# Standard Presentation Works.

In Two Vols. Handsome Cloth. Gilt top, 21s.

# A LITERARY HISTORY OF EARLY CHRISTIANITY.

BY THE REV. C. T. CRUTTWELL, M.A.,

Hon. Canon of Peterborough Cathedral; Formerly Fellow of Merton College, Oxford.

"It cannot be doubted that Mr. Cruttwell's method, although somewhat novel in English theological literature, is well adapted to harmonise with the dominant tendencies of modern religious thought.

The Times.

"The Sections on the Apostolic Fathers, the Apologists, and the Alexandrian writers are VERY successful and full of instruction. The translations which enrich the work—the Didaché, the Letter from the Churches of Lyon and Vienne, and the extracts from the lately-discovered Gospel of Peter-will certainly be heartly welcomed by many readers."—Theologisches Literaturblatt.

"Mr. Cruttwell's work betrays everywhere the heart and hand of the earnest admirer and scholaristudent. . . . We have interesting sketches and admirable translations of interesting documents and could wish there were more."—Manchester Guardian.

"Mr. Cruttwell's success in making early Christian literature interesting to the 'general reader' of to-day is GREAT."—Scotsman.

In Demy 8vo. Handsome Cloth. Gilt top, 21s.

# PREHISTORIC ANTIQUITIES OF THE ARYAN PEOPLES.

BY DR. O. SCHRADER, OF JENA.

Translated from the Second German Edition by F. B. JEVONS, M.A., Author of "A History of Greek Literature."

"Dr. Schrader's GREAT WORK."-Times.

"Mr. Jevons has done his work EXCELLENTLY."-Saturday Review.

"It would be hard to find any book more to be recommended."—Classical Review.

"Deserves richly the rank, which has been so generally accorded to it, of a first-rate authority." -

"Interesting from beginning to end."-Manchester Guardian.

Second Edition. With very Numerous Illustrations. Handsome Cloth, 6s.

Also Presentation Edition, Gilt and Gilt Edges, 7s. 6d.

## THE THRESHOLD OF SCIENCE:

Simple and Amusing Experiments (over 400) in Chemistry and Physics.

## BY C. R. ALDER WRIGHT, D.Sc., F.R.S.,

Late Lecturer on Chemistry, St. Mary's Hospital Medical School.

"Any one who may still have doubts regarding the value of Elementary Science as an organ of education will speedily have his doubts dispelled, if he takes the trouble to understand the method recommended by Dr. Alder Wright."—Nature.

"Step by step the learner is here gently guided through the paths of Science, made easy by the perfect knowledge of the teacher, and made flowery by the most striking and curious experiments. Well adapted to become the TREASURED FRIEND of many a bright and promising lad."—Manchest r Examiner.

LONDON: CHARLES GRIFFIN & CO., LIMITED, EXETER STREET, STRAND

Presentation Edition, cloth and gold, 12s. 6d. each volume Library Edition, half-bound, roxburghe, Do., morocco antique, 21s.

Each Series is complete in itself, and sold separately.

### OPINIONS OF THE PRESS.

dently the produce of years of re-search. We look up any subject under the sun, and are pretty sure to find something that has been said—generally well said—upon it."

-Examiner.

"Many beautiful examples of thought and style are to be found among the selections."-Leader.

"There can be little doubt that it is destined to take a high place among books of this class."—Notes and Queries.

"A treasure to every reader who may be fortunate enough to possess it. Its perusal is like inhaling essences; we have the cream only of the great authors quoted. Here all are seeds or gems."—English Journal of Education.

"Mr. Southgate's reading will be found to extend over nearly the whole known field of literature, ancient and modern."—Gentleman's

Magazine.

"Here is matter suited to all tastes, and illustrative of all opinions; morals, politics, philosophy, and solid information. We have no hesitation in pronouncing it one of the most important books of the season. Credit is due to the publishers for the elegance with which the work is got up, and for the extreme beauty and correctness of the typography."—Morning Chronicle.

"Of the numerous volumes of the kind, we do not remember having met with one in which the selection was more judicious, or the accumulation of treasures so truly wonderful."—Morning Herald.

"Mr. Southgate appears to have ransacked every nook and corner for gems of thought."—Allen's Indian Mail.
"The selection of the extracts has "The halds is rated and the greatest thinkers of all ages."—Star.

"The work of Mr. Southgate appears to have grand conversatione with the greatest thinkers of all ages."—Star.

"The work of Mr. Southgate far outstrips all others of its kind. To the selection of the extracts has "The selection

been made with taste, judgment, and critical nicety."—Morning Post.
"This is a wondrous book, and

"This is a wondrous book, and contains a great many gems of thought."—Daily News.

"As a work of reference, it will be an acquisition to any man's library."—Publisher's Circular.

"This volume contains more gems of thought, refined sentiments, noble axioms, and extractable sentences, than have ever before been brought together in our language."—The Field.

"Will be found to be worth its weight in gold by literary men."—The Builder.

"All that the poet has described of the beautiful in nature and art; all the wit that has flashed from pregnant minds; all the axioms of

pregnant minds; all the axioms of experience, the collected wisdom of philosopher and sage, are garnered into one heap of useful and well-arranged instruction and amusement."—The Era.

ment."—The Era.
"The mind of almost all nations

"The mind of almost all nations and ages of the world is recorded here."—John Bull.

"This is not a law-book; but departing from our usual practice, we notice it because it is likely to be very useful to lawyers."—Law Times.

"The collection will prove a mine, rich and inexhaustible, to those in search of a quotation."—Art Journal.

"There is not, as we have reason to know, a single trashy sentence in this volume. Open where we may, every page is laden with the wealth of profoundest thought, and all of profoundest thought, and all aglow with the loftiest inspirations of genius. To take this book into our hands is like sitting down to a

and the essayist, 'Many Thoughts of Many Minds' cannot fail to render almost incalculable service."

—Edinburgh Mercury.

"We have no hesitation whatever in describing Mr. Southgate's as the very best book of the class. There is positively nothing of the kind in the language that will hear a

very best book of the class. There is positively nothing of the kind in the language that will bear a moment's comparison with it."

—Manchester Weekly Advertiser.

"There is no mood in which we can take it up without deriving from it instruction, consolation, and amusement. We heartily thank Mr. Southgate for a book which we shall regard as one of our best friends and companions."

—Cambridge Chronicle.

"This work possesses the merit of being a magnificent gift-book, appropriate to all times and seasons; a book calculated to be of use to the scholar, the divine or the public man."—Freemasons' Magazine.

"It is not so much a book as a library of quotations."—Patriot.

"The quotations abound in that thought which is the mainspring of mental exercise."—Liverpl. Courier.

"For purposes of apposite quotation, it cannot be surpassed."—Bristol Times.

"It is impossible to pick out a single passage in the work which does not upon the face of it, justify its selection by its intrinsic merit."—Dorset Chronicle.

"We are not surprised that a SECOND SERIES of this work should have been called for. Mr. Southgate has the catholic tastes desirable in a good Editor. Preachers and public speakers will find that it has

in a good Editor. Preachers and public speakers will find that it has special uses for them."—Edinburgh Daily Review.

"The SECOND SERIES fully

"The SECOND SERIES fully sustains the deserved reputation of the FIRST."—John Bull.

## NOTE TO THE THIRTY-NINTH EDITION.

Since the issue of the previous edition of this work, every article has been carefully revised by the Editor, and where necessary has been altered to bring it into harmony with recent progress in medical science. Some articles have been largely re-written; and some additional subjects have been introduced with the object of increasing the usefulness of the work, and maintaining its reputation as a reliable guide.

As it is addressed largely to those who may be in situations where qualified medical aid is difficult of attainment, simplicity and clearness of language have been studied, and technical scientific nomenclature as far as possible avoided. It is hoped that it will thus continue to be in the future, as it has been in the past, both a work of reference for the general public, and of advice and instruction for the missionary, the settler, and the emigrant. It is issued at a low price to meet the popular demand.

LONDON, January, 1911.

## PREFACE

Since the first issue of Dr. Spencer Thomson's well-known Dictionary of Domestic Medicine and Household Surgery, now some thirty years ago, it has passed through sixteen large editions, a fact which testifies to public appreciation of its usefulness.

It is evident, however, that the vast changes which have taken place in this interval in the twin departments of Medicine and Surgery have not been without their influence on the more modest domain of Domestic Medicine. This fact was recognized by the publication, in 1864, of a Revised Edition of the work, embodying the improvements of that day; and now again the volume is once more presented to the public, after being thoroughly revised and recast, with the view of rendering it still more in harmony with our advanced knowledge and experience.

In the new issue the present Editor has had the valuable co-operation and assist ance of Dr. Thomson, who although unavoidably prevented from undertaking the supervision himself, has nevertheless found time to contribute many excellent notes and suggestions, which have been incorporated with the text.

The plan of the work, as indicated in the original preface by the Author, has been steadily adhered to, and what may be termed the "boundary line" between domestic and professional medicine, has been kept, it is hoped, sufficiently clear to prevent the possibility of error. Each article has been submitted to a thorough revision, and in some cases rewritten, while numerous additions and alterations have been made where necessary.

Much of the new matter introduced belongs specially to that branch of knowledge known as Preventive Medicine. Questions associated with Public as well as Individual Health (more especially in reference to the conditions under which it is maintained, or may become deteriorated) are discussed in the various articles bearing on Sanitation, while other matters of a more strictly medical and scientific character have had their due share of attention. The increasing desire among all classes to become acquainted with the elementary principles of the Healing Art—in the largest acceptation of the term-evidenced by the Ambulance Classes established by medical men in all parts of the country, the efforts made for the systematic training of Nurses for the sick, the voluntary adoption of Nursing as a vocation by ladies of refinement and culture, and, above all, the great advances made of late years in Sanitary Knowledge and Legislation, have rendered it necessary to devote considerable space to these and kindred subjects. For it cannot be too strongly impressed on the lay reader, that the highest aims of Medicine are far removed from the mere administration of drugs, and that the best and almost the only means of preserving health is a strict adherence and attention to those natural laws which govern our well-being, and which, daily experience is ever reminding us, cannot be disregarded with impunity.

On the other hand, occasions arise in the lifetime of every one when an acquaintance

viii PREFACE.

with the various forms of disease and casualty, together with the most approved methods of dealing with them, may prove of the greatest service, perchance may save life; and this, the second great aim of the work, Remedial Medicine—comprising the Treatment of Disease and the Measures necessary for Restoration to Health—has been amply considered from a domestic stand-point. In this the Editor has kept specially in view the circumstances of those to whom in time past the book has proved of the greatest utility; and the needs of colonists and emigrants from the mother country, of missionaries and the clergy in remote districts, and of many others whose lot is cast far away from professional assistance—have been fully considered.

Many new engravings have been introduced—illustrating subjects connected with the anatomical and physiological relations of the body—and designs of improved Surgical and Sanitary appliances.

To render the information more readily accessible, a Table of Contents, with references to articles bearing on kindred subjects, has been prefixed. A Glossary is further appended of such medical terms in frequent use as have not found a place among the alphabetical headings of the Dictionary; and Dr. Anderson's excellent Monograph on the Management of the Sick-Room, contributed to a former edition, appears again with slight abridgment.

In conclusion, the Editor can but express his sincere hope, in which the Author unites, that in its New Form the work may enter once more on a fresh and prolonged career of usefulness, and be found, as heretofore, a trustworthy counsellor and guide, and a ready help in the emergencies of daily life.

GUY'S HOSPITAL, December 1882.

## AUTHOR'S ORIGINAL PREFATORY ADDRESS.

THAT works professing to afford popular information on medical subjects may thoroughly answer the purpose for which they are designed, one especial point requires ever to be kept in view-the information given must be safely usable by those who are put in possession of it. It is an objection frequently adduced against such works, that they place a little dangerous knowledge in the hands of the public, in a form so apparently simple as to make it a source rather of evil than of benefit, and undoubtedly the allegation has in some respects been correct. But is it necessary, in preparing a work on domestic health, to incur this hazard? I think not. For without entering upon that difficult ground which correct professional knowledge and educated judgment can alone permit to be safely trodden, there is a wide and extensive field for exertion and for usefulness open to the unprofessional, in the kindly offices of a true Domestic Medicine; the timely help and solace of a simple Household Surgery; or, better still, in the watchful care, more generally known as "Sanitary Precaution," which tends rather to preserve health than to cure disease. "The touch of a gentle hand" will not be less gentle because guided by knowledge, nor will the safe domestic remedies be less anxiously or carefully administered. Inseparably connected with the intelligent use of these remedies, there must be correct general ideas respecting the anatomical arrangements and physiological requirements of the human frame. This also has been objected to. I hesitate not to say, that it is such knowledge as ought to be in the possession of every responsible man. Making apparent the importance and rational foundation of the means of preserving or of invigorating health, or of restoring it when impaired, it renders submission to the requirements of those means a more sure and cheerful service, when rendered to the conviction of the understanding rather than to the dictum of an adviser. Amid the humbler classes especially, the diffusion of such knowledge is highly requisite as a counter-agent to the impudent quackery which preys upon the credulity and the lamentable ignorance of the simplest principles or health, which pervade the mass of the people.

But health will fail, either in old or young, and accidents will happen, in spite of the most careful precaution; it then becomes a question, how far non-professional interference may go. In many of the emergencies and accidents of daily life, even in a settled country, but more especially in the thinly peopled colonies, ready information respecting what is best to be done, possessed by a neighbour or a bystander, is often of the most essential service; indeed, every medical man must have witnessed how much mischief may result, either actively or passively, and in a very short time, from ignorance of even the most obvious and common-sense modes of treatment. The information upon these points, given in a popular work, can scarcely be too full or too accurate. In the requirements of Household Surgery, or of sudden emergency, such as Poisoning, Burning, &c., the question is, "What must be done?" Generally speaking, little or no skill is requisite to determine the nature of the case, or of the injury, which is often too apparent—the anxious question "What must we do?" is that which calls for answer; and if, sometimes, it happens that the exact nature of the accident be not sufficiently evident, that is no reason why knowledge on the subject generally, aided by common sense, may not do much to relieve. Life may be saved, suffering may always be

alleviated. Even to the resident in the midst of civilisation, the "Knowledge is Power" to do good; to the settler and the emigrant, it is invaluable.

We come to a point more liable to cavil—the actual treatment of disease, properly so called, by the unprofessional, and how far it is well to afford information which may tempt the rash to use that which education only can safely employ. It may be trite, but it is true, that in order to treat a disease safely, and with benefit, we must learn its nature. Now, when it is remembered how the nicest judgment that observation and experience can form, the most patient attention, aided by practised ear and eye, by microscope and test tube, are frequently necessary to enable the conscientious physician to judge of his case before he can apply the remedy, it is evident how great must be the responsibility of those who, in rashness or ignorance, venture upon the treatment of serious disease, either in their own persons or in those of others; incapable of judging of its nature, still less capable are they of selecting the appropriate treatment. There is, however, a vast difference between the management of real disease and of ordinary ailment—between endeavouring to strike at the root, or only to relieve the symptoms. Any unprofessional man, or woman either, in this kingdom, who, with all facility that there is for procuring skilled advice, ventures to take the medical management of a case of real illness, acts most unwarrantably; but there are numbers of lesser ailments, many of the more painful incidents and symptoms, simply and easily removable by means which all may employ, and with which it is most important that all should be acquainted; which the parent may use to the child, or the pastor recommend to his parishioners, without fear.

One step further. If danger may result from rash treatment, none can arise from a general acquaintance with the most prominent symptoms which herald the approach of dangerous sickness; these, I think, should be made known; whilst all remarks upon the management, whether limited as for use in this country, or more extended for the sake of the dweller in remote or unsettled districts, I trust so to guard as to make

them safe and useful guides.

I know well what is said by a few about injuring the medical profession, by making the public their own doctors. Nothing will be so likely to make "long cases," as for the public to attempt any such folly; but people of moderate means—who, so far as medical attendance is concerned, are worse off than the pauper—will not call in and fee their medical adviser for every slight matter, and in the absence of a little knowledge, will have recourse to the prescribing druggist, or to the patent quackery which flourishes upon ignorance, and upon the mystery with which some would invest their calling. And not patent quackery alone, but professional quackery also, is less likely to find footing under the roof of the intelligent man, who, to common-sense and judgment, adds a little knowledge of the "whys and wherefores" of the treatment of himself and family. Against that knowledge which might aid a sufferer from accident, or in the emergency of sudden illness, no humane man could offer or receive an objection.

SPENCER THOMSON.

## DICTIONARY OF DOMESTIC MEDICINE.

ABDOMEN (figs. 1 and 2).—The abdocontaining the alimentary and other organs, which extends from the lower part of the walls of the chest to the bones of the pelvis. walls of the chest to the bones of the pelvis. It is bounded above by a strong muscle called the diaphragm, which separates the organs contained in the chest from those of the abdomen, and below by the bones of the pelvis. The cavity is partially divided into two anatomical parts by the brim or crest of the pelvis, but the divisions are so incomplete that they are better treated as any complete that they are better treated as one cavity. The enclosing walls of the abdomen are formed by muscles, tendons, and strong membranes, which, along with the support of the spinal column, furnish a means of protection from injury, while allowing freedom of action for the bowels. To facilitate description medically, the abdomen is mapped out into regions by horizontal and vertical lines; the intermediate spaces corresponding with, and consequently indicative of, the position of the internal organs, are represented in the illustration (fig. 1). The two cross lines divide the cavity into three zones, an upper, middle, and a lower, and with the two perpendicular lines, it is further subdivided into nine regions, viz., 1, epigastric, over the stomach; 2, umbilical or navel portion; 3, hypogastric; 4, 4, right and left hypochondriac; 5, 5, right and left lumbar; and 6, 6, right and left iliac.

When the abdomen is opened the organs or

viscera, as they are often termed, are seen to consist of two groups, an upper and lower, upper group comprises the liver, stomach, and spleen, and the first part of the small intestine; remaining organs placed in the cavity

The liver and gall bladder (1) (fig. 2), inverted men is the name given to that large cavity in the drawing, are situated in the upper zone,

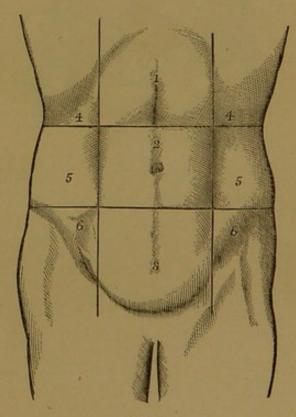

Fig. 1.

situated in the same zone, with its small end occupying the greater part of the cavity. The in the centre or epigastric, and its large end in the left hypochondriac region, where it is spleen, and the first part of the small intestine; in contact with the spleen or milt (3); the the lower includes the remaining portion of the small, and is surrounded by the large intestine, stomach. The middle zone is the site of the which, dipping into the pelvis, has its termination in the rectum. The bladder, the womb in the female, and the kidneys and large bloodand lower portion of the kidneys; the remains vessels situated behind, make up the principal ing parts being situated in the upper zone, but too deep-seated to be shown in the figure.

ABL ABL

numerous convolutions of the small intestine centrally (7), as well as on the right side, the

Fig. 2.

commencement, and on the left side the termination, of the large intestine in the sigmoid flexure, and the bladder in the case of children. All the parts or viscera named are covered and supported by a smooth, glistening, and moist membrane, the peritoneum, by far the most extensive and complex investing membrane of the body. It is continuous throughout its whole extent, and may be traced from one end of the cavity to the other, dipping into the spaces between the organs, and forming folds or ligaments to keep them in position, or to facilitate their movements. It also traverses the pelvic cavity, investing the bladder and rectum, and in the case of the female, the womb and its appendages. Both bladder and womb, when distended, rise from their own proper cavity into that of the abdomen. The viscera of the abdomen are divided into solid and hollow; of the former, the liver is an example; of the latter, the intestines and bladder. These, of course, give different sounds, when the covering of the abdomen, beneath which they lie, is slightly struck with the finger-a fact of great importance to the physician, in his examination of this cavity. The contents his examination of this cavity. The contents of the abdomen shift their position considerably according to posture. The diseases to ably according to posture. The diseases to which they are liable will be noticed under their respective heads. One of the most imhair-glove may be substituted. It is certainly

The lower zone also indicates the position of | portant accidents to which this cavity is subject, is protrusion of a portion of its contents through its walls, constituting hernia, or rupture. Accidental wounds penetrating the cavity of the belly are very generally fatal, and if they pierce any of the viscera, almost necessarily so. Within the last few years, however, surgeons have had much less hesitation than formerly in performing operations which required the abdominal cavity to be opened. The employment of antiseptics has of course aided

Refer to—Diaphragm — Liver — Stomach — Peritoneum—Rupture—Intestines.

ABLUTION.—Washing the surface of the body regularly, is, happily, in this country at least, becoming daily more common, but it is far from being so general a habit as it ought, particularly among the working-classes, who stand most in need of it; many go from January to December without even thinking it necessary to wash more than the face or hands. The skin ought continually to be throwing off, or excreting, gaseous, saline, and greasy matter, which it is necessary for the health of the body should be thrown off; but the skin cannot do this properly if caked over with perspiration and dirt, either its own or the dust to which many are exposed in the performance of their employments. The consequence of neglect is, that much is retained in the system which ought not to be there; an additional load of duty is thrown upon other excreting organs, as the liver and kidneys, and if they have not the power to compensate for man's own carelessness, languor, low spirits, headaches, local accumulations of blood, gout, gravel, and other diseases are the result. Fortunately, complete neglect cannot entirely stop the skin's functions, otherwise death itself must result. For the purpose of cleansing the skin, soft water ought to be used, if possible, with soap, -good brown is quite the most effectual, -and a thorough purification of the entire surface of the body should be effected once a week, at least, with these materials; along with this, washing over the surface with simple water, and rubbing well with a rough towel, every night or morning, as most convenient, will suffice to preserve a healthy state of skin. Those who are robust, and wash in the morning, ought to use cold water immediately on rising, while heat is abundant; but delicate persons cannot sustain the depression and subtraction of animal heat which this occasions; it leaves them chilled, languid, and with impaired digestion. There are some individuals, in whom cold sponging in the morning invariably produces heart-burn and indigestion after breakfast; such ought to try the water slightly warm, or content themselves with washing only a portion of the skin each morning; if even this cannot be borne, dry friction with a rough towel or

ABO ABO

a fact, that in many persons, and especially those of gouty habit, the use of the cold bath, in the morning, is injurious, unless it be followed by active exercise, which thoroughly kind, are dangerous. This is a very cogent restores the excretory functions of the skin. After washing, it is always desirable to rub the surface thoroughly with a towel till a warm glow is produced. For washing at night, water slightly warm is always to be preferred. The feet require very frequent washing. It is surprising how insensible individuals, even otherwise respectable, are upon this point; were it not so, they would never expose themselves to medical men in the disgusting state of dirt they frequently do. Happy are those who can have the use of baths for the purposes of ablution, but any man who can command water and a towel need not dispense with the luxury. For the aged, frequent and thorough ablution is most requisite; the often shameful neglect of this by those who have the care of old people, is visited upon them in querulousness, and troublesome bodily ailments, which attention to the duty would have prevented. When patients are confined to bed, it is very necessary that they should be washed or sponged daily, and afterwards carefully dried with a towel, well aired. This is the best preventive for bed sores, which are most liable to occur on the backs of dirty and neglected patients.

Refer to—Bath—Children—Skin.

ABORTION-MISCARRIAGE.-The terms abortion and miscarriage are applied to the expulsion of the human feetus from the womb of the mother, previous to the sixth month of pregnancy, that is, before it is sufficiently developed to maintain its own independent existence; when the process occurs after that period, it is named premature labour. Miscarriage involves pain and weakness, in addition to the loss of offspring, and is often a severe trial to the maternal constitution. It may occur at any period of pregnancy, but particular stages are more liable to the accident than others; these are generally considered to be at the times at which menstruation would have occurred if conception had not taken place, more especially from three to five months after conception. When abortion has once taken place, it is more liable to occur again, and some have so strong a tendency to it, that they never go beyond a certain stage, at which they invariably miscarry. The cause of abortion may exist in the constitution of the female herself, and be the result of weakness and irritability, of over full habit, or of a diseased condition of the womb; the fœtus may die, or be deficient in development, when it is cast off like a blighted fruit. Suckling after conception has taken place, is not unfrequently

of strong purgatives, particularly of the aloetic kind, are dangerous. This is a very cogent reason, for those who are pregnant, avoiding all quack aperient medicines; they almost all contain aloes, and may be very injurious. All undue exertion or agitation of body or mind, sudden jerks or jumps, riding on horseback in the early, or in a shaking carriage in the later, stages of pregnancy, may any of them bring on the mishap; to these may be added, exertion of the arms in doing anything on a level above the head; costive bowels and straining consequent thereon, sensual indulgences, and luxurious habits. Those who have once aborted ought to be extra careful in succeeding pregnancies, and all ought to bear in mind the possibility of the occurrence. The symptoms of threatened abortion vary with constitution; in the strong and plethoric, it is often preceded by shivering and febrile symptoms, and by feeling of weight in the lower bowels; in the weak, there is languor and faintness, flaccidity of the breasts, and general depression, and pains in the back and loins. Intermittent pains, and discharge of blood from the passage, tell that the process has begun. If miscarriage occurs within the first month or two after conception, the process may be accomplished with so little inconvenience as to escape notice, and to be mistaken for a menstrual period; more generally, however, the severity of the pain, and unusual clotted discharge, render the case evident. The pain, the discharge, and at the same time the danger of an abortion, are in proportion to the advancement of the preg-When miscarriage goes on, the pains increase in force and frequency, and continue with discharge of blood, fluid, or in clots, until the ovum is expelled; after which, both become moderated, till they cease altogether, and the red flow gives place to a colourless one. It is very important that those in attendance upon the patient should examine every clot which comes away, -if large, tear it in pieces, that they may ascertain whether the contents of the womb are expelled or not, for there is no safety or rest where miscarriage is progressing, till this has taken place, and everything cast When a medical man is in attendance, and in such cases he ought to be, all should be reserved for his inspection.

As soon as a woman experiences threatenings of abortion, she ought at once to retire to bed upon a mattress, and keep perfectly quiet till every symptom has disappeared: sometimes this simple measure, promptly adopted, is sufficient to avert the threatened evil. If there is much feeling of fulness, and the patient is of full habit generally, eight or a dozen leeches may be applied to the lower part a cause of miscarriage. Active disease occurring during pregnancy, such as severe inflammation, fevers, eruptive fevers, &c., is almost of carbonate of soda and tartaric acid, or lemon

juice; or if the bowels are much confined, much stimulant; nevertheless, wine or malt Seidlitz powders or Epsom salts, taken in liquor may be requisite. Convalescence is to a tumbler of warm water. When the pains are severe, particularly in the weak and irritable, twenty or thirty drops of laudanum should be given, and may be repeated in a few hours if the symptom is unabated. In the case of profuse discharge, the patient should be kept very lightly covered, movement avoided, and every article of food or drink given cold, iced if possible, provided the vital powers are not excessively reduced, cloths dipped in cold or iced water should be applied to the lower part of the body, and frequently changed; acid drinks, with cream of tartar, may be given freely. Ten or fifteen drops of diluted sulphuric acid, or of aromatic sulphuric acid, may be given in a wine-glassful of water every two or three hours. Should slight faintness come on, it is better not interfered with, it may be salutary; if it goes to an extent to threaten life, stimulants, sal volatile, or brandy and water must be had recourse to. But long before matters go to this extent, proper medical assistance should be sought. Profuse and continued discharge, though it may not threaten life, must occasion weakness which is long of being overcome, and which may ultimately favour the development of fatal disease. The discharge may be kept up, solely, by a state of matters beyond the offices of domestic management, but to be speedily rectified by a little manual interference on the part of the medical man, who, by assisting the womb to cast off the already partially expelled contents, at once puts an end to further loss of blood. But even if matters be not sufficiently advanced to admit of this interference, the use of measures or remedies which the unprofessional cannot or ought not to employ, may save life, must save strength. Let no one think lightly of loss of blood; it saps the foundations of health. Circumstances may occur in which medical assistance is not to be obtained, at least not speedily, and flooding is profuse, and uncontrolled by the means already mentioned; in such a case, one grain and a half of sugar of lead made into a pill with crumb of bread, may be given every two hours, and washed down with a draught of vinegar and water, to which, if there is much pain, from five to ten drops of laudanum are to be added; in addition, pieces of linen or calico, soaked in a strong solution of alum, or decoction of oak-bark, and oiled, are to be used to plug the passage, or the astringent fluid may be thrown up with a syringe. It is repeated, the unprofessional should never adopt these measures, if professional advice is to be had; if not, it is better they should do so than matters go on uncontrolled. Both during the time, and after miscarriage, the general strength must be supported; this is better done by must be supported; this is better done by strong animal soups, milk preparations, with in a cavity, formed in the substance of any of eggs, and meat, when it is proper, than by the bodily tissues, is named an abscess. The

be assisted by tonic medicines, those containing mineral acid, bark, or iron, are generally the most appropriate. The bowels, as indeed they do throughout, will require attention. Castor oil is very suitable; the cold or very cool water enema is most useful: a drachm of Epsom salts, dissolved in half a pint of water, either cold or slightly warmed, and fifteen drops of dilute sulphuric acid added, forms a most appropriate aperient, which should be taken before breakfast.

Three principles of treatment are to be kept in mind in the management of miscarriage.

The first, to prevent it, if possible, by rest,

opiates, &c.

The second, to allay pain; to moderate the discharge of blood; save and support strength. The third, when abortion must take place,

to expedite the separation of the ovum.

The two first may be much assisted by judicious domestic management, the third must be done by the medical attendant only.

Refer to-Pregnancy-Hæmorrhage.

ABRASION.—An abrasion, by which the outer or scarf skin, or cuticle, is forcibly removed, and the sensitive surface of the under true skin or cutis exposed, is a trifling, but sometimes a painful accident, and it may be, where the hands are necessarily subjected to the action of poisonous or irritating fluid, a dangerous one. The protecting cuticle is quickly restored; in the meantime it is necessary to provide a substitute. It must be an unirritating one. Persons often err by putting the common diachylon-plaster on abrasions, and frequently much irritation and pain, and sometimes ulceration, is produced by it. Courtplaster does not irritate, but is not useful for a large surface, in which case gold-beater's leaf is quite the best application, if not exposed to moisture. Collodion has been used of late; it is not soon acted upon by water, but it causes severe smarting when first put on; this may be prevented by putting gold-beater's leaf next the sore, and collodion over. In the absence of the above, a little strong gum mucilage with a piece of tissue paper over, is a good substitute. Isinglass plaster is used; those who are not in the habit of applying it find a difficulty in making it adhere. The principle in treating an abrasion is to protect the sensiin treating an abrasion is to protect the sensitive true skin by some light, perfectly unirritating, dry application, till nature restores the natural covering. A mixture of one part of collodion with two parts of castor oil applied over an abrasion or burn, forms a smooth elastic covering or artificial cuticle. The smarting caused by the first application soon

contained matter or pus may be either of a | changed for simple water-dressing, which must healthy or of an unhealthy character; if the former, it is of a yellowish-white colour, creamlike in consistence, and possessing a faint sickly odour; in the latter case it may resemble whey, with bits of curdy substances floating in

it, or it may be bloody, feetid, &c.

Abscesses are either acute or chronic, and may occur in nearly every tissue of the body. The first symptoms of an acute abscess are heat and tenderness of the part, followed by throbbing pain. If the matter is deeply seated, no external marks may be visible for a time; when it is near the surface, the skin quickly exhibits inflammatory swelling; this continuing, it becomes thinner with more or less rapidity, until, at last, it gives way, and permits the matter to escape. Such is the natural course of what we may call a healthy abscess; but that course is necessarily modified by the position and coverings of the collection of matter. Abscesses do not always discharge through the skin, they may do so internally. Generally, as soon as the contents of an abscess are discharged, the pain which has previously been severe, ceases. Boils may be classed as abscesses; they contain a distinct core or slough. Chronic abscesses may continue for weeks or months without change, but give comparatively little pain; they occur in weak or scrofulous subjects, and very generally in glandular tissues. In addition to pain and swelling, the sense of fluctuation, as of fluid contained in a bag, which an abscess conveys to the finger, is a symptom valuable in obscure cases; but when it is most valuable, it requires the educated touch of the surgeon to discover it. On the first suspicion of an acute abscess, frequent fomentation with water as hot as it can be borne, may succeed, if purgative medicine be given at the same time, in preventing its formation; but if it does not do this, it will then assist and hasten its progress, while it soothes pain. When it is tolerably certain that matter is formed, thick, warm, soft poultices must be continually applied to the part, the position of which should be regulated with as much regard to ease as possible. It is sometimes the popular custom to apply irritants, such as honey, soap-and-sugar, and such like, to boils or abscesses, with the view of assisting or "breaking" them; the practice is both hurtful and cruel, and ought never to be followed. For fomentation, simple water; and for poultice, bread or linseed, are most generally applicable; when there is much pain, decoction of poppy-heads may be used for either, with advantage. Medical men are in the habit of opening abscesses, or boils, with the lancet or knife, but as to do this safely in every case requires anatomical knowledge, the unprofessional should be content with simply relieving and assisting the painful progress by the means mentioned, till the matter is discharged natu-

be continued till the part is well. A little opening medicine should at the same time be given. Many persons are in the habit of squeezing abscesses after the matter discharges; the practice is useless and painful; very gentle pressure only is admissible. A chronic abscess is serious, from the indication it gives of a weak and unhealthy condition of body, and may also be so from size or position. The formation of an acute abscess is generally accompanied with more or less general inflammatory fever. In a chronic abscess, when there is fever, it has more of the hectic character, and is accompanied with night perspirations. A chronic abscess usually requires speedy evacuation artificially, and constitutional treatment is always called for: the first ought always to be done by a medical man, and the latter also, to be effectually carried out. Good light nourishment, with a due proportion of animal food, is indispensable; milk, if it agrees; wine or malt liquor, if there is not much fever. Regulation of the bowels by simple aperientsiron, mineral acid, with infusion of bark, and cod-liver oil, are the most generally applicable remedies in the constitutional treatment of chronic abscess.

dressing—Fever-hectic—Spine.

ABSINTHE or ABSINTHIUM —
wormwood—has long been used as a bitter tonic and as a worm remedy, both in this country and on the continent. It is omitted from the British Pharmacopœia, and its place is very properly taken by the active principle called santonin, which is one of the most valuable additions to our stock of medicines. There are various species of Artemisia absinthium, the unexpanded flower heads of which constitute santonica, from which santonin is prepared. Absinthe is also the name given to an intoxicating drink, much used in France, Algiers, &c.; its effects are thus described:-

Absinthism. — According to Dr. Decaisne, the consumption of absinthe has of late years increased to an enormous extent in France. It is made by infusing in alcohol ends of wormwood, both major and minor (sommités d'absinthe, from which the liquor takes its name), angelica root, Calamus aromaticus, aniseed, dittany seeds, and common marjoram. Some distillers, however, vary the recipe, and use fennel, mint, and balm. The concentration of the degree of the alcohol is generally very high. Indigo, tincture of turmeric, juice of hyssop, and nettles, are called to aid to improve the colour and appearance of the pernicious draught. The effect of absinthe is to produce a superabundant activity of the brain, a cerebral excitement which at first is agreeable. The intoxication "comes on rapidly, the head swims, and the effect produced is nearly the same as that of poisoning by a narcotic, which certainly does not rally. After this happens, poulticing ought to poisoning by a narcotic, which certainly does not be persevered in for a few days, and then ex- occur with an equal dose of brandy. With the absinthe-drinker, as with the brandy-drinker, the excitement the liquor produces diminishes daily in intensity. Each day he is obliged to augment the dose, in order to screw himself up to the right pitch." The diseases brought on by drinking brandy are produced much more rapidly by the use of absinthe. One of the greatest dangers of absinthe, says Dr. Decaisne, consists in its adulteration. Dr. Decaisne has observed more than 150 cases of chronic absinth-

ism, and concludes that absinthe ought to be prohibited. He has convinced himself that absinthe, even of good quality and in moderate doses, sooner or later invariably produces disorders in the human economy. He considers that the extent to which it is now consumed in France demands the intervention of Govern-

ment. He declares that the pale green demon has invaded all classes of society, the idler and the workman, the soldier and his officer; all professions, those who work with the brain, and those who work with the hand, swallow it with

frenzied eagerness.

ABSORBENTS.—Absorbents are minute vessels distributed throughout the body, the office of which is to take up nutritive material, and convey it into the current of the general circulation. The lacteal absorbents are those which take up the nutrient portion of the food, named chyle, from the alimentary canal; they unite in one common trunk, which runs up in front of the spine, and joins the large veins going directly to the heart. (See Digestion.) Soon after a full meal, these lacteal absorbent vessels become distended with the milky-looking chyle, the essential nutriment, separated from the food by the first process of digestion. As this chyle has to pass through a set of small glands—the mesenteric—before it can reach the blood, it must be evident how much the health of the latter fluid, and the nutrition of the body generally must be interfered with, when these glands become diseased, as they frequently do in children.—See Tabes.

The lymphatic absorbents are distributed throughout the body, and take up and convey back to the general circulation whatever nutrient matter is fit to re-enter the blood. The accompanying illustration (fig. 3) represents the superficial absorbents of the fore-arm and palm of the hand. The lymphatic absorbents also pass through glands, which are more particularly observable on the sides of the neck, in the arm-pits, groins, and insides of the thighs. These lymphatic glands are very apt to become enlarged, inflamed, and even to suppurate, particularly in weak constitutions, or when there happens to be a sore on a part of the body more distant from the heart than the gland. In some persons, even scratching the head with the comb will occasion the glands of the neck to become swollen and painful. Popularly these enlarged glands go by the name of "waxen kernels." When any of the lymphatic glands exhibit symptoms of irritation,

the first thing is to ascertain whether this be owing to some scratch, wound, or sore on the body; if the glands of the groin inflame, the

ABS

Fig. 3.

genital organs and the whole lower extremity must be examined, even between the toes; if the glands of the neck, the head must be well looked over, for it is evidently useless to be treating the secondary effect, while the cause, such as an irritable or irritated wound, continues, for they generally are, even though very small, irritable sores, which cause inflamed glands. If the exciting sore be soothed by rest, fomentations, poultices, &c., and a little simple opening medicine given, the irritated gland will generally resume its healthy condition; if it seems inclined to continue inflamed, it, too, must be soothed by the same means, and, if need be, one or more leeches applied, and the bowels more freely acted upon. Suppuration ought, if possible, to be prevented, in the neck especially, where it leaves an unseemly scar. In this situation, when matter has actually formed, the visible after-traces of the occurrence will be much less evident if the abscess be opened at the proper time, and in a proper manner, by the surgeon. The lymphatic glands, especially in weak or scrofulous persons, are apt to assume a state of chronic enlargement and slow suppuration. As this is usually due to the presence of tubercular bacilli in the glands, the condition should be combatted by careful attention to the thorough ventilation of rooms both day and night, by an out-ofdoor life, and by abundance of nutritious diet, of which milk and cream should form a considerable part. Cod-liver oil is of much value, and iron, iodide of iron, bark, and tonic medicines generally, are all indicated. Parrish's Chemical Food and Easton's Com-

ACC ABS

in appropriate doses. To these may be added Burrough's Beef and Iron Wine, and the various preparations of Maltine.

Refer to - Mesentery - Tabes - Glands-

Scrofula-Digestion-Villi.

ABSORPTION .- Absorption is not performed by the "absorbents" alone; the bloodvessels take a considerable share, more particularly in the case of fluids; neither is the process confined to the interior of the body; it may take place through the skin, and thus a person who, from disease or accident, is disabled from swallowing fluids, may have his distress partly relieved by warm or tepid baths. In cases of shipwreck, or want of fresh water, fluid may, without injury, be supplied through the skin, by wrapping the body in clothes soaked with the sea-water

ABSTINENCE.—Abstinence from food may be either compulsory or voluntary, the former depending on want and famine, the latter employed as a remedial measure in sickness, or with the view of combating a tendency to obesity. It is not so easy to deal with the effects of the first as with the last. Plague and pestilence follow in the wake of famine. We have forcible illustrations of this in every quarter of the globe. Death from absolute starvation is happily not a common occurrence in this country; but we have not unfrequently a condition of the body due to insufficient food, which renders it very susceptible to the influence of disease. This is exemplified by the general emaciation, sallow complexion, and feeble circulation of the sufferers, and their rapid return to health and activity when the conditions are reversed. On the other hand, more harm, it is often remarked, is done by over-abundance, than by a moderate deficiency in food. There are numbers of people who eat and drink less to the glory of God than to the gratification of their own morbid cravings, and who, if they persist in their indulgence, are carried off sooner or later by one or other of the numerous diseases which attack the intemperate eater as well as the drunkard-fatty heart, Bright's disease of the kidneys, and enlargement of the liver. Abstinence, moderate abstinence, in such cases is a real necessity, and it is fortunate that our knowledge of the physiological action of various kinds of food should render this by no means irksome, even to the bon vivant. He may partake with impunity of almost any kind of food, provided he eschews sweets and fats, and substitutes bran bread and green vegetables for white bread and potatoes, and takes pure or aerated water in preference to wines and malt liquors. But many persons suffer from forced abstinence with abundance of food at

pound Syrup are both excellent forms of tonic | nourishment insufficient to maintain health. These are cases requiring much medical skill to grapple with. Extreme habits of economy have been frequently known to foster abstinence, and it is a well-known fact that many persons live and fast without any serious injury to their bodies; but, to maintain the healthstandard, a tolerably liberal supply of food is essential, alike for physical as for intellectual exertion. This is absolutely necessary in the young, who, when placed in schools and beyond the maternal care, may not have the same inducements in the way of food as when surrounded by home influences. Abstinence may become a habit and a very pernicious one, and it must be guarded against. The effect on those who practise it on religious grounds is frequently very injurious, and has been known to induce organic disease of the stomach.—See Digestion —Diet—Obesity—Starvation—Fasting.

> ACARUS.—A genus of minute insects, two varieties of which are found on man, -(1) Acarus autumnalis, the harvest-bug; (2)
> Acarus scabiei, or itch insect.—See Itch.

> ACCLIMATION or ACCLIMATISA-TION.—These terms are employed to denote the powers of the constitution to accommodate itself to different climates and new surroundings. The inhabitants of temperate climates possess this facility to a larger extent than those indigenous to the tropics or the arctic regions, and hence they make the best Colonists, though their powers of endurance are sorely tried by a protracted residence in hot climates. Health is best preserved in a latitude above 40 or 45 degrees. The change from a temperate to a warm climate is usually attended at first with considerable febrile disturbance, but under judicious management this result is easily surmounted. Although the influence of hot climates on the white races is notoriously prejudicial, much can be done to moderate the effects by care and sanitary precautions. These are rendered absolutely imperative by the malaria which are always more or less present in the tropics. The ignorance and inattention which prevail upon the subject of acclimation are truly lamentable; great numbers of young men yearly leave this country for hot climates, without one word being said, or idea given them, as to the reasons for, and importance of, certain rules for preserving health: under the change of circumstances, the habits of their colder fatherland are continued, and fever or cholera puts an end to many a promising life, which a little rational information and advice might have preserved.

The air and its temperature are largly concerned in the process of acclimation; the former is so much more rarefied in hot than in command. These are usually the subjects of irritable stomach and weak digestion, who, after trying every conceivable kind of food, find that nothing agrees with them, and in is taken in, and the process of oxidation or combustion, which is continually going on despair are reduced to living on an amount of combustion, which is continually going on

within the body, is slower; we reasonably con- | either internal from mucous membranes, or from clude, that by this process of combustion, the animal heat, in part at least, is maintained, but, of course, in a hot climate, a less active condition is sufficient to keep up the average temperature. The process of oxidation or combustion effected on the one hand by the oxygen inspired, is supported on the other by some of the elements-carbon and hydrogen-of the food. It is evident, therefore, that if an individual who has become resident in a hot climate, makes a practice of consuming as much nutriment as he used to do, without injury to health in a cold one, he must take more than is requisite, consequently the blood becomes overcharged with a load of noxious matter, which the rarefied air and inactive habits of warm countries do not tend to remove; and if the course be continued, an attack of illness, probably of a biliary nature, is the consequence. Even in temperate climates, the difference between the consumption of oxygen in winter and in summer is considerable. In Germany it has been calculated by Liebig at one-eighth less in the latter. How great must be the difference to those who permanently settle in tropical heats! certainly, sufficient to require much alteration in habits of living. The abundant animal diet, the fats and alcoholic drinks of the colder climes, all of which contain carbon and hydrogen in abundance, and assist materially to sustain temperature, must give place to the farinaceous and watery fruits of warmer regions; vice versa, on going from a warm or temperate country to a colder—as the experience of all arctic travellers testifies-a larger proportion of animal diet, and that of a more fat or oily character, is requisite to maintain health and strength, and those only who are capable of consuming and digesting this full allowance, are fit for encountering the cold of the north.

The great increase of the functions of the skin, which takes place on removal to a warm climate requires attention; it renders the constitution more susceptible to the influences of a damp or chill air, such as frequently occurs in the evening. The above remarks apply to our own climate in summer. The best preservative is woollen clothing of some kind, be it ever so thin, worn next the skin. Persons who from a warm climate, of which they are either natives, or to which they have become accustomed, come to reside in a variable or cold country like that of Britain, are peculiarly liable to affections of the chest or lungs, and not unfrequently become the subjects of consumption.

Refer to—Appendix B., Maintenance of Health in the Tropics—Air—Respiration—

Diet-Climate.

ACID.—The general characters of an acid are, that it has a sour taste, reddens vegetable blues, and neutralises alkalies. Acids are vegetable or mineral. Their main uses in medicine are due to their astringent properties, arresting of glycerine, seven ounces of water and one hæmorrhage and checking excessive discharges, drachm of alcoholic solution of coal-tar.

the skin. The principal vegetable acids used in medicine are, acetic acid or vinegar, benzoic acid, citric acid, gallic, tannic, and tartaric acids, and hydrocyanic or prussic acid; the mineral acids are, hydrochloric acid, nitric acid or aqua fortis, nitro-muriatic acid or aqua regia, and sulphuric acid or oil of vitriol, also phosphoric and carbolic acids. They may be referred to under their respective heads. See Lemon-Tannin.

Acetic Acid.—The acetic acid diluted with water is often found efficacious as a reviving tonic for sponging the head (in cases of headache) and the spine. Care must be taken not to use the glacial acetic acid (see article Glacial), which is much stronger, and might do much injury.

ACNE.—This is a disease of the skin, taking the form of what is generally called a nimple

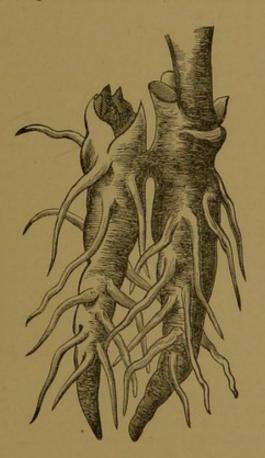

the form of what is generally called a pimple. It is due to an accumulation of secretion in the glands which produce the oily matter. In its simplest form, small white points are seen in the skin, or if, as is commonly the case, a little dirt collects in the orifice of the gland,—as black points, called "black heads." On squeezing these the accumulated secretion is removed as a little maggot-like body. Usually the skin becomes red and painful round these collections, and matter forms and is discharged. In others the part becomes hard and indurated, but still red and irritable. Acne occurs chiefly upon the face and over the shoulders, also on the chest. It rarely occurs in children; it is most common about puberty, and from that time onward to two or three-and-twenty. It is frequently met with for the first time at the age of forty or later.

It sometimes makes it appearance as large red pimples, upon the nose of those who have indulged too freely in the pleasures of the table. This form is called Acne rosacea—in common parlance "grog blossom." To prevent the disease, frequent and thorough washing with soap and warm water, followed by friction with a rough soft towel is a good plan. All black spots should be removed, either by squeezing between the nails or by pressing down upon them a ring a little larger than the black spot, such as a watch-key. The digestive organs must be regulated, and exercise in the open air taken. The former is especially necessary in Acne rosacea. As a local application, the iodide of sulphur ointment will be found the most useful, or a lotion containing two tea-spoonfuls of milk of sulphur rubbed up in a pint of water. Irritation is allayed by Goulard water. An infusion of an ounce of horse radish, in twenty ounces, of hot, not boiling, water, is said to prevent or cure acne, the dose being a small wine-glassful night and morning. A small tea-spoonful of carbonate of magnesia taken in water at bedtime will often relieve, and as an external lotion the following may be recommended:—an emulsion made with a dozen bitter almonds, one ounce

ACT ACO

BLUEROCKET.—This plant grows on hilly ground in many parts of Europe, and is frequently cultivated as a garden flower. All parts of the plant are poisonous, and its active principle, Aconitia, is probably the most deadly poison in existence. As its root has more than once been scraped and used as horse-radish, it is important to be accurainted with the distinctive important to be acquainted with the distinctive character of the plant. It grows from two to six feet in height, with dark green leaves, and a terminal spike of rich blue flowers. The leaves are The root of the monkshood, when chewed,

tion in the lips, with a feeling of enlargement, The treatment consists in the prompt administration of an emetic of mustard and water or sulphate of zinc, followed by a full dose of castor oil. Stimulants, such as hot brandy and water and strong coffee, should be given. The

causes a peculiar tingling and numbing sensa- extremities must be kept warm, and a mustard plaster be applied to the spine. As the sensiand this continues for several hours. The taste | bility of the skin is impaired and the feelings of the horse-radish is pungent and sweet, causing profuse lachrymation, without being very persistent. The symptoms of poisoning by aconite, besides the peculiar sensation experienced in the mouth and throat, are pain and tenderness of the epigastrium, followed by nausea and vomiting. The numbness and tingling become general with diminished sensibility of mouth. Medicinally, aconite is mighted and the feelings of the patient are no guide, the heat must not be too great. Of late, the tincture of digitalis or foxglove has been given in extreme cases and with success, but the use of this antidote should be left for the medical attendant. Twenty drops of the tincture may be injected subcutaneously or half a drachm given by the become general, with diminished sensibility of mouth. Medicinally, aconite is used in acute the surface, and giddiness and difficulty of diseases, such as erysipelas and inflammation of breathing ensue. The pulse is feeble and the lungs, but should never be employed except skin becomes cold and clammy. In the major- by a medical man. ACU ADU

with the rheumatic constitution in all their | the subject of a treatise written by Dr. forms and complications, of St. Vitus' dance, lumbago, &c.; but although it has met with favour from some, many, after having given it a fair trial, are still quite unable to accord it a recognised place as a remedy for rheumatism. The dose of the tincture is one drachm in water, either alone or in combination remedies. It has been much more generally used in America than in this country. The country is "black snake root." The scientific name is Cimcifuga racemosa; natural order, Ranunculaceæ. It is a native of North America, where it was introduced by Dr. Garden as a remedy for consumption, in 1823. Perhaps, however, actae is now best recognised as one of our most useful remedies in some affections of the womb, and to relieve symptoms resulting from them, such as headaches. It will frequently, too, relieve the pain at the monthly period, and regulate its frequency and excess. When taken continuously for some time, ten minims twice or thrice daily in water is a sufficient dose.

ACUPRESSURE—(Acus, a needle)—is the name given by the late Sir J. Y. Simpson, of Edinburgh, to a method originated and proposed by him for the suppression of bleeding from arteries which have been cut. Instead of tying the mouths of the bleeding vessels with threads or ligatures, which is the usual custom, the Professor asserted that it was much better and much less likely to cause suppuration, to pass a needle through the texture and fasten the vessel, just as a gentleman passes a pin through the lappel of his coat to fasten a flower. Since the practice of aseptic surgery was introduced by Lord Lister, the necessity of the exclusion of all possible sources of septic contamination of wounds has been recognised, and the method of securing arteries by acupressure has become practically obsolete. - See Artery - Hæmorrhage, &c.

ACUPUNCTURE .- Acupuncture is a mode of treating some diseases by the insertion of needles into the body, at or near the seat of the malady. The needles, which are about two inches long, are fitted into a small handle. The method has long been known and employed among the Chinese. In this country it is chiefly used in sciatica, and the relief is sometimes instantaneous. The pain of the operation is very trifling, and such as none

need shrink from.

ACUTE.—Acute is a term used in contradistinction to chronic, as applied to diseases, to denote such as are characterised by violent symptoms. Inflammation of the lungs, or erysipelas, are acute diseases; consumption, or ringworm, are chronic.

ADDER-BITES. - See WOUNDS, POI-

ADDISON'S DISEASE, BRONZED SKIN, OR DISEASE OF THE SUPRARENAL CAPSULES, with bronzing of the skin and anæmia, formed

Thomas Addison of Guy's Hospital. At the outset, the patient complains of feebleness, lassitude, great general debility and anæmia, with nausea, sickness and impaired appetite; the whites of the eyes have a peculiar pearly appearance; and there appears, sooner or later, a peculiar dusky bronzing of the skin which is most marked about the face and neck, the armpits, about the genital organs, and around the navel. The discoloration presents itself in all degrees, from the slightest darkening of the skin to the swarthy hue of the mulatto.

Cases of this disease have generally been found to terminate fatally, and there was often discovered after death, by Dr. Addison, disease of the little glands lying immediately above the kidneys, and called the suprarenal capsules. It has since been discovered that the group of symptoms described is always associated with a particular form of degeneration of the suprarenal bodies. In a few cases bronzing of the skin is absent during the whole course of the disease, even although the other symptoms are well marked. Nothing can be done in the way of treatment, except to improve the general health, and employ the remedies for debility and anæmia

ADHESION .- Adhesion is the growing together of parts of the body which are, or have been, separated, either naturally or artificially. A common cut unites by adhesion, and when it does so at once, without the formation of matter, it is said to unite "by the first intention." It is evident how essentially valuable this property of animal bodies must be; it is effected in the first place, by the exudation of a glue-like liquid, which becomes solid. In some cases of inflammation, especially of serous membranes, such as the pleura and peritoneum, this liquid, known as adhesive lymph, is exuded, and adhesions result which may be inconvenient, and even dangerous. Adhesions are also prone to occur in cases of burns of adjacent surfaces, such as the fingers, and should be guarded against.
ADIPOSE.—Adipose, fatty.

ADULTERATION. — The adulteration and sophistication of foods and drinks must be classified among the numerous vices incidental to civilisation. As the wants of the community increase, trade develops, competition multiplies, and the desire to buy in the cheapest, and to sell in the dearest market, gives an impetus to this first principle of political economy, which not unfrequently displays itself in unpleasant tendencies. Fortunate it is that in the onward march there are moral agencies to counteract the evils in question, and that the State now regards the health of the people as among its most important trusts. Among the numerous enactments made by the Legislature within the last twenty years, to advance the comfort and wellbeing of the community, there are few to compare in importance with such as have had

ADU ADU

for their object a bountiful supply of pure and | substances were used in the manufacture of unadulterated food. The first serious attempt of the British Government to deal with the subject of adulteration as a whole, dates from the year 1860, when a Parliamentary Committee collected a large amount of evidence, showing that extensive frauds were being carried on in connection with the sale of foods and drinks in all parts of the empire, and that severe measures of repression were necessary to check them. Long before this date, however, there had been numerous enactments made from time to time. These commencing almost from the earliest periods of our history, dealt with the sophistication of single articles of food, such as bread, beer, and wine, and had often as much reference to frauds on the revenue as to the health of the people. The regulations as to the sale or "assize" of bread, dates from the reign of King John; the statute was afterwards extended, and comprised some stringent regulations prohibiting the fraudulent mixing of meals of an inferior quality with the sound, and the use of false weights and measures. The punishments inflicted for these offences during the Middle Ages, prove how heinous they were considered by the State; for the first offence the enactment states that the offender "shall be grievously punished;" for the second, "he shall lose his meale;" for the third, "he shall suffer the judgement of the pillory;" and on being convicted a fourth time, "he shall foreswere the towne wherein he dwelleth." The Baker's Corporation in the city of London made diverse enactments as to the sale of bread, which bore on the digestion as well as on the morals of the citizens. The city bakers had evidently a jealousy of all breads imported within the sphere of their jurisdiction, that of Southwark being held as impure as that portion of the inhabitants who frequented the vile haunts near the south entrance to London Bridge. The servants of well-to-do people had a right to be present when the baker was preparing his dough, as a precaution against the latter making bread of a fine quality outside, and a coarse within, a practice not at all uncommon in those days. Two Acts passed in the early part of the present century refer to the abuse of alum in the manufacture of bread, rendering the offence penal, and providing regulations for the manufacture and sale of pure bread of specified size and weight. The same Acts render it criminal for the baker to add any mixture or ingredient other than those specified, and when bread was made from other cereals than wheat, the bread so made was to have a distinctive mark. Permission was also given to authorised persons to enter the premises of the baker to search for adulterated bread, or for substances used for the purposes of adulteration. The sophistication of liquors prepared from malt, also dates from a very early period. Prior to the introduction of hops, at the beginning of

beer, and it is highly probable that the main frauds in connection with the manufacture were due to the attempts to get too much liquor out of the malt. In 1660, brewers were placed under the control of the excise, and no ingredients save malt and hops were permitted in the manufacture. It is clear, however, that other substances, many of them deleterious, were often mixed with the liquor, either by the wholesale or retail dealer. In an Act passed in 1816, reference is made to the fraudulent addition of molasses, honey, liquorice, vitriol, quassia, pepper, &c., and instructions are given to the excise officer to seize the same, the adulterator in each case being liable to a penalty of £200, and the druggist supplying the deleterious product to a still heavier fine. This law came to an end with the repeal of the duty on hops, and although the brewer is still prohibited from employing any articles in the manufacture of his beer which would prove injurious to health, he is permitted to substitute quassia or other mild vegetable bitters for hops, as well as colouring

matter prepared from sugar.

The large consumption of tea following the introduction of the leaf to Great Britain, soon led to its extensive dulteration, and Acts passed in 1725 and 1730 were intended to prohibit the sale of tea mixed with leaves or with drugs of any kind. The latter Act specified the obnoxious ingredients with which tea was sometimes fabricated, to wit,-sloe leaves, liquorice leaves, tea leaves already used, terra japonica, sugar, molasses, clay, and logwood. It does not appear that these laws were very effectual, for in 1776 another Act was passed of a similar character, empowering the excise officers to enter premises and confiscate goods of known bad quality, which in a further warrant were ordered to be destroyed, the object being as much to protect the revenue as the consumer. Similar enactments were made with regard to coffee, which was often mixed with and simulated by roasted beans, peas, and other grains, not to mention its wholesale admixture with chicory, which has often been the cause of dispute. Statutes bearing on the sale of unwholesome meats and adulterated wines were also passed at varying intervals, notably in the reigns of Henry III., Charles II., and of William and Mary.

Without doubt the most important disclosures as to the extent to which adulteration was carried on in this country, were those brought to light by the analytical sanitary commission originated by the Lancet Medical Journal in 1851, and which was mainly instrumental in securing a Parliamentary Committee to inquire into the whole subject of adulteration. Dr. Hassall, who was employed by the Lancet, had made a vast number of analyses of articles exposed for sale in various parts of London, and to him is due the credit of bringthe 16th century, wormwood and other bitter ing into prominence the valuable aid afforded

ADU ADU

by the microscope in these investigations. The | any article of food, or any drug which is not of the results of his inquiries were contributed periodically to the Lancet, and afterwards appeared in a volume entitled Food and its Adulteration, which has long been considered the best work of reference on the subject. The Parliamentary Committee referred to above was formed in 1855, and its report, containing the results of extensive, almost exhaustive inquiries, led to the Act of 1860, commonly termed "The First Adulteration Act." By this Act, any one selling any article of food or drink which was not pure, was liable to a heavy penalty, and some provision was made for the appointment of analysts by local boards in different parts of the country; but as the more important clauses of the Act were permissive, and not compulsory, it became practically a dead letter. Some of its defects were remedied by the introduction into the "Sale of Drugs Act, 1872," of several important restrictions with regard to the sale of food; but in consequence of the great misunderstandings which existed among experts and respectable tradesmen as to what constituted adulteration, it was found necessary to repeal both Acts and to substitute for them a new one, "The Sale of Food and Drugs Act" of 1875, which, with its Amendment of 1879, is now the law of the land. The provisions of this Act are so important in their bearings on the public health, that a brief summary of some of the clauses, especially those relating to purchase and analysis, will not be out of place in this article.

At the outset of all legislation on the adulteration of food or drugs, there has been a difficulty constantly felt in describing the precise meaning of the term and its relative application. Mr. Wynter Blyth in his work, entitled Foods: their Composition and Analysis, prefers the American to the English definition of adulteration, and quotes the following suggestive clauses which have been in great part incorporated with the American Act:-"In the case of food or drink, the article shall be held to be adulterated :-

"1. If any substance has been mixed with it so as to reduce, lower, or injuriously affect its quality,

strength, purity, or true value.

"2. If any inferior or cheaper substance has been substituted wholly or in part for the article.

"3. If any valuable constituent of the article has been wholly or in part abstracted.

"4. If it be an imitation of, or be sold under the name of another article.

"5. If it consists wholly or in part of a diseased, or decomposed, or putrid, or rotten animal, or vegetable substance, whether manufactured or not; or in the case of milk, if it is the produce of a diseased animal. "6. If it be coloured, coated, polished, or powdered, whereby damage is concealed, or it is made to appear better than it really is, or of greater value.

"7. If it contain any added poisonous ingredient, or any ingredient which may render such article injurious to the health of the person consuming it." 5. If it consists wholly or in part of a diseased, or

The main provisions of the English Act are comprised under the following sections:-

any article of food, or any drug which is not of the nature, substance, and quality of the article demanded by such purchaser, under a penalty not exceeding £20, provided that an offence shall not be deemed to be committed under one or other of the following exception clauses:—

1. Where any matter or any ingredient not injurious to health has been added to the food or drug, because the same is required for the production or preparation thereof as an article of commerce instate fit for carriage or consumption, and not fraudu-

state fit for carriage or consumption, and not fraudu-

lently, to increase the bulk, weight or measure of the food or drug, or conceal the quality thereof.

2. Where the drug is a proprietary medicine, or is the subject of a patent in force, and is supplied in the state required by the specification of the patent.

3. Where the food or drug is compounded as mentioned in this Act.

tioned in this Act.

4. Where the food or drug is unavoidably mixed with some extraneous matter in the process of col-

lection or preparation

Sections 7 and 8 of the Act enact that "No persons shall sell any compound article of food or compounded drug which is not composed of ingredients in accordance with the demand of the purchaser, and that no person shall be guilty of any such offence as aforesaid in respect of the sale of an article of food or a drug, mixed with any matter or ingredient not injurious to health, and not intended fraudulently to increase its bulk, weight or measure, or conceal its inferior quality, if, at the time of delivering such article or drug, he shall supply to the person receiving the same a notice by a label distinctly and legibly written or winted on or with the article or drug. written or printed, on or with the article or drug, to the effect that the same is mixed."

The following section 9 enacts "That no person shall, with the intent that the same may be sold in its altered state, without notice, abstract from an article of food any part of it, so as to affect injuriously its quality, substance and nature, and no person shall sell any article so altered, without making disclosure of the alteration, under a penalty in each case not

exceeding £20."

Several sections of the Act refer to the appointment and duties of public analysts by various local authorities, and require that the analysts shall be persons of competent knowledge, skill, and experience, who may be permitted to act in their official capacity for one or more boroughs or sanitary districts. Provision is made for the purchase of samples by any purchaser for analysis by the public analyst on the payment to the latter of a sum not exceeding 10s. 6d., the analyst being bound to give a certificate of the analysis to the pur-chaser. Any medical officer of health, inspector of nuisances, inspector of weights and measures, or any police constable acting under the direction of the local authority, is at liberty to purchase samples for analysis, and to procure reports thereon from the analyst. To check fraud on the part of the purchaser, section 14 of the Act enacts that the person purchasing the article with the intention of having it analysed, shall at once notify his object to the seller, and divide the purchased article in the presence of the latter into three parts, each part to be scaled up separately on delivery-one to be returned to the seller, one to be retained by the purchaser for future comparison, and the third to be given to the analyst. An important section of the Act provides for a part of No person shall sell to the prejudice of the purchaser | the sample being analysed by the Government

AFF

analysts at Somerset House, in case of any | dispute as to the correctness of the analysis by the public analyst. Enactments are also made rendering it a penal offence on the part of persons forging warranties, or applying certificates of certain articles to others not so certified, and wilfully employing false labels for fraudulent purposes. The practical working of these clauses of the Act is largely under the control of the inspector or official purchaser, who soon finds it to his advantage to work by deputy, and to see that the numerous and stringent forms required by the Act are rigidly adhered to.

It is gratifying to learn that, notwithstanding numerous drawbacks in the frequent attempts at legislation with regard to adulteration, the improvement in the quality and character of food consumed by the population is most decided, especially in the articles of greatest consumption—bread, milk, tea and coffee. As regards bread, if we except alum (which is now employed but rarely to whiten the colour of flour), we seldom hear of any convictions for the use of extraneous articles in its manufacture; and although milk dealers are occasionally prosecuted for adding water to milk, the proportion of water is so much under the mark of what it was twenty or thirty years ago, that the present generation has reason to rejoice at a state of matters

unknown in the lifetime of its progenitors.

ADVICE, MEDICAL.—When a medical man is consulted, it is a tacit acknowledgment of confidence; that confidence should be implicit, or placed elsewhere. In the first place, care should be taken that the necessary directions given are fully and accurately understood; being so, they should be as fully and accurately followed out, unless some evident change in the condition of the patient, or in circumstances which the prescriber could not foresee, renders a departure from them necessary; but of this he should have as early notice as possible. There is no greater folly than to call in a medical man, and then, either from wilfulness or weakness of purpose, to controvert or neglect his prescribed rules; it is only equalled by that which conceals or deceives in the particulars of a case, and looks for benefit. It is too commonly the case in illness, that officious persons are continually offering their counsel and opinions, disturbing the mind of the patient or of the friends, and perhaps undermining the trust reposed in the attendant practitioner; if it is reflected for one moment, how worthless such counsel and opinions must be, they would be less attended to than they are. Again, if proper confidence is felt in the judgment of the medical attendant, his requirements should be submitted to without remonstrance or grumbling. When doubt and uneasiness respecting the progress or prospects of a case intrude themselves upon the mind of

desired, the matter should be openly, at once, stated to the ordinary attendant, and his views and wishes heard; but never should another be called in till this has been done; still less, even if a medical man can be found to demean himself so far, should a clandestine opinion be taken. Lastly, in sending for medical assistance, especially in country districts, as full an account of the symptoms of the illness, or accident, as possible, should be transmitted by written note. The precaution must save time; it may save life.

AERATED WATERS.—Water containing air is said to be well aerated, but the term is usually applied to effervescent waters, either from natural springs or artificially made, and which owe their effervescent property to the presence of carbonic acid gas. The most familiar of these waters are soda, potash, seltzer, and Apollinaris waters, but new beverages of this description are constantly being brought

AERATION.—Blood, during its circulation through the body, becomes impure in quality, dark in colour, and unfit for the support of the vital functions; being passed through the lungs by the powers of the heart, it undergoes purification, and the dark colour of the venous, is exchanged for the bright red hue of the arterial fluid; it has undergone "aeration"—it has robbed the air drawn into the lungs of a portion of its oxygen, and given off carbonic acid. This aeration of the blood is essential to the maintenance of life; if stopped entirely for a few minutes, death is the result. This fact is obvious, and known to all; not so, the injurious, ultimately fatal, effects of the imperfect aeration of the blood, to which thousands of our town population are daily and nightly exposed; living in a contaminated atmosphere, the vital fluid never fully purified, disease and shortened lives must be the result.—See Blood—Respiration-Circulation.

ÆTHERS are volatile liquids used in medicine as stimulants and antispasmodics.-See Nitrous Æther-Sulphuric Æther-Chloric Æther.

AFFUSION .- Cold water affusion in the treatment of fevers is a remedy, which after being abandoned for the greater part of a century, has again come much in favour, especially in hospital practice. Its object is purely a mechanical one, by the external application of cold to reduce the temperature of the body when it exceeds a certain standard, generally 102° or 103° Fahr. The success attending cold affusion in fevers both in this country and in Germany, warrants the belief that it may become more general, especially in the treatment of Typhoid, Typhus, and Scarlet fevers. The methods employed comprise the ordinary cold bath brought to the bedside, the douche bath, in which the patient, seated in a tub, has a bucket of water poured over him, wet sheet packing, and sponging the body with ice cold those most interested, and a second opinion is water. Of these, the bath and packing are

most in vogue; but the employment of the | parts and frequently changed; should extreme remedy requires great care and observation, and cannot be administered unless with the aid of a medical man and skilled attendant. These have to watch with the thermometer the effect of the cold on the body-temperature and on the pulse, lest at any moment the former should exceed the limited standard, and the bath or packing require repeating, which may happen several times during the day and night. As a rule, persons suffering from fever have a great repugnance to being immersed in a cold water bath, and it is now the general practice, at first to temper it with warm water to nearly blood heat and to diminish the temperature gradually to 80° or 76° Fahr. The time occupied with the immersion is to be governed by its effect, but it is not desirable to retain the person in the bath for a longer period than 10 or 15 minutes; a refreshing sleep with freedom from delirium is often the happy result, and apart from the somewhat irksome ordeal of the bath, the proceeding is not found to be attended with any untoward consequences. It is, however, not considered applicable to children or very old people, or to persons in whom there is reason to believe disease of the heart exists. By means of the douche cold affusion is much employed in India in cases of sunstroke.

AFTER-BIRTH.—In medical language the placenta. It is usually discharged at a period varying from five to forty minutes after the birth of the child. There is always some little anxiety, both on the part of the patient, and of the medical attendant, until this concluding part of child-birth has been accom-Within the above time in most cases, sometimes immediately after the child is born, the patient complains of an accession of labour pain, caused by the contraction of the womb which casts off the after-birth, at times expelling it entirely from the body, but generally propelling it so far towards the external orifice as to make its withdrawal perfectly easy. When all is as it should be, the business is concluded by the ordinary midwife without the least difficulty; at the same time, it must be remembered, that some of the most formidable accidents of the lying-in chamber are connected with the management of this part of its duties, and if a female only be in attendance, should the slightest embarrassment occur, not one moment is to be lost in summoning proper medical aid; above all things, let the attendants beware of any attempt to force matters by pulling strongly at the navel cord —they can only do mischief. The chief danger to be dreaded when the after-birth is retained, is loss of blood or flooding; if this comes on to any extent, the patient must be kept as quiet and cool as possible; gentle but firm pressure must be maintained over the bowels generally, and especially over their lower portion by the bandage and by the hand; cloths dipped in

faintness occur, a little wine, or brandy, or sal volatile may be given in water, but stimulants must not be too readily resorted to. The retention of the after-birth is at times the result of irregular contraction, but often of adhesion to the womb; the possibility of such an occurrence should make those who are advanced in pregnancy careful to avoid anything which may press upon any portion of the distended womb, as for instance, the stays, and guard against habitually leaning, even gently, against any hard body. A careful attendant will always examine the after-birth: it ought to be nearly circular, about the size of a dinner plate, and should not exhibit any signs of tearing on the surface which is next the womb. The membranes which line the interior of the womb during pregnancy, are for the most part discharged along with the after-birth, and are more readily and neatly brought away, by giving the latter body a slightly twisting motion as it is withdrawn. If they are very tender, a portion may remain and pass off with the discharge; it is well to be aware of the fact, as persons are often needlessly much alarmed at this occurring a few hours or more after delivery. Occasionally, the after-birth is so placed over the mouth of the womb, that it must necessarily be detached in the first stages of labour; the case is always attended with danger, and cannot be too soon put under medical superintendence; it may generally be suspected, if simultaneous with the occurrence of labour pains, a free discharge of blood takes place, which is increased every time the pain recurs. In the event, as in the country, of any delay in procuring medical assistance, the measures recommended in the treatment of hæmorrhage, in "Abortion," may be resorted to.

Refer to-Child-birth.

AFTER-PAINS, are the regularly recurring pains which women often experience for a day or two after child-birth. They are rarely troublesome after a first confinement, but are apt to increase in severity at each succeeding one. After-pains are, in moderation, salutary, and are caused by the efforts of the womb to attain that properly contracted condition on which the woman's safety depends. If they are very severe, it is generally owing to the presence of clotted blood, which must be expelled before they moderate. A constant, unintermitting after-pain, coming on very soon after the termination of labour, is often symptomatic of internal flooding, and should be attended to accordingly. If after-pains are very severe, they are advantageously relieved by the administrative advantageousl istration of twenty drops of laudanum or chlor-odyne, which may be repeated, but if the amount of pain be moderate this is unnecessary. If the discharge is not profuse, a hot flannel to the lower part of the abdomen affords comfort. cold water are to be applied over the external After-pains are often kept up after the first

AGE AGE

bowels being loaded; a table-spoonful of castor oil is at once a safe and effectual remedy. Too tight bandaging may aggravate after-pains.

Refer to -Child-birth.

AGE.—Age is the important factor in calculating the effects of disease and death in a population. The object of medicine is to prolong life; that of hygiene to prevent disease. We are continually hearing of persons who have died after living a century and upwards, and many enthusiasts believe, that were the laws of health rigidly enforced throughout the community, there is no just cause why this term of years should not be reached by many. From the cradle to the grave, however, we are engaged in a perpetual warfare with disease, accident and death, and the prospect of the individual unit ever becoming a centenarian is infinitesimal. Our best authorities reckon only half a century as a fair prospect of life for a child born even under favourable circumstances, and if we take the mortality tables for all England, and divide the total deaths over given periods into four nearly equal classes, we find that one fourth of the deaths occur in the first year of life; another fourth from the first to the fifteenth year; another is spread over the long interval of forty years (between the fifteenth and the fifty-fifth year), and the remainder take place after the age of fifty-five. Such a calculation, however, gives a very inadequate idea of the causes constantly at work

to control longevity.

