proper answers to such questions, since it is cruel to make the patient think for himself at all; in fact, he should be allowed the luxury of caring for none of these things, since entire rest of mind as well as of body may be quite essential to his recovery.

What we want, then, to impress upon the nurse's mind is that she must be accurate in making her observations, and that she must report them herself. If her memory is treacherous, we would recommend that she should note down facts upon a slip of paper, and she should remember that the facts only are valuable, and that her opinion is of no value whatever to the medical man when compared with them. With regard to this subject, we may be allowed to quote again the following practical remarks from Miss Nightingale's Notes on Nursing:—

"In diseases which have their origin in the feeble or irregular action of some function, and not in organic change, it is quite an accident if the doctor who sees the case only once a day, and generally at the same time, can form any but a negative idea of its real condition. In the middle of the day when such a patient has been refreshed by light and air, by his tea, by his beef tea, and his brandy, by hot bottles to his feet, by being washed, and by clean linen, you can scarcely believe he is the same person that lay with a rapid fluttering pulse, with puffed eye lids, with short breath, cold limbs, and unsteady hands, this morning. Now what is a

684

aurse to do in such a case? Not cry "Lord bless you, sir! why, you'd have thought he were a dying all night." This may be true, but it is not the way to impress with the truth a doctor more capable of forming a judgment from the facts, if he did but know them, than you are. What he wants is not your opinion, however respectfully given, but your facts. In all diseases it is important, but in diseases which do not run a destined and fixed course it is not only important, it is essential that the facts the nurse alone can observe should be accurately observed, and accurately reported to the doctor."

Without observation acquired by experience, scarcely anyone can tell, with any approach to certainty, whether a patient is better or worse, or whether death is near; but to those experienced in such matters, the countenance of the patient speaks a language which is quite unmistakable. By those who are not versed in this kind of observation, patients are often shought to be worse when they are actually better, and vice versa.

The signs of dissolution must be seen in order to be understood. The countenance of approaching death was so thoroughly well described by Hippocrates, the father of medicine, that it is common amongst medical men to talk of the facies Hippocratica. Of course, it is not the countenance alone that is to be depended upon, but the general aspect of the patient, modified by his general constitution and temperament, as well as by the symptoms of the disease from which he has suffered, or is suffering.

It has happened that a nurse or attendant upon a sick person, has been required to give evidence in a court of justice, with regard to the symptoms of the patient's illness, and to the action and effect of the remedies prescribed. Under such circumstances the importance of registering and attending to facts, instead of theories, will be forcibly demonstrated. In cases of sudden death, and where a person has been found dead in bed, evidence may be required of the nurse as to the appearances presented. When a new-born infant dies at the same time as the mother that gave it birth, important civil rights may depend upon the question as to which lived the longest, and the evidence of a nurse may also be taken as to whether the child ever lived at all. In cases of death owing to suspected criminal abortion, suspected infanticide, as well as in all deaths by or from accident, suicide by drowning, by hanging, by strangling, or by suffocation of any kind, evidence may also be required from the attendants or bystanders: in cases of death by starvation, or from extremes of temperature, from cold, from heat, by lightning, &c. The same remark applies to deaths by violence, and the nurse may be questioned, and may be required to give answers, so far as her ability lies, as to the nature. appearance, and apparent effect of wounds of the head, neck, chest, abdomen, or extremities. Questions may be put as to the appearance of marks of violence upon the body, the appearance presented by the garments, the detection of spots of blood, or any other circumstances calculated to be of weight in medico-legal cases.

Important questions may also be put as to the mental state and condition of a patient at given times, as to whether he was in his right mind at the time of the execution of some document.

The above remarks are especially to be kept in mind, where a medical man cannot be found, or where he has not the opportunity of making the requisite observations.

HOW TO ACT IN CASE OF ACCIDENT.—The proper disposal of the sick-room for the reception of accidents, as soon as possible after their occurrence, is of great consequence, so that the patient may at once be placed under circumstances the best adapted for his recovery, and the least likely to cause him pain or inconvenience.

Let us suppose the case of a shattered or fractured limb. The accident will probably have occurred at some distance from the house, and the patient will have been brought along on a litter or in some conveyance, in such a position as to rest as much as possible the wounded part. If the hand be shattered, or the arm, it is generally best to bend the elbow at right angles, so as to relax the muscles, to support it in a broad sling and lay it across the chest. If the leg be the part injured, it should be bent or flexed at the knee-joint, also to relax the

muscles, and laid upon its outer side (if this position be not incompatible with the state and condition of the injured parts). It may be laid upon a board, or a tray, or a pillow, or anything that will support it and can be easily moved along with the limb; as, for instance, in removing a patient by means of a carriage, or by railway, from the scene of accident. Bleeding seldem occurs in shattered or fractured limbs to such an extent as to endanger life, simply from the fact, that the blood-vessels are torn instead of cut through, so that the application of cold, or the mere exposure of the wound to the air, will generally suffice to arrest the hæmorrhage. Failing this a tourniquet must be applied over the main blood-vessel, or a handkerchief or bandage may be passed round the limb, and tightened by means of a stick twisted into it. The effect of this will be greatly increased by placing firmly a pad under the bandage over the situation of the leading blood-vessel, if that is known or can be felt beating by the fingers. A bleeding limb should always be held as high as possible, the bleeding part being rather exposed to the air than covered with a number of cloths, as is the popular custom. If cold is applied, it should be by means of a single cloth, which may be either frequently renewed, or a gentle stream of cold water may be kept playing upon the wound. These precautions, as to bleeding, will be much more necessary in the case of incised wounds where the cut ends of the blood-vessels bleed with great activity. It is to be remembered as a golden rule, that almost all bleeding, even of the most urgent kind, can be checked for a time, or, at all events, till the arrival of the medical man, by direct pressure applied to the part, either by the fingers, or by a pad of lint, or a dry sponge.

Another rule is always to keep a limb which is broken in a natural, easy, or relaxed position, otherwise, from the action of the muscles, the ends of fractured bones may be forced with violence through the skin, or may injure blood-vessels, and may convert what was a tolerably simple into a very severe injury.

Should severe shock and depression of the system supervene after an accident, wine and water, or brandy and water, may be freely given at once, and if there are any symptoms of coldness of the extremities and shivering, warm bottles, heated blankets, hot bricks, or bags of hot salt, should be applied.

Let us suppose, now, that the patient has been carried from the scene of accident to his own house, or to the room where he is to be laid up. The first thing to be done is to choose a good room, according to the principles laid down in the beginning of this article; a well ventilated, and well managed sick-room being quite as essential to the healing of a wound as to recovery from sickness. In case an operation should be required, a room should be chosen with a good light, or if artificial light is required, several good tapers should be provided, and the bed so disposed that it can be easily got at and easily lighted up.

The next thing to be done is to arrange the bed properly, and in doing this, reference should be had as to whether it is the right or left limb that is injured and that requires to be treated. If the patient is suffering much from the shock, or from cold, the bed should be warmed. A mackintosh, or piece of waterproof material should be arranged under the wound, so as to protect the bedding from blood and discharge, and when it is desired to irrigate a wound, the mackintosh should be large, and so disposed as to allow the current of water to escape over the bed into a vessel placed for the purpose of receiving it.

Everything now being in readiness, the patient is to be got into bed, and in getting him in it will be necessary to remove his clothes, an operation giving great pain to the patient unless properly conducted. They should be slit up the seams and cut off where necessary, so that the wound may not in any way be dragged upon, and in this manner they may be removed, as it were, in one piece, even when there are the most painful and extensive injuries, without any pain or inconvenience. While all this is being done, it should be the duty of one person to attend to and hold the injured part, and to support it in a relaxed position, which is one of ease to the patient. When all the clothes are removed, a night shirt may be put on; and if it be the arm that is injured, the corresponding arm and shoulder-piece of the night shirt may be slit open. The patient is then to be placed in bed, and the limb, being still held by the

person in charge, deposited safely on a pillow, or otherwise, in the required position. Some loose tow or cotton wool may be placed around it, to absorb the blood if there be any, and care must be taken to prevent the weight of the bed-clothes from pressing upon it, either by means of a "cradle," by pillows, or by supporting the bed-clothes in any other way. The wound must be looked at every now and then till the arrival of the medical man, in order to ascertain if there is any bleeding; and if there is much shock or faintness from previous loss of blood, stimulants must be freely administered.

In cases of accident from drowning, the reader is referred to the article, and references are also to be made to Bandage, Dislocation, Emergencies, Fracture, Hæmorrhage, Poison, Suffocation, &c.

In cases of injury to the head, or of suspected fracture of the cranium, the patient may be quite insensible, and consequently such patients are often much tumbled about by those who remove them and who put them to bed; but the most serious accidents have resulted from want of care in this respect, and it has happened that bleeding inside the skull, which had been temporarily arrested, has been made to burst out afresh, with a fatal result, owing to nothing more than rough handling.

Wounded parts, which are very painful and uncomfortable in any position, may be placed upon a water pillow, the yielding and undulating surface of which readily accommodates itself to them, and does away with the effects of pressure.—See Ambulance and Emergencies.

THE ARRANGEMENT OF THE SICK-ROOM FOR, AND THE DUTIES OF THE ATTENDANTS AT, A SURGICAL OPERATION .- Surgical operations may be classified into two kinds: primary and secondary, that is, those undertaken at once in a case of accident for the removal of injured limbs, for the arrest of urgent bleeding, &c., and those, on the other hand, which are undertaken deliberately for the removal of diseased parts, which may have been more or less affected for weeks, months, or years. Now, although an operation must be always a dreadful and formidable thing when it is necessary that it should be performed in a private house, it is still more dreadful when it comes under the head of the first of the two classes. The accident may have happened in a moment of time and in the simplest manner possible, and yet it may have hopelessly destroyed a fair working limb, upon which may depend the subsistence of the sufferer and that of his wife and family. We will suppose that the surgeon, after anxious deliberation as to what is best to be done for his patient, has decided upon an operation. In any private house, however well-conducted, there will be a great many arrangements to make, a great many orders to be given, a great deal of hurrying to and fro, and the safety and welfare of the patient will in some measure depend upon the coolness, promptitude, and common sense of those who may be called upon to assist. In country districts, and in places generally, where medical men are not easily found, assistance of the most important kind may be demanded of those who would otherwise shrink from such a duty, but the demand for their services is urgent, and with coolness and readiness, excellent service may be rendered on an occasion, even by those quite unaccustomed to such matters. What is especially to be avoided, is all hurry and bustle. In the excitement of the moment every new idea is acted upon hastily without reflection, and from want of deliberation in the making of plans and arrangements, things are forgotten and overlooked till they are wanted; therefore, at such a time, more than at any other, are we called upon to observe the time-honoured injunction, festina lente.

The following articles should be provided and laid out ready for an operation, whatever it may be—Two long vessels, pitchers, buckets, or cans, one containing cold and the other hot water; two or three small basins, which are to be supplied from the above when required. These basins should never be quite filled with water when they are to be used, but only half filled, or even not quite so much.

Three or four, or more sponges. These should be soft and should be well wrung out of hot water before they are used. A large sponge, if suitable, may be cut or torn up, so as to make several small ones.

A number of napkins will be required, and should be folded and arranged on a table close at hand.

Wine and brandy should always be ready in case of faintness, and should also be placed

upon a table close by.

The operator's instruments should all be neatly laid out on a tray, covered with a napkin before the commencement of the operation, so that they may be handed to him when required. The assistant, whose duty this is (if not accustomed to it), should learn the name of the different instruments so as to know at once which is meant when it is asked for.

And now that all the different articles required are arranged, everything will be ready for

the removal of the patient.

Minor operations are generally performed while the patient is in bed. The large and the capital operations, as well as those requiring great delicacy of manipulation and very good light, should be always performed upon a table. This should be of a convenient length and very stout, it should be covered with a blanket, and over this a piece of mackintosh cloth, or a piece of red blanket cloth. A shallow box containing saw-dust should be placed beneath, to absorb any blood which may drip down, and a pillow or two should be placed to support the head and shoulders. Above all, it is necessary to have good light.

In removing a patient from his bed to the operating table, the utmost care and discretion is necessary, and this will generally be superintended by the medical man, who, if chloroform is to be given, very often commences its administration before the patient is subjected to the pain

and irritation of being moved.

In the case of a limb being injured, or a joint diseased, or in cases of large tumours of the extremitics, it can easily be understood that great pain and even injury may be consequent upon the slightest movement, therefore we again repeat that one person should devote his attention exclusively to the management of the diseased or injured part, and while others are removing or raising the body, he will move or raise the limb in his charge simultaneously with them, and endeavour to lay it in as easy a position as possible, and to do so with as little pain and inconvenience to the patient as he can.

When several persons are engaged in lifting or moving a patient, they must act in concert, that is, they must all lift at the same time, or else the patient is sure to be the sufferer. Nothing is more aggravating than to see this clumsily done, as happens when one lifts after another, and each tugs at the patient without any other effect than to cause him pain. One person should support the patient's head, one each shoulder, and one at each hip, while another lifts the feet, and another, as we have stated above, devotes his whole attention to the diseased

or injured part.

Each of the attendants, before the operation commences, should have a particular duty assigned by the medical man. For example—Several will be required to restrain the patient's movements; and here it may be said, that at what is called the stage of excitement during the administration of chloroform, patients may require as much, if not more, forcible restraint, than when no chloroform is given at all. One attendant should take charge of the hands and arms, another of the body, and another of the legs and feet. If the patient is very powerful, one should have charge of each arm and each leg, and so on. Another attendant may be directed by the medical man to wring out and hand sponges. These are used to sponge away the blood, in order to enable the operator to see distinctly what he is doing, therefore he requires them frequently changed when they become saturated with blood. Another assistant may be directed to look after the hot and cold water and towels, and another may be required for handing instruments, &c.

It seems scarcely needful to say, that perfect silence should be maintained during the whole

time of the performance of an operation.

Quietness and attention to the wants of an operator, and to the movements of the patient are highly necessary, and mark at once a skilful and valuable assistant.

When the operation is over, the same rules are to be observed as to removing the patient

take charge of the part which has been operated upon, since bleeding of a dangerous and troublesome kind may arise from its being roughly handled or jarred. The greatest care will be required in placing the patient in bed again, and one grand point to be observed is always to keep the head low, in case of fainting, which is likely to ensue after the operation and after chloroform has been given.

After the patient has been placed in bed, he should not be left alone, because of the dangerous possibility of bleeding, or of the effects of the chloroform, if that has been employed.
Generally the part is covered by the bed-clothes, supported, of course, by a cradle, and it will
be the duty of the attendant to raise them from time to time, to examine if there be any tendency to bleeding, and to see if the part be lying comfortably. A stump will generally be
arranged by the surgeon upon a pillow or some other support, but after he has left, troublesome
and painful involuntary movements or twitchings not unfrequently take place, and these must
be counteracted by pinning a soft, light handkerchief, or a piece of a bandage, to the bed-clothes,
on each side of the stump or limb, so as to keep it steady.

An opiate or sedative draught is very generally given immediately after an operation, and then it will be requisite to soothe and quiet the patient as much as possible, so as to induce sleep, otherwise undue reaction and excitement are sure to follow.

Now-a-days, even to the most formidable wounds, only the lightest and most simple of dressings are applied, and in many cases nothing more than a strip of wetted lint. If orders are given by the surgeon that this is to be constantly kept moist, either the irrigating apparatus, described in this article, should be used, or it may be damped from time to time, by dipping a sponge or rag into cold water and allowing it to drop upon the dressing till it is saturated. The drops should not be allowed to fall from a height, but should be close to the wound, else the effect of the stream of water is too irritating.

For the first few days after an operation, more particularly if it is hoped to obtain union of the lips of the wound by what surgeons call the first intention (see article Wound), the dressing or dressings may not require to be moved at all; and, in point of fact, nothing may be required but careful watching and attention to the position of the part. The constrained position in which the patient is sometimes forced to lie is so irksome and painful, that a skilful nurse will have ample opportunity of showing her resources, by adjusting pillows and supports, props, cushions, pads, &c. Water pillows and air pillows are invaluable for the support of wounded parts, and ought always to be employed where practicable. A hand or foot, which has undergone an operation, when laid upon an ordinary pillow, even though it be covered with mackintosh, sometimes becomes so hot and painful, and so uncomfortable from the wet and stuffy feeling of the support, that the patient is prevented from sleeping, and suffers considerable uneasiness. This is the time when a water pillow, only half filled, and with cold water, is found to be of so much service, not only in affording a yielding and comfortable support, but in keeping the part cool. The good effects of these pillows in sloughing bed-sores can scarcely be over estimated. (See article Bed-sores.)

When it is required to remove dressings from a wound every day, in order to substitute clean or fresh ones, you will save the patient endless pain and discomfort by attention to one simple rule, viz., soaking them well. Tepid water should be used, that is, water about the temperature of new milk, and the parts where the dressings are adherent to the wound, that is to say, sticking to it by the blood or discharge, are to be repeatedly moistened with water dropped upon them from a sponge, held close to the wound, till they are quite loose, and can be removed without any of that tearing which is as painful as it is unnecessary. This process requires time of course, therefore, if the surgeon directs that the dressings are to be well soaked before his visit, the nurse should commence to do so in sufficient time, and should continue soaking till they are removed, without once allowing them to get dry. This is rather an awkward proceeding in the case of some wounds, because it involves the use of a considerable quantity of water, and if skill be not exercised the bed will infallibly be wetted. A mackintosh cloth with sponger

may be arranged to intercept the water in most cases; and in others, a pasin with a semilunar part of its brim cut out, so as to fit the limb, or the side, or other part of the patient's body, ought to be used when much of this bathing has to be done every day. Basins of this kind made of metal, porcelain, and vulcanite, are sold by the instrument makers, and are so contrived as to fit the irregularities of the surface of the various parts of the body. Anyone who tries to bathe a part with the ordinary basin and with such a basin as that described will appreciate the difference. In the one case the bed is probably deluged, and in the other, even though used by inexperienced hands, not a drop of water is spilt.