If we follow Dr. Farr in his interesting sketch of the march of an English generation through life (contained in the Supplement to the Thirtyfifth Report of the Registrar-General), we will find these causes of mortality graphically illustrated. It may be difficult to assign the true causes of death in infants newly born, and during the first twelve months of their existence, but there can be little doubt that the high mortality is due to the rapid development and fragile condition of all the vital organs, indicating the necessity for care and warmth. Hence, diseases of the nervous system, culminating in convulsions, of the lungs and air tubes, and miasmatic affections, due to unhealthy surroundings, comprise the bulk of the deaths registered at this early period. Young age fares very differently under diverse associations, for although collectively 75 infants in 100 bridge over their first year, yet the proportion as distributed over the various classes of society is far from equal. more favoured circumstances, such as we might expect among rich people, 87 in 100 survive the first year, and among the nobility 90 in 100. Again among the poor, crowded together in populous towns, these figures are often reversed, the death rate denoting 50, 60, 70, and 80 per cent.; while in a street in Liverpool, inspected by Dr. Parkes, it was found that 90 out of 100 children born, died before the end of

four-and-twenty or six-and-thirty hours by the | remarks: "Pneumonia, bronchitis, and convulsions are still the prevalent and most fatal diseases; many also die of hooping-cough, scarlatina, and diarrhœa. Scarlet fever asserts its supremacy in the 2nd, 3rd, 4th, and 5th years. Hooping-cough is at its maximum in the first year, measles in the 2nd, scarlatina in the 3rd and 4th years. Thus these diseases take up their attacks on life in succession and follow it onwards." Of such as have escaped these maladies, or when attacked, have surmounted them, and have entered life afresh in their 6th year, a large portion succumb, before they have arrived at 15 years, from scarlet and other fevers, to which must be added diphtheria and consumption. Near to and after the age of puberty the prospects of life are more favourable, the diseases most fatal at this time being chiefly consumption and fevers. 20th to the 30th year is the period in which consumption gains an ascendancy, nearly one half of all the deaths from 20 to 25 years being due to this cause alone. Affections of the brain and heart are also not uncommon at this time, and as years advance these diseases become more chronic and intractable, and the probabilities of recovery from accidents and

operations begin to lessen.

After 50 years of age the risks to life from fevers, and indeed from all maladies, are greatly increased, and the increase is noticed to continue till the end of life. As old age advances we come to a condition, of body rather than mind, sometimes termed the "second childhood," in which bodily infirmities become exaggerated by the most trivial causes; sudden changes of temperature, exposure to draughts or irregularities of diet, prostrate their victims. Old age itself becomes a disease, and the body, worn out by active work, succumbs at last, like an eight-day clock or similar piece of mechanism. Though the term "second childhood" is thus often applied to old age, it is, as a rule, more applicable to the body than to the mind, and this is especially the case among persons of both sexes who have spent their lives in active work, both physical and mental. Among our greatest men, -politicians, statesmen, judges, divines, and medical men,—we have minds as active and vigorous as they were in earlier life, though the bodies which they inhabit are weak and frail. certain amount of exercise is necessary for the aged, but it must be moderate and not sustained. All the organs become less active, there is less force in the lungs and heart, and a consequent diminution in the assimilative functions. The animal heat must be supplemented by warm clothing and warm rooms, and there should be no exposure to extremes of temperature. The appetite also diminishes with the powers of digestion, and food must be administered more sparingly, and at the same time more frequently than in earlier life. It should also be soft, easily masticated, and well their first year. In the second year, Dr. Farr | cooked. The longevity of families is sometimes

very remarkable, and the same remark fre- which malaria is most likely to be acquired, quently applies to certain villages and districts of the country, and is often quoted as an illustration of their comparative immunity from disease, while a higher death-rate is regarded as a sign of unhealthiness.—See Children—Old Age.

AGUE, or Intermittent Fever, is a disease very prevalent in tropical and subtropical countries; it is frequently termed "malarial fever" from the mistaken hypothesis that it is due to a "malaria" or "marsh miasma" emanating from unhealthy conditions of soil and climate. Researches of recent years have established conclusively its dependence upon the presence in the blood of its victims of a microscopic parasite known as the plasmodium malaria, which is introduced into the system by the bite of a particular kind of mosquito known as the anopheles. This mosquito acts as the host of the plasmodium, receiving it by biting a sufferer from malarial fever, carrying it for some time in its body, and transferring it by a bite to a healthy person, who thus becomes infected. The chain of events has been investigated and described in a most interesting manner by two distinguished English physicians, Dr. Ross and Sir Patrick Manson, and absolutely conclusive proof has been furnished, both experimentally and by observation, that the sole cause of the disease is the presence of the plasmodium, that its introduction is invariably effected by the anopheles, and that it is quite possible to avoid infection of malaria even in a place where the particular mosquito is prevalent, if sufficient precautions are taken to avoid risk of mosquito bites. As a deduction from these facts it follows that, if this species of mosquito could be banished from the districts at present regarded as malarious, the disease would gradually die out, and no fresh cases would occur. It has been found that the principal breeding grounds of the anopheles are shallow and stagnant pools of water, in which the young larvæ are developed. The drainage of such pools wherever practicable has been of much use in diminishing the numbers of the anopheles. The introduction of fish which feed upon the larvæ has also been suggested; and in cases where the pools could not be drained, and were not too large for treatment, covering the surface with petroleum at the breeding season has been effective. These methods of course can only be employed over limited tracts of country. When persons are living in countries known to be malarious, every precaution possible must be taken to avoid mosquito bites. Mosquito curtains carefully arranged should be habitually employed, and sleeping in the open Where possible it is desirable to air avoided. reside on hills or elevated ground, the mosquito tending to inhabit the lower lying districts.

At the same time every attention should be paid to maintaining the health in a satisfactory condition by moderation in diet, and by recrea-

the habitual use of quinine to the extent of at least three grains taken once every second day

is of much value as a preventive.

When an attack of ague is about to come on, the person complains of general lassitude, oppression about the stomach, and general chilliness, which at last amounts to actual shivering, with chattering of the teeth, when the disease is fully established. By this time the features are pinched and blue-looking, and the whole body seems shrunk; the pulse is feeble, the tongue pale; sometimes there is vomiting; there may be stupor or convulsive action. Flying pains are felt throughout the head and limbs. After a certain time, this first -the cold-stage gives place to the second, or hot; transient heat-flushes become more frequent, till at last the coldness is entirely superseded by a state of fever, with quick, full pulse, hot skin, furred tongue, and thirst, with highcoloured urine, generally throbbing headache; at length the third stage brings relief, by copious perspiration; the symptoms of disease subside to the level of health, and the patient remains comparatively well during what is called the remission, that is, until the next attack, which may come on in twenty-four, forty-eight, or seventy-two hours, or at longer or less regular periods. The periodicity ob-served by the attacks of ague is one of the most marked features of the disease, and the terms quotidian, tertian, quartan, are applied to denote the interval of return. The more frequent the paroxysms, the more serious the character of the malady, as a general rule. The marked features of ague, its occurrence in particular localities, and its tendency to return, render it one of the diseases most easily and certainly distinguishable by the unprofessional, whilst, at the same time, the peculiar circumstances under which it often occurs, and the comparatively regular modes of treatment, permit of timely assistance being extended to the sufferer, in the absence of regular medical advice. When an individual is attacked with advice. the cold stage of the fever, the application of external warmth is at once the most natural and beneficial remedy; this may be done either by means of bags of heated bran, salt, or any other convenient method; or if a vapour-bath be at hand it may be used, or an extempore one made, by seating the patient, wrapped in a blanket, on a chair over a bucket containing hot water, which is kept steaming by means of heated stones thrown into it from time to time. Warm, diluent drinks may be freely allowed, weak tea, barley-water, and such like; only in a very few debilitated cases may a little wine be added. Emetics have been given at this stage, but are not advisable; a brisk purgative is, however, required at the commencement; none is more convenient than a pill containing one grain of calomel, and three tive exercise. During the season of the year in grains of the compound rhubarb pill. Of these,

stage, opium must be given; it may be administered as laudanum, in one dose, averaging full five-and-thirty drops to an adult; the diluent drinks being freely allowed at the same time. The sweating stage is to be encouraged until the feverish symptoms are quite gone; if it then continues, wiping the skin dry, and changing the linen will put a sufficient check upon it. The individual paroxysm being over, the object is, next, to cure the disease, and prevent the recurrence; for this purpose, the one remedy, Peruvian bark, as formerly given, or its essence, quinine as now administered, is generally sufficient. If the bowels are not thoroughly cleared by the calomel and rhubarb, this point must be ensured by a full dose of castor-oil or some purgative, and two-grain doses of the sulphate of quinine in solution every five hours, immediately commenced with, and continued night and day, paroxysm or not. The dose of evils. quinine should be increased till its effects are shown by ringing noises in the ears; continued at the usual period of the paroxysm; and then gradually diminished. Other remedies which have been employed successfully when quinine has failed, or when the patient from some idiosyncrasy is intolerant of that drug, are arsenic and sulphate of zinc; these, however, should not be taken except under medical In all cases of malaria the treatment should be presevered in for some weeks after the active symptoms have disappeared, as the cessation of attacks does not necessarily indicate complete cure; and where possible a temporary change of climate is very desirable.

Such are the principal general modes of the treatment of ague which may safely be had recourse to by the unprofessional, and with them, no one who is resident in a malarious district, no intending emigrant who may chance to find himself in such a district, should be unacquainted. At the same time, however useful a knowledge of these general principles may be, it will not be everything in all localities; in each, especially abroad, the disease assumes varied features which can only be properly known and treated by the residents. Ague may resist every remedy, or may frequently recur, as long as the patient resides within the malarious influence, or having been contracted, it may be kept up by the air of another district, particularly an east one in this country, although it could not be produced by it. In such a case, change to a dry and more genial climate is necessary, for though ague is not in Britain immediately fatal, its continuance undermines the constitution, and originates serious disease. Ague is most general in spring and autumn, the latter being the more dangerous period of the attack. Those who are temporarily or permanently compelled to reside in a malarious district, will do well to

two may be given to an adult. During the hot | sufficiently generous living, or a moderate use of fermented liquors: they should protect the skin by woollen clothing, avoid night air, or if obliged to go into it, protect the nose and mouth by a handkerchief, and never go out early in the morning without taking food, or better, some warm fluid, previously. A few doses of quinine should be taken occasionally. Within the last few years, the blue gum tree of Australia (*Eucalyptus*), of which there are many species, has been planted in aguish districts as a counteragent to the malarious poison. Its beneficial action has been ascribed to its rapid absorption of water and consequent desiccation of the marshes, and also to the abundant aromatic essential oil exhaled from the leaves, and indeed from the whole plant. The beneficial effects, however, have yet to be fully proved. The sunflower is said to have a wholesome influence in correcting malarious

AIR .- The air or atmosphere which encases at this level till the temperature ceases to rise the globe, is the most necessary element for our existence. We are so accustomed to it that habit renders us almost unconscious of its presence, until we soil its purity, and then we treat it to unmerited abuse. It mainly consists of two gases mechanically intermingled, oxygen and nitrogen, in the proportion of 21 parts of the former to 79 of the latter. There is also present another important gas, carbonic acid, in the proportion of 4 parts in 10,000, and a small amount of watery vapour, fluctuating in quantity, with varying temperatures. To these must be added traces of ammonia and other organic and suspended matter in small amounts, noticeable under certain conditions and situations, and most marked when the wind is blowing in our faces. The impurities in the atmosphere are of more importance to us than their normal constituents, as such impurities are the causes of many diseases, and are usually the result of overcrowding and unhealthy sur-roundings. The chief of these are the emana-tions from the body itself, from the lungs and skin, the products of combustion from fires and lights, the presence in the atmosphere of living bodies in the shape of the lowest forms of animal and vegetable life, combined with an excess of carbonic acid, which though not of itself positively injurious, in the proportions it is usually met with, affords a facile indication of the amount of organic matter, so difficult to detect, in occupied apartments. The air of towns in proportion to their size, population, and the character of their manufactures, is more impure than country air, mainly from the products of combustion emitted from public works and coal fires, and from the emanations of decaying organic matter. Sulphuric, hydrochloric, and other acids, are being continually added to the atmosphere of large towns, which is also charged with particles of soot, when the keep up the general tone of the system, by air is partially stagnant to an extent greatly to ALB ALB

interfere with the healthy process of respiration. In the sick-chamber, and more especially in the hospital ward, these conditions are exaggerated by the floating presence in the air of fibres of lint, cotton-wool, and organic matter from wounds and excretions, all of which have been noticed by microscopic investigation. There is also good reason for supposing that germs of disease may be propagated from one person to another through the same influence, since the measures which have been everywhere taken to improve these conditions by cleanliness, ventilation, and the abundant employment of antiseptics, have been attended with the greatest success. Men engaged in various occupations in which they are exposed to the action of dust and chemical compounds, either in their gaseous or granular state, suffer also from these respective impurities. Such is especially the case with miners, stone masons, brassfounders, water gilders, painters, and the workers in many other trades; and the conditions under which most of them are carried on, render it imperative that employers of labour should fully appreciate the dangers, and exert themselves in their several ways to diminish them by well-ventilated workshops, and the use of shields and other contrivances recommended for the purpose.

As regards locality, we assume that air is impure in marshy places, and people who value their health and that of their children, do not select such for their residence. The purest air is to be met with in the mountains or at the seaside, and to judge from the anxiety felt to resort to either locality, when one is out of health or recovering from disease, the desire appears both instinctive and intuitive. So strongly has the necessity of fresh air for the maintenance of health been urged by medical men and others, that the Government authorities, acting on the advice of repeated commissions of inquiry, have laid down certain principles in the construction of barracks and hospitals, whereby a certain amount of cubic space, accompanied with facilities for a regular change of air, should be allowed for each soldier. The same principle now obtains in schools, workhouses, and civil hospitals.

Generally speaking, the sense of smell is sufficient to detect an unwholesome atmosphere, but the sense of smell is liable to become vitiated by those whom it most concerns. We are barely conscious of any unusual "stuffiness" in the bed-room, which we have occupied during the night, until we return to it after having breathed for a few minutes the outside air, when we immediately become con-vinced of its unwholesomeness. Professor de Chaumont (who has made a large number of experiments in connection with atmospheric impurities) finds that the "stuffiness" in question is nearly in direct proportion to the organic matter in the air, and that as long as it does not become perceptible to the senses, nourishing power of this substance. Besides that is to say, indistinguishable from the ex-

ternal air, it is not incompatible with good ventilation. When the stuffy odour is detected there is reason for changing the air, and this condition will be found to exist with an excess of carbonic acid, amounting to not less than 6 parts in 10,000 or 50 per cent. more than it ought to contain. Dr. de Chaumont considers that the minimum allowance of air for an individual, for health purposes, should be estimated at 3000 cubic feet per hour, and how to obtain this in inhabited houses, without causing bad results in the way of cold and draughts, is the key to successful ventilation. The agents employed for heating and lighting in most cases come next to the human breath in soiling the atmosphere of our rooms. With even a perfect combustion of coal and coal gas, the products of carbonic and sulphurous acids are certain to diffuse themselves to a certain extent; and with imperfect combustion, we have added to these the carbonic oxide and particles of carbon, which may be seen adherent to ceilings and walls. The well-known readiness with which carbonic acid unites with lime to form carbonate of lime or chalk, affords a very simple test for determining an excess of carbonic acid in the atmosphere of a building. If the carbonic acid should be in excess, it will form a white film on the surface of clear lime water placed in a saucer in any part of a room. A more correct and equally simple experiment, however, is that recommended by Dr. Angus Smith, and termed by him his "household" test. This consists in pouring half an ounce of clear lime water into a 101 ounce widemouthed stoppered bottle, previously filled with the air to be tested. If the lime water when shaken up becomes turbid, it is fair to conclude that the air in the room contains an excess (or more than 6 parts in 10,000) of carbonic acid, and is therefore unsuitable for respiration. There are various methods for determining the quality of air, in use among chemists, but they are of too elaborate a character to be commented on here. - See Respiration - Ventilation-Cubic Space, &c.

ALBINO .- An individual in whom the usual colouring matter of the body is absent. The complexion is unnaturally white, the hair white, while the eyes appear pink. White rabbits with red eyes are albino rabbits. Albinos are rare among Europeans, but are

found more frequently among the negroes.

ALBUMEN.—One of the principal constituents of the animal body. The white of stituents of the animal body. The white of the egg is nearly pure albumen. In the serum or watery portion of the blood it exists in large proportion, and may be coagulated from it by heat, like the white of egg. When it is reflected that from the albumen of the egg-for the volk is largely albumen also-the perfect chick is constructed, its blood, muscles, bones, nerves-it will be seen how great must be the

18

ALB ALC

also exists in the vegetable kingdom, more especially in the grains and pulses. Heat first coagulates, and then hardens albumen, thus impairing its digestibility—a reason for avoiding over-cooking meat, as well as eggs. In its pure state, albumen has the important property of being an antidote to various mineral poisons, such as corrosive sublimate, blue vitriol and chlorine. It also forms a precipitate with most acids. A mixture prepared with equal parts of white of egg and spirits of wine, makes an excellent application for a threatened bedsore—See Egg—Food.

ALBUMINURIA.—A symptom denoting the presence of albumen in the urine. See

Bright's Disease.

ALCOHOL .- Alcohol is the active principle on which the intoxicating and also the preservative character of most fermented liquors depends, and is mainly derived from malt and grape sugars, which have undergone vinous fermentation. It is a colourless, highly inflammable liquid, with a specific gravity of 825, and is largely used as a medicine in its diluted form in the various alcoholic beverages, as well as in the preparation of tinctures, liniments and lotions. It is also employed as a supplementary food, especially in cases of recovery from disease. The proportion of alcohol in spirits, wines, and malt liquors is variously estimated by different analysts, and must necessarily depend on the variety in strength of the different samples submitted for analysis, but the following table will give an approximation to the amount of alcohol in 100 parts of each liquor named :-

Whisky,				50 per	cent.

It has long been a disputed question whether alcohol is to be viewed in the light of a food, a medicine, or a poison, and as a very large portion of the population daily indulge in it, it is of the greatest importance that its action on the body should be fully understood. At the same time, there are so many puzzling issues involved in what becomes of alcohol when taken into the stomach, in the new chemical affinities and changes it undergoes, and in the variety of its effects on different individuals,

siderable proportion of the animal solids; it | the sugar contained in malt liquors and wines have certain dietetic properties, and that the half ounce or ounce of alcohol in a pint of beer, or the 4 or 5 ounces of the same spirit in a bottle of wine, are consuming agents, and as such, undergo combustion, or are burned up in the system. When taken either with or without water, the first effect of alcohol is to produce a sensation of warmth, beginning at the stomach, and then an increase of the pulse; if the dose is augmented it produces dulness of perception, inclination to drowsiness, and slowness in the circulation. In these effects we see the properties of alcohol exhibited as a stimulant, a sedative, and a narcotic. We know also that when taken habitually and in considerable quantities, the constitution gets as it were seasoned to its effects, but this toleration arises less from the open expression of the above characteristics, than from a dulling and partial prostration of the nervous energies, since it is entirely through the medium of the nervous system that alcohol acts on the body. Drunkards are known by their shaky hands and liability to complaints indicative of a low condition of the nervous system, and are occasionally subject to intervals of excitement and depression (caused by the withdrawal of their accustomed stimulus) in which the nervous tremor develops into a disease termed delirium tremens. În producing this result, alcohol undoubtedly acts as a poison, but we have far more fatal evidence of its poisonous action when we come to investigate the history of hospital patients, and to follow it up by post-mortem inspection. It is impossible to specify any organ of the body which would be entirely exempt from the effects of alcohol when taken in excess for a course of years. The liver, the kidneys, the heart are especially susceptible of its influence, so also are the arteries, while the brain and entire nervous system become unhinged and utterly unfitted for healthy service. In commenting on the physical results of alcoholism, it is scarcely possible to avoid noticing the moral injury it produces, though the subject scarcely comes within the compass of this article. In view of the misery, crime, and poverty which follow in its wake, it is not surprising that many good people should combine together to eschew alcohol in every shape and form, and that even medical men of repute should erase it from their materia medica, as fraught with danger in the treatment of disease. The most recent application of this principle is in the foundation of a hospital for the sick in London, where patients are treated for critical diseases and undergo severe operations without alcoholic stimulants, and to judge from the annual reports of the establishment, they do remarkably well. Taking all things into consideration, it would appear that that we are far from having arrived at any satisfactory conclusion regarding this action. We know for certain that the malt extract and should be avoided. If taken even in mode-

rate quantities habitually, their employment | The cesophagus extends from the throat to the is followed by a certain languor and depression which requires to be met by another application of the accustomed stimulus. There is no more common error than the supposition that a glass of brandy or whisky taken, say in a long journey, or in some task requiring much physical exertion, will assist a person in surmounting the difficulty. The late Dr. Parkes proved, by a series of experiments on soldiers in heavy marching order, that men who were plentifully supplied with water and their ordinary rations could accomplish more work than when they were furnished with beer and spirits. The alcoholic draughts were on each occasion followed by a kind of spurt in their work, which, in the course of an interval varying from three quarters of an hour to an hour, was succeeded by a corresponding depression which rendered their efforts less effective in the aggregate. Medical men differ materially as to the propriety of administering alcohol as a remedy in fevers and some exhausting diseases, but there are certain conditions of the system in which there is for the most part a consensus of opinion. If the patient has been in the habit of indulging in drink, his medical man would not rashly cut off the supply at once, but would probably prescribe it in diminished doses as a tonic. With a similar object he would prescribe it in convalescence from severe illness. There is always more or less torpidity of the alimentary canal consequent on serious maladies, and by stimulating the action of the stomach by alcohol in some form, digestion and the assimilation of food are promoted. question whether we could part with alcohol as a food, may possibly be a bone of contention for all time, though it is scarcely conceivable that such an important operation as alcoholic

fermentation, by which the fruits of the earth may be preserved, is not in some way intended for the benefit of mankind—See Stimulants.

ALCOHOLISM is a polite term often applied to signify intoxication due to the indulgence in spirituous liquors. It may be extended to indicate the origin of numerous diseases associated with the liver heart hid. diseases associated with the liver, heart, kidneys, lungs, air passages, and the brain and nerves.

ALE.—See BEER.

ALIMENT .- See FOOD, DIETARIES, &C. ALIMENTARY CANAL,—the entire tube through which the food passes from the mouth to the anus; the total length in man averaging thirty-three feet. Its divisions are the mouth, the pharynx or throat, the œsophagus or gullet, the stomach, the small intestines, and the large intestines and rectum. The accompanying diagram exhibits the course of the canal from the mouth to the rectum, with the salivary glands, lacteal vessels, and thoracic duct leading into the venous circulation at the left side of the neck. The liver and gall-bladder are turned up to show the parts underneath.

stomach, which it enters towards its larger extremity, passing down the posterior part of the chest. The shape of the stomach will be best understood from the figure; it has a larger

extremity, and a smaller. From the smaller proceeds the first portion of the small intestine, named the duodenum, divided, however, from the stomach by the pyloric valve. The small intestines, divided nominally into two more portions, jejunum and ilium, extend in a continuous coil to the length of about twenty-five feet, and then enter the large intestine in the

ALM

ALI

right iliac region. The opening of the small intestine into the large is slit-like (fig. 6 c), and is protected by a valve (D). The large The opening of the small intestine or colon, five feet long, ascends from where it is entered by the smaller gut, as high as the under surface of the liver, it then passes across the abdomen, and descending, after making a peculiar turn, ends in the rectum or vent gut. The calibre of the colon is much greater than that of the small intestine, and it is thrown into sacculi or folds by three longi-

tudinal muscular bands. As soon as food reaches the back of the throat, it passes from the power of the voluntary to that of the involuntary muscles, and is conveyed into the stomach by a regular wave-like action of the muscular gullet or esophagus. When persons eat too fast, and one morsel is passed into the throat too quickly after the other, this regular muscular action becomes spasmodic, producing a very painful sensation. The mass of food from a meal, being collected at the larger end of the stomach, is there mixed with gastric juice, and converted into a pulpy grey-looking mass, the chyme, which as it is formed, is propelled towards the pyloric or smaller extremity, by successive wave-like motions of the organ. the pyloric valve all well-digested food is allowed to pass, but in the healthy stomach, any portions which are not thoroughly softened are stopped, and passed back into the organ. The food having passed through the pylorus into the upper part of the small intestine, quickly becomes mixed with the bile (which flows into the duodenum from the liver by its proper duct), and also with the pancreatic juice. The mass of chyme is now propelled forward by a worm-like motion of the small intestines, the nutrient portions being absorbed from it as it passes onward, by the lactcal vessels, and by the minute blood-vessels which permeate the lining membrane of the bowels throughout

by some to undergo a kind of second digestion, assume the feculent character. After yielding up in the colon the remains of nutrient matter, the mass is discharged through the rectum and anus. The whole of these movements are effected by the muscular powers of the alimentary canal itself. The main object of the alimentary canal is, most undoubtedly, the digestion of food, but this is not its only office, it is one of the great and important drains and sewers of the body, and into it is cast a large proportion of the used-up material of our frames, which would be hurtful if retained, particularly so in illness, such as fever. The fact is a cogent one why, at all times, the bowels should be kept clear, and will explain to people wherefore, during illness, even when food is not taken, and when they often think and say, "there can be nothing in a patient," the medical attendant is so careful to keep this great drain, the alimentary canal, clear of its noxious contents.

Refer to — Abdomen — Absorption — Diges-

ALIMENTARY TUBE.—A flexible tube designed to enable helpless patients to take fluid nourishment or cooling drinks without raising the head from the pillow. The glass or vessel containing the fluid stands on a table by the patient's bedside; the tube is inserted into the glass, to which it is fastened by a clip with a swivel joint to prevent its upsetting.

This contrivance may be obtained from Messrs.

Arnold & Son, West Smithfield.

ALKALI.—An alkali is a substance which neutralizes acids more or less perfectly, forming, by the combination, a salt which differs from either of its components; thus, nitrate of potash or saltpetre is a compound of potash and nitric acid. Alkalies have also the general property of turning vegetable blues to green, and reds to violet. Potash, soda, and ammonia are the three alkalies; the two first are fixed, the last is volatile.

Refer to-Potash-Soda-Ammonia.

ALMOND .- The sweet almond as an article of food is not very digestible, but as it contains little starchy matter and much oil, it has been made into a kind of biscuit bread, suitable for cases of diabetes. When triturated with gum and sugar, so as to form an emulsion, it constitutes a pleasant demulcent vehicle for medicine in affections of the chest or mucous membranes, and may be taken freely. The bitter almond is most decidedly unwholesome, unless in very small quantity as a flavour; and some persons cannot even take it in that way with impunity. The essential oil of bitter almond contains, after distillation, prussic acid in sufficient quantity to act energetically as a poison. A single drop of the pure oil would be dangerous. Cases of poisontheir whole course. Having traversed the small, the chyme is discharged into the large intestine, or colon, through the slit-like valve, and here the contents of the bowels, thought to those in poisoning by prussic acid. The

strong peculiar odour of the oil will in most | Sarsaparilla, dulcamara, and taraxacum are cases betray the accident.

Refer to—Prussic Acid.

ALOPECIA.—See BALDNESS.

ALVEOLUS.—The socket of a tooth.

ALOES.—The inspissated juice of the cut leaf of the aloe, imported into this country from the East and West Indies, and from the coasts of the Red Sea. It is one of the most useful and extensively used purgatives, is seldom given alone, and is scarcely employed domestically except in its combinations, par-ticularly in pills; indeed, there are few active aperient pills into the composition of which aloes does not enter. The action is certain, and, except in peculiar cases, easy and safe. In pregnancy, and where any tendency to piles exists, the use of aloes is better avoided. The action of the medicine upon the stomach is, in small doses, tonic; but the principal effect of aloes is upon the lower bowels, the movements of which it appears to excite, without increasing the discharges; it seems to act similarly to the bile, and when that is deficient, as a substitute for it. The preparations into which aloes enters are generally better provided ready made. These are very numerous, and comprise the extract, pills composed either of the drug alone, or in combination with other drugs, the wine of aloes and the compound decoction. Of the pills, the simple aloetic, the compound rhubarb, and the compound colocynth are the best; the last is the most active. Of any of these, one or two pills, three grains each, may be taken at bedtime as an average dose. The compound docoction of aloes is a most excellent form, and may safely be given when quick action is required, in one to two ounce doses. For old people it often answers well, and is preferable to pills. It is made as follows:-take of aloes two drachms, saffron and myrrh bruised, of each one drachm and a half, carbonate of potash one drachm, extract of liquorice one ounce, compound tineture of cardamoms eight ounces. Add sufficient water to reduce to thirty ounces after ten minutes' boiling. Dose, one or two ounces. Aloetic purgatives may be taken habitually for a long time without an increase of the dose being required; the continued use, however, may induce piles.

Refer to—Purgatives—Pills. ALTERATIVE is a rather indefinite term applied to certain medicines which are supposed to have the power of changing the varied disordered actions of the body, without producing any sensible effect when taken. These embrace a large number of remedies having much variety of action, and their administration depends on the morbid or constitutional taint from which the person suffers. Those most employed are the mineral acids, the compounds of mercury and iodine, and a combination of rhubarb and soda in repeated small doses,

alteratives much in use, the action of which is not so well determined. There is, however, an alterative preferable to medicine—obedience to the laws of health. Temperance in eating and drinking, exercise, attention to the state of the skin, and to the ventilation of sleeping-rooms especially, are alteratives which every one may employ. A course of medicinal alteratives must be left to medical direction

ALUM is a compound salt of sulphuric acid, potash, and alumina. It is a powerful astringent, and is used as such in medicine. In bleeding especially, as from the nose, lint dipped in a strong solution of alum, and applied to the part as a plug, will often stop the flow, or in the case of leechbites, the powder of burnt alum may be sprinkled upon the puncture. Internally, alum is given in cases of protracted diarrhœa, and in hæmorrhage from the lungs or stomach, &c. In case of an individual being attacked either with coughing up, or vomiting of dark blood, in the absence of medical assistance, alum, which is generally easily procurable, may be given in doses of from five to twenty grains every two or three hours. In cases of that painful spasmodic affection of the bowels, named painter's colic, to which those who work much among lead are liable, alum has recently been found of much advantage, and might safely be given provisionally, by an unprofessional hand, to ameliorate suffering the dose from ten to twenty grains every three or four hours. Alum has also been found useful in the later stages of hooping-cough, in doses of three grains in honey or glycerine every three or four hours. As an astringent gargle in relaxed sore-throat, alum is most useful in the proportion of two drachms to half a pint of water. Alum may be given in pill, but better in solution, in distilled water flavoured with cinnamon, or some aromatic. Alum whey, made with five grains of the salt to every ounce of milk, and the curd strained off, is a pleasant and convenient form—a tea-cupful to be taken three times a day. A few grains of alum, agitated with the white of an egg, forms a coagulum, which, put between two folds of muslin, is used with benefit to the bed-sores of

Refer to—Hæmorrhage.

ALVINE.—Connected with the belly—as

alvine discharges, concretions, &c.

AMAUROSIS, the Gutta serena of Milton, is total or partial blindness, depending upon disease of some portion of the nervous connexions of the eye. The retina, the brain, the connecting nerve, may any of them be the seat of the disease. The appearance of the eye is unaltered beyond the dilatation of the pupil. which gives it a peculiar dark, deep look, but the expression is unmeaning. Persons who exercise the eyes much on minute objects, or which is perhaps the safest and simplest of all. | who are much exposed to the glare of intense

AMB AMB

some amount of inflammation going on within the eye itself, and if taken in time, is remedi-A person threatened with amaurosis, first observes, in the daytime, dark motes or specks floating, as it were, before the sight, at first distinct from one another, but gradually becoming connected, and forming, as it were, a thicker and thicker veil as the sight becomes obscured. In the dark, the motes or specks frequently appear luminous. Sudden flashes of light appearing is a sympton not unfrequent; there is usually pain in the eye and head. It must not be supposed, however, that every one who sees motes or specks is becoming amaurotic, some persons have this peculiarity of vision, either habitually, or whenever the stomach is disordered. In addition to the causes above stated, amaurotic blindness may be the result either of over-fulness of blood, or of the contrary condition, of disease of the brain, of indigestion, sexual excess, hysteria, gout, over-nursing, &c. In such a disease, requiring the nicest discrimination of the medical practitioner as to its cause, before he can adopt appropriate treatment, no unprofessional person is qualified to interfere. An individual threatened with amaurosis cannot too soon submit himself to skilled advice, and should let no consideration stand in the way of his doing so as quickly as possible. Should distance, or any unavoidable cause, occasion delay, all exercise of the eye should at once be stopped, the general health and condition of the bowels attended to, and unless there is evidence of extreme weakness, all stimulants avoided; if the patient is a nursing female, the child must be weaned at once. Amaurosis, or blindness without obvious cause, coming on suddenly in a person of full habit of body, is always a grave symptom, and, as in such a case, every minute may be valuable, if medical aid cannot at once be got, six or eight leeches may safely be applied to the temples; an active purgative of twenty grains of jalap, and four or five of calomel is to be given at once, and after the leeches, cold applied to the head; perfect quiet being observed. All further treatment in this disease must depend on the individual judgment of the medical attendant. Refer to—Eye—Brain.

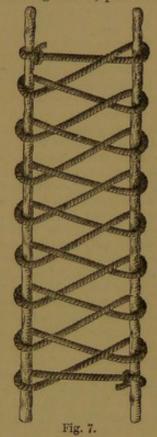

AMBULANCE. - This term, borrowed from France, where it refers to a department of the army employed in war time for succouring the wounded, has come of late much into use in this country, and has taken a wider signification, being applied to the means of securing immediate aid to the injured of all classes, and prompt action in cases of emergency and sudden illness. Short courses of lectures, as well as practical instruction on such subjects, are

light, are liable to become amaurotic, but in | volunteers, and other disciplined bodies, as well such cases, the disease is mostly the result of as to persons of both sexes who choose to avail themselves of them. In this article we will limit our remarks to the branch of the subject which relates to the conveyance of injured persons, from the spot where an accident happens, to their homes or to the hospital. In war time it is the province of the Hospital Staff-Corps in the British Army to carry the wounded to the rear or to the nearest field hospital, stretchers as well as other apparatus being provided for the purpose; but in civil life this duty is usually entailed on the people of the neighbourhood where the accident occurs, or on the police, when they are accessible. When a horsed-vehicle can be had, such as a cab, spring cart or waggon, the difficulty is readily solved, provided there is no unnecessary jolting, but much more frequently the onlookers are forced to have recourse to their own ingenuity for a means of conveyance. Many contrivances are resorted to, the readiest consisting in carrying the patient bodily to a place of safety. If only one man is present besides the injured person at the time of accident, and the patient is able to walk or limp, the former may give material help by allowing the patient to lean heavily on him, or he may' carry him on his back, but if two assistants are at hand and the injuries are not severe enough to require the recumbent position, a tolerably comfortable support may be obtained by the assistants crossing their four hands under the buttocks, and allowing the patient to put an arm round the neck of each. When a number of assistants are at hand, as in street accidents, or in accidents in public works, the difficulties of removal are trifling, for although stretchers of an approved character are not to be obtained at every street corner, it is easy to devise one from a door, shutter, or a few planks of wood riveted together. Any one of these temporary substitutes, fitted with a pillow, and a blanket or two in cold weather, may be carried easily on the shoulders of four men, but, if a couple of poles are to be had, it is infinitely better to extemporise a stretcher, or rather a hammock. In his valuable little work entitled The Surgeon's Pocket-Book,\* Surgeon-Major Porter has given numerous illustrations of methods of extemporaneous transport, suitable either for military or civil life. Carrying-poles, made of cedar, pine, or ash, to which cross bars are adjusted, can be fitted with a stout blanket or sheet, so as to form a comfortable conveyance, which can be borne by a couple of men; or a contrivance more nearly resembling a stretcher may be improvised by lashing round the poles, belts of leather, webbing, ropes of straw, or ordinary ropes as in fig. 7.

Whichever material is used, it is essentially necessary that the stretcher should first be given by medical men and others to the police, tested, to see that the lashings are thoroughly

Published by Charles Griffin & Co., London

secured against any possibility of accident. The | The stretcher, furnished with a hood which may best stretchers are, of course, those made for the purpose; and there are none more handy or efficient than those employed by the Metropolitan police, for removing drunk, dying or injured persons to the Hospitals, and obstreperous subjects to the police stations. These are made of strong canvas, painted and riveted

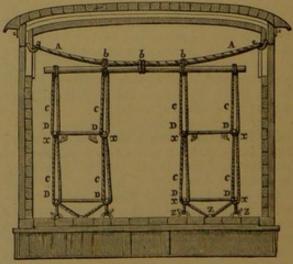

to the poles, which are kept apart by iron cross pieces at each end and furnished with side straps, to secure the person when required. A stretcher of this kind may be carried by two men or on the shoulders of four, and has four short iron feet attached, so that it is always raised above the ground level, when the person is laid on or removed from it. It is manufactured for the Metropolitan police, and for the London Hospitals, by Atkinson & Co., of Westminster Bridge Road, Lambeth. Of wheeled vehicles, that most employed, because of its universal use in street commerce, is the long narrow barrow known as the costermonger's. When filled with straw, the costermonger's barrow forms an excellent rest. The head of the patient should lie on a raised pillow at the far end of the vehicle, and care should be taken that the body should maintain either a perfectly head downwards. Somewhat on the same principle, but far surpassing it in elegance, ease, and comfort, is the wheeled litter of the "St. John" Ambulance Association, which consists of a stretcher and spring vehicle, now rapidly being brought into use in public works, and other places liable to accidents.

24

be opened or closed at pleasure, can be readily detached from the vehicle and carried with its burden by a couple of men up steps or staircase, into a private room or hospital ward, sparing the sufferer much pain and inconvenience. The accompanying illustrations (figs. 9 and 10, taken from the descriptive account by the Society of the litter in question) give an excellent idea of the mechanism of the vehicle

and its capabilities. When an injured person has to be put into the litter, the stretcher is detached from the vehicle, and its end carried as close as possible to the patient's head so as to be in a line with the body and to facilitate the transfer move-ments of the assistants. When at rest, the litter is supported by the wheels, a movable prop behind, and two legs in front; it has an inclination from the head downwards to facilitate ingress and egress, and the whole, is designed with the view of securing as easy and steady a position for the sufferer as can well be obtained. The philanthropic society which has patented the litter has its headquarters at St. John's Gate, Clerkenwell, and supplies it to the public, with no pecuniary advantage to itself, at a cost of £16. The entire apparatus is excellently and durably made, and is comparatively light, the weight of stretcher and vehicle combined being under 150 lbs. In the last war between France and Germany the ambulance departments excited much interest and attention, owing greatly to the efforts of the Red Cross Society, instituted specially to render prompt and substantial help to the wounded. All kinds of conveyances were in requisition for this purpose; among others, railway trains fitted up with hammocks, litters and extemporised kitchens, to convey the sick and wounded long distances. Mr. Porter, in the work referred to above, gives the accom-

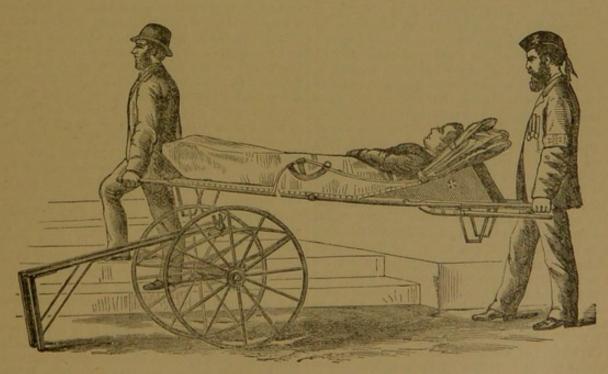

Fig. 10. The St. John's Stretcher as removed from the Vehicle.

The accompanying Illustrations are inserted by kind permission of the Society of St. John of Jerusalem.

been adopted in the Russian service, and is found to possess the power of preventing shocks

from travelling.

The apparatus consists of two cables (A A) an inch in thickness, which are suspended across the top of the car, and secured to iron hooks that fasten to iron rings 21 inches below the roof of the car. If hooks and rings are not available, the ropes may be passed through four holes bored into the side of the car. To each of the two ropes is attached at three points (b b b) a pole of oak, ash or other elastic wood, adapted to the width of the car, but at least 8 feet long, and 21 inches thick in the middle and 1½ inch at the ends. To the poles thus placed horizontally there are attached on either side four cords (c), with knots (x) so arranged that they may support on a level the stretchers (D D) on which the wounded men recline. To prevent the patients being swayed backward and forward when the car is in motion, the lower stretchers are fastened by 1½ inch ropes to three small iron hooks (z z z) screwed into the floor of the conveyance. For information respecting medical and surgical aid to the injured, see Emergencies - Wounds - Fractures-Hæmorrhage, &c.

AMENORRHEA. -See MENSTRUATION. AMMONIA-VOLATILE ALKALI-SPIRIT of Hartshorn-a gas in its pure state, which is used in medicine in solution, either in water or alcohol, or as a salt, in combination with carbonic acid or acetic acid. In the former case it constitutes the common carbonate of ammonia; in the latter, the solution of acetate of ammonia, known popularly as "spirit of Mindererus." The solution of ammonia in water is used of two different strengths, one very strong, generally employed externally in combination with oil, the other more diluted,diluted solution of ammonia, -given in cases of fainting, depression of the system, or as a stimulant ant-acid in indigestion; or in spasm, in doses of from five to twenty drops in water, or other simple fluid. In cases where very rapid effect is required, ammonia is advantageous, but when there is partial insensibility, care must be taken that choking is not produced in the administration. When combined with olive oil, ammonia forms a most useful and generally-used stimulant liniment. Two parts by measure of oil, to one of the diluted solution of ammonia, is a convenient strength; or equal parts of each may be used, if a stronger form is requisite. Poisoning by ammonia sometimes occurs, particularly by mistake: the best and most convenient antidote is vinegar, or any vegetable acid.

Carbonate of ammonia is an instance of two gaseous bodies forming, by their union, a firm solid. The actions and uses of this salt are the same as those of ammonia; it may, however, be given in pill; if in solution, five grains dissolved in three table-spoonfuls of water is an

average dose,

Chloride of ammonia, formerly known as sal ammoniac, is now one of our most powerful remedies in neuralgia, and is also much used in India and this country in liver affections-

The aromatic spirit of ammonia, or sal volatile, is perhaps the best and most convenient form for internal administration; certainly so for popular use. It keeps good any length of time in a stoppered bottle; and the dose, from a half to a whole tea-spoonful, in three parts of a wine-glassful of water, is easily and readily administered. Solution of acetate of ammonia is a very certain and safe diaphoretic, producing free perspiration. In colds and slight febrile ailments, it may be given without fear, in table-spoonful doses diluted with water, repeated every few hours, its effect being assisted by warm drinks and confinement to bed.

AMMONIAC GUM — a stimulant expectorant, used also in the form of stimulant plaster, especially in some cases of diseased

knee-joint.

AMPUTATION can never legitimately fall within the scope of unprofessional surgery, except when it is occasioned by violent accident; and when a longer or shorter time must elapse before surgical assistance be procured. The immediate danger in such cases is fatal hæmorrhage or bleeding; but, fortunately, from the usual nature of the accident, this does not occur to so great an extent as might be expected, the bruising or tearing which generally accom-panies the severance of the limb acting as a preventive. The first thing to be done in such an accident, if there is much bleeding, is to tie a handkerchief, a garter, or band of some kind, round the limb, between the bleeding points and the body, and if a pad can be placed over the trunk of the main artery, so much the better. It is wise not to attempt to wrap up the wound itself too soon, it should be freely exposed to the air; there is no better stauncher of blood than a cool breeze: above all things, the bathing with water, especially warm water, which is so frequently done, is to be avoided. In addition, the wounded member should be elevated above the level of the body. When the bleeding has ceased, which it will almost certainly do, if these means are properly attended to, a soft linen cloth, or cotton, if there is no linen at hand, should be placed over the wound, the patient kept quiet in a recumbent posture, with the limb slightly but easily elevated, and nothing more done until the surgeon's arrival. No mention has been made of the method by which the surgeon secures a cut artery by tying; it is not a pro-cedure to be attempted by the unprofessional, except in most extreme circumstances, such as the certainty of no medical assistance being procurable for many hours, it might be days. In such a case, it would be impossible to keep the tight band round the limb without mischief ensuing: by slightly relaxing it, after some AMY ANÆ

arteries likely to bleed would be made evident by their immediately doing so. A slender but firm hook, or pair of small forceps, should be used to pull forward every bleeding point in succession, so far as to allow of a ligature of silk, or fine twine, being tied around it by a second person. The cessation of the flow of blood will indicate whether this has been done effectually; at the same time, the band round the limb must not be removed, but only relaxed, and left so that it can be instantaneously tightened, should hæmorrhage return. In such an extreme case, it might be almost a matter of necessity to detach a limb, the bone of which had been crushed through and the main artery severed, by a few strokes of a sharp knife. Of course, after such an accident, watch, with light, must be kept up during the night. Should heat and inflammation come on, cloths dipped in cold water may be freely applied.

AMYL NITRITE—a volatile liquid of a strong odour prepared from amylic alcohol which has been treated with nitrous fumes. It is used chiefly by inhalation, a few minims (4 or 5) placed on a piece of lint or on a handkerchief, and held to the mouth and nose, give instantaneous relief to the pain of angina pectoris. It has also been found exceedingly serviceable in asthma, and in some cases of neuralgia. It is now prepared in glass capsules encased in cotton wool, which are crushed by the finger and thumb when the vapour is used. As the drug is very powerful, it requires to be used with extreme caution, especially with old people.—See Angina Pectoris—Asthma—

Epilepsy, Anasthetics.

ANÆMIA - CHLOROSIS-a condition of constitution, in which the quality of the blood is deficient in its red globules, or colouring portions, more especially. It is common in young females, especially of scrofulous habit. The pallor of all those portions of the body, such as the lips, which are usually well-coloured, sufficiently indicates the disease. Anemia may arise from accidental causes, such as deficient nourishment, unhealthy situation, extreme loss of blood, or may be of constitutional origin. In the former case, it is generally quickly recovered from, if the constitution be a good one, under the use of iron and good living; in the latter case, it often requires long and patient perseverance in these and other means to effect a cure. General languor and listlessness, very heavy sleep, headache, mental debility, impaired, capricious, or depraved appetite, constipated bowels, swelling of the feet, are the general accompaniments of anæmia; the monthly secretion is either absent or very pale. The primary cause of anemia is still obscure, but the direct cause of the symptoms

reaction has come on, the situation of any | improve the vital fluid must be the great aim of treatment. The bowels should be kept open, not purged, by some mild aperient, such as the compound rhubarb, or colocynth pill, and ten drops of the perchloride tincture of iron, or five grains of tartarated iron, given in a wineglassful of water twice or three times a day. If the appetite is deficient, and does not improve, a dose of tonic bitter, quinine, salicine, or gentian, must be given along with, or substituted for, one dose of iron. Cod-liver oil is also useful. The diet must be generous; meat twice a-day, eggs if preferred, puddings in small proportion, and bread partly substituted for vegetables. Malt liquor, especially porter, to the extent of one of the usual pint bottles, should be taken in divided portions, daily, or a couple of glasses of port wine, if the former disagrees. An anæmic patient ought to retire to rest by ten o'clock, and to rise, as a general rule, by half-past seven, but ought never te delay breakfast beyond the mere time required for dressing; going out before the meal is quite out of the question, and, indeed, in some cases, where there is a tendency to fainting, it is better to have a cup of coffee, or warm milk, before rising, and even to this, as a temporary remedy, it may be requisite to add a tea-spoonful of brandy. The skin must be attended to, and in many cases a cold sponge bath is of great service, while in others tepid sponging only can be borne. The bed should be a hair mattress. Exercise in the open air on foot or horseback, must be regular, but not carried beyond comfortable fatigue. Change of air to the sea-side, or to a chalybeate spring, is of great service. Mothers are often anxious about the non-appearance of the monthly discharge; its absence is but a symptom of the disease, and it is better that the constitution should not be drained even by it, until it is able to sup-Such are the general rules respecting anæmia, but a confirmed case should always be submitted to the medical man-causes may be aggravating, or effects such as consumption, springing from the disease, which he only can detect. Moreover, in extreme cases of this disease, sudden death has occurred.

Refer to-Chalybeates-Iron, &c.

ANÆSTHESIA. - Loss of sensation. ANÆSTHETICS are agents which produce insensibility to pain, whether applied locally, or to the system generally, by inhalation. It is now generally accepted that while chloroform is the most convenient, ether is the safest anæsthetic, while a mixture of the two, with some pure alcohol added, is at once a safe and convenient form. The relative proportions are one of alcohol, two of chloroform and three of ether. The anæsthetics should never be given but by a duly qualified person, and certainly should never be administered by any one to himself. It may now be said that deaths from the administration of chloroform are very is undoubtedly poverty of the blood, and to unusual, and we hope that they will become,

in time, almost unknown, especially since | breathe, with a low or absent pulse, livid lips, medical men are much more cautious in having chloroform given only by those who are ex-perienced in its use, in which case it must happen very rarely indeed that there is any cause for alarm.

There are a great number of chloroform "inhalers" used at present, but the fact is that none of them can be specially recommended, and that the simplest method is the best. The patient ought to lie down, to keep his eyes shut, and breathe freely; any tight article of dress around the throat or chest should be loosened; about two drachms of chloroform should be sprinkled over a folded towel, which is to be lightly applied over the patient's face, and afterwards, when this is partially evaporated, one drachm should be added from time to time, till insensibility is produced. How much chloroform should be given, can only be determined by an experienced person, who tests the sensibility of his patient by opening the eye and touching it, by raising the arms and letting them fall again; thus judging if the muscles are relaxed; or by otherwise testing his patient's power. Many patients, before getting under the influence of chloroform, struggle violently, and require to be restrained by one or two assistants, but the administration should be continued till this is overcome, which it speedily will be, the patient then generally passing into complete insensibility. The uninitiated ought to know that patients often shout, and even appear to suffer great pain, when they are quite unconscious, and that there are great differences exhibited by different people in the way in which they are affected by the drug. When it is desired to relax the muscles entirely, as, for instance, to allow of the reduction of a dislocation, it will be necessary to produce even a more decided effect than is required for a painful operation, as the amputation of a limb, the removal of a tumour, &c. On such occasions, the administrator of the chloroform most attentively and momentarily watches the condition of his patient. It cannot be too emphatically repeated that care and experience are the two great requisites in the giving of chloroform. Another mode, which deserves notice on account of its simplicity, and which is in great favour, though, in the writer's opinion, inferior to the abovementioned method, is to protect the nose of the patient by smearing a little glycerine or cold cream over it, then to spread a handkerchief over the face, and drop the chloroform, drop by drop, over the part just below the nostrils. Bottles are to be had with stoppers adapted for this dropping process. This has certainly the advantage of being a more economical method, but it is not so safe, nor so convenient, as the other. Should it unfortunately happen that a person has inhaled too much, or at all events does not appear to rally from the stupor, or should he, during the administration, cease to urgency occurring every now and then in the

and all the symptoms of suspended animation, then no time is to be lost, for on the energy and promptitude displayed within the next few seconds or minutes will depend, in all probability, the issue of the case. The head must be kept low, the face should be slapped smartly with a towel dipped in cold water, ammonia at once applied to the nostrils, and artificial respiration commenced, by pressing upon the chest, so as to expel the air, and then allow it to expand again of itself. This should be repeated at the rate of about twenty times in the minute, the surface of the body over the region of the heart being rubbed with a brush, or with the hand, warm blankets, or bottles, or hot bricks applied to the hands and feet, and the galvanic battery (which ought always to be in readiness where chloroform is frequently given) should be applied, to promote artificial respiration, in conjunction with the means mentioned above. The restoration of the pulse, the reappearance of the healthy colour of the lips and countenance, and, above all, the breathing of the patient, or his showing any sign of returning consciousness, will be hailed with joy, and if there still remains great prostration, a little brandy and water, or wine, may be given at intervals. Of late the nitrite of amyl has been used to restore consciousness. It is sold in capsules, which can be readily broken and held to the nostrils during a few inspirations until the face is seen to flush. If there is much pallor and depression after the anæsthetics, ten or fifteen drops of brandy injected subcutaneously will improve the heart's power. This may be repeated. It was formerly considered dangerous to administer chloroform to those suffering from heart disease, but, carefully handled, it may be given without hesitation. The only condition of the heart, which contra-indicates its use, namely, fatty heart, is rarely discoverable before death. It should also be given with extreme caution to young infants (in whom insensibility is quickly produced by using a very small quantity), to persons advanced in life, and to persons of feeble vital power.

It need scarcely be said, that many operations which formerly were very troublesome of performance, especially upon children, are now rendered comparatively easy by the use of chloroform; many operations also requiring great nicety of manipulation, and almost impossible, without the co-operation of the patient—a co-operation never to be obtained in the case of children, and even of some grown-up people—can be performed with the greatest ease, and without any trouble on the part of the surgeon.

Finally, it would be impossible to omit mention of the great value derived from the use of chloroform in childbed, and more especially in those cases of extreme difficulty and

ANA ANG

duction and use in this, as well as in all other departments of medicine, the world is indebted to the late distinguished professor of midwifery in Edinburgh, Sir James Simpson, whose genius devised, and whose indefatigable energy brought into general use this, which must rank first among the many improvements he introduced

into the practice of medicine and surgery.

ANALYSIS.—The art of separating and distinguishing the various constituents of a compound body, either as regards quality or quantity. In judicial inquiry, analysis is most important, and were its power and perfection more generally known, the dread of almost certain discovery, would tend to check the too common crime of poisoning. It is possible for the chemist to make the 1000th of a grain of arsenic demonstrable.

ANASARCA.—See Dropsy.

ANATOMY.—The science which treats of the structure of organized beings. It is divided under the heads of General Anatomy, which regards the general features and relative position of the various portions of a body; and Structural Anatomy, which regards the in-

ANCHYLOSIS is the stiffening of any joint caused by its impairment or destruction by inflammation. If complete, the joint cannot be moved; it can only be remedied by the surgeon. If partial, much improvement is often induced by passive movement, warm bathing, and gentle friction.

ANEURISM-a tumour communicating with the canal of an artery, and filled with blood. Its wall is formed by the dilatation of the coats of the vessel at some particular spot. The progress of the disease is for this sac to grow larger, whilst its coverings become thinner and thinner, until at last they give way, and the individual dies from loss of blood. In many cases, surgical interference can save life by arresting the disease, and the sooner this is done the better. Aneurism may be suspected, when a tumour is felt, which distinctly pulsates, conveys to the finger a thrilling sensation, and becomes smaller and less tense when the current of blood through the artery leading to it is interrupted. In such a case, the surgeon should at once be consulted. It is not, however, every tumour which pulsates that is aneurism, for proximity to a large artery may give the appearance of its doing so. The most common seat at which the disease can be recognised by the unprofessional is behind the knee. The symptoms frequently come on suddenly after severe exertion, they are often obscure and are mistaken for rheumatism. The chief are pain and swelling of the foot and leg with pulsation in the tumour.—See also Artery.

experience of all practitioners. For its intro- | human life; it occurs more generally after middle age, and is more frequent in men than women. The attack is characterised by the sudden onset of agonizing pain, referred to the centre of the chest, or a little to the left side of it, passing through to the spine, up to the left shoulder, and down the arm of the same side even to the extremities of the fingers. Sometimes both arms are affected. Along with the pain, which is always said to be agony be-yond description, there is a sensation as of instant impending death. The paroxysm ceases as suddenly as it comes on. Angina pectoris may be preceded by warning symptoms, palpitation, shortness of breathing, in-digestion, or it may come on unheralded by any of these, generally during some slight exertion, as walking up hill, or during strong mental emotion, but not unfrequently in the night, after the first sleep. An attack of angina pectoris is an emergency affecting life, to which there are few equal; full, instant, stimulation is demanded, and the first agent of the kind at hand must be used, till other remedies and proper assistance can be procured. A glass of spirits and water as hot and strong timate and microscopic structure of the various | as it can be swallowed, and with it, if procurable instantly, 40 drops of laudanum must at once be given. A strong mustard poultice is to be applied immediately to the front of the chest, and the same between the shoulders-hot applications to the feet. If the paroxysm be not subdued in a quarter of an hour, the stimulant is to be repeated with half the quantity of laudanum, and this again, after the same interval, if requisite. Spirits have been mentioned as being the most readily procurable, but when ether and sal volatile, either one or other, or both are at hand, they are preferable, and must be given in just so much water as will permit of their being swallowed; a tea-spoonful of each with thirty drops of laudanum. A person who has once suffered an attack of angina should never be without these three requisites, laudanum, or better, Battley's sedative solution, ether, and sal volatile. It is needless perhaps to say, that all these measures of an emergency in which not a moment is to be lost, are whilst waiting the arrival of the medical attendant, and that to him must be entrusted the direction of that regulated mode of life, which must ever be adopted after an attack of this disease. The treatment of the emergency it may be highly important for an unprofessional person to be acquainted with, that of the interval, which may extend to months or even years, with care, must be left in the hands of educated skill alone. Within the last few years, we have, in nitrite of amyl, the most effectual and rapidly-acting remedy in cases of heart-spasm. From two to remedy in cases of heart-spasm. From two to four minims may be dropped on a piece of lint, ANGINA PECTORIS, or Spasm of the Heart, is one of the most formidable and who suffer from attacks of heart-spasm frepainful of the affections which terminate quently carry about with them a little stop

pered bottle containing a small amount of with bare chests and limbs, and exercise not amyl, finding a few sniffs sufficient to ward off an attack. Martindale's capsules, however, only lately introduced, are. perhaps, the most convenient form in which amyl can be carried about the person.

ANIMAL HEAT is the temperature which every animal body is enabled to sustain, independent of surrounding media. In healthy men, the average temperature of the body is 98° or 99°, in febrile diseases it rises considerably. Whether our animal temperature is sustained in part from other sources or not, it is generally now considered to be chiefly due to the continual union of the carbon and hydrogen derived from the food, and from the bodily tissues, with the oxygen conveyed to every portion of the living frame, from the lungs, by the blood. One great fulfilment therefore of the food we digest, is to keep us warm, by the continual combustion of elements going on within us; consequently, persons who can consume and digest large quantities of food, have much greater power of resisting cold than those who cannot, and chilliness is one very constant symptom of impaired digestion; the stomach is unable to keep the system supplied with fuel. The point is one of considerable importance in the selection of crews for Arctic expeditions, and ought to have some influence with intending emigrants in their choice of a future home. An individual who suffers from habitual weakness of digestion, ought to choose a warm or genial climate in preference to a cold one. Fats and oils especially, which contain much carbon and hydrogen, afford great protection against severe cold; accordingly all northern people, like the Esquimaux, consume them in large quantity, and Europeans travelling in northern latitudes have always copied the natives in this respect. Alcoholic fluids, like fat and oil, contain much carbon and hydrogen, but their stimulant properties, and more evanescent influence, render them unfit for ordinary consumption to sustain animal heat, although on extraordinary occasions they are invaluable. When the tissues are impoverished through exhausting illness, and but little food can be assimilated, alcoholic stimulants are found often very serviceable in keeping up the animal heat. They are quickly absorbed by the circulation, and more readily oxidised than food proper, and there are many physicians who employ alcohol in this way and continue to do so until convalescence is fairly established.

But internal heat cannot do all in our cold clime, and with our artificial modes of living, and it is of the utmost importance, especially in the young and delicate, to maintain the full temperature of the surface by proper clothing. The subject is one, respecting which much carelessness and ignorance prevail in all classes of society in this country, and children, half-clothed for the sake of appearance, 2 and 1) on the one side, and the smooth,

sufficiently active to counteract the effects of the chill, are exposed to all the evils resulting from internal congestions of the blood repelled from the surface. Warm clothing is, in some respects, a substitute for food, and both man and animals require less nourishment when protected from cold. It is well known to agriculturists, that sheep or cattle will fatten more quickly under cover in winter, than if exposed to the weather. The reason is obvious, they are able to store up in their bodies that which otherwise must have gone to keep them warm. When it is considered that abstraction of animal heat, by cold and wet, is one of the most fertile sources of fatal disease, the importance of maintaining to the full the temperature of the body is manifest. It is well known that exercise is the best antagonist to cold; it is so, by quickening the respiration, and thus increasing the supply of oxygen taken in by the blood, which is also circulated more rapidly. In fact, to use the simile which compares the body to a stove, exercise gives a free draught for the process of combustion. Continued exposure to an extreme degree of cold, which carries off the animal heat more quickly than it can be generated, gives, it is well known, rise to overpowering drowsiness, which, once yielded to, is death. It must be resisted, and when one of a party thus exposed is inclined to yield, the others must resort to every means calculated to rouse, even—as has been done by thrashing him along; the temper which is excited is a most excellent resistant of cold.

Refer to—Aeration—Blood—Lung — Circu-

ANIMATION, SUSPENDED, is the term applied to that condition in which the life of the body is threatened, in consequence of respiration having been stopped or impeded, but in which there still exists a possibility of life being preserved. The chief causes of suspended animation are drowning, hanging, immersion in choke damp or irrespirable gas, and intense cold. These may be referred to under their proper heads.

ANISE - aromatic and carminative - is used chiefly in the form of the distilled water to correct flatulence in children, but is not so generally liked by them as dill water, which is equally efficacious. The dose is a tea-spoonful. The essential oil of aniseed is used to flavour mixtures, and is given in doses of five or six drops for an adult, upon lump sugar. The essence of anise, which is composed of one part of the oil and four parts of rectified spirit, is likewise employed as a carminative in doses of from 10 to 20 minims.

Refer to—Carminative.

ANKLE is the joint connecting the foot with the leg (fig. 11). It belongs to the class of hinge joints, and is formed by the extremities of the large and small bones of the leg (fig. 11,

ligaments (4 and 5). The position of the ankle joint renders it peculiarly liable to injurystrain, dislocation, or fracture of the leg-bones close to their extremities. Whenever the least suspicion exists that violence to the ankle has caused more than a sprain, no time should be lost in submitting it to the examination of the surgeon; such injuries are often extremely obscure, and there is much difficulty in making out their exact nature after swelling has come A simple sprain of the ankle is to be treated in the mode directed to be followed in these injuries generally. In cases of dislocation, occurring at a great distance from medical aid, and when, from the extreme distortion of the foot, the accident is distinctly apparent, some attempt ought to be made by those near to replace the parts; for this purpose, the sufferer being laid down, one individual should grasp the leg firmly just below the calf, whilst another, grasping the heel with his left hand, and the lower part of the instep with his right, endeavours, by extension in the first place, and slight turning of the foot towards its proper position, to reduce the dislocation.

The ankles in children are very apt to become gradually distorted from weakness generally, and of the ligaments in particular, and the de formity is often not discovered until it has considerably advanced; the bones become altered in shape, and even the spine becomes affected, from the habitual malposition of the body. The best general remedies are, attention to the general health and strength of the child, as directed in the article "Children," the prohibition of long standing, and enforcement of regular but moderate exercise. The ankles ought to be bathed every morning with cold salt water, and well rubbed afterwards with a rough towel. Many contrivances, boots of various kinds, &c., are, and have been used in cases of weak ankles; unless in extreme cases, they are better avoided, and the case left to the gradual strengthening measures above recommended. If artificial

the many forms of elastic socks or stocking may, however, be worn with advantage. In addition to the above means, considerable mechanical power may be exerted by making the inner or outer margin of the sole of the boot-for cloth boots should always be worn in such cases-thicker or thinner, according to the nature of the deformity; thus if the ankle be inclined to project inwards, the sole should be raised on the inner side, and vice versa. lar perseverance in the above mode of treatment will, in most cases, effect a cure without the more complicated contrivances often used. Attention, too, ought always to be paid to the habits of standing practised by the child at school or elsewhere. Children are sometimes born with ankles distorted.—See Club Feet.

Refer to—Dislocation—Joint—Sprain, &c. ANODYNES must be regarded as constituting one of the most benevolent provisions of the Creator for the relief of his creatures. The removal of pain by an anodyne is like a breath The more generally used anodynes of heaven. are — opium, belladonna, aconite, conium, hyoscyamus, lettuce, hop, camphor, chloral hydrate.

ANOREXIA.—Loss of appetite.

ANT-ACID, in medical language, means whatever directly neutralises acid secretions, more especially of the stomach and bowels. The principal ant-acids are potash, soda, ammonia, lime, chalk, and magnesia. The use of monia, lime, chalk, and magnesia. The use of ant-acids can only be palliative, and their continued regular use is productive of serious mischief; they inevitably destroy the tone of the stomach, and aggravate permanently the evil they may temporarily relieve. Whenever ant-acids are frequently called for, it is a sign that there is other disorder, though perhaps less prominent, which must be looked for and corrected.

Refer to—Dyspepsia—Digestion.

ANTHELMINTICS are medicines which remove the different species of worms found in the alimentary canal. The chief anthelmintics are—the liquid extract of male fern, santonin, quassia, turpentine, kousso; purgatives, especially jalap, calomel and scammony, are indirect. anthelmintics .- See Worms.

ANTIMONY is the metallic base of our antimonial preparations; of these, the most useful are tartarated antimony or tartar emetic, antimonial wine, antimonial or James's powder, and the compound Plummer's pill. Of these, tartar emetic, the most powerful, is a remedy which stands without a rival as the controller of some forms of inflammation. A compound salt of antimony, potash and tartaric acid-it is formed in crystals, but usually sold as a white powder. It is sufficiently soluble in water to be conveniently administered in that fluid, which should always be used soft or supports supply the place of the natural ones | distilled: a simple solution of the medicine is

ANT ANU

emetic acts as a powerful irritant poison, causing intense nausea, vomiting, severe pain in the bowels, purging, bloody stools, and extreme general depression; and even in comparatively small doses, these effects are sometimes liable to be developed in degree, especially in children. Great caution, therefore, is required. In case of a poisonous, or over-dose of tartar emetic at bedtime, in doses of from ten to thirty drops, having been swallowed, the best remedy is some astringent infusion, Peruvian bark, nut galls or strong tea. There is considerable variation in the strength of the dose of tartar emetic given by medical men; when, under necessity, it is dispensed by others, the sixth to the eighth of a grain only should be given to the eighth of a grain only should be given to an adult. A convenient form is to dissolve two grains of the salt in half a pint of soft water slightly warmed, and of this, to give a table-spoonful every three or four hours, so as to keep up continued nausea. Vomiting may follow the first dose or two, but after that, in most cases, the stomach becomes tolerant of the remedy. By giving tartarated antimony dissolved in a moderately small quantity of water, its irritant effects are less liable to be exerted upon the bowels, and should they come on, a few drops of laudanum, if otherwise admissible, must be given in some demulcent, -barley or rice water, and the demulcent alone continued as common drink. To children, tartarated antimony must be administered with great caution, and is better avoided by the unprofessional, except in the extreme cases of croup, or severe inflammation of the lungs, plainly existing, and occurring at a distance from proper medical assistance. In the former alarming disease, tolerably full doses are required to make a quick impression upon the system, and to induce speedy vomiting. For a child of six or seven years, a single grain must be dissolved in an ounce of water, and a tea-spoonful of the solution, given either alone or in a little water as drink, every quarter of an hour, till free vomiting is produced. In inflammation of the lungs half the dose must be given; but this advice, let it be remembered, applies only to the severe diseases above mentioned, when occurring at a distance from medical aid. The practice of administering antimony to children generally, is not well, unless under medical sanction, and in those of weak constitution may be productive of serious or fatal results. It is better for the unprofes-sional to trust to ipecacuan wine or syrup, which keeps better.

For a simple emetic, antimony is seldom well adapted, and should not be used when others are obtainable. Tartarated antimony is used for counter-irritation in the form of an ointment, composed of two drachms of the powder to an ounce of simple ointment. It produces a crop of pustules over the part to which it is applied, and it is not advisable to use it in young children.

preferable in most cases. In large doses, tartar | tartaremetic in wine, two grains to the fluid ounce; in many cases it is a convenient preparation, but of course liable to the same dangers as the watery solution; it is much-too much-used popularly, especially as an emetic. In inflam-matory diseases, the amount of wine which must be given with each dose is objectionable. It is most useful as a simple diaphoretic, given and combined with half an ounce of spirit of mindererus.

> James's powder, although a secret preparation, is comparatively so mild and certain in its operation as a diaphoretic, that it is very generally prescribed by medical men; dose, three to eight grains. The pharmaceutical imitation—antimonial powder—is not always to be depended on.

Plummer's pill contains antimony in small

proportion. - See Plummer's Pill.

ANTISEPTIC—a substance which counteracts the tendency to fermentation, or putrefaction, in organized bodies. These processes are due to the presence and action of minute organisms known as bacteria; antiseptics arrest their activity and destroy their vitality. Some antiseptics are themselves poisonous, such as perchloride of mercury and carbolic acid; others, for instance, boracic acid and permanganate of potash, are comparatively innocuous.

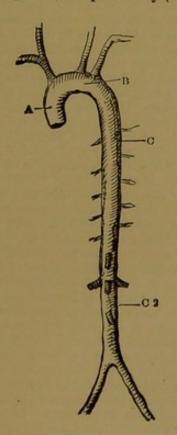

Refer to—Fermentation—Disinfectants.
ANTISPASMODIC.—That which allays pain arising from muscular spasm, or indeed any severe pain unconnected with inflammation. Anodynes, therefore, are antispasmodics, but there are others of the class which are stimulants, and which do not appear to possess any anodyne effect. The principal stimulant antispasmodics are ether, -which may also be regarded as anodyne,—ammonia, valerian, assafœtida, musk, and the various forms of spirit, brandy, &c. The most generally useful anodyne antispasmodic is chlorodyne, known officially as compound tincture of chloroform and morphia. It may be used safely to the extent of fifteen to twenty drops for an adult, taken in a little water. Heat is, however, one of the best, and certainly the safest antispasmodic for general use; in spasm of the stomach, in colic. in gravel, in gall-stone, indeed, in pain generally, the continued application of heatat as high a temperature as can be well borneacts certainly, safely, gratefully. The antispasmodics above enumerated are more directly applicable to the treatment of painful spasm; those which are employed in the treatment of pasmodic diseases, such as St. Vitus' dance, hooping-cough, &c., are many of them more properly tonic remedies; spirits of chloroform, as a general antispasmodic, is eminently serviceable.

Refer to—Anodynes—Spasm—Heat, &c.
ANUS. — The fundament or terminating outlet of the alimentary canal. Itching in this situation is at times extremely troublesome; it ANTIMONIAL WINE is a solution of will generally be allayed by slight relaxation

of the bowels, effected by a few doses of sulphur | tion of the fourth rib with the breast-bone. and magnesia, half a drachm of each taken every night, and by the use of a lotion composed of two or three grains of acetate of lead in the ounce of water. An ointment composed of oxide of zinc and solution of acetate of lead, of each one drachm, with an ounce of lard or vaseline to allay the irritation, is an excellent application. Fissure of the anus is a most painful affection, which requires the care of the surgeon. Prolapsus of the bowel, piles, and listula, all occur in this situation. The anus is kept closed by a sphincter muscle which surrounds it. When this muscle loses its power, as it does in some diseases, involuntary discharges occur. Infants are sometimes born with an imperforate anus, and it is necessary for the surgeon to make an opening in connection with the end of the gut to remove the obstruction. In some cases of intestinal obstruction an artificial anus is made through the walls of the abdomen to allow feecal matter

AORTA. - The main artery of the body, which arises directly from the heart, and from which all the secondary arteries have their origin except one, the pulmonary (see fig. 12).

The aorta is divided into an ascending portion aorta from the heart, is just opposite the junc- diseases.

The passage from the heart into the aorta is closed by three "semilunar" valves, which, when perfect, effectually prevent any regurgitation of blood.

Refer to-Artery-Heart.

APERIENT, -whatever opens the bowels gently, -a laxative, in contradistinction to purgatives, and cathartics, which act strongly. The best examples are sulphur, castor-oil, carbonate and sulphate of magnesia. See Purga-

APHASIA.—Loss of the power of speech, a distinctive characteristic in some cases of

paralysis.

APHONIA .- Loss of voice may be owing to inflammatory swelling, either acute or chronic, or to ulceration of the lining membrane of the larynx, to paralysis, or to hysterical affection. Coming on suddenly, accompanied with fever, pain in the larynx and upper part of the throat increased on swallowing, and difficulty of breathing, the above symptom must be regarded with some apprehension, as one of the concomitants of rapidly fatal disease, acute laryngitis. Loss of voice, however, frequently occurs, quite unconnected with the other symptoms mentioned, and is then not to be so seriously regarded. Many persons are liable to it after exposure to night or foggy air, or after much, or loud talking. Persons living in damp houses suffer from this form of aphonia, which is probably owing to the thickening or great susceptibility of the laryngeal membrane. When it continues, nothing affords greater relief than antimonial ointment, or croton oil, rubbed over the forepart of the neck so as to produce a free eruption. Mustard plasters may be used, but are not so efficacious. A hot bran poultice to the throat at night, and a tea-spoonful of paregoric, taken along with twenty drops of ipecacuan wine, will often remove a threatened attack. Inhaling steam from hot water or spray from Seigle's spray-producer is sometimes of great service. In the more chronic form, twenty drops of tincture of squills may be substituted for the ipecacuan. A syrup made with infusion of horse-radish, is popularly, and sometimes beneficially employed. Persons who are liable to loss of voice, ought never to expose themselves to damp, cold or night air, without protecting the mouth by means of a light shawl or respirator of some kind, and should keep the feet well protected, not so much on account of the symptom itself, though that is troublesome enough, but because of the indication it affords of general delicacy of the bronchial membrane. When along with loss of voice, there exists hoarse cough, pain, and expectoration of thick A, an arch B, and a descending portion c, the latter being subdivided into a thoracic portion c, and abdominal c 2. The origin of the must fall under the general treatment of these mucus, ulceration is to be suspected, and the

APH APO

Loss of voice in relaxed throat, is often | supply, all saccharine matters being avoided. quickly cured by brushing the back part of the throat over with a hair pencil, immersed in the following solution:-Take of nitrate of silver or lunar caustic 1 scruple; nitrous ether 1 ounce; dissolve. It must not be applied too often, otherwise the caustic effect will be too severely produced. Those suffering from enlarged and relaxed tonsils, with elongation of the uvula, such as clergymen, schoolmasters, and public speakers, or singers, will often derive benefit from this method of treatment, properly applied. Relief has also been obtained as above, in cases of that most distressing sore throat which often accompanies consumption. A little of the solution should be gently pencilled over the back of the throat, and allowed to trickle over the surrounding parts. The tannin lozenges of the British pharmacopœia and Brown's bronchial troches often alleviate the difficulty experienced in speaking and swallowing.

The voice is not unfrequently lost in young people, otherwise healthy, without the existence of any local disease in the throat. This is purely nervous, and is to be cured by change of air and scene, tonics and galvanism to the throat, administered by the continuous current

battery for a short time each day.

-Respirator-Inhalation-Electricity.