MANAGEMENT OF DIFFERENT DISEASES .- It would be impossible, within the limits of an article like this, and even if it were possible, it would not be desirable, to enter into the management of the sick-room, in all the different diseases which flesh is heir to. It must be well known to all who have any experience of illness, that no two cases, ev n of the same disease, are ever quite alike, and that the management and treatment must also vary according to the symptoms presented by, and the peculiarities of, each particular case. Take, for instance, two cases of inflammation of the lungs, always an anxious, and sometimes a highly dangerous affection-one will proceed from beginning to end without any unfavourable symptoms, and so long as he remains confined to bed, with scarcely any feeling of discomfort to the patient. In fact, so long as he remains quiet in bed, it is difficult to persuade him that he is ill at all, and, much more so, that he is the subject of a disease which oftentimes proves fatal. But another case of the same disease, under apparently the same external conditions, and in a person of, perhaps, the same constitution, will be accompanied from first to last by sympt ms of the most distressing kind, both to the patient and to those by whom he is surrounded. Pain the most urgent, difficulty of breathing, and delirium, may be present during the greater part of the progress of the disease. The greatest uneasiness, suffering, and distress may be felt by the patient, and he may either, after great care and long anxiety on the part of his physician and attendants, make a slow recovery, or death may put an end to the struggle. It will be obvious how, in such a case, and, indeed, in all cases, the treatment and attention required will be as different as possible in the one case and in the other. Disease assumes very different aspects also when it attacks persons of diverse constitutions and in varying climates. Children are affected differently from adults, and many other difficulties might be mentioned, which prevent one from generalising upon the treatment of different diseases to a non-professional reader. Throughout the body of this article we have endeavoured to place before the reader some of the main points to be attended to in the management of the sick-room during the course of diseases of a general kind, and in the treatment of injuries and wounds. Attention has also been directed to what will be required in the conduct of cases requiring surgical operations, yet it has not been attempted to follow out the steps of management necessary during the course of any particular disease or even class of diseases. It may not be out of place, however, to take one or two instances or examples, which may serve as typical illustrations of their class, and to indicate, however imperfectly, the course of treatment required.

If one were to attempt anything like a classification of diseases, so far as their nursing was concerned, it would be found that it will agree pretty closely with the practical allotment of diseases which obtains in our general hospitals. Besides the great subdivisions of acute and chronic diseases, we would classify by themselves, medical and surgical cases; fevers, and contagious diseases; cases of mental diseases; special diseases of women; and diseases of children. Every medical man knows that in each and all of these departments are to be found nurses whose experience and skill is of great value, but yet who, for the management of any other disease, not falling under the class to which they have been specially trained and accustomed, are little better adapted than those who are comparatively inexperienced. The proof of this is, that when an experienced nurse in a surgical ward is changed to a medical one, and instead of managing patients with wounds and broken limbs, undertakes the charge of those with acute

and chronic diseases of the brain, lungs, &c., much of her experience in her former capacity is comparatively valueless to her, and although she may have been a perfect adept in dressing a wound, or in changing the bed-clothes for a patient suffering from compound fracture of the leg, it may take some time before she acquires proficiency in, perhaps, the more nice observation required in studying and attending to the wants of a patient, with nervous, or heart affection, or understands all the precautions required in the case of those who may, in outward appearance, appear in tolerably good health, but who are no less the victims of mortal disease. Again, all hospital physicians know how invaluable the really good "fever nurse" is, and how often a desperate case of fever may owe its recovery mainly to the judicious, skilful, and constant care of a nurse accustomed to the conduct of cases of this kind. It is also notorious to every one, that some women can manage and control children, either in health or in disease, who are quite unmanageable when left in charge of others, and that the symptoms exhibited by a sick child speak an intelligible language to one woman which is a dead letter to another. To any one who doubts this, we beg to recommend the perusal of a small volume entitled How to Nurse Sick Children, by Dr. Charles West of London, Physician to the Hospital for Sick Children. The diseases peculiar to women, also, are occasionally of such a nature that a nurse who has experience and skill in their management is greatly to be preferred to one who has not this recommendation.

MANAGEMENT OF MEDICAL CASES .- Let us take as an example of an acute medical case of a general kind-acute rheumatism, or what is popularly called rheumatic fever. This disease, when it occurs in an aggravated form, leaves the patient wholly dependent upon his nurse, and consequently it may be taken as an example of many in which the best nursing is required. It is oftentimes accompanied with great pain and suffering. Moreover, it is one of the commonest diseases of this country, probably owing to our cold, damp climate, and our habits of life. It depends upon the presence in the blood of a poisonous material, probably lactic acid, and this poison expends its force, not upon any one part or organ, but affects all the different textures around, entering into the composition of the joints, as well as the fibrous tissue of the ligaments and tendons of the muscles. Consistently with this tendency to attack organs of the above description, it has a remarkable and most dangerous tendency to implicate the membranes surrounding and lining the heart, which may be looked upon as the most serious complication of the disease. Thus, whether we consider the intense agony which a patient experiences from the slightest movement of the affected joints, the intensity of the fever which invariably accompanies a severe case, or the above mentioned tendency to implicate the heart in a manner which may cause either sudden death or irreparable damage to that organ for life, it will be seen that here, perhaps, as much as in any other case, good nursing and management must be of the highest consequence. Immediately upon the thorough establishment of the disease, the patient is reduced to the last extremity of helplessness. He lies upon his back motionless and dreading the slightest movement, and is, in every respect, a melancholy spectacle of suffering and misery. He cannot and he dare not move, because the slightest motion gives rise to the most agonising pain in the affected joints-the weight of the bed-clothes is insupportable, and even the tread of an attendant crossing the room thrills him all over with pain. If any one standing near the bed happens to shake it, or to lay down any thing upon it, or forgetting the state of the patient for a moment, to sit upon the edge of it, or to rest his knee upon it, a cry of agony from the patient will quickly remind him of his thoughtlessness. The skin is literally bathed in sweat, which is acid, and of a peculiar odour, and adds much to the suffering and discomfort of the patient. Many of the ordinary symptoms of general fever are present, a quick pulse, foul tongue, constipation, high coloured and scanty urine, frequently with large sediment somewhat like pea soup. One of the most remarkable and dangerous features of the disease is its tendency to change about from place to place, so that a patient who, in the morning, complained bitterly of pain in the ankles and knees, may, in the evening, be quite free from pain in these parts, and refer all his sufferings to his wrists and elbows. At another time one wrist

will be very much swollen and full of pain, and perhaps next morning the pain will have entirely left it and taken up its residence in the wrist upon the other side. In the course of twelve hours or so, back again the pain flies to its original seat. But of all the changes which are apt to take place in this disease, which is so liable to shift about, the one by far the most to be dreaded is the change to the heart or its membranes. So common is this, that it is computed to occur, perhaps, once in every three cases of rheumatic fever. It is a result very much to be dreaded, inasmuch as the consequences may be very serious, either at the time of attack or in after life. Incurable disease of the heart may remain with the patient for the rest of his lifetime, and render existence completely miserable. On the other hand, the attack may be so violent as speedily to put an end to life. Patients have been known to die in a moment from the effects of the rheumatic poison suddenly changing to the heart. At every visit the physician anxiously examines the region of the heart to discover whether there be any signs of an impending attack, and he leaves directions with the attendants, of such a nature, that he may be sent for on the first approach of symptoms that would indicate that the heart was about to be affected. Besides the tendency to the complication of heart disease with acute rheumatism, inflammatory affections of other organs are very likely to occur, owing, no doubt, to the presence in the system of the poison, which acts as an irritant and gives rise to inflammation. The membranes of the lungs may become affected, giving rise to rheumatic pleurisy, or the substance of the lung itself may be inflamed (rheumatic inflammation of the lungs), or there may be inflammation of the bronchial tubes (rheumatic bronchitis), which is one of the most distressing and painful accompaniments of the disease, since the harassing cough, by shaking the patient, causes him the acutest suffering, and greatly aggravates his troubles. Another and rarer complication of rheumatic fever, but still one very much to be dreaded, is inflammation of the membranes surrounding the brain, or even of the substance of that organ itself. It does occasionally happen also, but quite exceptionally, that the inflammatory process runs so high as completely to destroy one or more of the affected joints. This, however, is quite contrary to the common progress of the disease, for in most cases it is marvellous to note, how, on the subsidence of the affection, the joints which a few days before were red and swollen and intensely painful, recover their natural size, colour, and motion.

When the disease is not attended by any of the complications enumerated above, when it occurs in a healthy subject, and is subjected to skilful treatment under conditions favourable for recovery, it may be said to run its course in a time varying from little more than a week to three weeks. The violence of the disease has almost always abated before the last mentioned time.

Patients, as a rule, do not die of acute rheumatism itself, for the disease is one that runs a certain course, arrives at its maximum, and gradually terminates in recovery. No doubt cases do occur in which the patient sinks rapidly, overpowered, as it were, by the violence of the disease, and from the presence of the poison in large quantities in the system. These cases, however, are to be looked upon as entirely exceptional, and when death does occur, it is almost always due to one or other of the complications mentioned above, by far the most commonly fatal of which is heart disease. Even should the patient recover at the time from the heart affection, he is sometimes, though by no means always, left the subject of chronic heart disease of an incurable kind. The consequences of this are sometimes, and in certain constitutions, comparatively trivial, while, in the majority of cases, they leave the patient an invalid for life. On the slightest exposure to cold he is liable to be attacked by some inflammatory affection of the chest, accompanied with difficulty of breathing, or with dropsy, and on the slightest excitement he may be affected by palpitation, or with some sudden seizure, which puts an end to life itself.

The disease is undoubtedly hereditary; in fact, every day we are becoming more familiarly acquainted with a variety of evidences of the hereditary nature of rheumatism, different members of the same family being affected by different diseases, which can all now be traced to the one rheumatic origin. Rheumatic fever itself occurs most commonly in grown-up people between the ages of fifteen and thirty-five.

The first thing that will probably be required, seeing that the patient at the commencement of the disease is generally suffering from all those symptoms depending upon disordered secretions, is the administration of a dose of purgative medicine. Now, if attention has been paid to the above description of the disease, it will be seen at a glance that this is a point which requires careful attention, and for which proper provision must be made. Nothing could be more cruel, and yet it is constantly done by unthinking persons, than to give a patient, suffering from acute rheumatism, a smart and active purge without making the slightest provision for its effects. It may be that the patient is in a private house, or in lodgings, where the wants of the sick-room are unknown. A bed-pan, or even a night chair, may not be at hand, and thus, even from the want of such apparent trivial precautions, the greatest suffering may be induced and the disease aggravated; and every one can fancy the torture which it must be to a patient whose joints are swollen and painful, upon the slighest movement, to jump out and in of bed several times, to respond to the calls of a brisk aperient which has been so thoughtlessly prescribed for him.

There are very few diseases accompanied by more suffering than acute rheumatism, the pain in the joints being often excessive, and many expedients have been devised to relieve this. Of all the numerous applications which have been recommended there is none so comforting, so easily managed, and so productive of advantage to the patient as cotton wool, loosely wrapped round every affected joint. Sometimes this may be covered with oiled silk or gutta percha tissue, so as to cause perspiration to exude in great quantity and constitute a local vapour bath, but at other times this cannot be borne at all, and after it has been kept on for any length of time the pain is thereby very much increased. If it is desired to apply this, a few turns of a bandage will secure the oiled silk or gutta percha over the cotton wool, and the heat produced will cause the gutta percha to mould itself into the required shape and to constitute almost an air-tight bag. A few drops of chloroform and of laudanum may be sprinkled on the surface of the cotton wool before it is applied. When the pain refuses to be allayed by these and similar means, and when it is very violent in any particular joint, the celebrated lotion of Dr. Fuller, or what is equivalent to it, may be employed; it may be made by adding an ounce of bicarbonate of soda and an ounce of laudanum to a quart of hot water. A piece of folded lint or of flannel soaked in this may be frequently laid over the affected joint or joints, and in order to keep it hot and moist as long as possible it may be covered with oiled silk. When the violence of the disease seems for a time to have centred in the wrists or ankles, this lotion will be found of special advantage. Great relief may be sometimes given to a very painful joint by placing it upon a water pillow, or in the case of the foot or hand, by carefully adjusting them to a padded splint so as to prevent all unnecessary movements.

As mentioned above, the great fear and great danger in this disease is the implication of the heart, or, in popular phraseology, that it should fly to the heart; let the attendants, therefore, be on the look-out for and carefully note the first signs of the impending danger, so that assistance may be had before it is too late. The first symptom complained of may be pain over the region of the heart, with fluttering or palpitating action of that organ, sighing, or perhaps a tendency to delirium. These symptoms, however, are somewhat like those occasionally presented by hysterical patients suffering from rheumatism, who have themselves perhaps been led to look out for them by leading questions, and who are possibly under the influence of medicines, and it may be, suffering from pain and distention of the stomach, causing uneasiness over the region of the heart. The attendants, therefore, must not rashly conclude that every pain referred to this situation of necessity implies that the heart is about to be affected. Until medical assistance can be obtained, the most important point to attend to in the event of the heart becoming affected is, on no account to allow the patient to rise up, or even to sit up suddenly in bed, since immediate death by fainting may be the result. Stimulants may be given if there is great tendency to faintness and depression; a current of cool air may be allowed to play around the patient, and smelling salts or eau-de-Cologne may be applied. 693

During the progress of the first part of the disease, the patient's diet will require to be very low indeed, and must be made up principally, if not entirely of fluids—such as beef tea, milk, arrow-root, &c.; while, owing to the excessive perspiration, and the consequent great thirst, abundance of cooling drinks may be allowed, especially potash water, or lithia, or soda water. Milk may be given with these, with lime water, or with the effervescing carrara water. Lemonade may also be given, or a drink made by adding a tea-spoonful of bicarbonate or nitrate of potash to a pint of water. Another excellent refreshing drink is made as follows—take of cream of tartar, one ounce, oil of lemons, fifteen drops, loaf sugar, two ounces, boiling water, two pints.

There is perhaps scarcely any disease in which it is more necessary to use the feeding cup for the administration of food, drink, and medicines. Sometimes the muscles of the neck are affected to such an extent that the slightest movement of the head is exquisitely painful, and yet the patient is tortured by a consuming thirst. In such a case the great advantage of the feeding cup is, that an attendant can administer a mouthful of some cooling beverage as often as

necessary, without the slightest movement on the part of the patient.

Any one who has seen much of rheumatic fever will be struck by the fact that the subject of it generally lies upon his back, sunk down in the bed, in an apparently helpless position: he cannot relieve himself by changing his position from side to side; hence the occurrence of bed-sores is very much to be dreaded, more especially if the rheumatic is complicated with any other disease, which either aggravates its severity or prolongs its duration. The back or part upon which the patient lies constantly must be carefully watched, and on the first symptoms of anything like a flush of redness, should be washed twice a day with brandy. The patient should be laid upon a water bed or water pillow, or, failing this, pads or supports of different kinds should be adjusted under him, that the pressure may be distributed and may not fall all together on one spot, so as to give rise to a sore. In fact, all, and more than all the ordinary precautions must be taken which are enumerated under the article Bed-sore.

APOPLEXY.—The most common form of apoplexy is that in which hæmorrhage takes place in the substance of the brain. It occurs most frequently in advanced life. The amount of effused blood varies from the smallest appreciable quantity to many ounces. The cause of it is generally to be found in a diseased state of the blood-vessels, and it takes place frequently as a consequence of heart disease, or of Bright's disease of the kidneys.

It is one of those affections which occur so suddenly, and with so little warning, that no preparation can be made for it. A person falls down in the street, or in church, or at a public meeting, and is conveyed home in a state of insensibility. Skilful attention in the sick-room may greatly assist recovery from this affection, while improper treatment or neglect may have an opposite effect. Promptitude of action is essentially required, since unless effectual measures are taken at the commencement they may be of no avail.

The pressure upon the substance of the brain, caused by the effusion of blood, gives rise to sudden insensibility, with loss of sensation, thought, and voluntary motion. As a rule, a second or third attack is more severe than a first, which is often comparatively mild, while the second is sometimes followed by paralysis, and the third is so frequently fatal that, according to popular belief, a person seldom survives a third attack.

When a person is brought home in a state of insensibility, and supposed to be suffering from apoplexy, if a medical man has not been sent for, those standing around should be careful not to form too hasty an opinion as to the nature of the affection, for it has often happened that a fit of "apoplexy" has turned out to be only a fit of drunkenness. On the other hand, policemen, and meddlesome persons, have caused fatal mischief by treating a patient really suffering from apoplexy upon the supposition that he was only drunk. The practical rule to be observed, therefore, is carefully to examine such persons; to endeavour to ascertain the absence or presence of the odour of spirits in the breath; to observe their general appearance or age, and to make all possible inquiry as to the probability of the seizure being due to narcotic poison, to drunken.

ness, to spoplexy, or to any other cause. As regards the general appearance, it may be said that those are most subject to apoplectic attacks who have forid features and short thick necks; a large ead, a flabbiness of the muscles indicating sedentary habits, a protuberant belly, and a general appearance of being accustomed to good living, all indicate a tendency to apoplectic seizure. The patient is generally seized without much warning; sometimes, however, he will have been heard to complain of headache or giddiness, noises in the ears, swelling of the eyes, with some alteration of vision, transient loss of memory, melancholy, rambling and incoherent speech, or a tendency to drowsiness. Sometimes also, paralysis, either of the face or of a limb, precedes the loss of consciousness, and is a terrible warning of what may be about to take place.

The patient will probably be found in the position of one who has fallen down suddenly, lying in a deep sleep without consciousness or movement. The face is generally flushed (though in some forms of apoplexy it is pale), the breathing is snoring or puffing, or a combination of the two, and the pulse is full and labouring, but not frequent. Care should be taken to ascertain, inasmuch as it is a great help in determining the nature of the case, whether the patient is suffering from paralysis of any part, or from rigidity or contraction of its muscles; whether there is any distortion of the features, and whether or not convulsions occur at intervals. Sometimes there is no absolute loss of consciousness at first, and the patient, after having suffered from some suspicious head symptoms, apparently rallies for a little, but this state is often, after a few hours, succeeded by complete unconsciousness, which very often ends in death. Again, there may be no unconsciousness at all, and the patient may be found paralysed on one side of the body and unable to speak, although he may be quite aware of what is taking place There exists the greatest variation as to the occurrence of the symptoms enumerated above in different cases. Sometimes the unconsciousness or the paralysis is complete, sometimes only partial, and so on.

With the preventive treatment of apoplexy we have nothing to do in an article on sick-room management. What we wish is to give directions by which the disease may be recognised, and all possible precaution taken to prevent further mischief being done, as well as also to indicate how best to carry out the appropriate treatment which may be prescribed.

In former times, when bleeding was so much in vogue, almost every patient who had or was supposed to have an apoplectic attack was immediately bled. If a doctor could not be found, any person who happened to be present did not hesitate to open a blood-vessel, if he could, with any instrument which came to his hand, and the writer once saw a servant endeavouring frantically to open the temporal artery of her master (who was seized with apoplexy) with a fork. It may at once be said that no case should be bled in the absence of a medical man, and that, indeed, the cases are very few where bleeding is required, while it may often do great injury. The greatest care should be taken in lifting and moving a patient, supposed to be suffering from apoplexy, since movements of the head and neck especially may increase hæmorrhage, or may bring it on again after it has once stopped. Yet how often do we see well-meaning but ignorant and officious persons raising up such a patient suddenly, and endeavouring to rouse him to consciousness! and in the case of poor patients found "in a fit" on the streets, what rough treatment or handling do they sometimes receive at the hands of the police, or others, to whose tender mercies they are entrusted! It often happens that some person who has once in his life seen a case of imposture successfully treated, insists upon trying his favourite remedy upon all the cases that subsequently come under his notice, forgetting that, unless he is certain (which no one but a medical man can be), that it is a case of imposture, he may inflict a fatal injury.

In all cases, a patient should be placed in a well-ventilated room, the head should be gently supported upon a pillow, and the shirt collar and neck-tie, and all tight parts of the dress should be removed, so as to admit of free circulation of the blood. If the face be flushed and the veins turgid, cold should be applied to the head, either by means of muslin rags dipped in cold water and vinegar (if the water is iced so much the better), or pounded ice may be applied in a bladder; in almost all cases of apoplexy, active purgatives do good, and should be ad-

ministered, especially if the face is flushed, and the veins turgid as before mentioned. It becomes a question how they are to be administered. If the patient is quite unconscious, and has lost the power of swallowing, it will be necessary to mix up three or four drops of croton oil with some syrup, or sugar and water, and place it on the back of the tongue, by means of a feather, when it will be probably swallowed at once; or ten grains of calomel may be placed on the back of the tongue. If, however, the patient can swallow, a black dose may be given, or five grains of calomel, with a scruple of jalap powder; or half a drop of croton oil may be mixed with ten grains of the compound colocynth pill mass, and divided into two pills, both of which A stimulating and purgative enema, consisting of two table-spoonfuls may be given at once. of turpentine and a wine-glassful of castor oil to a pint of gruel, should be administered slowly. Mustard plasters should be applied to the calves of the legs, care being taken that they be not allowed to remain too long, if the patient is unconscious or paralysed. There is a popular prejudice in favour of emetics in cases of apoplectic seizure, but, as the very act of vomiting causes a determination of blood to the head, it will be very unwise to employ them without proper medical advice.

Should the extremities be cold, owing to exposure or other causes, hot blankets or bags of hot bran or hot salt may be applied to them. It is to be particularly remembered that no hot bottles or hot tins, or anything hotter than a hot blanket, is ever to be applied to a limb that is paralyzed, else it may be followed by sloughing of the most painful and dangerous kind.

SMALL-POX.—Like the other eruptive fevers, small-pox is often attended by great irritation of the nervous system, and it may be by violent delirium. At the commencement, sickness and pain in the back are the symptoms most complained of. When the eruption comes out the itching is intolerable, and the desire to scratch the pustules is so great that the patient must be watched, and in the case of children, the hands should be muffled. Of all the cooling applications to soothe the itching, the writer gives a decided preference to carron oil, which should be kept in a pot by the bedside, with a feather or large camel's hair brush stuck into it, so that the nurse may at once apply it to any part that is irritable.

The very disagreeable odour which emanates from a patient afflicted with small-pox after the eruption is fully developed, requires to be counteracted by all possible skill and ingenuity in the use of disinfectants (see Disinfectants). In some bad cases of what is called confluent small-pox, the bad odour is so overwhelming as to cause immediate sickness to any one coming in from the open air, unless disinfectants be freely made use of, along with good ventilation. Scabs and crust, which form from the bursting of the pustules, should be kept constantly moistened with carron oil, and, if practicable, poultices should be applied in order to further their removal. A poultice made with charcoal and linseed meal is probably the best, because the charcoal destroys the bad smell. Particular care will be required to prevent bed-sores, and sloughing of the back, the hips, and even of the heels. In very bad or malignant cases, the skin has been seen to come off in great masses, and to adhere to the bed-clothes. Such cases will, of course, require all the care and skill which a good nurse can bring to bear upon them, to lessen the sufferings of the poor patient. The tongue, lips, and teeth should be repeatedly cleansed from the crusts which are apt to form upon them, and the best way to do this is by the finger either alone or with the help of a muslin rag dipped in lukewarm water, or in water to which a little borax and tineture of myrrh have been added. The nostrils are apt to be plugged by crusts which, impeding the breathing, cause great discomfort. These should be repeatedly softened with oil, and, if possible, removed; owing to the presence of pustules upon the inner membrane of the throat, the patient may complain of pain in swallowing, and of general sore throat. This is best relieved by frequently steaming the throat. The eyelids swell so that on or after the fifth day of the disease the patient is often quite unable to see, and his whole countenance is so altered that he can with difficulty be recognised. The eyelids should be repeatedly oathed with lukewarm milk and water to prevent their being joined together, and if matter forms inside of them, lukewarm water, to which a little alum has been added, should be fro

quently injected inside the eyelids by means of a syringe. This is to be particularly attended to in the case of children, else loss of one or both eyes may be the result.

Delirium, which frequently occurs, is to be treated in the manner directed under the head How to manage Delirious Patients.

The action of purgative medicines must be carefully watched, owing to an occasional tendency to exhaustive diarrheea.

There is no disease in which the patient requires more attention as to cleanliness. In bad cases, unless the hair is cut very short and repeatedly cleansed, filth and vermin will accumulate to a surprising extent. The long back hair of females has generally in such cases to be entirely removed, but, if practicable, part of the front hair may be left. Red precipitate powder may be sprinkled upon the hair after it has been cleansed to kill the vermin, but rubbing it with carbolic oil will be found the best remedy.

No special application has any influence whatever in preventing pitting, but this only occurs in very bad cases.

Suppuration in the ears often occurs after small-pox. When this happens, poppy head fomentation, or a poultice composed of bruised chamomile flowers, should at once be applied to the ears.

No special medicine has any effect whatever upon the progress of small-pox. It is a disease which runs a given course, and presents a variety of symptoms, according to its severity, which it must be the duty of the medical man and attendants to relieve as far as lies in their power. Cooling drinks, such as lemonade, soda-water, or plain cold water, or any of the numerous fever drinks, may be allowed ad libitum. The diet, at first, should consist almost entirely of beef tea and milk, arrow-root, gruel, fruits, &c. Afterwards, if the eruption does not come to a head soon enough, strong broths and wine may be allowed, and still later, when the discharge from the pustules is great enough to weaken the patient, the most nourishing and liberal diet, with a plentiful supply of stimulants will be requisite. If there be great irritability and restlessness, so as to prevent sleep at night, an opiate draught will probably be ordered by the medical man, after the administration of which the patient should be kept very quiet, and undisturbed by any noises which might prevent him from falling asleep.

When great heat of skin is complained of throughout the disease, tepid sponging and anointing with olive oil will often give great relief. The patient is only to be kept comfortably warm, and not smothered with bed-clothes, with the view of bringing out the eruption, according to the prejudices of some old-fashioned and ignorant nurses.

FEVERS.—There can be no doubt that a skilful "fever nurse" is able to deal with a case of fever much more easily and successfully than one who has had no experience in the treatment of that class of diseases. She has been trained and accustomed to observe the aspect and general condition of patients in the different stages of fever. She is able to understand and to cope with their delirium. At night when the fever patient's wanderings are most pronounced, or it may be delirium most violent, she is not easily frightened, and knows from experience of similar cases how to quiet and how to manage the patient. She also understands how to administer food and stimulants; she has been taught the importance of their being given regularly; and her assistance is of great value in keeping the patient clean and providing against the occurrence of bed sores. In many other details her knowledge of the course that is run by diseases of this kind leads her to administer to the comfort and supply the wants of fever patients at particular times, in a way that can be done by no other person, and in fact so valuable is good nursing in fever, that it may safely be said to be of more value than medicine.

The general remarks which we shall make as to nursing in fever may be made to apply with more or less modification to all the continued and eruptive fevers, and to cases of fever generally, whether occurring in this country or abroad. Fever usually commences with an indefinable preliminary stage, languor and lassitude, debility, want of appetite, shivering or chilly sensations, followed by heat of the surface of the body, quickness of the pulse, great

weakness, headache, pains in the limbs, and general disturbance of most of the functions of the body. All these may accompany the fever which is merely symptomatic of some other affection, but they are also met with at the commencement of those fevers to which have been given distinctive names. During this first or preliminary stage the patient, although evidently drooping, is not yet confined to the sick-room, but plods on as best he may with great weariness, and with the sensation that something is about to happen to him; at times very lowspirited, and at other times indulging the hope that his symptoms may pass away. Nothing can be done for him except to administer as much as possible to his personal comfort. He should be kept quiet and free from all mental excitement, and he should also be prevented from exposing himself to cold, or to anything which, when the disease does become developed, might tend to aggravate its severity or prolong its duration. When there is much shivering or chilliness, the patient should be put to bed, and hot bottles applied. Headache should be relieved by applying cold to the head, the bowels should be gently acted upon, perspiration encouraged, the simplest food given, and the strictest quiet observed. The symptoms above enumerated are generally most severe at night, and a slight remission occurs at the approach of morning. When the feverish state has become fully developed, the symptoms are much increased in severity, and several new ones are added. For example, the headache may become very severe, wandering, or even violent delirium, may supervene. The weakness of the muscular system may be so marked that the strongest patient is unable to turn himself in bed, while emaciation takes place with a rapidity and to an extent that is quite remarkable. At this time also, the lungs may become affected from the fever poison circulating in the system, and the case may become seriously complicated by the occurrence of inflammation of these organs, or of bronchitis. The prostration is so great that the patient is frequently unable to pass his urine, the discharge from the bowels takes place involuntarily, there is a great tendency to bed-sores on any part of the body subjected to pressure, and in fatal cases the pulse increases in weakness and rapidity; there is constant twitching of the muscles; or the patient seems engaged in picking things from the bed-clothes; the countenance becomes livid; the breathing very rapid; and the patient passes into a state of stupor which ends in death. (The reader is referred to the article Enteric Fever, and to Fevers generally, for information as to the treatment of these diseases; and reference is also to be made to the different articles, Small-pox, Scarlatina, Measles.)

The great heat of skin, complained of at the commencement of fevers, should be relieved by tepid sponging. In all cases, but especially where the throat is complained of, a free supply of cooling drink may be allowed. Plain water, iced, or ice itself, may be given; or toast water. or barley water, or any of the so-called fever drinks. The diet should consist almost entirely of milk, beef tea, and farinaceous food. Afterwards, in cases where there is great loss of strength, and where the vital powers evidently begin to fail, the strongest beef tea, mutton, or chicken broth, must be given regularly, and stimulants, wine or brandy, are to be administered as directed by the medical man, with the utmost precision and regularity. It is even insisted upon by some of the best writers on the subject, that when stimulants and nourishment are urgently required, the patient must not be allowed to sleep on without being awaked for his nourishment at the appointed hour, because, it is said, that if this is not done, it will be found that when the patient awakes he is in such a state of prostration that it is almost impossible to rally him again. The writer, however, does not, as a general rule, subscribe to this practice, and thinks that it is very doubtful whether or not a patient should be awaked from sleep in order to administer food or stimulants; in fact, he rather regards it as an instance of the ridiculous extreme to which the followers of the highly stimulating school of physicians have gone. Besides, it is notorious among nurses of experience that after a patient has been aroused out of a refreshing sleep, it is sometimes impossible to set him off to sleep again. The time spent in sleep may be looked upon as a reparation especially for the nervous tissues of the body, and it will generally be found that, however exhausted a patient may have been beforehand, he will lose nothing by being allowed to sleep as long as possible.

When patients suffering from fever are seized with pain in the chest, or cough, mustard

poultices, or turpentine fomentations may be at once applied. These symptoms generally indicate the commencement of bronchitis, or inflammation of the lungs, which are common complications of fever, and may often be arrested when treated in this way at once.

The skin of the body over the lower part of the back, the hips, and even the shoulders, or elbows, and all prominent parts of the body, must be carefully examined in case of bed-sores forming upon them; and the reader is referred to the article "Bed-sore," for information what to do. A very bad case of fever is almost sure to be followed by bed-sores, which may be so severe as to threaten a patient's life, or even cause death by sinking; but with constant care and vigilance, as well as diligence in the use of all the means recommended, the first formation of a bed-sore would be detected, and its further progress at once arrested. Fever patients, when thoroughly prostrated by the disease, are frequently unable of themselves to pass water, and sometimes for many days they require to be relieved by the medical attendant. This is a point in connection with which great trouble to the medical man may be avoided, when intelligent and accurate information is afforded him by the nurse. When this inability to pass water occurs, the fact is that the bladder is generally full and distended, the urine keeps dribbling or overflowing, so that an ignorant nurse might think everything was right, and in answer to inquiry, on the part of the doctor, as to whether the patient had made any water, might reply, "Oh yes, quite freely," whereas all the time the bladder was full and distended with urine, and a cause not only of suffering, but of harm to the patient. It will be necessary then to distinguish between the mere dribbling or overflowing of urine, and the real power possessed by the patient of voiding it voluntarily. It may be noticed here, in passing, that bed-sores are much more likely to occur when the bed is wetted by this dribbling of urine, or when the patient passes his motions unconsciously. Wherever practicable a water bed should be ordered at the very first sign of redness or excoriation of the skin at exposed parts. No delay can be permitted, for if the red parts are neglected and the continuous pressure permitted for many hours, unavoidable sloughing of the parts is sure to ensue, with the formation of a large sore, with a tedious recovery, if not a fatal termination to the disease.

any other time that the prudence and firmness of the nurse are put to the severest test. Any indiscretion, such as allowing the patient to get up too soon, or to eat or drink anything which he has been recommended to avoid, may be speedily followed by a relapse worse than the original distemper. The feeling of strength, which a patient may sometimes boast of after long illness, is often quite deceptive; and such patients are astonished to find that, on making the experiment, they cannot even stand upon their legs. In convalescence from very serious and protracted cases, the strength returns so slowly that it is almost imperceptible. For many days the strongest may be unable to turn themselves in bed. Any attempt to assume an erect position, in some cases, is immediately followed by fainting, and it must not be forgotten that death has occurred owing merely to convalescents getting up too soon from bed in the attendant's absence, to help themselves to some article in the apartment, or to go to the night-stool.

With regard to the diet of convalescence, it may be said truly that nearly all the relapses in typhoid fever are due to errors in diet at this period. During recovery from fevers, and most acute diseases, which have caused great and rapid emaciation, the appetite is wonderfully keen. The convalescent, under these circumstances, will be always eating. He has scarcely finished a meal, when he inquires eagerly what he is to have next, and his appetite may be truly described as ravenous. Now, this morbid appetite requires to be restrained within proper limits, in order that "good digestion may wait on appetite, and health on both." No more food must be given than the patient may make use of or assimilate, and above all, we must avoid giving much at a time. As convalescence advances, a liberal diet and allowance of stimulants may be granted. The patient should not be allowed to go long at a time without food, and every opportunity should be afforded him to make up for that excessive loss to which the tissues of his body have been subjected.

There is perhaps no time at which people are more liable to catch cold than during convalescence from disease. This is particularly to be borne in mind, in the case of those diseases which are followed by scaling or desquamation of the skin, such as scarlatina, erysipelas, measles, &c. A chill to the surface, after an attack of scarlet fever, may give rise to consequences worse than the original disease. The way in which the mischief arises is this-The skin is in a transition state as it were, and is deprived of its natural covering, the so-called scurf skin, so that all its numerous little glands and pores are exposed to the influence of cold. A chill occurs, the secretions from the skin (which are very large in quantity) are stopped, and thrown in upon other organs, such as the lungs or kidneys, which endeavour, as it were, to take on for a time the function of the skin; but this sometimes proves too much for them, and the overtaxed organs become inflamed. In this way, not only is there incurred great and immediate danger to life, but, in the case of the kidney especially, chronic and irreparable disease may be left which the patient can never get rid of, and which he will probably carry to his grave after a more or less wretched and miserable life. It follows from this that the greatest care should be taken to prevent chills; that the patient should be contented to abide strictly by the direction of his medical adviser in these respects, and should not leave his bed till permitted to do so; that he should be clothed in flannel from head to foot; and that in cold, damp, windy weather, he should not venture out of doors.

All over-exertion, both of body and mind, is to be strictly avoided. Exercise is to be kept within the limits of fatigue, whether in-doors or out of doors. The convalescent must not be allowed to sit up longer than he is able to do without feeling tired, and it must never be forgotten that, at this time, the nervous system is very easily upset, and that even trifles make a much deeper impression upon the mind than at other times, when the patient is in his usual health. The cares of life, and the anxieties of business, must not be too hastily resumed, since it often happens that the feeling of strength, which is thought to be sufficient for these things, proves to have been quite deceptive, and the consequence is that a very tardy and unsatisfactory recovery is made, and a much longer time elapses before the patient is really able for work, than would have been the case if he had not commenced before he was quite strongmentally and bodily. Above all, the mind is to be kept from preying upon all the evils connected with illness, and must not be allowed to dwell upon melancholy or unpleasant subjects. The patient must not be permitted to mourn over the time or opportunities which have been lost during the period in which he has been laid aside from business. Books of a cheerful description should be read to him, and everything done to call his attention as much as possible away from himself to external objects. These precautions are to be particularly observed when the head has been affected, or when the brain itself has been the organ implicated by disease; and, in fact, it may be laid down as an axiom, that when any organ has been attacked, care must be taken to guard it against a recurrence; for instance, if the disease has been inflammation of the eyes, common sense would teach us to refrain from using them for any work that involved close attention or exposure to a strong light, till they had quite recovered their former strength.