APHTHA.—Thrush, is more especially a disease of early infancy, affecting the mouth and fauces, the lining membrane of which in this disease appears as if sprinkled over with bits of milk curd. Recent researches have discovered, that upon these patches, a filiform description of minute fungus is developed, which probably finds a congenial habitat in the disordered secretions which are the main feature of the disease; excess of acid, and irritation of the mucous lining of the bowels always existing. The disease is not generally serious, it is accompanied by slight fever and drowsiness, and passes off in eight or ten days; during the time, however, it interferes with the child taking the breast properly. Aphtha is very often the result of improper feeding, with bread and other things unfit for the infant stomach. The first thing to be done when an infant is affected with thrush, is to correct the acid state of the bowels by a few grains of calcined magnesia-in this case preferable to the fluid form-or if the bowels be relaxed, of chalk, following the antacid by a mild dose of castor oil. Carbolic acid in very minute doses, grain, may be given with advantage in the chalk mixture, with glycerine. This may be repeated every second day. The quality of the milk, and state of the nipple of the mother, are to be examined, and the food, if any be given, regulated; milk and water, two parts of the former to one of the latter-in which a little isinglass should be dissolved if there is diarrhœa-is to be the sole addition to the mother's out; but whatever the condition, no time should

If the state of the bowels be corrected, the thrush will generally get well, but it is expedient to assist the cure by the use of a solution of borax in water, -one drachm to half a pint,-used to wash the mouth. The common system of mixing borax with honey is not advisable, as the saccharine matter may favour the fungoid growth. When the case is mild, the aphthæ separate in seven or eight days, leaving a healing surface below, and the mouth soon gets well; that is, if it be not injudiciously scrubbed ("cleaned") daily by the nurse. In children of weak constitution, or who are exposed to unhealthy influences, thrush may assume a malignant character; the aphthous specks become black, and ulcerations form on their site, diarrhœa increases, and the belly becomes tender, the child is drowsy, or it may be convulsed. In such cases, the chlorate of potash, internally, and saturated solution of sulphate of copper applied to the sores, as recommended by Dr. West, are most useful, the strength being at the same time supported by a tea-spoonful of strong broth, in which isinglass has been dissolved, given frequently. When, however, the disease assumes this dangerous character, medical assistance must be procured at once. Children past infancy, and even adults are sometimes affected with aphtha. Regulation of the bowels by a mild aperient,castor oil,-chlorate of potash internally, and borax wash, are the best remedies. Bismuth is sometimes useful. The diet should be mild and unirritating, chiefly milk and farinaceous.

APNŒA .- The most common mode of dying, caused by the gradual failure of the respiration. Death from suffocation may be

viewed as the acute form of apnœa.

APOPLEXY is an affection of the brain, during the continuance of which, sense and voluntary motion are wholly or partially ex-tinguished; the patient lies unconscious, as if in deep sleep, and cannot be roused by any ordinary means. More generally the face is flushed, and the vessels of the head and temples appear over filled; there is snoring, or stertor, as it is called; the upper lip margin, partially or entirely, is blown forward at each expiration, and the skin is covered with profuse perspiration; if the eyes are examined, they appear bloodshot and glassy-looking. In some cases, while the symptoms of insensibility, perspiration, &c., are present, the face is pale, and the appearance is one of general depression; the weak pulse contrasting with its full hard condition in the former case. If a person be found in a state of insensibility, as he can give no account of himself, it is important for others to ascertain whether there is any assignable cause for the circumstance. The head should be examined for signs of violence; the breath for the odour of alcoholic drink; any circumstances likely to give occasion to poisoning searched

be lost in procuring medical advice; in the or shorter interval which may elapse before the meanwhile, much is to be done by well-directed attentions. Few attacks of apoplexy come on without previous warning; the patienc, if of full habit, has suffered from headache or giddiness, especially on stooping, or has slept much and heavily; the mental faculties have been sluggish, the memory affected, or vision impaired; there may have been numbness or pricking in a limb, or in a finger only; to others, the face and eyes have looked full and red;-if of spare habit, there may also have been headache, giddiness, impaired vision, and confusion; but there has been, also, marked debility of the mental powers, memory affected, the power of following a consecutive train of thought impaired, articulation indistinct, while with these the face has been pale, the pulse weak, the whole manner inanimate, rather than oppressed. Individuals of sanguine temperament, with short necks and large heads, particularly if they live well, are the subjects of the first set of symptoms; those of spare habit, and weak, leuco-phlegmatic constitution, of the second. When in an individual, at any time of life, but more especially after the age of fifty, such symptoms show themselves, they should not be neglected for a day. It is evident, however, that depending on two very opposite conditions of body, the treatment for each must be very different. The extent and graduation of this treatment ought to be entrusted to the medical attendant; in the mean time, if any interval must elapse before that can be done, the man of full habit should at once reduce his diet, cut off entirely, or nearly so, his stimulants and spices, and animal food, eschew supper, take exercise moderately, and rise early. He should purge the bowels freely by a couple of calomel and colocynth pills, taken nightly for a few times, and by salines, such as bi-tartrate of potash or Epsom salts, a couple of tea-spoonfuls of the latter in half a pint of water, every morning. Mental excitement is to be avoided, the head kept well raised in bed, anything, either handkerchief or shirt, round the neck, worn perfectly easy. The man of spare habit must follow a more negative plan. Rest and quiet of body and mind are for him essential; anything likely to tax the nervous power, particularly of a sexual character, must be avoided; over fatigue is dangerous; while the bowels are kept regular, they must not be purged; the diet ought to be easy of digestion, and nourishing; and stimulants, if habitually taken, must not -unless found directly to cause uneasiness in the head—be discontinued, without medical sanction; spices, however, should be avoided. The temperature of the skin generally, and of the extremities, should be sufficiently preserved. When an individual is seized with symptoms denoting apoplexy, it being ascertained that they neither proceed from violence to the head, from intoxication, nor narcotic poison (see Head-Intoxication-Poison), during the longer

medical man can arrive, much is to be done. The patient should be laid on the back, the head and shoulders well raised, the neck bared, and a free current of air permitted to the head. Free purging should be resorted to. As the power of swallowing is lost or impaired, medical men usually effect this by means of a drop of croton oil placed on the tongue, and repeated if requisite; but in the circumstances now supposed, this can scarcely be obtainable, and instead of it, an enema containing salt or soapwater, Epsom salts, turpentine, castor oil, or whatever purgative is most readily available, must be given; the warmth of the feet must be preserved, but not excited, by hot water, mustard, &c. All attempts at giving nourishment must be suspended for many hours. In the event of the attack presenting the opposite symptoms, those of depression, all attempts at depletion are to be avoided, indeed, it may be requisite in an extreme case, to get a few spoonfuls of wine swallowed; purging must be let alone, but the extremities should be kept well warmed, and mustard poultices may be freely applied to the legs, thighs, or between the shoulders; liquid nourishment, such as meat broth, must be got down in tea-spoonfuls at a To the medical attendant must be left all beside. Ergotine, given hypodermically, is now employed in apoplexy, but could only be used by medical sanction and under medical supervision.

An attack of apoplexy may either disappear or be removed, and leave the patient apparently in perfect health, or it may leave him paralyzed in body, and weakened in mind, the man-but not the same man-changed; strength has been exchanged for weakness in every way, for weakness which increases as time goes on, loss of memory, irritability, childish desires, and childish weeping, till in all probability one or more attacks of the disease close the scene. Lastly, apoplexy may pass on to deeper and deeper insensibility, no sign of consciousness is ever given, the breathing becomes more laboured, the natural offices are performed involuntarily, the sweat becomes the cold one of death, which takes place with or without

convulsions.

Apoplexy may come on suddenly; the person is struck as if by a blow, but this form is less to be dreaded than that which creeps on more insidiously. An individual becomes giddy and faint for a few minutes, perhaps vomits, but seems to recover; shortly after, however, he becomes dull, the eyes heavy, and insensibility gradually comes over him. The first form is most probably owing to sudden congestion in the brain, or to rapid effusion of blood; the latter to slower effusion; in this case, the first shock is felt at the instant the vessel gives way, but it requires the further gradual effusion to complete the attack. An individual who has once suffered an attack of

APP APP

apoplexy, and recovered, cannot too carefully times very apparent swelling over the lower avoid every possible exciting cause. A momentary imprudence, the stooping to tie a shoe, looking at objects much above the level of sight, &c., a warm bath may be sufficient to induce serious symptoms. Especially must the bowels be kept so easy that straining at stool is never required. The system of diet and regimen should be strictly laid down by the medical attendant, and as strictly adhered to by the patient; the mind carefully kept from excitement. In no disease, with exception, perhaps, of that of the heart, does the man who possesses habitual self-control, in body and mind, possess more advantage, than in apoplectic tendency, over the slave of passion or of temper.

Refer to-Paralysis.

APPENDICITIS means inflammation of the appendix, a small diverticulum from the commencement of the large intestine (see diagram, page 20). A normal appendix is generally about three or four inches long, and about the thickness of a common lead pencil. It is hollow throughout, forming a small tube closed at its outer end, and opening at its inner end into the commencement of the large bowel. Its function is unknown, and does not seem to be important, as after its amputation for disease no inconvenience or discomfort arises. It is subject to various diseases which generally either primarily or secondarily present themselves in some form of inflammation to which the name appendicitis is given. Speaking broadly, these inflammatory attacks assume one of two different characters; they are either acute or subacute; and the subacute form tends to be recurrent, unless the recurrence is prevented by removal of the appendix. Acute has nothing to do in satisfying the appetite.

Mr. Beaumont, who experimented in the famous attacks of appendicitis are usually characterised by intense pain of a more or less cholicy character over the whole abdomen, with sickness and vomiting, and much tenderness on palpation over the abdomen. There is generally feverishness, with rapid pulse; and a symptom of a healthy state of system; as soon pained and haggard appearance of the countenance. If the initial symptoms diminish in severity, the tenderness is found to be more localised in the right iliac region (see Abdomen), and there may be noticed in that region increased fulness and resistance to gentle pressure. Acute appendicitis is a disease involving much danger to life, and calls urgently for surgical aid. Until that is obtained, something can be done to alleviate the pain by absolute rest in bed, warmth, and hot fomentations to the abdomen. All food should be withheld, and thirst alleviated by small quantities of hot water.

In the subscute form the symptoms may be much milder. The attack often commences with vomiting and cholicy pains, with a sense of uneasiness in the right iliac region, and usually constipation of the bowels. There may be some slight fever, and there is usually considerable tenderness to touch, and some-

part of the right side of the abdomen. Such cases may continue with these symptoms for a week or ten days, and then recover apparently completely; but always give occasion for anxiety from their tendency to develop into an acute form with immediately dangerous symptoms. For this reason many surgeons consider that in all cases of appendicitis an operation should be undertaken for the immediate removal of the appendix: others again hold the view that in subacute cases operation should be delayed until the symptoms subside, or until an operation is rendered necessary by the development of acute and dangerous symptoms. Removal of the appendix after symptoms have subsided is a comparatively safe operation, and is now generally recommended when a subacute attack ending in recovery has called attention to the liability of the sufferer to a recurrence with its conse-

quent risks.

APPETITE.—The instinctive desire for food which is periodically, and in health, regularly experienced, is a real blessing given to us by God, and its temperate enjoyment is a sign of a sound mind in a sound body. The sensation of hunger doubtless originates in the system at large, and its removal by the presence of food in the stomach, must be due to the sympathetic connections of that organ with the system. All that is required for the immediate appeasement of hunger is the presence of a substance, it may be of very small nourishing power, in the stomach; the unctuous earth consumed by the American Indians, and the berg meal of Norway act in this way. Taste case of St. Martin, found that appetite was quite as disorder occurs, the appetite flags, nature herself stops the supplies, which, instead of nourishing the body, would only increase the embarrassment of the functions; but this is not understood, and the sick are too often tempted and pressed by anxious attendants, to take nourishment, to their own hurt and discomfort. Even then, nature asserts her right, and the stomach rejects what it did not desire. The longings of appetite sometimes appear to be almost instinctive, especially in illness, particularly where there has been much or obstinate vomiting. The patient will express a strong desire for some article of food or drink which our preconceived ideas or theories would certainly forbid, but which, being permitted, seems at once to agree. When the various morbid deviations from natural appetite are considered,

morbidly active, is scarcely consistent with skin where the arnica is applied. health; in children, it is often indicative of worms. Depraved appetite consists in the longing for, or devouring substances not intended for food, such as chalk, slate pencils, cinders, earth, &c.; the symptom is not unfrequently a concomitant of the chlorotic diseases of young females. A morbid appetite is not an unfrequent symptom in pregnancy. The "dirteating" of tropical climates is another form of depraved appetite.

APPLES.—This fruit is wholesome and agreeable, and when roasted or boiled is much

relished by the invalid.

Apple water is an agreeable beverage for the sick room, and a quart of it may be prepared in the following manner:-Take six apples peeled and sliced with the cores removed, and place them with the rind of half a lemon in a jug to which a quart of boiling water is afterwards to be added. The hot liquor sweetened to taste with sugar, is set aside to cool, and is afterwards strained through a cloth, when it is in a condition for using.

AQUA-FORTIS.—NITRIC ACID.—Refer

to—Nitric Acid.

AQUA-REGIA.—NITRO-HYDROCHLORIC Acid.—Refer to—Nitro-Hydrochloric Acid.

ARCUS SENILIS .- The name given to the narrow ring which often forms round the outer edge of the cornea in old people.

ARECA NUT .- The seed of the betel nut

AREOLA—a term applied medically to the inflamed circle which surrounds a vesicular or vesicle. Also applied to the coloured circle surrounding the female nipple. Generally, not invariably, previous to pregnancy, this areola is light in colour, but in the majority of cases, soon after conception, it begins to darken, and in some individuals, especially in those of dark complexion, it becomes of a deep brown. The change of colour in the areola is, therefore, classed amid the more certain signs of preg-nancy, but as it has been known to exist in the virgin, and is not universally developed in the pregnant female, it can never alone be taken as a decisive proof, but only as a corroborative, along with other symptoms.

Refer to—Pregnancy.
ARM-PIT.—See AXILLA.
ARNICA MONTANA.—Leopard's bane, is a plant bearing a composite flower, found in mountainous regions. It is scarcely, if ever, prescribed internally in this country; as an external application the tincture of arnica was formerly widely employed as a remedy for contusions and sprains. some constitutions, however, its application is found to produce severe irritation of the skin with redness and swelling resembling erysipelas, accompanied by con-

In consequence of this liability it has fallen much out of use in recent years; and in most cases of sprain the application of diluted whisky or methylated spirit, or, when an astringent is wanted, of diluted hazeline or Pond's Extract, is probably equally effective, and certainly more free from risk .-See Hazeline

AROMATICS.—Stimulants derived from the vegetable kingdom, possessing a more or less powerful and generally agreeable odour, a warm and agreeable taste. They are for the most part products of warm climates, and appear specially adapted to the relaxed constitutions of the natives. A free use of aromatics is said to counteract the effects of malaria in tropical countries. Some stimulant is certainly requisite in those climates, and the native productions bestowed by Providence are evidently much better adapted to fulfil the indication than alcoholic excitants. Mace, cloves, cinnamon, are all aromatics. Angelica is one of the few aromatics of temperate climates, and perhaps the best.

ARROW-ROOT, now so well known, is procured of the best quality from the West Indies, especially from Bermuda, whence it is imported in soldered tin cases. It is now also imported from East India, and an inferior kind is brought from Tahiti. Arrow-root is subject to much mixture and adulteration, but generally —as with potato-starch, &c.—of a harmless character as regards the consumer. The best arrow-root ought to be pure white, slightly glistening in the mass, and the powder of which pustular elevation, such as that of the vaccine it is composed collected together in small crumbs or lumps, which break down with a slight crackling sensation beneath the finger. Arrow-root is pure starch, and forms a peculiarly stiff jelly. As an article of sick cookery it is invaluable, where mild support is required without stimulation, and in convalescence, and chronic disease. There are few stomachs with which it disagrees, and children both like and do well with it. At the same time, it is proper to caution against the too common error of trusting too much to the nutritive powers of arrow-root alone, especially for children. It may give support indirectly, that is to say, by supplying material for oxidation and animal heat, it may save the tissues of the body, or it may even go to build up some of these tissues, but alone it can never make bone or muscle, for the simple reason that it does not contain the elements necessary for these constituents of the frame. A child fed exclusively on arrow-root, water, and sugar (and such has been the case), must become unhealthy, and, without fail, rickety. The case is abundantly altered, when, with arrrow-root, milk is com-bined. In this fluid exists whatever is requisite for the animal frame, nitrogen for its muscle, phosphorus for its nerve, earthy salts for its bone. The combination of arrow-root with milk is one siderable fever. This is especially apt to of the best which can be given to a child, or to occur when there is any abrasion of the an adult in the early stages of convalescence

from illness. It must never be given to young the poison as possible evactuated from the infants. Arrow-root and milk is prepared in the stomach; it is seldom necessary to produce following manner. Take a dessert-spoonful of arrow-root and stir it in a basin, with a dessertspoonful of cold milk, until it forms a paste, and then add sugar, according to taste. Pour over this slowly half a pint of boiling milk, stirring the mixture at the same time, to render it smooth. Arrow-root pudding is best made by adding to the above mixture the yolks of two eggs, whipping it all well together. The whites of the eggs after being whipped into a stiff froth in a separate basin are to be added to the mix-ture, stirring lightly. The whole is then placed in a buttered dish and put in the oven to bake for ten minutes.

ARSENIC is a metal; the substance which usually goes under the name, and which is also called white arsenic, is an oxide of the metal; it is a too well-known poison, and was at one time more universally used than any other for destroying life. Its tastelessness, cheapness, and the culpable facility with which it was obtainable combined to make it familiar. The dangers arising to workpeople engaged in certain trades where arsenic is used, from the inhalation of arsenical vapour or dust are well known. Green flock papers which owe their delicate tint to an arsenical substance, Scheele's green, are injurious to the inmates of houses where they are used. Accidental poisoning has also occurred from the mixture of arsenious acid with soot used for cleansing sheep. Much controversy has at times taken place respecting the effect of arsenic upon the palate; it is certain the taste is very faint, but extreme irritation of the portions of the lining mucous membrane of the mouth and other parts quickly follows its contact. The length of time after arsenic has been swallowed that symptoms take to show themselves, varies much, depending in all probability upon the state of the stomach as to emptiness, or the reverse. Sometimes they appear in a few minutes, at other times not for hours. Poisoning by arsenic is distinguished by faintness, nausea, intense burning pain at the pit of the stomach, and vomiting of its ordinary contents, followed by that of a turbid brown fluid, and mucus, often streaked with blood; intense burning heat in the throat, and thirst; purging ensues, cold sweats, convulsions, death. The eyes may become inflamed, but this is more general when the case is prolonged, as it may be, in consequence of the small dose, or from other circumstances; in this case an eruption on the skin is not unfrequent. The symptoms of course vary, particularly that of pain, which occasionally has been almost entirely absent. It must, too, be remembered, that the symptoms of British cholera and those of arsenical poisoning, very closely resemble one another. When poisoning by arsenic is suspected, of course the first measure is to procure efficient medical aid. In the meantine, it is requisite to get as much of the meantime, it is requisite to get as much of | ing by arsenic, know beforehand with what cer-

vomiting, that most generally comes on soon; but if it has not done so, five-and-twenty grains of white vitriol, -sulphate of zinc, -if procurable, should be given at once, in a little water ; if this is not done, a table-spoonful of mustard in water, or tickling the throat with a feather, should be resorted to; milk, which by its coagulation may envelope the poison, or thick mulcilaginous drinks, olive oil, alone or mixed with lime water, may, any or all, be given, and with them, magnesia. The great object must be, to clear the stomach of the poison as thoroughly and speedily as possible, for unlike many other poisons, there is no chemical antidote to arsenic which can be relied on. A preparation of iron has been vaunted, but it is of doubtful efficacy; if either this, or the stomach pump is used, it will be in medical hands. In following the directions already given, the friends or neighbours of the poisoned person will be doing good service. Should the patient survive, and pass on to the second stage of arsenical poisoning, inflammation of the stomach, nervous symptoms, &c., will perhaps end life, or recovery may follow, but these changes must necessarily be attended to under medical guidance. White arsenic is not the only preparation of the metal by which poisoning occurs; the colouring substances known by the name of King's yellow, and Scheel's green, are both compounds of arsenic, and being frequently, and culpably, used in confectionery, have proved fatal. Similar symptoms occur, and similar treatment is to be followed as after poisoning by white arsenic. Whether in poisoning by arsenic, or by any other agent, the vomited matters should always be carefully preserved in a vessel by themselves, for medi-cal inspection; and if there is any suspicion of foul play, some responsible person should place them under lock and key. The antiseptic properties of arsenic tend to prevent the decay of the tissues after death. As a medical agent, it is employed in the form known as Fowler's solution, a compound of carbonate of potash, with arsenious acid, and in doses of three to eight minims. It is the remedy in most favour in such skin diseases as eczema, psoriasis, pemphigus, and lichen. It is also used as an antiperiodic in ague and neuralgia, but it must be limited to professional hands.

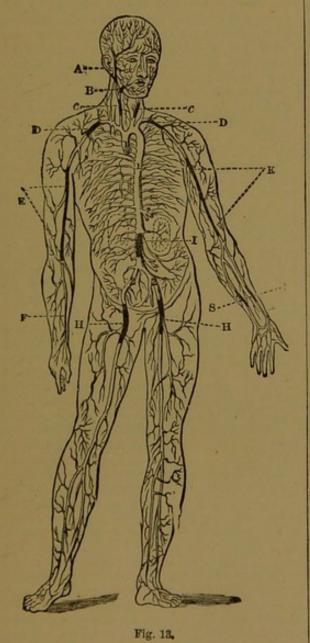

The tests for the detection of arsenic are numerous and accurate. The best are Marsh's, by which the metal may be separated from a solution, and deposited on a piece of porcelain; the ammonio-nitrate of silver test, which will detect 12000 of a grain of arsenic in a mixture; and sulphuretted hydrogen gas, which, passed through a solution of arsenious acid throws down a golden yellow sublimate that may be further reduced.

Did those who perpetrate the crime of poison-

ART ART

tainty the analyst can separate for exhibition | the viscera of the chest and abdomen. Low in a court of justice, the instrument of their wickedness, perhaps from the body of the victim, years after it had been buried : selfish fear, if no other consideration, might stop the deed.

ARTERY .- An artery is a vessel which invariably conveys blood away from the heart, the blood, with one exception, -in the pulmonary, or artery of the lungs, -being bright red, "arterial," and flowing in waves or pulsations, corresponding with the beats of the heart. When red florid blood flows, or is spirted from a wound in jets, an artery is certainly wounded, and the case is most probably serious. Blood from a vein is dark and black-looking, and flows in a continuous stream.

down in the latter cavity, the aorta itself divides or bifurcates into the two large vessels which supply the lower limbs (fig. 13, 2). From the secondary arteries other branches are given off, until, at last, by division and subdivision, the vessels become "capillary," hair-like, in their minuteness, forming an intricate net-work, in which the arteries end and the veins begin. Arteries consist of three separate coats, an outer or protective, an inner or lining, and a middle, partly elastic and partly muscular. It is the thickness and firmness of this middle coat which chiefly dis-

tinguishes the artery from the vein.
As a general rule, the main arterial trunks run upon the anterior and inner surfaces of the body; some knowledge of their positions, and especially of those points in their course at which they can be most easily felt and compressed, may at times be useful to all. is no uncommon thing for medical men to be called to accidents in which immense and injurious loss of blood has taken place from a wounded artery, which might have been saved to the sufferer by any one possessed of sufficient knowledge and presence of mind to put his thumb on the main trunk of the vessel. In the annexed figure, the portions of the main arteries most easily found and compressed are marked black, and any one, unless very corpulent, may verify the positions by examination of his own person. Wherever the finger is placed upon an artery, pulsation is felt.

In wounds of arteries of the head, such as

upon the temples, there is the advantage of the bone, against which it is possible directly to compress the bleeding point, and when this can be done, it is the best method; otherwise, pressure may be exerted according to the position of the wound, at A in front of the ear; or just behind the ear; or at B, where the pulsation of an arterial branch may be found, as it winds over the edge of the lower jaw.

In wounds of the large carotid arteries of the neck, pressure is, unfortunately, of little avail; there is no point to press against, it is impossible to compress the artery without at the same time compressing the large vein, and from the size of the vessel and its proximity to the heart, the current of blood has much power. The vessels may be felt beating on the side of

the windpipe.

In wounds of the large arteries about the shoulder or arm-pit, pressure must be made with the thumb, or handle of a moderate-sized key, wrapped in a few folds of handkerchief, upon the large vessel, at the point D, just behind the middle of the collar-bone, and where it passes over the first rib. In the From the Aorta (see fig. 12 and fig. 13, I), the main artery conducting directly from the heart, various secondary vessels are given off to supply the head and upper extremities, and | divides into two main branches, one of which

(F), the pulse artery, runs towards the thumb; | the vital fluid. Various styptics to arrest the other (s) towards the finger, in which courses both may be felt; from the free intercommunication of the arteries of the hand, pressure is more certain to arrest hæmorrhage if exerted upon the single trunk of the arm (E). In case of arterial bleeding from wounds of the lower extremity, it is most certainly and easily arrested by pressure on the large artery of the thigh, at the point H, in or just below the groin. In all these cases pressure may be exerted by means of the thumb, or by some convenient body, such as the key above-named. To compress arteries in the limbs, surgeons use the tourniquet, specially adapted for the purpose; but as a temporary measure, a handkerchief will answer well, tolerably firmly tied round the member, between the body and the wound; if any one has knowledge enough to place a pad-a rolled-up stocking will do-over the course of the main vessel, so much the better.

ARTERIAL HÆMORRHAGE may also be arrested by compression directly upon the bleeding point, and this should be tried until the surgeon's arrival, but it must be in positions, such as the hand, foot, &c., where pads can be firmly bound over the wound. These pads must be graduated, that is, a small firm one is to be placed direct over the bleeding vessel, over the first pad a larger, and one still larger over that, and the whole to be firmly bound with a bandage or ribbon-or strip of cloth of some kind; at the same time, the site of the wound is to be raised above the level of the body. Above all things loose wrapping up is to be avoided, the wound had better be exposed to the air than enveloped in a hot poultice of clotted blood, which only causes it to bleed the Two cases which recently occurred in the writer's practice will illustrate the above directions:—(1) A girl when cutting some bacon off the flitch, slipped the knife and plunged it into her hand, dividing one of the arteries; it bled fast, and when she was seen by the author some time after, a large quantity of blood had been lost; compresses and a bandage being at once applied, not another drop of blood was iost, the wound was undisturbed for a good many days, and quickly healed. (2) A man when sheep-shearing, had the shears driven into his hand by a plunge of the animal, and the artery which runs between the thumb and fore-finger severed; he had to come three miles to the author's house, and must have lost above a quart of blood. In this case the vessel was tied, but in either of the cases, if, instead of the wound being loosely covered, and the hand kept down, some one had been sufficiently informed to tie a firm pad over the wound, until proper assistance was obtained, it could not fail to have saved either of these individuals a considerable amount of blood—and to a poor man blood is money, he must pay the butcher

bleeding are recommended, such as alum, matico, fungus, &c., but in arterial hæmorrhage, pressure is more to be trusted to. Surgeons arrest hæmorrhage from a cut artery by tying the ends with a ligature of silk or fine cord. This might be done in emigrant life under necessity. The bleeding point being distinctly seen, is by one person to be pulled forward, either by a pair of forceps, or by a hook-tenaculum (see Instruments) made for the purpose, sufficiently far to allow of another individual tying it securely. The sailor's reef knot is the proper one for the purpose. The end of the vessel next the heart is to be tied, but should the lower end bleed, as it may do, especially in a few hours after the accident, it must be tied also. The ends of the ligature are to be left uncut, and the wound covered with a cloth dipped in simple water, till the surgeon's assistance—as it must be—has been procured. After arterial hæmorrhage, a person should always be watched, with light, during the night, and a handkerchief which could be tightened at any moment, kept closely round the limb. The application of water, unless it be ice-cold or nearly so, to a bleeding artery, is better avoided, free exposure to the air is preferable. In severe hæmorrhage or flooding after delivery, com-pression of the aorta (fig. 13) may be of much avail in preventing further loss of blood until the arrival of the medical man. The hand of an attendant must be firmly pressed into the centre of the abdomen, until the pulsation of the aorta is felt, and felt to be acting against the compression, and not beyond it. The pressure must not be relaxed for an instant.— See Ligature—Emergencies.

ARTICHOKES—whether the vegetable properly so called, or the root, Jerusalem artichoke-are not adapted for persons of weak digestion, for those liable to flatulence, or for the aged. On some persons the artichoke proper acts as an aperient.
ARTICULATION.—See JOINT.

ARTIFICIAL RESPIRATION.—See RESPIRATION - SUSPENDED ANIMATION -DROWNING.

ARTISAN .- The diseases to which workmen are liable in consequence of the nature of, or materials employed in, their respective businesses, always a subject of great interest, is too extensive to admit of being otherwise than very briefly entered into in the present work. Legislation and invention have of late years done much to screen the various classes of artisans from many sources of injury to health to which they were formerly exposed, much more remains to be done, and would perhaps be done more quickly, were it not for the apathy, and sometimes even contradiction, of those who are chiefly to be benefited. It is useless to supply miners with Davy lamps, and fork grinders with magnetic respirators, when the some hard days' work to make up a pound of means of safety are so constantly and carelessly

ASC ASS

neglected. One immense source of evil-now | quence of their exposure to contagion, and happily ameliorated-has been exertion too prolonged, especially in the young; nutriment which should have gone to build up the growing frame, is consumed in mere physical exertion, the powers of the brain are used up in the same; and if not deformity of body, at least great weakness, and with it mental inaptitude, are the consequences. Many of those who are liable to disease in consequence of the materials they work in, owe much to their own want of cleanliness; this is the case with regard to the metals, especially lead, and a striking improvement has taken place in the health of workmen who have been compelled to observe certain rules of cleanliness, such as washing the hands before their meals. Workers in quicksilver are liable, in addition to affections of the teeth and gums, to a species of shaking palsy, or tremor of the limbs. Modellers in coloured wax, makers of wax flowers, &c., are in danger of suffering injury from absorption through the skin of the hand, of the poisonous colouring ingredients, and should be extremely Workers in lead, such as plumbers, typefounders, or painters who use it in the form of white or carbonate of lead, are apt to suffer from paralysis, more particularly of the muscles of the forearm; their more usual disease, however, is the "painter's colic," or dry belly-ache (see Colic). Men employed in the manufacture of bichromate of potashare affected with a curious disease of the septum of the nose, which increases gradually till the partition disappears. Coppersmiths, smelters, lucifer-match makers, all have their peculiar affections, that of the latter being a disease of the jaw-bone. Those who are employed in filing or dry-grinding substances which give off a hard dust, are peculiarly liable to chest diseases, from the mechanical irritation caused by the particles continually inhaled. So much is this the case in some trades—such as the Sheffield fork-grinders—that most, if not all, of their members die before reaching the age of forty. Millers, and those employed among fine dust of a softer quality, are not so likely to become consumptive as the former class, but have more tendency to asthma; they also suffer from the consequences of the cutaneous pores and functions being clogged and hindered by the dust. Grocers and bakers who are in the habit of handling flour, sugar, &c., suffer frequently from a disagreeable skin disease affecting the fingers, well known by the name of "grocer's itch." Housemaids who kneel at work have their peculiar swelling, which forms, and sometimes suppurates, over the knee-cap; this may be prevented by kneeling on a soft substance. Thatchers who press their knees against the steps of the ladder, are exposed to the same thing. Clergymen, actors, and public speakers, have their peculiar throat affection,

irregular hours of business; in short, there is scarcely a trade or profession which does not expose its follower to some peculiar ailment, but there is scarcely one of these ailments which may not be prevented or much ameliorated by proper care—by cleanliness more especially, but also by attention to the various other prophylactic means which are now so generally known and provided.

Refer to-Colic-Consumption-Lead-Skin,

ASCARIDES .- The small thread worms which infest the rectum. - See Worms.

ASCITES.—See Dropsy.

ASPARAGUS, when young, well boiled, and not overloaded with melted butter, is wholesome and digestible; it gives a peculiar odour to the urine. Its peculiar vegetable principle, asparagin, contains nitrogen.

ASPHYXIA.—Suspension of sensible vital phenomena in consequence of the blood not having undergone the proper change by respiration. In this condition the brain, the lungs, the organs of the body generally, all suffer from the obstruction to the natural current of the circulation; the heart is less and less excited, until, at last, it ceases to act, and death ensues, unless the cause of the asphyxiated condition, such as hanging, &c., be quickly removed, and suitable measures adopted for restoring the suspended animation. —See Animation, Suspended -Apnœa-Death.

ASPIRATOR.—The aspirator is an apparatus now much employed by medical men to draw off fluids from the various cavities of the body, without exposing them to the risk of septic infection from the air. It consists of a glass bottle, fitted with an india rubber cork and a couple of tubes with stopcocks; one of the tubes communicates with an air-pump syringe to remove the air from the vessel, and the other is attached to a trocar and canula employed in the operation. The matter or other fluid from the abscess cavity flows through the tube into the bottle.

ASS'S MILK contains seven per cent. of milk sugar, and in many respects approaches the composition of human milk. It is a most excellent dietetic article, and restorative in all cases of debility. If drunk too freely it acts upon the bowels.

ASSAFŒTIDA.—A gum resin and powerful antispasmodic, is useful in hysterical cases, and in flatulent distension of the bowels; in the latter case, especially, given as an injection, it is the most efficacious agent we possess. Two tea-spoonfuls of the tincture of assafcetida may be added to a simple gruel enema, or thirty grains of the drug to one of the purgative enemas, if requisite. When assafætida is given by the mouth, it is best in the form of pill. The compound assafætida pill may be given medical men below middle age experience a in three-grain doses three times a day. Where mortality much above the average, in conse- aperient action is required, especially in de-

ficient menstruation, the aloes and assafætida | of other affections of the lungs or of the pill is a most excellent combination, and may be given, three grains, twice or three times a day. The, to most people, disgusting smell of assafœtida, is a great obstacle to its employ-ment, and yet in some countries it is used as a condiment as we use onion.

Refer to-Enema

ASSIMILATION, the first process of nutrition in animals, by which the nutrient portion of the food is rendered fit for absorption by the veins and lacteal vessels, which convey it into the general current of the circulation.

Refer to—Digestion.

ASTHMA is an affection of the chest, characterised by distressing inability of the person suffering from it, to inspire sufficient air to fill the lungs. The term, although applied by medical men to a defined disease, is used popularly to denote any difficulty of breathing, from whatever cause occurring, whether from disease of the heart, or any of the varied affections of the lungs. Asthma, although a nervous or spasmodic affection, is very frequently connected with actual changes in the lungs themselves. Asthmatic fits, or paroxysms, come on at irregular intervals; for several days, or rather nights, successively the patient is attacked, and a considerable time may then elapse before he again suffers; not that a regular asthmatic is in the interval entirely free from uneasiness, for there is generally some slight oppression of the breathing, liable to be aggravated by slight causes: changes in the weather, peculiarity of situation, errors in diet, anxiety, fatigue, mental excitement, may any of them induce a paroxysm of asthma in the predisposed. The attack itself is premised by feelings of indigestion and flatulence, frontal headache, chilliness, languor, and drowsiness; after having experienced these sensations during the day, the asthmatic individual is probably awakened from his first sleep by a distress-ing sensation of constriction of the chest, he is forced to sit up in bed, labouring for breath, or it may be to seek an open window; the distressed state of the breathing, if not relieved by remedies, continues for some hours, and at last gradually subsides; the characteristic wheezing becomes less, the cough, almost impossible before, is now brought out, and sleep, never more welcome, comes on. latter stage of the paroxysm of asthma is generally accompanied with expectoration of mucus, sometimes it is not, and upon this a distinction into dry and humid asthma is founded. Confirmed asthmatics have a distressed cast of countenance, and acquire a peculiar rounding or elevation of the shoulders, perfectly characteristic. Asthma may occur at any period of life, but is more general about the middle; and men are more commonly the subjects of it than women. The disease in itself, though most distressing, is not dangerous, asthma is threatened or has come on, care must further than as it tends to lay the foundation be always taken, as far as possible, to remove

No one can witness a paroxysm of asthma without distressing anxiety to relieve the suffering individual, and not without alarm. if it is the first time of seeing the attack. The patient seems as if he must die for want of air in the lungs, but death rarely, if ever, occurs. In a disease of so long standing, and of so peculiar a character, as asthma, those who are the subjects of it generally have their own remedy, to which they habitually have re-course. The remedies are very various, and indeed happily so, for what gives immediate and full relief to one person totally fails in The practice of smoking the leaves and stems of stramonium or thorn-apple, is now extensively and popularly resorted to; with some it succeeds admirably, to others it seems to be hurtful, -it may be tried. A pipe of tobacco often affords relief. Antispasmodics and stimulants, as might be expected, are frequently beneficial. Ether and laudanum is a favourite combination; half a tea-spoonful of the former, along with twenty drops of the latter, in a wine-glassful of water. A teaspoonful of sal volatile may be substituted for the ether, but is scarcely so efficacious. Assafœtida, henbane, hydrocyanic acid, all powerful antispasmodics, have occasionally been found serviceable. Bromide of potassium in a half drachm dose, with forty minims of sal volatile, taken in a wine-glassful of water at bedtime, will often avert or lessen a night paroxysm of asthma, and the same may be said of ni-trite of amyl, a few drops of which may be administered by inhalation. Twenty grains of ipecacuanha powder given in half a wineglassful of water, to act as an emetic, may be of service, particularly if the attack has come on after a full meal, or if there is any suspicion of the stomach being loaded. Some experience much benefit from strong coffee, drunk without milk or sugar. The inhalation of chloroform, a few drops sprinkled on a pocket handkerchief, has lately been found to afford relief; but this remedy, in the first instance, must not be tried without medical sanction. Sir T. Watson recommends the fumes of burning nitre (saltpetre) diffused through the air of the apartment, by means of pieces of blotting-paper, dipped in a saturated solution of the salt, and dried. One of these, about the size of the hand, ignited, and placed upon a plate or tile in the room, quickly diffuses its fumes throughout the apartment. When there is great dryness and deficient expectoration, steam, inhaled either simply, or with a few drops of sulphuric æther is worth a trial. If there is much acidity of stomach, ten or fifteen grains of carbonate of soda, with a tea-spoonful of sal volatile in a little water, should be given. Indeed, when an attack of

AUS

warm tea, and retirement to a warm bed, will remove the chill sensation. Constipated bowels ought to be relieved by a gentle dose of castoroil, or of rhubarb and magnesia; flatulence or acidity corrected. Flatulence particularly must pe obviated, and all sources of it avoided. Effervescing draughts, soda water, and such-like, are almost always hurtful. The effects of situation and of atmospheric peculiarity upon asthmatics are most varied; some can breathe freely in clear dry air, which drives others into a damp cellar for temporary relief; a close warm room which suits one, will be unbearable to another. Individuals who are never free from asthma in some situations, lose their attacks as soon as they remove. These are peculiarities of which all should be aware. Certain odours produce asthmatic breathing in the predisposed: the powder of ipecacuanha is notorious for this effect; and the smell of newmade hay, so pleasant to most, produces hayasthma in a few unfortunates.

AST

The habitual asthmatic soon becomes aware how much his freedom from paroxysms of the disease depends on the state of the general health, particularly of the digestive organs. He may not be altogether able to command situation, he cannot avoid atmospherical vicissitudes; but he can by temperate living, avoiding food before bedtime, exercise, attention to the bowels and to the functions of the skin in particular, pass long intervals without an attack. Sponging the chest and shoulders every morning with cold or salt water, friction being afterwards made with a towel or hairglove, is a practice to be recommended, provided no other predisposition forbids. Asthma is one of those diseases long continued, marked in character, and not immediately affecting life, for which much may be done by welltimed and well-directed domestic management, whilst the frequent recurrence of the attacks renders the attendance of a medical man a serious consideration in the case of limited income. Nevertheless, an asthmatic patient ought from time to time to be examined professionally, especially should there occur any change in the nature of the paroxysm, which may be indicative of other and serious disease.

ASTIGMATISM describes a condition of the eye in which vision is defective owing to unequal refraction in opposed diameters. It may be remedied by suitable spectacles.

ASTRINGENTS produce diminution of the secretions and contraction of the tissues when applied to living parts. In cases of relaxation or debility, in hæmorrhage, either external or internal, in increased and injurious secretions from glands or mucous surfaces, astringents are the chief remedy. The amount of astringent action, however, depends greatly upon the mode and circumstances of its application. The astringent principle in the vege-

any existing disordered action. A basin of gallic acid, is very widely diffused. The principal vegetable astringents used in medicine are—oak-bark, matico, galls, kino, catechu, tor-mentilla, uva-ursi or bear-berry, logwood, &c. The mineral astringents are the acids, alum, salts of iron, particularly the perchloride, sulphates of copper and zinc, a nitrate and oxide of silver, and salts of lead. Cold in any form is astringent. Refer under the individual heads.

ATMOSPHERE.—See AIR.

ATONY .- Deficient tone of the system characterised by debility and laxity of the

muscular fibres generally.

ATROPHY, WASTING, may be either general or local. General atrophy is in one sense natural to advanced life, when the powers of nutrition being diminished, the muscles, the brain, and the organs generally, shrink. There may be fat, but at the same time much atrophy of the other bodily components. Atrophy occurring earlier in life, without obvious cause, ought to be regarded suspiciously. When an individual, without departing from ordinary habits, begins to lose flesh, the cause ought to be looked for, and if the change continues, the person should be submitted to a thorough medical examination, and the existence or not of incipient disease, if possible, ascertained. In young children atrophy occurs as a consequence of faulty digestion, most frequently from improper feeding; it is also the result of a diseased condition of the glands of the belly, through which the nutrient portion of the food passes on its way to the general circulation. For this condition, cod-liver oil is the remedy, given in tea-spoonful doses twice a day, to an infant of six or eight months old, and the same quantity well rubbed into the skin of the abdomen night and morning. Some medicines, such as iodine, have the power of causing local or even general atrophy.

Local atrophy is liable to occur from various causes. Whatever diminishes the supply of blood to a part will cause it to waste. Pressure on the main artery of a limb, obliteration of the smaller vessels of a part by previous inflammation, disuse of a member from paralysis or any other cause, are all followed by diminution

in size of the part affected.

Refer to-Infancy.

AURICLE.—The external ear, as well as the name given to the two smaller cavities, right and left of the heart.—See Heart.

AUSCULTATION.—The application of the sense of hearing to the detection of disease. The art is most extensively useful to the medical man in the case of the chest; but in diseases of the abdomen it is also a great assistant, and indeed applicable to most circumstances, such as affections of the blood-vessels, fractures, &c., in which, movement makes sound audible. When the medical man elicits various sounds by tapping on the body with his fingers or by any other means, it is called percussion, and table kingdom, in the form either of tannic or of the present meaning of auscultation is the

practical investigation of those sounds which are | istic element of animal substances; it is also preproduced by the movements within the living Probably no addition to the science and practice of medicine has more extended the power of detecting the existence and nature of diseased action than the practice of auscultation. The stethoscope, now so well known from its universal use by medical men, is but a conductor of sound, used for obvious reasons of delicacy and convenience, and in some cases to prevent unpleasant contact with the uncleanly, but the sounds are equally well heard by the un-assisted ear. The stethoscopic examination of females may always be conducted with perfect delicacy and sufficient nicety through a covering of linen, and never (as sometimes is done, though rarely) should this means of investigation be denied to the attendant practitioner.

AXILLA.—The arm-pit, is an important region of the body, on account of the large blood-vessels and nerves which occupy its space. A wound of the large artery in this situation, unless efficient means are speedily adopted to control the bleeding, must be quickly fatal. When from the copious flow of florid blood from a wound in or near the arm-pit, such an accident is supposed to have occurred, a bystander should with all speed exert pressure by means of his thumb upon the artery as it passes over the first rib, just behind the middle of the collar bone, until the effusion of blood ceases. This pressure of course must be kept up, but as to do so with the thumb simply, would be too fatiguing, some solid body-the handle of a moderate-sized key is generally recommended — wrapped in a few folds of handkerchief, may be used for the purpose. While this is done, if medical assistance be many hours distant, as an additional safeguard, firm graduated pads should be tightly fixed into the hollow of the axilla, and firmly retained by a handkerchief or bandage crossed over the opposite shoulder; but this must be a supplementary aid, until the artery is properly secured by the surgeon. The pressure behind the collar-bone cannot be relaxed for one moment without risk to life.

Refer to—Artery.

AXUNGE, Hog's-LARD, is used as the principal component of various ointments, but is often injurious, in consequence of being slightly rancid, in which case, instead of soothing, it has an extremely irritating effect upon abraded or blistered surfaces especially. Even when applied fresh, if allowed to remain too long unchanged, it will become a source of

irritation.—See Lard.

AZOTE, NITROGEN.—One of the gaseous components of the atmosphere, of which it forms 77 per cent. by weight. It is one of the most abundant and widely distributed of the elementary bodies. With oxygen, it forms various sent in vegetables, but in smaller proportion.

BACK .- Pains in the back may be owing to affection of the spine itself, or of the kidneys; to rheumatism of the muscles (lumbago) or to sympathy with disorder in some distant organ -as in females, in the uterus.

Refer to Spine-Kidneys-Lumbago, &c.

BACON.—The flesh, or rather fat and flesh of the hog, salted and dried, and sometimes smoked, forms the staple article of diet of the English labourer; the dietetic breakfast of the invalid. In the former case, it is undoubtedly a relishing, convenient, and economical addition to the general fare; at the same time, it is a question whether it does not in many districts form too large a proportion of the ordinary nutriment consumed, and whether an advantageous exchange might not be made, in part at least, for a more nitrogenous diet. Owing to the great proportion of fat in bacon, there is comparatively little of those elements of food which go to build up the constituent tissues of the animal body, and which are contained so abundantly in meat and in the grains and Where the choice lies between bacon and bread, or bread and milk, or oatmeal and milk, as consumed in Scotland and in the northern English counties, there is no question that much more real nourishment will be obtained from the vegetable grain and milk, which contain whatever is requisite for every portion of the frame, than from that of which simple fat forms so large a share, and which does little more than afford respiratory food. To full-grown men this may be of comparatively little importance, but to growing children and youths, it must of necessity be a consideration, whether, in consuming the amount of nutriment circumstances permit, they consume that which really will afford them strength and substance, or not. Of course these remarks apply principally to the pure bacon fat consumed in such large quantities by the labourers and servants in the midland and southern counties of England. Bacon used as a dietetic, as it is usually done, with breakfast, is often of much service in cases of biliary disorder. It is the fat alone, toasted in slices before the fire, which must be eaten, the lean is hurtful, and must be discarded by the bilious dyspeptic. When used in this way, a slight aperient action is certainly exerted, and it is to this, gently but regularly carrying off its daily proportion of bile, that the undoubtedly beneficial effect is most probably to be attributed. - See Pork.

BAKING is the exposure of any substance to a high temperature in a confined space. Though both convenient and economical, baked compounds, of which nitric acid is the best meat is not usually considered so palatable, or known. Combined with hydrogen it forms ammonia. Nitrogen is regarded as the character- open fire. The process of roasting by gas in a

the old plan of baking in most public establish-

ments and in many private houses.

The disinfecting oven, used for destroying contagion and vermin in bed and body clothes, acts on the same principle as the baking oven. The temperature must be 230° Fahr. to be effectual. If raised much above that, the heat

will destroy most fabrics.

BALDNESS, or loss or deficiency of hair on parts usually covered by it, is sometimes seen in infants; it frequently occurs in adults of the male sex, even in the prime of life, and almost universally in a greater or less degree, in old age. The direct occasion of baldness is defect in the hair follicles, from which the hairs are developed, and this defect may arise from diseases affecting the skin itself, from acute general disease, as fever, or chronic constitutional disease, such as consumption; it may also arise from constitutional peculiarity, or the diminished circulation of blood, such as occurs in advanced life. Some families appear to be peculiarly liable to become the subjects of baldness even early in life; those who perspire much about the head are often bald. Generally, however, whatever occasions diminished supply of blood to the scalp or skin, gives the hair a tendency to shed, and the treatment must be directed to stimulating the skin as much as possible. After acute disease, if the hair falls off, shaving the part two or three times in succession will probably strengthen the growth. In other cases, much covering upon the head, which causes perspiration, and consequently weakens the skin, must be avoided; the head should be well washed with cold water every morning, and afterwards rubbed and brushed to promote reaction. Various applications are recommended to prevent or cure baldness; they are all stimulant. Those of which cantharides, or Spanish blistering flies, form an ingredient, are generally most serviceable. A drachm of the tincture of cantharides, rubbed up with an ounce of lard, will form a sufficiently stimulating ointment. Falling off of the hair, which is occasioned by eruptive disease, or which is accompanied with inflammation of the skin, of course requires a different and more soothing treatment; probably medi-cine is required, and the case is better submitted to the treatment of a medical practitioner.

In the baldness of early life, the hair drops off without the previous change of colour which occurs in age; in the latter case, of course, no freatment is either likely to be resorted to, or

to be of service.

The following has been found an excellent hair-wash:-

Take of

Tineture of Cantharides . . . 1 drachm. Spirit of Rosemary . . . . 1 ounce. Elder Flower Water, . . . 1 pint.

This wash may be freely applied night and | Balsam is from ten to sixty minims.

closed oven is much better, and is superseding | morning, to the roots of the hair, by means of a piece of lint or sponge.

Or, take of

Eau de Cologne . . . . 2 ounces. Tincture of Cantharides, . . 2 drachms. Oil of Lavender and Rose-

mary, of each . . . . . 10 drops.

This may be applied once or twice a day, but if the scalp becomes sore, it must be discontinued for a time.

Baldness often arises from fungus in the hair, in which case it is likely to show itself in isolated bald patches, until it involves the greater part of the scalp. In such cases, it is advisable to remove the hair from the immediate vicinity of the patches, and to destroy the fungus by a stimulating application, consisting of equal parts of collodion and tineture of cantharides. Sir Erasmus Wilson recom-mends this to be alternated with a wash, consisting of two drachms of oil of almonds, the same proportion of ammonia and two ounces each of honey water and spirits of rosemary.—See Hair—Skin.

It may be stated as a rule, that all the vaunted specifics of advertising quacks fail in producing the results said to be obtained, and generally consist merely of some irritating or stimulating application, while many of them

are positively injurious.

BALSAM .- The term is derived from two Hebrew words, signifying the "prince of oils." It was formerly applied to many more substances than it is at present. The balsams of Peru and Tolu, and of Copaiba, are most generally known medicinally. The two former are used popularly as external applications. Tolu balsam is used to impart a pleasant flavour to lozenges, cough mixtures, and a syrup and tincture are prepared from it. It undoubtedly exerts a beneficial expectorant action. Quarter of an ounce of gum acacia powder, an ounce of Tolu syrup, one drachm and a half to two drachms of ipecacuanha wine, and water sufficient to make up six fluid ounces, form a pleasant and good cough mixture for children, to be given in from teaspoonful to table-spoonful doses, according to age. When fever is absent, and the cough getting loose, a drachm of tincture of squill may be added with advantage to the above.

BALSAM OF COPAIBA is an oleo-

resin which acts decidedly upon the mucous surfaces of the body, and is employed in bronchitis, and in irritation of the urinary passages. It is extremely nauseous, and liable to disagree with the stomach. These properties are endeavoured to be overcome by enclosing the medicine in gelatine capsules, and by preparing it in various ways, as by covering the taste with aromatics, such as cinnamon or peppermint water. When active inflammatory or febrile action is present, copaiba must not be used. The dose of the

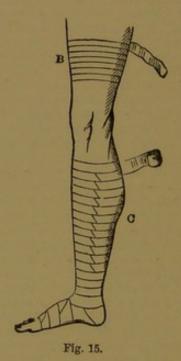

BANDAGES are strips of calico, linen, | are troublesome when the roller is applied. flannel, or of any other convenient material, employed to envelop in rolls any portion of the body requiring artificial support, or upon which it is requisite to produce pressure, or to retain dressing. The art of applying a band-age well, that is, both neatly and efficiently, requires some practice and attention, and it is always a most useful accomplishment; for a bandage, if required at all, must be properly applied, otherwise it is worse than useless; if, therefore, none but the surgeon can undertake the task, it necessitates a much more frequent attendance on his part than might otherwise be requisite. In general, the first few applications of a bandage, will be made by the medical attendant himself, and ought to be in the presence of the individual to whom the duty may be afterwards deputed. By careful attention on the one hand, and kind explanation on the other, much may be learned and taught, but not all, as the inexperienced bandager will discover on the first attempt; by all means, therefore, let the first beginnings be made on some one in health, before the call is made to the invalid. Attention to the following directions will facilitate the application of the previous practical lesson, or in some measure supply its place, if from circumstances it has been wanting. Whatever the material, the width of the bandage or roller must be proportioned in some degree to the size of the part to which it is to be applied; if too narrow, it is apt to be stringy, and to cut; if too broad, it does not adapt itself readily to the inequalities, and the pressure is unequal. For an ordinarysized adult male leg, a bandage of 21 inches broad is a good proportion; for the arm of the same person, 1 or 2 inches ought to be sufficiently well adapted. The material for bandages must neither be too strong nor too weak; ordinary "shirting calico" is a very convenient texture, or unbleached calico will do very well. When there is much tenderness, cotton wool should be placed under the bandage. The length, of course, must vary according to what is required, but rollers are usually put up in six or eight yard lengths; they are better torn in one continuous strip, free from joinings, and without selvage edge. The strip, when prepared for use, must be rolled up as firmly as possible, either into a single or double head, fig. 14, the former is much the most generally

Fig. 14.

employed. If the bandage is a new one, of calico or linen, the loose threads of the roll | the other varieties. at each end must be roved off, otherwise they

Bandages may be applied in simple circles (fig. 15 B), in spiral, &c., or in reverses (fig. 15 c). They are also applied in various other forms to suit the different portions of the body. In applying a bandage, the rolled-up strip being held in the right hand, the end which is commenced with is secured by the first turn. If it be the simple circular bandage, round the trunk of the body, or round a limb of nearly equal girth throughout, either naturally, or from swelling, the roller is carried round and

round, each succeeding turn slightly over-lapping the one before it; if the spiral bandage be required, the rolls are carried up very obliquely, but if, as most likely, it is the re-versed bandage, then, wherever the inequality of the parts prevents its being laid on flatly and evenly, the band must be turned upon itself (fig. 15), so as to become reversed, the

Fig. 16.

surface of the cloth which was next the skin, being turned outwards, and vice versa. It is difficult to describe the manœuvre, and it is a little difficult at first to execute it neatly and well, but when practised it becomes perfectly simple. This is by far the most useful form of bandage, and a person who can put it on well, will have but little difficulty in accomplishing

For the purpose of retaining dressings upon

the head, nothing answers better than a closefitting calico cap; a handkerchief will often serve every purpose, or the split cloth (fig. 16) may be used; applied—fig. 17—the upper tails being brought beneath the under ones, and fastened under the chin, the under tails

Fig. 17.

being carried to the back of the head. When it is desirable to retain the head in one position, it may be done by bands attached to a cap, and fastened as required to a band going round the chest. When for this purpose, or to fix a broken rib, such a band is required, it ought to be from eight to ten inches wide, made of tolerably strong double calico, and sewed firmly

round the body.

To retain a pad or poultice in the arm-pit, a good-sized handkerchief answers better than any bandage, the middle being placed at the arm-pit, the ends are crossed at the side of the neck opposite, carried under the corresponding arm-pit, crossed and brought up and tied on the shoulder. Slinging the arm, a very simple business, is often very badly done—in almost every case the forearm should be supported throughout its entire length, and it is generally well to include the hand, especially in children. The simple sling handkerchief may be put on as at fig. 18, but a much more

Fig. 18.

confining sling is made by enveloping the elbow in the long side of a triangular handkerchief, fastened up into a little pouch at the centre, the point, including the hand, being fastened up to one of the ends going round the neck (fig. 19).

Upon the trunk of the body, dressings, blisters, &c., may be retained by means of a broad band of any convenient material, fastened round and prevented from slipping down by braces over the shoulders (fig. 20).

Fig. 19.

For bandaging the abdomen, a broad band, of whatever material is suitable, is generally made, the ends split for convenience of fastening either before or behind, and a triangular

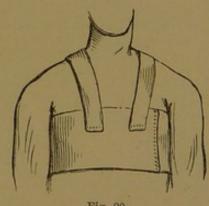

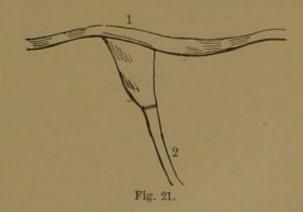

Fig. 20.

piece cut out of either edge at the centre, and the edges joined, in order to fit the shape of the region. In order to retain poultices, &c., at or near the groin, a piece of cloth is to be

shaped to fit the region (fig. 21), a band long enough to go round the body, and to cross and fasten in front, is to be sewed to one end (1), and to the opposite point another small band (2)

is attached, which, passing between the legs, is brought up to the band behind. To retain dressings, &c., between the legs or nates, the double T bandage (fig. 22) is used. For the groin and parts adjacent, the spica or figure of 8 bandage is also used. Two turns should be made round the thigh of the affected side from within outwards, then the bandage is to be

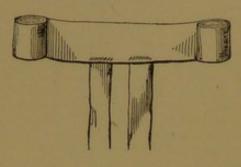

Fig. 22.

carried along the lower part of the groin, and over any pad which it may be desired to hold there; then to pass round the pelvis and back over the pubes, crossing the former fold at the groin, and thus completing the figure of eight. A series of similar turns, each slightly overlapping the other, may then be carried round the same way (fig. 23).

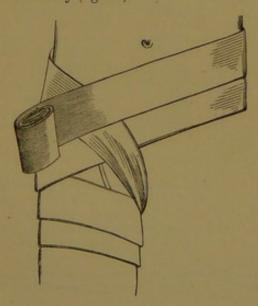

Fig. 23.

For the extremities, the simple roller applied in reversed turns is generally used. Bandaging from above downward may be required, but generally it is upwards. There are various methods of commencing the application of the roller at the foot. The heel is covered by laying the end on the inner ankle, bringing the roller under the heel, then round the ankle so as to secure the end, from thence going down to the toes, and carrying the bandage up from that point round the foot and leg, reversing where required. The arm is to be bandaged thoroughly saturated, as it is put on, with strong starch or flour paste, and if requisite, brown paper pasted on the top of the first bandage, and another dry one put over all. In thinly settled countries, where it might be requisite to move a person soon after a fracture, the foregoing application would prove simple, safe and efficacious. It must not, however, be useful bandage, and one which may be handled and carried about like a handkerchief is that known as Esmarch's. It is cut in a triangular

—with the requisite modifications—by the reverse, like the leg. As a general rule, leg bandages, habitually worn, ought to be put on before the individual gets out of bed in the morning. A bandage which gives pain after its application, without obvious cause, ought to be taken off, and reapplied. If there is reason to suspect inflammatory swelling beneath, it will be well to try the use of cold water before disturbing matters. There is some little management required in taking off a roller as well as in putting it on: as each successive turn is unrolled, it should be gathered in a bunch in the hand, and not, as is often done, three or four yards of bandage at full length pulled round the limb every time. A manytailed bandage (fig. 24) is used to bandage the

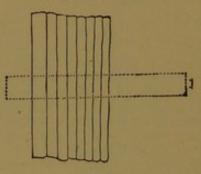

Fig. 24.

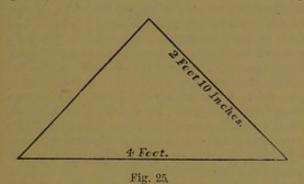

leg where it is an object to avoid the slightest movement. It is formed of a number of short strips of bandage, long enough each to go once and a half round the limb. They are placed obliquely, and overlapping one another; they may, or may not, be joined by a central strip (1). Upon these arranged strips the limb is laid, and each strip in succession is brought round the limb, every succeeding strip securing the previous one. The advantage of the many-tailed bandage is, that it can be changed, either partly or entirely, if soiled, without the slightest dis-turbance. It is only necessary to attach a fresh strip to that which is to be removed, and pull the one away, and the other into its place. When, from movement, a bandage is liable to become displaced, the inconvenience is in great measure prevented, by brushing a weak solution of starch or gum over the turns as soon as applied. This is different from the starch bandage which is so useful in many cases fractures, &c. For this bandage the roller is thoroughly saturated, as it is put on, with strong starch or flour paste, and if requisite, brown paper pasted on the top of the first bandage, and another dry one put over all. In thinly settled countries, where it might be requisite to move a person soon after a fracture, the foregoing application would prove simple, safe and efficacious. It must not, however, be put on till inflammation has subsided. useful bandage, and one which may be handled and carried about like a handkerchief is that

or may be bought stamped with illustrations of the methods of applying it. It measures 4 feet along the base by 2 feet 10 in. (fig. 25). For illustrations of its application see Fractures.

For the uses of Martin's india rubber band-

age in ulcers, see Ulcers.

In bandaging the hand (see fig. 26), the bandage may be from 11 to 2 inches broad according

to circumstances; for the finger of an ordinarysized person, it may be 2 of an inch. In bandaging a finger, the band may first be carried round the wrist, and crossed over the back of the hand to the root of the finger, round which it is carried both up and down again in spiral

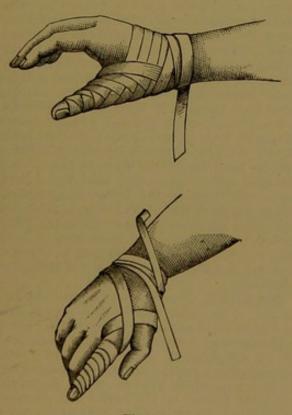

Fig. 26.

coils; it is then brought back to the wrist and fastened by splitting the end so as to make two A bandage may either be fastened by pins or split up in the way described.

In many cases, in which bandages used form-

form, and can be made of the ordinary material, by elastic materials, of which stockings and belts of all kinds are fabricated: elastic rollers are also manufactured. The flannel bandage unites at the same time support and protection to the surface; it is useful in rheumatic cases, and also when applied over the abdomen in diseases of that cavity.

> There are now many forms of manufactured bandage, some of which have their own special The woven or double stocking bandage is more easy of application than that made of simple calico, and is more comfortable in wear; while the solid rubber bandages are most effectual when support is required, either for enlarged veins in the legs, for the cure of eczematous eruptions, or of ulcers, frequently

resulting from such enlargement.

PANTING SYSTEM (or "BANTING"), so called after Mr. Banting of London, who has made his name celebrated from the fact that from being an immensely stout man (so much so, that he was a burden to himself, and was obliged to walk down stairs backwards, and with great care), by adopting a certain regimen he soon became of normal size and weight, and was so grateful that he made known the details of his system in a public pamphlet, the perusal of which soon gained him many imitators amongst all classes of the community. Let no one imagine, however, that there was contained in this pamphlet anything that was startlingly new, or anything whatever that was not per-fectly well known to physiologists, and indeed, taught by them in detail, at all medical schools. Mr. Banting only brought forward a wellknown fact in a striking manner; and, unfortunately, it is probable that the too general adoption of his system in cases not exactly suitable for it, has been attended with harm. In a word, the system consists in the avoidance, as far as possible, of all articles of food likely to favour the production of fat in the body, such as sugar, starch, and fats of all kinds, as well as substances containing fat or assisting in its formation, such as bread, milk, butter, beer, sugar, and potatoes. Malt liquors, port wine, champagne, and the sweet wines, generally, are also to be avoided; and sherry, claret, or Madeira substituted. An occasional tumbler of grog (made of gin, whisky, or brandy, without sugar) is not forbidden, and on the whole, a very liberal diet is allowed, as will be seen from the following table, taken from the amus-

ing pamphlet of Mr. Banting himself:—
"For breakfast, take four or five ounces of beef, mutton, kidneys, broiled fish, or cold meat of any kind except pork, a large cup of tea (without milk or sugar), a little biscuit, or one ounce of dry toast. For dinner, five or six ounces of any fish except salmon, and meat except pork, any vegetable except potato, one ounce of dry toast, fruit out of a pudding; any kind of poultry or game, and two or three glasses of good claret, sherry, or Madeira; erly to be applied they have been superseded | champagne, port, and beer are forbidden. For

tea, two or three ounces of fruit, a rusk or two, | of bark are concentrated in the alkaloid suband a cup of tea without milk or sugar. For supper, three or four ounces of meat or fish, similar to dinner, with a glass or two of claret. For night-cap, if required, a tumbler of grog (made of g.n., whisky, or brandy, without sugar), or a glass or two of claret or sherry."

A similar diet, though less luxurious, is used

by men and lads in the course of training for sports of various kinds, but in these cases it is associated with a good deal of exercise, and the waste of tissue is made up by the consumption of a larger amount of meat, which is generally

preferred half cooked .- See Training.

The Banting system, with modifications suited to particular cases, is an excellent one, only it should be borne in mind that (as recommended by Mr. Banting himself) it is not one which every corpulent person should rush headlong into, without, first of all, consulting his medical adviser.

BARBADOES LEG. - See ELEPHAN-

BARK .- The term used alone is always applied to the bark of the cinchona, also called Peruvian or Jesuit's bark, which was introduced into Europe from South America about 1640, and at first was enormously expensive. Many marvellous tales are told of the way in which the virtues of cinchona bark were first discovered by the natives of the country, but they have been proved erroneous. The remarkable power of bark in curing, not only intermittent fever or ague, but periodic diseases generally, and its efficacy as a general tonic, have rendered it one of the most valuable drugs possessed by man. The varieties of cinchona have been classed as pale, yellow, and red barks, but there are many more than these, and some of them are almost worthless as medicine. The kind of bark has now, however, since the discovery of quinine, become almost a matter of indifference to the general purchaser; when the drug itself, either whole or in powder, is required, the only security is to procure it from a respectable chemist. powder, which was formerly given so largely, is scarcely ever now prescribed, but the infusion, decoction, and tincture of bark still retain their places. The infusion may be made by pouring a pint of boiling water upon an ounce of coarsely powdered bark, and allowing it to stand near the fire, in a covered vessel, for two hours; the dose, a wine-glassful twice or three times a day. The decoction is made by adding double the quantity of water to the same quantity of bark, and boiling down to one half. The dose is about the same as of the infusion. A favourite domestic method of administering bark, is to steep an ounce of the powder for a week in a bottle of port wine, and of this to give a small wine-glassful once or twice a day. Where the stimulant is admissible, the form is a good one. If the tincture is required, it water depends upon the proportion of the barley is better bought. The characteristic properties to the water, which may be altered to taste,

stances, quina and cinchonia. The former of these is much the most widely known and used, but the latter is considered by many equally efficacious. Quina or quinine is used in medicine in the form of sulphate, or rather disulphate. Pure white in colour, it is in the form of silky crystals, and has a most intensely bitter taste. Its high price renders it liable to much adulteration; it ought, therefore, always to be procured from respectable parties. The dose of quinine is one grain twice a day, as a general tonic, but as an anti-periodic in ague, neuralgia, &c., much larger and more frequent doses are required. It may be given in pill made up with bread crumb, but is more usually administered in the form of mixture, by the addition of five or ten drops of dilute sulphuric acid in a small wine-glassful of water, or it may be taken in a glass of sherry, if stimulants are admissible.

As a curative agent in ague, and in diseases generally of an intermittent or periodic character, bark, either in its original state, or in the form of quinine, is quite unrivalled; as a tonic, in diseases of debility, in the advanced stages of fever or at its very commencement, in weakened digestion, it is equally efficacious. In some persons, quinine, even in small doses, is apt to occasion headache and other uncomfortable symptoms, and to disorder the bowels. When given as a stomach tonic, it cannot be long continued with advantage. Where there exists inflammatory action, or tendency to head affection, quinine must never be given, except by medical sanction. Quinine in combination with iron -the citrate of quinine and iron, forms an admirable tonic in certain cases, in three-grain doses. The use of quinine in various diseases will be found under the separate heads, such as Ague-Neuralgia. The cinchona is now much cultivated by the Indian Government, which seems anxious to introduce the use of the other alkaloids obtained from the bark, especially quinoidine and cinchonine. These may be obtained at half the cost of quinine, and are considered nearly, if not quite, as efficacious.

BARLEY, when prepared as pearl-barley, is one of the most useful additions to sick cookery; its decoction, "barley-water," being a pleasant and extremely beneficial demulcent in all affections of the mucous membranes, and forming a grateful and nutritious beverage in fever; it ought, however, to be made considerably thicker in the former case than in the latter. To make plain barley-water, two ounces of pearl barley should be well washed with cold water, and the washings thrown away; the barley should then be boiled with about two pints of water for twenty minutes in a covered vessel and strained. The thickness of the barley-

Any harmless flavouring agent, such as lemon | temperature of the skin. If it has not this juice, syrup of orange flower, or sugar, may be added to make it more palatable; or some orange or lemon peel may be boiled with it. Barleywater does not keep very well, and ought to be made fresh every day. A compound and very pleasant drink is made by adding, to a quart of simple barley-water, figs sliced and raisins stoned, of each two and a half ounces, liquorice root sliced, five drachms, and a pint of water, the whole to be boiled down to a quart and strained. This compound decoction is not so well adapted for a fever drink as the simpler form.

In irritation of the urinary passages, from gravel, or after the application of a blister, or from any other cause, barley-water is most valuable; its soothing properties are still further increased by the addition of an ounce of gum arabic to each pint of liquor. catarrh, and irritable cough, or simply as an article of mild unstimulating nourishment, it is serviceable. The late Dr. A. T. Thomson recommended equal parts of barley-water and milk, sweetened with a little refined sugar, as a good food for infants brought up by hand. It may act upon the bowels.

BAROMETER, the instrument by which the amount of atmospheric pressure is deter-

BARRENNESS. - Sterility of the female,

may be the result of defect of structure in some portion of the generative organs, or of functional disorder resulting from local or constitutional causes. Such cases always require the care and consideration of a medical attendant.

BASILIC VEIN.—Frequently opened in

the operation of bleeding from the arm. - See Blood-Letting

BASILICON OINTMENT, or RESIN OINTMENT, is made with resin in coarse powder eight ounces, yellow wax four ounces, simple ointment sixteen ounces, which after melting is strained, while hot, through flannel, and stir constantly while cooling. It is a stimulant ointment, not as much used at the present day as formerly.

BATH.—Applications to the surface of the body, either general or partial, in the form of liquid, vapour, or hot air, are now comprehended under the term "bath."

Water baths may be simple or medicated. As regards temperature, they may be cold, tepid, warm, or hot.

As regards application, they may be general or partial, shower, cold affusion, douche, sponge, wet sheet.

Vapour and hot air are both used as baths. The extreme vascularity, the nervous sensibility, and sympathies of the skin, and its important functions as an excreting organ, all render it a most important medium through which to impress and act upon the system generally.

effect, it is injurious to a person otherwise The temperature of a cold bath canhealthy. not be well specified, as it depends on the condition of the weather; but 60° Fahr. is usually about the average in our climate, the effect upon the system varying with the length of time it is endured, and the amount of muscular movement exerted during that time. A single plunge into ice-cold water, may depress less than a longer-continued bath of a higher temperature. As a rule, individuals with weak hearts, or slow circulation, do not bear well the effects of cold bathing, it robs them of an amount of animal heat, which they cannot readily again make up; it produces nervous exhaustion, and perhaps, internal congestion, unrelieved by reaction to the surface. In fevers, the application of cold abstracts heat from the skin, and if continued long enough, from the internal organs as well, but the reaction after the bath soon restores the temperature. In cases of very high fever, the reduction in the temperature is more permanent.—See Cold-Affusion.

When an individual in comparative health, after the cold bath, in any form, remains chilled, the fingers and lips blue, the countenance pale; and when languor and drowsiness succeed: he may be certain that more harm than benefit is being derived from the custom, and that it be must be modified or given up.

In such a case, if the bath has been usually taken before breakfast, the hour should be altered to a couple of hours after that meal; this with some will be quite sufficient to make the difference between agreeing or not; indeed, it requires a person of very good vital power to derive real benefit and comfort from bathing before breakfast. If the change in hour does not alter the effect of the cold bath, something may be due to its low temperature; or the bather, especially if he be not a swimmer, may expose himself too long to the depressing influence; he may be in the habit of going into the water after his powers have been exhausted by much exercise, or when he is in too chilled a condition. All these points require consideration, before either the undoubted good effects, or the comfort of bathing, whether in fresh or salt water, are given up as unattainable. The last point mentioned is one on which particular caution is required; many persons, in dread of going in to bathe too hot, run to the other extreme, and allow themselves to become so chilled that reaction will not come on. After coming out of a cold bath the skin ought to be well rubbed with a rough towel, till a glow is felt; or the hair glove, now so well known, may The above remarks apply to the be used. nder it a most important medium through application of cold water generally to the skin, in whatever form. are liable to head affection, should not take the | Its temperature ranges from 95° to 105° Fahr. general cold bath; for them the shower bath is Females should not bathe in cold

water during the menstrual period.

Sea-bathing and the Salt-water bath. - Some persons who cannot bathe in fresh water, can do so in the sea; the saline ingredients producing a more stimulant effect upon the skin; sometimes, however, the stimulation goes so far as to produce a painful rash, which forces the person to give up the custom. The restorative and tonic effects of cold bathing are undoubted in many cases, if the mode of taking it be properly regulated. As a general rule, five or six minutes immersion is sufficiently long. Sea water, from its containing numerous salts, is more buoyant and invigorating than fresh, and undoubtedly exerts a more tonic influence upon the bather. Moreover, its temperature is more equable, and seldom so low as that of the latter. Hence, many persons, unable to take a cold bath in their own dwellings, can do so with impunity in the sea. From the beginning of June to the end of September, according to weather, may be considered the sea-bathing season, during which the temperature of the water on our shores averages from 55° to 70° Fahr.

Sea-water baths, however, especially on a small scale, are now readily procurable in one's own house or room, by means of the sea salts, such as Tidman's, Palmer's, &c., abundantly advertised, and sold at so moderate a rate as to put them in the power of most. As directions accompany the packets of salt, it is needless to give them here. Better still for those whose place of residence enables them to avail themselves of it, sea water is supplied by the various railway companies which have branches or termini at the chief watering places, and arrangements are made by which many inland towns may be supplied with it

regularly at very reasonable prices.