MANAGEMENT OF SURGICAL CASES.—We come now to consider the management required in cases of injury, or of disease requiring surgical interference, of which one may almost be made to serve as a type for the whole, so far as regards the general directions necessary for the attendants of the sick-room. Let us take, for example, compound fracture of the thigh, an injury which entirely disables a man, and which, during the treatment necessary for recovery, leaves him wholly dependent upon those around him, without whose assistance he would be quite unable to perform the ordinary functions of life, as well as unfit to provide for his ultimate cure. A compound fracture is one in which the bone is not only broken, but has protruded through the skin, so as to leave a wound of the surface. Part of the bone may be found sticking out of the wound immediately after the accident, and may have to be removed by the surgeon, or it may have receded. It may be broken in one place, or it may be

shattered into many fragments. There may be hamorrhage more or less from the wound, owing to the fractured or splintered ends of the bones having wounded the blood-vessels. If no large blood-vessel, however, is wounded, and the bleeding only amounts to oozing, this is not a complication of any importance, and all that is necessary will be to apply cold by means of sponges soaked in cold water, or wet linen rags. When the hæmorrhage is very profuse, and evidently coming from a large vessel, pressure must be applied upon the main blood-vessel of the limb, either by means of a tourniquet, or by the best means that can be provided for the purpose. It is here necessary to give one precaution as to the application of this tourniquet, or of the temporary substitute for it, and that is, it should not be applied unless it is absolutely required, as in the case mentioned above. The objection to its use is, that it presses tightly upon the veins of the limb and prevents the return of the blood, causing what is called venous bleeding, that is, bleeding from the cut end of the veins. Bleeding of this kind from veins may be generally distinguished by the dark colour of the blood, and it may almost always be stopped by the removal of pressure above the bleeding part, or the application of cold. Every care must be taken in moving the limb to prevent the ragged ends of the bone from doing injury, and for information on this point and others, the reader is referred to articles Ambulance, Emergencies, Fractures, Hæmorrhage, Wounds. It will be obvious that since a fractured limb requires to be placed and to be maintained very accurately in position, a bed with a firm and unyielding bottom will be necessary, it may therefore be requisite to put boards or some unvielding material under the mattress to prevent it sinking down at any part. This should be done before the patient is put to bed at all, since it saves a great deal of after trouble, and it is important in the case of a fractured thigh, in which it may very likely be requisite by means of a splint to extend the patient's limb in a perfectly straight line. It is no part of the intention of this article to describe the surgical treatment of fractures of the thigh, but merely to explain, if possible, the rationale of it, and to indicate in a general way how patients require to be managed who are suffering from fracture of a limb. It is usual to put up a fractured thigh either in a straight line, with a long splint extending from the arm-pit beyond the foot, or to lay the limb upon a splint such as the one called MacIntyre's splint, which is a doubleinclined plane. In either case perfect immovability of the limb is desired, and may be obtained by adjusting the bandages and securing the limb and the splint to the bed. But in the case of a compound fracture, open spaces or "windows" must be left, through which the wounds may be dressed from day to day. As a matter of course, the patient must remain constantly on his back, and the mere mention of this fact will suggest how much care and trouble will be required at the hands of the nurse. When the night shirt or bed-clothes are changed, the body must be raised, as it were, in one piece, if raised at all. The patient will require to use the bed-pan, and especially in the case of the aged, the feeble and delicate, or of those suffering from a complication of injuries, the greatest vigilance will be requisite to prevent the occurrence of bed-sores, and to relieve the pains and aches consequent on lying in one position. In addition to this, the nurse must be careful to report to the doctor any complaint of the patient as to pressure of the bandages upon any particular part, and in the case of delirious and insensible patients, must note for herself whether any of the bandages or appliances are chafing the skin, since dangerous sloughing, followed by the most troublesome sores, have occurred from this source. After recovery from all fractures, but especially from fractures of the thigh, the use of the limb must be resumed very gradually indeed, crutches being used at first to bear the weight of the body. It seems almost superfluous, and yet the patient must be cautioned against breaking the limb for a second time; since numerous cases have occurred in which the patient, either owing to a slippery floor, to his being unaccustomed to the use of crutches, or to his not being sufficiently supported by his attendants, has fallen upon making his first essay to walk, has broken the limb a second time, and has had the whole course of treatment to go through again. It should be considered that for some time the broken leg is absolutely useless, and that even the sound one is comparatively so owing to long confinement to bed. Patients find the constrained position very irksome, and it will be well that the attendant should pay particular attention to the direction of the

medical man as to the limb, and should carry them out with firmness, otherwise a bent, shortended, or otherwise deformed limb may be the result of a nurse's culpable good nature in yielding to the desire of a patient to loosen his bandage or to change his position for a time.

MANAGEMENT OF DISEASES PECULIAR TO WOMEN .- With regard to these, it may simply be said, that in special cases, where there is great pain and suffering, in many incurable cases, and in cases requiring operation, a very great advantage will be gained to both the doctor and patient by securing an attendant who has had experience in this department, and who, where occasion requires, will consequently often be able to alleviate suffering, and to save trouble. In incurable cases, much is to be done in the way of palliation; and although a skilful general nurse, by careful attention to the directions of the medical man, may and can do all that is necessary, yet experience in a nurse in this department is very much valued by those who suffer from such diseases, and it will, therefore, be the duty of those concerned to procure such a nurse for them when it is practicable. This is perhaps still more necessary in cases where operative interference has been required, and every medical man of experience knows the luxury of having the assistance of a skilled nurse in this department, both during, and in the after treatment of an operation. Nervous and hysterical patients also can sometimes be thoroughly controlled and kept quiet by such a nurse; while a weak and foolish person, or one who has had no experience in such symptoms, by injudicious management frequently prolongs and aggravates a case.

GENERAL MANAGEMENT IN DISEASES OF THE EYES.—Whether we consider the extreme delicacy of the organs in question, or their near relation to and intimate connexion with the brain itself, it will be easily understood how much caution and care are requisite in the treatment of them in disease. Any one also who is conversant with eye disease knows well how much, in the case of one eye being affected, the other sympathises with it; so much, indeed, is that the case, that removal of the diseased eye is often resorted to, mainly from the desire to save the other and sound one. The fibres of the optic nerves within the cranium interlace, at what is called the optic commissure, in such a manner as readily to account for their sympathy, seeing that morbid impressions or stimuli can be so easily conveyed along the nervous filaments from the morbid to the sound eye, in the same fashion as the electric current is transmitted along a series of iron wires.

Within the last few years great advances have been made in the treatment of diseases of the eye, owing to the introduction, into medical practice, of the ophthalmoscope, by means of which the morbid conditions of the internal structures of the eye can be discerned, and the results of treatment observed.—See Ophthalmoscope.

Another point in which we have unquestionably progressed is in the simplicity of our general treatment of eye disease, and in the almost total abandonment of the administration of mercury, and the reckless and indiscriminate blood-letting that used formerly to be so much in vogue. In the forms of inflammation of the eyes met with in scrofulous children, and in those of a weak constitution, all lowering and depleting measures are now generally discarded in favour of a highly tonic and stimulating plan of treatment. Even the youngest infants, when afflicted by purulent inflammation of the eye, are often cured by the physician ordering them better support, either in the form of cow's milk, or by substituting the milk of a strong and healthy wet nurse for that of the mother, which may be poor in quality; and by prescribing (of course in addition to proper local treatment) a tea-spoonful of port wine two or three times a day. In the case of delicate and neglected children, the greatest benefit often ensues from directing the attention of the parents, or of those interested in them, to the importance of warm clothing, regular exercise in the fresh air (or change of air in some instances), good nourishing diet, with a plentiful supply of milk and eggs, cod liver oil, and tonics, especially quinine. Such cases are often tedious, but seldom fail to yield, in a marked manner, to constitutional treatment of this kind when efficiently and persistently followed out.

Some discussion has taken place as to what is the colour most agreeable to or most adapted for weak eyes, or those which are unable to bear the light. Slate colour and green are the favourites, and at the present time a preference seems to be given to the former in the colouring of the walls of hospitals for the reception and treatment of ophthalmic disease. Shades also are made now of this colour. They may be easily manufactured from cardboard and calico; the latter material may be obtained of a slate colour, at almost any place.

It is a point to be recollected in the treatment and management of diseases of the eye, especially of those accompanied with a discharge of matter, that this matter is sometimes capable of communicating the disease to the sound eye of a healthy person, hence the utmost caution is to be observed in the use of towels, sponges, &c., in the sick-room. Instead of using a sponge at all, it is perhaps better to employ cotton wool or fine tow, or a syringe, for the purpose of bathing the eye, and of ridding it of the accumulation of purulent discharge which takes place. The advantage of using wool or tow is, that each piece can be thrown away or burnt after use, whereas a sponge is valuable, and is kept carefully by the nurse, and may be used in other cases. A syringe is peculiarly valuable, and indeed quite indispensable for those cases, occurring so frequently in children, where purulent matter collects under, and is retained within the eyelids. It is sure to do mischief, and to destroy the textures of the eye, unless it be carefully and regularly removed by syringing the eye, either with warm water or milk and water, or with a weak solution of alum and water, or some other astringent solution, which may be prescribed by the medical man. It is well worth knowing that an eye or eyes may often be saved from untimely destruction, owing to the care, skill, and regularity shown by the nurse in attending to this apparently simple procedure. After each time of syringing, a piece of cotton wool should be placed over the closed eyelids, and retained in its place by being bound round the head, either with a very light silk handkerchief, or a turn of a bandage.

When the eyelids, as often happens, not only in eye disease but in fevers, and other acute diseases, are glued together at their margins, so that the patient is unable to open or separate them, they should be frequently bathed with tepid water, or milk and water, till they can be easily separated, and then the edges should be smeared gently with a little simple ointment to prevent them from adhering again. When a case of this kind has been neglected for some time, and when a sort of milky crust has formed owing to the inflammatory secretion having been poured out, and become thickened and hardened upon the eyelids and cheeks, frequent poulticing and fomentations should be resorted to till the scabs or crusts are quite softened, and can be removed without hurting the patient.

HOW TO PUT DROPS INTO THE EYE.—In the course of the treatment of many eye diseases, it is necessary to drop certain solutions into the eye with the view of producing different effects. The object may be merely to allay pain, or to contract or dilate the pupil of the eye, or, on the other hand, to check discharge from the surface of the lining membrane, or to promote the healing of ulcers. In any case the method of procedure is the same, and is perfectly simple. A quill with the end cut off is to be dipped in the solution till it contains a few drops. The operator then gently separates the eyelids with the two fingers of his left hand, while with his right hand he applies the end of the quill to the inner angle of the eye in such a manner that the fluid rapidly runs along and diffuses itself over the surface of the eye. Various kinds of eye douches are in use for the application of solutions of different kinds to the eye. They are so numerous that none requires any special description, and they may be had at the different instrument makers.

Pain in the eye, either from disease, from the presence of foreign bodies in it, or from application of strong medicated solutions, or caustics, may be very much relieved by poppy-head fomentations, or by fomenting with warm water, to which a little laudanum has been added.

It is well known that blisters applied to the temples, behind the ears, or even the nape of the neck, and between the shoulders, have an effect, not only in relieving the pain, but in promoting the cure of certain diseases of the eye. One of the readiest and, at the same time, most 703

effectual methods of applying a blister with this view, is to soak a few threads in blistering fluid and lay them behind the ear. They can be frequently renewed or not, according to the effect it is desired to produce.

After certain operations upon the eye for extraction of cataract, &c., the greatest care and caution is sometimes required on the part of a nurse to prevent the patient from making any sudden strain or exertion, the consequences of which might easily be to expel the whole contents of the eye through the hole made during the operation, by which accident, of course, sight is completely lost. After such operations the eye is carefully protected, as far as possible, by the medical man; still, with some patients, and more especially with those who have had chloroform, and who may not entirely recover from the effects of it for some time, it is absolutely necessary

to watch them most assiduously, in order to prevent such a catastrophe.

It should be known that the feeling of a foreign body being present in the eye is not always a sure indication that such is actually the case, but is often one of the precursory symptoms of

Patients frequently complain that they see floating before them black specks, like flies, when they look at any object, and they are naturally very much alarmed and apprehensive of incipient disease of the eye; it is well, therefore, to remember that these may be, and are frequently, the consequence of indigestion, or of some other functional disturbance of the system. They are not to be looked upon as in any degree serious if they float or move about when the eye is fixed steadily upon any object; a persistent black spot, however, which steadily remains and does not leave the spot upon which the eye is fixed, is not unfrequently a symptom of grave organic disease.

## MAINTENANCE OF HEALTH

AND THE

# MANAGEMENT OF DISEASE IN WARM CLIMATES.

By JAMES CANTLIE, M.A., M.B., F.R.C.S.;

LECTURER, APPLIED ANATOMY, CHARING CROSS HOSPITAL; SURGEON, WEST-END HOSPITAL FOR NERVOUS DISKASES; FORMERLY SURGEON, CHARING CROSS HOSPITAL; DEAN OF THE COLLEGE OF MEDICINE, HONG KONG, ETC., ETC.

When a person bred and born in a temperate climate, such as we enjoy in the British Isles, is about to proceed to the tropics for either business or pleasure, for residence or travel, a host of questions arise to which at times it is extremely difficult to get satisfactory answers. The principal points one wishes information upon are:—

- 1. The nature of the climate and its probable effect on the health.
- 2. What clothes are required for the voyage and for the stay.
- 3. How goods ought to be packed.
- 4. Whether it is advisable to take children to the selected place of residence.
- 5. Whether medicines or simple surgical appliances are necessary.
- 6. What books written in simple language can be obtained to serve as a guide to health, and the treatment of simple ailments.

These and a host of other more or less relevant questions arise, and as some of them are all-important for the comfort and well-being of the tropical visitor and resident, it is the purpose of this article to reply to them. Before, however, dealing with these in detail it is necessary to give a short résumé of the climates and countries included in the word "tropical."

Tropical Climates.—The part of the world named "tropical" embraces a wide area and includes countries possessing a variety of climates. In it are comprehended such countries as Java and Japan, which, although lying some 2,500 miles north and south from each other, are both spoken of as "tropical." In Java the days and nights vary but little in temperature, there is nothing to mark the seasons as regards foliage or flower, seed-time or harvest, but day follows day with almost exact meteorological similitude. In Japan all this is changed. The seasons are mapped out as they are in Britain, the heat of the day is followed by the cold of the night, fierce typhoons prevail at times in place of the calm of equatorial regions; the winter is severe and snow falls regularly. From this single statement it is evident that the region "tropical" includes countries differing widely in their meteorological characteristics, necessitating different measures to be taken to meet the requirements of existence in climates so totally unlike.

As it is impossible in a short article to deal with every one of the many districts within the tropics frequented by Europeans, and more especially by British people, I propose to deal with the question by dividing the region tropical into three zones—the equatorial, the tropical, and the sub-tropical.

1. The Equatorial Zone. —Immediately adjacent to the equator, the meteorological conditions are quite special and characteristic. The equatorial zone includes the region within 12°

north and south of the equator; it is marked by a wonderful uniformity of temperature by night and day, as well as throughout the year. The greatest heat seldom exceeds 90° or 95°, and rarely falls below 74°, the maximum may be taken at 95°, and the minimum at 68°; the usual range of temperature is only 11°. In this region the rainfall is excessive, and vegetation is rife. The whole belt is practically a forest-girdle round the earth; and across these hot, damp forests no great storms of any kind sweep to stir and vivify the air, for it is a region of almost perpetual calm. There is a popular belief that the nearer the equator, the greater the heat. This is only true in the average for the year, but it is not the case that within the zone the highest temperature obtains. Far other is the case, for it is seen from the above statement, that the maximum temperature is much below that experienced in, say, New York or even Moscow. The heat is equable, and one is not subjected to those sudden variations in temperature which are so trying and so fatal in their effects. Of all tropical regions, it is the safest to live in, so far as the direct effects of intense heat are concerned.

- 2. The Tropical Zone.—The northern and southern limits of this zone are mapped out by the tropics of Cancer and Capricorn, 22° respectively north and south of the equator; these limits include the equatorial belt, so that the specific regions here discussed are those lying between 12° and 22° north, and 12° and 22° south of the equator. Marked contrasts in climate characterise this zone; the summer heat attains a high maximum and the cold in winter is decided, more especially towards the out-lying limits. The annual rainfall in many places exceeds 100 inches, but in it we find the rainless regions of Arabia and Africa. Storms of great force, constituting the cyclones of the Indian Ocean and the typhoons of the China Seas, disturb the air, and the monsoons and trade winds heat or cool the air according to their direction. In the tropical zone, therefore, it is apparent that the European has to be prepared to resist both cold and heat, and it is the cold, slight though it seems to be, that renders him most susceptible to illness.
- 3. The Sub-Tropical Zone. Northwards of the tropic of Cancer the hottest places on earth are met with. In the Valley of the Indus, more especially around Multan, the heat is intense, and yet Multan is situated in 30° north latitude.

The Persian Gulf lies wholly to the north of the tropics, but not even the Red Sea can compete with it as regards heat. The heat of the tropics is due more to the direct solar influence than to telluric conditions, for the hottest countries known are beyond the tropics. Maps, and the study of longitude and latitude, give but an imperfect notion of a climate, for the isothermic lines are determined by winds, ocean currents, the poximity of land, the contour of the land itself, and not wholly by the distance any given place lies north or south of the equator. Some of the most unhealthy places of the "tropics" are strictly extra-tropical; so that it is impossible to define the term "tropical," from other than a solar point of view, with any exactitude, as regards meteorological conditions. This being so, we return to the terms "tropical" and "tropics" as an undefined region which has come to be associated with prolonged and intense heat; and in this sense the terms are to be employed in this article.

As a general rule, the regions to the south of the equator are relatively much cooler than corresponding latitudes to the north. This is no doubt determined by the winds, and by the expanse of open sea. To the north a greater extent of land affects the climate. The great area of Asia bestows a continental climate on almost the whole of the countries within its boundaries, and has direct influence upon Eastern and Central Europe likewise. Northern Africa and the northern part of North America are also continental in their climate; and the north of South America and the great continental Island of Australia come under a similar category.

In these regions the temperature of the night and day are widely divergent, and the winter and summer seasons are marked by intense cold and fervent heat.

Outfit. - Traditions handed down from the days when steamboats and railways were unknown, when trans-continental crossings and overland routes were unheard of, when a voyage to most tropical countries took as many months as now it takes weeks, still cling to us, and scare the traveller into all sorts of unnecessary expense, as regards outfit. There are, of course,

certain places where a bulky "kit" is needful, but these are few indeed. The stay-at-home for the most part imagines every tropical place to be uncivilised, and unprovided with such domestic appliances as are to hand in Britain. One still hears of people providing themselves with endless suits of clothes "for the warm weather"; with numerous pairs of boots; with extensive wardrobes of underclothing and haberdashery, when they are starting to take up their residence in a warm climate. This is at once an unnecessary proceeding and a great expense. Young men or women starting to earn their livelihood in the tropics are frequently landed in debt before leaving home, owing to having provided themselves with clothing and other articles which are not only unnecessary, but, more often than not, wholly unsuitable to the climate they are destined to endure. The grand rule is: Buy as little as possible in Britain before starting, and get clothes, &c., on arrival at your destination. The people, already located in the place of selection, have their clothing, their boots, their hats, and other apparel supplied to them by local tradesmen. The clothing supplied locally is that which is requisite for the particular climate, and is more likely to be suitable than raiment furnished by London tradesmen, who perhaps have never even heard of the name of the country for which they are intended. Few persons who have bought their tropical clothing in London have not repented it. Native tailors are cheaper than, and for the most part quite as good as, those in Britain; and as they have no goods to supply, except those required for the particular climate in which they dwell, one gets exactly what is wanted.

One great mistake constantly made is, that winter clothing is left behind. A greatcoat is given away, and a fur cloak is left with friends. In the tropics, it is thought, these cannot be wanted, and if this idea is acted upon, repentance comes with the cold weather, by having to obtain a complete refit of warm clothing. Anywhere north and south of the equatorial belt, "winter" clothing is required. The ordinary tweed suit and overcoat are the daily dress for well-nigh four months in the year; and fur coats are not unwelcome during the north-east monsoons. As with outside apparel, so with underclothing; it is unwise to leave any behind in the belief that they will not be wanted. Even if the destination is somewhere in the equatorial belt, and the altitude some 2,000 feet or more, a blanket is required at night, and a tweed suit after sun-down is a comfort; again, if one has to travel northwards, for change or business, winter clothing is wanted.

On the Voyage.—Travellers proceeding eastward through the Suez Canal do not change their clothing until after Malta is passed; and, in winter, it may be that the shores of Egypt are in sight before a change is requisite. During the first part of the voyage, therefore, tweed suits and ordinary underclothing are necessary. The safest plan is to regulate one's clothing by that of the officers of the ship; they are old hands at the journey, and may be trusted as useful indicators of the time to change.

When the hot weather is really upon one, a thin flannel suit is the safest and best attire. A pith hat or helmet, or double "Terai" hat is required for head protection. A shirt of thin flannel or Elgin twill is the best, and an undervest of Indian gauze or fine silk and wool. Socks ought to be of thin wool, and not of cotton or silk. If a waistcoat is left off, a cumberbund should take its place. At night thin flannel pyjamas and a cholera belt of flannel are all that are required. The shoes or boots are best made of canvas, with leather soles. India-rubber soles should never be worn in hot climates. A social question as to dressing for dinner on board always crops up. It may at once be said that some change in attire is expected of everyone before sitting down to dinner. For men, white duck or flannel trousers, and a thin black cloth or alpaca jacket with a cumberbund (black), and no waistcoat, is a common garb. A white shirt, collar, and a black necktie complete the change necessary.

On arrival at the place of destination, the intending resident should immediately take advice of the residents as to what to get in the way of clothing. It depends upon the season of the year one arrives, whether it be in the cold or wet weather, the dry spring, or the trying autumn, what the texture of the requisite clothing is to be.

During the cold season, summer clothing as used in England is to be worn. Light tweed

suits are then in vogue, and a greatcoat, more especially for evening wear, is a necessity. Corresponding underclothing is worn, and, in fact, summer dress, as used for instance in the

south of England, is the rule to go by.

In hot weather, flannel is the material most to be recommended, and, moreover, it is the safest. Many tropical residents, more especially women, object to flannel next the skin, and use linen or cotton instead. Linen should be entirely discarded in the tropics. It is very cold to the touch; it absorbs moisture but to a small extent; and, when wet, clings to the body uncomfortably.

Women's Dress.-When the advice of inexperienced lady friends is asked for, the lady traveller is not infrequently scared at the amount of money she is expected to spend on clothing previous to starting. The governess, nursery-maid, or hospital nurse who has accepted a situation in the tropics is appalled at the list of things she is expected to provide before starting. She views with dismay the fact that, if she follows the advice, her contemplated first year's earnings are perhaps more than swallowed up before she sets foot on board the vessel that is to convey her to her destination. The usual amount of even a modest wardrobe is seldom put down as under £40, and not infrequently she would break her engagement if she could; but, when she cannot, she starts considerably in debt. Let me advise the lady traveller to divide her estimated expenditure of £40 by ten, and what £4 or £5 cannot purchase to do without. Even should she be going to an ever so-out-of-the-way place, she will be able to procure raiment better adapted to her wants at the port of call, before she goes up country, than she can "at home." With ladies in a more luxurious state of life, of course, the initial expenditure is of no moment, but even with them, except for "Parisian-fashioned" attire, more suitable clothing will be obtained locally than in Britain.

As a general rule, the recommendations as to the texture of clothing laid down for men apply

to women.

Underclothing.—By far the best material for "combinations" is merino.

Corsets should be of the best and strongest make. On the "providers" list net corsets are vaunted, but they are to be condemned for two reasons. In the first place, they do not last long; the perspiration soon tells upon them, and they wear badly; in the next place, they do not protect the body sufficiently from chills. The corset plays a most important part in protecting the body from the inevitable chills of the evening and nightfall; to this article of dress more than to any other is to be ascribed the immunity women enjoy from abdominal ailments, compared with men. Corsets serve instead of the cumberbund and flannel belt of men. Moreover, they are not apt to be laid aside as is the cumberbund, and, therefore, act as a permanent good. It is a well-known fact that women do not suffer in the tropics from abdominal troubles in anything like the ratio that men do, and it is admitted that corsetwearing is a great conducive to that desirable end.

Knickerbockers, since that is the fashionable underclothing for the lower limbs nowadays,

should be of alpaca.

Stockings of fine merino are better than when made of open thread or silk. The reasons for this are, in the first place, merino is more suitably adapted to absorb perspiration and prevent the feet getting hot, and its closer texture assists in preventing mosquito bites. Women are apt to suffer from the bites of mosquitoes in a most irritating manner; hence the advantage of wearing knickerbockers, which fasten at the knee, instead of the loose petticoat; and the advisability of having stockings of close texture. So annoying are these insects at some seasons, that women at times wear two pairs of stockings when sitting, say, at dinner, or in the verandah, especially in the evenings.

The Skirt may be of any material the wearer fancies, but the Blouse should be of cotton, or, better still, cotton-silk material. The covering for the head is seldom of consequence for women, unless they are likely to be exposed to the sun for a length of time, as during journeys on horseback. Then a helmet or solar topee, covered with silk, is requisite. Women's hair, no doubt, serves as an adequate protection from the sun, and when it is platted and made

up at the back of the head, it affords greater protection than when coiled on the top of the head.

Waterproofs of mackintosh or india-rubber are too hot for wear, especially if walking exercise is contemplated. Light waterproof cloth is the best material to ward off rain, and the garment should be made quite loose, so that air may circulate between the dress and the waterproof covering.

The Night Dress ought to be of flannelette. This material is cooler than silk and wool, and allows of perspiration being carried off better than a garment of cotton.

Children's Clothing in tropical countries errs in almost every instance by being insufficient. The cotton dress one generally sees little children in, with their lower limbs bare from above the knee to the short cotton socks coming just above the boot, may be very pretty, but in proportion to its prettiness so is it dangerous. In the first place, mosquitoes and sand-flies have their full meals off the bare and tender limbs, and the bites they leave are apt to become irritable sores in consequence of scratching and the action of the sun. Let the material be as light as possible, but the child's limbs ought to be covered completely, and cotton materials ought to be avoided. Children cannot be kept quiet; they are perpetually active, be they in the temperate or tropical climes. A child's cotton clothing gets soaked with the constant state of perspiration in which they are, and wet cotton clothes, when the sun approaches the western horizon, induce chills, and lay the child up with fever, diarrhea, or dysentery, with pernicious frequency. Light flannel or flannelette clothing, both for under and for outer garments, is the only safe dress for children.

Cotton.—The native in the tropics, however, dresses in cotton, and it would seem at the first glance that it must surely be best to dress as the natives do. This depends on circumstances. The whole question resolves itself into whether one is so situated that perspiration is imperative, or whether it can be reduced to a minimum. If a man engaged in business has to get about in the sun, to climb many stairs, or make journeys afoot, then he must perspire freely, and flannel in that case is the material to be worn. If, on the other hand, one's lines in life are such that exertion is uncalled for, then cotton may be worn with comparative comfort and safety. It should be carefully noted, however, that when a native of the tropics is about to undertake any muscular exertion he casts off, or lessens, his cotton clothing, and his body may be seen dripping with perspiration. When the task is finished, he remains quiet a few minutes, wipes his body with a cloth, and, when his skin is dry, resumes the cotton clothing. In this way cotton clothing may be worn by Europeans, but in a damp, hot climate, where one's skin is constantly perspiring, independently, it may be, of any exertion, then flannel, and not cotton, is the only safe clothing to have next the skin. Wet cotton clothing is uncomfortable, is apt to induce chill, and is, in every way, an undesirable material to have next the skin. Woollen material retains within its meshes a moist atmosphere, which is an excellent non-conductor, preventing sudden transitions of heat and cold.

Flannel.—The one material, we repeat, which it is safe and wise for Europeans to wear next the skin in tropical countries is flannel. There is no gainsaying this maxim, although many people transgress in this, as they do in many other sanitary laws. Those who wish to avoid it plead a series of objections, all of which, however, are assignable to immediate personal comfort. Flannel next the skin is said to irritate, to produce prickly heat, to harbour parasites, and to induce a profuse perspiration, which is weakening. Women are chief offenders in this respect, and it is at times impossible to overcome their prejudice. Not only so, but they dress their children similarly, in the same belief, and cause endless ailments which might be avoided.

In hot climates, when the air is laden with moisture, the least exertion causes perspiration. When this season, more particularly, is upon one, it is essential to wear clothing which will serve as a bad conductor of heat and a good absorber of moisture. For this purpose flannel garments are an ideal clothing. During exercise it is necessary to provide for the absorption of the moisture on the surface of the body. Flannel, from its material and texture, possesses so

high a hygroscopic power that it rapidly absorbs the moisture, and thereby cools the surface of the skin, and reduces the body heat. When the exercise is finished, the evaporation still goes on: if cotton or linen is worn, the perspiration passes through them, and evaporates from their external surfaces without condensation, and the loss of heat is rapid; with flannel, however, the perspiration is condensed in the wool, and slowly gives out again the latent heat. A woollen fabric, therefore, feels cool during sweating, and prevents the chill which is sure to be induced by too rapid evaporation from soaked linen or cotton clothing. In fact, flannel clothing preserves a covering of air around the body which absorbs moisture and gives out heat gradually. It is the air in the flannel, not the material itself, which serves as the safeguard.

Silk.—Rich Orientals dress in silk. All their garments are of this fabric, but it has nothing to recommend it for the European of active habits. When absence of free perspiration is guaranteed, as when sitting or lying about under a punkah, silk may do no harm; but the moment any exercise is taken, silk behaves like linen, it becomes soaked, retains little air, and

acting as an evaporating surface, reduces the body temperature too rapidly.

Cellular Clothing.—What is termed "cellular" clothing has much to recommend it. The material of which it is made varies; it may be of silk, wool, or cotton, or a mixture of these; the chief advantages claimed for it are its porosity and retention of air which gives it, in common with woollen tissues, the property of being a non-conductor of heat. Indian gauzes are mostly a mixture of silk and wool, and especially suit those who cannot tolerate wholly woollen fabrics next the skin.

Night Clothing ought invariably to be of flannel or flannelette. Linen or cotton sheets are not to be recommended, but Europeans have difficulty in bringing themselves to consider it wholesome or cleanly to lie in flannel or flannelette sheeting.

Bedding.—When the weather is very hot a fine straw matting is, more especially in the Malay Peninsula, spread over the mattress. It is cooler than sheets, and does not get soaked

by perspiration.

Even in the hottest weather, however, a thin flannel sheet should be placed over the abdomen or, at anyrate, kept on the bed so that it may be pulled over one during the cooler early morning hours.

Exercise.—In the tropics the first effect of the heat is to increase and stimulate the energies, and for the first twelve months or so, the newcomer rejoices in abundant exercise. After the initial effects of the heat subside, taking exercise is less of a pleasure and more of a task. One cannot live in a vapour bath and expect to preserve the vitality engendered by a cold climate. The nervous stimulus lessens, and the body loses its vitality, thereby inducing a muscular indolence which increases with advancing years of residence in hot climates. Anemia is a constant factor in tropical life, and no one escapes it, however free he may remain from actual disease. The red-blood corpuscles become fewer, and, as these minute bodies are the means by which oxygen is picked up from the air in the lungs during respiration and carried to the tissues, it comes about that an insufficient amount of oxygen is supplied for the purposes of the body, be they muscular or digestive. Unwillingness to take exercise, therefore, is an organic condition and not merely to be ascribed to what are called "luxurious" habits. How far this is to be humoured or fought against is a nice question. To yield to it is, however, most injurious; whilst, on the other hand, over-fatigue is yet more to be avoided. Want of exercise will soon induce a condition of the digestive system which will end in chronic dyspepsia and liver derangements. The kidneys may cease to accommodate themselves to the necessities of the economy, and renal calculus or Bright's disease may supervene. Over-fatigue, also, has its train of evils, the chief amongst them being the extreme liability to inroads of malaria. Walking exercise usually presents but little attraction; the monotony of a mere constitutional walk is not calculated to induce one to take outdoor exercise.

Horse-riding is much more attractive, and possibly more beneficial, than walking exercise. The infinite succussions experienced during the act of riding on horse-back are of great value in promoting the functional activity of the liver, which, in all warm climates, is apt to become

torpid. The popular maxim that there is nothing better for the inside of a man than the outside of a horse is specially applicable in the tropics.

Early morning, before the sun becomes fiercely hot, is the best time for a ride; but, if that hour is not favourable, the cool of the evening ought to be selected. Polo is a species of game on horse-back which has everything to recommend it.

Lawn-Tennis, as an outdoor game, perhaps, plays a larger part in maintaining health in tropical countries than any other. There is much in its favour. It is played usually near home or at any rate near a house or shelter where a change of clothing may be had immediately the game is finished. It can be stopped at any period of the game, hence there is less chance of over-fatigue. Women can join in the game on fairly equal terms with men, and a rational dress can be chosen to suit the occasion.

Tennis matches for those who are not robust should on no account be indulged in.

Cricket and Football are excellent games during the cool weather, and even in the equatorial regions they may be played with benefit. Cricket is much the more dangerous, owing to the length of time one may be kept in the field exposed to great heat.

Cycling.—In tropical countries with good roads—a by no means common circumstance—eycling in moderation is a most healthy form of exercise. Long rides, however, are more deadly in their consequences there than at home. Not only is there the direct effect of heart-strain to be considered, but the liability to malarial incursions induced by over-fatigue are ever before one. Racquets, Fives, Rowing, &c. are calculated to preserve health if indulged in with judgment and due precautions.

Baths.—All Europeans dwelling in the tropics soon appreciate the pleasure of frequent bathing. It is a daily necessity, imperative for cleanliness, and especially calculated to prevent chills when taken after violent exercise. As a restorative agent in over-fatigue, or after a long day's outing, such as a shooting expedition, it is at once a pleasure and a therapeutic agent.

It was through contact with tropical countries that the bath came into frequent use in Britain. Daily baths are a recent introduction; in our grandfathers' time the daily bath was unheard of. It was the returned tropical residents that brought it into fashion, nor has it yet spread to the Continent of Europe to any great extent.

The temperature of the bath is an all-important question. Without entering into physiological details it may be at once stated that it is the hot-bath that is in vogue in the tropics. The cold bath is indulged in by young men, in robust health, for some time after they take up residence in the tropics; but it has to be given up, and it is doubtful if it is conducive to good health at any time. The water ought to be about the temperature of the body, that is, between 90° and 100°, if full benefit and enjoyment are to be derived from it. Cold and tepid water are apt to induce chills and "internal" congestions, which are dangerous. One should not stay in the bath beyond five minutes at the outside, otherwise exhaustion is produced, and a weakening instead of a stimulating effect is the result.

Food.—In the tropics, British-bred folk miss the beef and mutton of their home diet. Beef, even when it can be obtained, has neither the flavour, relish, nor nourishment of the home product; and although the mutton may be better, it is far below European value. In many, in fact, in all parts outside big towns where Europeans congregate, "butchers'" meat is a rarity, and fowls form the staple flesh diet obtainable. The sameness of this regime tends to cause the appetite to flag. Game comes, in some districts, as a welcome change, and serves as a relish and appetiser. Luncheon, or "tiffin," as it is locally called, ought to be a very light meal. This is not usually the case, and the consequence of disregarding the rule is fraught with evil effects. A chop or bit of chicken, with toast and a glass of water, or claret and water, is the model to go by, and any departure from the rule brings repentance in time.

Fish.—The products of warm seas have not the flavour or crispness of those of more temperate regions. The fish yield of the Pacific generally is of a lower quality than that of the North Atlantic. The quality of fish caught on the Atlantic seaboard of America is much superior in every way to that procurable on the Pacific shores of America. Still, edible fish is obtainable, and, for those dwelling on the seaboard, it is wholesome.

Vegetables.—Where any considerable gathering of Europeans reside, European vegetables are usually grown; but, even without these, as most natives are vegetable eaters, there is seldom any scarcity.

Fruits in season should be taken freely, and, for some unexplained physiological cause, the

morning is the best time for their consumption.

Drink.—The question of alcohol is one which has given rise to great controversy. It may at once be said that teetotalers thrive as well as those who take alcohol; but that they thrive better than do moderate drinkers is not the case. Alcohol would seem, therefore, not to be a necessity. The amount of alcohol that can be taken with safety is very small. It should never be taken before five in the afternoon, nor after nine at night. Whisky or gin is the safest spirit. Beer-drinking, except an occasional glass, is a mistake. Claret with water is the best drink at dinner, and, if anything is drunk at luncheon, it should be a glassful of thin claret undiluted. A glass of champagne after a long, fatiguing journey, shooting expedition, or continued violent exercise, is the safest alcoholic beverage.

But it is not only the alcoholic element in drinking that leads to trouble. Excessive indulgence in fluids of any kind during the heat of the day is to be avoided. The imbibition of a "long drink" of any kind whilst the sun is up brings on at once intense perspiration, and induces prickly heat. The kidneys are not flushed by the fluid, but the skin is drenched. The fluids requisite for health and for flushing the kidneys should be taken during the cooler hours of the morning and evening; then, and then only, do the kidneys get the benefit of the fluid imbibed. The soldier on a long day's march, or the sportsman who can restrain himself from imbibing fluids, be they alcoholic or not, until the sun sets, will be able to withstand the climate infinitely better than he who keeps continually gratifying his appetite. The habit of sipping cold tea is an excellent one, as thirst is relieved thereby without the ills arising from long drinks being induced. Aerated drinks are very tempting beverages, and soda waters and such like are too constantly in evidence. They induce a form of dyspepsia which is fed by its further imbibition, and cause a fulness of the abdomen with a stomachic "sinking," which is deleterious and depressing in the extreme.

Sleep.—As a rule, one requires more sleep in warm than in temperate climates. Late hours are a great drawback to the maintenance of health in the tropics. Ten o'clock is the recognised hour for retiring, and sunrise the time to get up. The mid-day or afternoon sleep (siesta) is not a necessity; it is chiefly caused by a heavy luncheon, and, in proportion as it is indulged in, so is the night's sleep restless. Those who maintain the best health do not sleep during the day. During the hottest period of the day it may be necessary to keep in doors and to rest, but if the night's sleep is to be restful and refreshing the habit of taking a siesta ought to be fought against.

#### DISEASES.\*

Insolation.—Synonyms: sun-stroke, heat-apoplexy, heat-stroke, ardent fever, &c. The foremost enemy to be fought in the tropics is the sun. Always take the shady side of the street when there is one, and by every means possible ward off the direct rays of the sun from the body. It is said that it is when the sun strikes the back of the neck that its most injurious effects result; and many declare that the slanting rays of the early morning or afternoon sun are more deadly than when the sun is in the meridian, no doubt because they can reach the back of the neck more easily. Others declare that sun-stroke is brought about by the glare of the sun acting through the eyes. Hence the necessity for coloured glasses to shade the eyes. Where shade is impossible, a sun-shade of silk, or bamboo and paper, such as natives use, is an excellent protection.

As a protection against the sun, a pith helmet for the head covered by white pipe-clayed calico, a pair of coloured glasses for the eyes, a light sun-shade, where such can be carried,

\*In addition the reader should refer to certain articles in this book, such as Tropics, Fever, Liver, Ague, Jaundice, Cholera, &c.

will for the most part serve to ward off the direct rays of the sun; when these are not available wetting the head-dress, or wearing a plantain leaf inside the hat will serve as an alternative. Whatever the head-dress chosen it ought to be ventilated freely so that air may not only find entrance but exit. The most fatal forms of sun-stroke are met with in those who are alcoholic.