A bath is either ordered as a remedy, or desired as a comfort, and if when cold it does

not agree-

The Tepid bath, of a temperature varying from 85° to 94°, may be used—about 88° is an agreeable and convenient standard. Of course, the tepid bath involves the use of a receptacle for the water. It does not produce the shock to the system like the cold, and the person may remain in it from a quarter of an hour to twenty minutes. The tepid bath relaxes and purifies the skin, and promotes the insensible perspiration. For the purposes of cleanliness and comfort, it is most generally applicable. After fatigue from travelling, hunting, shooting, &c.; in irritable states of the system, with dry or chafed skin, the tepid bath is at once grateful to the feeling, and salutary. Neither the tepid bath, nor any other, should be taken soon after a full meal.

The Warm, or Hot bath is, or ought to be, a remedial agent only, not one for general use. a new and convenient form of bath (manu-

-100° is the most general standard. The warm bath is used to promote reaction, to allay pain, spasmodic or inflammatory, to soothe convulsive action, and to cause relaxation of the tissues prior to some surgical operations. It is invaluable in soothing children who suffer from simple and inflammatory fevers, while in the treatment of numerous skin affections, and in Bright's disease, it is frequently employed with benefit. The time for remaining in the warm bath is generally from twenty to fiveand-twenty minutes, but this must be regulated somewhat by the effect required. The hot bath of a temperature of 105° is a powerful stimulant agent, to be used cautiously, and rarely without medical advice; in disease characterised by extreme depression, coldness, &c., it is useful. In the employment of these baths generally, persons who are the subjects of any organic disease, or have a tendency to acute attacks of functional disorder, such as determination of blood to the head, &c., must be very cautious, and ought if possible to have medical advice. The regulation of the temperature of baths ought never to be left to the sensations, the thermometer is the only trustworthy guide, and, indeed, is an article which no house ought to be without; the price of the instrument is now extremely low, and whether for the bath, the temperature of the room, or the instruction of a child, it is equally useful. -See Thermometer.

Mode of Application of the Bath.—Baths are made either to contain the whole person, as the "slipper bath," or on a smaller scale, as the "hip bath" and the "sponge bath." In choosing a bath, it is well to have one which will answer the desired purpose with as large a quantity of water as possible. Every house where it can be afforded should have the means of providing a bath, be it ever so small, and every town and village should have its public

baths for the use of its poorer inhabitants.

Hip baths and Foot baths are used where a full bath is unnecessary. The former, either cold, tepid, or warm, is extremely useful in affections of the loins, hips, &c. The foot bath, generally used as a derivative, should be at as high a temperature as can be borne, and another to radden the skip after the immersion. ought to redden the skin after the immersion. If a stronger effect is requisite, an ounce of mustard, and a couple of handfuls of salt may be put in the water. To reap the full benefit of the foot bath, the extremities should either be clothed in woollen stockings, or wrapped in flannel immediately on coming out of the water. In using the foot bath in cases of insensibility, the fact must always be kept in mind, that it may be so hot as to scald, and that the patient cannot complain. The best mode is to use the thermometer, and not to raise the heat above 110°.

The accompanying illustration (fig. 27) shows

BAT BAT

bone Lane, London) for invalids and general purposes. The bath when mounted on the stand, as figured, prevents the trouble of raising and lowering the body in helpless cases, while, by lifting it out of the stand, it can be used as an ordinary hip bath. For nursery purposes it is useful, preventing splashing, and affording a support to the child to hold by when being

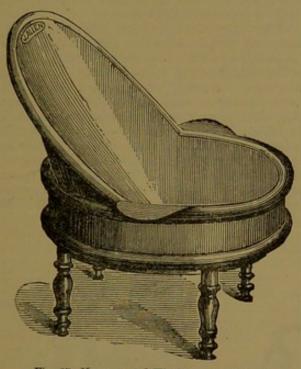

Fig. 27. Nursery and Hip Bath combined.

The Sponge bath is now universally used for purposes of cleanliness and comfort. It may, however, produce depression if employed before breakfast. Partial sponging, sponging with tepid water, changing the hour, or having a cup of tea or coffee on rising, before taking the bath, may obviate this effect. Rough friction is to be employed after. Persons who suffer

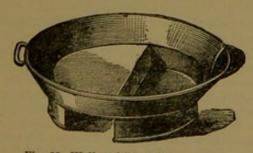

Fig. 28. Well and Dry Platform Bath.

from a determination of blood to the head, are often compelled to give up the practice of the daily sponge, finding this tendency intensified by the standing in cold water. To meet this difficulty, the same firm to whom we owe the last bath mentioned, has invented a small portable bath with a dry platform on which

factured by Messrs. Allen & Son, of Maryle- | the bather stands during the operation. In cold weather, a quart of hot water poured over the platform will suffice to keep the feet warm during the period of bathing.

Portable baths made of Mackintosh material

are extensively used by travellers, military men, emigrants, and others. They fold up into small space, and can be readily inflated when desired for use.

Cold Affusion (see Affusion—Cold).

The Douche bath consists of a compact stream of water, either warm or cold, allowed to impinge forcibly upon any portion of the body. In some bathing establishments, on the Continent especially, the douche stream is of great force and bulk. Domestically, the most familiar douche instrument is the pump, and a most efficient one it is to strengthen a limb which remains weak after an accident, such as fracture or sprain, -it must be used till aching is produced. The most convenient domestic douche is a watering can without a rose, but a jug will do; in short, whatever will send a stream of water upon the part required. Addi-tional force is obtained by the person administering the douche standing upon a chair.

The Shower bath whether of fresh or salt water, whether quite cold or tepid, is a valuable agent in the treatment of many nervous affections, and is more powerful than the cold bath. It is frequently recommended in cases of St. Vitus' dance and hysteria, when the patients can safely bear it. It is well for persons of weak habit, or who suffer from the head, to have a thin layer of warm water put in the bottom of the shower bath before getting in. Useful hand-shower baths are sometimes employed which greatly moderate the shock when compared with the ordinary shower.

Another useful appliance may be mentioned here. This consists of a bell-shaped tin vessel, the bottom of which is pierced with holes, and from the top of which rises a hollow tube. To use it, the bell must be immersed in a basin of water, and then the thumb or finger must be placed over the aperture of the tube, which serves as a handle. If the thumb be kept firmly pressed over the aperture, the atmospheric pressure will keep the bell quite full of water while it is raised over the head or any part of the person to whom the shower is to be applied. By raising the thumb the water is suddenly discharged in a shower. This bath is invaluable as a means of applying all the benefits of a shower bath to children, without any of its terrifying accompaniments. It is peculiarly valuable, and has been much used by the writer in cases of nervous disease among children, such as chronic St. Vitus' dance, &c. The intensity of the shock may be varied according to the height at which the instrument is held; and, of course, the temperature of the water may be varied to suit the individual cases of disease.

As a rule, the use of the shower bath should

not be persisted in with children to whom it | continues to be very irritating and disagreeable, after the first few applications. When administered as above, many children become exceed-

ingly fond of using it.

The Swimming bath which is now—thanks to the liberality and enterprise of our town corporations, or of public companies-to be met with in almost every large town, must be looked upon as an important means of improving public health, as well as of affording an opportunity of learning the art of swimming to many who, from being resident in towns, would otherwise remain ignorant of it. It is generally resorted to as a pleasure and luxury, or for the purposes of ablution, or healthful and most useful exercise. The bath should be spacious, and its temperature should be maintained at a pitch which will render its use agreeable as well as safe, even for the comparative invalid who cannot remain any length of time in perfectly cold water. Salt water should a vessel of boiling water underneath the coveralso be added in sufficient quantity, if possible, ings of the patient, and keeping up the steam by this means its action is rendered more by means of hot stones or metal. The Turkish salutary.

The Wet Sheet bath is sometimes, by misnomer, called the cold wet sheet. It is, in fact, a warm bath, or rather a large warm poul-tice, kept warm by the animal heat. It is formed by enveloping the person in a sheet (or several large towels), wrung out of cold or tepid water, and covering or packing him up with layers of blankets; very free perspiration is the result. It is a most useful remedy, and might with advantage be more generally used. Sponging with cold water after the use of this bath is occasionally practised.

The Vapour bath produces free perspiration and may be used whenever that is required, as in incipient cold. It is very relaxing. Many different forms of vapour baths have been invented. A small kettle to place on the fire, with tubing to convey the steam underneath the blanket or oilcase, in which the person is enveloped, forms a good vapour bath. A simple extempore vapour bath may be made by placing bath is partly a vapour bath, but as the Turkish

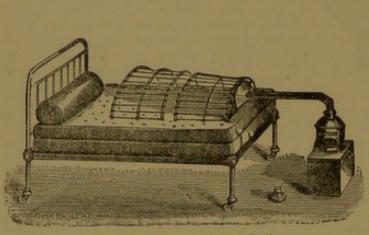

Fig. 29. Vapour or Hot-Air Bath.

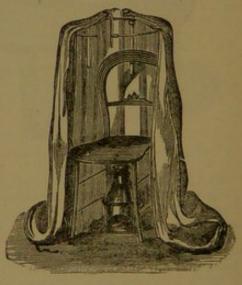

Fig. 30.

bath cannot be employed in the case of a person | bath has been now practically discontinued for confined to bed, other expedients are had recourse to. The best of these is an enclosed copper vessel or boiler, heated by one or more spirit lamps placed on a stool, or on the floor near the bed as in the illustration (fig. 29); communicating with the boiler is a piece a gas burner conducted under the bed-clothes, of copper tubing about 11 inches in diameter, which is carried under the bed-clothes. The steam is in this way projected over the body of the patient, a wire or wicker work cradle, placed in the centre of the bed, preventing the bed-clothes from touching his body, and thus admitting the free dispersion of the vapour round him, while an ingenious contriv-ance protects his feet from being scorched. In consequence of the saturation of the bedclothes with the vapour, the ordinary vapour (as in cases of Bright's disease) the tempera-

general use, and has given place to

The Hot Air bath, which is both more convenient and more stimulating. Apparatus of various kinds for the generation of hot air are employed, such as hot bricks, the hot air from &c. The most convenient and effective apparatus, however, is either Messrs. Allen's, as figured above, which (by removing the boiler, as shown in the illustration) can be made to supply hot air only—or a lamp-cage suspended within the cradle figured. With due precaution, there is little danger of either form of apparatus scorching the person or the bed-clothes, and in order to obtain a good action of the skin and to lessen the dropsy

Medicated baths are those in which chemical compounds are added that they may effect a certain action by absorption through the skin. Thus the addition of carbonate of soda, to the extent of four ounces to thirty gallons of hot water, is used sometimes in skin diseases and chronic rheumatism, and is known by the name of the alkaline bath. The well-known property of sulphur in destroying the itch mite has caused it to be used in the form of a bath. The preparation employed for the purpose is the sulphurated potash, four ounces of which are to be added to thirty gallons of hot water to make a bath. The best known form of bath medication is the mercurial vapour bath, which is arranged by placing the patient on a canebottom chair and enveloping his body in a Underneath the chair is blanket or two. placed a small boiler surmounted with a platinum saucer or crucible into which are put about twenty grains of calomel. Heat is applied to the apparatus by means of a spirit lamp, and the vapour with the calomel is soon dispersed about the body of the patient. In the illustration (fig. 30) is shown the same apparatus described as applied to a bed (fig. 29), but which can be used with equal facility under a chair for the purpose of giving either a medicated or mercurial bath. The operation takes about twenty minutes, and is used as a remedy in persons suffering from constitutional syphilis, and when it is not desirable to give mercury by the mouth.

Mineral baths .- The natural mineral waters, besides being drunk, are also much used as baths in their warm state, and may be classified under the several headings of chalybeate, sulphurous, saline, alkaline, and gaseous. The best known in England are those of Bath, Buxton, Cheltenham, and Harrogate, and on the Continent, Spa in Belgium, Aix-la-Chapelle, Kreuznach, numerous resorts in the Pyrenees, Wiesbaden, Homburg, Baden Baden, Carlsbad,

Marienbad, Vichy, and many others.

The Turkish bath.—There are few subjects, perhaps, upon which less accurate information is possessed by the public than upon Turkish baths. The Turkish or Oriental bath has been known from antiquity, and used more or less by all Eastern nations, though at present it is chiefly patronised by the disciples of Mahomet. How much of the effeminacy and sensuality of that race may be attributed to its use or abuse, it is not easy to say. The ancient Greeks and Romans were also acquainted with the use of oaths of a similar kind; and we can trace menion of them up to the time of Hippocrates, the Father of Medicine, himself. They were undoubtedly introduced into this country and into France with the Roman conquest, and vere extensively made use of for centuries.

The great principle of the Turkish bath is to

ture may be made to range from 120° to 150° | to brace and stimulate the nervous system through the medium of the skin. To effect this, it is necessary to alternate the greatest amount of heat with a due proportion of cold, and the arrangement consists of a chamber supplied with heated air, not dry, but with a little fluid-just enough to moisten or soften the skin, and allow of the free escape of its secretions, which takes place to a remarkable extent, thus relieving congestion or obstruction of internal organs, and favouring the circulation of blood through the fine capillary vessels of the skin itself. Exhalation from the lungs also is favoured, so that the body gets rid of impurities by both channels. Of course the building in which the bath is so administered must be one adapted and intended for the purpose, with all the appropriate chambers, the tepidarium, calidarium, &c., and skilful attendants must also be provided, who, remarkable to say, are not found to suffer in health from their residence there. We would advise people not to be too anxious to have an enormous quantity of cuticle or scurf rubbed off their skin by the attendant whose duty this is. Some persons are apt, from having read the exaggerations that have been circulated on this subject, to measure the benefit they are likely to derive from the bath by the amount of the matter which is removed by the hair-glove. Finally, let it be clearly understood that the Turkish bath is a very useless remedy in some, if not in most, of the cases for which its help is sought by the ignorant, and that in many cases it is likely to prove hurtful and dangerous, so that there can be no greater folly than its use by an invalid without the advice of a properly qualified medical practitioner, who will always be ready to point out the cases (and there are many such) likely to receive benefit from its proper and discriminate application. Some people are so stupid they cannot see that it does not follow that because A. derived advantage from the use of a Turkish bath, B. must necessarily do so, because his case seems to them to resemble A.'s. They forget that there may be many other circumstances connected with B.'s case which might make the use of a bath hurtful to him. We, therefore, hope to hear less for the future of the reckless gratuitous advice tendered by the public to their friends on this subject; and still less of the public being so silly as to follow the advice of those who are interested in the

use of baths from pecuniary considerations.

Amongst the number of cases likely to be benefited (due attention being paid to the precautions aforesaid) may be mentioned chronic rheumatism and gout, especially those cases followed by deposits in the joints, and scaly eruptions upon the skin. Certain cases of sciatica and tic douloureux, as also certain chronic diseases of the lungs, stomach, and liver. It has been known to act as a charm in produce the freest perspiration, and afterwards | removing local dropsies, as of the feet and legs,

when not depending upon any serious organic | ventilation will do much, but it will do far We hope to see a wider application of the Turkish bath as a means of treating disease upon scientific principles, as a preventive of disease, as a promoter of cleanliness and of health, and this is only to be effected by its moderate and judicious employment, since nothing will be more calculated to drive it into the regions of obscurity and neglect than the intemperate and ill-advised encomiums of those who are neither capable of understanding its action nor of judging of its effects, but who are disturbed by an uneasy desire to try anything and everything that is new.

BATH—The city of, is celebrated for hot The waters springs, the only ones in England are used for bathing, and are drunk. They are found useful in gout, rheumatism, paralysis, Persons who liver and stomach affections. suffer from impaired health, in consequence of long residence in a hot climate, frequently derive considerable benefit from the use of the Bath waters. One time the Bath waters were considered an infallible remedy for rheumatism and dyspepsia, and are still held in considerable repute. They contain salts of lime, soda, and

magnesia, as well as iron, in solution.

BATTLEY'S SOLUTION OF OPIUM is a secret preparation, but one largely prescribed by medical men on account of its It is more purely sedative than the other preparations of opium, and is said to be twice the strength of laudanum, but this it is Twenty drops of the sedative solution are almost equal to thirty-four of laudanum. It more certainly produces sleep than the latter, and excites less.

BEAN.—The various species of bean are most nutritious to those whose stomachs can digest them; they are used either young and fresh gathered, or old. The nutriment they afford, as shown in the case of the miners in South America, who live almost exclusively upon them, is calculated to sustain a high condition of muscular development and vigour. Garden-beans as brought to table in this country, must be avoided by those of weak digestion. They are less likely to disagree if deprived of their skins.

BEBEERINE.—An alkaloid prepared from Bebeeru bark, and sometimes employed as a substitute for quinine. Useful in excessive uterine discharges, such as "Whites."-See

"Whites.

BED-ROOM (THE), IN HEALTH. The fact that civilised people spend on an average about one-third of their lives in their bed-rooms, is quite conclusive as to the importance of their salubrity being a first consideration with every Whatever the public rooms, bed-rooms should be as spacious, lofty, and well aired, as circumstances will permit. Unfortunately the reverse of this is the general rule, and we have contracted, they cannot do this. The air, close, small, sleeping apartments, crowded and warmed by respiration, ascends to the top of ill-ventilated nurseries, and bad health. Good the room, where it must remain till it becomes

more if aided by plenty of space. During the daytime there is much less danger of persons generally suffering from want of fresh air than during the night, when, in sleep, they are many hours confined to one place. Every respiration of the sleeper contaminates a certain amount of air, and as a matter of course, the smaller the space around, the sooner will the contamination of the whole body of air contained in that space be completed; it will become loaded with an amount of carbonic acid and organic matter injurious to health. The room must be sufficiently large, -and this is rarely the case in modern houses,—to supply pure air for respiration during six or eight hours, or some means must be provided for carrying off the impure atmosphere. This, certainly, is not to be effected by closed doors and windows, and blocked-up chimneys, assisted in their injurious operation by closely-drawn curtains, which might be contrived for the special purpose of enveloping sleepers in their own exhalations, rendering sleep unrefreehing and realized excitations. freshing, and waking a painful, rather than a pleasurable operation; it cannot be otherwise, after the poison of carbonic acid has been regularly inhaled for the last few hours of slumber.

If the door of a sleeping apartment must be locked, the upper panels ought to be perforated for the admission of air, but the purpose is much better answered by the door being left ajar, while it may be rendered equally secure by means of a chain-bolt. There is an advantage in admitting the fresh air by this channel, for it must be warmed in some degree in its

passage through the house.

Air may be admitted directly from without, through the window, left slightly open at the top, or better, by means of barred glass or perforated panes (fig. 31, A, B, C). Some of these panes are made so that the perforations may be opened or closed at pleasure.

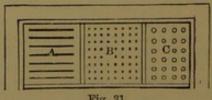

Fig. 31

It is not sufficient to let in pure air, the impure must have some means of escape, and for this the chimney-and no sleeping-room either for rich or poor should be without oneis the most ready channel, and perhaps the best, if under proper arrangements. In former times, when fire-places were ample and lofty, the chimneys were of themselves sufficient to carry off bad air; but since, by change of fashion, the openings have been lowered and

BED B E D

cooler, but not more wholesome, it descends to | be rebreathed, and reaches the level of the oreather's nostrils before it can pass up an ordinary chimney. All this may be obviated by making a proper opening for the escape of the impure warm air into the chimney. Neil Arnott's chimney ventilator (fig. 32) was contrived for this purpose. A brick is taken

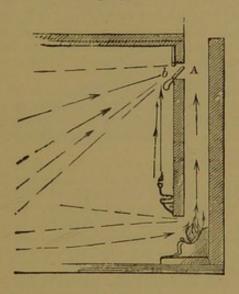

Fig. 32.

out of the wall at the top of the room, so as to make an opening into the shaft of the chimney, the opening being kept closed, and smoke prevented during the use of fires, by means of a balance valve (b). Thus, a bed-room, to be healthy, must have a sufficient entrance for good air; must have a proper exit for that which has been rendered impure; should have space, if possible. The greater the number of sleepers, the more requisite the fulfilment of these conditions. Arnott's ventilator, though still in use, has been superseded by other contrivances, not so liable to get out of order. The best of these is a simple grating furnished inside with a movable diaphragm made of tale, oil-silk, or other light material, which cannot interfere with the current of air as it is drawn by the chimney suction from the upper part of the room, and closing on the open orifices of the grating, should the smoke from the chimney attempt to make a counter current through the valve. This ventilator, introduced by Mr. Ayres, gasfitter, of Tooley Street, is now largely used in private houses, and in numerous public institutions.

Fires in bed-rooms are frequent sources of impure air, uncomfortable sleep, and morning headaches, and should not be adopted by people in health. During the first hours of the night, when burning briskly, the fire promotes ventilation; but when, as often occurs, towards morning, it smoulders down, and becomes choked with ashes, it has not sufficient power to create a draught; the current of air is repasses down, carrying with it into the room a very deteriorated atmosphere, perhaps loaded with sulphurous gases. None who regard health will have curtained beds; it is difficult to conceive what other purpose the huge masses of drapery around a "four-post bed" can serve, than to collect dust, and when drawn, to con-

fine impure air around the sleepers.

However perfect the provision for the venti-lation of a bed-room during the night may be, it must require additional purification in the morning. As a rule, the window should be opened as soon as the occupant is about to leave the room, or even before, in summer, and the bed-clothes turned down over the end of the bedstead, or thrown entirely off, for at least an hour before the bed is made up for the day; in this way, perspiration, and the emanations which take place from every animal body, are evaporated and got rid of. Turn-up beds, boxbeds, and all enclosures of the kind, are perfect abominations. Slops of all kinds should be removed from sleeping-rooms as early as possible. Children even more than adults require fresh pure air during sleep, yet how often are nurseries crowded and shut close up during the night; the beds made as soon as left vacant; and the little creatures confined to the room in which they have slept, for a great part of the day. This ought not to be, nor would it be, but for the generally prevailing ignorance upon all points connected with health, and the rules for its preservation. There are few parents but would make sacrifices to give their children a change of room were they sufficiently aware of the importance of so doing; even selfinterest would dictate the course, could they know how often the first cause of illness, and all its expenses, has originated in the badlyaired nursery.

It is much to be regretted that in the houses of the poor, crowding at night is so frequently compelled by circumstances; if it must be so, its evils ought to be counteracted by the means of ventilation already pointed out, and by strict cleanliness; at the same time, floors should not be washed in damp weather, and when they are washed, it should be done early enough in the day to permit of their being thoroughly dry before the room window is closed for the night. It would be much better if all bed-room floors were stained and polished with bees'-wax and turpentine. It will be long before this process of floor-scrubbing will be adopted by the poor, but it is gaining ground among the well-to-do. Rooms which are at all crowded at night, ought to be white-washed

at least twice a year.

The Bed-room in Sickness.—The chamber of sickness requires all the provisions for health to be attended to with increased care, more especially if the illness be of an infectious character. In this case, as free ventilation with cool pure air as the case will admit—the versed, instead of passing up the chimney, it | window, if possible, being open through the

day-must be continually preserved; and all have tea or coffee and something substantial, superfluous furniture or clothing, of cotton or wool especially, and bed hangings, removed; dirty linen must be taken away at once, and excretions—kept, as they should be, for the inspection of the medical attendant—removed to an unoccupied room, or out of doors. The zeal for cleanliness, however, must never, either in infectious disorders or not, go so far as to dictate washing the floor of an apartment occupied by the sick; it should be cleaned when necessary by the use of damp dusters. Cooking of any kind is out of the question. If it is possible to have a second bed into which the sick person can be moved occasionally, it is a valuable resource. A thermometer to regulate the temperature of a sick room is at all times a safer guide than the sensations of individuals, and the best average temperature to be maintained is from 60° to 65° Fahr. (See Thermometer). All sources of unpleasant or teasing noise, creaking hinges or shoes, the ticking of a clock, &c., are to be obviated; if there is a mirror into which the invalid can gaze, it should be removed. Vessels, whether for food or medicine, should be carefully cleansed each time of using. The medicines ought to be kept in some regular order in a place by themselves, never, as is frequently done by the poor, placed in the window, where they are liable to be decomposed by the action of light, or by the heat of the sun's rays. All external applications should be unmistakably marked Poison.

Even in disease of an infectious character, if proper ventilation and cleanliness be observed, the attendants upon the sick have comparatively little to fear, though at the same time, every additional precautionary measure is to be adopted. The evacuations from the patient and all napkins and dirty linen should be treated as directed under Enteric Fever and Disinfection. The practice of hanging a sheet previously soaked in carbolic acid solution outside the entrance to the sick chamber is useless, and only tends to produce a false security. A bottle of Condy's fluid ought to be always in readiness, so that a small portion may be added to the water used for washing the hands. (See Carbolic Acid-Disinfection.) Aromatic vinegar sprinkled about has no power of protecting against, or of destroying the power of morbid emanations; but it is sometimes grateful to the patient, and pleasant to the attendants Darkening a sick room is too often resorted to, and should not be done except by order of the medical attendant, for some special reason. Bed and body linen of course require to be frequently changed, in fever, &c., once in twenty-four hours, if possible, that is, if it can be done without exhausting the patient.

Those in attendance upon the sick, especially of an infectious disorder, should live sufficiently well, but they cannot indulge with impunity

during the night, and those who have to go about a fever patient in the morning, ought previously to take a cup of one or other of these beverages. The breath and exhalations generally of any one labouring under an infectious disorder are to be avoided; and, as much as can be done, any continued position, towards which a draught of air may be directed from the patient. With these precautions, those whose duty calls them to attend upon the sick, ought never to shrink from that duty, but face it with cheerfulness and trustful reliance upon Providence.

There are now so many inventions for promoting the comfort and convenience of the sick, that it would be impossible to enumerate them here, but a few of the most useful requisites may be suggested.

Bed-room Requisites for the Sick.—Commodes of various descriptions are manufactured for sick-room purposes, and are exceedingly useful when the patient may be permitted with impunity to get out of bed. The best form of commode is that made to resemble an arm chair, which, when out of use, may be of service for the

latter purpose. It ought to consist of a porcelain pail, with handle and porcelain cover, fitted into the sunken rim of the pail, which, when filled with water, forms an excellent trap to prevent noxious exhalations from the receptacle. The pan rests in the wooden framework of the chair, and a wooden seat with hinges closes over the lid of the pail when it is out of use, and completes the apparatus. Fyfe's night chairs, employed in many Government and other hospitals, are made somewhat on this principle, but are furnished with metal lids, and have metal pails outside the porcelain ones, an objectionable arrangement, as all metal work has a tendency to corrode and smell. A commode made on the principle of the earth-closet has been found exceedingly convenient for bed-room purposes, as the necessity of continually emptying its contents is obviated, and at the same time the

excreta are disinfected. When persons are too ill to use the nightchair (as is the condition in fevers, in paralysis,

Fig. 33.

and in fractures of the lower limbs, pelvis, and spine), it is essential that the bed-room should be furnished with a bed-pan of the shape and size best fitted for the requirements of the indiin alcoholic beverages. A sitter-up should vidual. This useful utensil may be had in BED BED

carious materials, such as metal enamelled | ful, and a table-spoonful; while another form inside, porcelain, and vulcanite. Mr. Hooper manufactures excellent bed-pans of pure india rubber, but those made of porcelain are the best and cleanest, the two shapes represented being found most convenient, the round form (fig. 33) as a rule proving more applicable for men, and the slipper form (flg. 34) for women.

Before using, it is better to warm the pan by rinsing it in warm water, and, in most cases, it

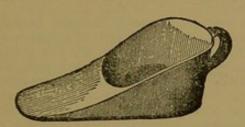

Fig. 34.

is necessary to protect the tender skin from injurious pressure, by placing a thin cushion of flannel over those parts of the utensil which are brought into contact with the skin.

Medicine spoons, though not essential, are often found useful adjuncts to the sick room.

of spoon, occasionally employed in giving medicine to children, is so made as to conceal the noxious potion from the eyes of the little ones.

A metal spoon furnished with a hinged lid, suggested by Dr. A. T. Thomson, has been much used in administering medicine to delirious patients and refractory children. This spoon, which is illustrated by the drawing,

Fig. 35.

answers the purpose of a wedge or gag when introduced between the teeth, but it is scarcely necessary to say that the instrument should not be employed until all other means of persuasion have failed.

Many excellent contrivances are now sold for the purpose of heating and keeping warm nourishment, preparing tea, &c., during the night. Of these, the one figured below, and manu-They are made of metal, porcelain, or glass; Of these, the one figured below, and manuthose of porcelain are the best, and are marked factured by Messrs. Allen, of Marylebone Lane, inside to denote a tea-spoonful, a dessert-spoon- is useful. Another, which may be recommended

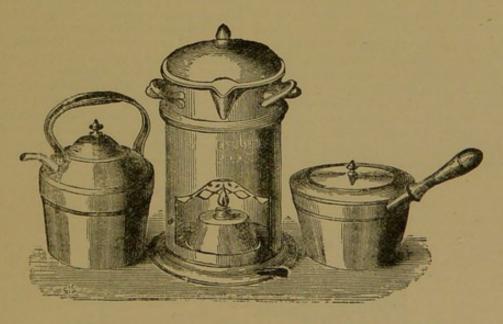

Fig. 36.

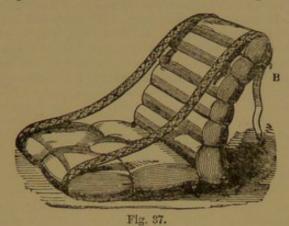

n. account of the little space which it occupies, | apparatus, which is furnished in a neat japanned is patented by Mr. Lloyd of Birmingham. It consists of a movable stand containing a lamp for burning methylated spirit, a kettle with elongated spout for imparting moisture to the air, telescoped over a shorter spout which may be used when hot or boiling water is required for any purpose. A water bath with earthen-

tin box, where it is kept when out of use.

Other useful articles in the sick-room are a drop or minim measure; a piece of water-proof sheeting, of some one of the numerous materials now manufactured; a fan; a night-light, either simple or made to keep water hot; an air or ware basin, in which milk, gruel, broth, or other food may be heated as required completes the which can be used either as a cushion or as a water cushion, of waterproof material, similar

either liquid aliment or medicine in severe illness, when it is desirable that a patient's head should not be elevated -See also Alimentary Tube.

Fig. 38.

During illness of any kind, the chamber in use ought daily to undergo a general cleansing; after fever or other infectious disorder, everything should be separately cleaned. The room itself ought to be first disinfected by means of sulphur vapour, and afterwards papered, painted, or white-washed afresh, the bed-frame taken down, scoured, and with houses, and in the abodes of the poor, but they other furniture exposed to the open air for are discarded in all public institutions, and are

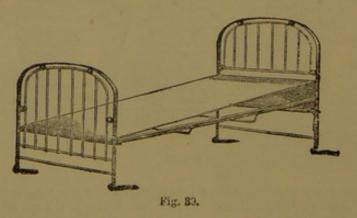

taken to pieces, their coverings washed, their be washed, should be. Expose articles which have been about the sick freely to the action of air or boiling water, and they will speedily get rid of the noxious particles,— "fomites," as they are called. Shut them up, or bundle them together, and they will retain the power of propagating disease for months, it may be for years.

The crowded rooms of the poor have been mentioned—bad enough in health, they become ten times worse in sickness, and this is chiefly felt in country districts. In towns, a person seized with an infectious disorder, if accommodation and means at home are insufficient, has the hospital as a resource; in the country he has not; the consequence is, that to their own detriment and that of others, the sick are compelled to be lodged in the crowded family dwelling, with every chance of the disease spreading through the house or village-the case is continually occurring. It might easily be prevented by providing some isolated cottage in a healthy situation, properly laid out and furnished for the reception of the sick, with proper nursing attendance. Cottage hospitals

considerate provision for infectious disease; but there still appears to be a want, in many country districts, of more isolated accommodation than at present exists, to assist, if possible, in mitigating, if not in stamping out, the seeds of infection.—See Hospital. BEDS and BEDDING .- The first neces-

are now extensively dispersed throughout the country, and the Local Government has made

sity of a sleeping-room, whether in health or in sickness, is a healthy and comfortable bed. Wooden bedsteads still linger in old-fashioned

bedsteads. These are cleaner, cheaper, and parted to the bed, but in many cases the old take up much less room than wood, and are custom of employing strong canvas (laced to constructed in a variety of forms to suit the the sides with stout cords) to form a support convenience of all parties. In most modern to the bed, is still adhered to, and is even con-iron bedsteads, the bottom part is composed of sidered preferable, as it admits of easy removal iron laths interlacing, and fixed by pivots to and cleansing should it be necessary.

being gradually replaced everywhere by iron the sides, by which a certain elasticity is im-

this principle, has been introduced by Mr. Stidolph of Dartford, and, from its durability, cleanliness, and comfort, bids fair to command general approval (fig. 39). Instead of the canvas bottom being attached to the bedstead by laced cords, it is double and endless, and is made to revolve round bearers placed at the head and foot of the bed, much on the principle of a round Tension may be kept up by tightening the canvas from time to time, the elasticity imparted being almost equal to that of the spring mattress. Not the least important of the advantages of this bedstead, is the facility with which the sacking can be moved from one part to another, or detached altogether from the iron frame-work when soiled. In all cases, the head of the bedstead should be at right angles with the wall, and sufficient space should be left on either side of it. As regards the mattress or bed itself, nearly all experience is in favour of horse hair. It is clean, durable, and elastic, and is not likely to form into When furnished with a palliasse as well, the hair mattress makes the best form of bed we possess; but it is expensive in the first instance, and the necessity for its periodic renewal, especially when used for sick-room purposes, almost debars its adoption among the poor. Any other material which takes the form of the tufted mattress is subject to the same disadvantages as regards renewal, but for the sake of economy, cheaper substitutes are generally had recourse to. The more common are wool of various qualities, from that taken direct from the fleece to the refuse of old carpets and old clothes; cotton waste, cocoa fibre, sea weed, and Indian grasses, are also in use, but none of these possess the elasticity of horse hair, and all are liable in time to form into knots. For the poor, the most available and easily-cleaned bed is the loose one, which can be filled with any of these materials, and which, when in use, should be shaken up every day like a feather bed. The feather bed itself is still much in use, and, although considered a trifle too luxurious for the present generation, it would be hard to deprive the aged of the comfort they associate with it. Probably the most economical and at the same time cleanly bed, is the loose bag filled with flock of a fairly good quality. Flock is a mixture of cotton and wool, and sells at about threepence per pound, and as it takes on an average about twentyfive pounds weight to make a bed, the total cost, inclusive of the linen ticking, will not much exceed ten shillings. Good wheaten straw, now very much discarded, makes an excellent bed, and is usually easily obtainable under circumstances when the others cannot be had.

Beds for the Sick.—For the bed of an invalid. nothing answers better than the spiral spring mattress. It makes movements easy and pres-

excellent bedstead, with an improvement on | of gear, and on this account numerous adaptations of the same principle, but in a less bulky form, have been recently introduced into hospitals and private households. That most in favour is termed the wire-woven mattress, an American invention, which may be rolled up when out of use, and can be fixed to any bedstead of ordinary dimensions. This, covered only with a blanket, makes an excellent sanitary bed in hot weather, and at ordinary times it requires only a thin mattress to complete it.

Great comfort is experienced by the invalid from the air or water bed. These are specially useful for the prevention of bed-sores, and need not be so large or so costly as they are usually made. It is, as a rule, only necessary to relieve pressure from the hips and back, the shoulders and legs being comparatively exempt from it, so that a water mattress half the length of the bed will be sufficient in the vast majority of cases. Air and water pillows are designed for the same purpose, but their utility in the above cases are perhaps over-estimated, as it is barely possible to keep them on a level with the patient's body and with the bed or A modification of the ordinary mattress. water mattress has been introduced by Mr. Pocock of Southwark Street, by which it may be rendered more serviceable for various purposes. It consists in the division of the mattress into eight or ten compartments, like a series of long flat bottles placed crossways, any one of which may be removed at pleasure, and filled more or less either with air or water to suit the patient's requirements. The water bed is usually preferred to that containing air alone. It is filled to about two thirds of its area with warm water at about a temperature of 98° Fahr., and it is astonishing how the warmth imparted from the body keeps up the temperature. Should the patient complain of chilliness, it can easily be remedied by withdrawing a portion of the water, and replacing it by warmer

BED LIFTS.—Numerous contrivances have been invented for elevating patients in bed, to afford facilities for making the bed under them, and for dressing wounds on the back. Some are independent of the bedstead and are brought to the bedside when required, while others form an essential part of the bedstead. One form, manufactured by Hooper, of Pall Mall, is found valuable in many bedridden and other cases where it is impossible to change the patient without much risk and pain. The patient is supported by a movable stretcher composed of bands of webbing forming a false bottom to the bedstead, which the nurse has no difficulty in raising on account of its attachment by iron supports with hinge joints to the horizontal bars connecting the feet of the bedstead. But in order to change a helpless invalid, and to have his bed re-made, it is more usual to have him removed entirely from the sure slight, but it is liable to rust and get out | bedstead. If there is another bed in the room,

BED BEE

he is usually transferred to it for the time; not over six inches in width, connected by in hospitals for the sick, folding stretchers reaching from the floor to the level of the bed, are employed for this purpose, and where numerous assistants are at hand this mode of changing is the simplest and most convenient.

It may be desirable, however, to employ an invalid-lift, which by its action would relieve the attendant, and to some extent the patient, and such an apparatus has been suggested by the late Dr. Thomas Thomson of Learnington, as figured in the next woodcut. It is made of

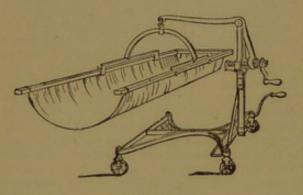

Fig 40.

wrought iron, and the lifting force is obtained by a crane, raised and depressed by a lever. The crane is fixed on a framework on castors, and at the end of it is suspended a cradle stretcher, which, when detached, can be drawn

under the body of the patient.

Another lift of a cheaper and simpler construction, manufactured by the invalid furniture makers, consists of a couple of wooden poles, to which are attached several bands of webbing, to form a stretcher. A wooden triangle placed at the foot and another at the head of the bed, and connected together by a longer pole above, support the stretcher, and the raising and lowering is accomplished by means of a handle and screw attached to the triangle at the foot of the bed, which a child might turn with its hands. The cost of this apparatus is about fifty shillings.

BED RESTS.—In persons suffering from great difficulty in breathing, arising either from disease of the lungs or the heart, or among convalescents, a bed rest is often found a great boon. As a makeshift, an ordinary bed-room chair propped up with pillows is made to answer the purpose, but it is an uncouth arrangement. The old fashioned rest, stuffed with hair and furnished with elbow pieces, is not a bad one, but it is beyond the reach of the poor, and, like most bed rests, it has a tendency to push the patient forward in the bed, as the bottom part, to give freedom to the rackwork motion, occupies usually eighteen inches, or more space, near the head. To remedy this, and in other respects to make the rest more available and cleanly, it is now usual to have it made of cane | digestion; but this depends in some degree upon

hinges with the incline, which is moved to any angle by a single curved iron support fitted with a pinion. A very simple and excellent rest is made by Hooper, of Pall Mall, and another by Mr. Nixon, of University College hospital, while a third, introduced by Mr. Thomas Allen, of Bristol, made of iron with canvas backing, of easy adjustment to any angle, may be recommended as both cheap and cleanly. Specimens of these and other bed rests may be seen in the Parkes' Museum of Hygiene, Margaret Street, Cavendish Square, London.

In many cases of heart disease, patients experience most comfort by bending their bodies forwards, and resting their arms on some support in front of them. A convenient rest for this purpose will be found in a horizontal board placed across the bed, and supported on either side by two iron uprights made to fit into the sides of the bedstead.

BED-SORES on the back and buttocks of bedridden persons are caused by long-continued pressure from lying in one position, and, owing to a want of vital power in such cases, they are often extremely difficult to heal. They are most frequently met with as a consequence of paralysis of the lower part of the body, and occasionally in fractures of the pelvis and lower limbs, in long-continued fevers, and in other debilitated conditions of the system, where due attention has not been paid to the state of the parts subjected to pressure. Bed-sores com-mence with a red patch on the skin, which soon loses its vitality and becomes a sloughing wound, always retarding recovery, and often accelerating death. To guard against its occurrence is alike the duty of the doctor and the nurse, and every precaution-notably the sponging of those parts of the back most liable to be affected daily with water or spirits and water, and then carefully drying them—must be rigidly attended to. Where there is much constitutional depression, languid circulation, or great emaciation, the patient ought to be put upon a spring mattress, or the parts most liable to suffer should be relieved from pressure by the air or water pillow, or, better still, by the water bed, should the circumstances of the patient allow it. When a bed-sore has formed, which it will occasionally do notwithstanding every precaution to the contrary, it is best treated by relieving in every possible way by pads and cushions the pressure upon it, and by dressing it once or twice daily with lint thickly spread with boracic acid ointment. If necessary the lint may be maintained in its place with isinglass plaster; ordinary adhesive plaster 18 too irritating for such cases.

BEE.—See STINGS.

BEEF.—BEEF TEA.—Beef, the most strongly nutritious animal flesh in use, is not quite so digestible and light as mutton for those of weak work in a wooden frame, with a bottom part, the part selected. A slice from a course-grained

BEE BEL

shoulder of mutton may be much more difficult | the slightest degree of acidity or hardness of digestion than one from the under side of a sirloin of beef. As a general rule, however, mutton is preferable for the dyspeptic and the convalescent.

Beef tea is a most important article in sick cookery, but is very often badly made, and much too weak for the purposes for which it is ordered. In diseases of exhaustion, or in the last stage of fever, strong beef tea is perhaps the form of nourishment most easily assimilated, and best adapted to afford powerful support to the system. Beef tea may be made from beef cut into thin slices; but the method recommended by Professor Liebig has been much employed. This celebrated chemist directs a pound of lean beef, freed from fat and bone, to be chopped small, as for mince meat, and to be "uniformly mixed with its own weight of cold water, slowly heated to boiling, and the liquid, after boiling briskly for a minute or two," to be "strained through a towel." A little salt, or any allowable seasoning, may be added. The more general plan is to take a pound of lean meat, and after tearing it into shreds and mineing it, to place it in an earthen jar or jampot, adding to it a pint of cold water, allowing the mixture to stand for an hour and stirring it occasionally. The pot containing it is then put into a saucepan half-filled with water, which is placed on a slow fire or gas stove for an hour. The jar when removed should have flowers (fig. 41) grow solitary from the axils of its contents put through a strainer, after which, with the addition of a little salt, it will be ready

BEER, which includes ale and porter, constitutes the principal beverage of the working classes in England. It is prepared from malt by simple fermentation, and contains more or less saccharine matter, alcohol, and the bitter principle of the hop; it also contains, especially when old and hard, a proportion of lactic acid. As an ordinary beverage for most people, good table beer is particularly well adapted; it contains just enough spirit to afford gentle, almost inappreciable stimulation, and its bitter undoubtedly assists to maintain the tone of the stomach, so apt to fad in the hard-working, anxious-minded citizen. Ale is too strong for ordinary every day use for the robust, but in the delicate, and in convalescence from illness, when it agrees, it is often admirably adapted to support the powers of the constitution. Pale ale or bitter beer agrees well with some persons, and the great amount of bitter it contains, acts as a powerful tonic to weak stomachs; but for this very reason, its use ought not to be persevered in long at a time. The amount of spirit it contains is not large, but the narcotic properties of the hop are apt to affect the head. It is lighter, however, than the more saccharine ales. Malt liquors never agree with

aggravates their bad effect tenfold. A single glass of hard ale is sufficient to induce an attack of gravel in the predisposed. Those who suffer from plethora, and consequent head symptoms, from chronic cough, or oppression of breathing, from gout, gravel, or habitual acidity of the stomach, should never touch malt liquors. Hard or acid malt liquor is always injurious; some persons on this account habitually add a small portion of carbonate of soda to their malt liquor-the practice is most hurtful, and rapidly debilitates the stomach and deteriorates the blood.

BEET-ROOT contains so large a quantity of sugar, as to make its extraction an object of commerce. The sweetening powers are less than those of cane-sugar. The root itself, when boiled, is easy of digestion. Its beautiful colouring-matter might often be substituted more frequently than at present for more dele-

terious substances.

BELLADONNA, the deadly nightshade, grows wild in many parts of Britain. The juice of the plant is powerfully narcotic and anodyne. It is a valuable medicine in proper hands. Domestically, belladonna should be known as a poison, which has proved fatal to children, who have been tempted to eat its violet-black shining berries, which are about as large as a

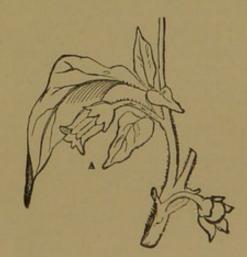

Fig. 41.

the leaves, are bell-shaped, and purple at the border. Wherever the plant is found, children should be warned against it. The symptoms of poisoning by nightshade, are dryness of the mouth and throat, difficulty in swallowing, a kind of laughing delirium, followed by insensibility, and extreme dilatation of the pupil. With such symptoms, a powerful stimulant emetic cannot be too soon administered, and will probably make the case clear, by bringing up the black skins of the berries. Cold douche those who are liable to gout or gravel, and if to the head, mustard plasters to the back and their use be continued, they are almost certain legs, and sal volatile internally, are appropriate to induce a paroxysm of either of these diseases; remedies, and may be used until the arrival of

BEL BIL

by medical men to allay pain in neuralgia and muscular spasm. It is also occasionally employed in hooping-cough and asthma, in the form of tincture, prepared from the leaves, and is given in doses ranging from five to twenty minims. The liniment prepared from the root is a useful remedy to dull local pain. There is also an extract prepared from the leaves, used mainly for plasters, and an ointment, consisting of eighty grains of the extract to an ounce of lard, very serviceable in breast-abscesses and kindred complaints.

BELLY.—See ABDOMEN.

BENZOIC ACID, obtained from gum benzoin, is in the form of white silky scales, and has a penetrating not unpleasant odour. has been found useful in cases of obstinate wetting the bed in children. Dose: five grains made into pills with bread crumbs, twice a day, to a child of ten years old. It is an ingredient

BERIBERI and BARBIERS.—Diseases

peculiar to India.—See Tropical Diseases. BILE.—The peculiar fluid secreted by the liver from the blood, is in man of a brownish yellow colour, and has a bitter taste. position is complex, and it undoubtedly fulfils more than one important office in the functions of the body. Bile is separated by the liver from dark blood, which passing through that gland, on its way to the heart, from the abdominal organs, is thus purified of noxious matters, containing a large amount of carbon, before re-entering the general circulation. separated bile is discharged into the duodenum (see Alimentary Canal), and mixing with the digested food, appears to assist in fitting certain of the constituents for absorption into, and assimilation or transformation in, the body. A large proportion of the constituents of bile are along with the food reabsorbed into the system, and are probably intended and adapted to support the processes of respiratory combustion. It is chiefly the colouring matter of the bile which is discharged from the bowels in health. Bile itself when duly formed, even when absorbed along with its colouring matter into the blood, as we see in jaundice, scarcely produces injurious effects upon the system, but the elements of bile allowed to remain unformed in the blood, act almost like a narcotic

poison.—See Liver, Digestion, &c.
BILIARY CALCULI.—See GALL STONES.
BILIARY DISORDER.—Biliary derangement is so frequent an ailment in civilised life, its history is so intimately connected with the general principles of health, and the prevention, or at least alleviation, of the disorder is so much under individual control, that it has special claims upon our attention.

It has been shown in the last article, that in ordinary health there must be a certain balance maintained between the secretion and ultimate destination of the bile, the assimilation of food, | in diet; fats, melted butter, pastry, meat,

the medical attendant. The drug is much used | and the functions of respiration; that in the by medical men to allay pain in neuralgia and excreted bile the blood is freed from certain principles—containing a large amount of car-bon—which could not be retained in it without injury to health; that further, the bile, after being separated from the blood by the liver, and thrown out into the general tract of the alimentary canal, performs an important part in the function of assimilation; and that lastly, a considerable proportion of the bile-without the colouring matter-is reabsorbed into the system, with the nutriment, in such a state as to fit it-or rather its carbon-for union with the oxygen which enters by the lungs, so that while heat is generated, the carbon, by taking the form of carbonic acid, is fitted for excretion by the lungs or skin. Upon these facts hinge the causes of one at least of the most prevalent biliary disorders, that which depends upon the introduction into the system of a proportion of carbon aliment too great to be removed by the oxygen obtainable through the lungs, and which has its ordinary termination in the attacks which are termed, "bilious attacks," "sick headaches," "bowel complaints," "bilious or British cholera," according to the manner in which the patient is affected.

The second form of biliary disorder depends upon torpidity or inactivity of the liver itself. The third form is the reverse of the first: the gland itself may be sufficiently active, but the blood does not afford sufficient material for it to work upon, and bile is deficient. This is

most frequent in children.

In addition to those affections, there is jaundice, which will be treated of in its proper

The first form of biliary disorder, that dependent upon the accumulation of carbon, or of the elements of bile in the blood, must evidently be owing to one of the following causes, or a combination of them; either too much food, especially of a highly carbonized character, such as fats, oils, sugars, &c., is habitually consumed; or the habits are too physically inactive to keep the functions of respiration, animal heat, and motor change and circulation in healthy action; or the external atmosphere is so temporarily or permanently rarefied by heat, that the individual cannot obtain the full supply of oxygen in respiration; lastly, the excretory functions of the skin may be impeded. Now, although it is unquestionable that some individuals have a much greater tendency to biliary disorder than others, it is also unquestionable that all have it in their power, in a great degree, if not entirely, to control or obviate that tendency, by attention to, and practical application of, the above principles. In those who suffer habitually from sick headaches-which depend generally upon the presence of bile in the stomach-and from other forms of biliary disorder common to this country, there is generally traceable great error

BIL BIL

malt liquors or wine, and other highly carbon- as an enema, will be a most suitable aperient, ised articles of diet, are taken too freely, or at least, are too regularly indulged in, whilst at the same time very little active exercise is taken; the blood becomes overloaded with carbon; langour, sleepiness, headaches, giddiness, loss of appetite, furred tongue, depression of spirits, are the consequences, and continue, until at last the system is relieved, wholly or partially, by an excessive excretion of vitiated bile, which passes off either by vomiting or purging. That deficient exercise has much to do with the formation of such a state of system, is evident from the much greater prevalence of such attacks among females, who take little exercise, than among men; and, indeed, they would be still more prevalent among the former, were it not for the monthly relief. Habitual neglect of the skin, also, by impeding the excretion of carbonic acid from its extensive surface, undoubtedly assists the evil. Again, we have bilious attacks, more especially those known by the name of British cholera, prevalent among the community generally, but at particular periods of the year - that is, in summer or autumn, during or immediately succeeding a prevailing high temperature; and to this high temperature must we look for the cause; for whilst, as a general rule, habits have not been changed, people have been, in consequence of the rarefied atmosphere, inhaling a less proportion of oxygen than usual. Liebig calculates the difference at one-eighth between winter and summer in Germany. have another traceable and universally-acting cause, permitting the accumulation of carbon in the blood, and one which is likewise found to operate upon Europeans especially, who in tropical climates, adhere too nearly to the habits of comparatively full living, admissible in colder climates.

From what has now been said, it is evident how much the avoidance of biliary disorder is under individual control; the question is in reality not one of medicine, but of diet and regimen; medicine certainly may be required, but not by any means to the extent it is often used. Those who are habitually liable to biliary disorder ought most strictly to regulate the diet; fats of all kinds-except, in some cases, toasted bacon-must be avoided; butter either entirely avoided, or used in very small proportion, and never when melted; animal food may be taken in moderation, but should never be consumed at night; much sugar, strong tea or coffee, malt liquor, and the heavier wines, such as port or sweet wines, are all bad. In addition to plain meat, bread, well-boiled vegetables, farinaceous preparations, and fruits ripe or cooked, are the best articles of diet, and if stimulants are required, a little sherry, brandy, or gin with water. Exercise regularly in the open air must be taken, and the skin kept clear and in an active state. If the bowels are confined, a pint of warm water, used

or one or two of the compound rhubarb and blue pills may be taken; it is much better, however, not to trust to medicine. from any cause, the languor, sleepiness, furred tongue, &c., give notice of an impending bilious attack, five or six grains of blue pill should be taken, and followed by a black draught or dose of infusion of senna, or of castor oil, in the morning. Having thus cleared the system, it is better to trust to diet and regimen, than to a repetition of the dose as a corrective of indulgence.

After the attack has somewhat subsided, keeping in mind that the tendency of it is to clear the system, the bowels must not be allowed to get confined, but kept slightly re laxed; if requisite, a desert-spoonful of castor oil, with half a dozen drops of laudanum or chlorodyne, or a small dose of rhubarb and magnesia, with or without laudanum, may be given. The diet should be chiefly of a diluent character for a short time, but nourishing. Should any of the symptoms which preceded the attacks, such as languor, fulness about the region of the liver, pain between the shoulders, furred tongue, &c., continue, a few doses of the compound rhubarb and blue pill will be advisable; if the stomach remains weak, from five to ten grains of carbonate of potash in a wineglassful of infusion of calumba or gentian will be found useful; if the tongue is perfectly clean and there is debility, one grain of quinine in half a glass of sherry twice a day.

There are, however, states of biliary disorder, generally connected with stomach derangement also, which are not the consequence of excess of aliment, but may even arise from the reverse, and which require the aid of medicine for their removal; the liver is torpid, the blood is insufficiently freed from its superfluous carbon, and in addition to impaired digestion, the individual suffers from the train of symptoms above enumerated as attendant upon such a condition of the circulating fluid, mental and physical depression being the most prominent. bowels are confined, and the motions inclined to be light or chalky, at other times almost black; there is pain between the shoulders, and sensation of fulness in the region of the stomach. When such a train of symptoms occurs, it is better to take proper medical advice; if this cannot be done, in order to relieve, two grains of blue pill or euonymin, given every night, or every other night, are each to be followed by a moderate dose of castor oil or infusion of senna in the morning. At first, the infusion of taraxacum, with five to ten grains of carbonate of potash, and, if the stomach is weak, a tea-spoonful of tincture of calumba, taken twice a day, will be of much service. The diet should be nourishing and easy of digestion, such as plain meat, potato, and light puddings, but pastry, cheese, and oily preparations of all kinds, except toasted bacon, must

BIN BIN

liquor, or a little weak brandy and water (whichever generally agrees best), are not to be allowed merely, but must be taken medicinally in moderation. Daily exercise to the extent of slight fatigue, relaxation from business, cheerful company, early hours, and attention to the state of the skin by means of the tepid bath or sponging, are all assistant means, and will, even of themselves, be sufficient to remove slight attacks. Where the bowels are obstinate, an enema of tepid water is especially useful, and preferable to the continual use of purgatives, which weaken the digestive power of the stomach. When the tongue is tolerably clear, and debility of the stomach or of the system generally remains, twenty drops of dilute nitric acid may be taken with advantage twice a day, either in water or in infusion of taraxacum, with or without the addition of a tonic bitter.

It is important to have a clear distinction in the mind between the two conditions of biliary disorder treated of. In the former, that which precedes the attack of British cholera, the liver fails because there is more given it to perform than it can do, even in its most healthy state; in the latter, the liver itself is incapable of doing the work it ought, to maintain a healthy condition of body. In the former case, reduction of diet is evidently the most common-sense prevention and cure; in the latter, the organ must be brought up to its work; and made, if possible, to do its part in the assimilation of sufficient nutriment for health. The diet is to be regulated, not diminished, the general functions kept active, and, especially, the nervous system, by moderate exhilarating exercise both of mind and body, is to be maintained in such a state of regular tonicity, as will enable it to impart that due stimulation-which is so much wanted in these cases—to every function When cases of connected with assimilation. chronic biliary disorder present feverish symptoms, the mercurial at night, and the aperient in the morning, are still to be used, and also the potash and taraxacum, but without the bitter; animal food and stimulants strictly forbidden, and milk and farinaceous diet substituted; the tepid bath used, and enemas.

Although such general directions as will be found useful in the treatment of chronic biliary disorder have been given, it is not recommended that home medicine should be resorted to when medical assistance is within reach. certainly may be done by judicious management, but it is probable that efficient medical advice will save both time and suffering.

In children, particularly those of fair complexion, deficiency of biliary secretion is frequently evidenced by the irregular action of the bowels, and light-coloured chalky motions. It is of course desirable to correct this, but it must not be attempted by the "grey powders," so usually resorted to. They, will, undoubtedly, for a time improve the appearance of the motions | about ten inches wide in the centre, and made

be avoided. In cases of debility, wine, malt | by causing an increased flow of bile, but this is obtained at the expense of the system, which does not appear able to furnish sufficient material for the secretion-in a few days the motions are as deficient in bile as ever. Such a condition can only be permanently corrected by a good allowance of animal food, and general tonic treatment, iron being especially requisite. A few grains of grey powder, however, may be given once or twice a week, or, better still, from quarter of a grain to a grain of "iridin," according to age, iridin being one of the new remedies found to have special and beneficial action on the liver. - See Iridin-Euonymin-Diarrhaa.

BINDER - the bandage which is put round the abdomen of the mother in childbirth, and which forms a most important requisite, both as regards the comfort and safety of the patient. Many forms of binder are used, but none are so generally applicable, or so efficient, as a light, small tablecloth, or shawl, or square of calico, folded broad like a cravat, so that it will embrace the whole of the lower portion of the abdomen, and can be pinned with strong safety-pins at the back, underneath the bed-dress, where it is under the control of the attendant. The binder ought always to be put on at the commencement of labour, and pinned so as just to give comfortable and moderate support to the abdomen; as the process of parturition progresses, it must be gradually tightened, and as soon as the child is born, as much so as will afford comfortable support; lastly, after the separation of the after-birth, it must be tightened again. In all these changes, the best guide is the feeling of the patient; comfortable efficient support being all that is requisite; if tied too tightly, the binder will do mischief. The greatest benefit which results from the early application of the binder, is the prevention of faintness. The sudden emptying of the abdominal cavity which takes place when the child is expelled, is quite as frequently a cause of the above symptom, as loss of blood, the effect being in great measure purely mechanical, and similar to what occurs when fluid is drawn This mechanical from the belly in dropsy. support given by the binder, moreover, exertsregular and regulated pressure, which must give some assistance to the efforts of the womb, and lastly, after the concluding processes of labour are over, it is no slight advantage to have a firm efficient binder in its place, instead of having to disturb the patient by its adjust-ment. In cases of hæmorrhage or flooding, such an arrangement may be of the very highest importance. In the course of an hour or two after labour is concluded, the form of binder which has been recommended above, can be exchanged for the ordinary broad band, fastened round the abdomen by pins, or buckles, or for one of the numerous forms of binder, shaped to fit the abdomen. A very useful form of binder may be made of double calico,

to go twice round the abdomen; one of the situated in the pelvis, just behind the pubic ends being rather broader than the other, so as to admit of the latter being passed through a slit, and both being sufficiently long to be brought round and fastened in front. A very good form of obstetric binder is manufactured by Mr. Salmon of Wimpole Street, it is made of strong linen, and dispenses with the usual pinning.

Refer to-Child-birth.

BIRTH. - See CHILD-BIRTH.

BISMUTH is administered in the form either of the subnitrate or the carbonate, a white, rather heavy powder. It is found useful, and frequently prescribed, in nervous pain of the stomach (gastralgia), and in waterbrash. In the distressing diarrhoa of the last stages of consumption it will sometimes afford relief when other remedies have failed. The usual dose is ten or twelve grains, twice or three times a day, in any thick vehicle, such as linseed tea, or thick barley-water. Bismuth is also given in the form of lozenges and mixture; the former contain two grains each of the subnitrate, and are useful in cases of heartburn and gastralgia. An ounce of the mixture, which is the form usually adopted, contains ten grains of the subnitrate, with an equal quantity of gum tragacanth and an ounce of water. There is a very useful sedative mixture of bismuth in the Guy's Hospital pharmacopeeia, composed of subnitrate of bismuth, bicarbonate of soda, compound powder of tragacanth, of each ten grains, with ten drops of the solution of hydrochlorate of morphia and an ounce of water, to form a dose.

BISTOURY - a kind of small surgical

knife

BITES .- See WOUNDS.

BLACK-DROP is a preparation of opium, formerly secret. It is, essentially, a preparation of acetate of morphia, and is devoid of some of the stimulating properties of crude opium. Black-drop is estimated at three times the strength of ordinary laudanum.

mainly used to deaden the pain in toothache.

BLACK-DRAUGHT, so well known as a domestic remedy, is a mixture of infusion of senna with Epsom salts, and frequently some aromatic, such as ginger or caraway. It is a certain and active purgative, but not well suited for weak habits. Quarter of an ounce of senna leaves may be infused in a pint of water, to this is added one ounce of Epsom salts, and along with it, if there is no fever, a couple of drachms of tincture of senna; of this mixture a small tea-cupful should be taken every two hours, till the desired effect is produced.

BLADDER.—The urinary bladder (fig. 42) is the receptacle for the urine, after it has been secreted by the kidneys, and previous to its discharge from the body; it is an oblong membranous bag composed of three layers or bones, rising, however, when much distended, into the abdomen. At the neck of the bladder, in the male, is situated the prostate gland (fig 42, i).

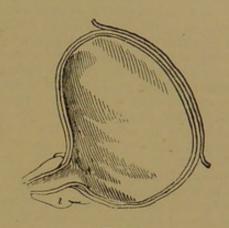

Fig. 42.

Many of the diseases and disorders of the bladder are brought on by carelessness, neglect, or too great subservience to the conventional restraints of society; those persons especially, who habitually or necessarily are frequently compelled to restrain the desire, and forego for a time the relief, of emptying a distended bladder, are liable to affections of the organ. Not infrequently in childhood, and sometimes even later, the bladder habitually empties itself during sleep; night after night this occurs, and proves a serious annoyance, and expense too, from the consequent destruction of beauting. The habit or disorder is sometimes extremely difficult, if not quite impossible, to eradicate. The regular use of the cold hip bath every morning is one of the most efficient remedies; and the tincture of the perchloride of iron, given twice a day, in ten-drop doses, in water, is often useful. Benzoic acid, and nitrate of potash are both said to have proved successful. In such cases fluid is to be taken in small quantity only, in the evening. Malt liquor always increases the evil. Where the habit is inveterate, it is better to use one of the indiarubber urinals attached to the person, than to allow the patient to be a nuisance to himself and others.

Rupture of the bladder is almost invariably fatal. It is generally caused by blows or falls when the viscus is full of urine; but sometimes without violence, simply from over-distension. In the former case, intoxication is in most instances the first cause of the accident; the individual sits drinking till the bladder is quite full, staggers out to relieve himself, and either falls or stumbles against some object; the urine is effused into the cavity of the abdomen or surrounding tissue; agonizing pain, and extreme vital depression are the immediate consequences, and the patient speedily dies. In coats, the middle one being muscular, and is the latter cases, when the bladder is ruptured

BLI BLI

generally caused by long retention of urine, from obstruction to its discharge. In this case, the first sensation of rupture is rather one of relief than otherwise, the rent being at the lower part of the organ; the fluid is diffused into the loose tissues of the scrotum and surrounding parts, giving rise to severe inflammation and mortification. The bladder is sometimes ruptured by extreme violence, such as that of the passage of a cart over its region. In all these cases the attendance of a surgeon is absolutely requisite if possible. Death is all but inevitable, but if life cannot be saved, much relief may be afforded by the moderate Death is use of stimulants, and the free use of large

doses of opium. Strangury .- During the prime of life, the bladder is not generally liable to suffer from chronic disorder, except in persons of dissipated or intemperate habits, but one acute and very painful affection, strangury,—generally caused by the application of a blister,—is not uncommon. The affection is characterised by burning pain, extending through the urinary passages up to the neck of the bladder, accompanied with constant and distressing desire, and straining effort to pass urine, which will only come away in very small quantities, often mixed with blood. While it lasts, the condition is a painful and most distressing one. The means of relief are warm hip baths and demulcent drinks, such as barley-water and linseed tea, taken copiously and freely. Warm injections, consisting of half a pint of gruel containing twenty or thirty drops of laudanum, give much relief; twenty drops of laudanum, or ten or fifteen drops of the sedative solution, may be given by the mouth, and repeated if When the patient is not in the requisite. bath, hot linseed meal poultices are to be used over the lower part of the abdomen. Enlargement of the prostate gland is a frequent cause of retention of urine amongst old people.

Stoppage of Urine. —With declining years, the bladder becomes more subject to disorder and disease; perhaps the most frequent affection is sudden inability of the organ to expel the urine. This may arise from its having been allowed to become over distended; from cold; from drinking hard malt liquor, -a very frequent cause in England,—or sometimes from external violence. The case is one of much distress and alarm, and being not devoid of danger, cannot be too soon placed under proper medical treatment. In the meanwhile, the person should be got into a hip bath, temperature 100°, and kept in it for at least half an hour, a warm bed being ready to receive him on coming out; hot bran poultices must be ready to be applied as soon as he is placed in it; just before entering the bath, a table-spoonful of castor oil with ten or fifteen drops of laudanum should be administered. It is of laudanum should be administered by symptoms indicative of head affection, will sometimes be occasioned by simple disorder of the stomach, which abstinence and one or two doses of the blue and compound colocynth, or rhubarb pills, not improbable that relief may be obtained by | will rectify; but in the event of the symptom

from over-distension without violence, it is | these means; but all efforts at straining must be avoided as useless and hurtful. Of course, fluid must be eschewed as long as the stoppage continues. Whilst the above measures are being carried out, medical assistance ought to be procured; for should other means fail, the introduction of the catheter must be resorted to, to save life. Nevertheless, the prosecution of the mode of treatment recommended, if it does not prevent such a necessity, will certainly facilitate a sometimes difficult operation.

Weakness of Bladder. - Weakness of the bladder, and inability perfectly to retain the urine, is a frequent disorder of advanced age. It often commences with, and is accompanied by, imperfect emptying of the organ, either through carelessness or weakness. Sponging the lower parts of the abdomen, &c., with vinegar and water, or salt water, may be of service. Dr. Day recommends the use of tincture of ergot of rye in these cases; but as a general rule they should be placed under regular medical superintendence. The same may be said of that very troublesome complaint of old age, catarrh of the bladder, in which large quantities of thick mucus are discharged.

Stone in the bladder may be suspected when the urine is liable to become bloody after exercise, when there is pain in the bladder and surrounding parts, in the back and down the thighs, and when the stream of urine is apt to stop suddenly during the act of passing. Under such circumstances, proper advice cannot be too soon obtained.

Refer to—Kidney—Urine—Blister.
BLINDNESS.—Loss of sight may be the one effect of a great variety of causes. Disorder of the brain itself, or sympathy of that organ with the stomach, may be the occasion of the symptom; the optic nerve or its expansion within the eye, named the retina, may be the affected part; or, lastly, some of the transparent structures of the organ of vision may, by becoming opaque, obstruct, wholly or partially, both light and vision.

Loss of sight may come on suddenly, or very gradually; in the former case, it is generally consequent upon some disorder, actual or sympathetic, of the brain or nervous tissues, and is always to be regarded seriously. It may last only for a few seconds, or it may be permanent. In diseases such as apoplexy, or water in the head, loss of sight is a very constant symptom; at least, the eye is insensible to the usual impressions; in these cases it is dependent upon pressure on the brain. In diseases attended with exhaustion, or after copious loss of blood, the same symptom occurs.

A transient loss of sight, unrepeated, and occurring unaccompanied by symptoms indi-cative of head affection, will sometimes be

BLI BLI

recurring, and with it other symptoms, such | in every 1800 of the population suffers from as headache, giddiness, or sickness, medical advice should be instantly procured; in the meanwhile, if the person be of full habit, a few leeches may be applied to the temples, a smart dose of calomel and compound colocynth taken, and abstinence and perfect quiet enjoined; if the habit be spare, milder action upon the bowels, moderate diet and quiet will be the safest course till the case is seen by a medical man. For other information on this point see Amaurosis.

Blindness which ensues in consequence of changes of structure in the eye itself, is either the result of active inflammation, or if not, is

very gradual in its approaches.

It was discovered by the late Dr. George Wilson, that colour-blindness, or inability to distinguish certain colours, was a much more common affection than is generally supposed. He proved conclusively from his experiments that a large number of persons were unable to distinguish the different colours, and also that these same persons were quite unaware of the fact themselves. It follows that railway com-panies should be exceedingly careful with regard to this particular in the selection of their servants, as it is easy to suppose how accidents might arise from the wrong interpre-

tation of signals.

A remarkable form of temporary colourblindness is produced by the administration of santonin, a remedy employed for long round worms. Patients taking this drug complain that they see everything coloured green or red, and they are often afraid that the condition may continue, whereas it always ceases when the medicine is left off for a few days. It colours the urine of a deep citron-yellow tinge, and this is at once changed to a brilliant scarlet on adding a few drops of solution of caustic potash to it, hence we may easily understand how the tissue of the eye may be acted upon to cause the above-mentioned effects. Santonin has even been tried as a remedy in some cases of blindness, but without much success.

In some cases colour-blindness is complete, and in others it only exists to a slight degree. The following table of Dr. Wilson's will show how frequent this defect is :-

1 in 55 confound red with green.

1 in 60 brown ,, ,, 1 in 46 blue

Hence, one in every 17.9 persons is colour blind. Most persons will be surprised to learn from the above table what a large proportion of people are unable to distinguish colours; but it is not after all so astonishing when we reflect. how many people have peculiarities as to their other senses of taste, smell, touch, and hearing. Dalton, the celebrated chemist, was colour blind, and hence the affection is often called

blindness, either inherited, or caused by disease, or accident, and there are numerous institutions in various parts of the country founded for the purpose of teaching the blind to read by means of raised type, or instructing them in some manual occupation. There are other establishments in which music and the higher branches of education are also taught.

BLISTER.—The term is applied either to that which causes effusion of serum-the watery portion of the blood-underneath the scarf or outer skin, or it is used to denote the effect itself, that is, the bag or vesicle containing fluid, which is formed. There are various methods of producing blisters on the skin, in fact, any powerful irritant may have the effect; and we may regard the effusion of fluid underneath the insensible or outer skin, as an effort of nature to protect the true and acutely sensible skin from the action of the irritant substance. Steam, boiling water, strong ammonia, mustard, and many other irritants, have the power of raising blisters, and are used for the purpose by medical men; but by far the most convenient, certain, and generally adopted agent, is the Cantharis vesicatoria, or Spanish fly. The most usual form in which this is used is the common blistering plaster, which being spread upon leather, or some other material, is applied to the skin. A solution of the active principle of cantharides in strong acetic acid, and a collodion blistering fluid are also used; but the most convenient, elegant, and sufficiently efficacious applications, if properly

applied, are the blistering tissues or papers.

To the old form of blistering plaster there are many objections; its weight and smell in the first place, its tendency to leave small par-ticles of irritating matter adhering after its removal, and more especially its liability to occasion strangury (see Bladder), rendered an improvement desirable, and the end has been quite accomplished by the blistering liquid of the British pharmacopæia, and by the very efficient blistering tissues now manufactured; they are light, almost free from smell, are removed with the greatest ease, are not liable to affect the kidneys or bladder, and are remarkably well suited for children. In applying a blister to any portion of the body, the first care must be to ensure accurate contact with every portion of the surface it is intended to affect, the fitting to irregularities being ensured by snipping the edges; and all hairs, whether about the head and face, or elsewhere, being shaved off clean, just before the blister is put on. In the case of the paper blisters, it is better to add the weight of a folded napkin placed about them. If the old form of blistering plaster be used, the cantharides ointment should be spread on leather or adhesive plaster according to the prescribed size, leaving half an inch of margin bare. A few drops of oil "Daltonism." It is calculated that one person rubbed over the surface will increase its

BLO

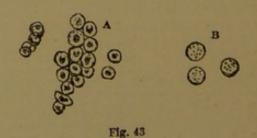

activity, and facilitate its removal; this, however, is still better ensured, and the injurious effects apt to follow the use of this preparation prevented, by the interposition of a piece of thin muslin between the plaster and the skin. The evening is generally the best period of the four and twenty hours for the application of a blister, which, on an average, takes twelve hours to rise well, but sometimes much longer, especially in those who have very dry skins, or are far advanced in life, or when there is much nervous depression. In children, and in those of very delicate skin, the time is much under twelve hours. In the former the action of a blister ought to be closely observed, and the more so the younger the child, and the application removed as soon as it begins to rise; a soft bread poultice being substituted, and kept on for a few hours, full rising will take place. When a blister has well risen, the plaster being removed, and a cloth placed so as to catch the fluid, the vesicle or bag is to be punctured at the most dependent part by the point of a penknife, or with a pair of seissors, and the thin skin which has been raised allowed to subside unbroken, and the dressing applied. If there are more vesicles than one, each must be punctured, unless very small. It is very common for medical men to be told that a blister has only risen in one place, or at the lower part, but this is generally erroneous, the blister having risen all over, but the fluid gravitated to the lower side. It sometimes happens that instead of watery fluid, blisters contain a jelly-like matter, which will not run out; no attempts at squeezing should be made in such a case; if the dressing be applied, gradual oozing will drain the vesicles.

Very various methods of dressing blisters have been proposed and practised, that more generally followed, being by means of lint and linen spread with lard, or simple cerate or spermaceti ointment. Prepared cotton wool is probably the pleasantest dressing that can be used, and is the one, now, always preferred by the writer. If properly applied and left undisturbed, no further dressing beyond the first need be required. Brown's Tissue Dressing, which consists of a cerate evenly and thinly spread upon fine tissue paper, also answers well, being unirritating, easily washed off, should there be profuse discharge, and so light as to require no extra applications to retain it in place; in this point differing from the heavy, ointment-covered, serum-hardened, lint or linen, which in many situations it is impossible to keep on, and which, falling off, usually pulls the cuticle with it. When a blister, from mismanagement, or any other cause, becomes inflamed, or as it is popularly called, gets "the fire in it," a soft bread and milk poultice applied for a few hours will give great relief. Blisters should always be healed; the custom of dress ing them with irritant ointments to keep them 43 A), which are much the most numerous, "open," is at once barbarous and injurious; the and white or colourless (fig. 43 B). These

teazing pain, by its irritating effect upon the nervous system, does much harm. If continued counter-irritation is required, it is much better to apply a succession of small blisters, not on, but close to the same spot. "Flying blisters" are blisters which are taken off as soon as the skin is reddened and irritated-a diluted mustard poultice answers much the same purpose.

Blisters are often applied domestically, without medical advice, but often injuriously during the continuance of acute inflammation and fever. In such cases, especially when put on just over, or very near, the affected part, they do harm, they increase general fever, and may aggravate instead of relieving the local disease. This error is frequently perpetrated in cases of acute inflammation affecting the throat, or in pleurisy, when a bran poultice would be much more serviceable. In persons who are suffering under, or who are liable to, affections of the kidneys, blisters must not be used, except under medical sanction, and that will be given in but few cases. Persons are sometimes needlessly much alarmed at the fact of a blister not rising. Unquestionably, such a result may be owing to extreme and fatal depression, but is quite as frequently due to trivial causes. - See Bladder.