Sun-stroke is the term usually applied to that form of sun-fever which comes on whilst exposed to the direct rays of the sun; heat-stroke to the development of symptoms which supervene after sundown.

Symptoms.—In sun-stroke, or true heat apoplexy, the person attacked may fall down suddenly, and become insensible. The face is flushed, the eyes blood-shot, the breathing stertorous, the pulse strong, full and quick, the skin dry, and the heat of the body, especially the head, most marked. Frequently, however, there are premonitory symptoms, such as shivering, intense headache, pains in limbs and back, thirst, nausea, and dry, parched tongue. This condition, sometimes designated "ardent" fever, may subside or pass into that of heat apoplexy.

Treatment.—For the more severe forms immediate steps must be taken, otherwise death is imminent. These consist in stripping the patient of his outer clothing, laying him down with his head and shoulders slightly raised, pouring cold water, jug after jug, from a height of three or four feet, over his head and body. The patient should lie in a free current of air, or he may be fanned vigorously, or placed below a punkah. Rub the extremities strenuously, apply mustard poultices over the heart and the nape of the neck. The cold applications must not be kept on too long—not more than 10 minutes—otherwise serious depression of temperature may be induced.

As soon as the patient can swallow, give a little wine or brandy, wrap him up in blankets, and give Warburg's tincture with a drop of croton oil if these remedies are at hand; if not, a dose of castor oil followed by 10 grains of quinine will do good.

When the symptoms are less severe a cold bath, or wrapping for 10 minutes in a sheet wrung out of cold water, and the administration of castor oil and quinine will afford relief. When combined with heat-stroke, the patient is markedly alcoholic and the temperature very high, 107° to 110°, the application of 20 leeches to the nape of the neck, or a free bleeding from the veins at the bend of the elbow are the only remedies likely to prove efficacious.

Malaria.—All tropical residents live in the dread of "fever." It is a constant quantity to be reckoned with, and one lives in a perpetual state of taking precautions to ward it off. Within recent years it has been proved that malaria is due to a parasite in the corpuscles of the blood, which, whilst it causes deterioration of the blood itself, lowers the vitality of the various organs of the body. Indiscretions of any kind favour its development; fever shows itself in the form of ague, intermittent fever, remittent fever, continued fever, and a host of visceral ailments which include dysentery, enlargement of the liver and spleen, and a marked form of anæmia. The indiscretions referred to are:—Sitting in draughts, "cooling off" without changing the clothing more especially when cotton or linen garments are worn, over-fatigue, upsetting the liver and the digestive organs generally by indulging too freely in the pleasures of the table, getting a chill at night owing to throwing off the bed clothes, in fact, any circumstance which lessens the powers of the body to resist the malarial parasite. In other words, the body's debility is malaria's opportunity.

Intermittent Fever—Symptoms.—Typical ague presents three stages in its course—the cold, the hot, and the sweating stages.

The cold stage is ushered in by rigors of more or less severity, lasting, it may be, from a few minutes to a few hours. In some parts of the tropics the cold stage is prolonged and the rigors attain a marked intensity, the very bed shaking beneath the patient; in others the cold stage is evanescent, and the shiverings but slightly, if at all, noticeable. If the temperature, however, be taken during this stage, it will be found that the heat of the body is gradually rising, and, whilst the patient is still complaining of feeling cold, the temperature may reach 102° to 105°.

During the hot stage, when the skin is dry, the thirst intense, and the headache severe, the

pulse excited, and the breathing distressed, the temperature may reach excessive limits. As a rule, the younger the patient the higher the temperature. Children may show a temperature of 106° without the symptoms indicating great danger, but the same temperature in an adult is to be viewed with alarm. The hot stage usually exists for an hour or two, but may exceed these limits, and continue for several hours.

The sweating stage is ushered in with restlessness, and a desire to get rid of the clothing. Perspiration going on, it may be, to saturation of the bed and clothes, is followed by relief, and

the patient, except for weakness, feels quite comfortable.

After a complete intermission, during which time the temperature becomes sub-normal, the temperature may again rise, and a series of signs and symptoms similar to those of the attack described above recur. The interval may be of twenty-four, forty-eight, or seventy-two hours' duration, and the types of fever are named quotidian, tertian, or quartan, according as the attacks develop daily, every third day, or every fourth day. If the fever appears at an earlier hour during the recurrences than at the initial attacks, it is evidence that the fever is of an intense nature, and likely to recur; but, if the hour of re-appearance is delayed, it is a hopeful sign of its early disappearance.

Remittent Fever.—When, instead of the temperature falling to, or below, the normal during the sweating stage, it continues above the normal, when, in fact, the feverishness is continuous, and not intermittent, the name remittent is applied to designate the disease. This form seems to continue, in spite of treatment, and may last three days, a week, a fortnight, three weeks, or even a month. It is very similar to typhoid at times, and requires careful study of the individual case to be sure of the diagnosis.

Besides these more typical forms, there are several types of fever which have defied classification up to the present, but which will, no doubt, in a few years be definitely grouped.

Treatment.—The prophylactic methods to be adopted are indicated by the statement just given as to the cause. Avoid draughts and chills; wear flannel next the skin night and day; to prevent night-chills wear a flannel belt round the abdomen; mosquito curtains are considered to be useful, not only in warding off the mosquitoes, but in guarding the body from cold currents of air and mosquitoes in the early morning hours; use hot, and not cold, water baths; avoid fatigue and over-indulgence in eating and drinking. Quinine, as a preventive against malarial poison, is, when wisely given, at once safe and effective. Of course, quinine, when continued abnormally, will lose its effect somewhat; but there are seasons, localities, and situations in which one is more exposed to malarial poisons than in others; it is then quinine should be taken, and when infection is less likely to take place it may be left off. However, for months together, quinine may be taken with advantage. Before going out, especially in the very early morning hours, and again in the evening, or when fatigued after a hard day's work, 3 grains of quinine suffice to afford a protection of considerable effectiveness against malaria.

Treatment of Fever.—Quinine is the remedy par excellence in malarial fever. Its prophylactic value has been indicated above, and its curative powers are undoubted. There is a proper time, however, to administer quinine, and that period must be chosen if the greatest good is to be effected. When the temperature is rising, or at its height, quinine should not be given. If, however, feelings of feverishness are merely threatening, 10 grains of quinine taken at once will often help to stave off an attack. It is during the intermissions that the drug should be given. In quotidian ague 10 grains of sulphate of quinine every four or six hours will modify, if not completely arrest, the disease in its course.

If the disease is tertian or quartan, 10 grains given every eight hours during the whole period of intermission will, in all probability, render the expected attack abortive.

Quinine is best taken in powder. Place the prescribed amount in the palm of the hand, and lick it off; this is perhaps not the most elegant, but it certainly is the most efficacious, method of administration. Quinine tastes less strongly when dry than when dissolved in a mixture, and it is easily washed down by water. If made in a mixture it is necessary to add about a drop of dilute sulphuric or nitro-hydrochloric (muriatic) acid for each grain of quinine taken.

Quinine in the form of pills is objectionable, more especially when the pills are coated, as they at times refuse to be dissolved, and the pill is passed in much the same state as it was swallowed.

The drug ought to be continued in 5 grain doses twice a day for three days after the date of the threatened attack has passed. In remittent fever it is well to commence, first, with a 4 or 5 grain calomel purge, given at bed-time, when the stomach is empty. After ten hours a "driver" should be exhibited, such as a dose of Epsom salts, a seidlitz powder, or some other saline purge. When the bowels have been well cleared out, quinine should be given with a free hand, 10 to 15 grains every eight hours for two or three days. If, after three days, the temperature does not yield to quinine, then, in all probability, the fever is not malarial, but typhoid.

To procure the free action of the skin, the patient should be placed between blankets and means taken to make him sweat. This is effected by a variety of methods-hot drinks, alcoholic or simple; by such drugs as sweet spirits of nitre in drachm doses (measured teaspoonful), combined, it may be, with sal volatile in half drachm doses. Antipyrin and phenacetin are largely used drugs in the tropics; the latter is, perhaps, the safer, but the former is the favourite. Ten grains of either given half an hour before the dose of quinine, will no doubt help to promote perspiration. With both, a dessertspoonful of brandy should be given to prevent any evil effects of depression inherent in the drugs themselves. No more than three doses of either should be given consecutively. Many people declare they cannot take quinine; this is an ill-founded prejudice, and at times an unfortunate belief. Every one can take quinine, if it is given at the proper time, and with judgment. Quinine should not be given to pregnant women except it be combined with opium, nor should it be freely administered at the menstrual period. Many substitutes for quinine have been tried. Arsenic is the favourite after quinine, and 2 to 5 drops of the liquor arsenicalis-Fowler's solutiongiven after a meal in a wineglassful of water, and continued for a week, is a useful remedy in malaria when quinine cannot be borne.

Tropical Diarrhoea—Treatment.—In tropical, as in temperate, climates undigested food irritating the bowel is apt to set up gripes and intestinal flux. Removal of the cause by

a dose of castor oil is the essential, and in most cases the only, remedy required.

In the tropics, diarrhoea is frequently caused by a chill, as when during the night the bed-clothes get adrift; in such cases it is wise to give the castor oil in a small dose, 1½ drachms, combined with 15 to 20 drops of laudanum (tineture of opium) and to apply a wet pack to the abdomen. The "pack" is made by wringing a towel or piece of flannel out in hot water; laying it upon the abdomen, so as to cover the surface from the nipples to the groins, and round the sides as far as the flanks; then covering it up by wrapping the body tightly round in a thick dry bath towel, securely pinned. The pack may be renewed after two hours if required.

The food should be of the simplest nature, sips of equal parts of milk and water (not sodawater) being administered occasionally, or sips of toast-water, whey, weak tea, or roasted-rice tea, being all that is requisite for the first twenty-four hours. Should the diarrhœa continue

it will in all probability go on to muco-enteritis or dysentery.

Muco-enteritis.—Synonyms: Inflammation of the Bowels; Enteritis.—When, in addition to fluid excrement, patches of the mucous lining of the gut appear in the stool more decided steps in the treatment are required. It is of primary necessity that the patient be put to bed. The hot wet pack may be tried if there is much pain and griping, or when the temperature is above the normal; to be followed by the cold wet pack when the acute symptoms have subsided. Milk usually perpetuates the disease, being impossible of digestion, but whey, with lime water, or rice-water (the water rice is boiled in), is well tolerated. As an alternative chicken-tea, from which all fat has been removed, or weak beef-tea is useful. A preliminary purge of one or two teaspoonfuls of castor oil should be administered, and in the case of children small doses of grey powder ( $\frac{1}{6}$  of a grain) ought to be given every four hours. For adults, Dover's powder in 10-grain doses should be given after the castor oil has had time to do its duty, and

the dose kept up every four hours for twenty-four hours. For children, Dover's powders in 1 to 2 grain doses are to be given every three hours, if the grey powder fails to effect an improvement. If the temperature keeps above the normal, more especially if there is marked sweating, quinine deserves a trial, as frequently malaria complicates the condition. Rhubarb at times has an excellent effect, and either Gregory's powder in small doses (3 grains for a child and 10 grains for an adult), or powdered rhubarb root, in 1 to 3 grain doses every six hours, may be exhibited.

Washing out the lower bowel by an enema of warm water, with or without boracic acid

(30 grains to the ounce), has a soothing and beneficial effect.

Dysentery.—When, along with mucus, blood appears in the stool the patient is said to be suffering from dysentery. Blood is met with in the evacuations from other causes than dysentery, so it is necessary to note the condition of the stool and the attendant symptoms before pronouncing the case to be one of dysentery. The disease may come on suddenly or may be ushered in by an intestinal flux, which instead of subsiding grows more and more intractable, and ends up as a true "bloody flux." The symptoms most noticeable in dysentery are—griping pains in the abdomen, especially before a motion; tenesmus, or a desire to strain and continue at stool; alternate sweatings and rigors; clammy skin; fever; quick pulse and intense weakness. The stools may occur every few minutes or at intervals of half-an-hour or an hour. The evacuation at first may be slightly flocculent, but as the disease advances blood and mucus alone obtain. Sago-like particles imbedded in flocculent mucus shreds and stained with blood are a sign of deep infection. In the later stages, hiccough is an untoward symptom, and should large sloughs appear in the stools the disease is usually of the malignant type, and of a very fatal nature.

Treatment .- Dysentery must be looked upon as a specific disease, and the "bloody flux" as no mere symptom of bowel derangement. The mucous membrane of the gut-the larger bowel-becomes ulcerated from a specific cause, and according to the extent of the surface involved so does the danger vary. Hence, it is an illness that has to be guided towards recovery, rather than one that is to be suddenly arrested by vigorous treatment. When the evacuations are partly fæculent and foul smelling, it is well to commence with a dose of castor oil 1 to 2 teaspoonfuls (drachms), together with 30 drops (1/2 drachm) laudanum. Should benefit arise therefrom it is well to continue the oil in teaspoonful doses, combined with 20 drops of laudanum, morning and evening. If, however, there is no appearance of true fæcal matter in the motions, but blood and mucus only, reliance is to be placed on ipecacuanha in large doses. The method of administration is as follows:-Give 30 drops of laudanum in a little water twenty minutes before the time fixed to administer the ipecacuanha; ten minutes after giving the laudanum, apply a mustard plaster, about the size of the hand, to the pit of the stomach; five minutes before the ipecacuanha is to be given the patient is to suck ice if it can be had. At the time arranged, give 30 grains of powdered ipecacuanha root in pills or wafer papers. Let the patient continue to suck ice and lie flat on the back, neither moving nor speaking for some time, so as to avoid vomiting. After ten minutes remove the mustard plaster. No food is to be given for some two hours before the ipecacuanha is given, nor for four hours afterwards, when a little tea may be sipped. If no vomiting occurs one may look for immediate benefit. The same dosage may be repeated in twelve to twenty-four hours and kept up until the motions become fæculent. A very excellent adjunct is the application of a wet pack to the abdomen. At first the water used may be warm, but the temperature should be gradually reduced until cold water, or even ice-cold water, is employed. The pack ought to be ample, and changed every two hours. When there is great pain morphia may be given hypodermically, 1 to 1 grain at a time, until relief is obtained.

When the tenesmus is distressing, an enema of warm water will ease it, or an enema of starch and laudanum (30 to 50 drops to 2 ounces of starch emulsion) may be administered. On no account should the patient be allowed to get up to stool; the bed-pan must be insisted on, however much the patient resents its use.

When dysentery becomes chronic other methods of treatment in force are adopted. Amongst these Epsom salts, a teaspoonful dissolved in a few drops of sulphuric acid and given with a minimum quantity of water is much vaunted. The dose is repeated every few hours until the motions become feeculent. Washing the bowel out with boracic acid (20 grains to the ounce of hot water) or nitrate of silver (½ grain to the ounce) are used as alternative methods. In almost every part of the world some local drug is in favour as a means of dealing with this prevalent disease. The bowel washings may be combined with the exhibition of drugs by the mouth. In East Africa, lungili is in use amongst the natives; and in the Malay Peninsula mangostine (3 mangostine skins boiled in 1½ pints of water, until reduced to a pint, when a fourth of the quantity is to be given at a time) is similarly employed. All fæces should be disinfected as they are passed, and deeply buried in the soil when it is feasible. An acute attack of dysentery will in even favourable cases last a week, but it is more usual for it to continue for two, three, or four weeks, in a more or less acute phase.

Malignant dysentery—when large sloughs are shed—usually proves fatal within a week.

Cholera.—Choleraic attacks may occur at any time, and in any country, in a sporadic form; but true Asiatic cholera is always epidemic in character in all but a few endemic centres in India.

Symptoms.—When cholera prevails all attacks of diarrhea ought to be seriously treated. What seems a mere laxity of the bowels may be the onset of an attack of true cholera. Cholera, on the other hand, may set in suddenly, and the disease may terminate fatally in a few hours. At the commencement of an epidemic recovery is less probable than when it is on the wane. The onset of the disease is usually marked by vomiting and purging, and cramps in the extremities proclaim the true nature of the illness. The tongue is white and tremulous, thirst is intense, and a peculiar feeling of sinking at the pit of the stomach, especially after a motion, attended by marked depression, occur at an early stage. The stools soon exhibit that peculiar character termed rice-water. The eyes are sunken, the nails and skin generally become markedly bluish, the pulse feeble and frequent. The temperature of the skin falls, whilst that of the rectum may rise to 105° or 108°. Noises in the ears, suppression of urine, restlessness, speedy exhaustion, and threatening collapse, complete a category of symptoms which render diagnosis unmistakable.

Treatment.—No case of cholera is to be considered hopeless; even the most severe cases recover, but no patient is considered safe until the urine secretion is well re-established. When cholera is prevalent, a case of diarrhea should be at once treated by giving a pill of 1 grain of opium and 4 grains of acetate of lead. If these drugs are not at hand, chlorodyne, 30 drops, with a tablespoonful of brandy in a small quantity of water, is usually to be had. In India, a cholera pill consisting of opium (1 part), asafeetida (2 parts), black pepper (3 parts), made into a 5-grain pill, and exhibited every two hours, is highly efficacious. Dover's powder in 10-grain doses, repeated according to the number of stools, is an excellent substitute.

Should choleraic symptoms develop, hot-water bottles ought to be applied to the feet and abdomen; a mustard plaster to the pit of the stomach; cramps are to be relieved by friction with the hands, or by flannel dipped in warm turpentine. An application of the same kind may also be applied round the loins, so as to induce the return of activity to the kidney. Ice should be sucked, but if it cannot be had, hot water or hot tea will allay thirst. Medicines are, unfortunately, of but little use in severe cases, as they are speedily rejected by the stomach. Stimulants are really the sheet anchor; brandy and champagne are to be freely administered in quantities according to the exhaustion. When, in spite of these, collapse threatens, ether is to be injected hypodermically, 15 minims at a time, and repeated every ten or fifteen minutes. Raw meat juice is often retained when nothing else can be kept down; but, during the vomiting stage, it is well night useless to give food by the mouth. The writer has seen great improvement brought about by immersion of the whole body in a bath at a temperature of 100°. Anomalous as it may seem, ice in the rectum, or cold water enemata administered at the same time, have a reviving effect, and help to restore the balance of temperature between the skin and the bowel.

During the third or collapse stage of cholera, when the pulse at the wrist fails and the breathing is laboured, and the features pinched, there is little to be done medicinally. Although the vomiting diminishes in frequency, it is unwise to give anything by the mouth; the number of stools also lessen, allowing of rectal nutriment being given. However far spent a patient seems, recovery is never beyond hope; the possibility of recovery is dependent, for the most part, on the state of the heart. When the temperature at this stage begins to rise very speedily to high above the normal, death is imminent; but a gradual rise towards the normal is a satisfactory and hopeful indication.