THE BLOOD.—The vital fluid. Life."-As the living blood, circulating in the living body, it is made up of "liquor san-guinis," or the liquid of the blood, and of blood corpuscles or globules. The liquor san-guinis holds dissolved the animal principles fibrine and albumen, and various mineral salts, and in it float the globules. Blood consists of 79 parts of water, 4 of albumen, 14 of globulin together with fibrin, and salts 3 parts. It also contains the 3 important gases, oxygen, nitrogen, and carbonic acid, with a small portion of ammonia. When blood is drawn from the body, it separates, as most are aware, into a solid and a watery portion. The former consists of the fibrine, which thus solidifies out of the blood liquid, when withdrawn from the direct influence of vitality, and entangles the globules in the process; the latter, or serum,—the same kind of fluid which is thrown out in a blister, -still retains in solution the albumen and the salts, the former being easily coagulated,

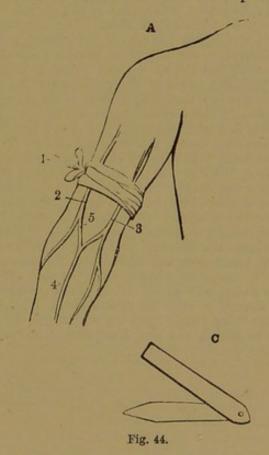

like the white of egg, by heat. The blood-corpuscles, or globules, are of two kinds, red (fig.

BLO

bodies are of course very minute, the average diameter of the human red globule, being the 3200th of an inch-of the colourless, a little more. The red globules of the blood are composed of protoplasm permeated with red colouring matter; under the microscope they have the appearance of flattened disks with a depression in the centre (fig. 43 A). When fresh drawn from the body they have a tendency to arrange themselves in connected rows. When the red corpuscles are deficient in amount, as in persons suffering from anæmia, often termed poverty of blood, tonics, especially the preparations of iron, are required. It is iron which gives the red colour to the blood. Blood circulates in the living body in the two very different forms of arterial and venous blood. In the former case it flows in the arteries, is bright red, and conveys life-giving influence and nourishment to every portion of the frame; in the latter, it is black-looking, flows in the veins, and possesses properties destructive to life, until by the action of the liver, and more especially by exposure to the action of the atmosphere in the lungs, it becomes purified. The properties and composition of the blood in health, and the changes which these undergo in disease, have of late years received much attention, and many important discoveries bearing upon the nature and treatment of disease have been the result; but the greatest improvement as regards the blood, in the practice of medicine, is the much greater caution exercised in the abstraction of the vital fluid. Bleeding from the arm, which formerly was so generally resorted to, even as a periodical habit, is comparatively rarely practised. This is strikingly evident from the newspaper reports. Very few years ago, the addition to the accounts of accidents, of whatever kind, might have been stereotyped, that "a surgeon came and bled" the sufferer, and with it the too frequent addition of "the vital spark had fled;" and certainly, if anything could extinguish the spark of life flickering after the shock of a severe accident, it must have been the senseless, unmeaning custom of bleeding, when perhaps brandy and water or ammonia were required. The disappearance of such notices as above from the public prints, evince the improved practice; but even now, in the country, it is difficult to persuade people that they do not require bleeding after an accident, and all bad consequences are attributed to the omission of the mysterious agency of blood-letting. Blood, we are told, on the highest authority, is the "Life," or at least the medium of life to the body, and it is we know the great feeder of every portion of the frame, and to feed, it must be fed, and every drop extracted unnecessarily is money from the poor man's pocket; but worse still, if largely abstracted by design, or lost by accident, it frequently cannot be recovered, and the constitution receives a shock, and facility of yielding to disease, which it never gets the better of.

Blood-Letting.—But yet, in blood-letting, we have a powerful auxiliary in the treatment of some diseases, although one to be used with due caution; and the ability to perform the operation may be serviceable in remote or thinly-settled districts. Any man who has the idea of using the lancet, if required, should see the operation performed: one practical lesson, accompanied with a little kind explanation, is worth all description, although this may be useful as a reminder afterwards.

Bleeding with the lancet may be performed wherever a superficial vein can be detected. The large vein of the neck (the jugular) is not unfrequently opened by the surgeon, also the veins of the hand or foot; but the bend of the elbow is the most usual site of the operation

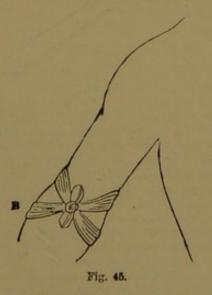

In this position, if regularly distributed, there should be a tolerably large vein (fig. 44, 2-3) running up each side of the arm, and a central vein (4), which, dividing into two branches, sends one to each of the vessels above-mentioned. It is the branch (5) going to the outer vein which is usually opened in bleeding; the veins on the inner side of the arm are, as a rule, avoided by the surgeon, if blood in sufficient quantity can be procured from the more external branches. The reason of the selection is the presence of the main artery of the arm close beneath the inner veins, and the possibility of its being wounded in the operation. A skilful bleeder may undoubtedly avoid so serious a mishap; but certainly no unprofessional person should run the risk, and,

ever a vein is opened in the arm, it must always be ascertained beforehand, by pressing the finger down upon the part, that no artery is

pulsating underneath.

The first thing when the operation of bleeding from the arm is to be performed, is to have all things in readiness. These are, a bandage of some kind, or soft half handkerchief, a piece of linen folded six or eight times into a pad an inch and a half square, a basin, or two or three cups, a stick to support the patient's arm if requisite, a towel, and a little cold water. The band is to be tied round the arm, with a bow knot, about two and a half inches above the elbow (fig. 44-1), with sufficient tightness to stop the flow of blood in the veins, but not in the artery, which may be ascertained by feeling the pulse at the wrist. The operator, whilst supporting the arm of the patient with the fingers of the left hand, presses upon the vein with the thumb a short distance below the intended opening, this pressure serving to steady the vein under the incision of the lancet, and also, if the operator be alone, to prevent the free flow of blood until he has had time to lay down his lancet, and hold the basin. The lancet being held between the thumb and forefinger of the right hand, with its sides in the position represented (fig. 44 c), and the hand being supported by the other fingers, the point of the instrument is to be made to pierce the vessel, and it is carried forward so as slightly to enlarge the opening, and then withdrawn. If the blood does not flow freely, the patient may be made to grasp a stick, or any solid body which will partly fill the hand. When it is desired to stop the flow of blood, the left thumb being placed upon the wound, the band is to be untied, the arm, if requisite, cleansed,

the linen pad substituted for the thumb upon the wound, and secured by the band or handkerchief passed round the arm in the form of mation affecting the true skin, and subjacent a figure of 8 (fig. 45 B). The arm ought to be | cellular membrane. A whitish-looking point,

indeed, in whatever situation, and by whomso- | kept at rest for some hours after the operation, and not used in exertion for some days.

Such is the operation of bleeding, not to be undertaken rashly, never by one who has not seen it performed; but yet one which it is desirable that some person in a remote district should have the ability to perform. Again it is repeated, the lessons must in the first instance be practical, and then the few simple directions above given may afford timely aid to the memory. It must be kept in mind that a person in the upright posture faints sooner from loss of blood than one who is lying down, and that when faintness does come on, a little cold water, and a perfectly flat position are the best restoratives.

The emergencies in which bleeding may be ventured upon by the unprofessional will be noticed under their proper heads.

Local Blood-letting, Cupping, Leeching, Scari-

fying.—See their respective articles.

Bleeding.—See Hamorrhage.

BLOWS may be serious either from the violence used in their infliction, or from the site of the injury. A blow on the head may cause merely bruising of the scalp—if more severe, concussion or injury to the brain, or fracture of the skull. The latter accident is most likely to happen at the side of the temple, where the bone is thin; but severe injury to the brain frequently occurs from blows at the under and back parts of the head. A severe blow on the spine may cause paralysis of the lower limbs, with or without fracturing the vertebræ. When a blow, even comparatively slight, is inflicted upon a spot immediately over a collection of nerves, most distressing effects, and sometimes immediate death, may result; such is the case from blows on the neck, on the pit of the stomach, or over the region of the heart. The deadly faintness which ensues should instantly be combated by the first stimulant-ammonia, ether, or spirit of any kind-which can be procured. Cold water should be suddenly dashed over the surface, or down the spine; if this is unsuccessful, the patient is to be put into a warm bed, and artificial respiration employed along with external heat, mustard plasters to the spine and pit of the stomach, and stimulant injections.

Refer to—Brain—Bruises, &c.
BLUE DISEASE—CYANOSIS—a condition dating from birth, in which, from mal-formation of the heart, the blood is only partially arterialised in the lungs. Few sub-jects of the disease survive infancy, but there are instances of their attaining mature age. The disease is characterised by the purple appearance of parts which are usually red, as the lips and cheeks, by languor of all the functions, and by great susceptibility to cold.

BLUE PILLS .- See MERCURIALS. BOIL - a boil consists in local inflam-

in the conical centre, is surrounded by an | that is, till all appearance of redness has disinflamed hard base. A core or slough occupies the interior of the boil, and this must be discharged before there is relief to the often intense pain, and before a cure can be effected. The pain may, however, be soothed, and the natural process facilitated by the use of warm fomentations, simple, or made with poppy capsules, and poultices, the latter being continued until the core is fully thrown out, after which simple water-dressing may be applied. Persons who are compelled to go about their occupations during the progress of a severe boil, will find a small piece of lint dipped in olive oil, and retained in its place by a disk of adhesive plaster, a very soothing and con-venient application. Boils are apt to recur in succession, for the reason, probably, that they depend upon some derangement of the system which requires attention. If the person-and boils generally occur in the young-be of full habit, the diet should be reduced, all fat and rich things eschewed, meat partially or entirely given up for a time, and stimulants avoided. A blue pill and black draught, or one or two doses of calomel and compound rhubarb pill are to be taken, and regularly for some time every morning, a tea-spoonful of Epsom salts in half a pint of water. If the habit is delicate, tonics and nourishing diet should be employed, and the bowels should be regulated by aperient medicines.

Boils are popularly said to be "healthy," and in one sense they may be so; that is, if the deranged state of the system relieves itself by their eruption; but they are also to be regarded as warnings that some change in habits, or that medicine, is required. A series of neglected boils may wind up with a carbuncle. Carbuncle is of the same nature as a boil, but more severe and dangerous. - See Carbuncle.

BOILING—is the process in cookery by which food is submitted to the action of water at the boiling point of 212° Fahr. Theoretically, this is the case, but in the cooking of meat especially, boiling, that is ebullition, should not be permitted—a temperature 20 or 30 degrees lower being sufficient, if proper time be given, to cook meat thoroughly, whilst it is rendered much more tender and easy of digestion than when the process is carried on more quickly, and by a greater degree of heat. In fact, meat to be properly cooked in this way ought rather to be stewed than boiled. Somewhat, however, must depend upon the end in view in cooking the meat. If it is desired to be simply a piece of well-cooked meat, not only as regards taste, but as to nutritive powers, the water in which the meat is to be cooked should be made to boil briskly at the time the latter is put into it, and for a few minutes after, and then sufficient cold water is to be thrown into the pot to reduce the temperature of the whole to 180°, at about which point it should be

appeared. The principle of the process is, that by the sudden immersion of the meat in boiling water, the most external of the constituents of the flesh, but more particularly the albumen, become quickly hardened and coagulated, so as to form a kind of case around the interior portions. Of course, if the high temperature is preserved, this process of hardening will go on throughout the whole mass, which is thus—and too often it is the case made hard and indigestible. But in consequence of the reduction of temperature produced by the addition of cold water this is prevented, the meat is cooked by a heat which cannot harden it, and its nutritive soluble principles are kept from exuding by the case-hardening of the first few minutes' boil. The reverse of the above must, in some degree, be the case, when meat is boiled for the sake of the soup: it must then be put into the water whilst it is cold, and the temperature gradually raised to near the boiling point. In this way there is no outer hardening to interfere with the water dissolving out the soluble nutrient principles of the whole mass; the latter, of course, losing proportionally. As meat cannot be cooked in water without a certain portion of its nutrient matters being dissolved out, the water should never be thrown away; if the saving is unimportant to those who cook the meat, there are plenty of poor to receive the unused liquor; but if it is a consideration that nothing be lost, then may the soup be turned to account by being consumed along with the meat. Of course the cooking may be so managed as to make both palatable.

Vegetables require thorough boiling, and

often disagree for want of it.

Refer to-Food.

BOLUS—a large, rather soft pill, which is be swallowed. This form of administering can be swallowed. medicine is now out of use.

BONE is the component of the hard frame-work of the animal body, which supports and protects, and to which are attached the soft parts. Bone, in mass and in its dry state, is made up of about two-thirds mineral or earthy, and of one-third animal matter, and both are so intimately united and diffused through one another, that either (the one by the action of heat, or the other by the aid of an acid) may be entirely removed, and yet the form of the bone be maintained by the remaining constituent. The animal matter of bone consists of gelatine, fat, and a trace of albumen, which may be, and are, used as articles of food in various ways. The extraction by manufacturing process is complete; but for domestic purposes, much of the bone gelatine may be extracted by the use of Papin's digester. There is not, perhaps, as much real nutriment in gelatine as is popularly imagined; but there is quite enough to make whole to 180°, at about which point it should be its extraction worth while, even domestically, maintained until the meat is thoroughly cooked, as an addition to soups. The mineral matter

of bone consists mainly of phosphate of lime | digestion, and should never be used for keeping combined with a smaller proportion of the sweet milk given to babies. Mixed with an

carbonate and some mineral salts.

The bones of the body are divided into flat bones like those of the head, long bones as of the arm and thigh, and irregular bones, of which the vertebræ are examples. The outer case of a bone is always harder than the interior, and is covered by a firm investing membrane, the periosteum. Bones are liable to various diseases; one of these, caries, is to this tissue what ulceration is to the soft parts of the body; another, necrosis, is the actual death of the bone substance. In both these cases, there is generally deep-seated continued pain in the bone, followed by swelling and redness of the soft parts covering the affected spot; matter forms and is discharged, but healing does not take place, as after a common abscess; the discharge continues, it is thin, perhaps acrid, frequently feetid, and communicates a dark stain to the dressings. The opening in the skin, or rather openings, for there are usually more than one, may be small, or there may be diffused ulcerations of the integument. These diseases -unless from situation, as in the head-are not rapidly fatal, but if unremedied, wear out the patient, by long-continued irritation. suspicion of their existence should be the signal for placing the sufferer under proper medical advice without delay. Too often they are trifled with, and one quack ointment after another-each professing more than its neighbour-is had recourse to, whilst the constitution of the patient suffers irretrievably. Bones may become softened in consequence of a deficiency of earthy matter. In adults, this is the result of defective constitution, insufficient nourishment, and unhealthy dwellings, and is a fatal disease. In children, the disease named rickets, in which the bones likewise become soft and capable of bending, is the result of similar causes; but in the latter, good diet, change of situation, and a course of tonic remedies will effect a cure.

Refer to-Rickets-Fractures-Papin's Di-

BORAX is a compound of boracic acid and carbonate of soda, and was formerly thought a useful and convenient antiseptic as well as a serviceable drug. Until recently its use as a preservative was extending, but preparations of borax for preserving meat are now forbidden in the German navy. Boracic acid is now largely used as an antiseptic, and as an application in irritable skin affections. Fifteen grains of boracic acid, rubbed up with an ounce of vaseline, will greatly allay the itching of nettle rash, and a wash composed of sixty grains in a quarter of a pint of water will be found useful in various skin diseases, such as eczema, &c. Boracie lint, now much used as an application to foul and sloughing wounds, is prepared by the action of a saturated solution of boracic but if the concussion be severe, the state of acid on lint. Boracic acid interferes with the unconsciousness continues, the power of motion

equal quantity of oxide of zinc it is frequently used as an antiseptic drying powder for dusting inflamed surfaces; in this form it is especially useful for application to inflamed vesicles resulting from vaccination.

BOUGIE—a surgical instrument used for

the dilatation of the male urethra.

BOURNEMOUTH, on the east coast of Hampshire, is said by Sir James Clark to "deserve a place among our best climates, and for a certain class of invalids, capable of taking exercise in the open air, to afford a very favourable winter residence." The soil is porous and dries quickly after rain, and the place is sheltered from the north and east by hills and pine woods.

BOWELS.—The tract of the alimentary

canal contained within the abdomen. -See Ali-

mentary Canal

BRAIN.—The brain is the large mass of nervous matter contained within the cranium or skull case. By anatomists, and in medical science, the organ is variously divided and subdivided, but more especially into the cerebrum, or large brain (fig. 46-1), and the

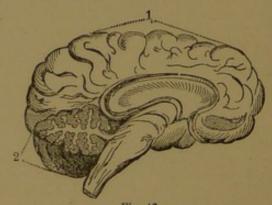

Fig. 46.

cerebellum, or little brain (fig. 46-2), the latter being situated at the inferior and posterior part of the cavity within the head. The nervous matter is partly white and opaque; partly greyish, and semi-transparent. The whole organ is supported and enveloped by three membranes, and is defended from all ordinary injury by the arched bones of the head. The next figure (47) represents a side view of the brain (1) and cerebellum (2), and their connection with the spinal cord (3), as well as of the skull case (4) and upper part of the canal formed by the cervical vertebræ through which the cord passes (5).

Concussion of the Brain. - One of the most frequent injuries to which the brain is exposed, is concussion. Either in consequence of a fall or a blow, a person becomes stunned; the effect may be but momentary, there is transient unconsciousness, and the individual "comes to himself," without further symptom;

BRA

is almost or entirely lost, the breathing is slow and quiet, the pupils frequently contracted, but sometimes dilated, and very generally there is vomiting; the pulse is small and weak. This cases are generally so urgent, and their cause and nature so palpable, that they not only require the most active treatment, but also render that treatment justifiable in the hands

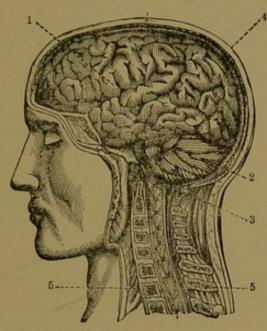

Fig. 47.

condition may continue for a longer or shorter period, according to the violence of the shock, and may terminate in death; but if it be simple concussion, there is generally a restoration of the usual condition of health, permanent or otherwise. In some cases of simple concussion of the brain, but little active interference is required; the patient should, if possible, be put in bed, and the warmth of the surface, particularly of the feet, attended to: if there is extreme depression, a little sal volatile or brandy and water may be given, but sparingly, on account of the subsequent reaction. The chief danger to be apprehended after concussion of the brain, is inflammation affecting either the organ itself or its covering membranes, and on this account the sufferer from the accident ought to be extra careful for at least ten days or a fortnight after the receipt of the injury. All alcoholic stimulant is to be avoided, and rest both of body and mind submitted to; the diet should consist entirely of milk, the bowels being kept relaxed by the use of gentle aperients. If the immediate reaction is great, that is, if a few hours after the accident, there is much pain in the head, shivering, followed by heat, quickened pulse, sickness, the case demands the most serious attention, and should be seen by a medical man as soon The hair must be cut or shaved as possible. off, and the head kept cool with cold or iced applications; the most perfect quiet, in a dark situation, observed, and active purging with calomel and colocynth, jalap and calomel, or the most active aperient at hand. The diet is

and nature so palpable, that they not only require the most active treatment, but also render that treatment justifiable in the hands of the unprofessional, in the absence of, or during a lengthened interval of the non-arrival of medical assistance. Symptoms, similar to those detailed above, though not directly referable to reaction, may, coming on some days after a concussion of the brain, indicate the commencement of inflammatory action. such a case the above measures should be cautiously carried out. It ought to be known, that direct violence to the head is not always requisite to produce concussion; a heavy fall on the feet may equally cause it, by the shock conveyed through the spine to the brain. But violence may go beyond the production of mere concussion-there may be rupture of the substance of the brain, or of a single vessel, causing effusion of blood. In such a case, the individual may never rally from the first condition of unconsciousness, or he may rally only partially, to sink again as reaction comes on into a state of apoplectic stupor, or become the subject of those symptoms of inflammation of the brain already described; in which case, of course, the same treatment is to be pursued. If the case runs on to a fatal termination, there is generally apoplectic stupor, paralysis, convulsions, one or all of them.

Fracture of the Skull.—Violence applied either directly to the head, or communicated to the skull through the spine, may be sufficient to fracture the bone with or without breaking the skin. The accident is sometimes sufficiently obvious even to the inexperienced, at other times, as in the case of a simple crack, it is not detectable even by the most skilful; but whether plainly apparent, or only suspected, the existence of fracture amounts to the same thing, as far as the unprofessional are concerned, as concussion; the case ought to be seen as soon as possible by a surgeon. The symptoms will in many respects resemble those of and following concussion, and may be similarly treated; if there is external wound as well as fracture, simple water dressing should be used. When a portion of bone is driven down upon the brain by external violence, it occasions apoplectic insensibility by the pressure it produces; in such cases, the aid of the surgeon is imperatively called for, to relieve, by elevating the depressed bone.

followed by heat, quickened pulse, sickness, the case demands the most serious attention, and should be seen by a medical man as soon as possible. The hair must be cut or shaved off, and the head kept cool with cold or iced applications; the most perfect quiet, in a dark situation, observed, and active purging with calomel and colocynth, jalap and calomel, or the most active aperient at hand. The diet is to be reduced to the very lowest ebb. Such

75

it may be, such cases can only have proper | for a child of two years of age, and it may be energetic treatment in the hands of the practitioner; but until his assistance can be procured, the plan of treatment recommended to be followed in cases of inflammation after violence is to be adopted-particularly cold to the head, thoroughly applied by means of ice bags (see

Inflammation of the brain may arise from a variety of causes; violence is one of the most common; it may arise in the course of acute disease, or after the suppression of an accustomed discharge; it is not uncommonly set up in cases where there has been long-continued

discharge from the ear.

In children, particularly those of scrofulous constitution, inflammation of the brain most frequently presents itself in the form of what

is popularly termed-

Water in the head, or water on the brain, technically termed tubercular meningitis. The fatality of this disease when it has once established itself in the constitution, renders a knowledge of its earlier symptoms a matter of serious and important interest to every parent. As mentioned above, children of scrofulous constitution, are most liable to this disease, and should be closely watched, especially from the second to the sixth or seventh year of life, the most general period of attack, and particularly after the child has suffered from any of the diseases incidental to childhood. At first, the patient is languid, looks heavy, is subject to irregular heats and chills; the appetite is capricious, the bowels irregular, and the discharges from them unnatural in colour; the sleep is disturbed, there is frequent starting, moaning, perhaps screaming; the teeth are grated, the thumbs folded across the palm of the hand; when awake, the brow is contracted; the nose is continually picked; the child, if able to speak, complains of the head, which is hot. As the disease advances beyond the first stage, all these symptoms become more marked, and probably obstinate vomiting, and when the stomach is empty, retching, occur. Towards the termination of the disease, insensibility, dilated pupils, convulsions, &c., come on; but long before the latter stages the case should be under proper medical treatment. The object here is to put parents on their guard as to the advances of an insidious and very fatal malady, not to induce them to incur the responsibility, and unless under very extreme circumstances indeed, the culpable responsibility, of its treatment. Many of the symptoms above detailed undoubtedly occur in less alarming combination in many of the diseases of children; but come as they may, and when they may, they should not be neglected. Some amount of treatment ought, however, to be employed to save time, and the most important and safest indication, is to purge the child well with calomel and scammony, a grain of calomel with two grains of scammony is a very efficient dose | are certain to be followed by an aggravation of

repeated according to the effect produced, which should be two or three motions in the course of twenty-four hours; the head is to be kept cold, and quiet strictly to be observed. One or two leeches may be applied. The term "water in the head," as regards the disease above treated of, is erroneous; the effusion of water which takes place is but one of the stages of the affection, which is truly inflammation of the brain and its coverings. The causes are numerous, but sometimes the disease arises without any being distinctly traceable; the irritation of teething, long-continued disorder of the digestive organs, falls or blows on the head, exposure of the child's head to the heat of the sun, infantile febrile disorders, may any of them give the first impetus to the diseased tendencies. Most important, as undoubtedly it is, to detect the first symptoms of threatened inflammation of the brain in children, still more so is it to detect and improve that state of constitution which facilitates the incursion of that and so many other disorders. If a child is scrofulous, or has a tendency to scrofulous constitution, let not parents foolishly shut their eyes to the fact, but rather endeavour as far as possible to correct the misfortune; more especially, let them beware, lest they in any way foster into activity the seeds of so deadly a malady as acute meningitis. Those children who are most obnoxious to its attack, are often the most endowed intellectually; there is a morbid tendency to excitement in the brain, which gives it power beyond what is natural to its age; if permitted or encouraged, the child will give up the sports and exercise of its time of life for the sake of mental employment, and sometimes a parent's pride permits the errone-ous system, which in all probability leads either to early death from active disease of the brain, or to the possession in after-life of a sickly body and morbid mind. In no children is it so necessary to insist upon strict observance of all the laws of physical health, as in those who exhibit precocious development of mind.

Water in the head, properly so called, is a chronic disease, dating from birth or very early infancy. The effusion of water advances by slow degrees, distending more and more the brain and the bones of the head, until the latter attains an enormous size. It has been measured as much as forty-four inches in circumference. The disease may last for years

with no hope of recovery.

Brain in Old Age. - In the aged, the brain becomes more liable to disease than heretofore. Congestion of blood from various causes, more especially in consequence of earthy deposits and ossification of the arteries is frequent, but quite as often, headache, giddiness, slowness of intellect, or paralysis, arise from deficiency of blood in the brain. The distinction is important, as in the latter case lowering measures

BRE

quent a disease of advanced life, has many symptoms similar to those consequent upon deficiency of blood, but in an aggravated degree; the mental functions are more regularly and permanently impaired, paralysis is more certain. Although cerebral softening is incurable, if its threatenings are early detected, it may be retarded by the use of tonics and abundant nutriment. The arteries of the aged brain lose their elasticity, become brittle and liable to rupture if unduly distended, a fact which renders all excitements, whether of the passions or otherwise, so dangerous to those advanced in life. The other affections of the brain, such as apoplexy, paralysis, delirium tremens, will be found under their respective heads.

BRAN is the broken-up husk of the grain of wheat, which is separated from the flour after grinding. It contains a considerable amount of nitrogenous and fatty as well as mineral matter, and when mixed with the flour it is made into brown or whole meal bread. When heated it is one of the most useful adjuncts we possess in the alleviation of disease and pain, and particularly in a domestic point of view. It is generally to be procured, is soon made hot, and retains the heat well; it is at the

same time soft and adaptable.

Heated bran is best applied in a flannel bag, which should be made ample in size, compared with the part affected; it may be either a dry or a moist application, but the latter is in most cases preferable. The best method of heating, is in the frying pan, sprinkling with hot water during the process, so as to give just perceptible moisture, and turning over and over until the substance is thoroughly hot throughout; it is to be quickly transferred to the bag, and the latter fastened by pins or thread. When moist, if covered after it is applied to the skin, by a piece of oiled silk, oiled calico, or any other waterproof material, the heat will not only be better retained, but the vapour also, and no dampness will be communicated to the clothes. Sometimes, the bran is put into the bag dry, and the bag and all dipped into boiling water, but in this way too much moisture is absorbed.

Dry, hot bran may produce perspiration, but frequently it causes only feverish dry heat, and if it does not do harm, does little good, compared with the soothing heat and vapour of the moist preparation, which is in fact a continued local vapour-bath, causing free perspiration from the skin over the affected part, and often relieving to an extent sufficient to render the use of leeches or cupping-which would otherwise have been required—uncalled

In severe pain, whether spasmodic or inflammatory, the bag of hot moist bran efficiently used is one of the best, softest, and most certain alleviators we possess; and, greater advantage than all, may be used in most cases of

the disorder. Softening of the brain, so fre- | acute inflammatory affections, such as those of the chest or abdomen, its use is very often preferable, both as regards the comfort and real good of the patient, to either blister or mustard plaster. In the inflammatory affec-tions of childhood, and in threatened croup, it is invaluable from its easy application, soothing, and, at the same time, most beneficial effect. When weight is an objection, of course the bag must be more lightly filled. The bran may be heated in a dry state, and the effects of moisture procured by laying underneath it a double fold of flannel wrung out of hot water. Again it is repeated; the hot bran bag, to be efficient, must be sufficiently ample and well filled to retain the heat so long that frequent changing is not required. It must be thoroughly hot, slightly moist, but not wet, and is better covered after it is put to the part by some material which will prevent evaporation.

For the dietetic uses of bran see Bread.

BRANDY is procured by distillation from grape wines, and owes its peculiar flavour to the presence of an ethereal spirit formed by the action of the acetic or tartaric acid on the alcohol.

Brandy, like every other ardent spirit, ought not to be freely or regularly used, either diluted or otherwise. As an addition to our stimulant medicines, and as a dietetic, it is most valuable. As a medicine, it does not, perhaps, possess any particular advantage over pure spirit of any kind; but in England, at least, it is preferred by most to either whisky or gin, and it is generally the first procurable stimulant in most cases. As a dietetic, dyspeptics, and the aged, who require stimulant, and yet cannot take it in other forms, can often use regularly and with the greatest benefit a measured quantity of brandy in a little cold water, with their meals, once or twice a day, and certainly without any of that subsequent depression, or craving for an increase of the dose, which is by some said to be the consequence of the habit. -See Alcohol.

BRANKS .- The Scotch name for the mumps.

BREAD .- The term, as usually applied in this country, means the leavened, raised, or fermented loaf of wheaten flour, but may also be appropriate to any of the other forms in which flour or meal is made up, either from wheat or the other cereals. The flour of wheat consists of several ingredients; the gluten, which approaches animal matter in composition, starch, and dextrine, with small amounts of oily and mineral matters. Wheat flour, simply made into a cake with water, and baked, like the "damper" of Australia, will undoubtedly yield nourishment equally as well as leavened bread, to those whose digestion is equal to the task; but for the general purposes of civilised life, fermented bread is much to be preferred for the greater ease with which it is assimilated. The careful mixture with the pain with the most perfect safety. In many saliva during the mastication of bread, is a

BRE BRE

the starch into sugar. Hence the increase of digestibility obtained in bread by the porous form given to it. This porosity and lightness is produced in the dough by a process of fermentation. Beer-yeast is added to the dough, which brings into fermentation the sugar formed by the action of the gluten on the starch; and the open porous texture of the mass is the result of the carbonic acid thus

formed in every part of it.

Various kinds of "digestive bread," raised without fermentation, are, however, occasionally Carbonate of ammonia has been employed for this purpose; but carbonate of soda, with the addition of some acid—butter milk will do—to disengage the carbonic acid, is the most general agent. The following method is a good one:—Two drachms of carbonate of soda in fine powder are to be well mixed with a pound and a half of flour; to rather less than a pint of water there is to be added two and a half drachms of dilute hydrochloric acid, and the water and acid together are to be added to and mixed up with the flour. A rather liquid dough, which must be baked immediately, is formed, and if properly managed, is well and lightly raised by the disengagement of the carbonic acid from the soda, the latter being at the same time converted into common salt by union with the hydrochloric acid. These various kinds of unfermented bread have been extolled as particularly digestible; it is a question whether they are more so than the ordinary bread which has undergone fermentation.

Bread made by the process introduced by Dr. Dauglish, and called aerated, from the dough being subjected to the action of highly carbonated water, agrees better with some people than bread made in the ordinary way. It is lighter and more easily digested, and is less likely to turn sour. It has also the great advantage over other bread, that it is manufactured free from contact with the hands of

To be thoroughly wholesome, bread must be well raised, well baked, and at least twentyfour hours old before it is used. The finer descriptions of bread made with fine flour are liable, it is said, to constipate, and the coarser, which contain much coarse bran, are too irritating for many stomachs. As bread is at present made in this country, that made with "seconds" flour is quite the most generally wholesome. It is a matter of much importance, as regards the nutritive properties of bread,—
"the staff of life,"—in what manner the flour from which it is made is prepared. Generally, in consequence of the very large separation of bran effected in grinding, in this country at least, a great proportion of the real nutriment is abstracted, and the fine flour which remains has too large a preponderance of starch, which does not afford so much nutriment.

condition essential to the rapid conversion of | more thoroughly grinding it into the flour, not only would bread made from the flour be much more nutritious and wholesome, but the actual amount of bread-food supplied to the people would be considerably increased. Moreover, the mechanical aperient action of the bran upon the bowels could not fail to be useful in a country where constipation is so general a disorder, as it is in this. No one who is liable to habitual constipation should regularly eat fine bread, but should systematically vary his diet in this respect by the aid of the wholemeal bread, now extensively prepared, which is not so irritating to the stomach as the common bran bread.

A certain proportion of bread should form an addition to every meal, with those whose digestion is at all weak. It must not be new; fatal accidents have occurred from the distention of the stomach by an excessive meal of newly-baked bread. Sour bread is, of course, most unwholesome. A great mistake is often made in feeding young infants upon bread in various forms; it always occasions disorder, griping, and flatulence. If circumstances render it necessary that bread must be given, it should, at all events, be slowly toasted, or re-baked as hard as a biscuit or rusk throughout, and then well soaked. Water is largely contained in When newly taken from the oven it bread. consists of nearly one-third water, which it gradually parts with as it becomes stale. The same, or rather a greater, loss of water is pro-duced by toasting bread, and its digestibility is thereby improved without any detriment to its nutritive properties. Rusks, tops and bottoms, and other kinds of bread used chiefly in the nursery, owe their estimation to the fact of the water having been dried out of them by keeping them longer in the oven. They form grateful additions to the limited diet of a sick person, and contain variable proportions of butter, milk, and sugar, which render them Biscuits are made more valuable as foods. in a similar way, and are chiefly valuable on account of the length of time they may be preserved, but as a rule they are less digestible than bread. Biscuit powder is a useful preparation, and is sometimes employed in the nursery mixed with milk and a small portion of sugar.

Refer to—Grain, Flour, &c. BREAKFAST—The first morning meal is to the strong and healthy a most enjoyable one, and it may always be taken as one of the best signs of health when a man can eat and digest a good breakfast, especially after exercise. The circumstance that the strong and healthy can enjoy with impunity a full breakfast, has given an erroneous idea as to the advisability of invalids making it a hearty meal, and still worse, of prefacing it by exercise. With very many, perhaps the majority of people in this as too large a preponderance of starch, which country, especially in towns, the interval between rising and breakfast is not one of great vigour; the powers both of body and mind are BRE BRE

undoubtedly recruited if there has been due | is found so flattened into the breast that it is rest, but they are not in full action, and if, injudiciously, too long an interval is permitted to elapse before food is taken, they become exhausted, and still more so if physical exertion is engaged in. Instead, as is too frequently supposed, of the exertion improving the digestive power, it weakens it; appetite there may be, but digestion will, in a weak individual, be sadly deficient; the nervous power which should aid the process has been used up. The very same deficiency of nervous power renders a full breakfast, under any circumstances, inadmissible for those of weak digestion; instead of giving strength it causes discomfort and inaptitude for business for the first hours of the Thus it is why it speaks well for the health and constitution of the individual who can make the first meal of the morning a hearty one.

It would, perhaps, be difficult to find a social custom more suited to the present state of civilised life than the warm tea, coffee, or cocoa breakfast, taken along with bread, and, if it agrees, with the addition of meat, fish, or egg; it just affords the gentle stimulation which the system requires. The amount and nature of the nourishment taken at breakfast must vary, of course, with the habits and powers of the individual; if digestion is weak, it is better to be content with little, and wait for an early luncheon. Some dyspeptics can scarcely take any kind of food at the morning meal without its disagreeing; such will sometimes find it of advantage, when it can be done, to have a small cup of hot coffee, or some warm fluid, brought to them just before rising; with others, a very slight supper, just before going to bed, a biscuit or piece of toast, with a little wine and water, will relieve the weakness in the morning. Above all, it should be kept in mind by those with whom breakfast is apt to disagree, that exhaustion of any kind before the meal, such as walking, gardening, bathing, or even cold sponging, is almost certainly in-As a breakfast for children, bread and milk is better than the stimulants, tea and coffee; for strong children, nothing is better than oatmeal porridge, as used in Scotland and

northern England.

BREAST .- The term, as here used, is applied to the female breast, the organ peculiarly devoted to the nourishment of offspring. The essential component of the breast is the "mammary" gland, which secretes the milk. This gland, along with the breast generally, becomes fully developed, and fitted for its functions, as womanhood advances; and at the same time, the nipple enlarges, if it is permitted to do so by the stays, which too often offer such impediment to its development as to

nearly impossible, sometimes quite so, to get it drawn out sufficiently; much suffering, and not unfrequently abscess in the breast, is the conse-

Females are often morbidly sensitive respecting any ailment affecting the breast, and render themselves unnecessarily miserable if they detect, or fancy they can, anything unusual. Sympathetic pains are put down as the certain precursors of some dreaded disease; or the slightest hardness is observed and fingered, till it really becomes tender and inflamed, and in consequence enlarged. In such cases, if the patient is reasonable, and can be persuaded to give up the habitual interference with the ailment, the uneasy symptoms and suspected "lump" will often disappear together. Still, they may not do so, at least quickly, but that is no reason why the affection is necessarily a serious one; quite the best plan in these cases, is to take professional advice without delay; if the cause of alarm is unimportant, the mind is set at rest; should it be otherwise, its nature cannot be too soon detected. Above all things, tampering with such matters must be avoided; the rubbings, &c., too often employed, may irritate a slight swelling into rapid and painful increase, or something worse.

If the above advice is followed, as it ought to be, it is unnecessary in a work like this, to treat of that dreaded disease, cancer of the breast; a suspected case ought neither to be left to unprofessional opinion nor domestic treatment, and to detail the incipient symptoms which are many of them common to more harmless affections, might only tend to excite groundless fears. When cancer has reached the confirmed open stage, opiates and narcotics are the chief sources of physical comfort; hemlock poultices will sometimes relieve pain, and a chlorine lotion will in some measure neutralise the fœtor. The disease

generally occurs after the age of forty.

Inflammation and Abscess. - The disease from which the female breast most frequently suffers is inflammation, followed by abscess. This may occur at any time, but most commonly it is within the first few weeks after child-birth. Generally within one or two days after the birth of a child, the breasts become turgid, and slightly hot, from the increased flow of blood which is directed towards them to supply the secretion of milk; in this excited condition, and indeed during suckling generally, they are peculiarly liable to become inflamed; slight irritation or injury to the nipples, giving admission to septic bacteria, cold, or even mental excitement or disturbance, may, any of them, give rise to inflammation which ends in abscess. All these causes, and offer such impediment to its development as to entail much suffering when women come to be mothers. Too frequently, when the nipple attention must be given to cleanliness. If ought to be fit for the suckling of the child, it from flatness of the nipple, weakness of the

BRE BRE

drawn out, measures which will relieve must be adopted. Various forms of breast-pumps are used, the suction being made either mechanically, or by the mouth-by their means; a leech-glass is tolerably convenient; or a widemouthed bottle, capable of holding a couple of quarts, may be employed, being first dipped into hot water to exhaust the air, and then applied to the breast, the suction exerted as it cools will cause the milk to flow freely. Artificial breast-pumps of various designs are to be obtained from all druggists, and may be used as often as is necessary to maintain comfort. The first symptoms of threatened abscess, are pain and knotty hardness in the part; if the process goes on unchecked, there is much throbbing and a sensation of weight, the skin over the part effected becomes red, gradually thins, and at last gives way, allowing the escape of the matter, occasionally mixed with milk. Some amount of irritative fever accompanies the progress of the affection. After the discharge of the matter, the abscess may quickly heal, or it may remain open and

running for a considerable time.

The first few hours of threatened mammary abscess are the most valuable; if it is to be prevented, it must be then. The breasts being well emptied, gentle friction, continued for ten minutes at a time, and repeated every four or five hours, must be most assiduously employed. A soft palm is indispensable for the process, and fresh olive or almond oil is the best for rendering the friction easy; the various applications, such as goose fat, &c., often recommended and used, are disagreeable, and not better than the simple oil, the mechanical friction being the active agent for good. During the intervals between the friction, the best application is lint soaked in tepid water, and covered with oiled silk. The bowels should be kept clear: ten grains of Plummer's pill may be given, and followed in four hours by castor oil, and from six to ten grains of carbonate of potash, with the same quantity of nitrate of potash, and five minims of tincture of aconite rising to ten minims, are to be given every five or six hours in a wine-glassful of water. The diet light and cooling. Leeching the breast in cases of threatened abscess is useless, and tepid moisture is better than much heat. It is of much importance to support the breast, and it is sometime found beneficial to exert pressure by strapping with plaster, or, as lately practised, by means of collodion applied all over, which, as it dries, contracts and produces an equable compression. When from the throbbing character of the pain, or from the tension and in-flammation of the skin, there is reason to suspect that matter has formed, the treatment must be changed; hot fomentation and poultices are to be regularly applied, the distressing weight of the whole breast being relieved by slinging with a handkerchief round the neck.

child, or any other cause, the milk is not well | The bowels are to be kept open, not purged, the pain and restlessness relieved by an opiate at night, cooling drinks allowed, and the diet light but nourishing. In certain stages, and under certain conditions, it is the practice of medical men to open breast or milk abscess with the lancet; for the unprofessional the safest course is to permit it to discharge itself. The hot poultices ought to be continued for a few days after the evacuation of the matter, and then exchanged for simple waterdressing.

After the discharge of the abscess, a more nourishing diet is to be allowed, and wine or malt liquor may probably be required. If there is much debility, a wine-glassful of infusion of bark, with thirty minims of sal volatile, or a grain of quinine in a glass of sherry may be taken twice a day. If the sys-tem is relaxed, and tendency to perspiration exists, twenty minims of diluted nitric acid should be substituted for the sal volatile in the bark infusion. As long as mammary abscess is merely threatened, the child ought to be allowed to suck, but from the time of matter having formed, till its discharge, it must be

kept from the affected breast.

Even when milk or breast abscess has considerably advanced, it may often be checked by the use of extract of belladonna tolerably thickly smeared over the swollen and inflamed part, the extract being, in the first place, well mixed with an equal quantity of glycerine. If the application is used near the nipple, care must be taken that it does not come near the infant's mouth-a piece of linen is of course placed over the breast .-- See Belladonna.

If hardness remains after the breast is healed, friction may be used with soap liniment, either simply, or with the addition of a drachm of compound tincture of iodine to each ounce.

Refer to-Nipple-Child-birth, &c.

The breasts of infants a few days after birth are liable to become distended with a thick milky-looking fluid, which some nurses barbarously squeeze out. This should never be practised; bathing with warm water, and the use of cold cream, or some simple ointment, is all that is requisite

Youths, about puberty, occasionally suffer from a hard, slightly painful swelling around the nipple, which sometimes creates alarm. It is

of no moment, and requires no treatment beyond warm fomentation, if painful.

BREATH and BREATHING are terms which are sometimes applied synonymously to denote the double act of respiration; but a distinction is as often made, and the first restricted to signify the single act of expiration, when the air, having traversed the lungs, issues from the mouth loaded with watery vapour, after having exchanged a portion of its oxygen for carbonic acid.

The odour of the breath is a good index of the state of the body. When tainted, it is so,

BRI BRI

a morbid secretion of the tonsils; but more frequently, in children especially, it is indi-cative of disordered stomach, and of loaded bowels. The cause of the symptom should always be inquired into, and as far as possible remedied. A brisk purgative may be all that is required. Disease of the lungs is sometimes, and gangrene of the lungs always, accompanied with intolerably feetid breath.

Some persons suffer habitually from tainted breath; and many remedies have been proposed. The first thing to do is to ascertain the cause of this very disagreeable affection. If it is dependent upon carious teeth, the dentist should at once be consulted. The holes or cavities in decayed teeth, besides at times giving off an offensive odour from their carious or ulcerating surface, become filled with particles of food, which

stant passage of the heated breath over them. When foul breath proceeds from ulceration of the gums, whether connected or not with bad teeth, a medical man should be consulted, as also when there is ulceration about the

rapidly undergo decomposition from the con-

palate or posterior part of the nostrils.

The following is probably the best and most effectual wash for destroying the odour from all sloughy sores or conditions of the mouth, gums, or throat, giving rise to foul breath:— Take of solution of permanganate of potash, one ounce. Fifteen drops of this, mixed with two or three table-spoonfuls of water, may be used frequently for rinsing the mouth. If the foul breath proceed from disordered conditions of the stomach or bowels, and be accompanied with an offensive odour of the evacuations, ten drops of the solution, mixed with two tablespoonfuls of water, may be swallowed twice a day, with the best effect. A good plan also, in cases of the latter kind, is to take five grains of powdered charcoal three times a day, either alone or with an equal quantity of white bismuth. Charcoal biscuits are prepared for this purpose, and may be had at most of the principal chemists. Animal charcoal is the most effectual. In a very offensive and intractable case, a respirator of charcoal might be worn, such as is recommended to be used by persons exposed to foul or to infectious odours. The breath has such an exceedingly bad odour in cases of mortification of the lungs, that it will be necessary to employ some of the means recommended under the head Disinfectants, in order to make the atmosphere of the room, or even of the house, in which the patient is situated, at all tolerable. The peculiar odour of the breath in patients who are undergoing what is called a course of mercury, is so characteristic as to have received the name among medical men of mercurial fector. In cases of bad breath caused by offensive dis-charge from the nose, the diluted solution recommend above, or a weak solution of carbolic

not uncommonly, from decayed teeth, or from | should be sniffed up through the nostrils, and then expectorated. In such cases, tonics, cod-liver oil, and residence at a bracing part of the sea-coast are very beneficial. It is again repeated, however, that such cases, especially if ulceration be suspected, should at once be put under the care of a medical man.

People who suffer from foul breath, from whatever cause, should never employ musk, or any other aromatic substance, with a view to covering or masking the unpleasant odour by a stronger one. Such practices are always disgusting, and, of course, have no effect in

remedying the evil.—See Lungs—Respiration.
BRIGHTON. — The favourite wateringplace on the south coast of England. It is well sheltered from the north by the downs, and the air as a rule is dry and bracing, and many Londoners flock to it annually as a health resort. Cold winds prevail in the spring and late winter, and it should be avoided by invalids at these times.

For convalescents, and all persons who require bracing, and in whose cases sea-air is suitable, Brighton presents one of the most favourable climates which can be selected. For children and young persons generally, it forms an excellent residence.

BRIGHT'S DISEASE.—An affection of the kidneys in which albumen remains persistent in the urine. This symptom is characteristic of acute and chronic inflammation of the kidneys (nephritis), which are often termed simply albuminuria. Acute Bright's disease is by no means an uncommon complaint, being due sometimes to exposure to cold, causing a suppression of the cutaneous secretion; but it is far more frequently met with as a consequence of scarlet fever, and occasionally of measles and exysipelas. The symptoms vary with the nature of the attack, and are sometimes so slight as to escape observation; there is usually, however, a feeling of chilliness, with pains in the back and loins, and other febrile symptoms. Then appears swelling of the face, feet, and legs, which frequently extends over the whole body. From the first the urine is loaded with albumen, and when heated in a test tube by means of a spirit lamp, it becomes first flocculent and then a solid mass. The urine also contains a little blood and casts of the tubules from the kidneys. In the most favourable cases, the amount of urine secreted is not much diminished, and the blood and albumen are limited in amount; but in the unpromising class, the reverse is the case. In professional hands, the treatment consists in aiding the action of the skin by warm and hot-air baths, and in keeping the bowels freely open. Diuretics require to be administered of the mildest character, such as linseed tea, barley-water, and tincture of digitalis.

The chronic forms of Bright's disease are far more numerous than the acute, the kidneys acid, made warm by the addition of hot water, | being subject to different kinds of degeneration,

BRO

often difficult to distinguish during life. Apart | before putting on the fire. Broiling is not so from the albumen in the urine, there may be swelling of the ankles and eyelids, and the person may for months and even years have no other symptoms. Dropsy, however, sets in sooner or later, the swelling of the ankles goes higher and higher, and the urine decreases in consequence, the dropsy at last carrying off the sufferer. Death very often results from the urea of the urine accumulating in the blood, giving rise to coma, and sometimes to delirium; but the causes of death are very various, being some-times assignable to the heart, occasionally to the liver and to the lungs, and, most frequently of all, to a collective influence of disease in various organs. If no serious complication occurs, recovery in the first stage of the complaint may be hoped for; but as the disease becomes developed, the prospect is very unfavourable. Bright's disease occurs at all ages and in both sexes, but it is more common after forty or fifty than before that time, and may be traced to intemperance, exposure to cold and unwholesome atmosphere, and to the scrofulous diathesis. Medical men can do little more in the way of treatment than relieve urgent symptoms of distress, since the disease is universally recognised as an incurable one. The drops is treated by medicines which have an action on the bowels, the skin, and the kidneys themselves, namely purgatives, dia-phoretics, and diuretics. The diuretics used are more powerful than those employed in the acute stage of the complaint, and comprise nitric ether, broom decoction, and digitalis; the purgatives, Epsom salts, jalap, cream of tartar, and elaterium, a powerful cathartic which is given in doses of one-eighth of a grain. the early stages (and in fact throughout the course of the disease) it is of essential importance that the patient be kept warm; and diaphoretics, such as spirit of mindererus and the diaphoretic saline mixture, as well as the hotair bath, are usually recommended. benefit accrues from tapping in Bright's disease, though it may be occasionally beneficial to give freedom to the fluid in the limbs by acupuncture, -the insertion of an instrument like a darning needle into parts which are most tense.

BRITISH CHOLERA. - See DIARRHEA. BROCCOLI—belongs to the cabbage tribe, the portion eaten being the undeveloped flower buds. When well boiled, it is one of our lightest and most wholesome vegetables.

BROILING is, perhaps, the most primitive method of cooking; the savage puts his piece of flesh or his fish upon the burning coals In civilised life, the gridiron is lium for the process. The prinmade the medium for the process. ciple involved in broiling is, that by sudden exposure to the fire, the outer portions of the meat are so hardened that they retain the juices of the inner, during the process of cooking. This is still more fully effected by brushing over the surface of the meat with white of egg and at the same intervals. If these stimuli are

well adapted for weak stomachs as either roasting or boiling; but meat cooked in this way is very nutritious.

BROKEN BONES.—See FRACTURES. BRONCHITIS-is inflammation of the membrane lining the air-tubes or bronchi. its subacute and chronic forms, it is one of the most common diseases of the climate of Britain; prevailing at all seasons, but especially in spring. It may be either acute, subacute, or chronic, and varies according to age. Acute bronchitis may commence directly in the chest after exposure to cold; but very often, particularly in children, the lining membranes of the eyelids, nostrils, and throat are first affected, and the disease spreads downwards into the airpassages of the chest. In the latter case, watering of the eyes, &c., precedes the actual bronchitic attack for a day or two. Acute bronchitis, as it occurs in the adult, is a severe disease, requiring the most prompt medical attendance; it is generally the result of exposure to cold in some way, but may be caused by irritant vapours. In it the fever is high, the breathing extremely oppressed, the cough frequent, and expectoration at first difficult. The disease terminates, either with the subsidence of these symptoms, the breathing and expectoration in particular, becoming easy; or respiration becomes more and more oppressed and difficult, the mucus which ought to be expectorated accumulates in the bronchial tubes, and the blood being unchanged, the lips and surface generally become blue and cold; delirium preceding death. The rapid progress which this disease sometimes makes, from its commencement to a fatal termination, renders the sending for medical assistance as quickly as possible an imperative duty; but the same reason renders it important that those around should be aware of the best method of treatment. Confinement to bed is a matter of course; but foot-baths, hot bran poultices to the chest, and warm diluent drinks, are all serviceable. The chief dependence is to be placed upon expectorant medicines, and ipecacuanha is the best and Two tea-spoonfuls of the ipecacuanha wine should be given, or, better still, grain doses of the powder, either in milk or in some fluid, should be given in a little water every twenty minutes, till free vomiting is produced; and this repeated every two or three hours. About an hour after the first vomiting, four grains of calomel are to be given, and if the disease continues severe, repeated in six or eight hours In the event of symptoms of collapse, or sinking coming on before the arrival of medical assistance, it will be necessary to stop the nauseating treatment, and to give stimulants, such as five grains of carbonate of ammonia, in three table-spoonfuls of water, every half hour

BRO BRO

not to be procured, the most readily obtainable | chest affection, and assumes every condition, alcoholic stimulant must be substituted; but ammonia is always preferable; the strength must at the same time be sustained by tablespoonfuls of strong meat broth frequently given. When the urgency of the attack has yielded under the use of the expectorant and emetic systems, the severity of the treatment may be relaxed, and the following substituted; Three grains of ipecacuanha powder, a drachm of carbonate of potash, and an ounce and a half of spirit of mindererus are to be made into an eight ounce mixture with water; and of this two table-spoonfuls should be given every three or four hours. If the cough is very trouble-some, three or four drops of laudanum may be added to some of the doses-but this cautiously. The diet must be light and nourishing.

The acute bronchitis of children is not usually so rapid and strongly marked a disease as that just described; it often begins with the irritation of the membrane of the nose and eyes, and extends itself into the chest. Languer, succeeded by fever, oppressed and quickened respiration, and cough, are the usual symptoms. With these there is a dry hot skin, full and rapid pulse, and great increase in temperature. If these set in severely, from one to four leeches, according to the age of the child, may in an early stage of the disease be applied to the chest; but here, as in the adult, the chief dependence must be on ipecacuanha, half a grain to a grain, or more, frequently repeated so as to cause occasional vomiting. Poultices ought to be used to the chest. If the child is unweaned, it must not be allowed to suck, either from the breast or bottle, during a severe attack of bronchitis, but ought to be fed with the breast milk, or its usual food, by means of a spoon. The bowels, of course, will require attention. It is of the greatest importance to attend to the atmosphere surrounding either child or adult suffering from bronchitis: the chamber should be well ventilated, and the temperature not suffered to fall below 60° Fahr. The bronchitis kettle (see Bronchitis Kettles) should be employed to add moisture to the air of the room, and the warm bath may be occasionally employed, taking care that the child should be thoroughly dried before being put back in its cot. In the later stages of the complaint, the warm bath is not advisable. Bronchitis in children is so hazardous and frequently fatal a disease, that its domestic of the chest will frequently stop the further under necessity. Its exciting cause is almost diet of course ought to be reduced, and meat invariably cold and moisture, particularly during the prevalence of east wind in the spring months; whilst careless and insufficient clothing amongst the poor, and absurd modes of dressing amid the higher classes, render children more susceptible of these injurious influences.

Chronic bronchitis, known also as wintercough, catarrh, and often erroneously called influenza, is quite the commonest form of this by the neglected cold.

from the almost acute attack, to the cough which comes on with the first advent of cold weather, and lasts through the winter and spring. The malady may commence with irritation of any portion of the continuous membrane of the eyes, nostrils, throat, or trachea; the part affected feels sore and raw, and instead of its usual bland mucus, secretes a thin, somewhat acridfluid; along with the local symptoms, there is more or less feverish disturbance of the system, and often severe frontal headache; cough is present, or not, at first, according to the part affected. If a threatened attack of bronchitis is to be checked, it must be done in the earliest stage, and for this purpose nothing is more efficacious than the hot-air bath, and in its absence, the employment of means to produce free perspiration, such as hot footbaths, a hot bed, and the free use of warm diluent drinks. The most efficient medicine for the purpose of checking is opium, in small doses, and no better form can be found than that of English paregoric or compound tincture of camphor, one or two tea-spoonfuls, along with a table-spoonful of solution of acetate of ammonia, and twenty drops either of ipecacu-anha or antimonial wine, should be given at bedtime, along with sufficient water to fill a wine-glass. A tea-spoonful of spirit of sweet nitre may be substituted for the spirit of mindererus. An aperient should be taken in the morning. The above dose may be repeated for two or three nights in succession, if the disease is unchecked. In this case, of course, confinement to the house, or to bed, is required; and demulcent drinks-barley-water is the bestare to be freely used. There is seldom occasion for much medicine; for the alleviation of the cough, the following mixture will be found useful:-Tolu syrup, one ounce and a half; thick mucilage of gum arabic, one ounce and a half; ipecacuanha wine, one drachm; water, sufficient to make up six ounces. Of this, a table-spoonful may be taken every four hours. If the cough is very troublesome, forty drops of laudanum may be added, and towards the end of the attack, a drachm of tincture of squills.

Linseed meal or bran poultices to the throat and chest are of service at the commencemen progress of the malady. In the attacks, the and stimuli eschewed whilst they last. An attack of subacute bronchitis ought never, if it possibly can be avoided, be allowed to establish itself for any length of time; consumption, asthma, and other chest affections are too nearly allied to it, and too often the seeds of fatal disease, which otherwise might have lain dormant for years, are quickened into activity

BRO BRO

to be regarded with serious attention; what in youth might be but a slight cold, may now be a fatal disease; this arises partly from the viscid nature of the secreted mucus, but more especially from the inability of persons advanced in life to expectorate it; accumulation of phlegm takes place in the bronchial tubes, the oxygenation of the blood is interfered with, torpidity of the vital functions ensues, and adds to the already existing inability to free the lungs, and death quickly takes place, often unexpectedly sudden. For the above reasons, colds in old people must always be watched; all lowering measures must be avoided, the dist kept populating and the medicines have diet kept nourishing, and the medicines be stimulant expectorants. Opium should not be ventured on without medical sanction; the compound squill pill is useful. Camphor, in the form of julep, carbonate of ammonia, and sal volatile, are frequently required. The inhalation of steam by means of the bronchitis kettle or ordinary inhaler, will assist the expectoration of viscid mucus. Confirmed chronic bronchitis, or winter cough, requires rather management than medicine-protection of the skin generally, particularly that of the chest, by flannel worn next it, being most important. Some persons derive much comfort from wearing on the chest a dressed hair-skin, with the lungs or air passages, is now universally recog-

The bronchitic attacks of the aged are always | fur inwards, or cotton wadding, or chamois leather. The feet, of course, are to be well protected from cold and damp by thick or corksoled shoes; and the air passing into the lungs warmed by means of one of the various respirators now in use. As an ordinary method for allaying irritation, a tea-spoonful of paregoric, taken at bedtime in a little water, is most serviceable; or where the opium is objectionable, three or four grains of extract of henbane, or of hemlock, in the form of a pill. In all forms of bronchitis the condition of the stomach and digestive organs requires due attention. When cough is frequent and violent, the mechanical effect upon the stomach is liable to disorder digestion, and this again reacts upon the lungs, increasing irritation; for this reason the food must be kept light, and a dose of compound rhubarb and blue pill taken occasionally. The infusion of hop, at once a good tonic bitter and a sedative, is useful. In some forms of bronchitis, in which the cough assumes a spasmodic character, and particularly in children, coming on when the stomach is empty, a little food taken will more certainly allay its incessant irritation than any other means.

BRONCHITIS KETTLES .- The importance of imparting moisture to the air inhaled by a person suffering from disease of the

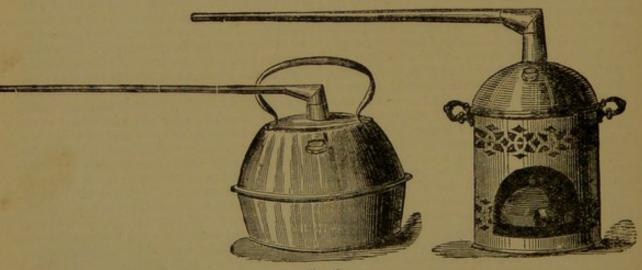

Fig. 48

nised by medical men, and various apparatus are employed in the sick-room for this purpose, the best known being the croup or bronchitis kettles, which are made either fitted for an ordinary fireplace or furnished with a spirit lamp, so that the apparatus may be brought near to the bed of the patient. The kettle is fitted with one or more steam pipes, usually of a long horizontal shape, telescoped into each The two specimens represented secure the conditions above stated; they are each made to hold five pints of water, and are manufactured by Allen & Son, of Marylebone Lane.

Refer to-Expectorants, &c.

BRONCHOCELE - GOITRE - DERBY-SHIRE NECK-FULL THROAT-are all names for the same disease, an enlargement of the "thyroid gland" situated in front of the windpipe. The disease is endemic, that is to say, it is confined to particular districts of country. In England, Derbyshire, and the adjoining counties of Stafford, Leicester, and Nottingham, form its chief locality. In Switzerland and the Tyrol it is common; and it occurs in Hindostan, Canada, &c.

Full throat varies in size, from the enlargement so slight as to be scarcely perceptible-or even, in some eyes, to add grace to the neck-

to a tumour many pounds in weight. In or liniment, the former being preferred. It is Britain, however, it seldom attains the immense size it does elsewhere. The thyroid gland consists of two lobes, which lie on either side of the windpipe, and of a connecting neck. The whole of these parts may suffer enlargement at once, or only one of them. Bronchocele is much more common in females than in males; indeed, in this country it is rarely seen among the latter; and in both sexes, as a general rule, does not appear till after puberty; children, however, do suffer from it even from earliest The rise and progress of bronchocele are for the most part slow, unaccompanied with pain; but occasionally rapid enlargement occurs, and then pain is severe. Coughs, childbearing, strong muscular exertions, are all liable to induce and accelerate the progress of bronchocele; the monthly period also exerts considerable influence upon it. Females of lymphatic temperament are more liable to be attacked.

Bronchocele is a disease for the most part devoid of danger; the chief inconvenience attending it when of large size being impediment to the breathing, and fulness of the head arising from obstruction to the circulation in the vessels of the head and neck. The appearance of a large bronchocele is of course unsightly, although in those localities in which it

prevails it is scarcely observed.

Various causes have been assigned for the production of bronchocele; but none with so much probability as that which attributes it to the regular use of water containing lime and magnesia, which are always found in excess in goitrous districts. The use of snow water, as formerly supposed, is now proved to have nothing to do with its development. Carrying heavy weights upon the head has been said to cause the disease; it is not probable that of itself the practice could produce true bronchocele; but undoubtedly, in common with all other physical efforts or forces, such as cough, which tend to impede temporarily and violently the general circulation about the neck, it will hasten its progress. It certainly is more common among the class of females who are forced to make strong physical exertions. Many different remedies have been proposed, but none possess the same efficiency as iodine; of course, so long as the disease is due to the water or air of the district, it is useless to attempt to remedy it by medicine, but in order to change the constitution, iodine has a powerful influence. Even before its discovery, the element was used, though ignorantly, in the form of the lozenge of burnt sponge. The best form of administering it is in the form of mixture, combined with iodide of potassium,what is popularly termed Lugol's solution. The dose of this should commence with a tea-

made of equal parts (thirty-two grains) of iodine and of iodide of potassium, a drachm of proof spirit, and two ounces of lard, and should be rubbed into the swelling night and morning, intermitting the application, if the skinas it often does-becomes sore; or the tumour may be painted over every night with compound tincture of iodine.

Acute attacks of bronchocele require the application of leeches and the use of purgatives, to allay excited action, before iodine can be used with advantage. Bronchocele ought always to be submitted to treatment as soon as discovered. If this is done there is seldom much difficulty in its removal; but if it is allowed to gain a large size, or if it is of old standing, it will resist the most persevering treatment, and perhaps prove a serious cause of inconvenience, especially if it becomes hardened, which it not unfrequently does as life advances. When the ordinary remedies have failed to give relief, and the disease becomes so aggravated as to interfere with important functions, it may be necessary that the surgeon should puncture the cyst, or even remove a portion of the tumour. The latter operation is, however, very dangerous, and is not often attempted.

A special form of bronchocele is found in association with protrusion of the eyeballs and rapidity of the heart's action; the disease thus characterised is known as Exophthalmic Goitre or Graves' Disease. It is most common in young women, and is apt to be tedious and

troublesome in treatment.

BROOM .- The common broom is one of our most certain and valuable diuretics, too much neglected; it is, also, perfectly safe. The decoction is made from the dried tops of the broom, which grows so extensively in these islands; an ounce of broom is to be boiled for ten minutes in a pint of water, then strained and as much water poured over the contents of the strainer as will make up a pint. The dose is from two to four ounces twice or thrice a day. It may be combined with juniper berries and acetate of potash to increase its diuretic properties. In cases of liver affection, the substitution of half dandelion root for one half broom is a valuable combination. The seeds may be used when the tops cannot be procured.

BROTH is the decoction obtained from animal substances, and, when made for the sick, must, of course, be varied in strength, according to the state of the patient. It is best made by putting the article from which it is to be formed into the quantity of cold water requisite, and keeping the whole at a heat somewhat short of boiling, for many hours: it should then be allowed to become cold and the fat skimmed off. In cases of diarrhœa, broth, spoonful three times a day, and be gradually but it is at the same time extremely beneficial, increased. In addition to this the remedy is if properly managed; in such cases, it is best generally employed in the form of ointment | made from veal or fowl, and thickened with

BRO BUR

rice—which may be strained off—and gelatine; | poultices for a few days, and after that, should and it must be given in small quantities only at a time. In Scotland, by broth is meant the decoction from meat, boiled with pearl barley, and a good proportion of vegetables; it is a much used and wholesome article of diet, and might, with advantage, form an addition to the fare of the English,—the labourer in particular. To be wholesome it must be thoroughly boiled.

BROW AGUE—a name for neuralgia of the head, derived from the marked periodicity of the attacks of pain. Refer to—Neuralgia

BRUISES and CONTUSIONS are the effects of external violence applied to the body, and may be simple, or complicated with wound of the skin. The effects of bruises depend, of course, greatly upon their situation, and the possibility of the violence which produced them having injured important parts, this being more likely to happen when the contusion affects the head, neck, or trunk. The first effect of a bruise is to cause effusion of blood, more or less, within the textures injured; on the head this is very evident from the large tumour which will often rise immediately after a blow ;—a black eye renders the effused blood visible. Blood effused, as the result of a bruise, does not remain in one spot, but diffuses itself through the loose surrounding textures, and causes discolorations to appear at a distance from the bruise, days after the receipt of the injury. The changes in colour, from black or blue to greenish-yellow, &c., which take place during the recovery after a bruise, and which are caused by the mode of absorption of the effused blood, are too well known to require description. After bruises of the abdomen, particular attention should be directed to detect the occurrence of blood, either in the stools or urine; if a medical man is called in, it is highly important for him to have information on these points. In bruises of the surface generally, the best and most agree-able application is ice-cold water, kept up by means of india rubber bags, or a cold lotion made with half an ounce of methylated spirits to the pint of water. Should inflammation increase and symptoms of suppuration appear, hot applications—poultices—will be most required. If heat be used too soon, it may tend to increase the effusion of blood, which the cold checks. The same treatment may be followed, whether the bruise is simple, or complicated with a wound. It is a frequent error, popularly, to apply leeches immediately after a bruise, when they cannot possibly be of service; they cannot remove the blood which is effused, and are only useful in the event of inflammation succeeding the injury. After pain and inflammation in a bruise have subsided, simple water-dressing may be substituted for the

discoloured swelling remain, friction with soapliniment will hasten its removal. The blebs which frequently follow a bruise may be pricked, and the fluid allowed to escape, after which cotton wadding should be applied to protect the part from the external air. The new American remedy, hazeline, prepared from the wych hazel, may well supersede arnica as an outward application. A severe bruise may run on to the formation of an abscess, or end in mortification of the part. In either case, the effect is known by the supervention of the usual symptoms attendant on these processes, and must be treated accordingly. Severe bruise of a bone is liable to be followed by death and separation of the injured part.

Refer to—Abscess—Concussion—Mortification

- Wounds, bruised.

BUBO is the inflammatory swelling of a lymphatic gland, tending to suppuration. The term is most generally applied to the glands of the groin, when affected, either by venereal causes, or from an injury to the foot or limb affecting the lymphatics. The treatment of bubo is similar to that required in abscess gene-

BUCK-BEAN is one of the most beautiful of our marsh plants. It bears a trefoil leaf, and flowers in June. The blossoms are white and feathery-looking, with a tinge of pink. The leaves of the buck-bean are powerfully bitter, and might, perhaps, be more generally used as a tonic than they are at present. It has also been recommended as a remedy for worms. The infusion may be made with an ounce of dried leaves to a pint of water.

BUCK-THORN is a shrub, native to Britain. A syrup made from its berries is used as a purgative, but it is apt to gripe, and need not be used when there are so many better

medicines of the same class.

BUNION is the result of chronic inflammation of a small bursa which is situated over the joint-at the ball-of the great toe, and is generally occasioned by the pressure of tight shoes. It is a most inconvenient and unsightly affection, and the more it enlarges, the more does it become exposed to those sources of irritation which originated it. A bunion ought to be attended to at first, and one or two leeches, warm fomentation and poultice used to allay irritation, the offending shoe being at once discarded. Malposition of the bones at the joint, is a frequent attendant, and perhaps, an antecedent cause of bunion. When the disease is fully formed, the best plan is to avoid, by the make of the shoe, &c., every source of irritant pressure.

BURGUNDY PITCH is a resin obtained

from the pine tribe, but the real article is seldom procurable; that sold for it being a preparation made from common resin. It is used for plasters and is slightly stimulant.

BURIAL. - As a general rule, it is de-

BUR BUR

consigned to the earth as soon as consistent with decency and necessary arrangement, more especially where, as in the dwellings of the poor, space is confined and crowded. As a rule, some means for the purification of the air in the chamber occupied by a corpse should be provided, and this is best done by thorough ventilation of the room and the use of a disinfectant, such as carbolic acid or chloride of lime. This is especially called for in cases of infectious well pitched inside.

Refer to-Death.

BURNETT'S SOLUTION, or, as it is sometimes called, Sir Wm. Burnett's Disinfecting Fluid, is one of the cheapest and best liquid disinfectants (see Disinfectants). It is composed of a solution of chloride of zinc, and, from its cheapness, has been much used in the departments of the public service. When diluted with water, it may be used to cleanse night chairs, water closets, chamber utensils, &c., and is especially useful for this purpose in cases of gastric, enteric, or, as it is often called, typhoid fever, in which the stools are not only offensive, but are the means of conveying to others the contagious poison peculiar to the disease. The solution is so cheap that it may be freely used for the above and for similar purposes. It may be used as a stimulant, disinfecting and deodorising dressing to foulsmelling ulcers and sores, but for such purposes it must be freely diluted, according to the directions which are furnished for its use in the different ways recommended. The chief objection to the free employment of Burnett's disinfector is its poisonous character. If used at all in private houses, it ought always to be carefully labelled Poison, and placed in the custody of some responsible person. Sulphate of iron and carbolic acid are now being more generally used than chloride of zinc.

BURNS and SCALDS are injuries inflicted upon the body by heat, the latter term being confined to those cases in which the medium has either been liquid or vapour. burn may vary in intensity, from the slightest scorch, to complete roasting of the tissues; a scald is not so severe in its effects. There are, perhaps, no accidents for which more remedies have been proposed and used than those resulting from heat; but it will be sufficient if the best, and most generally and easily applicable, are kept in mind. The following may be laid down as at once the simplest and the best, as well as the most readily applicable, and the least painful and troublesome method of treatment. Suppose a person, whose clothes have been set on fire, to be badly burned. The clothes should at once be cut off and removed. The patient must, however, be kept warm, as he invariably suffers much from cold and depression soon after a burn. The burned surface In the case of slight burns, and of scalds should next be smeared over with a feather generally, quite the best application is the

sirable that the bodies of the dead should be with some oily substance, it does not much matter what, provided it be fresh. Carron oil is good, if it can be had (i.e., equal parts of olive or linseed oil and lime water). Next, linen or muslin is to be steeped in this oily substance, and laid over the burned parts. Those parts which are much burned ought to be well protected with this, and finally a layer of cotton wool should be put on and secured by some light turns of a bandage. Cold water is perhaps the most directly grateful application to disease. The coffin in these cases should be a burnt or scalded surface, and if continued sufficiently long, will undoubtedly restore the usual condition of the part, but it must be persevered with for many hours, and when a burn or scald is extensive, this is a serious objection, in consequence of the extreme constitutional depression which so often follows the accident, especially in the young; and here the opportunity is taken of warning parents of the necessity of watching closely the effects of even slight injuries of this kind upon children, particularly when the chest or abdomen is the seat of the accident; extreme depression requiring the free use of stimulants may unexpectedly come on, and death, from an apparently very slight cause, be the result. Whatever very slight cause, be the result. Whatever application is used in the treatment of a burn, should be calculated to exclude the action of the external air; it ought to be one also, which does not require frequent changing; indeed, the more extensive the surface involved in the accident, the greater care should be taken not to expose it to atmospheric influence, which, in the first place, increases pain, and in the second, adds to constitutional depression. This depression must always be carefully watched, and combated by the use of ammonia, wine, or spirit, sufficient to support without stimulating. When pain is excessive, and is irritating the nervous system, a gentle opiate is required; but in some of the severest burns, the sensation, not only in the injured part, but generally, is either wholly or partially abolished, in consequence of the shock to the nervous system at large. The symptom is of most serious, and indeed fatal, import. In the less severe forms of injury from heat, if the treatment has been properly pursued, little after-treatment is necessary; but when a burn has been neglected or badly treated, or caked with flour or other powder, when the blisters are broken, and the true skin beneath is inflamed, and secreting matter, a simple tepid bread and water poultice should, in the first place, be applied for six or eight hours, and after it an ointment composed of one drachm of glycerine of subacetate of lead, rubbed up with an ounce of perfectly fresh lard, or carbolic oil dressing may be applied. The ointment, spread on linen, quickly relieves the very painful condition of the injured surface, and is often preferable to the lead lotion sometimes used.

BUR BUT

cotton wadding in sheets; it should be at once | four grains of calomel administered at once. If used to envelop the injured parts, double if possible, and bound or bandaged on with moderate firmness. If this mode of treatment be resorted to within the first twenty minutes after the injury, nothing more need be done; the cotton may be allowed to remain on from twenty-four hours to three or four days, according to the severity of the accident. Under its use blistering rarely occurs, and if it has commenced before the application, it subsides quickly and painlessly. For the first ten minutes after the cotton dressing is put on, the pain of the injured parts seems increased, but ere long it diminishes, and the inflamed skin appears to relieve itself by gentle perspira-In the cases above named, when cotton is to be procured—and no house in the country ought to be without one or two sheets of itit is perfectly unnecessary to use any other

During the cure of burns involving contiguous parts, such as the fingers, care must always be taken to keep the surfaces asunder by the interposed dressings, otherwise they may become united. After extensive burns or scalds, the constitution requires attention; the stimu-lating treatment of the first few hours or days must be dropped when feverish symptoms come on, and mild and cooling diet, gentle aperients, and cooling and saline medicines administered; opium being given if requisite to allay pain or nervous irritation. This system will again require to be changed for one of stronger nourishment; meat soups, meat and wine, or other stimuli, if there is continued discharge. The use of stimulating diet, however, requires caution, on account of the tendency to inflammation of the lining membrane of the stomach and bowels, which exists during convalescence from injury to the skin by heat.