Intestinal Worms.—Many worms inhabit the intestine in tropical countries, but of these the round worm—the Ascaris lumbricoides—is by far the most frequent. Although children are most frequently attacked, both men and women, more especially the latter, are subject to be infested. In children they give rise to irregularity of the bowels, at one time looseness, at another constipation; blood may appear in the motions, and a well-simulated dysentery supervene. Fever which is ready to appear, whatever the ailment may be, is apt still further to complicate the disease, and render diagnosis difficult. During teething also—for children of but nine months' old may have worms—the round worm may cause untoward symptoms, often of a puzzling character. In fact, in all intestinal troubles, the fact of worms complicating the disease must ever be present to one's mind, and steps to eliminate the doubt should be immediately taken.

Santonin is the drug par excellence, and it is to be administered as follows:—Take six powders of 2 grains each for a child and 4 grains for an adult, and give them morning and evening until all six have been taken; it is well to give a dose of castor oil after the third as well as after the sixth. The stools must be carefully examined after each motion, and the patient must be warned that red urine and "seeing yellow" whilst taking santonin is only the direct effect of the drug, and not attended by any element of danger.

Other worms are met with in the intestine in tropical as in temperate climates, and they are to be treated in the manner described elsewhere in this work. Piles are, perhaps, more common amongst tropical residents than amongst home dwellers. They are no doubt a direct result of the hepatic (liver) congestion so frequently present, more especially in the case of those who live freely. They are to be treated as directed elsewhere in this volume.

Itching and moisture of the anus is a sure indication of liver or intestinal derangement, more especially the former. Local applications of a soothing nature will relieve the complaint, but strict attention must be paid to the diet and the general regimen if it is to be cured.

Hill Diarrhæa.—It has been observed in the hill stations of India, that, when dwellers on the plains go to recruit in the mountains, a form of diarrhæa not unfrequently develops. The stools are of a light pipeclay colour, and come on in the early morning. As many as six stools may occur before 11 a.m., after which hour the diarrhæa ceases, to recur again the next morning. Should ordinary remedies prove unavailing, it may be necessary for the sufferer to return to the plains when the troublesome affection will in all probability promptly cease.

Sprue, or as it is technically called psilosis, is a complaint prevalent in India and China. It is preceded by gastric derangements of a persistent nature, and characterised by sore mouth, bare tongue, and a persistent diarrhea, of a more or less matutinal character. The mouth is so tender that only the most bland food can be tolerated. Salt, pepper, mustard, curry, and in severe cases even bread causes irritation and pain when consumed. The patient is often reduced to a milk diet, as the only form of nourishment possible. The stools are pipeclay in colour, pultaceous in consistence, and at times fermented. The patient waxes thin and feeble, and in time becomes altogether an invalid.

Treatment.—The usual treatment of sprue is to put the patient on milk, given at regular intervals every two or three hours, a half pint of fresh milk to be slowly sipped or taken in spoonfuls at a time. On this regimen in all probability the diarrhœa will subside, and the

stools become solid. The writer, however, does not hold with the milk treatment of sprue for several reasons-firstly, because although milk will check the flux, it will not cure the ailment. Whenever the patient attempts to take food other than milk, all the symptoms return; and as sprue is associated with a small and atrophied liver, the ingestion of milk tends to continue the liver in its shrunken condition. The writer has for many years stopped milk in sprue and allied diseases, and adopted instead what is known as the "beef-and-hot-water" treatment. At first when the disease is acute the patient may have to be fed every half hour on raw meat juice, scraped beef, raw meat sandwiches, or underdone fresh beef minced very carefully. Byand-by a piece of fresh underdone meat may be chewed, and if all goes well a small quantity of steamed rice is to be taken with the meat. The white of an egg (poached) is a safe addition to the diet after a few days. Within a week in ordinary cases a cut from the joint will be found to be easily digested. The great thing in the treatment is to withhold vegetables and starchy foods until the irritation of the bowel abates, and the stools cease to be fermented. As regards drugs they are for the most part deleterious; but a teaspoonful of castor oil every second morning will help to keep the bowel empty and clear away any fermenting matter that may develop. Opium or any and all drugs which arrest the diarrhea are to be avoided, as the diarrhea is only a symptom of the disease and not the disease itself. In addition, a cold wet pack to the abdomen, applied as indicated above, is of immense service in restoring the gut to a normal condition.

Skin Affections.—There are one or two skin diseases which are well nigh peculiar to the tropics. Amongst these, Lichen Tropicus, or prickly heat, takes a prominent place. It is a very annoying ailment, causing painful "prickling" of the skin, whilst associated with the nerve irritation is a "rash," consisting of an eruption of red-based watery vesicles. The condition is induced by sudden bursts of perspiration during violent exercise, by imbibing a quantity of fluid at a draught, or by wearing too heavy clothing. Coarse flannel next the skin is a frequent incentive, and provokes prickly heat on the slightest provocation.

Treatment.—Light clothing, desisting from violent exercise, and abstaining from "long" drinks, are the chief means of alleviating the discomforts of prickly heat. Warm baths, to which have been added a handful of bicarbonate of soda or potash, are pleasant and efficacious. After the bath, sponging with Eau de Cologne or spirits of wine (1 part to 3 of water) allays the itching. No soap should be applied to the skin. If the "rash" is very pronounced, 20 grains of sulphate of copper to 1 ounce of warm water may be dabbed on the skin with great benefit. If the disease is very aggravated it will be necessary to spend a day or two indoors, so that the extreme irritation may pass off and allow the skin to recover.

Dhobhee Itch.—A variety of Tinea known as Dhobhee's or Washerman's itch is a common tropical skin affection. It is supposed to be contracted from the clothes that have been returned from the wash, owing to the "habit" the oriental washerman has of wearing his customers' apparel whilst it is in his possession. The sites of selection are the arm-pits and the fork, where it spreads to the groins and to between the hips. In stout people, especially, a true eczema may ensue. Happily it is easily cured, if proper attention is paid to treatment. Wash the parts with warm water softened by the addition of bicarbonate of soda. Afterwards apply a lotion consisting of sulphur and lime, made thus: Take of slaked lime and of sublimed sulphur, 4 ounces, add to these 1½ pints of water. Boil the water until the fluid measures a pint only, when it is to be filtered through a handkerchief. The lotion thus prepared is very strong, and requires to be dabbed carefully on the patches of affected skin, especially round the margins. If done too vigorously the part will smart severely. Three or four applications of this lotion are sufficient to cure the disease. If continued too long the skin becomes inflamed. After the lotion has dried it is advisable, especially in very stout people, to dust the irritated parts with powdered starch, or equal parts of boracic acid and starch.

Skin affections are prevalent in the tropics, no doubt, in consequence of the moist condition in which the skin is kept by the profuse perspiration. Eczema, tetter of the soles of the feet, in which the skin is kept by the profuse perspiration. Eczema, tetter of the soles of the feet, in which the skin is kept by the profuse perspiration. Eczema, tetter of the soles of the feet, in which the skin is kept by the profuse perspiration. Eczema, tetter of the soles of the feet, in which the skin is kept by the profuse perspiration. Eczema, tetter of the soles of the feet, in which the skin is kept by the profuse perspiration.

diseases in temperate climates. Leprosy is seen in many countries, but the European need not dread contracting it unless exposed to intimate contact with lepers. It is necessary to keep a sharp look out amongst one's servants in case of a so-called skin disease being leprosy.

Tropical Anæmia.—Every European dweller in the tropics becomes in time anæmic. The blood corpuseles diminish in number independently of any actual disease; but should illness supervene, more especially malaria, the anæmic process is hastened. Residents in warm climates do not appreciate how anæmic they are until some visitor or fresh arrival from "home" appears amongst them, when the contrast makes their relative pallor evident. On the other hand, when an old tropical "hand" comes to Europe, it is easy to perceive that the complexion is very different in its freshness from that of the home-dweller. The absolute cure for tropical anæmia is change to a temperate climate; one's native air is preferable. But it is not always easy or possible to command this luxury, and one must be content to fight the condition locally. Nothing produces the deterioration of the blood more speedily or surely than malaria; and liver derangements are a fruitful source of inducing the same condition. To these may be added insufficient exercise, irregularity or over-indulgence at table, over-fatigue, and alcohol. Women are more liable to become anæmic than men, chiefly, no doubt, on account of their disinclination to take exercise. "Tiredness" is, in many instances, held to indicate that exercise, more especially walking exercise, is inadvisable. The muscles, especially during the hot weather, are allowed to become soft and flabby, and the least exertion brings on a feeling of "tiredness." The wisely-advised will learn, and be persuaded, that the way to overcome the feeling is to take more exercise, and to strengthen the muscles so that they may carry the body weight without As a rule, it may be stated that the greater the feeling of impossibility to take walking exercise in health, the more should it be insisted upon. Happily, tennis, cycling, and horse exercise play a considerable part in the social life of the Europeans in the tropics, and thereby some of the evil effects of tropical lethargy are counterbalanced.

Treatment.—In temperate climates the administration of iron in some form is the means of effecting relief, but in tropical countries the same drug does not act so beneficially. The liver in warm climates cannot stand being deluged with iron, and the congestion induced but adds to the baneful effects of the disease. Anæmia is best treated by relieving the engorged liver by saline draughts. Vichy water at or after meals, an occasional blue pill, and strict attention to diet will often bring about an improvement independently of iron or any other "blood-making" drug. When iron can be given, it ought to be in some digestible form, well diluted with water and in small quantities. The Japanese have an ærated iron water of great value, "Tansan." It is a natural water, impregnated with carbonic acid, and containing carbonate of iron.

Tansan is readily digested, and requires only to be known to be universally used.

The Liver.—The liver is the organ of all others that commands the attention of the tropical dweller. The effects of a warm climate tell on the liver more markedly than on any other organ, and, although many ailments are ascribed to the liver that arise from other causes, there is no doubt that, according to the power of the liver to accommodate itself to its surroundings, so is life rendered possible or impossible in the tropics. Continued or intense heat is, no doubt, the direct cause of hepatic troubles, but it is only when the body is exposed to chills that the consequences become recognisable. In temperate climates it is the lungs and pleura which register the deleterious influences of sudden changes in temperature, but in the tropics the liver has to bear the burden. A sudden chill drives the blood from the skin to internal organs, and the liver becomes surcharged beyond its powers of accommodation. This tells its tale in many ways. Dyspepsia, either catarrhal or atonic, usually ushers in the train of symptoms, to be followed by intestinal derangements, give rise to either constipation or flux. The effect upon the liver itself is to cause it to become engorged, congested, or inflamed, causing enlargement, tenderness, fever, and possibly abscess. The spleen harmonises with the liver in all its departures from the normal, and enlarges or diminishes in consonance with it. These organs being both intimately concerned with the welfare of the body generally, and the elaboration of the blood more immediately, any interference with their functions is attended by injurious 720

effects of a widespread and vital character. It is essential, therefore, to see that the indications of liver derangement are fully recognised, and timely dealt with.

Constipation .- Chronic constipation is a condition requiring careful handling and close attention. Violent purgations are, as a rule uncalled for, seldom attended by any good, and frequently cause considerable harm. Of all drugs cascara is the best; it is not to be used as an active purge, but to be taken continuously for a time with the object of effecting a cure. It may be taken in tabloid or liquid form; the former is perhaps the more agreeable. The drug may be given alone or along with one or two adjuvants, and should be of strength sufficient to induce one stool daily. The plan of taking a small quantity immediately after meals. twice or thrice daily, is preferable to one larger dose. If the constipated habit is of long standing it will be necessary, before effecting a cure, to take it for say three months. During the second month the dose should be reduced, and again it should be still further diminished during the third month. Other means of treating the habit is to eat plenty of fruit. The best time for taking this more natural remedy is the early morning, on first getting out of bed, or at 11 a.m. Fruit should not be eaten, during, or at the end of a meal, except sparingly. Exercise, especially horse exercise, massage to the abdomen, or exercise in any form contribute to alleviate constipation, but it is seldom that some drug is not required. Laxative mineral waters taken in the early morning are useful and efficacious, but when once the habit of their use is established it is difficult to break away from it. Cold wet packs to the abdomen applied for an hour or two every morning for a few weeks have frequently a most salutary effect.

## GLOSSARY.

Glossary of Scientific and Medical Terms not included under Alphabetical Headings in the Dictionary. References in italics are to Articles.

ADEPS. Hog's lard. ADYNAMIC. Applied to a want of vital power. Nervous sensibility. ÆSTHESIA. AGUE CAKE. Enlargement and hardening of the spleen. ALIENATION, Mental. Insanity. AMBLYOPIA. Indistinct Vision.
AMENTIA. Idiocy. Communications between the ANASTOMOSIS. extremities of blood-vessels. ANTHRAX. Carbuncle. ANTIPERIODIC. A remedy against a crisis or paroxysm of disease. ANTIPHLOGISTIC. A remedy opposed to Inflam-ANTIPYRETIC. A remedy antagonistic to Fever. ANTISCORBUTIO. A remedy opposed to Scurvy. ARTERITIS. Inflammation of the Arteries.

ARTHRITIS. Inflammation of a Joint. ARTICULO MORTIS. The moribund condition. ASTRAGALUS. Want of strength.

ASTRAGALUS. The ankle bone. ATAXIA. The febrile condition, without any special character; disordered locomotion. ATHEROMA. Fatty and calcareous deposits.

ATLAS. The first Vertebra.

ATONIA. Want of tone in the system. ATRA-BILIOUS. Denoting the biliary diathesis.

ATRESIA. Imperforate condition of the natural openings of cavities of the body.

ATTENUANTS. Remedies to induce thinness. AURA. A sensation or an exhalation from the body.

AUTOPLASTY. Repair of injured, by transplanting healthy, skin. AUTOPSY. A post-mortem examination. Axis. The second Vertebra. BACTERIA. Rod-like bodies, representing the lowest forms of organic life.

Balm of Gilead. The resinous juice of a small tree, native to parts of Arabia. BASEMENT MEMBRANE. The base of mucous membranes and the dermis. BIOPLASM. Rudimentary material of growth. BLACK DEATH. Name given to a malignant form of fever. A name given to one form of BLACK VOMIT. yellow fever. BLACK WASH. A lotion made with calomel and lime water.

BLASTODERM. The germinative membrane. BLEB. A bladder-like swelling of the skin.
BLENNORBHEA. A term synonymous with gonorrhoea. 722

BLOODY FLUX. Dysenlery.
BLUE GUM. The purple line on the gums induced by Lead poisoning. BLUE STONE. Sulphate of Copper. Breast Pang. Angina pectoris.
Brow Ague. Neuralgia of the parts above the eye-brow. BRUNNER'S GLANDS. Small granular bodies in small intestine. BUCKU. The leaves of some species of Barosma, used as a drug.
Bullæ. Skin Vesicles of large size. CALAMINE. Impure carbonate of zinc. CALCANEUM. The heel Bone. CALCIUM. Quick Lime. CALEFACIENTS. Substances which excite warmth CALLUS. New matter which unites Fractures. CANALICULI. Minute canals in Bones. CANNABIS INDICA. Indian hemp. CANTHUS. The angle of the Eye. CANULA. A small tube. CARUNCULE. Small bodies in canthus of Eye. Casein. The organic constituent of Cheese and Milk. CAUDA EQUINA. Lower part of the Spinal Cord. CEPHALIC. Connected with the Head. CERATE. Combination of Lard and Wax. CEREBRAL. Connected with the Brain. CEREVISIA. Malt liquor. CERVIX. The neck, a term chiefly applied to Bladder and Womb. CHELOID. A disease of the skin. CHOLESTERIN. A crystalline substance found in the Bile. CHORION. The external coat of the Eye. The external covering of the fœtus. Filamentary processes on the surface of Mucous membranes. CINNABAR. Vermillion, a sulphide of Mercury.
CIRRHOSIS. Chronic atrophy of the Liver.
CIRSOID. Term applied to enlarged Arteries. CLINICAL. Applied medically to bedside instruction. CLONIC. Spasmodic contraction, alternating with relaxation. Peculiar kind of knot used in CLOVE-HITCH. Dislocations. Coccus CACTI. Cochineal. COLOSTRUM. First milk secreted after Child-

Compression. Comprising Fracture, indentation

of skull and extravasation of blood.

CONDY'S FLUID. Potash permanganate.

CONDYLOMA. A wart-like tumour. CORROBORANTS. Strengthening remedies. CORYZA. Cold in the head. COXA. The Hip.

CREMATION. Disposal of dead by fire.

CREPITATION. Sound heard in diseased Lungs, Fracture, &c.
CRUSTA LACTEA. A form of Eczema.

CRYSOPHANIC ACID. The chief constituent of Gon powder.

CUCURBITULA. Cupping glasses.
CUTIS ANSERINA. Goose Skin, induced by Cold and Fever.

DECUBITUS. The horizontal Position of the body. Defæcation. The expulsion of Stools.

DEGENERATION. Morbid alterations in structure. DEGLUTITION. The act of Swallowing.

DEMENTIA. Deficiency of intellect.

DEPLETION. The act of unloading, as in Bloodletting or evacuation.

DETERGENTS. Substances cleansing the Skin. DISCRETE. A term applied to pimples or pustules when distinct from each other.

DRACUNCULUS. The name of the Guinea worm.

Ecchinococcus. The hydatid or bladder Worm. ECLAMPSIA. Convulsions.

EFFLORESCENCE. A term descriptive of some cutaneous rashes.

ELEVATOR. An instrument used to raise depressed bone.

ELIMINATION. The act of expelling matter from

the body.
EMACIATION. General wasting, either of the

whole, or part of the body.

EMBRYO. The ovum and early growth of the foetus.

EMUNCTORY.

EMUNCTORY. An excretory duct. ENCEPHALON. The Head. ENSIFORM. The term applied to the cartilage of the sternum.

EPHELIS. Freckles.

EPIPHORA. Flow of tears as in Weeping Eye. EPULIS. A fibrous tumour of the dental sockets.

EROSION. Destruction of tissue by *Ulceration*.

ETHMOID. Cribriform bone of the *Nose*.

EVACUANTS. Medicines which empty the bowels,

Purgatives, &c.

EXACERBATION. An increase in the local or general Symptoms of a disease.

EXALTATION. A marked increase of Symptoms. EXCITO-MOTOR. A term applied to the reflex functions of the Nervous System.

EXCRESCENCE. Warty and fungoid growths. EXFOLIATION. Separation of necrosed bone. EXOPHTHALM'S. Protrusion of Eye-ball.

Exostosis. Osseous tumour of Bone.

EXPLORATION. Examination of the interior of

EXTRAVASATION. Escape of blood and other fluids from their natural passages.

EXUDATION. Discharge of fluid from the Skin or Membrane.

FALSE CONCEPTION. An imperfectly developed embryo, a mole.

FAUCES. The back part of the Mouth. FIBRIL. A small filament of mu filament of muscular or nervous tissue.