The frequent occurrence of accidents from burns or scalds, renders it desirable that all should be aware of the best methods of managing these painful injuries, which, when slight, may be well attended to without the aid of the surgeon; but which, when severe and extensive, and when, in children, the chest or abdomen is involved, ought, without delay, to be put under professional care; accidents and symptoms may arise which educated skill alone can foresee or counteract. Scalds of the throat are not unusual accidents to children in consequence of their attempting to drink from the spout of a kettle of boiling water. The injury is imminently dangerous, and when it has occurred, whether alarming symptoms come on at once or not, a surgeon should be summoned; it may probably become necessary very speedily to open the windpipe to save from death by suffocation; and the operation may be resorted to with good hope of success. In the interval, before the arrival of medical aid, leeches, from two or six, according to the age of the child, should be applied to the throat externally, and to have been proposed first by Mege Mouries, a

ice is to be procured, it should be constantly put into the mouth in small fragments.

In managing burns or scalds immediately after their occurrence, the following should be

remembered :-

To protect from the action of the atmosphere and the greater the extent injured the more necessary the precaution—to give stimulants or opium cautiously. The external remediescotton-wool, oil and lime-water, and carbolic

Refer to—Skin, Water-dressing, Emergencies. BURSÆ are small bags of membrane, containing an oil-like fluid. They exist naturally in various parts of the body between the bones and the skin, acting as lubricating pads; in other parts they are occasionally developed by internal pressure or friction. The most conspicuous are those on the knee-cap and the elbow; when irritated or inflamed the bursa on the knee-cap gives rise to "housemaid's knee." Occasionally, if

much inflamed, they degenerate into abscesses.

BUTE—an island in the Frith of Clyde, possesses "a mild, equable, but rather humid" climate, resembling in this respect the south-west of England. Invalids, for whom the air is not too relaxing, find Rothesay, in Bute, a

good winter residence.

BUTTER consists of the fatty part of milk, and is one of the most wholesome articles of diet. It is obtained by the direct churning of milk, and besides the fatty constituents, it contains a certain amount of casein and milk-sugar. Possessing the same characters as fat, it is essentially a heat-giving or respiratory food, and, in combination with bread, supplies a want which is almost instinctively felt by every one. It has the advantage over fat in being less likely to disagree with a delicate stomach. It is to be avoided by invalids when at all rancid, as it then produces stomach-irritation owing to the presence of butyric acid, the product of decomposition. Butter has always more or less salt added to it, and cheap butters have often more than their due proportion, which ought never to exceed eight per cent. To preserve it better, a small amount of sugar is sometimes added to it. The chief adulteration of butter is with water, of which it may take up as much as thirty per cent., though it should never exceed twelve per cent. The other adulterations of butter with fats from various sources are not so easily recognisable, they are usually sold as Brittany and Normandy butters, and are imported into England from various sources. These butters may be wholesome enough in their way, but ought to be sold as substitutes, and not as the genuine article.

BUTTERINE - "DUTCH" BUTTER -OLEOMARGARINE OF EDIBLE FAT-all denote varieties of an article made expressly to imitate butter. This artificial butter appears to have come into commerce about the year 1872, and

chemist. Its chief constituent is beef-fat (which | consists for the most part of stearin, margarine, and olein), and it is largely manufactured in the Netherlands, and also in the United States of America, where animal life is abundant and cheap. As conducted in Chicago, however, the operation of transmogrifying beef-fat into a presentable imitation of butter, is managed in a cleanly fashion, and is thus described by a recent writer (Wynter Blyth on Foods).

"The beef-fat, freed first as much as possible from fibre, passes in a very finely divided state from a sort of mincing machine, technically called a 'hasher,' to large tanks, where it is melted. . . . . The result of this process is, that the fat appears as a clean yellow oil, the water and débris sinking to the bottom, and a thin scum of impurities rising to the surface. The latter is skimmed off, and the oil run into wooden cans in which the externing of the slittle. wooden cans in which the stearin, after a little time, begins to deposit in a more or less crystalline or granular condition. . . . . The refined fat is then filtered through cotton cloths, and pressed, when the stearin is left behind as a white cake, and is ultimately disposed of to the candlemaker. The oleo-margarine, at this stage, is quite tasteless, and has no flavour of butter. This flavour is given to it by churning with milk; lastly, the product is coloured with annatto, and rolled with ice; after which it is either made up into pounds, or packed into kegs for export. Arrived, in this country, it is either sold honestly as butterine at the price of about a shilling per pound; fraudulently, at a higher price, as butter; or it is used as an adulterant of butter."

Mr. Blyth adds that, in all such preparations, there is a great deficiency of the soluble fatty acids as compared with true butter-fat.

BUTTERMILK, the thin acid fluid left after the separation of the butter, is a most wholesome and refreshing article of diet, either in health or sickness, and one too much neglected. In diseases attended with fever it may be given largely with benefit. It can be made artificially, by shaking a quantity of milk in a bottle, capable of containing four times the quantity, until the butter-which must be strained off-is separated; the cork of the bottle being removed occasionally during the process, to permit of the renewal of the air.

BUXTON, celebrated for its mineral springs, is situated in an elevated part of Derbyshire. It is much frequented for the purpose of bathing, during the summer months, by those who suffer from chronic gout and rhuematism; and many persons derive much benefit in these diseases from the use of the The season extends from the beginning of June till October. The waters contain carbonates of lime and magnesia, with chlorides of lime, sodium, and potassium, together with a large amount of free carbonic acid, and issue

CABBAGE, as an article of diet, is not only wholesome but nutritious; it is, however, best suited for persons of good digestive powers. From the extreme liability of cabbage to pass into a state of putrefaction, it should always be

used as fresh as possible.

CACHEXIA is a term used to express an unhealthy state of the system, induced by causes-such as deficient or unwholesome nourishment-which tend to depress, without causing fever. The word is also employed to characterise a condition of the body brought about by disease such as cancer, and is usually indicated by the sallow and dusky hue of the complexion. —See Scurvy—Rickets, &c.

CADDIS.—LINT.

CÆCUM.—The commencement of the large

intestine. —See Alimentary Canal.

CÆSARIAN OPERATION is the process of extracting the infant by cutting through the walls of the abdomen and womb. It is occasionally resorted to by medical men, as a fearful necessity, to save life, when delivery can in no other way be effected. It derives its name from the tradition that Julius Cæsar was brought into the world in this manner.

CAFFEINE is the characteristic principle of coffee, identical with that of tea, "theine." It is a compound, nearly approaching the kreatine of animal muscle in its constitution. In some forms of nervous headache caffeine is specially useful. Bishop's granular effervescing caffeine is an excellent and convenient prepar-

ation. - See Coffee.

CALABAR BEAN, THE ORDEAL BEAN OF OLD CALABAR.—This is the seed or bean of a plant called the Physostigma venosum. It is of a brown coffee colour, kidney shaped, and about one inch long by half an inch thick. The kernel is the active part. When given internally, it acts as a powerful poison, causing paralysis of the heart and asphyxia. The extract of the bean and the powdered bean are sometimes used in medicine, as remedies in cases of strychnine poisoning and tetanus. Their power of rendering flaccid muscular rigidity is undoubted, but their virtue in other respects is questionable.

The Calabar bean first attracted attention from the discovery by Dr Argyll Robertson of Edinburgh, that when a solution of it was applied to the eye, it caused contraction of the pupil. Now previous to this, medical men were not acquainted with any substance which could be practically used for this purpose. It is well known that the opposite effect, viz., dilatation of the pupil of the eye, can be readily produced by belladonna, or by its active principle atropia, which are extensively used for this purpose in the treatment of eye diseases. The Calabar bean is used to counteract this effect of belladonna when it is excessive, or when it continues too long. It is from the limestone rocks at a temperature of also used in the treatment of disease of the eye where it is necessary to produce an effect the

power of vision owing to the faulty adaptation of the structures of the eye to distances. For this purpose an alkaloid obtained from the Calabar bean known as Eserine is usually employed, either in solution or in gelatine

CALCULUS .- See GRAVEL. CALOMEL.—See MERCURIALS.

CALORIC.—The term used to distinguish the cause of the sensation of heat, from the sensation itself.—See Heat.

CALUMBA, or COLUMBO or COL-OMBA, are different modes of spelling the name of the same root. Calumba-root is sold in transverse sections of various diameter and

Fig. 49.

thickness (fig. 49), which are covered by a brown wrinkled bark, are of a greyish-yellow colour, and rayed on the cut surface. Calumba is one of the best pure bitter tonics we possess; it is free from astringency, and exerts a sedative action. In irritable dyspepsia, with vomiting, and particularly in the vomiting of pregnancy, its effects are most beneficial, especially when it is combined with from five to fifteen grains of either bicarbonate of soda or of potass. Calumba may be given in powder, in infusion, or tincture, but never in decoction. The dose of the powder is from ten grains to twenty; of sight, and delirium; an emetic is the bestremedy. the infusion, from a table-spoonful to a wineglassful; of the tincture, one to two tea-spoonfuls in water. The powder of calumba may be taken in water, simple or aromatic: eight parts of calumba powder, eight parts of carbonate of soda, and two parts of ginger, form a most excellent stomachic in dyspepsia, of which half a tea-spoonful may be taken in a wine-glassful of water once or twice a day. Infusion of calumba is made by pouring a pint of cold water upon an ounce of calumba root cut small, and macerating for a couple of hours in a covered vessel. It ought to be made fresh every day, as it quickly spoils. Tincture of calumba is better purchased.—See *Tinctures*.

CAMBOGE.—See GAMBOGE.

CAMPHOR is a white, semi-transparent, volatile substance, but resembles in some degree the volatile oils. It is a product of the camphor tree, and is prepared by sublimation, and again sublimed in bell-shaped masses for and again sublimed in bell-shaped masses for the purposes of commerce. It is stimulant, diaphoretic, anti-spasmodic, and anodyne. It frequent seats of the disease; of these the purposes also some preservative and antisentic possesses also some preservative and antiseptic symptoms will be noticed under the head of

opposite to that of belladonna, and it is capable | properties, and is much used for destroying of application to many cases of alteration of the | moths and other insects, which it probably does from its narcotic action. Camphor is but sparingly dissolved by water, but sufficiently so to communicate both taste and smell, and to form a slightly stimulant solution, or julep, which may either be used internally, or as a refrigerant lotion. It is most simply made by keeping a few fragments of camphor in a bottle of water. In the low stages of fever, camphor is one of the most valuable remedies we possess, exerting at once a stimulant and a soothing effect; it is sometimes given for the purpose in almond emulsion, but quite the best vehicle is milk. From twenty to thirty grains of powdered camphor are to be rubbed up in a mortar with an ounce of milk and five ounces of water gradually added; of this mixture the dose will be two table-spoonfuls. It must be remembered that camphor cannot be reduced to powder unless the lump is first wetted with a few drops of alcohol, or spirit of some kind. Spirit, oil, and acetic acid, all dissolve camphor readily; its solution or tincture, in the first, is well known as a dentifrice, and is frequently given domestically, dropped into water, as a stimulant, in colic, hysteria, &c. It is made by dissolving one ounce of camphor in eight ounces of spirit. The dose from ten to forty drops, in water. The solution of one ounce of camphor, in eight ounces of olive-oil, forms the common domestic stimulant embrocation, camphorated oil. The compound camphor liniment is also an excellent application in cases where it is advisable to use a more stimulating embrocation; it is made with two and a half ounces of camphor, a drachm of oil of lavender, five ounces of strong solution of ammonia and fifteen ounces of rectified spirit. An over-dose of camphor produces giddiness, confusion of

Refer to—Dentifrice—Embrocation.

CANCER is one of the most fearful, and justly one of the most dreaded diseases to which the human frame is liable; and whilst its formidable nature classes it with those which ought at once to be placed under proper medical care, the same reason renders it most important that its first symptoms should be known and attended to, whilst there is yet time to save life. Cancer usually commences as a hard tumour, unaccompanied with inflammation, and either painless, or the seat of intermittent shooting pain. It more frequently occurs in females than in males, and attacks the breast oftener than any other organ. In men, the genitals are liable to be affected, and chimney-sweeps particularly, become the subjects of cancer of the scrotum, produced in all probability, from continual contact with the soot. The skin generally may become the seat

the individual organs. Cancer is very rare the cheek and gums. It occurs in children of under thirty years of age. When, from the nature of a tumour, its hardness, situation, age of the patient, and particularly if there be any hereditary bias towards the disease, incipient cancer is suspected, there should be no trifling, no leechings, or rubbing, or fomentings; the advice of a skilled surgeon should be sought at once; and neither time, distance, nor expense, should stand in the way of procuring that assistance which may not only preserve life, but save from a lingering and painful death. Should the suspicions be unfounded, the mind is restored to peace; should they be correct, the one remedy, excision, cannot be too soon submitted to, before the glands adjacent to the disease, or other textures of the body, become tainted. In any stage of the disease, however, the advice of the regular practitioner ought to be taken; above all, let the sufferer and the friends beware of being tempted by the specious advertisements of quack remedies, and of wasting time of which every day is precious.

When, unfortunately, cancer has reached the stage at which hope of cure must be given up; when it has become an open grey-looking ulcer, discharging thin feetid matter, the seat of shooting and stinging pain, and when the constitution is affected, it only remains to make the situation of the sufferer as comfortable as possible. Opium in its various forms is the great soother, and the other anodynes, hemlock especially, both internally and as a poultice, are all of service. Cod-liver oil in some cases allays the pain and retards the progress of the disease; but the regulation and administration of these remedies must be committed to the care of the medical attendant; the domestic remedies must be, the most perfect cleanliness and kindest consideration for the comfort and irritabilities of any one who is the victim of cancerous disease. Much may be done to mitigate the fector from cancerous sores by the application of antiseptics, of which charcoal in coarse powder is by far the best. The charcoal should be put in bags of fine muslin, in layers of not more than a fourth of an inch in thickness, and placed over the ordinary dressings. Cotton wadding prepared with charcoal has been found useful for a similar purpose, and wool soaked in a solution of boracic acid or chloralum is also employed with benefit. Cancer cannot be said to be propagated by contact; but this should be avoided as much as possible; in the intimate relations of husband and wife, especially, whatever the organ or structure affected.

The lower lip is not unfrequently the site of cancer in old people; especially in those who smoke much; a painful sore in this situation which will not heal, ought not to be neglected, but submitted to medical examination.

Refer to-Breast-Stomach-Womb, &c. CANCRUM ORIS is a species of morti-

weak scrofulous constitution, who are ill fed, and exposed to the influences of unhealthy habitations; and most generally immediately after acute disease, particularly measles. Mercury is often blamed as the originator of this disease, and if given too freely, it may perhaps contribute towards its development; but the main fault is in the constitution. The usual first symptom of the disease is a red, hard, angry-looking spot on the cheek, which quickly opens into a gangrenous fœtid ulcer inside the mouth, the gums become affected, the teeth drop out, the breath, as might be expected, is unbearably feetid, and the extending ulceration goes on destroying the cheek and contiguous parts, till it is either stopped, or death ensues.

As the first cause of this fearful affection is traceable to poverty of constitution, the first remedial measure is to nourish. The strongest meat soup-beef-tea is the best-must be given in small quantities frequently repeated; milk and eggs if the little patient will take them. Wine may be allowed if the debility is extreme, but scarcely, if at all, should fever run high and there be much heat of skin. The preparations of chlorine are most to be relied on as medicines. A drachm of chlorate of potash is to be dissolved in six ounces of water, and to this added twenty drops of diluted hydrochloric acid - a table-spoonful of the mixture to be given to a child of six years of age every four hours; it may be slightly sweetened. Halfgrain doses of quinine, or an ounce of infusion of bark, may be given twice or three times in the twenty-four hours. A lotion made with an ounce of Condy's fluid to ten ounces of water, or weak carbolic acid solution, is extremely serviceable applied to the affected parts, and diminishes the fœtor, or solution of the chlorinated lime or soda may be used for the same purpose. The case ought to be seen by a medical man as soon as practicable, and the diseased structure, if possible, destroyed.

CANELLA BARK is an aromatic tonic, and is used as a spice. It may be given in powder, in doses of fifteen or twenty grains, but it is now superseded by other aromatics

CANINE TEETH. See TEETH.

CANTHARIDES .- The word is the Latin plural of Cantharis vesicatoria, the Spanish blistering fly, an insect with long wings of a bright green colour. It is now chiefly brought from Hungary, where it is brushed in masses from the trees, and afterwards dried and reduced to powder. In addition to its uses as a blistering agent, the Spanish fly is used internally; but is too hazardous a remedy for general use. It is sometimes given as a poison for malicious or criminal purposes. When swallowed in a poisonous dose, cantharides quickly produce severe pain in the stomach and fication, or gangrenous inflammation affecting irritation of the urinary organs follows, with bowels, and intense inflammation; distressing

CAR

constant desire to pass urine, which comes away in small quantities, with or without blood, or is entirely suppressed; stupor and delirium pre-The remedies in a case of poisoncede death. ing by Spanish fly must be of the most soothing character; milk given cold may, as it coagulates in the stomach, envelop the irritant particles, or it may be used boiled with flour; white of egg, linseed tea, or indeed the emollient most quickly and easily procurable should be swallowed largely; and vomiting, if not present, promoted by a feather in the throat, or by ipecacuanha. Oil is sometimes forbidden in such cases, from its being a solvent of cantharides; but after vomiting, or even before, if the dose is not large, one or two doses of castor oil may safely and advantageously be given, each in combination with twenty or thirty drops of laudanum. Injections of starch, linseed tea, or the like, with or without laudanum, will allay the irritation in the lower bowels. Hot applications to the abdomen generally should be used, and if there is much tender-Should the patient ness, leeches, freely. recover, the state of the alimentary canal and urinary organs for some time require care, and the mildest and most unirritating mode of living must be pursued.

Refer to-Blister

CAOUTCHOUC, or ELASTIC GUM, or INDIA RUBBER, is obtained from different species of trees, both in South America and in the East Indies. It is interesting in medicine, from being the basis of the various elastic mechanical contrivances, now so extensively used in the relief and cure of disease. One of the chief inconveniences in the use of caoutchouc, was its becoming hard when cold; the discovery of its combination with sulphurvulcanized india rubber-has obviated the difficulty, and we now have a material which remains perfectly elastic and soft at all temperatures. This valuable property has been quickly taken advantage of, and various appliances for the sick-room and hospital, composed mainly of india rubber are now constantly employed. Among these are air and water curnions, mattresses, bags, and other contrivances for the application of cold or heat. Articles made of india rubber should always be kept in warm rooms, and should be gently warmed before use. See India Rubber.

Refer to-Elastic.

CAPILLARY—hair-like. The term is applied to the minute vessels connecting the arteries with the veins in the animal body;

also to tubes of minute calibre.

CAPSICUM .- Cayenne pepper is better known as a condiment than as a medicine, though it is extremely useful in the latter capacity also. A product of warm climates, it is admirably suited as a stimulant counteragent to the bination with lime or in simple solution, to relaxing effects of heat. It is extensively used destroy and prevent offensive smells from in this country, and when not immoderately, dung heaps, privies, and drains. Calvert's is undoubtedly serviceable to persons of languid powder, which is also in much request, is a

digestion. In too large quantity it will of course, prove an irritant poison. Capsicum is extensively used to check the craving for drink among dipsomaniacs, a dose composed of ten drops of the tincture, ten grains of bromide of potassium, and a drachm of spirits of ammonia, administered in a little water three or four times a day, will in most cases be found very beneficial. Two parts of cayenne, three of compound rhubarb pill, and one of quinine, form an excellent dinner pill, from three to six grains of which may be taken twenty minutes before the meal, for a week or ten days at a time, by persons of feeble habit of body, with tendency to constipation. Dr. Christison recommends a strong infusion of cayenne-a tea-spoonful in six fluid ounces of boiling water-to be used as a gargle in incipient sore throat-fever being absent. The tincture of capsicum is perhaps a more convenient preparation for this purpose, and may be used in the proportion of two drachms to five ounces of water. The accidental introduction of a particle of cayenne into the larynx is dangerous; it has occasioned death. The pepper is known to have been adulterated with red lead and other colouring matter

CARAWAY SEEDS are the fruit of an umbelliferous plant, and are too familiarly known to require description. They are a good carminative, may be given whole, in teaspoonful doses, or in the form of Caraway water, a wine-glassful at a time, or may be added to other medicines, such as senna.

CARBOLIC ACID is obtained from the distillation of coal, of which process it is one of the products. It is an oily-looking liquid, having an odour and taste somewhat resembling creasote. Like creasote also, it possesses the property of destroying noxious smells and vapours, and is a powerful antiseptic or preserver from decay and putrefaction. It is given internally in the dose of one drop made into a pill, in cases of obstinate vomiting, and it might be tried in cases of sea-sickness, but its chief use is as an external application to foul and grangrenous sores or ulcers, and in cases of disease of the bones in which the discharge is very offensive. The strength of the lotion should be twelve grains of the acid to an ounce of water, being one in forty parts. Some have advocated carbolic acid as a disinfectant; but for a statement of its real value in this respect, we refer the reader to the article on Di infection. The popular custom of suspending about a sick-room, sheets, &c., dipped in the solution, is useless, so far as disinfection is concerned, and encourages a false security.

Carbolic acid, when pure, forms long needleshaped crystals, (which are very readily dissolved). It is now largely employed, in comsilica.

Carbolic acid is now employed on a very extensive scale, in what is termed antiseptic surgery, whereby atmospheric impurities of all kinds are rendered innocuous, and wounds and open sores protected from germs present in the atmosphere. It is also largely employed as a deodorising agent and as a disinfector, though we have no satisfactory evidence of its power in this latter respect. As an antiseptic dressing for wounds, it remains without a rival. This system of dressing (which was introduced by Professor Lister, many years since) has gradually gained ground in hospitals and private practice, and has been productive of much benefit in reducing the mortality from surgical operations, as well as rendering practicable numerous operations which would be otherwise hazardous. One of its main benefits is its power of greatly lessening the tendency to erysipelas, blood-poisoning, and other complaints which were formerly considered to be more or less due to the crowding together of persons suffering from open sores. In order to obtain the full benefit of carbolic acid dressing, Lord Lister insists on attention being paid to the most minute details of the process, and there is no doubt that where the system fails of success these details are not rigidly carried out. One of the features of the process used to consist in rendering the air round a wound free from noxious germs, accomplished by a stream of spray from carbolic acid solution, which was made to play upon the wound and its surroundings, prior to its being thoroughly protected from the air by numerous prepared dressings. This is not now considered necessary, if the skin of the patient at the site of operation, and the hands of the operator are made thoroughly aseptic. Carbolic acid is largely employed for numerous surgical purposes without reducing it to the condition of spray; a weak solution may be injected into the cavities of abscesses, or into the internal passages in cases of cancerous and other offensively-smelling diseases. Mixed with olive oil in the proportion of twenty-four grains to the ounce (one in twenty), it is an excellent dressing for burns in a certain stage, and of wounds which have a tendency to suppurate or slough. Soaps made with variable quantities of carbolic acid are now largely used for scouring the floors and wood-work of rooms in which infectious disease has been located, and a toilet soap is much employed by doctors and nurses to remove noxious matters from their hands. Many cases of poisoning by carbolic acid have occurred from mistakes in its administration for other medicine. If the strong acid is taken, death follows quickly, and little can be done to alleviate the symptoms, but if the lotion is wrongly used, an emetic consisting of twenty grains of sulphate of zinc should be at once administered, and after the

combination of carbolic acid with alumina and | demulcent drinks should be given. Bottles containing carbolic acid and kept in a house, should always be labelled Poison.

CARBON—Carbon, Charcoal, occurs in its purest natural state in the form of the diamond, and of plumbago, both of which are pure carbon. It is one of the bodies considered elementary, and forms a large proportion of the matter of our globe and of its productions. The most familiar form of carbon is that of wood charcoal, which is interesting in a medical and hygienic point of view, from its powerful antiseptic properties, and the rapidity with which it removes the signs of, and tendency to putrescency. Water which has become putrid, as it frequently does at sea, is quickly restored to wholesomeness by agitation with charcoal powder. The powder is frequently applied to feetid and sloughing sores, either sprinkled upon them or mixed with one of the common poultices: it is also a good dentifrice. Charcoal powder is often used with advantage in indigestion, particularly when it is accompanied with fœtid eructations and foul breath. A tea-spoonful of the powder may be given in a glass of water two or three times a day. Charcoal biscuits are prepared and taken for a similar purpose.

Either in a fixed or in a transitory condition, carbon is an important and abundant constituent of organized bodies. Of the vegetable kingdom it is the characteristic element; every leaf and every blade of grass which is exposed to the influence of day-light, is busy abstracting from the atmosphere the carbonic acid which is continually diffused through it in small proportions, decomposing it, and rendering back to the air the vital oxygen, but fixing the carbon as a component of the vegetable solids, and putting it in that form, in which, along with other elements, it is fitted to become the nutriment of the animal. Carbon, although not so characteristic a component of the animal, as of the vegetable kingdom, yet enters largely into the constitution of the former; it assists to give permanent form to the various tissues, and furnishes one of the most active material agents, which, under the influence of life, make up the sum, and contribute to the varied changes and effects which are ever going on in the animated body. We have every reason to believe, that carbon is the medium by which, as it combines with the oxygen inhaled by the lungs, and carried through the system by the blood, the animal temperature is maintained. Such being the case, it is evident, that next to oxygen, carbon is the element which must be most regularly and sufficiently supplied to the living body; the other constitutent elements must undoubtedly be provided in food, but their omission for a time is not so apparently and quickly felt as that of carbon; if this be not furnished from outward sources, it is used up from the vomiting has ceased an ounce of castor oil and | bodily tissues as long as they will yield it,

even though its use involves their destruction, | guished, the atmosphere is certainly destructive and the dispersion of the other elementary bodies of which they are composed. actually happens in cases of starvation and in some diseases, during which little or no nourishment is taken: the carbon (and hydrogen) of the fat in the first place, and afterwards of the other portions of the body, is used up in sustaining the animal heat—as fuel—until a point is reached when it can be yielded no longer, and when the patient will actually die of cold, unless there is freely administered the gela-tinous soups, the wine and spirit, with their abundant carbon and hydrogen, which yield their own combustible elements, to maintain the heat, and to protect the tissues of the already exhausted patient.

The discoveries of modern chemistry show us how beautifully the Almighty, in His goodness, has arranged the products of the various latitudes of the globe, has disposed the varied articles of food He gives to His creatures, to man, in accordance with the various climates and modes of life in those climates, so that carbon may be consumed in due proportion along with the other elements; less in the watery fruits of the tropics and of our own summers, more in the fats and oils of the cold north.

Refer to—Aeration—Blood—Bile—Digestion

-Food-Respiration, &c.

CARBONIC ACID GAS or "choke damp," is a compound of one part of carbon with two parts of oxygen; it is colourless, and much heavier than atmospheric air, a property which gives it a dangerous tendency to collect at the lower parts of any enclosed spaces in which it may be disengaged. Old wells, brewers' vats, the holds of ships, &c., are all liable to become the receptacles for carbonic acid gas, which, formed from some decomposing vegetable matter, lies like a stratum of water at the bottom of the receptacle. Should any one incautiously descend, so as to become enveloped in the carbonic acid atmosphere, respiration is either instantly stopped by spasmodic closure of the chink at the upper portion of the windpipe, and complete suffocation is the consequence; or if the gas is sufficiently diluted with air to be drawn into the lungs, it speedily manifests its narcotic effects upon the system, and the person quickly falls into a com-plete state of stupor. The respiration becomes laboured, and after a time ceases; the countenance is livid or pale, and there may be convul-sion, and frothing at the mouth. In such a case, the body of the individual must be removed, if possible, and as soon as possible, from the poisonous atmosphere, or the latter must be destroyed or dispersed. The many fatal accidents which have occurred from persons venturing rashly into old wells, and such places, might be a warning for the future, and prompt the invariable employment of the happens, that the discovery of the accident simple test of lowering a lighted candle into does not take place until morning, long after the suspected place. If the flame be extin- it is too late to remedy the fatal effects;

to life; if it burn even with a feeble and diminished intensity, there is danger. Of the various modes of destroying a carbonic acid atmosphere, none is more speedily effective than the introduction into it of newly-slaked lime, either spread upon a board, or mixed with water and dashed into the place; fresh lime, having a powerful affinity for carbonic acid, quickly absorbs it. In the absence of lime, a quantity of fresh water dashed freely down, so as at the same time to absorb the gas and promote circulation of air, will be serviceable; or large bundles of combustible material, which will cause currents of air, may, when blazing freely, be thrown in. Caution in the first instance, is the best preservative; but in the event of an individual dropping in an atmosphere of choke damp, it is perfectly useless for others to rush in to bring him out; they can no more exist in it than he could, and in stooping to lift a fallen body, they become all the more thoroughly immersed in the poisonous Instead of rashly sacrificing life in the ill-directed endeavour to rescue another, let those who are present dash bucket after bucket of water or weak lime and water into the place, and on the fallen person, until the unextinguished flame betokens that the fatal atmosphere is weakened at least; and when they do venture in, tie over the mouth a cloth soaked in lime-water, in a weak solution of caustic potash, or of simple water if these cannot be obtained.

In cases of suffocation from immersion in choke damp or from any other irrespirable gas, cold water should be dashed freely over the individual as soon as he is removed into the open air, and this measure is to be followed up by heat applied to the surface, stimulant embrocations to the chest, spine, &c., stimulant injections, and ammonia held at intervals to the nostrils, whilst artificial respiration is at the same time brought into action, and steadily persevered in for some hours.

Carbonic acid is produced during fermentation, or by the slow decomposition of vegetable matter, such as damp straw, sawdust, wood chips, &c. It is the gas disengaged in effer-vescing liquors generally; it is also produced along with other vapours of which carbon forms a constituent, in the burning of charcoal.

Poisoning by charcoal fumes, either by design or accident, is not an unfrequent occurrence. In the latter case, it usually occurs from persons ignorantly retiring to sleep in a closed-up room, in which burning charcoal is used as a means of warmth. The carbonic acid, and other fumes disengaged, act slowly and insidiously, and exert so powerful a narcotising effect, that those exposed to the influence are quickly rendered insensible. Too often it

the sufferers are usually found dead. living, they will probably be perfectly in-sensible; the countenance pale and livid. Immediate removal to the open air, and free exposure to its influence by removal of the greater part of the clothing, is the first proceeding, and the treatment recommended in cases of poisoning from choke damp is to be followed. Carbonic acid is largely evolved in the pro-cess of lime-burning, and persons who have incautiously slept in the immediate neighbourhood of a kiln have been destroyed by it. The poisonous contamination of the air in crowded assemblies has already been treated of in the articles, Acration, Air, Blood, &c.

In medical practice, carbonic acid is given in the form of effervescing drinks. Some mineral waters contain it naturally; soda water, and other similar fluids, are mechanically impregnated with the gas; it is, too, very frequently given as disengaged from one of the carbonates of the alkalies by means of an acid. In most cases, the action of carbonic acid, given in this way, on the stomach, is very beneficial; it appears to be at once stimulant and sedative, and no remedy is more generally useful in cases of vomiting; it is an agreeable form of medicine to most persons. Iced soda water will often remain on the stomach when other drinks are rejected, and effervescing wines, especially champagne, are retained where still wines like port or sherry disagree. effervescing drinks are given to persons confined to bed, they should always sit up for a few minutes after the draught is swallowed, to allow of the eructation of the air, which not being got rid of in a horizontal posture, may produce uncomfortable distension.

Refer to-Effervescing.

CARBUNCLE resembles a boil in many respects, but is larger. It is a hard, inflamed, intensely painful swelling, of any size, up to that of a saucer, or even larger; it is flat on the top, and contains a slough, or mortified portion of cellular tissue, which must be discharged before the disease can subside. After the inflamed swelling has existed for some days, small points of ulceration through the skin on its surface begin to show themselves, they enlarge, coalesce, and at last form one or more large openings, through which the slough or core is discharged, either entire or broken down and mixed with bloody matter. all has been got rid of, the cavity begins to fill up from the bottom; and generally in the course of a few weeks becomes entirely healed. Such is the progress of a carbuncle, which does not require interference. The treatment consists in the first place, of assiduous fomentation, and poultices of bread, oatmeal or linseed meal with laudanum sprinkled on the surface to allay pain, and in the open stage, yeast; when the cavity is fairly emptied of sloughs, the poultice must be exchanged for carbolic oil or water dressing, which will in all pro-

If | bability require no alteration during the cure. A small carbuncle may thus, as far as the sore is concerned, be simply and safely attended to, but much more may be required. Carbuncle occurs in two very opposite states of systemin those of full habit, and in those of broken constitution. In the former, eight or ten leeches may with advantage be applied round the base of a large incipient carbuncle, and cooling saline medicines, and moderate diet be resorted to; should a surgeon be in attendance, he will probably make a free crucial incision to facilitate the exit of the core. In those of broken constitution, the opposite treatment will be requisite—all unnecessary loss of blood must be avoided, and whilst gentle alterative mercurial aperients are given, the system must be soothed by opiates, and supported by quinine or bark, along with strong meat broths, wine or porter. When the tongue has become tolerably clean, twenty minims of the dilute nitro-hydrochloric acid may be given with advantage three times a day, in a wine-glassful of water or infusion of bark, or with a grain of quinine. The addition of five or ten drops of chloric ether to each dose is pleasant and useful. In such constitutions, a carbuncle of any size is a serious, and not unfrequently a fatal affection. Carbuncle is certainly indicative of a deranged state of the system generally, and of the assimilative powers in particular; it more frequently happens too, that a large carbuncle has been preceded by two or three smaller ones, or boils, in succession, indications of blood poisoning. The occurrence of these ought always to be taken as a warning; the man of full habit should reduce his diet, meat and stimuli in particular, take exercise freely, and five or six grains of blue pill and compound colocynth pill occasionally with a gentle saline aperient in the morning. A carbuncle, if seen in its earlier stage, may often be checked by passing through it and or more strands of thread eature. through it one or more strands of thread saturated with carbolic acid and glycerine. A tendency to carbuncle in the delicate or aged, must always be regarded seriously, not only as indicative of serious functional disorder of the assimilations, but from the direct danger arising from the disease itself. On this account, it is always desirable that the case should be put under efficient medical care early, so that, if possible, constitutional treatment may arrest the threatened evil. In the case of a carbuncle of any size being developed on persons advanced in life, of weak constitutional power, the case is too dangerous to be left to domestic management, if medical assistance can be procured; if not, the treatment must be carried out as above directed. Carbuncle may occur

CAR

measure the result of the ignition of this gas when it has collected in quantity. Its con-stant use in dwelling-houses, as a means of light, sometimes gives rise to similar accidents, and occasionally life has been endangered and death resulted by the inhalation of it when it has escaped into an apartment. This has sometimes occurred from persons unused to gaslight, blowing out the flame on going to bed, instead of turning the stop-cock. In such cases, treatment very similar to that pursued in poisoning by carbonic acid may be followed out

CARDAMOMS are the seed capsules and seed of a shrub, a native of the islands of the Indian Sea. They resemble orange pips in shape, are about half an inch long; the covering which envelopes the seeds is brown and tough, and must be removed. Cardamoms are one of the best stimulant aromatics we possess, particularly the compound tincture, in one or two tea-spoonful doses in water. The powder of the seeds may also be given; from ten to fifteen grains at once.

CARDIAC.—Belonging to the heart.

CARDITIS. -Inflammation of the sub-The more common inflamstance of the heart. matory affections of the heart are, pericarditis, when the inflammation involves the outer covering or pericardium, and endocarditis, when

it affects the lining membrane.

Acute inflammatory affections of the heart may arise from cold, violence, &c., but in the majority of cases, they are concomitant with rheumatic fever, in the progress of which they are so apt to arise that the medical attendant must be constantly on his guard to counteract the slightest symptom indicative of a tendency towards the heart becoming involved. This a quarter of an hour in cold water, is to be boiled tendency be marked to a quarter of an hour in cold water, is to be boiled tendency he may sometimes detect by means of in a pint and a half of water till it is dissolved. the stethoscope, even before the patient complains or is conscious of any uneasiness about pared effervescing water, holding carbonate of the organ; this is of course a great advantage, and strong argument, why every case of rheumatic fever, however slight in appearance, should be placed under the care of the regular But the symptoms of inflammedical man. mation, particularly in the above disease, may come on suddenly - whilst medical aid is hours distant. The patient is seized with palpitation, increased rapidity of pulse, oppression of breathing, and sense of extreme anxiety in the region of the affected organ-pain may or may not be present. Every minute is of consequence. Continued nausea should be maintained by the fourth or sixth of a grain of tartar emetic, given every three or four hours, and a pill containing three grains of calomel and half a grain of opium, given every four hours. Perfect quiet must be observed, and the lowest diet. If the rheumatic inflammation has suddenly deserted a previously inflamed joint, it will be well to apply a mustard plaster to advantages over the ordinary materials for the place, with the view of possibly re-exciting poultices, bran or linseed meal,

explosions in coal mines are in a great | the action which appears to have been transferred to the heart; at the same time, it must be remembered, that the heart may be affected without any such apparent transference.

The above measures judiciously carried out, will do much to retard the progress of so serious a disease as inflammation, and there is the advantage, that from its so frequently accompanying rheumatic fever, an unprofessional person will have less difficulty than in many other affections, of making up his mind on the nature of the seizure. Inflammation of the heart, whether arising in the progress of rheumatic fever or not, will of course be characterised by the same symptoms. The treatment recommended above, is to be resorted to irrespective of cause.

CARIES, the most common affection of the bones, consists in the disintegration of a part of a bone by a process equivalent to ulceration. It is usually due to the presence of tubercle. The treatment is both constitutional and local.

-See Bones.

CARMINATIVES relieve flatulence and spasm in the bowels. The principal carminatives are, dill, anise, caraway, lavender, peppermint, pennyroyal, and their various preparations; but any stimulants and aromatics, such as nutmeg, ginger, spirituous liquors, &c., are carminatives

CAROTIDS are the large arteries which pass up the neck on each side of the windpipe, to supply the head with blood —See Artery.

CARRAGEEN or IRISH MOSS .- The article sold under the name is a see-weed. When boiled in water it yields a vegetable jelly or mucilage, which requires flavouring to make it palatable. It contains very little nutritive

CARRARA WATER is an artificially prelime in solution by means of an excess of carbonic acid. It is useful in some forms of dyspepsia.

CARRON OIL is a mixture of equal parts of lime-water and olive oil; it has been much celebrated as an application in burns, having first come into use at the Carron iron works, in Scotland. It is certainly soothing and extremely serviceable in bad burns and scalds. When used, it is smeared over the burnt part by means of a feather, or by lint or rags previously steeped in the oil and placed over the skin, and afterwards covered with cotton wool.

Refer to-Burns.

CARROT, the well known vegetable, is nourishing, and contains a considerable proportion of saccharine matter, but it is not easily digested by weak stomachs, and requires thorough boiling to make it wholesome for any. Grated carrot is frequently used as a poultice to foul sores, but it does not possess any special

CAR CAS

CARTILAGE-GRISTLE-is a white-look- | habit of body. Its certain action, and the ing semi-transparent substance, closely resembling gelatine in composition. It covers the extremities of the bones at the joints, and also serves as a bond of union between different Bone itself is in the first place deposited in cartilage, which is abundant in the young; but as age advances, much of the latter substance—such as that which connects the ribs with the breast bone—becomes ossified.

CASCARA SAGRADA is an extract made from the dried bark of Rhamnus Purshianus. It is a useful laxative, and may be by any other remedy. obtained in tablets, each sufficient for a dose.

CASCARILLA BARK is obtained from a tree native to Jamaica and the Bahamas. It bears considerable resemblance to cinchona bark, but is more aromatic. It is stomachic, tonic, and expectorant; and in the latter capacity it is often combined with other remedies. In dyspepsia and debility generally, it is useful. The infusion is made by pouring on an ounce and a half of bruised cascarilla bark, a pint of boiling water, and mascerating for two hours. The dose, from half to a whole wine-glassful. The tincture is of course a warmer stimulant. One to two tea-spoonfuls of the latter may be taken in water, or added to other bitter infusions. Cascarilla is used in the formation of pastilles, its spicy pleasant odour rendering it a valuable deodorant.

CASSIA.—See CINNAMON.
CASSIA PULP is obtained from the pod of a species of cassia by boiling. It is purgative in its effects and seldom used alone, and it forms a constituent of a very useful preparation, the confection of senna.

CASTILE SOAP is a hard soap, compounded of soda and olive oil, and is used in medicine for making pills, plasters, &c. It is sold both white and mottled; the former is pre-

CASTOR OIL the well-known aperient, is obtained from the seeds of the Ricinus communis, or castor oil plant, by expression either hot or cold, or by boiling in water. Cold drawn castor oil, or what is sold as such, is most generally used in this country. Castor oil is one of, if not the most certain and safest of our aperients; in most persons it acts quickly, without pain, clears the bowels effectually, and does not require the dose to be increased in consequence of repetition. From earliest infancy to old age, castor oil may, as a general rule, be given with perfect safety; but yet there are some persons who cannot take it. Some stomachs will not retain the oil, however disguised; in a few individuals it acts almost drastically, and produces a painful sensation of piles, and occasionally it causes, during its action, deadly faintness. These, however, are but exceptional instances.

In consequence of its gentle but effectual action it is most valuable as an aperient, in properly regulated doses, for persons of weak

circumstance that the dose requires rather to be diminished than increased by continued use, renders castor oil peculiarly adapted for those who suffer from habitual constipation. In all conditions of body in which it is desirable to clear the bowels, effectually, but without much disturbance, the oil is invaluable, in pregnancy more particularly. Irritation of the mucous lining of the bowels, whether inflammatory, or in the form of simple diarrhoea, is in many cases more quickly relieved by easter oil than

The great objection to castor oil, its sickly nauseousness, has given rise to a variety of modes of taking it. Floated between brandy and water, in barley-water, or some aromatic water, are favourite modes with many; others take it best in hot fluids, tea, coffee, or gruel, the heat getting rid of the feeling of oily consistency so disgusting to some. A piece of orange or lemon peel chewed just previous to taking a dose of castor oil, blunts the acuteness of the nerves of taste. Castor oil may be taken in emulsion, made with mucilage or milk; but rubbed with yolk of egg is the best form of mixture. In this way it is not so active an aperient as when uncombined; but in irritable and inflamed conditions of the lining membrane of the bowels, it is especially valuable when combined with opium. Six drachms, by measure, of castor oil, are to be well triturated in a mortar with the yolk of one egg, and to this soft water, or some aromatic distilled water, is to be added gradually, to the extent of six ounces. If an aromatic water is not used, a few drops of some essential oil, such as cinnamon, may be added before the water. The mixture resembles custard in consistence. The dose an ounce-two table-

A good mode of administration for children is to simmer a small quantity of milk and sugar with cinnamon, till the flavour is well imparted, and then to shake up the castor oil and hot flavoured milk in a bottle. Another mode is recommended by M. Martin. The quantity of oil required is put in an earthen pan; an egg is broken on it; the pan is then heated, and the oil and egg shaken up together, so as to produce an œuf browillé. A little salt is then added. "I have given," he says "to a man an omelette made of three eggs and forty-five grammes of oil, and he has eaten it without finding out the oil." In China, we are told, castor oil is daily used in common

"In some parts of Central America, where the castor oil plant grows abundantly, it is scarcely, if at all, used as a medicine, being considered poisonous, or to cause fever. Its effects cannot be calculated on with certainty. This might be useful to emigrants."-Vigne's Travels in South America.

The usual dose of castor oil alone, is about

tion of the nervous system, caused generally by sudden and violent mental emotion. Sensibility to external things, and the power of voluntary movement is lost; the limbs become rigid, and retain what position they may be placed in. The signs of life are, in this affection, occasionally so obscured, that the person has been accounted dead. After a time, varying from a few minutes to hours and even days, the fit passes off and consciousness returns. some foreign countries persons are said to have been buried alive in the cataleptic condition, but such statements are always very doubtful. Stimulants-ammonia to the nostrilsshould be used, and stimulant enemata, with continued friction over the body, particularly down the spine.—See Electricity.

Refer to—Death, Signs of.
CATAMENIA.—The female monthly dis-

charge. - See Menstruation.

CATAPLASM.—A poultice.—See Poultice. CATARACT is an affection of the eye which produces opacity of the crystalline lens, and more or less obstructs vision according to the extent of the disease. The affection is most common in persons advanced in life, but may occur at any age. An individual who is becoming the subject of cataract, complains of seeing objects, as it were, covered by a mist or veil; vision is sometimes better in an obscure light, when the pupil becomes When the disease is a little advanced, anything placed a little to one side is better distinguished than if it is directly in front, the first opaque spot of cataract occupying usually the centre of the lens, or the axis of vision, in which situation it can be detected by examination.

When cataract is in its incipient stage, its progress may perhaps be arrested by judicious treatment, and for this reason the case should, as quickly as possible, be placed under medical care; in the interim, the bowels must be attended to, stimulants avoided, and a blister applied to the nape of the neck. When cataract occupies the whole circle of vision, and produces blindness, it may be removed by operation. An oculist or surgeon should al-

ways be consulted on the case.

CATARRH is inflammatory irritation of the mucous membrane lining the air-passages—the nostrils and bronchi. It usually commences in the former, and extends to the latter. Catarrh, or "a cold," as its popular name implies, is generally the result of cold combined with damp, but quite as frequently of checked perspiration, in consequence of the individual passing from a heated room to a current of cold air. Catarrh commences with feverish symptoms more or less severe, shiverheat of the lining membrane of the nostril, is requisite in this climate, but as guarding

half-an-ounce, or one table-spoonful.—See followed by discharge of thin, acrid, watery fluid, "a running at the nose," and with this, there is intense headache between the eyes. Or the throat may be first affected, or the chest itself may be directly attacked, though, if not, it will quickly become so; the windpipe feels as if raw, there is frequent cough, dry and harsh, or with thin expectoration, and the breathing is oppressed; there is, in fact, sub-

acute bronchitis.

The evil of a "neglected cold" has become proverbial, and justly so-it is great. The attack ought to be checked at first. The first measure in incipient cold, is to restore, and excite the action of the skin to get free perspiration. This is best accomplished by the vapour or warm-bath, but if these cannot be had, the best remedies are hot water to the feet, a warm bed and hot diluent drinks, along with diaphoretic medicine. A draught consisting of half an ounce of spirit of mindererus, one to two drachms of paregoric, and ten to fifteen drops of ipecacuanha wine, with water sufficient to fill a wine-glass, should be given with five grains of Plummer's pill, on getting into bed, and about an hour after, a warm drink composed either of gruel or barley water; in the morning, some gentle aperient, senna, or castor oil, or Seidlitz powder, is to be taken. If there is much irritation of the chest at night, a fomentation, a mustard plaster, or friction with a stimulant liniment may be employed. A pill composed of six grains of Dover's powder or a one-grain opium pill will often relieve the symptoms. Should the cold not disappear, the treatment above recommended may be followed up for two or three nights in succession, confinement to the house, low diet and demulcent drinks, such as barley water, &c., being superadded. When catarrh is not checked, it runs on to cough, in fact to bronchitis, more or less severe.

Catarrh is unquestionably the effect in many cases of unavoidable atmospheric changes and influences, but it is much oftener the result of carelessness or imprudence—of carelessness in not guarding the body against the effects of our changeable climate (for catarrh is a very English disease), and particularly the neglect of wearing flannel or some woollen material next the skin, which is the very best preservative. Over-heated rooms and exposure to the air insufficiently clothed, are fertile sources of catarrhal affection, especially in children. Insufficient protection to the feet and dampness is another. There is, too, in females, the exposure of the chest, after heated ball rooms, public amusements, &c. The use of fur round the neck is not unfrequently the cause of cold affecting the throat: whilst close to the skin, it produces warmth and perspiration, but when the covering is thrown back, a chill at once ensues. The writer would not be understood as disapproving of the use of fur, so against the incautious and sudden relinquish- | parts of the body implicated, and of the direcment of the protection.

Refer to—Bronchitis—Influenza.

CATECHU-an extract obtained principally from trees of the acacia genus; is brought chiefly from the East Indies and Singapore. It is powerfully astringent, and is met with in masses of various sizes, either of a dark brown or of a pale reddish-brown colour. It is used both externally and internally, its astringent property being due to the presence of an acid very similar to tannic acid and known by the name of Catechu tannic acid. In most forms of diarrhea, catechu, used either in the form of infusion, compound tincture, or lozenge, is serviceable, and also in the form of infusion as a gargle in relaxed sore throat, or elongated uvula. In the latter cases, a convenient mode of employing catechu, is to permit a few grains to dissolve in the mouth-for this purpose the pale catechu is the pleasantest. In sponginess of the gums, powdered catechu forms a good dentifrice. One of the most valuable external applications of catechu is in the chapped nipples of nursing mothers; it must be used in the form of tincture, put on the nipple each time after the infant has been nursed, by means of a small paint brush or feather, and wiped off with the wetted corner of a towel before the child is put to the breast. To make the in-fusion of catechu, a pint of boiling water is to be poured upon six drachms of the powdered extract, along with one drachm of bruised cinnamon, and the whole infused for an hour; the dose is from two to four table-spoonfuls. The dose of the tincture is from one to two teaspoonfuls, of the powder from ten to thirty grains or more, and three or four of the lozenges may be taken at a time.

CATHARTICS are medicines which stimulate the bowels to increased action, such as senna, castor oil, Epsom salts, &c.

Refer to—Purgatives.

CATHETER -an instrument used by surgeons, and with slight exception to be used by them alone, for drawing off urine from the bladder, when it is retained in it in consequence of disease. The male catheter is a long curved tube, varying in calibre according to requirements, the female catheter is shorter and easier of introduction. All good nurses should be capable of using the female catheter in the absence of the doctor. Some peculiar cases are entirely dependent upon the use of the catheter for relief, and remain so for years; under these circumstances, the patient ought to learn to employ the instrument for himself, and many do so; with this exception, it must be used by professional hands alone, for even in these it requires both skill and care, and may do serious mischief. In cases which require a catheter to be regularly passed, the operation generally becomes easier. The passage of the catheter being simply a mechanical operation, requiring tact, and a correct knowledge of the tubes and instruments.

tion of the urethra, may of course be acquired by any one who will take the trouble to educate himself upon these points.

Refer to-Bladder.

CAUL .- The old name for the omentum or covering of the intestines. The term is also applied to a portion of the uterine membranes, which is sometimes carried along with the head of the child at birth, and covers it like a veil. The caul is frequently preserved. Much superstition used to be attached both to the circumstance and to the object itself.

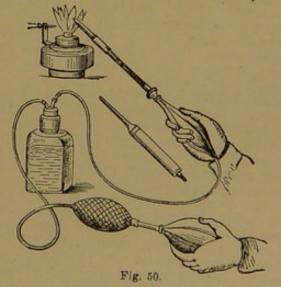

CAULIFLOWER, a vegetable of the cabbage tribe, agrees better than most other vegetables, with those of weak digestion. The addition of melted butter is injurious to deli-

cate stomachs.

CAUSTICS are substances which destroy organised tissues by combining with their constituent elements. The mineral acids, strong acetic acid, potassa, lime, nitrate of silver, belong to the class, and may be referred to

under their respective heads.

CAUTERY .- Any agent which is capable of producing and retaining great heat, and which on being brought into contact with the skin or internal passages, destroys living textures. The cautery is employed to check hæmorrhage, to destroy superfluous and diseased growths, and to produce counter-irrita-The actual cautery is a knob of iron which is applied at a red or white heat, but it

is being rapidly superseded by the galvanic cautery. Paquelin's benzoline cautery (made by Mr. Coxeter, of Grafton Street, East) is a useful little instrument, which produces intense heat, and is often employed instead of the actual and galvanic cauteries, being more portable and in many respects more convenient. The illustration shows how the hollow instruments intended for operation may be kept at a white heat by passing a continuous current of air over the benzoline in the bottle through

CAYENNE.—See Capsicum.

CELLULAR MEMBRANE or CON-NECTIVE OF AREOLAR TISSUE, is the reticular membraneous web, which connects the various portions of the body, and fills up the interstices. It is made up of numberless little fibres and bands crossing each other in every direction, and enclosing small spaces, which freely com-municate throughout the body. The most The most familiar exemplification of cellular tissue, and of its free inter-communication, is seen in the blown-up veal of the butcher. In the living body, the areolar tissue contains a thin water or serous fluid, which, when it accumulates in undue quantity, constitutes one form of dropsy, finding its way by permeation through the cellular meshes to the most dependent part of the body.

CEREBELLUM.—The lesser brain.—See

Brain.

CERIUM .- Several of the salts of this metal have been used in medicine, though it has not been thought advisable to admit any but the oxalate into the British pharma-

copœia.

These preparations have been principally used to allay vomiting, especially that occurring during pregnancy, and during the course of pulmonary consumption. The late Professor Simpson, of Edinburgh, recommended the oxalate to be used for the vomiting of preg-nancy, and it has been extensively used for this purpose, with a certain amount of benefit. It is a white powder, and is given in the dose of from one to three grains.

The salts of cerium have been used by some practitioners in the treatment of epilepsy, but it is not certain that their use has been fol-

lowed by good results.

CERUMEN is the waxy matter of the ear, of which the chief purpose is, probably, the repulsion-by its bitterness and other qualities -of insects which might enter or harbour in the passage. It sometimes accumulates to so great an extent, especially in the aged, and in the young, particularly after acute diseases, as to cause deafness, more or less complete, which is generally accompanied with noises and other uneasy sensations in the affected organ. The accumulated wax may, possibly, be detected, by examining the ear-passage with the aid of a candle. In order to remove the hardened mass, a small portion of warm olive or almond oil must be dropped into the ear for two or three nights in succession, for the purpose of softening and loosening the wax; after that has been done, the passage must be thoroughly syringed out with warm water, by means of a two-ounce syringe, till the wax is detached and washed out. Some persons become faint and giddy on having the ears syringed; in such cases the operation is best undergone in the horizontal

CHAIRS, INVALID.—Easy and luxuri- by which process the finer particles are separ-

ous chairs of every variety and description are made for persons in health, and may often be used by the invalid; but, as a rule, they are unwieldy, and cannot be employed for carrying patients from one apartment of a house to another, or into the open air. One of the first steps towards convalescence is a change from the depressing influences which more or less pervade a sick room, to a more cheerful apartment, and on the facilities with which the change can be effected, depend much the comfort of the patient and the convenience of the attendants. The removal is easy of accomplishment by means of a carrying chair made expressly for the purpose. There are several kinds in use in public establishments, most of which have long poles slipped through brackets on each side of the chair when in use, but for private households there is nothing better than the carrying chair manufactured by Mr. Carter, of New Cavendish Street. This chair is furnished with sliding handles which can be pushed backwards under the seat; one of the main advantages of the chair being its ready adaptation to narrow passages or winding staircases. A modification of this chair, made with a reclining back and leg-rest which draws out from under the seat, combines in one piece of mechanism the ambulance stretcher and chair, and is advantageously employed for invalids or injured persons who prefer either the horizontal, reclining, or the sitting posture. The most useful invalid chair, however, is that in which the patient may propel himself about from room to room, or in the open air, as in the garden or on the sea beach. This is best managed by providing the carrying chair with a wheeling platform; or for rough usage, a couple of large wheels with a small guiding wheel behind may be fixed on an ordinary Windsor or cane-bottomed chair, without the addition of the platform. For a person recovering from a broken limb a leg-rest may be easily adjusted to the seat. Among other novelties in chair manufacture, Mr. Carter has designed a patent exercising chair, with horse, lever and rowing action combined, by attaching a couple of handles or levers to the sides and centre of the seat, which is made to move up and down. The effort necessary to move the levers to and fro, is similar to that required in the exercise of rowing, while the undulating and oscillating movement given to the seat has some kind of analogy to the motion conveyed by a sharp trotting horse, over a rough country, to the rider. These exercising chairs are made to suit children, as well as adults, and for children suffering from debility, paralysis of one or both inferior limbs, and who cannot take exercise in the open air, daily exercise in a chair of this description may be safely recommended.

CHALK .- Carbonate of lime occurs abundantly in various parts of the world; it is used in medicine as an astringent and antacid. For medicinal purposes it requires to be levigated,

sted: when dried, the preparation constitutes | they are the most general—in which the metal the "prepared chalk" of the shops. As a is in combination with carbonic acid, when the general antacid, chalk is scarcely to be recommended, but in cases of diarrhœa, especially in children, where much acidity exists, it is highly useful. For the latter purpose, from twelve to eighteen grains of chalk rubbed up in an ounce and a half of dill water, form a mixture of which a tea-spoonful may be given to an infant six weeks old, every few hours if

requisite.

In the case of adults, the ordinary chalk mixture is an excellent preparation; it may be made with prepared chalk two drachms, powder of gum acacia two drachms, cinnamon water, or water simply, eight ounces; a drachm and a half of sugar may be added, but is quite as well omitted; better, if the climate is a warm one, as it causes fermentation. To the above mixture, rhubarb, laudanum, &c., may be added if requisite. The dose, two or three table-spoonfuls, repeated more or less frequently, according to the amount of diarrhœa. The aromatic powder of chalk—dose thirty to sixty grains-and the same powder with opium -dose five to twenty grains-are both useful and easily carried preparations, which ought to form part of the domestic medicine chest of the emigrant, or, indeed, wherever the usual sources for procuring efficient medicines are far distant. The powders ought to be procured ready prepared. Forty grains of compound powder of chalk and opium contain one grain of opium. Chalk forms an ingredient in the grey powder, a combination of mercury and chalk. The practice of sprinkling chalk powder upon sores, for the purpose of absorbing discharges, &c., is not to be recommended. Prepared chalk is used universally as a dentifrice, either alone or more commonly with an aromatic as camphor, orris root or cinchona bark.

CHALK-STONE-is the concretion deposited around and in the joints of those who suffer from chronic gout. It consists mainly of urate of soda, a comparatively insoluble salt. The liability to the formation of chalk-stone, is a reason why those who are subject to gout should, when an antacid is required, make use of the potash carbonate, which, in union with lithic acid, forms a much more soluble salt than soda does.

CHALYBEATES—are medicines containing iron. The term is well known in connection with mineral waters. The most generally used chalybeate springs in this country are those of Tunbridge-wells, Cheltenham, and Scarborough; Leamington and Harrogate also possess chalybeate waters, and there are many others, metuding Strathpeffer and Ballater, in Scotland, scattered throughout the island. In chalybeate waters the iron is generally in combination with carbonic acid, the taste of the

is in combination with carbonic acid, when the water has stood exposed to the air for some time, it lets fall a yellowish sediment. Chaly-beate waters are, by virtue of the iron they contain, powerful tonics, and well adapted as curative agents in diseases of debility generally; but they are not to be lightly and unthinkingly used, or without professional sanction. Many persons do themselves serious injury by unadvisedly drinking mineral waters, under the idea that if they do no good, they cannot do much harm. To persons of full habit, and with any tendency to head affection, even a short course of chalybeate water might be most seriously dangerous.

CHAMOMILE, the Anthomis nobilis of botanists, is too well known to require description. The flowers, either fresh or dried, are deservedly classed amid the most useful, safe, and generally employed domestic remedies. They are often used in making fomentations, with or without poppy heads. A handful or two of the flowers are boiled in the water intended for fomentation, and after straining, the flannel dipped in the liquid is applied to the part. Chemists now sell a concentrated preparation of poppy and chamomile ready for immediate use. The infusion taken internally is an aromatic bitter of undoubted tonic properties, and without nauseousness. In simple debility of the stomach and loss of appetite, chamomile tea, if not used too frequently, and for too long time at once, is a safe and good remedy. Half an ounce of chamomile flowers may be infused like common tea, in half-a-pint of boiling water, or, if time be given, in cold water, which makes an equally efficacious and pleasanter dose. Chamomile tea drunk warm is often employed as a gentle emetic by itself, or to aid the action of other medicines of the class; alone it is very uncertain, unless made very strong. From five to ten drops of the essential oil of chamomile, dropped on sugar, is a useful, and not unpleasant carminative.

CHAMPAGNE, the well-known wine, contains about twelve per cent. of alcohol, a much less proportional quantity than the strong dry wines, such as port, sherry, Madeira, When effervescing, however, it exerts a powerful but transient intoxicating effect. It is an excellent restorative, and may be taken and retained by the stomach when other wines are rejected. Hence it may be used for the great nervous prostration following surgical operations, also in exhausting diseases and in convalesence from fevers. Champagne is often accused of causing gout, indigestion, &c., but perhaps these are more likely to be the results of the other luxuries which accompany a champagne dinner, than of the wine itself.

water is inky, and if it be one of those—and of inoculation with the venereal poison. They CHANCRES are small ulcers, the result

CHE CHA

after breaking, degenerate into yellowish greylooking sores, around which the skin feels firm or hard. They may be single or multiple and vary very much in position, size, appearance, and progress. As in almost all cases their presence is followed by general constitutional disease, the result of syphilitic poison absorbed at the site of the chancre, recourse should always be had at once to skilled medical advice. Until then the chancre should be kept clean by pouring water over it once or twice daily, and afterwards dusting thoroughly with iodoform.

CHAPPED HANDS, so troublesome to many in frosty weather and during cold dry east winds, may partly be avoided by care in thoroughly drying the skin after washing. Only unirritating superfatted soaps should be used; and a little lanolin rubbed in after washing is very soothing. Gloves should always be worn out-of-doors. An ointment prepared with Goulard solution, oxide of zinc, and glycerine, a drachm of each, with two ounces of lard or vaseline, makes an excellent application, and may be used every night.

For this very common complaint, numerous remedies have been suggested; a few more pre-

scriptions are appended :-

Benzoate of zinc, . . one drachm. Oil of almonds, . . . one drachm.
Cold cream, . . . one ounce.
Mix. To be applied to the hands every night.

Oxide of zinc, . . . one drachm. Carron oil, . . . half-an-ounce. Simple ointment, . . half-an-ounce.

Vaseline, either alone or with a small quantity of sugar of lead added to it, is very useful, and ought to be applied to the hands of those who suffer much in this way, after each time

they are washed.

Those who are obliged, from the nature of their occupation, to wash their hands frequently, are the great sufferers from chaps, the chaps or cracks themselves becoming dangerous, in some occupations, from their liability to absorb poisonous substance into the blood.

CHARCOAL.—See Carbon.

CHARPIE.—The loose fibres from scraped linen, used to absorb the discharge from sores. It is more used in France than in this country.

CHEESE is the curd or caseine of milk mixed with a proportion of butter, pressed, salted, and dried. A general and nutritious article of diet, it is not one suited to weak stomachs. A meal of bread and cheese alone requires a thoroughly strong digestion to dispose of it comfortably. Many, however, who cannot eat cheese in this way, may take it in small quantity with impunity, and when old almost with advantage, at the close of a moderate meal. Much of the indigestibility of cheese arises undoubtedly from its toughness, and the cohesion of its particles, this diminishes as | containing much carbonic acid, they do not

commence in a form of small pustules, which, | it verges towards decay, and is not observable in the soft cheeses, which owe their digestibility to the larger amount of butter they contain. The toughness is much increased by toasting, which renders the article decidedly unwholesome. Cheese is said to assist the digestion of other articles of diet; and there is an old rhyme :- "Cheese is a peevish elf,

Digests everything but itself."

Probably, the power put forth by the stomach for the solution of the cheese acts more readily upon the less tenacious substances submitted to it at the same time. The habitual use of old cheese in any quantity is injurious, and may occasion cutaneous eruptions. In Germany, a pecular kind of decay in cheese has occasioned symptoms of irritant poisoning.

The caseine, or curd of milk, which forms the basis of cheese, very closely resembles albumen in composition; its nutritive power may be known from the fact, "that from caseine alone the chief constituent of the young animal's blood, as well as its muscular fibres, membranes, &c., are formed in the first stage of its life."

The contrast afforded by tough indigestible cheese to the milk curd adapted for easy solution in the stomachs of the young, is a good example of the manner in which an article of diet, nutritive and wholesome, may be modified as regards its digestibility, by preparation. Caseine is found in the vegetable kingdom chiefly in seeds.

Refer to-Milk.

CHELTENHAM.—The climate of Cheltenham is considered particularly adapted for health, there being neither great extremes of heat, nor of cold. To those, however, with whom a dry and bracing atmosphere agrees, its climate is less favourable than some other localities.

"The mineral springs of Cheltenham are exclusively employed for internal administration. They, for the most part, resemble each other as to the nature of their component parts, yet present considerable differences in the relative proportions of their ingredients. They are rich in the chlorides and in sulphate of soda. Several of them contain a small proportion of iron, and iodine has been lately detected in them. They are but slightly gaseous, and though two or three of them have, when first drawn, a slight odour of sulphuretted hydrogen, it soon passes off, and is probably dependent upon the springs passing through a layer of mud, or matter in a state of decomposition. It must not, therefore, be supposed that the so-called sulphuretted wells are analogous in their action with the class of sulphurous springs. . . . . Besides its saline springs, Cheltenham possesses two chalybeate ones, which, like others of the same class, have a disagreeable inky taste, and are somewhat dark coloured. From their not CHE CHE

to the atmosphere.

"There are many diseases in which the Cheltenham springs may be used with advantage. Persons who have lived in India and other tropical climates, who have been accustomed to take large doses of mercury, will generally derive benefit, less from the aperient than the tonic properties of the waters. For gouty patients, also of a plethoric or irritable habit, they are advisable. And in cases of amenorrhoea and chlorosis they do good service, where with it a faulty condition of the digestive organs exists.

For the substance of the above article, and of others similar to it, the author is indebted to the work of Mr. Edwin Lee on the Watering Places and Mineral Springs of England, and those who desire further information cannot do better than have recourse to the publica-

tion itself.

CHERRY.—The fruit of the Prunus cera-Like other stone-fruits it is apt to dis-

CHEST, or, in medical language, the thorax, is the important cavity situated between the neck and the abdomen (fig. 51)

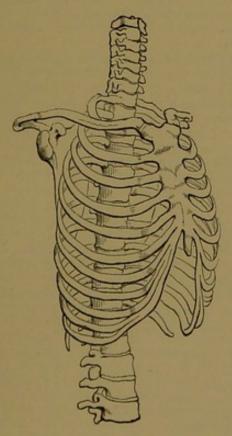

Fig. 51.

which contains the heart and large blood vessels and the lungs. It is separated from the abdomen by the diaphragm, it is bounded by the breast-bone anteriorly, laterally by the ribs, and is supported posteriorly by the spine.

sparkle, and are soon decomposed on exposure | tion of what is called the chest; generally it is referred to the pit of the stomach; and what is called "a pain in the chest," is in many instances, a pain in the former situation. In ordering applications, leeches, blisters, and such like to the chest among the poor, it is absolutely requisite to indicate with the finger the exact spot on which they are to be placed, otherwise the chances are, that if simply the chest is named, the pit of the stomach will be understood; a serious mistake in many of the acute affections of the chest, particularly in children.

The form of the chest itself is, or ought to be that of a truncated cone or bee-hive, broad below, narrow above (fig. 51). It is true it appears the reverse of this, even naturally, and is made to do so still more by the absurd ideas about small waists; but the greater apparent width at the upper part of the chest in the living person is due to the shoulders and arms; when these are removed, the contrary is seen to be the case, and the cavity itself, as exemplified in fig. 52, is evidently much more capacious in its lower than in its upper part.

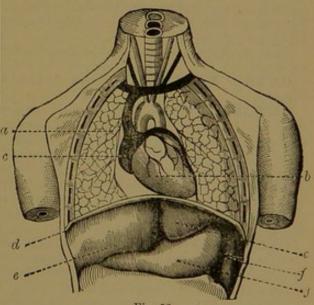

Fig. 52.

d. Diaphragm.

Right lung. Right ventricle of

e, e. Liver. c. Right auricle of heart. g. Stomach.

When, by tightly-laced stays or other contrivances, the lower part of the chest is compressed, the contained viscera must find room somewhere; the diaphragm yields more readily than the long ribs, and is pressed down upon the liver, stomach, and bowels, disordering their functions, and laying the foundation of disease, whilst at the same time the free play of both lungs and heart is impeded. In other words, the possessor of that most desirable physical conformation, a capacious chest, is It is singular how much ignorance there doing all that is possible to render it otherwise; is among the uneducated regarding the situa- or should the cavity be naturally small, to make

CHI CHE

ft still more deficient in size, by artificial re- | guished by the absence or extreme mildness of straint, instead of every means being used to sugment its capacity. A small chest always gives a greater liability to disease; all tendency therefore to contraction, stooping of the shoulders, &c., ought most sedulously to be watched and attended to, particularly in young people, whilst the bones are still soft and yielding; disease may be either the cause or the consequence; the spine too should be well examined. Exercises, which from moderate exertion call for full expansion of the chest by respiration, and full play of the arms are generally useful. The elastic "chest expander," made of vulcanised india rubber, is a most excellent contrivance for the purpose. Some trades, particularly that of shoe-making, tend in the course of time to affect the conformation of the cavity of the chest.

The physical examination of the chest as regards measurement, the sounds elicited by tapping upon it in various ways with the fingers, and heard by the application of the car, either directly, or mediately by means of the stethoscope, are most important aids in the investigation of disease, and should never be omitted or objected to. For the purpose of facilitating description, the cavity is mapped by vertical and horizontal lines, in a similar

manner to the abdomen.

Refer to— Abdomen — Heart — Lungs — Respiration.

CHEST-WATER IN. -See Dropsy-Pleurisy.

CHESTNUT is the fruit of the Castanea vulgaris; it is nutritious, contains much starch, and no oil, like many others of the nut tribe. It is certainly indigestible from its firm and coherent substance, but is rendered much more unwholesome by being converted into flour, in which state it is largely used on the continent. Roasted chesnuts are more wholesome than raw,

but are not fit for weak stomachs.

CHICKEN POX is a mild eruptive disease which spreads by infection, and chiefly attacks children, occurring once during life. It is preceded in most, but not in all cases, by slight feverishness, for one or two days. The eruption first appears in the form of conical pimples with a white head, on the breast, shoulders, and neck, more sparingly on the face, and on the body generally. On the second day, the vesicles appear like little globular blisters, but with very slight surrounding inflammation; on the third and fourth days, the fluid they contain becomes opaque or whey-like; they now either break or shrivel up, forming thin puck-ered crusts, which fall off piecemeal in one or two days more, seven or eight days being the whole time occupied by the course of the dis-Little or no treatment is required beyond a gentle aperient repeated once or twice, and care taken that the child does not irritate

premonitory fever, and by the rapid development, course, and different form of the vesicles, particularly in the absence of the central depression, which characterises the true small pox vesicle. The antecedent history, whether or not the child has been exposed to the contagion either of small pox or chicken pox, will also assist in throwing light on the matter.

CHICORY .- The Chicorium intybus, the root of which, when roasted and ground, forms the well-known adulteration of coffee. Some persons consider the admixture of chicory with coffee an improvement, and at all events harmless, but it has been proved that it contains certain narcotic properties which occasionally produce a sense of weight and depression combined with languor and headache. A strong infusion of chicory occasionally acts as an aperient, at other times as a diuretic. In consequence of chicory not containing essential oil, it has not, when roasted, the fragrance of coffee, its infusion has a "sweetish and mawkish taste, and is dark coloured, thick and glutinous." But although chicory is used as an adulteration, there are many to whom it is grateful and who prefer their coffee mixed with it on account of its agreeable flavour. It is always to be bought apart from coffee.—See Caffeine.

CHILBLAIN .- A chilblain is an inflammatory affection of the skin, more particularly of the fingers or toes, caused by alternations of cold and heat, and is characterised rather by irritating and troublesome itching than by pain. Persons of fine skin, scrofulous constitution, or languid circulation, are most liable to suffer from chilblains, and old people and children more than those of middle life. The sudden exposure of the skin when very cold, to a high temperature, is generally, and justly, considered to be an exciting cause of the affection, but one quite as frequent, is keeping the surface in a state of artificial warmth by the use of sleeping socks and hot applications in bed, or of fur-lined shoes and foot-warmers in the day-time. All these appliances keep the skin in a continual state of unnatural perspiration, weaken its tone, and so render it more susceptible of the effects of cold when exposed to it. To prevent chilblains, in the predisposed, the feet ought to be regularly bathed with cold-or, in the case of the aged, tepidwater, or salt water, every morning, and afterwards well rubbed with a rough towel, and exercise trusted to, to preserve the warmth of the extremities rather than artificial heat. When chilblains have formed and the skin is unbroken, stimulant applications are requisite; numerous remedies are employed; spirit, such as brandy, camphorated spirit, glycerine, or even turpentine, will any of them be of service, by scratching.

Chicken pox might be mistaken for modified small pox by the inexperienced; it is distin-

discharges a thin slimy fluid and is often difficult to heal. In this case, the inflammation should be subdued in the first place by means of a poultice, and afterwards an ointment used, made either with forty drops of goulard, or ten grains of red precipitate, to the ounce of lard. Of course all friction or pressure from boots or shoes must be guarded against.

Chilblains, when the skin is unbroken, are frequently quickly cured by the following :-Take of tincture of iodine, two drachms; chlorinated solution of soda, six drachms. Apply over inflamed parts twice or thrice daily, drying

in before the fire.

The following ointment is also very good, and may be used whether the skin is broken or not:-Take of benzoate of zinc, one scruple; fresh lard, one ounce. Mix. To be applied

night and morning.

The following domestic remedy is also sometimes of service:-Shake well together in a bottle, spirits of turpentine, white vinegar, and the contents of an egg, in equal proportions. Rub gently when the chilblains are in a state of irritation, and until the redness and swelling are dissipated.

Two parts of glycerine to 100 of collodion make an excellent protective application.

When there is great pain and irritation, the following powerful remedy may be used :-Take of tincture of aconite, an ounce and a half; atropia, two grains; rectified spirit, half an ounce. Mix. Mark Poison. Twenty drops to be rubbed into the affected parts night and morning. N.B.—It is not to be applied where the skin is broken.

CHILD-BED. The term may be applied either to the actual labour itself, or to the confinement generally, from the first commencement of the symptoms to the completion of convalescence. It is in the latter sense it will

be considered in this article.