FIBRO-CARTILAGE. A combination of Cartilage and ligamentous substance.

FILARIA SANGUINIS HOMINIS. Worms found in the blood and lymph.

FILM. An opacity, generally applied to the cornea of the eye.

FIRE DAMP. Carburetted Hydrogen, found in coal mines.

FISSURE. Abnormal opening or slit in the skin and soft parts.

FLUKE. An intestinal Worm.

FLUXION. Determination of blood to any part, flow of mucus.

Foetor. An offensive smell.

Follicle. A small secreting cavity.

Foramen. An aperture in any part of the body.

Forensic Medicine. Medical jurisprudence.

Formication. A creeping sensation on the surface of the skin.

FORMULA. A prescription.

FOWLER'S SOLUTION. A solution of arsenic. FRÆNUM. Folds of the mucous membrane, con stituting a bridle or tie.

FRAGILITAS OSSIUM. Brittle Bones.

FROST-BITE. Numbness and gangrene produced by cold.

FURUNCULUS. A small boil.

FUSEL OIL. Deleterious product obtained from alcohol.

GALACTOMETER. An apparatus for measuring the amount of cream in milk.

GALLIC ACID. An acid obtained from Gall nuts. GLEET. A mucous discharge from the urethra. GLENOID. The socket of the shoulder.

GLOBULINE. The chief constituent of the blood globules.

GLUTEAL. The region indicated by the buttocks. GONORRHEA. A purulent and infectious discharge from the urethra.

GRET POWDER. Mercury with chalk.
GUMMA. A tumour caused by the poison of syphilis.

GUSTATORY NERVE. The nerve of taste. GUTTA. A drop, not a minim.

HEMATOCELE. Blood effused into the sac of the Testicle.

HEMORRHOIDS. Piles. HAUSTUS. A draught.

HAVERSIAN CANALS. Minute canals in Bone.

Hemidesmus. Indian sarsaparilla.
Histology. The study of minute textures.
Hordeolus. A stye in the Eye-lid.

HUMOR. Moisture or discharge from any part. HUMULUS LUPULUS. The Hop plant.

HYDROCHLORIC ACID. A compound of hydrogen with chlorine.

HYDROMETER. Measurer of water in connexion with the specific gravity of fluids.

HYDROPS. Dropsy.
HYOIDES. A bone at the root of the Tongue.
HYPERÆSTHESIA. Excessive sensibility.
HYPERTROPHY. Excess of nutrition.

HYPNOTICS. Medicines which induce sleep.

ICHTHYOSIS. Fish-like disease of the Skin. ICTERUS. Jaundice.

ILEUM. The lower part of small Intestine. IMPACTION. Obstruction in any part of the circu-

lation.

IMPERFORATE. Congenital or abnormal closure of a natural passage. 723

INANITION. Exhaustion, want of vitality.

INCARCERATION. A term used to denote the state

of the bowel in Rupture.

BATION. The interval between the first INCUBATION. germination of a disease and its appearance. INDIGENOUS. A term applied to endemic disease.

INDURATION. An increase in the natural hardness

of a part.

INFILTRATION. Diffusion of fluid into the tissues. INFLUENZA. Epidemic Catarrh.

INGESTA. Food and Drink.

The functions of the Brain and INNERVATION.

Nervous System.

CULATION. The insertion of poison or other INOCULATION. matters into the skin.

INOSCULATION. The union of blood-vessels.

Combining the food with the INSALIVATION.

Saliva. Insolation. Sun-stroke, or exposure to sunlight as a remedy.

Insomnia. Sleeplessness.

INTUMESCENCE. Large swelling.
INTUSSUSCEPTION. The descent of a part of a bowel inside another part.

IODOFORM. A crystallised preparation made from Iodine, pearl ash, and alcohol.

IRIDECTOMY. Excision of a portion of the iris, for a new pupil.

ISCHURIA. A term applied either to retention or suppression of urine.

Isinglass. Gelatin obtained from the swimming bladders of fishes.

JABORANDI. A sudorific remedy obtained from Brazil.

Headache. KEPHALALGIA.

KERATITIS. Inflammation of the cornea of the

KLEPTOMANIA. A morbid desire for other people's goods.

KNOCK KNEES. A deformity, now remedied by surgical operation.

KRAMERIA. Rhatany.

KREATIN. Organised material obtained from Flesh.

LACTIC ACID. A product of Fermentation.

LARDACEOUS. A term applied to diseased growths

of a lardy consistence. Soothing medicines, mild Aperients. LESIONS. Wounds, or the results of disease in organs.

LIPOMA. A fatty tumour.

LIQUOR SANGUINIS. The Blood without its corpuscles.

LITHIC ACID. A product of the urinary secretion, uric acid.

LOCOMOTOR ATAXY. A form of Spinal paralysis.

MACULE. Temporary or permanent spots on the skin.

MALASSIMILATION. Faulty digestion and improper nourishment.

Malingering. A term applied to feigning disease for improper objects.

Mania. Synonymous with most forms of insanity. MARSHALL HALL'S METHOD. A method of treating suspended animation.

MATURATION. Ripening, such as the full formation of pus in an abscess.

MELENA. Hamorrhage from the bowels.

MENINGITIS. Inflammation of the membranes of the Brain.

MENTAGRA. An eruption on the chin.
MIDRIFF. The Diaphragm.
MITRAL VALVE. The valve of the left ventricle of the Heart.

MOLLITIES. Softening of any part, though applied usually to the Bones.

MULTILOCULAR. Tumours having several cysts or cells.

MUSCE VOLITANTES. Small bodies which appear to float before the Eyes.

MYOPIA. Short Vision.

NARES. The cavities of the Nose.

NATES. The gluteal region or buttocks.

NOMA. A spreading ulcer of a malignant type. NUCLEUS. The solid centre of a Growth or Concretion.

OBSTRUENTS. Medicines which tend to close the natural passages.

Closure of a blood-vessel or cavity OCCLUSION. of any kind.

OLECRANON. The head of the Ulna, the elbow. ORPIMENT. The yellow sulphide of Arsenic.

OTALGIA. Earache. OTORRHŒA. Purulent discharge from the ear. OZENA. Offensive discharge from an Ulcer in the Nose.

PALUDAL FEVER. Marsh fever. Ague. PANNUS. Thickening of the membrane, covering the Cornea.

PAPAVER SOMNIFERUM. The white poppy, which yields Opium

PARENCHYMA. The spongy substance of organs,

as of the Lungs, &c.
PARONYCHIA. An abscess near the nail, Onychia. PARULIS. Gum-boil.

PEDICLE. A band of attachment to a Tumour.

Pellagra. Another name for Leprosy. PELVIMETER. An instrument for measuring the Pelvis.

A disease of the Skin. PEMPHIGUS.

PERCOLATION. Filtration, specially applicable to Tinctures.

The space between the anus and PERINEUM. scrotum.

Perinephritis. Inflammation round the Kidneys. Periosteum. The investing membrane of the Bones.

Pertussis. Hooping or whooping cough. Phalanges. The bones of the Fingers.

PHOSPHATIC DIATHESIS. A condition in which Phosphates appear in the urine.

Phymosis. An affection of the prepuce.

MATER. The vascular membrane of the brain and spinal cord. PIA MATER.

PITYRIASIS. A desquamative Disease of the Skin. PLACEBO. A prescription to please or soothe, Matter from which new bodies are

PLASMA. formed.

Plumbism. Lead poisoning.

PODAGRA. Gout which attacks the foot.

The department of Materia Medica Posology. which treats of doses.

POTT'S FRACTURE. Fracture of fibula and tip of tibia immediately above the Ankle.

PRESBYOPIA. Long sight, the common form of defective Vision in old people.
PRIMA VIA. The Alimentary Canul.

PRIMIPARA. A female in her first pregnancy.
PROPHYLAXIS. Measures intended to ward off disease.

PROTOPLASM. Germinal matter forming the basis

of Life.
Prosis. Paralysis of upper lid of the Eye.
Melignant Tunhus Figur. PUTRID FEVER. Malignant Typhus Fever.
PYELITIS. Inflammation involving Kidneys and

membranes about the pelvis.

RECRUDESCENCE. Return or relapse of a disease. RECTUS. A name applicable to several muscles of the abdomen.

REFLEX ACTION. A term denoting certain functions of the Nervous System.

REGURGITATION. Check to the natural flow of blood through the heart.

RESECTION. Excision of the ends of broken bones or of the ends of the bones forming a Joint.

RETROVERSION. An abnormal inclination of the Womb backwards.

RHINOPLASTIC. Employed to denote the method of making a new nose.

RHYTHM. The course of successive pulsations or sounds of the Heart.

RING FEMORAL. An internal opening in the groin through which the bowel passes in Rupture. RODENT ULCER. An ulcer having a tendency to

gnaw and destroy the skin. RUBEOLA. A cutaneous eruption of a dull rose hue. RUBEOLA. Measles.

RUPIA. A skin disease, associated with syphilis.

SARCOMA. Tumour of the consistence of flesh. SCLERIASIS or SCLEROSIS. A term usually applied to hardening of the nervous centres. Scorbiculus Cordis. The region underneath the

lower end of Sternum.

SCORBUTUS. Scurvy.
SCRIVENER'S PALSY. Writers' Cramp.
SCROTUM. The skin and investing membranes of the Testes.
SENSORIUM. The base of the Brain.

SEPTIC. Connected with poison or putrefaction. SEQUELE. The after consequences of disease.

SEQUESTRUM. An exfoliated portion of bone. SILVESTER'S METHOD. Means of restoring animation in Drowning, Suffication, &c.
SINGULTUS. Convulsive sobbing.

SORDES. The dark matter on the teeth.

SPHYGMOGRAPH. The instrument used for defining the character and beats of the Pulse.

SPICA. The name of a particular form of Bandage. SPINA BIFIDA. A congenital deficiency in the vertebral canal.

SPIROMETER. An instrument for ascertaining the

capacity of the Lungs. SPLINT BONE. The Fibula. SPUTUM. The Expectoration.

STAPHYLOMA. Protrusion from the front surface of the Eye.

STAPHYLORAPHY. The operation, for closing fissure of the Palate.

STHENIC DISEASE. Acute and inflammatory forms of Disease.

STOMATITIS. Inflammation of mucous membrane of Mouth.

STRABISMUS. Squint.

St. Vitus' Dance. Chorea.
Superfectation. Multiple Pregnancy.

SUSPENSORY. The name of a bandage or bagtruss for the scrotum.

Sycosis. A cutaneous eruption affecting the hairy parts of the face.

SYNTONIN. The chief constituent of Muscle.

TACTILE CORPUSCLES. The delicate nerve filaments of the papillæ of the Skin.

TACTUS ERUDITUS. The skilled sense of touch.
TALIPES. Club-foot.
TARSUS. Part of the foot between the Toes and the Heel.

THROMBOSIS. Coagula in the course of the Circulation.

TINEA. An eruption of the Skin produced by parasitic fungi.

TORMINA. A twisting or griping of the Intestines.

TORSION. Twisting the ends of blood-vessels to check hæmorrhage.

TORTICOLLIS. Wry Neck.

TOXEMIA. Another name for Blood Poisoning. TRANSFUSION. The name of the operation of injecting blood into the veins.

TRANSUDATION. The passage of fluid from one porous organ to another.

TRAUMATIC. Connected with wounds.

TRISMUS. Locked jaw.

TROCHANTERS. The processes at the upper extremity of the *Thigh bone*.

TYMPANUM. The drum of the *Ear*.

TYPHLITIS. Inflammation of the *Cœcum*.

UNILOCULAR. A cavity or Tumour containing one cyst or cell.

UREMIA. Blood poisoning induced by the retention of Urea in the Blood.

URIC ACID. A constituent of healthy Urine. URTICARIA. Nettle Rash.

UTERO-GESTATION. The interval of Pregnancy.

VARICELLA. Chicken Pox.

VARIX. A knotty and twisted state of the veins. VASELINE. Petroleum jelly.

VASO-MOTOR. A term applied to the Nerves which supply the Blood-vessels.

VEGETATIONS. Fungus growths either in the interior or on the external surface of the body. VERMICULAR. Peristaltic movement of the Intestines.

VIRUS. Poison or venom, applied usually to the Contagium of infectious diseases.
VITELLUS OVI. The yolk of Egg.
VITREOUS HUMOR. The chief fluid contained in

the Eye-ball.

VOCAL CHORDS. The elastic ligaments forming the sides of the Glottis.

WEBBED FINGERS. Adherent fingers, a congenital Deformity.

WHITE LEAD. Carbonate of Lead.

WHITE PRECIPITATE. A compound of Mercury and Ammonia.

WHITLOW. Onychia and paronychia.
WORMIAN BONES. Bones formed between the occipital and parietal bones.

YELLOW WASH. A lotion formed by the decomposition of corrosive sublimate and lime water.

# STANDARD BIBLICAL WORKS

BY THE REV. JOHN EADIE, D.D., LL.D.

In Large 8vo, Handsome Cloth, Gilt, 10s. 6d.; also in Half Moroccc for Presentation, 16s.

TWENTY-SEVENTH EDITION. Thoroughly Revised, and re-written, with many additional Articles. Reset throughout with new type.

PREFACE BY THE REV. A. H. SAYCE, M.A., LL.D., D.C.L., Professor of Assyriology at the University of Oxford, who has also contributed new articles on The Hebrews, Hittites, Sinai, Egypt, Division of Nations, &c.

THE REV. CANON TRISTRAM, M.A., D.D., F.R.S., has revised the Botanical,

Natural History, and other Subjects.

EADIE'S BIBLICAL CYCLOPÆDIA

Or DICTIONARY OF EASTERN ANTIQUITIES, GEOGRAPHY, AND NATURAL HISTORY, ILLUSTRATIVE OF THE OLD AND NEW TESTAMENTS.

Beautifully Illustrated with New Plates, specially prepared from Photographs of the Holy Land, Maps, and Engravings.

Important Revision throughout by

PROFESSOR W. M. RAMSAY, D.C.L., of Aberdeen;
PROF. VERNON BARTLET, M.A., of Mansfield College, Oxford;
THEOPHILUS G. PINCHES, LL.D., M.R.A.S. of the British Museum; and
REV. HENRY A. REDPATH, M.A., who contributes articles on 'The
Septuagint,' matter relating to 'The Apocryphal Books,' and other
valuable articles, besides exercising general supervision over the passage o the work through the press.

"Gipsy Smith says in the story of his life 'my first books were the Bible, an English Dictionary, and Professor Eadie's Riblical Cyclopadia."—Sunday School Chronicle.
"Those who have known the book in the past will MISS NOTHING that they have hitherto valued, while they will find a large amount of fresh matter, and the latest results of Archæological and Scientific while they will find a large amount of fresh matter, and the latest results of Archæological and Scientific criticism.

The Dictionary puts an ENORMOUS COLLECTION OF VALUABLE MATERIALS WITHIN HANDY REACH."—The Guardian.

SEVENTH EDITION. In Handsome Cloth. 7s. 6d.

## THE CLASSIFIED BIBLE:

An Analytical Concordance to the Sacred Scriptures.

EDITED BY JOHN EADIE, D.D., LL.D.

The Latest Press Appreciation.—"No Bible student, teacher, or preacher ought even to try to do without it. . . All Bible themes, even to the least important, are classified. . . . We have not references merely, which involves much time in hunting up the texts themselves, but we have all the text in full, so that the reader has lying before him all that the Bible says on the subject."

EADIE (Rev. Prof.): CRUDEN'S CON-CORDANCE TO THE HOLY SCRIPTURES. With Portrait on Steel, and Introduction by the Rev. Dr. King. Large 8vo. One Hundred and Fiftieth Thousand, Handsome cloth, 3/6.

\*.\* Dr. EADIE'S has long and deservedly borne the reputation of being the COM-PLETEST and BEST CONCORDANCE extant.

LOND N: CHARLES GRIFFIN & CO., LIMITED, EXETER STREET, STRAND

## MR. SOUTHGATE'S WORKS.

FIRST SERIES-THIRTY-SEVENTH EDITION. SECOND SERIES-TENTH EDITION.

# MANY THOUGHTS OF MANY MINDS:

In Square 8vo, Elegantly Printed on Toned Paper.

"The selection of the extracts has been made with taste, judgment, and critical nicety."— Morning Post.

Morning Post.

"This is a wondrous book, and contains a great many gems of thought."—Daily News.

"As a work of reference it will be an acquisition to any man's library."—Publishers' Circular.

"This volume contains more gems of thought, reflued sentiments, noble axioms, and extractable sentences, than have ever before been brought together in our language."—The Field.

"All that the poet has described of the beautiful in nature and art, all the axioms of experience, the collected wisdom of philosopher and sage, are garnered into one heap of useful and well-arranged instruction and amusement."—The Era.

Era. "The quotations abound in that thought which

is the mainspring of mental exercise."-Liverpool

is the mainspring of mental exercise."—Liverpool Courier.

"For purposes of apposite quotation, it cannot be surpassed."—Bristol Times.

"It is impossible to pick out a single passage in the work which does not, upon the face of it, justify its selection by its intrinsic merit."—Dorset Chronicle.

"We are not surprised that a Second Series of this work should have been called for. Mr. Southgate has the catholic tastes desirable in a good Editor. Preachers and public speakers will find that it has special uses for them."—Edinburgh Daily Review.

"No one who is in the habit of writing and speaking much on a variety of subjects can afford to dispense with Mr. Southgate's Works."—Glasgow News.

Glasgow News.

#### THIRD EDITION.

"So ADMIRABLE is this work, that it is difficult to imagine how it could be better."-Colliery Guardian.

## At Sea.

THIRD EDITION, Revises. Crown Svo, Extra

Handsome Cloth. 6s.

## A MEDICAL AND SURGICAL HELP

FOR SHIPMASTERS AND OFFICERS

MERCHANT NAVY. IN THE

INCLUDING

## FIRST AID TO THE INJURED.

BY WM. JOHNSON SMITH, F.R.C.S., Principal Medical Officer, Seamen's Hospital, Greenwich.

With Coloured Plates and Numerous Illustrations.

\*.\* The attention of all interested in our Merchant Navy is requested to this exceedingly useful and valuable work. It is needless to say that it is the outcome of many years PRACTICAL EXPERIENCE amongst Seamen.

" Sound, Judicious, REALLY RELPFUL,"-The Lancet.

"It would be difficult to find a Medical and Surgical Guide more clear and comprehensive than Mr. Johnson Smith, whose experience at the Greenwich Hospital eminently qualifies him for the task. . . A most attractive work. . . . We have read it from cover to cover. . . It gives clearly written advice to Musters and Officers in all medical and surgical matters likely to come before them when remote from the land and without a doctor. . . We recommend the work to giver Shipmaster and Officer."—Liverpool logged of Commerce. Journal of Commerce.

LONDON: CHARLES GRIFFIN & CO., LTD.; EXETER STREET, STRAND.