The process of child-birth consists of a series of the most beautiful adaptations to the mechanism, the structural and vital endowments of the human frame, with every providential provision for the safety both of the mother and infant, during the trying but important event.

When the full period of pregnancy is completed, the process which is to free the womb of its contents, commences with the preparatory relaxation of the various parts connected with the passage of the child into the world; shortly, the long-closed orifice, or "mouth" of the organ begins to open or dilate, allowing, in the first place, the protrusion of the membraneous bag which contains the fluid, or waters, in which the infant floats, and which protrusion forms a soft wedge, dilating the maternal structures preparatory to the passage of the hard head of the infant, which follows as pro-

becomes, in great measure, the dilating agent Although not in the position at the commencement of labour, at its conclusion, the head of the infant should pass from the mother with the face looking directly backwards, and in the great majority of cases it does so, attaining the position by a series of turns which cannot be profitably explained to the unprofessional. In some cases, however, the position of the head is reversed, so that it passes with the face directed forwards, causing a more protracted and painful labour. Moreover, the head may not come forward, or "present" first, at all, but some other portion of the child, causing an irregular or cross birth.

Most women form, or endeavour to form, a calculation as to the period at which they may expect to be confined, and while some do it with considerable apparent exactness, others get far wrong, much to the inconvenience of themselves and of those appointed to attend upon them. The most usual calculation as regards the duration of pregnancy, is forty weeks from the last menstrual crisis, and this is generally made the basis of the calculation; but as more cases fall within the period than extend beyond it, it is safer for expectant mothers to arrange their preparations for the thirty-eighth week than later. By some it is thought, that the duration of pregnancy in the case of a male child is longer than in that of a female. however, cases of premature confinement of living children are not uncommon, it is always desirable that essentials be provided for, as early

as possible.

While with many women no indications of the approach of labour are present until slight pains from the contraction of the womb occur, with others, usually about three weeks before confinement, there is a well-marked descent of the abdominal swelling, giving rise to some diminution in the waist measurement, and increased comfort and freedom in breathing and This is occasionally accompanied by walking. some irritation of the bladder and increased frequency of passing water, the womb apparently pressing somewhat on the bladder and diminishing its capacity. During this stage the comfort of the expectant mother is much promoted by attention to the regular daily action of the bowels, either by enemas of warm water, or by laxatives, such as liquorice powder or confection of senna. The actual confinement commences with pains resembling slight colic, felt in the abdomen and sometimes also in the back, and recurring at more or less regular intervals. These are not unfrequently accompanied by a slight discharge which may be simply slimy mucus, but which is often stained by blood.

As time advances, the pains become more pelled by the expulsive efforts of the womb. Sooner or later, however, this membraneous bag gives way under the pressure, the waters are discharged with a gush, and the head itself from six to twelve hours, but may, of course, defined and regular, and when these, the

CHI

much exceed, or fall short of this stated period. | arrangements most suited to her individual During its continuance, the mouth of the womb undergoes "dilatation," or full opening. Towards the close of the first or dilating stage of labour, the pains are altered in character, and become expulsive, or as they are popularly termed, "bearing down," at first slightly so, but as the process advances, their forcing character is more strongly marked, and in most instances, the nearer the birth of the child, the more powerful and more frequent they become, until at last the infant is expelled. Generally towards the middle of the expulsive stage, the "waters" are discharged; the sudden gush sometimes causes alarm to the inexperienced, who ought on this account to be forewarned of the circumstance. The whole process of labour, in the case of first children, averages from twelve to thirty hours; it is, however, not only as regards time, but in every other respect, liable to great variation. Attacks of spurious pain, resembling true labour, are not uncommon during the last month of pregnancy, but these may be known by the absence of the previous sinking, and of most of the other symptoms above enumerated, as characteristic of the real process. The attack is often the result of confined bowels, or of indigestion, and is removable by a table-spoonful of castor oil with ten drops of laudanum, or by a dose of rhubarb and magnesia. Occasionally, active labour commences with a species of spurious spasmodic pains, which want the regularity of the true ones, and only tease and exhaust the patient, who is herself conscious that they are "doing no good." In such a case, the best treatment is to administer five-andtwenty drops of laudanum, and to keep the patient perfectly quiet, so that she may sleep, if possible; if she does so, in all probability she wakes in a few hours with real labour in full activity; but sometimes even if sleep does not intervene, the anodyne seems at once to convert the spasmodic into the real useful labour pain, and contrary to its usual effect, actually to stimulate the progress of the case. Occasionally, when labour has reached a certain stage, pain becomes suspended without obvious cause, and continues so, for a longer or shorter period: in such cases patience is the best resource, unless the cessation of pain appears to be connected with some of the complications of child-birth to be hereafter noticed. The discharge of the waters is sometimes the first sign of the commencement of labour, or perhaps, more correctly, their discharge from imprudent exertions, such as shakes, jumps, &c., hurry frequently occurs, when some other portion of the child than the head is first in the birth. It being presupposed, that every female. expectation of her confinement, if inexperienced herself, will, under the advice and guidance of moved, and whatever may be wanted put in female friends, provide for, and make those order; the guard placed upon the bed, and the

case and circumstances, as soon as the first symptoms of approaching labour exhibit themselves, the female attendants ought certainly to be summoned; but should a medical man be engaged, it is proper before sending for him, to feel assured that the process has commenced in earnest. When, sinking pains recurring regularly every ten minutes or quarter of an hour, are accompanied with slight "show," as the discharge of slimy mucus is termed, the medical attendant may be safely summoned, and he will, or ought to, see to all subsequent details.

When female attendance is trusted to, these details require to be carefully and judiciously

insisted upon:-

A lying-in chamber ought to be as roomy, and, whilst free from draughts, as well ventilated as circumstances will permit (see Bedroom); it ought too to have a fireplace, which it is ascertained beforehand can be used without half suffocating the patient with smoke—not an uncommon annoyance. The bed should be of such moderate height, that an attendant can conveniently give assistance to the patient. A mattress is always preferable to feathers, and curtains, as in beds generally, are better dispensed with. In addition to the ordinary furniture, a night-chair and bed-pan should be provided; and a vessel of some kind which can be used as a bath for the infant. Some waterproof material is requisite for "guarding" the bed against injury from moisture. Formerly, a prepared skin used to be the general material, but there are now many waterproof articles, quite as well or better adapted for this purpose. Sheet gutta percha answers well, and is cheap. An easy chair, a bottle for pure water, a little brandy, a fan, and bottle of smelling salts, cups and vessels, including a sick-feeder (see Bedroom) for administering either food or medicine, are all advantageous additions to the numerous little etceteras; these are, sponge, washing flannel, and starch powder; a little vaseline, or cold cream, soft towels, and abundance of napkins or doubles; four ties or ligatures, each six inches long, and composed severally of four plies of stout linen thread; a pair of blunt-pointed scissors that will cut, and a flannel receiver for the infant. A little laudanum and sal volatile ought always to be at hand; but when a medical man is in attend ance, he more generally carries these with him.

One female friend, and no more, in addition to the nurse, should be present at the accouchement; but it is advisable to have another female in the house, though not actually present in

should be prepared, all extraneous articles re-

upon her left side near the edge of it, there may be plenty of room for those about her to pass The patient herself ought to be encouraged to walk about, and her mind kept occupied and cheerful by conversation; light nourishment, such as a cup of tea or gruel, being given as desired, in small quantity at once; at this time too, if the bowels are at all confined, they should be unloaded by a dose of castor oil, or better still, by an enema, consisting of a pint of thin gruel, to which a tablespoonful of olive oil is added. As time advances, and as soon as the pains exhibit signs of "bearing down," the patient if not previously undressed, should now be so, and the folded binder (see Binder) placed on the abdomen, so as to give gentle and equal support. The patient may still continue to walk about a little, but as soon as the pains become decidely expulsive, she must be placed in bed upon her left side, and remain so, unless raised up for necessary purposes, until the infant is born. During all this time the room should be kept moderately cool—if regulated by a thermometer, about 60° Fahr. The patient, most likely, particularly towards the end of her labour, will become extremely hot, and then the occasional and moderate use of the fan is very agreeable. She should be induced, from time to time, to take a few spoonfuls of gruel; but the stomach is not to be overloaded, and above all things, the pernicious and too prevalent custom of giving stimulants, brandy, rum, &c., is to be avoided. A case which really requires such aids, requires also the presence of a medical man to sanction and regulate their use; if given when not required, feverish heat, headache, thirst, general uncomfortableness, and, it may be, after bad consequences, are the only results. Amid the poorer, and indeed among some of the better classes in the country, it is customary for patients to be "put to-bed," in their dayclothes; independent of the uncleanliness of the proceeding, it is not at all times free from danger, when, after the confinement is over, it becomes requisite to remove these clothes, and substitute the night-dress; the usual excuse, that it is for the support given by the stays, is quite inadmissible when the binder is used, which amply supplies the place of the above andesirable articles; besides, the presence of the stays and clothes may seriously interfere with measures which must be taken in some particular cases, such as those of flooding. Another practice which is often followed by midwives cannot be too strongly condemned, it is that of delivery being effected with the patient kneeling on the floor; it is highly dangerous. Such attention must always be given to the bladder that it may be duly emptied, although, in most instances, the sen-

sations of the patient herself ensure this point.
When the last strong pains of labour are

latter so arranged, that when the patient lies | who has, or who ought to have, sufficient experience to be aware of the progress of the case, should elevate the upper knee during the occurrence of each pain, for the purpose of affording free space; this mode of proceeding is preferable to the pillow placed between the knees, which heats, and is always getting displaced. A towel or some such material is frequently attached to the bed post or some fixed point, and many women appear to derive comfort from holding it during the paroxysm of pain; it may be permitted, if it does not encourage too great efforts at straining. The feet must be kept warm; cold feet may retard the frequency and force of the pains.

> It cannot be too strongly impressed upon the minds of all, that child-birth is a natural process, and one fully competent in all ordinary cases-and in more extraordinary ones than might be imagined-to accomplish its end, safely and unassisted. And without assistance or any attempt at assistance, it must and ought to be completed as far as female attend-

ance is concerned.

As soon as the head of the infant is born, the attendant midwife ought to pass her fingers around its neck, to ascertain, as sometimes occurs, that the navel cord is not twisted around it; should it be so, she must endeavour gently to slip it over the head, otherwise the neck may be so strongly compressed as to occasion fatal strangulation. The cord may be coiled once, or two or three times around the At this period also, the mouth and nostrils of the child-if there is any delay in the passage of the body-should be kept as free as possible from the surrounding discharges, which may be drawn in by the efforts to breathe. Neither ought the body, or even the legs of the infant to be drawn from the mother, their expulsion should be left to the natural efforts of the womb, for if too suddenly emptied, its natural action becomes embarrassed, and irregular contraction, accompanied with un-necessary pain and discharge, may be the consequence. The infant being fully born, the navel cord must be tied by the ligatures, which have been ready provided; the first being placed about three fingers' breadth from the body of the child, and the other about an inch and a half further; the intervening portion of cord being divided by the scissors. The infant now separated from the mother is to be placed in the flannel, in the arms of the nurse, and put in a moderately warm situation.—Sec Childhood.

In tying the navel cord one or two cautions are requisite. The first ligature must not be placed nearer the body than the distance abovenamed; and before the second is put on, it is well—to prevent spurting—to squeeze the blood up towards the body of the mother, out of the intervening portion. For cutting the cord, a pair of blunt-pointed scissors should be expelling the head of the child, the midwife | used, and care taken at the moment, that no

other portion of the child is intruded between | cases must be left to female care, the foregoing the blades; it has occurred that a finger or toe has been lopped off by a careless attendant. After the cord is cut through, the cut extremity attached to the child must be carefully examined, to make certain that it does not bleed, particularly if the cord be thicker than usual, in which case the tying must be most carefully performed. From careless tying and neglect, infants have bled to death from the navel vessels immediately after birth. Should the infant not appear to breathe as soon as born, it is well to delay the severance of the cord for a minute or two, whilst at the same time the mouth and nostrils are freed from all adhering mucus, and efforts are made to rouse, by blowing upon the face, or by two or three smart taps on the back. As soon as the infant is separated from the mother, it is proper to ascertain by the hand placed upon the abdomen that there is not a twin child; if there be, the remaining bulk will indicate it in a way that can scarcely be mistaken, and should it prove so, the recurrence of the pain which is to effect the expulsion of the second child, must be quietly waited for, unless hæmorrhage, or some other occurrence, dictates a different course. In most cases of twin children, the second is quickly and easily born after pain sets in.

As soon as the child is born, the nurse should place her left hand on the abdomen, underneath the binder, and grasp gently but firmly the contracted womb, which can be felt easily as a hardened globular swelling inside the abdomen. This grasp should be kept up until theafter-birth is thrown off, and for a few minutes afterwards. When the hand is taken away, the binder should be tightened at once, and a warm diaper applied. At this time, chilliness, succeeding the profuse perspiration, is often complained of, and should be counteracted by some additional covering. The female must now be allowed to remain quiet, but not left alone, and so far attended to, that any symptoms of faintness, or undue discharge of blood-flooding-may be detected. If all goes well, in the course of half an hour, if desired, a cupful of gruel or arrow-root may be given; in the course of another half-hour, a dry, warm, open, flannel skirt, and dry napkins should be substituted for those which have become wet; by this time, everything ought to be arranged and quiet for the patient's repose.

Such are the incidents of natural and regular labour; and could we calculate upon the process following undeviatingly the same course in all cases, it might safely and at all times be left to the care of judicious and instructed females; but, as too well known, accidents and difficulties of the most formidable nature will arise, which tax to the utmost the skill

directions will, it is trusted, lead to their safer and better management, whilst those which are to follow, are intended to point out what cases ought never to be trusted to a female attendant, and what symptoms occurring in a case under female care, indicate the approach of such difficulty or danger as requires the attendance of the male accoucheur. As a general rule, in a first confinement, it is desirable to have the attendance of a medical practitioner, and especially so, should the female be the subject of any deformity, such as curvature of the spine, should she in early life have suffered from any tendency to rickets, or been the subject of epileptic fits at any period of life. Also, if there exists any suspicion of heart or other organic disease. If a previous confinement has in any way been irregular, or has required instrumental or artificial delivery of any kind; if convulsive fits have occurred; or if there has been flooding, either from difficulty with the after-birth, or any other cause, the woman ought never to trust herself in the hands of a female.

When a midwife, either professed or otherwise, is in attendance upon a case, fainting coming on at any period, any symptoms of wandering or delirium, or of convulsion, any unusual discharge of blood whilst the process is going on, should at once be the signal for summoning medical assistance; also, should the labour be more than usually protracted, without obvious cause, provided the pains are regular, sufficiently numerous or forcible; should the navel cord, or anything unusual, such as the infant's hand, be felt protruding externally; and lastly, if after the child is born there is any difficulty with the after-birth (see After-birth) either with or without flooding.

In protracted labours, or in what may be termed the accidents of labour, delivery by means of instruments is much more readily had recourse to than formerly, and many a life, both of mother and child, has been saved by their use, of course, in educated and skilful hands. Powerful for good, they are also powerful for mischief, if clumsily applied. The prejudice against the use of instruments has greatly died out, and women who have experienced the benefit in one confinement, will frequently ask for instruments to be used in another.

In the interval which must or may elapse in many cases before medical assistance can be obtained, should fainting come on, the female must be laid on the bed with the head on a level with the body, air should be freely admitted around her, and smelling-salts used to the nostrils, whilst brandy, or sal volatile is administered by the mouth. It ought to be ascerand nerve of the well-educated practitioner; and with some, this is an argument why every case of confinement should be attended by a medical man—in many situations at least, a physical impossibility. As, therefore, many

tions to the head, and mustard plasters to the calves of the legs; whilst, if the person be of full habit, and if the face is full and flushed, from six to a dozen leeches are to be applied to the temples. In all cases of unusual discharge of blood, the measures recommended under the article Abortion are to be employed, and it must be borne in mind, that if the accident occurs after the birth of the child, the womb the walls of the abdomen, and gently kneaded, while napkins wrung out of cold water are applied repeatedly to the external parts. In a case of sudden and profuse outward flooding after the birth of the child, occurring in a thin individual, much may be done to arrest it, by some one instantly pressing the hand firmly and steadily upon the belly—at the navel -until the pulsation of the great main artery, or aorta, is felt, and felt, as arrested by the pressure, to beat up to the hand, but not beyond it. Women of full florid habit have more tendency to flooding, especially internally, than

those of spare make.

It must, however, be kept in mind that alarming, and even fatal loss of blood-internal hæmorrhage as it is called—may be going on within the womb, and yet be unmanifested by any outward flow, the first signal of the mischief, probably, being faintness, and if the abdomen is now examined, it will be found to have enlarged more or less since the birth of the child. This dangerous condition requires the most energetic and well-directed efforts of a medical man to save life, and not one moment should be lost in procuring the assistance. In the interval, the binder well spread over the bowels, and two or three folded napkins placed underneath it, to assist the pressure, is to be tightened well up, and in addition, firm pressure must be exercised with the expanded hands of an attendant on the outside of the binder. this method, the ordinary attendants will do much to retard the further filling of the womb with blood; at the same time cold is to be used to the lower part of the bowels, and absolute rest maintained. The medical man, on his arrival, will take much more active measures which could not properly be employed by others. The above dangerous accident of the lying-in chamber will sometimes occur in spite of every care, but it frequently results from bad management, such as too sudden emptying of the womb by abstracting the child, instead of allowing the natural efforts to accomplish the entire process; by impatience with the after-birth, neglect in putting on the binder insufficiently, or not at all, or by moving too soon after delivery. The existence of cough has a tendency to promote its occurrence. The occurrence of internal flooding is sometime indicated by continued pain complained of in the bowels or back, different from the usual intermittent after-pain.

fect quiet, and by the free use of cold applica- | lying-in room, it should be the endeavour of those around to avoid the excited hurrying, which too often seeks to do everything, and does everything but what is right. This is one reason at least why it is proper to exclude all but the necessary attendants, and especially mothers, from the scene; they communicate their own alarm to the patient, and aggravate the danger, if it exists, by so doing.

occurs after the birth of the child, the womb should be grasped firmly by the hand through the walls of the abdomen, and gently kneaded, relieved, it should now be so; a little light nourishment, such as gruel, taken, and the infant applied to the breast, whether it appears to contain milk or not (see Breasts). If the confinement be a first one, the after-pains will scarcely give trouble. When they are severe, twenty drops of laudanum may be given in a little water (see After-pains). Perfect quietude

is to be observed.

Sponging the parts involved in child-birth with a weak lotion of Condy's fluid is very desirable, and should be repeated two or three times daily for the first few days after confinement, and twice daily for at least a week after. Every precaution for the most extreme cleanliness should be observed; and the night-dress and sheets changed as frequently as may be

necessary.

It is not probable that the bowels will act of themselves, particularly if opium has been given; it is therefore right on the morning of the third day after confinement to give an Castor oil is almost universally preaperient. scribed; but when the person is of full habit, and if there exists any tendency to fever, a common black draught is preferable. After the bowels have been moved, the patient, if going on well, is to be allowed an improved diet. According to the state of the patient, a little solid animal food is to be allowed with the moderate use of tea or coffee. At the end of the week, if all goes on well, the female may get on the sofa, towards the tenth day begin to put her feet to the ground, and gradually return to her usual mode of life. During the whole of the convalescence, there is no greater comfort, or more salutary practice than the free use of tepid water, so as to preserve the strictest cleanliness; by the use of waterproof sheeting, drawn under the patient, it may be fully employed without wetting the bed.

When the confinement has been a moderately favourable one, if the foregoing directions are attended to, there are few cases that will not progress regularly to complete convalescence; it is true, that among the poer, some of the means and conveniences cannot be carried out or procured so fully as could be wished; but the most essential, fresh air and cleanliness, are mostly at command, and might be more freely taken advantage of than they are, and in all cases something like moderate care ought to be observed-which is too often not the case. Lastly, whatever accident may occur in the As regards comforts and conveniences, in

no way can the charity of the more fortunate be applied to the relief of their poorer sisters, than in the bestowal of articles of food and clothing, suitable to the time of trial, when

poverty is often so severely felt.

But recovery after child-birth does not al-ways preserve the smooth course. The accession of the milk may be accompanied with feverish excitement. This, if not extreme, is to be allayed by means of aperients, castor oil, black draught or Seidlitz powder and effervescing saline draughts, to each of which may be added five grains of nitrate of potash. Within the first few hours or days after delivery, the woman may be attacked with shivering, or rather shaking so severe as to shake the bed, succeeded by heat of the skin, thirst, delirium, and with or without severe pain in the bowels; she is attacked with child-bed fever, and cannot be too quickly seen by a medical man. In the meantime, the diet must be kept at the lowest ebb; if time must elapse before efficient aid can be got, there should at once be given a pill composed of one grain of opium and five grains of calomel, and the dose of opium repeated regularly every six hours; if pain is severe, a dozen of leeches at least, if they can be procured, must be put on the abdomen, and if not, light fomentations continually applied. If the bowels have not been moved, they must be opened by an enema of gruel and castor or olive oil. The thirst is to be relieved by toastolive oil. water freely allowed. But the above active measures are not to be the substitutes for a medical attendant; the attack threatens life, and may require all that skill can do for its removal; if only a few hours are likely to elapse before aid is procured, the fomentations, a single dose of calomel and opium, and the enema, should only be resorted to.

If a woman, at any time during the first few weeks after her confinement, becomes excited and talkative, if she wanders slightly, if the eye becomes restless and wild-looking, and if sleep is absent, she requires immediate attention, for an attack of child-bed mania is probably impending. A medical man should be immediately summoned. In the meanwhile, the most perfect quiet is to be preserved around the patient, who should be placed in bed, in a room with the light slightly shaded; cloths dipped in cold or iced water are to be applied to the head, the feet kept perfectly warm, and the bowels, if confined, opened by a gentle aperient, but not purged. This, perhaps, is all that it is desirable should be done before the case is seen by a prefessional man, but on an emergency it may be requisite, without this aid, to resort to the use of opium-Battley's sedative solution is the best-of that ten drops, or of laudanum, fifteen drops, along with a grain of ipecacuanha powder, should be given in a little water, every half-hour, till quiet sleep is procured, or till at least four doses of either of the above have been administered.

Occasionally, shortly after labour, the skin of the patient becomes covered with a "miliary eruption, consisting of numberless points re-sembling minute blisters. This is generally the result of excessive perspiration, and was much more frequently met with in former times than now, that a more cooling and rational system has been adopted.

The principles to be kept in mind in the domestic management of child-birth, by those in attendance are:-to have everything in order and ready at hand; to exclude all useless attendance; to encourage the mind of the patient; to preserve the moderate temperature of the room, and its free ventilation; to abstain from giving stimulants, and from loading the stomach with food; to have the bowels clear; to avoid all meddling interference; to summon medical assistance on the first appearance of anything unusual; lastly, let the patient be assured, that the process, though a painful, is a natural one, and He, who has ordered its marvellous arrangement and adaptations, will

be present in the hour of travail.

CHILDHOOD. - INFANCY. The period of childhood, including infancy, may be said to extend from birth to the thirteenth or fourteenth year, and truly may it be said, that the child is the father of the man, for upon the original constitution, and upon the physical and mental training of this most important epoch of human life, depends in great measure the usefulness, and consequently the happiness -it may be the eternal welfare-of the future man and woman. The subject of the manage-ment of childhood, all important as it is, can, however, be but briefly treated of in a work like the present; and the reader who wishes further information than is to be found under the head of this article, is referred to the admirable work of the late Dr. Andrew Combe.

Infancy (continued from Child-birth). -When an infant is born, should it, in consequence of protracted labour or some other cause, not draw breath, and appear purple on the surface, it is advisable in the first place to pass the end of the finger, covered with a piece of thin calico or linen, into the mouth, for the purpose of clearing away the stringy mucus which not unfrequently obstructs the passage of air into the lungs. If, under these circumstances, the navel cord continues to pulsate, it should not be tied for at least two or three minutes, during which efforts are to be made to rouse the child, by blowing sharply on the face, or by one or two slight slaps on the back; at the same time an attendant ought to be getting a warm bath (temperature 98° Fahr.) in readi-If, after the lapse of time above mentioned, animation still seems suspended, the cord should be tied without further delay, and the infant at once removed and placed in the warm water up to the neck, the body being well supported, and the mouth and nostrils carefully kept from being accidently submerged.

obstructing mucus as above directed, some one, whilst the nostrils of the infant are closed, should, by placing their mouth over that of the child, endeavour to inflate the lungs with their breath, and then withdrawing the mouth, to empty them by pressure exerted upon the abdomen and sides of the chest. The direct effort to inflate the lungs having been repeated a few times, the artificial respiratory movements-alternately pressing upon the ribs and abdomen, and allowing them to recover by means of their own resiliency-should be persevered in for a considerable period. In these cases of suspended animation in infants, electricity is unquestionably a powerful restorative; but hitherto the difficulties attending its ready application just at the moment, having rendered it almost unavailable. Most medical men now possess in comparatively small compass an electrical apparatus of some kind, which is always serviceable in cases of suspended ani-

When an infant exhibiting full signs of life is separated from the mother, and placed in the flannel receiver, it must not be covered up too closely—the caution is not superfluous, for infants have actually been smothered in this way by the extra carefulness of the nurse; it must, too, be placed where it will be warm. As soon as the child can be attended to, it ought to be examined all over, to ascertain whether it be perfectly formed; and the tying of the navel cord should be seen to be secure. Washing with warm soft water (temperature 98°), soap, and soft flannel, is the next requisition. The skin of a newly-born infant is covered with a white unctuous matter, which is to be removed; this should be done as gently and effectually as possible, without fraying the skin, the arm-pits and other folds of the body being particularly attended to. The child, after being washed, is often dried upon the receiver, placed on the nurse's knees; a better plan is, to have placed on the lap a moderately soft pillow, covered with two or three large warm napkins, on which to lay the child. The drying, which should be done, in cold weather, in front of a warm fire, having been effected gently, without scrubbing, a little starch powder should be dusted into the folds of the groin and arm-pits, but not elsewhere, unless the skin appears frayed. The portion of the navel cord remaining attached to the child, is now to be wrapped in a piece of soft linen, which is kept in place by a binder of fine flannel, five inches wide, and long enough to pass twice round the body of the child, so as to give sup-port without pressure, and fastened by needle and thread-not by pins : if too firmly applied the respiration of the infant is interfered with. The remainder of an infant's clothing is so much regulated by custom and other considerations, that it is unnecessary to mention it here,

The mouth and throat having been cleared from | be perfectly loose and easy, and fastened entirely by tying or sewing. A cap should never be placed upon a child's head, which is naturally hot enough to do without artificial covering. When the infant has been dressed, it should be laid to rest in the cradle, or place prepared for it, perhaps beside its mother, but at all events where it will be sufficiently warm. It will probably sleep for some hours. It ought not to be fed for the first few hours after birth. As too frequently practised, the unfortunate baby is dosed with "rue tea," "sugar and butter," or some such mess, or stuffed with soaked bread or gruel, and the first foundation laid of the disordered bowels, wind. screamings, &c., which are so general in young infants. When the infant wakes from its first sleep, or, at all events, in the course of four or five hours after birth, it should be put to the breast; even should there not be sufficient secretion of milk to satisfy the child, it is well both for it and the mother, that it should be thus early induced to take the nipple. If, as may occur, the milk-flow is delayed, it will be necessary to give the infant the artificial support of cow's milk, unskimmed, but diluted with nearly half water, and very slightly sweetened, this may be given, either from a common nursing bottle, or by means of a spoon, but the former is preferable. On no account should anything like bread, gruel, or the like be allowed to pass the lips of a newly-born infant, unless under the pressure of extreme necessity, such as might happen on board ship, and then, the powder of grated biscuit, or of twice-baked bread, softened in water, is the least hurtful substitute. The first milk of the mother is thin and serous, and is generally considered to exert an aperient action upon the infant's bowels, by which the slimy olive-green discharge named "meconium." which first occurs from them, is carried off. Should the bowels not act within twenty-four hours after birth, from six to eight drops of castor oil should be given, mixed with a small quantity of moist sugar. Should this have no effect, it may be repeated; but should the infant appear to make the straining effort to relieve the bowels, without its being effected, the vent ought to be carefully examined by a medical man, as it may happen that closure of the bowels, complete or partial, exists, but which may, nevertheless, be remediable. The case is not common, but its possibility is not to be forgotten.

The majority of mothers are able, and ought, as a sacred duty, to nurse their own infants; but cases occur in which, from illness succeeding the confinement, or from general weakness of constitution, a female is unable to do so, either with benefit to herself or the child. When she cannot, it becomes a serious question, whether the duty of nursing is to devolve upon another, or whether the infant is to be brought up by hand. The general further than to impress the rule that it should | voice says the former, the author confidently

CHI

first place, it is requisite to provide a nurse, whose own infant is of the age, or nearly so, of bottle, which should always be of glass. There the infant to be wet-nursed; it will not do to are many varieties of feeding-bottles in use. put a young infant to the breast which has The essential feature should be that it can be been nursing for many weeks or months. This is the first but the lightest difficulty. But cludes all bottles which have india-rubber there is a much more serious consideration. We tubing, as it is impossible to be satisfied of the have yet to learn the full measure of influence, both physical and mental, which may be exerted upon the child by the peculiar physical and mental constitution of the foster-mother from which it draws its first nourishment. It is true, the physical development is generally rigorously scrutinised, but how are passions and mental tendencies to be measured ?- and we do know that the class from which wet nurses are often selected, are certainly not in the habit of controlling their appetites and passions; and farther we know, that the physical qualities, at least, of the milk, are very liable to be affected by the mental emotions of the nurse; here at least is one source of danger, were we sure, which we are not, that there is no deeper, more lasting, life-felt influence exerted. And withal, it is quite possible, that some physical taint, venereal perhaps-it has happened and may happen-has escaped the searching examination of the selecting physician. These are all serious considerations for a mother before she submits her child to draw its first nourishment from the body of a stranger, one too, who must either be suffering from the intense grief which every mother feels who loses her infant from her breast, and whose milk must be affected by that grief, or who must have been compelled by poverty, and all its physical evils, to undertake the task; or one whose mental constitution is so unscrupulous, that, without necessity, she will consent for gain to cast aside her own infant, and, at the risk of its welfare, give its birthright to a stranger. Are any of these the qualifications which a mother will choose for the nurse of her child, even if she has the selfishness to tempt another to desert her own legitimate offspring? Medical men often witness the painful sight of one infant declining away, whilst the mother is nourishing another into strength. The system and importance of wet-nursing has been much over-rated; for it is perfectly possible, if the care and trouble requis-ite will be incurred, to bring up a child by hand, as well and healthily as at the breast of a foster-mother. Care and trouble it does involve, but if these are grudged, the child had better go to its grave at once.

In bringing up a child by the hand, milk must be its only nourishment for the first three or four months. Ass's milk, or goat's milk, may be employed, but more generally cow's milk will be used, either with or without the cream removed, according to its richness, and according-as the first few days' experience will show-to its effect upon the infant. The milk is to be diluted with one-half water, and just

asserts that the latter is preferable. In the perceptibly sweetened. It is not to be given by spoon, but by means of a common nursingcleanliness of the interior of the tubing. of the best forms is made by Messrs. Allen & Hanbury. The bottle is open at both ends, and when empty can be washed by allowing water to flow into one end and out at the other. When in use one end is closed by a hard rubber stopper; the other has attached to it an india-rubber teat, which can when desired be turned inside out, and thus kept perfectly clean. Both the bottle and the india-rubber teat should be washed most carefully after each meal; if it is done immediately there is no need to use anything but water for the purpose. If the cleaning is postponed for an hour or two, it is better to use hot water to which a little boracic acid has been added; and the teat should be scrubbed with a small The time and care given to the feeding of the infant and to the cleanliness of the bottle will be well repaid by the increased comfort of digestion, and by the satisfactory progress which will be observed.

Of these bottles there should be two, both on account of accidents, and also, that the unvarying and essential cleanliness may be Without the most scrupulous careobserved. and on this depends the success of bringing a child up by hand-the purity and wholesomeness of the food cannot be preserved. The milk and water should be mixed fresh, at least twice a day, and, in summer, kept in vessels immersed in cold water; it is to be given to the child at nearly the temperature of the bodyabout 98° F. Again it is repeated, that the most thorough cleanliness, in milk-can, bottle, and teat, is to be observed, and must, except in rare instances, be a mother's care. Another caution is requisite. In feeding children from some bottles, careless nurses may frequently be observed to incline them the wrong way, so that the infant goes on for a time sucking wind. Thick food may be given with most feedingbottles by using a differently perforated leech-bite teat. Where the old forms of feeding-bottles are used, one little matter requires special attention, namely, the ball valve at the top. This little valve is generally formed by a pea of metal, and should this metal be of such a

nature, for instance lead, as to be slowly acted | curdy evacuations, a change to a bouilli made upon by the milk, the most serious consequences may arise; in fact, an infant may be slowly undergoing lead poisoning, without any one in the least suspecting the cause of the illness. Such a case occurred within the writer's knowledge, and was only detected by the acumen of the physician called to consultation.

For the first three or four months this milk and water food is all that is requisite, with the addition, if at any time the bowels should be too much relaxed, of a portion of isinglass, from one to two small tea-spoonfuls dissolved in the half-pint of fluid. About the fourth or fifth month, a small portion of arrow-root or wheatflour may be boiled in the water before it is added to the milk, and about the seventh or eighth month, the spoon may be used to give some of the more solid milk and farinaceous hours for the first three months at least, about four table-spoonfuls or one ounce and a half on the average being given at once at first, and the amount gradually increased. Small delicate children, however, will scarcely take half the amount above stated, and great care must be taken, both with them and others, not to allow the stomach to be overloaded. If an infant is habitually sick after feeding, the quantity allowed at once must be reduced, for, though happily the infant stomach relieves itself easily of superfluous food, it is better to avoid the superfluity, than trust to the sickness, notwithstanding the popular fallacy that sickness is a sign of infant health.

The system of rearing by hand is much more prevalent in some parts of Germany than in this country. The following passage from the work of Dr. Andrew Combe, the substance of which he says he derived from the German work of Dr. von Ammon, is so full of practical instruction, that the author makes no apology

for quoting it at length :-

"In some constitutions, however, cow's milk does not agree when merely diluted and sweetened; but answers perfectly well when a large proportion of water and a small quantity of any well-prepared farinaceous substance is added. In this case, it is a common custom in some parts of Germany to dilute the milk with a weak infusion of any light aromatic, such as linden tree flowers, instead of pure water. But after the first month or two, where liluted milk does not agree, a small proportion of well-boiled arrow-root, grated Dutch rusk, or well-baked or toasted bread, sometimes forms a very useful addition wherewith to thicken the milk to the consistence of thin gruel. Briand, indeed, remarks that milk diluted and boiled for a length of time with any light farinaceous substance, is more easily digested by some infants than pure milk: and that when the

of milk and farina, often restores them to a healthy colour and consistence. reason, he recommends panada, made by boiling for a length of time in water, or milk and water, thin slices of bread, previously well dried in the oven. Another of which he speaks highly, is the crême de pain, made by infusing in water for several hours well-baked bread, previously dried in the oven in slices, and boiling it gently for some hours more, adding water from time to time to prevent it becoming too thick. It is then strained and sweetened, and a few drops of orange-flower water are added. For infants a few months old, arrow-root, sago, or semolina, may be used in the same way. The bouilli in common use in France as the first food of infants, is made by gently roasting the best wheat-flour in an oven, preparations. In bringing up by hand, the child will, as at the breast, require feeding about six or seven times in the four-and-twenty sugar to it. When carefully made, not too sugar to it. When carefully made, not too thick, and free from knots, it is considered an excellent food, especially where the use of milk excites a tendency to diarrhoa, or colicky pains. On changing to the bouilli, the digestion immediately improves, and the evacuations become healthy and unattended by pain.

"In some instances, especially when the bowels are sluggish, barley water or thin gruel, with or without the addition of weak chickentea, or beef-tea, answers best; and the grand rule ought to be to follow what seems best suited to the individual constitution. In soft flabby children, the chicken or beef-tea is often most useful; while in thin, active, and irritable infants, the milder milk and farinaceous diet answers best. But in trying the effect of any alteration, we must not be too rash, and because no advantage is apparent within a day or two, conclude that therefore it will not agree. In many instances, the effects of a partial change of diet show themselves so gradually, that it is sometimes only after an interval of a week or two, or even longer, that we can tell positively whether benefit will result from it or not."

When the infant is to be nursed at the breast of its mother, it ought, as above directed, to be put to it, unless some cogent reason forbids, within six hours after birth, and from that time it will require it every three or four hours for the first few months. It may be requisite, either from weakness of the child, or some other cause (see Breast), to have the nipple drawn out either by a stronger or older infant, or by some other means. Should the mother not be able to nurse her infant entirely, the extra feeding must be conducted upon the rules laid down for bringing up by hand.

It not unfrequently happens that a mother, for some time at all events after the birth of her child, especially if it be her first, is unable to suckle it without great pain, owing to the nipple being so exceedingly tender, that when use of milk alone is followed by white and the child continues its efforts to suck, darting

CHI

nurses are ignorant and foolish enough to believe, and to tell young women that this is good for them, and ought not to be relieved, when the fact is that many women are seriously injured, and run a great risk of abscess and fever from the excessive irritation they are forced to endure. In such cases immediate relief may be obtained by using one of Maw's glass nipple shields, with elastic tube and mouthpiece attached. Nothing could be more simple and perfect. The mouthpiece is just the shape of a well formed nipple, and the glass shield fits over the nipple, supports it equally, and allows of the free, gentle, and painless flow of milk through it. A small brush, attached to a wire, is supplied with each, for the purpose of keeping it quite clean, and the whole is so cheap as to be quite at the service of the poorest of poor patients. Special attention ought to be paid to keep the tube and teat perfectly clean, else the child is sure to suffer in health. They ought to be thoroughly cleansed after each time they are used.

The first few weeks of an infant's life are spent principally in sleeping and taking nour-ishment, movement is but little indulged in, and consequently the power of sustaining the animal temperature is but slight; for this reason care is always requisite that sufficient heat be preserved, both of clothing and of situation, during the day, and by the infant sleeping with its mother or nurse during the night, for the first few weeks of its life at least. Equally important with temperature, nay even more so, is the purity of the atmosphere which a young child breathes; errors in this respect have led to the most deplorable loss of infant life. One instance is sufficient to illustrate the point: it is the well-known one of the Lying-in Hospital in Dublin, in which, at one period, one child out of every six died within the first fortnight of existence, but by the adoption of proper means of ventilation, this very great mortality-was at once reduced to one death for every nineteen or twenty children born. It is unnecessary here to repeat what has been said in the article Bed-room, upon the means of ventilation, &c., and to that article the reader is referred. The craile or swinging cot in which an infant sleeps should not be smothered up with curtains, and it is better, for some time at least, without sheets, light blankets only being used or an eider down quilt.

The mattress should be hair if possible, but where economy is requisite, cotton-wool will answer the purpose; it should be protected from wet by means of waterproof material of some A pillow too large and soft is not advisable, for by allowing the head to sink into it, an injurious amount of heat and perspiration is promoted, and the child rendered susceptible of cold when taken up. The skin of an infant requires the most scrupulous care; by its power-ful agency it frees the body from matter which is applied. The plasters will probably require

pains are felt through the whole breast. Some | must be noxious if retained, and which is especially apt to act injuriously upon the susceptible infant nervous system. The skin ought to be washed with tepid water and soap, night and morning, and after each washing, reaction promoted by gentle friction with the hand for a few minutes. Care must always be taken that the situation for washing is sufficiently warm, but not, as is too often the case, before a scorching fire; draughts of air are especially to be guarded against. Before leaving this subject, it is requisite to notice the filthy custom prevalent amongst the poor, of allowing the scurf, the oily secretion, and the dirt, to cake upon the skin of the head, under the idea that it preserves from cold. The habit is not only disgusting, but is productive of disease-perfect cleanliness is as requisite here as elsewhere.

In fat children, the creases or folds of the skin require extra attention, from the liability of the opposed surfaces to become inflamed, and to pour out an irritating moisture; dusting with starch-powder, or the intervention of a piece of soft linen spread with simple ointment, may either of them be used as a remedy. The portion of navel cord which is left attached to the child, will require attention. This separates by a kind of moist decay; it may come off entirely by the fourth day, or take a fortnight to do so; it must never be hurried. Generally, when the navel separates, it leaves the puckered closing of the skin perfectly complete, it sometimes, however, occurs, that bleeding or inflammation and ulceration take place at the time of separation; such cases ought at once to be placed under medical care. When actual bleeding occurs, the condition is all but hope-When the opening at the navel does not thoroughly close at birth, protrusion of a portion of the bowel takes place when the child cries. This state of things, apt to occur when the cord has been of more than average thickness, requires much attention, as the comfort and safety of the individual, especially of a female, in after-life, may be considerably interfered with if the reals interfered with, if the malformation is not, as it may be, cured in childhood. The belly-band or binder, has of course considerable power in preventing the protrusion through the navel opening; but in these cases it is not sufficient; and for the first few weeks, one or two graduated compresses, made of folded linen, should be placed over the navel, underneath the binder; and when the child is a month or six weeks old, the following apparatus must be used:-from a cork, the diameter of which is about half as large again as that of the protrusion, a slice the eighth of an inch thick is to be cut, flatly padded, covered with linen, and affixed to two cross pieces of plaster by stitching (see fig. 54). The plasters being warmed before application, are used to retain the padded cork directly over

renewal every few days. It is better to trust to | inflammation which takes place in the progress the linen pads alone, as long as any tendency to inflammation of the skin exists, using at the

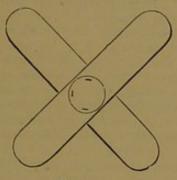

Fig. 54.

same time, water dressing with a thin piece of gutta percha foil or oil silk next the skin. Instead of either linen or cork pad, one of vulcanised india rubber, filled with air, might be substituted. Elastic belts and pads are now to be had at the instrument makers for the same purpose. The treatment of navel protrusion, or hernia, in infants, and the management of the apparatus, involves some amount of care and trouble, but not more than the necessity and importance of the evil demands for its rectification. In such cases, the infant should be kept from crying by all reasonable means, the best preventive being the careful attention to the rules of health laid down in this article.

Rupture at the groin may occur in children at birth, and may be suspected to exist, when unusual fulness or swelling is observed in this situation, and if the fulness and tension is increased when the child cries, the case should at once be seen by a medical man.

Any malformation with which an infant is born, ought as soon as possible to be submitted to the judgment of the surgeon, so that he may have full opportunity of fixing the appropriate time for its rectification or removal. operations for hare-lip, distorted joints, such as club-feet, are now performed at a much earlier period than they used to be formerly. In the case of vascular nævus, or mother-mark, which often increases rapidly from a mere perceptible point to a large size, surgical interference as early as possible is most important. These nævi are composed of so thick a network of capillary vessels as to be almost spongy, and should they be accidentally wounded, bleed freely, and if of any size dangerously; they vary in colour from bright red to purple; if the finger be pressed upon a nævus, it becomes emptied of blood, and pale; but the instant the pressure is removed, the blood, and consequently the colour instantly return. There are various methods employed for their removal; but the one used in each case must depend upon the surgeon; a simple, painless, and frequently successful mode of cure, is vaccinat-

of the vesicle. The possibility of this being done is an additional reason why the disease should be seen as early as possible by a medical man. The continued use of the compound tincture of iodine to a nævus, the surface being painted over with it night and morning, will, sometimes, if perseveringly adhered to, be successful in removing it; the application being intermitted for a few days should the skin become sore.

Tongue-tie in infants is not uncommon; it depends on too great prolongation of the "frænum," or bridle which retains the tongue in place. It is easily rectified by a snip of the

surgeon's blunt-pointed scissors.

The time at which an infant may first be taken out of doors after birth, must depend, of course, greatly upon the time of year; in fine warm summer weather, in the course of ten days or a fortnight, it will be safe to make the change; in winter it can scarely be prudent to do so for a month or six weeks, and then only on a fine day. In either case, free exposure in the house should first be practised, the first airing should not extend longer than twenty minutes, and the eyes, especially at first, must be shaded from the glare of the sunlight: of course, either the chill of morning, or the damp of evening, must be avoided. A young infant should not be taken out during the

prevalence of east wind.

The principal ailments, likely to come under domestic management, to which infants are liable, are thrush, red gum, colicky pains in the bowels, and diarrhea. For the first-thrushthe reader is referred to the article "Aphtha." Red gum is a mild species of "papular" eruption, to which many children are subject soon after birth. It is quite devoid of danger, and requires no treatment if the bowels are in good order, if not, a dose or two of castor oil may be given. The usual friction after washing must be moderate during its continuance. Inflammatery swelling of the breasts in infants is not unfrequent (see Breast). Most infants are troubled, more or less, with wind, or colicky pains in the bowels, and not unfrequently with diarrhœa, but these are much aggravated by the errors in feeding so universally prevalent, particularly among the poorer classes; sometimes when the child is nursed entirely at the breast, particularly of a wet-nurse, they are caused by the nurse's transgressions in diet. Attention to the rules already laid down under the head of feeding, will greatly prevent the above ailments; but when they do occur, they must be rectified as simply as possible, but never by the dangerous and baneful quack carminatives so extensively sold and used. Pain, and wind in the bowels in children, are generally connected with superabundant acidity; for the correction of the cause and its consequences, either of the two following mixing upon the nævus, which is dispersed by the tures may be used moderately, both with safety

CHI

magnesia twelve grains, dill water one ounce and a half. No. 2,-Take of prepared chalk ten grains, dill water one ounce and a half, and to each of these mixtures add twelve minims of chloric ether. Of either of the above mixtures, a small tea-spoonful may be given, and repeated if requisite. The first, or No. 1, is to be selected, should the bowels be at all confined: the second, No. 2, should they be too relaxed. It is not recommended that either of these medicines, simple as they are, or any others, are to be given too freely to infants, and on every slight occasion, but it is better to give them than to allow a child to suffer; they, or something similar, ought to be the substitutes in every nursery for the secret quack nostrums. It is true they will not either as quickly stop pain, or soothe a child, as mixtures which contain opium or poppy syrup; but they cannot, like them, either put it into its last long sleep by an over-dose, or injure not less fatally, when frequently used, even in small doses, by gradually disordering the brain and nervous system. When either of the mixtures above recom-mended is given to children, or indeed whenever magnesia or chalk is given habitually, it is always prudent to give an occasional dose of castor oil, as cases have occured in which concretions of the above antacids have accumulated in the intestines. The dose of castor oil for a young infant may be from ten drops to half a tea-spoonful. In cases of diarrhoea, should the affection be slight, and the infant be a hand-nursed one, the addition of isinglass to the milk food will, in most cases, stop the tendency at once, particularly if assisted by a few doses of mixture No. 2, and by a warm bath for five or six minutes, at a temperature of 98°, regulated by a thermometer. Should the affection be more severe, the emulsion of castor oil with yolk of egg (see Castor oil) must be given. To one ounce and a half of the emulsion, made with a tea-spoonful or drachm of castor oil; two drops of laudanum are to be added, and one tea-spoonful, or twelfth part, given once in six hours. And here the opportunity is taken, to warn, respecting the administration of opiates to children. They are most susceptible of the influence of the drug, and accidents are continually occurring-more frequently perhaps than comes to light-from its effects: a single drop of laudanum has been known to prove fatal to a young infant. The above treatment is given, not as an inducement for parents, who can readily procure medical aid, to take the treatment of their children, when ill, into their can hands, but it is because it may be of service in situations when skilled assistance is not readily procurable. Many of the diseases of children commence insidiously, but after attaining a certain stage, run their course rapidly. No parent, therefore, who either values his child's life, or his own peace course rapidly. No parent, therefore, who either values his child's life, or his own peace of mind, should delay procuring medical assist-

CHI

and good effect:-No. 1,-Take of calcined | ance when real illness shows itself; but at the same time, the very same reason ought to induce every parent to inform himself upon the nature of the symptoms which most generally usher in real illness in children, and also, how and by what means the illness which these symptoms indicate, is to be most effectually retarded and obviated. More upon this head will be given when the diseases of childhood generally are touched upon. Within the first three months of an infant's life, vaccination ought to be performed, that is, before the constitution is liable to suffer from the irritation of teething.

-See Vaccination.

The period of teething varies extremely, and not less so in the manner in which it affects children. For information upon the mode in which the teeth are developed, the reader is referred to the article Teeth. Some children cut the two front teeth of the lower jaw-which generally appear first—as early as the fourth or fifth month, whilst others, apparently equally strong, do not have them developed within the year. The usual, and popularly received sign of approaching tooth-cutting, is watering of the mouth, but this may continue for many weeks before the teeth appear. Before the teeth come through, the gums flatten on the top, look semi-transparent and full, and are sometimes extremely swelled and inflamed. The constitu tion of the child always sympathises more or less with the cutting of the teeth, most simply and beneficially so by the occurrence of mild diarrheea, which is always-unless it goes to an unduc extent-a safeguard, and is better not interfered with. When the gums are much swollen and inflamed, and must be very painful, the susceptible brain and nervous system of the child is strongly and injuriously affected by the irritation. The little sufferer is fevered, flushed in the cheeks, and peevish, sleep is disturbed with moaning and starting, and the fingers are constantly in the mouth, or the lower jaw is moved from side to side. In such cases, lancing the gums thoroughly, warm baths, and aperients if the bowels are not relaxed, are the remedies, the first especially, without which the others are useless or nearly so. The popular idea, that lancing the gums is beneficial, by assisting the passage of the teeth through them, is quite erroneous, and may lead to an erroneous method of performing this simple little operation, which every parent who lives at a distance from medical assistance, and particularly in emigrant life, ought to know how to The real benefit is derived from the relief which the incisions afford to the tense and distended gum, and from the slight flow of blood which follows, and on this account it is advisable, not only to cut the upper surface, but also the side of the gum, so as to divide the vessels freely. The operation is most conveni-

being wrapped with a piece of linen, to within | commences walking it must get falls, but it is a short distance of the point, to prevent any chance cut to the lips. It is superfluous to

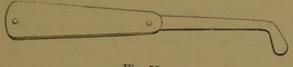

Fig. 55.

describe this simple proceeding, it should be seen done once, or at least the method shown. It is not recommended, of course, that the gums are to be lanced for every slight irritation of teething, but when the child exhibits the graver symptoms above described, it ought to be done at once, and, if requisite, repeated again and again. In addition to lancing the gums, a warm bath for ten minutes will be found eminently serviceable in soothing the irritated system, and aperients should be given—a couple of grains of grey powder at night, followed by a small tea-spoonful of castor oil in the morning, or if stronger action be thought requisite, a powder composed of one grain of calomel to two of powdered scammony is to be given at bedtime to a child of six or eight months old. If the irritation attendant on teething produces convulsion, medical aid must be had as soon as possible, and in the meantime, those remedies employed which are suitable. - See Convulsion.

In judging of the diseases of children, it ought to be borne in mind that the pulse of an infant is always quick, averaging from 120 to 130 in the minute, and that at the end of the first year its average is still considerably above

100.—See Pulse.

The regulation of the exercise of young children is of much importance. At first, the mere respiratory movements, occasional crying, and the effort of sucking, are exercise sufficient, if gentle nursing movements be employed; but gentle they must be; the system so often adopted of jerking infants about is much to be condemned, and may be extremely hurtful. In the course of a few weeks after birth, the infant begins to show signs of increased power of movement, and evidently experiences physical pleasure in the exercise of its limbs; as time goes on, its next effort is to sit up in the nurse's arms, till, if a vigorous healthy child, at about fourteen months, generally, it tries to walk;all these movements will come spontaneously to the child, when its frame and muscular powers are adequate to the exertion, but they should never be forced. It is astonishing what an amount of practical ignorance prevails on the above point; children are put to sit in chairs, held upon their feet, or put in go-carts of various construction, long before the bones are fit to bear the weight, and curved spines and distorted legs are the consequences. Again, it is repeated, every advance of the child towards of real fatigue. At all times it adds much to

surprising how little material injury the head, which most generally suffers, seems to receive. At the same time, in families in which tendency to head affection exists, extra care must be taken—a padded band round the head is a useful and frequently used protection.

When a child begins to walk, and to attempt to talk, the period of infancy may be considered as ended, and childhood begun. Many of the directions applicable to the former are equally so, in a modified degree, to the latter, and vice versa; but Childhood requires further re-When distinct nursing is no longer requisite, the child becomes more truly the inhabitant of The Nursery, and much of its health and happiness for the next few years of its life, will depend upon the proper regulation of this important department of the household.

Whatever is said respecting the necessity for pure air, and proper ventilation, either in this article or in any other, such as Bed-room, applies of course to the nursery, or rather nurseries; for every parent, whose means will admit, should provide a night and a day nursery for his children, and in neither, should such operations as washing clothes, cooking, &c., ever be carried on. The double room will allow of all necessary airings, washings of floors, &c., to be perfectly carried out without the health or comfort of the children being interfered with. Should one nursery only be available, the children should be taken out of it as soon as possible after rising in the morning, the windows thrown wide open, and all necessary cleaning performed before they again enter it, and, both now, and at every period of the day, all kinds of slops removed. Should any action of the bowels take place during the night, the receptacle should be put out of the room at once. The observations respecting the sanitary regulation of the nursery, are more particularly applicable in the case of the middle classes, who want the abundant accommodation of the wealthy, and whose children, in towns at least, do not have the same free access to the open air, as those of their poorer neighbours. The situation of a nursery in the house is important; it must, if possible, be in the upper stories, it should have a south aspect, and be abundantly supplied with light—the latter is a most necessary consideration. A guarded open fire-place is the best means of warmth, and the heat, regulated by a thermometer, should be kept as near 60° as possible.

But, however salubrious the nursery arrangements, children must have as much open air as possible; when the exercise can be taken as play, in summer, upon the grass, or otherwise, it is quite the most beneficial; when weather and other considerations forbid, and walking walking and the upright posture, can only be safe when spontaneous. When a child first engaged pleasurably in it,—and therefore, all

active plays, either in-doors or out, are prefer- | a point which should be settled by a medical able to the mere walk, which few children enjoy.

The clothing during the whole period of childhood, in a changeable climate like that of Britain, requires much attention; woollen texture next the skin, both winter and summer, is indispensable for health; during the former season, it should cover the chest and abdomen, and come at least half way down the thighs; in the latter, it may be a lighter material, and not extend so far over the chest; woollen stockings extending over the knees ought always to be worn in winter, and at all times should the entire clothing be such as will keep the surface of the skin comfortably warm; there is no greater or more fatal error than that which exposes children lightly clad to the influences of our variable climate, with the view of hardening them.

Thorough purification of the skin must be maintained. A child should be washed all over with soap and water at least once a day. In the case of strong children the water may be cold, in the weaker, tepid, and in both friction with a tolerably rough towel should be used after the bath, both to cleanse and to promote reaction. If a child continues chilled and cold-looking, and appears languid after a cold bath, it is a sign it does not agree, and the temperature of the water should be raised, or the washing should first be performed in tepid water, and just at the last, a little cold

water dashed over the body.

The food in childhood claims care, equally with air, clothing, exercise, and cleanliness; its regulation in infancy has already been sufficiently noticed. For strong healthy children, particularly those inclined to full or gross habit, the milk and farinaceous diet—such as rice, sago, bread, &c., cannot be exchanged for a better, for the first fourteen months at least, but if children are delicate, and incline to the lymphatic constitution, the use of animal broths ought to be commenced even as early as the sixth month. The broth made from fowl, mutton, beef, or veal, should not be too strong, should be free from fat, and is better thickened with arrow-root or sago for a young child, or with rice or bread crumb for an older one. Towards the twelfth month, a lightly-boiled egg may be given, but quite the best method of giving the powerful nutriment of egg to children, is to break the raw egg into some one of the milk preparations, whilst the latter is quite hot, and to beat up together. In this way, the albumen is sufficiently cooked, but not hardened. When the teeth of a child are sufficiently advanced to masticate it, animal food in the solid form may be given, but the quantity and frequency must entirely depend upon the constitution of the child. Strong ruddy children are better with it only twice or three times a week, weaker children should have it once a day at least, and in the more advanced stages of childhood, perhaps twice, but this is | mation ending in effusion of water, convulsive

adviser. Potatoes, and the more wholesome vegetables, ripe fruits in their season, may all be allowed to children, in moderation, after the first eighteen months, and particularly should there be a tendency to costiveness, or to eruptions on the skin and other affections depending upon gross habit of body; weaker children may also partake of them, but more moderately, and provided they do not become substituted for more indispensably nourishing food. Children at any age are better without baked pastry of any kind, but boiled paste puddings are not unwholesome,—cheese, and all sorts of spiced and seasoned dishes are quite objectionable. A healthy child should never have an alcoholic stimulant within its lips, and tea or coffee, if allowed, should be very weak, and made with much milk; but there are some delicate chil-dren, nay infants, who may derive much benefit from a portion of alcoholic stimulant, carefully given as medicine, and as medicine requiring so much care and consideration, that it should only be employed when and as advised by a medical man. Children should not be made to wait long without some nourishment in the morning; the rapid changes which go on in their systems render them peculiarly sensitive to any, even temporary, want of nourishment. Regularity in meals is important even from the earliest period of existence; it is always advisable that the principal meal be taken early in the day.

Physical training, however, and the closest attention to physical regulations, require the addition of mental training to carry out thoroughly even the physical education of a child. For the infant a cheerful nurse is most valuable. As childhood advances, whatever may depress or frighten ought especially to be guarded against, and all threats or practices which excite undefined terror especially avoided. Affection of the brain may be the result. Undue precocity in a child should always be regarded, if not with alarm, at least with suspicion. Many scrofulous children are unusually precocious, and as a general rule in such instances, the brain is more prone to disease, which may end life, or predispose to mental affection. In such cases it is of the highest importance not only to avoid everything which can stimulate to mental effort, but to excite them to such moderate and regular physical exertion, as will in some degree draw off from the brain itself, both the activity of circulation

and of nervous energy.

There are some diseases which are more particularly considered as those of childhood, such as measles, hooping-cough, scarlet fever, and chicken-pox; not that they do not occur in adults, but more generally, being passed through but once, it is in the earlier years of life. In addition to the above, such affections of the brain and its membranes as acute inflam-

lungs, and diarrhea, are the most common acute affections of children. These and other diseases may be referred to under their proper heads. Children quickly exhibit the general symptoms of illness, but it often requires much more tact and discrimination to make out its exact seat and nature than it does in the case of adults; it is, therefore, always desirable to place them under proper medical care, as quickly as possible. At the same time, the following ought to be some guide as to the site of the affection,

and to its provisional treatment.

When in a child complaining of illness, or appearing ill, the eyes look heavy, and are wholly or partially closed against the light, if the brow is contracted, and if with these symptoms there is general fever, some acute affection of the head is to be dreaded, and the indications should not be neglected for an hour; if sickness is present with the above, so much the worse. Oppression of the breathing, along with general appearance of depression, is often the forerunner of severe inflammatory affection of the chest, which may be considered as established, if heat of skin, general fever, rapid breathing and cough succeed. In the chest affections of children, the movements of the nostrils are much affected. Constipation, which can scarcely be classed as a disease, is almost natural to some children, but requires correction, and this should be effected if possible by food or by gentle friction (see Circulation — Constipation). Brown or whole meal bread should always be employed, and fruits, either cooked or ripe, such as roasted apples, given in moderation; honey and treacle are useful, but nothing is more so, than the daily use of porridge made from Scotch oatmeal. When the tendency to constipation in children cannot be overcome by diet or friction, the next best remedy, is the use of a small enema of gruel simply, or medicated with castor oil, senna, or any simple aperient, or made with soap water, but the simple gruel ought always to be tried first. When an infant is being brought up by the hand upon ordinary milk, diluted, as it should be, with one third water, constipation may frequently be corrected by the addition of about a table-spoonful of raw cream to the half pint of the mixture. An enema for a child of six years old, should not exceed twelve ounces, and ought to be administered slowly. When medicine must be given, as general aperients, castor oil or sweet essence of senna is most useful: caution must, however, be exerted in forcing the former medicine—as sometimes must be the case—upon very young children; death has been occasioned from its getting into the wind-pipe. Rhubarb is a most excellent and safe aperient medicine for children, but its bulk and nauseousness frequently make it difficult to get it taken satisfactorily: magnesia the kind of observation that is required, and

disease, croup, diphtheria, inflammation of the | effects are not required, but the former especially ought not to be long continued. Calomel and grey powder, given alone, are too much employed for their aperient action; they should not be administered except under medical

The general establishment throughout the country of hospitals for sick children is likely to do much to improve the system of nursing and caring for children. In connection with this subject, we may state that those who wish to know more upon it should read the admirable little work by Dr. West, called How to Nurse Sick Children; intended especially as a help to the nurses at the Hospital for Sick Children, for the benefit of which institution it was published. It contains directions which will be found of great service to all who have the management of the young, whether healthy or sick; and is from the pen of one whose name is a sufficient guarantee for its excellence. Dr. West tells us that between thirty and forty young women are trained every year as nurses in the children's hospital, and no one but a medical man can know what a great boon this is to the community at large; seeing that there is often no greater difficulty than to get a clever child's nurse. We make the following extract, as showing the sort of observation and knowledge required by those who would be skilful nurses for children :- "The signs of disease differ, as well according to the age of the child as according to the disease from which it is suffering. Cries are the only lan-guage which a young baby has to express its distress; as smiles, and laughter, and merry antics tell, without a word, of its gladness. The baby must be ill, is all its cries tell one person; another, who has seen much of sick children, will gather from them more, and will be able to judge whether its suffering is in the head, or chest, or stomach. The cries of a baby with stomach-ache are loud, and long, and passionate; it sheds a profusion of tears; now stops for a moment, and then begins again; drawing up its legs to its stomach, and, as the pain passes off, stretches them out again; and, with many little sobs, passes off into a quiet sleep. If it have inflammation of its chest, it does not cry aloud, it weeps no tears; but every few minutes, especially after drawing a deeper breath than before, or after each short, hacking cough, it gives a little cry, which it checks apparently before it is half finished; and this either because it has no breath to waste in cries, or because the effort makes its breathing more painful. If disease is going on in the head, the child will atter sharp, piercing shrieks, and then, between whiles, a low moan or wail, or perhaps no sound at all; but will lie quiet, apparently dosing, till pain wakes it up again." This is quoted as an instance of is easily given in milk, and may be useful to show how much a skilful nurse in such either in the solid or fluid form where active matters may help the doctor to find out quickly

CHI

cannot speak for himself. It is very often the case that, when a child's nurse is asked what sort of a night he has passed, she either can give no answer at all, or one which is quite unsatisfactory. How important a question this is, however, may be in some degree realised by reading the following, also from Dr. West:"With the approach of night very many diseases get worse; and while you expect this to be the case, you must carefully notice what are the signs of increased illness which, in each instance, manifest themselves. Fever is generally higher-you must notice if it is very much so; the dull, heavy state of many children suffering from inflammation of the brain, or from some forms of fever, in which they lie dosing during the day, is often succeeded by delirium and loud outcries for some hours at night; or, if the child sleeping, talks much in its sleep about its lessons or its play; and the observation that these things have happened will serve to help the doctor in his judgment. If, though these things do not occur, yet the child is restless, you must try to ascertain from what cause. It may be from pain, or it may be from thirst, or from cough which disturbs the child, or from difficult breathing, whith grows worse whenever the child falls asleep, and then wakes him up again every few minutes; or it may be from that sleeplessness which illness brings with it. If, then, you are to give a useful report to the doctor at his visit, you must not merely be able to tell whether the child slept or was restless, but you must have watched so attentively as to be able to describe exactly the manner in which the night was passed; to report when the child slept, and how-when it was restless, and why." A good nurse further observes all particulars relating to the breathing of her little patient, cough, &c.; whether there is any tendency to sickness, or to excessive thirst; whether there has occurred anything like a convulsion, drawing in of the fingers or toes, squinting, or twisting of the features, flushing of the face, any eruption on the skin, or any fact whatever which may be of importance.

One of the most common and troublesome matters to deal with in the case of infants, is a tendency to excoriation and redness of the skin in those suffering from diarrhea. Now, this is very troublesome; and from the excessive irritation gives rise to great suffering. It can be almost entirely prevented by extreme cleanliness and good management after the bowels tilation-and to the articles on Diseases and are moved. Soap must not, however, be used, as it increases the irritation, but very thin starch should be employed instead. The child should then be carefully dried with a soft napkin, and the parts dusted with fullers' earth or with zinc powder, and afterwards dressed with an ointment made with one drachm of benzoate of zinc to an ounce of lard. The ointment must be kept quite fresh, as rancid ample dimensions, the people enjoyed an effici-

what is the matter with his little patient who | ointments never fail to increase the irritation and soreness.

Many children are destroyed by being too much moved about when suffering from exhaus tion owing to excessive sickness, purging, or some severe disease. In such cases the little patient is lifted by its mother or nurse from its cot many times in an hour, whereas it should never be removed from the recumbent posture at all. By turning it from side to side it may be shifted and changed, and even a new nightdress may be put on in this way, if it is slit up the back and run together afterwards by means of a few stitches.

Sickness and diarrhoea are among the most frequent troubles of children, especially those that are brought up by hand; in fact, many children at one time or other of their existence are reduced so low by them that, to an inexperienced spectator, it would seem almost impossible they could recover. Now, in checking the tendency to these, the nurse can do a great deal by means of a little common sense, and can greatly aid the doctor. Foolish and inexperienced nurses, when a child is either sick or purged after everything that he takes, go on cramming him with food under the idea that as what he has had has come back or gone through him, it can have done him no good, and therefore he had better have some more. It is painful to see the poor little creatures sometimes in this state, vomiting taking place every time they are moved. The obvious indication under such circumstances is to give the tired and irritable stomach an hour or two's rest at a time, and then cautiously at first, and without moving the child, give only a small tea-spoonful of cold water, to be followed, if that is retained, by a little cold milk and water, or something of the simplest description, small in quantity and cold. If that is retained, a gradual return to its accustomed food may be attempted .-Chlorodyne is a most useful addition to our medicines for children's diseases, especially diarrheea. It requires, however, to be very carefully and cautiously used. - See Chlorodyne.

As a general rule, in giving medicine to children, deception should not be practised; but whilst the child knows that it is medicine which it takes, it ought to have it in as palatable a form as may be, without interfering with

the efficacy of the drug.

CHIMNEY.—A chimney, by intention the channel by which the smoke and fumes of fire are conveyed away, also performs the no less important office of a ventilator. In former times, when the chimney formed almost a

ent means of ventilation, although in ignorance of the benefit. By change of fashion, the chimney has been gradually contracted and lowered to the model of the present modern fire-place; whilst this has been done, from ignorance of the necessity for pure air, no provision has been made to supply the loss of the efficient ventilating power of the old-fashioned ecnstruction, and consequently health must have suffered, and does suffer materially from the omission, although it is to be hoped that the diffusion of popular knowledge upon this and other points of sanitary regulation, will not allow such to be the case much longer. The chimney, however, is a notable instance of society enjoying ignorantly an arrangement conducive to health; and of that ignorance, whilst making alterations more consistent with comfort and convenience, doing away with one great advantage, of which it remains for science to point out both the loss and the means of reparation. As whatever goes up, or ought to go up, the chimney, are vapours and gases which cannot remain down without injury to health, it is a matter of importance that the chimneys of a house draw well, more especially those of bed-rooms in which fire is used. As a means of ventilation simply, independent of the fire, the importance of a chimney is so great, that rooms in this climate which are destitute of one cannot be considered healthy, although it must be confessed, that this secondary office appended to the original intention, is rather a clumsy method of effecting so important an end; it is one, however, of which it is requisite to make the most, and therefore chimneys ought to have a thorough good draught for smoke, ought never to be stopped up when not in use, unless other means of efficient ventilation are possessed, and, when possible, should be fitted with some efficient mechanical contrivance for increasing their ventilating power. -See Bed-Room-Ventilation, &c.

CHIN-COUGH.—See Hooping-Cough.
CHIRETTA or CHIRATA, is an Indian plant, the stems of which are imported in bundles about three feet in length; they are of small calibre, and have generally their roots attached. It is an admirable tonic, improving the appetite, and giving tone to the stomach. Hence it is useful in cases of indigestion with debility, and in convalescence from disease. It is very similar in its action to gentian, and is probably not superior to that drug. It is often called bitter-stick. The infusion and tincture of chiretta are now in the British Pharmacopæia. The dose of the former is from half an ounce to an ounce and a half, and of the latter from half a drachm to a drachm.

Chiretta is much used in India as a substitute for gentian. It contains a bitter principle, and very little volatile oil; hence it is a more simply intense bitter than gentian. Lozenges made with chiretta are exceedingly useful in relaxed throat and loss of voice. In India chiretta, or, as it is variously called, chirayta, chirayta, chirata, and chiraeta, has been used instead of quinine as a remedy in intermittent fever or ague, and it has also been prescribed by some in preference to sarsaparilla in cases in which that drug is specially used. It is also said to be peculiarly beneficial in cases of want of tone dependent upon affections of the uterine system.

CHLORAL HYDRATE, HYDRATE OF CHLORAL, or, as it is more frequently termed. simply Chloral, is a compound produced by the action of chlorine gas on alcohol after treatment with sulphuric acid and lime, and the subsequent addition of water. It is an excellent remedy for producing sleep, and has now largely taken the place of opium for this purpose. In cases of nervous disturbance in which sleeplessness is a prominent symptom, such as hypochondriasis, chorea, delirium tremens, &c., it is especially valuable, as the inconvenient effects which often follow the administration of opium are thus avoided. The dose of chloral is from ten to thirty grains in water. There is also a syrup prepared from the drug which may be taken in doses of from one to two drachms. Unfortunately, the properties of chloral render it liable to great abuse, and many persons have seriously injured their health by frequent and large doses; in some instances death has resulted from one overdose, inadvertently or intentionally taken.

CHLORINE is a gas of a green colour. is an important agent in manufactures, on account of its bleaching properties, and its powers as a disinfectant or destroyer of the noxious emanations from decomposing bodies, whether vegetable or animal, render it a most valuable assistant in sanitary arrangements. When undiluted, it exerts an extremely irritating effect upon the lining membrane of the respiratory organs, and as serious and even fatal accidents have occurred from this cause, caution is requisite in its use. A small proportion of chlorine gas diffused through the atmosphere, very quickly and thoroughly destroys not only the smell, but the injurious properties of floating emanations, which are capable of engendering disease. Chlorine gas is obtained in various ways, but the great magazine for its supply is common salt, which is composed of chlorine and sodium. sanitary purposes, various preparations, calculated to yield chlorine simply and easily, have been used; of these the chloride of lime now called chlorinated lime is the best known. This and most of the preparations, however, have the disadvantage of, when alone, yielding the gas too slowly and sparingly to be of much service, and when mixed with an acid, of pouring it out in quantity so great as to affect disagreeably or injuriously any persons exposed to its influence, particularly the sick. Though, in consequence, chlorinated lime has been banished from general use in private houses,

121

the same objection does not hold good where it | equal weights of common salt and oil of vitriol is employed in outhouses, privies, or dung heaps. Other preparations require sprinkling about the place to be purified, and as this is often done in ignorance of its colour-destroying powers, much damage is done to furniture, &c. A preparation, known by the name of Collin's disinfecting powder, seems to be free from the above objections; when a portion of it is exposed to the atmosphere in a plate or saucer it keeps up a certain, but sufficient exhalation of chlorine for some days, as it continues to absorb moisture. It is quite the best, most effective, and agreeable method for employing chlorine in the chambers of the sick which the author has met with.

The principal preparation used in medicine into the composition of which chlorine enters, is the liquor chlori, which is a solution of the gas in water, and which, diluted with eight or ten parts of water, may be used as a an ounce of chalk-mixture may be given. In gargle for affections of the mouth and throat, attended with fœtor and sloughing. chloric acid is a gaseous compound of chlorine | fifteen drops of chlorodyne with fifteen to with hydrogen gas, but is usually met with in solution of a yellow colour. It has a suffocating odour and gives off pale yellow fumes when exposed to the air. It is, of course, a powerful corrosive poison when swallowed alone; its antidotes are the carbonates of potash, chalk, or magnesia in any form, or milk, or white of egg, whichever is first at hand, until the antacids are procured. In the absence of any of these, soap water may be given; but, in poisoning with any acid, it should be remembered, that mortar or whitewash, rubbed up finely with water or milk, may be used on emergency as an antidote; the lime neutralising the acid. Of course the other antacids, particularly magnesia, are to be used if procurable at once. Of the latter, a dessert-spoonful may be given every ten minutes, and repeated according to the effect and probable amount of acid swallowed.

Hydrochloric acid is used in medicine as an unstimulating tonic, particularly in diseases such as malignant scarlatina, which are accompanied with tendency to putrescency; it is also used as a mouth-wash or gargle in the same disease. The diluted hydrochloric acid is given in doses of ten drops, in a wine-glassful of water sweetened with sugar, or it may, if preferred, be taken much more largely diluted, and then forms a pleasant drink. It may be used as a gargle, in the proportion of two drachms to the pint of water. As in the case of acids generally, unless largely diluted, the doses should be sucked through a quill or glass tube, to preserve the teeth from corrosion, and it is likewise a useful precaution, for the same purpose, to rinse the mouth with a diluted solution of carbonate of soda. In the absence of means for procuring chlorine, if fumigation is required, hydrochloric acid gas may be used as a substitute, as it is disengaged by mixing | fluid possessing an agreeable, fruity flavour and

-sulphuric acid-care being taken against inhaling its irritating fumes in too concentrated a state.

CHLORODYNE.—There are few remedies which have proved more general favourites than the above. It is said to consist of prussic acid, in combination with morphia, chloroform, and Indian hemp as its principal components, and it possesses, combined in an eminent degree, many of the best properties of an opiate and an antispasmodic. It is agreeable to the taste of many persons, and can be given either alone in water, or combined with other remedies. Perhaps its greatest value has been in cases of irritating cough, as in consumption, and in irritation of the bowels, accompanied by pain and diarrhea. In the former case, five or ten minims in an ounce of camphor mixture three times a day; and in the latter, the same dose in cases of acidity, with much irritation of the Hydro- stomach, an excellent prescription is, ten or twenty grains of bicarbonate of soda, in a wineglassful of water, two or three times a day. From its warm, aromatic taste, and comforting action in cases of griping and uneasiness in the bowels, it is generally a favourite remedy with patients. It was first introduced as a patent medicine, but has now been given a place in the British Pharmacopœia under the name of Compound Teneture of Chloroform and Morphia. Either alone, or combined with other remedies, it has proved of eminent service in cases of sea-sickness which have resisted many other kinds of treatment. It has been extensively used, both in this country and abroad, by domestic as well as by regular practitioners, in the treatment of diarrhea and dysentery, and it has been authoritatively stated that it is one of the best of known remedies for cholera. One thing is certain, that its uses are so varied and general that it should form part of the equipment of every domestic medicine chest. Chlorodyne of known composition can now be obtained, so that those who have a very proper objection to using remedies, the constituent parts of which are kept secret, may employ it without further scruple.

Of course, as it has the action of a powerful opiate, it must be given with extreme caution to young children, and in all cases where opiates are likely to exert an undue action.

Infantile Diarrhæa.—For a young infant twelve grains of bicarbonate of soda in five minims of chlorodyne and an ounce and a half of water, form an excellent mixture where there is griping and flatulence; one tea-spoonful may be given twice or thrice in the twenty-four hours. When diarrhoea is present, chalk may be substituted for soda.

CHLOROFORM is a transparent heavy

sweet taste. It is prepared by the distillation! of rectified spirit off chlorinated lime, and puri-

fied by redistillation.

Its power of producing "anæsthesia," or insensibility to pain, when inhaled, is now too universally known to require comment. It is, however, too potent an agent to be trusted in unprofessional hands, except, indeed, under direct medical sanction and direction in each particular case. In the more painful and the larger and is characterised by a peculiar greenish operations of surgery it is one of the greatest pallor of the skin of the face, and to some its use tends to diminish the average mortality after them. Fatal cases have, however, followed administered, still the fact of their having occurred, is sufficient to make us pause before a result, for the sake of avoiding a momentary though sharp pain. Moreover, cases do occur, in which very disagreeable effects, such as headache, sickness, hysteria, &c., have succeeded the use of chloroform. No one should ever be tempted to inhale this agent, without the previous assurance of a competent medical man that in his or her case no contra-indications are present.

On account of numerous fatal results from the employment of chloroform singly, it is now frequently administered in conjunction with sulphuric ether, which possesses similar anæsthetic properties. Different inhalers are which a bellows is attached, the object of the inhaler being to reduce and dilute the strength

greater safety.

The late Sir J. Y. Simpson, who first introduced the anæsthetic uses of chloroform to the notice of the medical profession, employed it largely in midwifery practice, and in this branch it has been attended with most beneficial results, and with apparently less danger. Its power of sciousness has caused it to be used extensively passage of renal and biliary calculi, and in other the guidance of a medical man. Should any threatening symptom appear in the course of and resort to means of artificial respiration.

affections, and in some skin complaints attended with intolerable itching. It has also been found serviceable as a stimulating liniment to produce a certain amount of counter irritation on the chest, in cases of bronchial and pulmonary disease.

CHLOROSIS is a form of anamia or bloodlessness which occurs most commonly in young women between the ages of 15 and 25,

boons conferred upon suffering humanity, and extent of the body also. Among the more prominent symptoms resulting from the impaired quality of the blood are breathlessness its inhalation, and although these have been on very slight exertion, palpitation of the heart, in very small proportion compared with the lassitude, and frequently mental depression, numbers in which it is daily and hourly headaches, and absence of the usual menstrual periods. In severe cases considerable swelling of the feet and legs may be present, with incurring even the remote chance of so serious | pitting or pressure. Constipation of the bowels is usually a prominent symptom, and has by some physicians been regarded as the main cause of the condition. The gums are exceptionally pale and colourless; the interior of the lower eyelids also are noticeably white, and the small blood-vessels ramifying there almost invisible. The treatment consists in attention to the regular action of the bowels, as much exercise

fatigue, and the administration of tonics con-

CHOLERA-ASIATIC OF MALIGNANT. employed for the purpose, from the towel or pocket handkerchief to the more elaborate apparatus introduced by Mr. Clover, consisting of a large bag charged with the mixture, to trict at the mouth of the Ganges, from whence it spread over India to various parts of Asia of the vapour that it may be administered with and Europe, and finally reached England in the year 1831, where it continued till the end of 1832, disappeared for seventeen years, and re-appeared in a more virulent form than before in the year 1849, in which latter visitation it carried off, in London alone, 15,000 people, and in the entire kingdom, not less perhaps than 80,000. Another epidemic of relaxing the muscles and producing uncon- a less extensive character occurred also in the year 1866, since which time the disease has in lock-jaw, convulsions, in colic, and in the been absent from this country until the years 1892-93 when, each autumn, a limited number spasmodic affections. The greatest care is of cases occurred. Cholera is endemic in In-required in the administration of chloroform, dia, and especially Lower Bengal, and when and it should never be attempted unless under it appears in this country it is invariably imported; on its transit it has been fairly conclusively proved to follow the lines of human inhalation, such as faintness or great difficulty communication. Dirt, bad air, bad water, bad of breathing, it is necessary to desist for a time food, insufficient clothing, and irregular and vicious habits, are all the favourers of cholera, Although chloroform by inhalation is not to be carelessly indulged in, yet its external application, in the form of liniment or as an lightly over our land. Although, since 1866, addition to other liniments, may be employed the sanitary surroundings of the people have with perfect safety in numerous neuralgic vastly improved, we have by no means reached

the stage when we can afford to view with composure the approach of the disease towards our shores; yet increased attention to sanitation, and a properly organised system of inspection of vessels arriving from foreign ports have done much to protect Great Britain from

serious epidemics of cholera.

Symptoms.—As a rule, a person who is attacked with cholera feels unwell previously, and often suffers from slight diarrhœa for a day or so before; when the disease sets in earnestly, however, which in the large proportion of cases it does during the night, the patient vomits, and is purged with more or less frequency and violence, the evacuations quickly coming to resemble thin gruel or ricewater; cramps of the limbs succeed, the surface becomes cold, blue, bathed in sweat, and has, particularly the fingers, a peculiar shrunken sodden appearance, the tongue is cold, the pulse imperceptible; the urine is suppressed, and the voice acquires a peculiar pitch of tone. Many die in this, the collapse stage of the disease, but if it is passed through, reaction comes on, the surface gets warm, the thirst continues, the quick pulse becomes perceptible, the tongue is dry and brown, and delirium is present; in short, fever is established, and may end either in recovery or death.

Management. - During the prevalence of cholera it is not well to make any change in the ordinary mode of living, provided no indiscretions have been indulged in. course, if a man is aware that he is habitually indulging in practices injurious to health, such as intemperance, debauchery, &c., he only acts wisely as regards his physical safety, in changing those habits; but it is hazardous to alter regular modes of living, which have hitherto been found compatible with good health, it being understood, that whatever tends to lower the standard of health, favours the attack of the disease. There is, however, one important precaution which ought to be observed, at all times indeed, but more particularly during the epidemic of cholera—the perfect purity of the drinking water should be ascertained, and its freedom from all decomposing organic matters made certain. Care is also to be observed not to take active purgatives, particularly salines, which produce watery evacuation; if aperient medicine is required, it ought to be of a simple character, such as castor oil; for whatever produces free action of the bowels, apparently increases the susceptibility to attack. For this reason, too, the slightest tendency to diarrhœa should at once be arrested, by chalkmixture, repeated as often as requisite, with the addition of from five to ten drops of laudanum to each dose, and the use of milk and farinaceous preparations, containing gelatine, for food. The speedy adoption of these measures, in places distant from medical assistance; and their enforcement by the clergy-

man or some intelligent individual, might do much to check the disease.

With regard to the actual treatment of the disease itself, when fully established, many different methods have been proposed and practised, and few of them, perhaps, without apparent advantage in some cases; but as yet no treatment which can be called decidedly successful-a cure-has been discovered. Of course, in so formidable a disease, proper medical assistance ought to be obtained as quickly as possible; but as far as our present knowledge extends, those around the patient would be fully justified in using every possible method of hot application to maintain the temperature of the body, and in permitting the gratification of the intense thirst to the full, by iced cold water. In doing this there will be at least the consolation that the comfort of the patient is promoted; everything further must be left to medical judgment.

The following summary of the precautionary measures which should be adopted may

prove useful:-

As cholera is not a disease which is likely to be conveyed from person to person, like scarlet fever and small-pox, those in contact with the disease need not fear any risk of contracting it, provided ordinary precautions are observed. These precautions we give below in the form of Rules, and also refer the Reader to the section on Enteric Fever, for the channel by which both diseases are conveyed is practically the same, the discharge from the patient in both cases being the poison carrier. Safety lies in scrupulous care with regard to cleanliness both of person and surroundings, and the destruction or disinfection of all articles which have been in contact with the patient and of the excretions. The process of disinfection must be carried out precisely on the lines indicated in the article on Enteric Fever. Those in attendance on cholera patients must remember that they are responsible to the public generally in the management of the case, so that the disease may be prevented from spreading; and it must be remembered that carelessness in the observance of the rules regarding disinfection may lead to a needless and terrible sacrifice of life.

A few simple Rules may be of service (a) to the nurse in charge of cholera patients,

and (b) to the general public.

Precautions for the Nurse. -1. The nurse should carefully attend to her general health by observing the ordinary rules with reference to diet, exercise, and rest. Wholesome food at regular intervals, daily walking exercise, and eight hours rest in bed, are indispensable requirements.

2. No meals should be partaken of in the sick-room, and only such food as is necessary

for the patient should be kept there.

3. The nurse alone should be held responsible for the disinfection of all articles (utensils,

CIN

laid down in the section on Enteric Fever must be | against the risk of contracting the disease. adhered to even as regards the smallest detail.

4. After attending to the patient, and form of diarrhea. —See Diarrhea. having carried out any necessary act of disinfection consequent upon such attention, the soap and water containing a disinfectant, and this precaution should be observed on all occasions before leaving the room.

5. As regards the room, no articles used in cleansing the patient should be allowed to lie about. Those which are of no value (rags, &c.) should be burned, and other articles (towels, &c.) which are of value, should be plunged at once into a covered utensil containing a disinfectant, and kept there until such time as they can be sent to the laundry. The room itself must of course be kept thoroughly clean and well ventilated.

On the termination of the case the room should be disinfected in the manner laid down

in the section on Disinfection.

General Precautions.—The general public, when cholera is prevalent, should observe the

following rules :-

1. Special attention should be paid to the general cleanliness of houses and premises. Water should be freely used to cleanse yards and out-buildings, and to keep the drains thoroughly flushed. Rubbish should not be allowed to accumulate, and particularly in those cases where frequent removal of refuse is not provided for by the sanitary authority, the kitchen fire should take the place, as far as possible, of the scavenger.

2. As water is the chief agent by which cholera is conveyed, it is essential to boil all water which is used for domestic purposes; the same rule applies in the case of milk. Domestic filters must not be depended upon for purifying water, boiling alone will remove

all danger from this source.

3. All indiscretions in diet or conduct which are likely to interfere with the healthy functions should be strictly avoided. Excessive eating or drinking, late hours and irregular habits, in fact, any departure from a whole-some régime should on no account be permitted. Fresh and well cooked meat, well boiled vegetables, milk puddings and stewed fruit may be partaken of. On the other hand, tinned foods of all sorts, uncooked vegetables, unripe or decaying vegetables, and indigestible articles generally, should be avoided.

4. Attention should be paid to the regular action of the bowels; simple aperients, such as castor oil, may be taken if necessary, and any tendency to diarrhoa should be checked by simple astringent remedies if it should continue; but it is well to obtain medical advice if ordinary remedies fail to have the desired effect.

5. Not the least important precept is to avoid apprehension of danger, and to have confidence that the observance of the Rules laid

&c.) used by the patient, and the instructions | down will, under Providence, prove a safeguar 1

CHYLOPOIETIC is a term applied to the viscera which assist in the formation of the

CHYME is the pultaceous, grey-looking, acid substance, to which food is reduced by digestion in the stomach, before it passes-in the healthy state at least-into the small in-

CICATRIX is the scar or mark left upon the skin or upon an internal organ, at the place where separation of substance, either from violence or ulceration, has been healed. Cicatrices arising from burns, unless carefully treated, often produce great disfigurement and deformity, which it may be necessary to remedy by surgical operation. Cicatricial tissue is very difficult to heal, when cut or injured, and is often the seat of chronic sores and cancer; it is apt to be both troublesome and painful, particularly in cold weather.

CIDER — a fermented beverage obtained from the juice of apples, contains from five to nine per cent. of alcohol. It is a wholesome drink, and is largely consumed instead of beer in districts where apples are abundant. Care ought to be taken that lead is not used in the process of preparation, as it is acted on by the malic acid, and is liable to cause colicky pains and other intestinal derangement. In some cases of rheumatic gout, cider acts beneficially, and wherever the tendency exists, is a much safer beverage than any form of malt

CINCHONINE .- The hydrochlorate and sulphate of cinchonine, especially the latter, as well as cinchonine itself, have of late been much recommended as substitutes for quinine. They have certainly this advantage, that they are much cheaper, but pretty extensive experience of them in hospital practice, has not warranted physicians in coming to the conclusion

CIN CIR

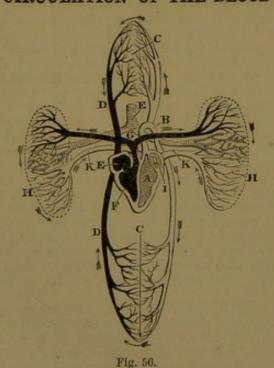

either as tonics, or as antiperiodic remedies. The Madras Commission, however, of 1868, reported that quinidine and cinchonine were only a little less efficacious than the corresponding salts of quinine, and there can be no doubt, that they are worthy of a more extensive trial than they have yet received at the hands of the medical profession. Quinine is a somewhat expensive remedy, and, of course, it would be a great boon to the poor if a cheap substitute equally efficacious could be obtained, and it is far from improbable that some of the other alkaloids obtained from the bark will be found,

which will take its place.

CINNAMON—the well-known spice, is the bark of a tree. It is brought from Ceylon and the islands of the Indian Archipelago. is largely used in medicine for the same purposes as other stimulant aromatics; chiefly as an addition to correct the nauseant, or add to the aromatic properties of other more active medi-The distilled water made from the bark is well known. In consequence of the high price of true cinnamon, a coarser description, the cassia bark, is very generally sold in place of it in this country, and though not so fine in flavour as the true bark, is equally well adapted for medicinal use. True cinnamon is thinner, lighter in colour, and consists of more quills one within another, than cassia bark. dose of the oil is from one to five minims on

CIRCOCELE—an enlargement or varicose condition of the veins of the testicle.

CIRCULATION OF THE BLOOD is

the entire course of the fluid from its leaving the heart to its return to that organ. In man, and in warm-blooded animals generally, includ- attained by the active exercise of our limbs.

that they are to be considered equal to quinine, | ing birds, there are two complete systems of circulation (see fig. 56), the one through the body at large, the other through the lungs, and this double circulation involves the presence of a double propelling organ, that is, a heart con-

sisting of four cavities.

The structure and requirements of our animated bodies as they have been constituted by the Creator, depend for their maintenance in healthy existence and action, upon the continual passage of arterial blood throughout every portion of their structure; for this the circulation provides. The heart, which is muscular, consists of four cavities, two auricles, and two ventricles; of these, the left ventricle (A) which gives the first propulsion to the arterial wave of blood, is considerably the most powerful. When it contracts, the blood contained within it at the moment, is forcibly propelled into the aorta (B), or main blood-vessel of the body, from which it diverges into the secondary branches, until at last, by the division and subdivision of the vessel, it is conducted into the capillaries (c), in which it comes into more intimate connection with the elementary components of the body, and undergoes such chemical change, that when it emerges, it is an altered fluid; instead of the bright red arterial, it is the dark blacklooking venous blood, unfit for the maintenance of the vital functions. It is now collected by the veins (D) and conducted back to the heart, the right auricle of which (E) it enters; from this cavity it passes into the right ventricle (F), and is propelled by its muscular power into the pulmonary artery (G), and through the lungs (H, H), in its passage through which it is brought into contact with atmospheric air, casts off the carbonic acid with which it has been laden, absorbs oxygen, and being chemically changed is once more the bright arterial fluid, which, returning through the pulmonary veins (K) to the left auricle of the heart (L), is transmitted by them to the left ventrical, to le sent once more upon its mission of life.

Although the forces which circulate the blood, namely, the muscular propelling power of the heart, the muscular and elastic contractility of the arterial coats, and the suction power exerted within the chest, are sufficient of themselves, during health, to maintain the vital current, which flows, and must flow from the first moment of life until death; their power and efficiency is much assisted by the muscular movements of the body, by exercise, which, quickening the respiration and the action of the heart, sends the blood with increased force and frequency throughout the frame, and stimulates every function to increased action. Thus, provision has been made by the Creator, that whilst the powers which circulate the blood can, of themselves, carry on that necessary process sufficiently to preserve life; high health and vigour can only be

126

CIS CIT

who are long confined to a horizontal posture, the circulating powers become too feeble to overcome the force of gravity, and the blood tends to accumulate, more particularly in the lungs, in the most dependent part; for this reason change of posture is advisable. those whose circulation is feeble generally, and in certain cases of bed-ridden patients, friction by the warm hand of the attendant, moistened with a little oil, is often of great service. The spine should be rubbed daily with very gentle pressure, from the nape of the neck downwards. This simple remedy is very effectual in the case of delicate children, and often removes a tendency to curvature of the spine, as well as to constipation.

tion, &c.

CISTERNS. - The importance of maintaining the cisterns of a house in good working order, and of preventing the water contained in them from being contaminated with impurities, has induced us to insert the follow-ing useful directions issued by the "Society for the Sanitary Inspection and Construction of Houses." The recommendations refer to the connection with the cisterns, and to house fittings generally:-

"1. In cleaning out water cisterns, great care must be taken not to allow any of the deposit to get into or pass down the service pipes; these must be plugged, and the residue of water must be taken out with sponge and bucket. If the cisterns are of lead, or lined

with lead, they must not be scraped.

"2. After the cisterns have been cleaned out, the covers (if any) should be replaced, the efficiency of the ball-taps should be tested, and the ball, levers, and cranks oiled.

"3. Examine whether there is a stopcock in the main service; if so, its description and

working condition.

"4. Examine whether the cisterns are covered; whether they have overflow pipes, and if such overflows discharge into the open air or into

any soil-pipe, closet, or drain.

"5. Examine the service pipes and valves of all water-closets, to see whether they act properly, and note from what cistern the water comes, i.e., whether there is a separate cistern for drinking water, or whether the same cistern supplies the water for drinking and domestic purposes, as well as for the use of the water closets.

"6. Examine the nature and condition of the safes, traps, soil, and waste pipes, &c., connected with all water closets, baths, and sinks, to see if they are in good working order or

otherwise.

"7. Examine the soil-pipe throughout its course, to see whether it is air-tight or not;

any points of leakage should be noted. "Useful hints to householders are, that all

In the aged, and in those exhausted by disease, | that in case of severe frost, or in the event of repairs, the water can be easily turned off without having to hunt for the regular official, and causing great inconvenience to neighbours by having to turn off at the main. All water cisterns should have a properly fitted cover. It is advisable, when practicable, to provide a separate system for the storage of water for drinking and household purposes, distinct from the cisterns that supply the water closets. The frictional parts of all sanitary fittings should be kept regularly oiled. The seats of water closets should be loose or fixed with hinges, so that the apparatus underneath can be examined without disturbing the woodwork. It is of great importance that all pipes and fit-tings should be easily come-at-able. To prevent the bursting of pipes in severe frost, the water should be turned off at the main, and the supply for immediate daily use should be stored in buckets. Covering cisterns and pipes with thick boiler felt, or casing them in sawdust, will generally prevent the water from freezing

"N.B.—The pipes burst from the expansion of the water in the act of freezing, and not after it is frozen. Water will rarely freeze if it is kept slightly running from the tap. In order to secure clean and wholesome water for drinking and cooking purposes, all water cis-terns should be cleaned out at least twice a

year."—See Houses—Traps—Water.

CITRATE OF IRON - AND AMMONIA, is a compound of citric acid and a salt of iron, precipitated by ammonia from the sulphate. 160 grains of the compound, added to a pint of orange wine, forms the Vinum citratis ferri of the pharmacopæia. It is a pleasant tonic, and the wine may be given to children in twotea-spoonful doses. The dose of the citrate which is also given with water is from five to ten grains.

Citrate of iron, like the tartrate, dissolves freely in the "solution of potash" (Liquor potassæ), and in this form is an admirable mode of administering iron to children. Twentyfour grains of the citrate or tartrate, two drachms of potash solution, with sufficient distilled water to make up two ounces, is a convenient form, of which one tea-spoonful may be given in half a wine-glassful of milk,

twice daily to a child four years old.

CITRATE OF QUININE AND IRON is a compound of iron, citric acid, and quinine, and is an elegant and highly useful form of tonic; it may be given in a similar way, and in doses similar to the above.

CITRATES .- Compounds of citric acid with salts of potash, magnesia and soda, are agreeable forms in which these remedies may be administered. The citrate of magnesia forms a cooling and aperient drink, that of potash a saline febrifuge which helps to increase the secretion from the kidneys, and the houses should be supplied with a stop-cock, so effervescing citro-tartrate of soda, an agreeable

CLI CIT

CITRINE OINTMENT is composed of the nitre e of mercury, with lard and olive oil. From its bright yellow colour it formerly went by the name of golden ointment; it is used in some skin affections, and is also frequently employed in inflammatory affections of the eyes. In its ordinary form it is too strong; and should be mixed with once or twice its weight of lard. Iron utensils or spatulas must not be used in its manipulation. It is an ointment which very quickly spoils.

CLARET is one of the most wholesome of the light wines. It contains about 15 per cent. of alcohol. In convalescence, from acute febrile disease in which wine is admissible, but where there exists tendency to febrile action from slight causes, claret is most useful, and preferable to the stronger and heavier wines. In diabetes, claret has been recommended as superior to every other form of

stimulant. - See Wines.

CLAVICLE - THE COLLAR-BONE - extends from the upper part of the breast bone to the point of the shoulder. It is particularly liable to fracture from falls upon the shoulder; the accident is easily detected. - See Fracture.

CLERGYMAN'S SORE THROAT is a peculiar affection of the throat and organs of voice to which public speakers are liable; according to the late Mr. Macready, actors, who have to assume feigned tones, are more liable to it from that cause. The seat of the disease is the mucous follicles scattered over the membrane of the throat, larynx, &c., being extended to the latter from the former. The commencement of the disease is insidious; it begins with an uneasy sensation, as if there was something in the throat which required to be hawked up or swallowed down; at the same time the mucous secretion is viscid. As the larynx becomes affected the voice is changed, becomes hoarse, unequal in tone, or quite extinguished; there may be slight pain about the parts, but not much cough in the earlier stage of the disease. All the symptoms become aggravated by cold, by vicissitudes of temperature, or by exertion of the voice in reading, speaking, &c. The above sources of aggravation are, of course to be guarded against, and the general health attended to. Good diet, cold bathing, and change of air, with some astringent lotion for the throat, are generally sufficient to check an attack of clergyman's sore throat. If they do not suffice, it may be necessary for the medical man to touch the parts with a pencil of lunar caustic, or what is better with a solution of nitrate of silver, by means of a sponge fixed to a piece of whalebone. The liability to the recurrence of the affection may be diminished by wearing the beard, and benefit is derived from the use of cayenne, tannic acid, and other medicated Brown's bronchial troches have disease or premonitory of a break up of the lozenges.

and useful aperient as well as a pleasant drink | acquired a considerable reputation in relieving the hoarseness. One of the best and simplest remedies is the inhalation of steam, either from an ordinary inhaler, or better, by means of Siegle's spray producer, the spray being mixed with some astringent, such as nitrate of silver, sulphate of zinc, or alum. - See Inhaler.

CLIFTON lies within a mile of Bristol. Sir James Clark speaks highly of its climate: "In its local advantages and geographical position, it yields, perhaps, to no place in the kingdom as a residence for a large class of Within its own limits it affords a invalids. sheltered winter, and an open airy summer residence; while it is surrounded by numerous places of agreeable resort in the fine season, suited to the various classes of persons who may seek its shelter during the winter. Compared with the south and south-west coasts, the spring is the period of the year in which this climate appears to the greatest advantage. For consumptive patients, and those labouring under irritable affections of the bronchial membrane, the softer and more humid air of Devon will be found more soothing, while for invalids whose constitutions have suffered from longcontinued derangement of the digestive organs, or a congested state of the mucous membrane, with copious secretion; and also for young scrofulous persons, and those of relaxed habits of body, generally, Clifton will prove a pre-ferable climate.

"The spring termed Hotwell rises at the base of the lofty St. Vincent's Rock, and is said to yield as much as forty gallons of water in a minute. . . . The temperature of the water is 76° Fahr. Like the springs of Bath and Buxton, the salts of lime predominate. The following table exhibits the proportion of the saline constituents in a gallon of water:

Saime Constituents .		0		Grains.
Chloride of magnesium,				7.25
Chlorinated lime, .				3.80
Sulphate of lime,		×		7.5
Sulphate of soda,				16.15
Carbonate of lime,				13. 5
				47:30

"A gallon also contains, according to Dr. Carrick, thirty cubic inches of carbonic acid gas.

"The water emits a few gas bubbles when drawn into a glass. Taken internally, it generally acts upon the kidneys, and occasionally produces vertigo and headache. It is recommended in various states of deranged health. The baths are not much used. The internal use of the water is considered to be very efficacious in cases of dyspepsia with acidity, in affections of the kidneys, as diabetes, gravel, and tendency to stone.

CLIMACTERIC DISEASE is an indefinite term, usually applied to denote some radical change in a person's bodily condition, which change may be productive either of

128

CLI CLI

vital powers. The change seldom occurs before fifty years of age, and is more common in men than women, for one reason, probably, that its most frequent exciting cause is over-work and anxiety of the mind in business. The person who is becoming the subject of climacteric disease, complains of weakness coming on gradually, the appetite gives way, sleep is deficient, the bowels sluggish, the pulse quick, and the tongue furred; the flesh falls away, and the altered countenance assumes an aged look in a short period: in other words, the "constitution is breaking up," and the individual's friends remark that "he ages very fast." Swelling of the limbs, eruptions of the skin, and mental apathy, are further con-comitants of the disease, which, if unchecked, may run on to a speedy fatal termination; whilst it also renders the patient liable to sink easily under any attack of acute illness, even of a common cold, which, too, it may be observed, is often the first traceable commencement of the climacteric attack. Another very frequent cause, is grief caused by the loss of friends or relatives, who have been much mingled in the affections and habits of daily life. It is a question whether many climacteric symptoms are not due to gout of an atonic character.

The term "climacteric" is frequently used in relation to that period in a woman's life characterised by the cessation of the regular monthly periods. There is usually at that time some constitutional disturbance, manifested both physically and mentally, which when excessive may call for judicious medical advice and treatment,

CLIMATE is the condition of the atmosphere which generally prevails over any particular tract of country, a condition which is, of course, regulated and modified by a great variety of circumstances. The latitude, the elevation, the proximity to, or distance from the sea; the soil, the absence or presence of water, including the drainage, the amount of wood, and the shelter or otherwise from prevailing winds, all exert important influence upon the characteristic climate of any locality, and have to be considered in the recommendation given to, or plan of action adopted by invalids. The subject is quite too extensive to admit of profitable consideration in this work, and the decision respecting the climate to resort to which is likely to benefit each indi-vidual case, is so much matter of judgment, and is really so important, that medical opinion ought always to be taken, when change of air or climate is seriously sought as a remedy in Very much precious time is often lost, and real injury inflicted, from want of due care upon this head, and from persons acting upon their own ideas, or upon insufficient advice. Those who desire to get for themselves the most complete information upon the subject of climate, will find it in the valuable work of Sir James Clark. I

There are few diseases, perhaps, which do not derive either temporary or permanent relief from change of air and climate, but some are more strikingly benefited than others; they are particularly diseases of a neuralgic, intermittent, or spasmodic character, of which hooping-cough and asthma are good examples. Chronic rheumatism, scrofula, weakness of the constitution generally, including pulmonary consumption, and dyspepsia may also be mentioned. As a general rule, benefit appears to result from change to a climate presenting characters which contrast with those of the one in which the individual is or has been generally resident; the dyspeptic or consumptive patient will derive advantage by removing from the colder to the more genial region; the fever-stricken resident of the sultry or vaporous plain, will regain health and strength in the bracing air of the hills, and even the country child, in whose constitution hooping-cough lingers, will probably lose it if transferred to city air for a short period. Perhaps no air exerts such universally tonic effects as that of the sea, but to some it is too stimulating in certain particular localities, though not so in others; but in fact, the differences in climate, and its effects, are so numerous and varied, that it is impossible here to pass beyond the general consideration of the subject. Unquestionably some amount of the beneficial influence of change of climate is due to the stimulant effect upon the mind, which excitement and change of scene produce, this being more particularly the case, if the condition of the individual permits or calls for the continued change of travelling from place to place.

The error is frequently committed, of resorting to the change of climate as a last resource, which, if earlier had recourse to, might have proved of essential or real service. Another error, is trusting too much to the curative power of climate; and invalids, by throwing aside the restraints of the regimen to which they have been previously subjected, and neglecting the other accessory adjuncts to recovery, fail to derive the full measure of benefit which they ought; and this, more especially if they do not consider and endeavour to accommodate themselves to the modes of living, and other requirements, adapted to the climate in which they are resident for the

Sir James Clark divides the "mild region of England" into four districts or groups of climate; that of the south coast, comprehending the tract of coast between Hastings and Portland Island; the south-west coast, from the latter point to Cornwall; the district of the Land's End; and the western group. In Scotland, the Island of Bute, situated in the Firth of Clyde on the west coast, is a remarkable instance of climate modified by situation: surrounded by sea water, and sheltered by lofty hills, its climate is remarkably mild and

CLI CLI

above a few hours. It is much to be regretted, that the beneficial effects of change of air are so little attainable by the poor, particularly in recovery from acute illness, when it is frequently all that is requisite to re-establish firm health, and to hasten an otherwise lingering convalescence. The establishment and support of convalescent homes for the poor, especially on the coast, constitutes a useful means for meeting the difficulty; and it is to be hoped that the efforts made for this purpose by many benevolent individuals and societies, will obtain

increased support. The question of acclimatization is one of great importance in many respects, and one demanding the closest attention of naturalists, of political economists, and of scientific men generally throughout the world. For a time the idea seemed to have acquired a pretty firm hold of the public mind, that men and animals, after passing say from an arctic to a tropical climate, acquired, after a certain time, an

immunity from the evil effects which the change was calculated, in the first instance, to produce. Many careful observations and experiments have been conducted in this country and (with regard to animals especially) in France, with a view to determine, if possible, how far we are justified in relying upon this hypothesis. Now, although wonderful results were at first obtained-so wonderful that it seemed likely that the power of certain animals to endure changes of climate was almost

unlimited, it must be admitted that recently our ideas have been forced to undergo a revulsion on this subject, as we have found that, in many cases, the endurance was only a temporary one; and, more especially, was not likely

to be followed out by the propagation of a vigorous progeny.

That man can live and flourish in very cold or in very hot temperatures (provided that in the latter cases there be no malaria or marsh poison) is proved by the fact that the Esquimaux, when well nourished, are a remarkably strong and healthy race; and that the same observation applies to many of those tribes inhabiting regions of the world characterised by the highest temperatures. Experience has now abundantly proved, to the satisfaction of all, that our emigrants in the North American States, living in a climate with a much lower temperature than that to which they had been accustomed, not only enjoy good health, but transmit it to their progeny. In fact, it is questionable whether, if the external conditions surrounding the emigrant be favourable, he is not improved in health, mentally and physically, so that he may become the progenitor of a superior race. A similar certain toleration and possible improvement cannot so confidently be expected from Europeans emigrating to hot climates, although we have seen how well many thrive in certain parts of Australia and New | malaria or marsh poison, new known to be the

equable, so much so, that snow rarely lies | Zealand; while it is a melancholy and wellknown fact, that residence in a country much hotter than our own is incompatible with the long preservation of health. Dr. Parkes, in his work on Practical Hygiene, in speaking of this subject, says,-"There is a general impression that Europeans do not flourish in countries much hotter, i.e., with a yearly mean of 20° Fahr. higher, than their own—as in many parts of India; that the race dwindles, and finally dies out; and, therefore, that no acclimatization of race occurs. And certainly it would appear that in India and in the West Indies sickness and mortality increase with length of residence; and there is some evidence to show that the pure race, if not intermixed with native, does not reach beyond the third generation. Yet it seems right to say, that so many circumstances besides heat and the other elements of climate have been acting on the English race in India, that any conclusion opposed to acclimatization must be considered as based on scanty evidence. We have not gauged on a large scale the effects of climate, pure and simple, uncomplicated with malaria, bad diet, and other influences adverse to health and longevity.

For some remarks as to the peculiar effects of heat, the reader is referred to the article upon

The effect of winds, or of movements of the body of air, whether hot or cold, with which we are surrounded, is very remarkable. In cold climates, a very low temperature, which has easily been borne before, becomes then unendurable. The movement, on the other hand, of hot air over the surface of the body is said, by greatly aiding evaporation from the skin, to chill the body, in spite of the warmth

of the air. It has long been a matter of dispute among medical men whether mountain air—that is, air rarified, or exerting a less pressure is favourable to health, or the reverse. There seems now to be little doubt of the fact, however much wrangling there may remain as to the explanation of it. Not only in such situations are consumption, scrofula, and similar diseases, very rare in occurrence, but their progress is actually arrested in the case of strangers who go to reside in the localities. The high Alps of Switzerland, and mountain ranges of Thuringia and Silesia, and of Mexico and Peru, may be mentioned as typical ex-amples of places where consumption is unknown to originate, unless from some special social

habit or vice, or from want of food, &c.

Much remains to be done in the way of observation and experiments to enlighten us as to the relation of the presence of ozone and to other conditions of the atmosphere, as well

as of the soil, to a healthy climate.—See Ozone.

It would be impossible to conclude this subject without a word upon the question of

cause of so many diseases, especially fevers of more than average degree of heat, and even different kinds. The popular idea is, and it induces perspiration, and which is liable to be is so far correct, that these poisons are to be met with in low situations, and that an elevation of a few feet will, in many cases, give a protection from their evil consequences; but it should also be known that, in other situations, they have been found in active operation at an elevation of 6000 feet; and that in some instances their favourite locality is in elevated plains, at elevations varying from 1000 to 3000 feet. As a general rule, the greater the elevation the greater the security; and it may be assumed that, although exceptional instances occur, yet a moderate elevation of, say 1000 feet, will generally be sufficient to afford promise of immunity. The whole subject, however, is one of deep interest, and is always undergoing full and highly necessary investigation at the hands of competent observers .-See Health Resorts, Ague.

Refer to-Atmosphere-Convalescence, &c. CLOTHING. The protection of the body from the influences of climate, by means of clothing, is most intimately connected with health, more especially in a climate like that of Britain, subject to the numerous and sudden vicissitudes of temperature, moisture, &c. The form of clothing must ever vary with fashion; the principle ought always to continue the same, that is, it should involve complete and thorough protection of the surface of the body, and especially of the cavities of the chest and abdomen, from cold or sudden chill. This is best insured by a covering of woollen material next the skin; the habit should be commenced from the earliest childhood, and continued through life in every season of the year, varying only the thickness of the flannel, or other woollen texture, according to the average temperature. No outward clothing can be so uniformly efficacious as the inner one of wool, as a protection against our variable climate, and yet very many there are, who, both in their own persons, and in those of their children, neglect this real preservative of health, and therefore, this real economy, although the cost at first may seem much to the poor. In addition to the inner clothing, the outer ought of course to be sufficient, and in winter, an addition made on going from the warmth of the house into the open air. In this respect, men are generally better provided, under all circumstances, than women and children. Women, from the nature of their dress, and from the pernicious custom of exposing the chest and arms-not always, which would be less hurtful, but occasionally-suffer much from errors in clothing; they subject them-selves to the extremes of fur and thick shawls in the morning, and of thin dresses at night, added to which there is often exposure to currents of air when heated, and without any protection against their effects. Any article GEN of clothing, such as fur, &c., which keeps up a

induces perspiration, and which is liable to be thrown off or put on easily and as fancy dictates, is hazardous and injurious. Children are in many cases most insufficiently protected from the weather; numbers are without a single article of woollen under-clothing, either in consequence of carelessness, or from the erroneous idea of rendering them hardy; a system which may answer in the offspring of hardy parents, whose children are hardy in every other respect, but which can only be productive of injury to health in those who spend most of their time in warm, perhaps too warm, rooms and nurseries. The surface of a child, from the neck downwards, ought to be kept warm by clothing; exposed chests, bare legs, and thin insufficient coverings, are synonymous with croup, inflammation of the lungs, and scrofula. For the same reason that furs for the neck are unsafe articles of dress for women, comforters and woollen neck wrappers are not advisable, except under particular circumstances for boys; they heat the neck, and if thrown off carelessly, predispose to cold or bronchitic affection. Vests of chamois leather constitute a most important protection against changes of temperature. They are best worn over a thin merino vest, and should be perforated to allow escape of perspiration.

The clothing of the feet is a matter of the highest importance to all; dryness and warmth must be attended to by those who value health. On the other hand, the head is often, in infants

and children especially, kept too hot.

CLOVES are the undeveloped flower buds of a tree originally a native of the Molucca Islands, but which is now cultivated in various parts of the tropics. They are well known as a spice, and used as a stimulant aromatic in medicine, their properties depending upon the volatile oil, which is intensely acrid. The oil of cloves is occasionally used as a topical remedy for toothache, and is a useful adjunct to purgatives

CLUB-FOOT.—See DEFORMITY.

CLYSTER.—See ENEMA.

COAGULATION is the conversion of the whole of a fluid, or of some of its constituents, into a solid. The solidification of the white of an egg by heat is an instance of the former, that of the clot in blood, or of the curd in milk, of the latter. The coagulating power of the blood is the great safeguard in bleeding, which could not be permanently stopped by any appliances, without this property of the vital fluid; and it is the loss of this property that gives rise to the occasional cases of danger or death from bleeding, in consequence of comparatively slight wounds, such as those from leech bites, or from the extraction of a

COAL GAS .- See CARBURETTED HYDRO-

COAL TAR .- This is used in several forms

COB COD

carbolic acid and many other articles, used both in commerce and in medicine, are derived. Its value as a remedy in many skin diseases is well known, and there is an excellent soap made from it much used by persons liable to eruptions of the face and hands. The Liquor carbonis detergens, or concentrated alcoholic solution of the active principles of coal tar, is used as a dressing for putrid sores, in the form of emulsion with a little water, and is a favourite remedy with many in skin diseases, especially of a scaly character. Its antiseptic or preservative qualities have made it a favourite with those interested in the collection of specimens of natural history.

COBRA DI CAPELLO.—The name of a snake common in India, and very destructive to the native population on account of the deadly nature of the poison it emits. The bite of the reptile should be treated vigorously by the excision of the wounded part, and the application of caustic, but it too frequently happens that those remedies are without avail.

COB-WEB, employed as a styptic, to arrest bleeding from simple flesh wounds, or from leech bites, is often used in the country, but its virtues can be better supplied with rag

or cotton wool.

COCCULUS INDICUS is the fruit of an East Indian shrub. It resembles a large brown shrivelled pea in outward appearance. The kernel is intensely bitter, and on this account is sometimes said to be used fraudulently in the manufacture of beer, instead of the hop; also with the view of increasing the intoxicating power of the beverage. This power of stupefying has occasioned cocculus indicus to

be popularly used by poachers as a fish poison.

COCHINEAL, an insect which yields the well-known colouring matter, carmine, is brought from Mexico, being gathered from various species of cacti, on which it feeds. It is used chiefly as a colouring agent; but has been employed, especially as a domestic remedy, in hooping-cough. Its powers are very doubt-

ful.

Refer to-Hooping-cough

COCOA-CHOCOLATE.-Cocoa is prepared from the seeds or beans of a tree-the Theobroma cacao - cultivated chiefly in the West Indies and South America. The beans are roasted to develop the aroma and free them from the husks, which are comparatively innutritious, though frequently mixed up with the prepared cocoas of commerce. Cocoa, when genuine and properly prepared, is a wholesome and nutritious article of diet; it is made up of one half of fat or butter and one fifth part of albuminoid matter, besides starch, &c., and a peculiar principle, "the theobromine," which, according to Liebig, nearly approaches theine and caffeine-the characteristic principles of tea and coffee. It is consequently highly species; it was formerly employed in medicine nourishing, as it contains both heat-giving and in this country, fell into disuse, was revived

as a disinfectant, and is the material from which | flesh-forming elements in fair proportions and in a concentrated form. Cocoa does not, however, affect the nervous system in the same manner as tea and coffee, and may therefore be taken in cases when these are inadmissible. Cocoa, as a food, ought to be prepared only from the crushed beans themselves, or "nibs," as they are called. As a beverage, cocoa requires to be deprived of a good deal of its fatty matter and to have starch added to it, when it is known as soluble cocoa. Flake and red cocoa are made from the nibs and whole seed, combined with the husk, and then manufactured into paste.

Chocolate is professedly a manufactured article, and should be made with the kernels of the cocoa bean, perfectly free from husks, and reduced to a smooth uniform paste with sugar, and starch of some kind, such as arrowroot; vanilla or cinnamon being used to impart flavour. Tallow is said sometimes to be used in the preparation of the cheap forms. It need scarcely be said that those who make use of chocolate ought always to procure it from dealers on whom they can depend. That of French make is generally to be preferred. As an article of diet, chocolate is extremely nutritious, but, on account of the oil it contains, is apt to disagree with weak stomachs, particularly if too great heat be used in preparing; moreover, the addition of vanilla or bitter almonds is apt still more to increase its indigestibility.

COCOA-NUT .- The well known fruit of the palm, is, in its ordinary state, extremely indigestible, from the same cause that most other nut kernels are so, the solidity of the structure and the oily constitution, a combination which strongly resists the digestive powers. The reduction into paste or flour probably remedies the objection. The milk of the cocoa nut is a cooling and nourishing fluid, much valued by the native population of districts where the

palm abounds.

CODEIA is one of the alkaloids derived from opium, and has been used, in the form of lozenge, for the purpose of allaying irritating cough, in cases in which it was not thought desirable to produce the full and characteristic effects of opium itself upon the constitution. It is well known that some persons cannot take opium in any shape without unpleasant effects, and it is to such persons that the above lozenges may prove valuable as a means of soothing cough that has resisted other more simple methods of cure. It is of doubtful efficacy as an anodyne, and its soporific effect is small. Used hypodermically, codeia is an effectual preventive of incipient influenza cold, and its beneficial effects in diabetes are now acknowledged, but of course its administration requires educated medical supervision.

COD-LIVER OIL is obtained from the liver of the common cod-fish and other allied

COD COF

as a remedy in Germany, and again brought | method of correcting its smell and taste; of into public notice in Britain, by Dr. Hughes Bennett of Edinburgh in 1841, since which time it has advanced rapidly, and deservedly, in the estimation both of the profession and of the public. It had never, however, been entirely abandoned as a domestic remedy in rheumatism; and among the sailors, particularly those connected with the northern fisheries, had been regularly used both internally and externally, in the above disease. Now, it is principally employed and celebrated for its curative powers, especially in pulmonary consumption, in scrofula, and in all diseases connected with the scrofulous constitution, or depending on general debility. In the atrophy or wasting of the flesh in young children, connected with enlarged glands in the belly, when the latter becomes tumid and hard, feels knotty, and with the veins of the surface enlarged, cod-liver oil, given internally, a tea-spoonful twice a day, and well rubbed into the skin of the belly two or three times a day, will in many cases relieve in a way which no other remedy we are

acquainted with could do.

For some time, the dark, heavy, strong oil was considered to be most efficacious; but now, especially since more care has been bestowed on the manufacture, the purer and lighter oil, almost colourless, is to be preferred, and is the preparation admitted into the British pharmacopæia. The dose for an adult is generally one table-spoonful twice or three times a day; it is, however, by some given much more largely. It is always advisable at first, to begin with smaller, such as tea-spoonful doses, till the patient and the stomach become accustomed to the remedy, which even children quickly do, although sickness is sometimes produced at first. Tastes differ much as to the best method of taking cold-liver oil; floated in a little bitter beer answers well, or the dose may be shaken up with half the quantity of syrup of marsh mallow, and swallowed at once, or it may be taken in water, simple or aromatic. Every means should be taken to conceal the nauseating taste of the oil, to secure its being taken regularly-especially in the case of children, and in addition to the above vehicles, orange wine, strong coffee, or a flavouring of bitter almonds or cinnamon, are all occasionally employed. A compound of the oil with malt extract is an agreeable preparation. following form of administration will suit some persons who cannot take the oil otherwise :-Rub down two ounces of loaf sugar in a quart mortar to fine powder, add the yolk of an egg, and blend thoroughly with the sugar, adding three drops of oil of cinnamon; add two ounces of cod-liver oil by small quantities, and rub with the above till thoroughly incorporated; finally add, still rubbing, an ounce of orange-flower water. The dose—one table-spoonful, thrice daily, before meals. It is said that shaking

course, the laurel water is separated before taking the oil. With many, cod-liver oil acts slightly upon the bowels. In some cases of chest affection, the breathing is certainly apt to become more difficult for the first few days of its use, but this effect passes away where the oil is persisted in. There cannot be stronger evidence of the nutritious power of cod-liver oil, than the way in which patients increase in weight and strength after they have taken it for some time, a restorative effect which no other remedy we are acquainted with possesses.

Refer to-Scrofula, &c.

COFFEE. - Coffee is the berry of a shrub, the Caffea arabica, indigenous to Abyssinia and afterwards introduced into Arabia, and now cultivated in the East and West Indies, in South America, &c. Though long known and used elsewhere, it was not introduced into this country till the middle of the seventeenth century. It contains a considerable amount of essential oil, and a peculiar principle, caffeine, which is identical with "theine" the characteristic principle of tea. The berry requires roasting to develop the well known

fragrant aroma.

As an article of diet, coffee is for most persons wholesome and stimulating, but when there exists any tendency to head affection, or when the biliary secretion is apt to be overabundant, it ought not to be used. Dr. Paris remarks, that coffee, "if taken after a meal, is not found to cause that disturbance in its digestion, which has been noticed as the occasional consequence of tea; that on the contrary, it accelerates the operations of the stomach." When strong, it most undoubtedly exerts much influence over the brain and nervous system, producing watchfulness and feverish symptoms; it is thought, too, to affect the skin, and the sallow hue of the Parisians has been ascribed to their excessive use of coffee. Coffee is more suitable for most persons for the morning meal than tea, which is more likely to affect the nervous functions. of strong coffee taken immediately after rising, is considered a good protective from the effects of malaria. In poisoning by opium, coffee is one of the most useful antidotes, but in this case ought to be fresh, pure, and strong, and taken without milk or sugar. The infusion of one ounce taken every twenty minutes is considered a suitable dose.

Coffee should always be infused, never boiled; when made with half milk, it is more nutritious for the weak, if it agrees with the stomach in this form. The adulterations of coffee are numerous; for that with chicory, which is the most prevalent, the reader is referred to the article Chicory. The only real security is, for persons to grind their own coffee, not too much at once, and to preserve the oil with cherry-laurel water is a good ters, or wide-mouthed, well-closed bottles. both the whole berry and the powder in canis-

COL

used by the negroes, and found serviceable, it hydrogen already existing in the body. This is said, in promoting the flow of urine.

Refer to \_\_Diet \_\_Tea, &c.
COLCHICUM. \_\_Colchicum autumnale is the botanical name for the autumnal crocus, or meadow saffron, found wild in many parts of England, south of the Trent. The root and bulb and the seeds are used in medicine, particularly in gout and rheumatism, but the drug requires too much care, and its improper use is too liable to produce evil consequences, to make it a safe domestic remedy, unless previously sanctioned by medical authority. In some persons, particularly, it acts most powerfully upon the liver and bowels, even in small doses. The preparations chiefly used are the tincture, the wine, and the extract, the dose of the tincture and the wine varies from ten to thirty minims, and of the extract from one half grain to two grains. According to Dr. Christison, two drachms, or tea-spoonfuls, of the wine of colchicum has proved a fatal dose. The symptoms produced by an over-dose of colchicum are, vomiting, purging, colic, heat in the throat and abdomen, general depression, headache, and stupor or delirium. The remedies to be used until medical assistance is procured are, diluents, such as barley-water, linseed tea, or thin gruel, and laudanum or opium in some form.

Refer to-Opium.

COLD is generally considered to be a negative result of the absence of heat, rather than an active principle; in consequence, however, of its energetic influence upon the living body, either in health or disease, it is usually spoken of as an active agent. The animated human frame is endowed with the power of maintaining a certain average temperature, which-except in rare instances-is higher than that of the surrounding medium, and this power is adequate to resist all ordinary impressions of cold; but when, from great intensity, or long continuance, and especially when combined with moisture, the depressing action of cold is much augmented, the powers of life sink, and disease or death is the consequence. power of the living body to resist cold is in great measure dependent upon the supply and proper assimilation of a sufficiency of nourishment; the ill-fed and the dyspeptic always suffer most from the effects of cold. order that full benefit may be derived from the power of food to protect against low tem-perature, particularly when at all severe or long continued, it is requisite that more or less muscular exercise-according to circumstances -be engaged in, for the purpose of quickening the functions of respiration, circulation, and metamorphosis of tissue; in other words, for the purpose of increasing the supply of oxygen taken into the system, and thereby facilitating the consumption of the internal fuel (see less of the necessity of due protection against Animal Heat), either obtained directly from an agent so potent for evil. In many warm

the West Indies, an infusion of raw coffee is | the food, or from the compounds of carbon and is no more than common experience testifies; for all know that of two men exposed to a continued degree of intense cold, even if equal in other respects, should one persevere in muscular exertion and the other give way to indolence or torpor, the former will be much more likely to survive the effects than the And even under exposure to cold, not latter. so immediately dangerous to life, and especially if combined with moisture, the most ignorant are aware that "as long as they keep moving, there is comparatively little danger of those bad consequences which almost invariably result if rest is indulged in. In fact, as long as the muscular movement is kept up, the circulation, respiration, and change of tissue go on with sufficent activity to maintain temperature adequate to resist the cold, which, however, prevails as soon as inactivity permits the cessation of the resisting forces. Thus we have a point of every day experience confirmed, and its rationale explained, by the researches of modern

In northern latitudes, however, the internal means of resisting cold are of themselves insufficient for the purpose, and therefore clothing, shelter, or habitations, and the production of artificial heat, are resorted to, and these, indeed, in some degree stand in the place of nourishment; for the man who is sufficiently well protected from the effects of cold certainly requires a less supply of food to maintain health than he who is not. As regards food, habita-tions, and fuel, most who have it in their power are inclined to use their protecting influences sufficiently; it is in clothing that the chief errors and negligences are met with, and the reader is referred to the subject itself for their exposition. There may, certainly, be such over precaution in guarding aminst cold, that it is impossible to keep up the protection on all occasions, so that an accidental omission in dress, or exposure, after being habituated to air of too high a temperature, at once gives rise to disease; but the abuse is no argument for the non-employment of sufficient rational pro-tection against the influences of weather, especially in latitudes like our own, in which a low temperature frequently prevails, and that, too, combined with moisture, whilst at the same time, the vicissitudes from heat to cold are often extreme and violent. It may safely be asserted that a large proportion of the diseases to which the inhabitants of this country are liable, are, either directly or indirectly, the result of cold. It is sufficient to mention inflammatory attacks, general and local, apoplexy and paralysis, rheumatism and neuralgia, scrofula with its long train of disease, and consumption, as diseases, among many others, traceable to the influences of low temperature-to convince the most careCOL COL

climates, the principal danger from cold is in- | Experience proves, that those who are likely

after hot days.

The effect of extremely low temperature acting upon a limited portion of the body, is rigidity of the muscles, blistering of the skin, particularly from grasping metallic bodies with the bare hand, and frost-bite or death of the part affected. The general effect of extreme continued cold, is depression of the nervous system, of the functions of the respiratory organs and skin, deterioration of the blood, torpor, insuperable drowsiness, and death. In case of frost-bite, as of the fingers or toes, although the part may appear quite lifeless, pale, and shrivelled, it may often be saved by proper treatment, and the principal thing to be attended to is, that the temperature be not suddenly raised; circulation, nervous power, and heat, must be very gradually restored, and probably the method followed in countries in which this accident is common, will be found safest and best, that is, continued friction of the part affected, with snow, till reaction is established; at all events, friction should be used; after-inflammation may be soothed by tepid poultices.

When, in consequence of long exposure to extreme cold, drowsiness comes on, both mind and body must be exerted to keep off the influence; to indulge it is death; muscular motion must be kept up-a harmless stimulant, tea, coffee, hot milk, or Liebig's extract of meat at rest. should be administered: only in extreme cases should alcohol in any form be resorted to,

curred by exposure to the chill dews of evening to be exposed to great continued cold, should provide abundant nourishment, particularly of a fat or oily character; they may have a flask of spirits in reserve, but should never have recourse to it, except as a last resource. The sudden application of cold, even if it be not intense, may be very serious, in case the nervous powers are at all exhausted; of this, the cramp to which bathers are subject is an example, and likewise the fatal accidents so frequent during harvest, from persons drinking largely of cold water. The fatal effect is usually ascribed to the heated state of the body, but much is also due to the shock communicated to the stomach and its numerous nervous connections, while the system generally is exhausted. The effect of cold, not extreme, but long continued, especially if combined with moisture, is one of the most fertile sources of diseases, some of which have been already enumerated. The young and the aged are more peculiarly liable to suffer, and for this reason require especial protection. The partial application of cold, particularly by a moving current of air, most generally produces disease of a neuralgic or rheumatic character, partial paralysis, especially of the face, or erysipelas. All these injurious influences are more readily exerted, if the body is at the time in a state of heated excitement combined with nervous exhaustion, the result of previous exertion, and

> The partial application of cold and wet, may produce inflammatory action in the immediate

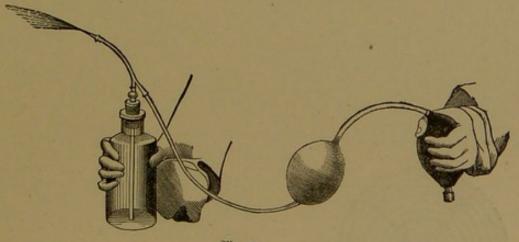

Fig. 57.

of wet feet, in some distant organ.

The most effectual remedy for the effects of "a chill," is warmth with moisture, in the form of bath, hot air, vapour or warm, or of hot bricks or hot water bottles, and the free use of warm diluent drinks, such as tea, gruel, &c., and in case of much depression, wine and hot water.

Cold is sometimes used for producing local

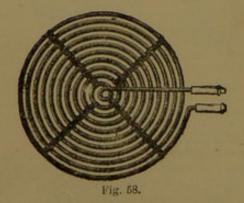

vicinity of the part exposed, or, as in the case applied to the part, or what is better, the spray from sulphuric ether, will in a short time freeze the tissues, which may then be submitted to painless operation. An apparatus for producing local anæsthesia by freezing the skin, was introduced some years ago by Dr. Richardson, in his spray producer, the mechanism of which is represented in fig. 57. It consists of a bellows and bottle containing ether, into which a tube continuous with that which teranæsthesia; ice and salt in a muslin bag minates in the nozzle of the instrument is

COL COL

inserted, and by working the hand bellows, | the ether, atomized into a fine spray, is made to play on the part to be operated on. Most of the hand Spray-producers now in use for antiseptic dressings are worked on similar

principles to the above.

The use of cold as a hygienic agent, or in the treatment of disease, is invaluable. When, either as cold air or cold water, it is adapted in intensity and continuance, to the resisting power of the constitution, it is a most admirable tonic. In certain conditions of the system, a bracing atmosphere, which means fresh and comparatively cold air, is recommended, especially in recovering from illness and to throw off the depression consequent on luxurious When used to subdue certain forms of living. excited and inflammatory action, the temperature must of course be suited to the case, but ice-cold is most generally useful, care being taken, in the application of ice itself, that the part is not, as has happened, actually frozen or killed. Various forms of evaporating lotions, made with spirit, &c., are employed, but as the additions are made simply to increase the cold by increasing the evaporation, if a sufficient supply of ice can be procured, it is all that is requisite; the best mode of application is, by india rubber bags, and by renewing the ice again and again by a careful nurse. When, from circumstances, this cannot be done, the next best method is, to keep up a continued system of irrigation, by means of a vessel of cold water placed a little higher than the part to be cooled, the fluid being conducted from the vessel to the part by an elastic tube, to which are attached bundles of woollen thread, or thin strips of flannel, care being taken, by means of waterproof material of some kind placed underneath, to carry off the superfluous water; in this way, the head, or a broken limb, may be kept constantly under the influence of a stream of cold water, without the necessity for constant attendance. There has always been considerable difficulty in the applica-tion of cold to the head in a person confined

to bed; this is in a great measure removed by the ice caps and pillows manufactured for made by Messrs. Krohne & Sesemann of india total abstinence from liquids. To these who

rubber tubing alone, and fed by an icedwater supply from a vessel placed over the bed; or a similar contrivance, made of pliable metal tubes (Leiter's, see illustration, fig. 58), which may be adapted to any part of the body, are the best apparatus for the application of cold when it is necessary to keep it up for an in-

definite period.

Refer to—Animal Heat.

COLD CREAM is a pleasant cooling ointment, made by melting four ounces of white wax in a pound of almond oil, by means of gentle heat, and mixing gradually with a

pint of rose water in a warm mortar.

COLD IN THE HEAD, or CORYZA, is an inflammatory affection of the membrane lining the nostrils; it is accompanied with more or less fever. It commences with a sense of dry fulness or obstruction of one or both nostrils, which is quickly succeeded by watery discharge of an acrid character, and there is frequent sneezing. The membrane of the eyes and their lids, being continuous with that of the nose, is also affected, and from a similar cause, extension of the irritation to the membrane lining the frontal sinus, there is more or less headache. If simple cold in the head be not renewed, which it is extremely apt to be, it gradually subsides within the week; more generally, however, as it leaves the nostrils, it travels downwards into the lungs, and ends in catarrh, cough, &c. Coryza is a concomitant of some other diseases, such as measles and influenza.

From its tendency to recur, and also to produce and keep up irritation of the bronchial tubes, coryza is not only not to be neglected, but should be checked at first, if possible, and for this purpose various methods of treatment are recommended. A dose of opium either in the form of a large tea-spoonful of paregoric, or six or eight grains of Dover's powder, or quarter of a grain of morphia, when taken at bed-time, will often check a cold in the head at once; and the usual system of hot foot-baths, confinement to bed, low diet, and diluent drinks, along with diaphoretic medicines, such as spirit of mindererus, antimonial wine, &c., is certainly calculated to mitigate the disorder, and may be followed with advantage. The following mode of treatment was recommended by the late Dr. C. J. B. Williams. He says,— "It is the common practice to drink copiously of tea, gruel, or some other diluent during a cold; as long as this promotes perspiration, it is of some utility, and although it augments the flow from the pituitary or nasal membrane, it. has the effect of diminishing its acrimony by dilution. It is the acrimony of this discharge which reacts on the membrane, keeps up the inflammation, and its accompanying disagreeable symptoms. On this circumstance depends the efficacy of a measure directly opposed to that just noticed, but to the success of which

have the resolution to bear the feelings of thirst for thirty-six or forty-eight hours, we can promise a pretty certain and complete riddance of their colds, and what is, perhaps, more important, a prevention of those coughs which commonly succeed to them. Nor is the suffering from thirst nearly so great as might be expected. This method of cure operates by diminishing the mass of fluid in the body to such a degree, that it will no longer supply the diseased secretion. Any thing that will contribute to reduce the quantity of fluid in the body will assist in the plan of cure, and shorten the time necessary for it to take effect. It is, therefore, expedient to begin the treatment with an aperient, followed by a diaphoretic, as is usual, and this is the more necessary when any fever attends; but beyond this, no further care need be taken, and the individual can devote himself to his usual employments with much greater impunity than under the ordinary treatment. The coryza begins to be dried up about twelve hours after leaving off liquids: from that time the flowing to the eyes and fulness in the head become less and less troublesome, the secretion becomes thicker and between the thirtieth and the thirty-sixth hour ceases altogether: the whole period of abstinence need scarcely ever exceed forty-eight hours. It is then as well to return to the moderate use of liquids, as the first indulgence is apt to be excessive. It is not necessary to limit the solid food any more than to that which is plain and simple, except where there is an acceleration of the pulse, or gastric irritation, in which cases animal food should be proscribed. For the sake of comfort in mastication, the food should not be of the driest kind. Thick puddings and vegetables, with or without meat, will be the best dinner; and toasted bread or biscuit, merely moistened with tea or other liquid, for other meals. A single cup of tea is sufficient to bring back the coryza immediately, after twelve hours abstinence has removed it. We doubt not that it will be said that this plan of cure is worse than the disease, and so it may be in some instances. It may be called always a choice of evils; but we do not believe that any one who is liable to severe colds, after once experiencing the amount of good and evil resulting from this method, would hesitate between them, and it is for them that we make it known.

"We have never witnessed any evil from this abstinence from liquids for the time prescribed; but it is not unlikely that it may do harm in persons with irritable stomachs, or in those liable to urinary disorders. Moderation in liquid food, which may be assumed as a corollary from what has been already said, is one of the best preventives against the bad effects of exposure to cold. When there is a large quantity of liquid in the system, there

If coryza be not in itself a disease of import ance, its tendency to frequent renewal, and as often as it is renewed to the reproduction of irritation in the lungs, renders it really a disease of consequence, and one not to be neglected. Moreover those individuals who are most susceptible to repeated attacks of coryza, are those who are most likely to suffer from frequent or continued irritation within the chest.

COLIC is the painful spasmodic contraction of the muscular fibres of the bowels, particularly of the colon, occasioned by the presence of an undue amount of wind, or of some irritating matter, such as accumulated fæces, undigested food, acrid bile, overdoses of strong purgatives, or poison; it may also be brought on by exposure to cold. The pain of colic comes on and goes off suddenly, is of a rolling or twisting character, is referred chiefly to the umbilical or navel region, and is relieved by pressure; there may or may not be vomiting. In some cases of colic, the spasmodic contraction of the bowel is so complete and permanent, that inverted action takes place, and the fæcal contents are vomited; to this form, the name of ileus, or iliac passion, has been given. The above symptoms distinguish colic from inflammation, the pain of which is of a more per-sistent burning character, and is aggravated rather than relieved by pressure; in the latter case, too, febrile symptoms are present from the commencement. The distinction is, of course, requisite for active medical treatment; but many remedies, which may be used safely and effectually to relieve the one, will also be beneficial in the other, and, indeed, in other spasmodic or inflammatory attacks within the abdomen, which might be mistaken for colic.

The sudden accession of an attack of colic, its peculiarly painful character, and the danger that, if continued, it may pass on to one of inflammation, render immediate relief imperative. The first remedy is heat, either locally to the abdomen by warm fomentations, as hot as they can be borne, or by the hot bath of the temperature of 100°, if not undesirable on other accounts. The use of heat, if promptly and effectually carried out, will often of itself relieve the attack at once, particularly if it is the result of cold; but even should it do so, it will be well to give a dose of castor oil or rhubarb and magnesia, to ensure the freedom of the bowels from irritating matter, a few drops of laudanum being added to either medicine should the spasm show a tendency to return. Should the pain not be relieved by the employment of external heat, as recommended, a warm enema, temperature 102°, should be administered, and a cup of tea or of some unstimulating fluid taken, as hot as it can must be increased perspiration, and therefore drops of laudanum must now be given, and repeated every quarter of an hour, until relief

have been administered. If the case is violent, an enema containing twenty drops of laudanum may be given. These means, if thoroughly carried out, will scarcely fail to afford relief until the arrival of medical assistance, which should always be procured, if the case is at all severe or continued; it may depend on causes which a medical man alone can discover or Alcoholic stimulants are scarcely to be recommended for use in non-medical hands, not because they are not serviceable in colic, but because, should the case be mistaken, and prove one of inflammation, they would prove most injurious, which the remedies above prescribed could not. Still, in a case in which no doubt could exist, a table-spoonful of undiluted tincture of rhubarb, or a glass of hot brandy and water, with or without laudanum, are either of them good remedies.

In severe colic, however, nothing affords such certain and speedy relief as a small dose

of morphia given hypodermically.

Painter's colic, or dry bellyache, is a disease to which persons are subject who work much among lead; it is also occasioned by drinking cider prepared in leaden vessels. It is severe colic, accompanied with obstinate constipation. The disease, either in itself or from concomitant constitutional affection, may prove fatal, and should always be treated by a medical man if possible. The treatment is much the same as that for common colic as far as allaying pain goes, but the obstinate constipation which accompanies it, requires the laudanum and other means to be combined with active purgatives, castor oil, senna, compound colocynth pill, &c. Much might be done by those engaged in employments connected with lead to avoid, not only this, but other bad effects, by due attention to cleanliness, particularly of the hands at meal times. The use of lemonade, acidulated slightly with sulphuric acid, or of aromatic sulphuric acid, in water, would probably be additional protection. Lead colic has been induced in whole families, by the use of water which acted strongly upon leaden pipes or cisterns; and it is well to bear in mind that very soft water is more dangerous when conveyed through lead, and especially new lead, than water which contains a tolerable amount of hardness. The introduction of lead into the system and its results are often occasioned by means little suspected. Many cases are narrated where the long-continued use of snuff which had been imported in coverings made of thin sheet lead, had produced the usual symptoms of lead poisoning.

Those who have once suffered from an attack of colic should pay particular attention to the bowels. The colocynth and hyoscyamus pill of the pharmacopœia will be found the most

useful aperient.

is obtained, or until forty drops, or even more, | of sinking, or prostration of the powers of

COLLAR-BONE.—See CLAVIOLE.

COLLIERS, DISEASES OF .- Miners as a class, are short-lived and unhealthy, breaking down prematurely from a variety of diseases, but principally from those engendered by the circumstances under which their work is carried on. Light and fresh air are both essential to health; and if many have sufficient difficulty in preserving vigour "with all appliances and means to boot," what must be the disadvantage under which the collier labours when deprived of both essentials? A large number of the mines of this country are insufficiently ventilated, and accidents from choke-damp and fire-damp are of too common occurrence, and it is to be feared will continue so, unless an unlimited supply of air be afforded for the consumption of the men, horses, and lights. It is an established law, that to preserve the body in a state of health, not less than 3000 cubic feet of air should be supplied per hour to each individual; and it has been shown by inquiries into the the condition of collieries, that, in the vast majority of instances, nothing approaching this amount is obtainable. Mr. Robert Stephenson even thought that 100 cubic feet per man per minute would not be enough. This includes, of course, all the air wanted in the mines for horses, lights, &c.

Miners suffer much from the inhalation of particles of carbon, coal, charcoal, or dust, in the pursuit of their occupation. These being swallowed, produce dyspepsia, or still worse; and, as is more frequently the case, being inhaled, and becoming lodged in the lungs and air passages, give rise to bronchitis and inflammation of the lungs, and to a peculiar disease now well known as miners' lung or colliers' phthisis, in which innumerable atoms of charcoal are incorporated with the substance of the lung itself, the epithelium of which has actually

grown over them.

The collier also suffers much from the damp, and from the constrained position in which he is often obliged to work for whole days to-

gether.

The grand remedy is efficient ventilation of the mines, which is at once a preventive of the sudden explosions, and of the continual deterioration of health to which our colliers are ever subjected. In addition, it is of great importance that employers should endeavour by all means in their power to elevate the moral and social character of those who, being debarred from the employments and enjoyments of open day, are too apt, in times of recreation, still further to enfeeble their health by debauchery and excess of all kinds.

Some idea of the difficulty of effectually managing the ventilation of mines may be acquired when it is known that, in many cases, COLLAPSE—the term applied to a state | the air has to travel immense distances through COL COM

the various long winding galleries, before it | ing process to go on below undisturbed. Colarrives finally at the up-cast shaft, as it is called. | lodion is best kept in a stoppered bottle, the The method employed is on the same principle as the ordinary fire and chimney; that is, a fire is lighted at the bottom of one shaft, up which the air rapidly flows, after having been made to traverse down the other shaft and along the various galleries. Double doors and partitions are used, and much skill is shown in directing the current of air for such incredible distances. In mines in which there is only one shaft, this is divided in two, a fire being lit at the bottom of one half, while air descends down the other.

COLLIQUATIVE—a term applied to any profuse exhausting evacuation, more particularly the diarrhea and perspirations of pul-

monary consumption.

COLLODION is made by dissolving two scruples, or forty grains of gun cotton, in three ounces of ether, and one ounce of rectified spirit. It is a very useful application to cuts, small wounds, and abrasions, chapped hands, or chapped nipples, &c. It should be gently applied by means of a hair pencil. The ether evaporates, and a thin layer of cotton is left as a covering, which is not removed by washing in water. Collodion may also be applied to leech bites, or small wounds of any kind, to stop the bleeding, which it does, owing to the contraction of the film of cotton constricting

the vessel of the bleeding part.

Combined with canada balsam and castor oil a better preparation for medical purposes called flexible collodion is manufactured, as it obviates the tendency which pure collodion has to crack

on being stretched on the skin.

A mixture of two parts of glycerine, to 100 of collodion, makes an excellent protective application to chilblains, burns, bed-sores, &c. It has also been applied as a protective covering in many cases of disease of the skin, accompanied by great pain, itching, or irritability. It forms a good covering for pills, the anpleasant taste of which it conceals, without in any way interfering with their action.

One of the best known ways of applying a liquid blister, is to paint the surface of the skin over with collodion, in which cantharides or cantharidin, the active principle of the fly blister, is dissolved. It may be applied with a brush directly, which saves the trouble of spreading a blister, and vesication is as quickly produced as with the ordinary plaster, while it is much less bulky, and more convenient in every way for general use.

Collodion is a very good application to small cuts after they have been strapped or stitched up, when it is desirable to exclude the air, and to let them heal, if possible, by what is called primary union or the first intention. It causes a little smarting for a few seconds, but this soon passes off, and a pellicle

stopper of which may be fitted with a camel's hair pencil, to allow of its ready application.

COLLYRIUM -a lotion for the eyes. - See

COLOCYNTH, or BITTER APPLE, is the fruit of a creeping plant, and is brought to this country, chiefly from the shores of the Mediterranean. An extract made from the dried puip is used in medicine. It is a powerful irritating purgative, never used alone, and only likely to be employed domestically in its well known combinations, the compound colocynth and the colocynth and hyoscyamus pill, two of the most universally useful purgatives we possess, of which the dose is from five to ten grains.

Refer to-Pill.

COLON .- The large bowel .- See Alimen-

COLOTOMY .- The operation of opening the colon to form an artificial anus, sometimes had recourse to in obstruction of the bowels.

COMA—a state of insensibility, resem-bling heavy sleep, from which the person either cannot be roused at all, or only to partial consciousness. The condition is generally the result of pressure on the brain, either from injury to the skull, or from effusion of blood or watery fluid, or of matter, within the head. In apoplexy, poisoning by narcotic drugs, and complete alcoholic intoxication, the comatose condition exists: it may also occur as a symptom preceding death in various diseases, especially of the brain and kidneys, and is not uncommon in the contagious fevers. In coma the action of the heart continues sufficiently perceptible; in fainting it does not.

Refer to—Apoplexy, &c.
COMPLEXION—the hue of the face. Much information may frequently be obtained of the existing constitutional condition, by observation of the complexion; but, in judging, it is requisite to consider the original temperament, and the family descent of the individual. In fair races, such as the Anglo-Saxon, a certain amount of colour is usually associated with our ideas of health, and in some respects truly so; the reverse, a perfectly pallid face, can scarcely be consistent with a sound bodily condition. But colour may be too high at all times, and the capillary vessels of the face, partaking of the fulness of those of the body generally, may indicate that from some cause, such as over-feeding, or indolence, combined with good digestive powers, the system of the individual is too full of blood; for the colour is not confined to the parts naturally tinged, but is diffused over the face generally, and even the white of the eye is covered with distended vessels. Such a state is one of danger, is left which forms an admirable protective diness, confusion of thought, sleepiness; and covering for the wound, and allows the heal- when these occur, apoplexy may be dreaded.

A high or brilliant colour, also, may accompany the consumptive constitution, but in this it is very generally associated with a fine skin, and often with light or red hair, with freckles, and also with a pearly or blueish appearance of the white of the eye. This appearance of high health is apt to deceive the inexperienced, but the colour is generally not equal or persistent; it varies much, being easily heightened by excitement, or depressed by the reverse, and it continues to add beauty even to the last stages of the hectic of consumption. In the dark haired, and dark complexioned, colour is less commonly developed. The complexion of disorder or disease is very varied; it may be muddy, pallid, pasty, white, sallow, cachectic,

vellowish green, and purple.

The muddy complexion may be the natural one of the skin, but it frequently accompanies dyspeptic ailments, and is directly dependent on depressed nervous power, and languid circulation of blood; it is most strongly marked in the dark depressions underneath the eyes. Whatever lowers or exhausts the nervous power, will produce this complexion, which may be seen in perfection, when the light of morning shines in, either upon the votaries of a too protracted dance, or upon the weary watcher beside the bed of sickness. Sleep is the best restorer of the exhaustion of nervous power indicated by this condition of complexion; but if rest is impossible, it is one of those cases in which stimulant, hot tea or coffee first, and then alcoholic stimulant, is perfectly requisite. The pallid complexion is often the result of too close confinement to the house, and especially of deficient exposure to diffused daylight: it is well marked in miners. The pasty complexion accompanies the lymphatic constitution; the subjects of it require a good allowance of animal food, in preference to milk and grain preparations, puddings, &c., of which they are often too fond. They almost invariably derive benefit from preparations of iron. A marked white complexion not natural to the individual, is often indicative of serious disease, probably of the kidneys or heart, and when it appears in persons advanced in life, the cause ought most certainly to be investigated by a medical man. The sallow complexion is very generally a natural one. The cachectic accompanies a diseased state of the system, and often of the abdominal organs-it is muddy, and accompanies emaciation of the features. The yellow complexion may be the bright hue of jaundice, or the muddy yellow associated with malignant disease, especially cancer. In the greenish yellow skin of chlorosis or green sickness, there is also extreme pallor of parts usually coloured—such as the lips. A purple complexion is indicative of deficient oxygenation of the blood, either from disease of the heart or lungs; generally of the

Refer to-Skin-Countenance, &c.

CONCRETION is a term applied to the unusual aggregation of any substance or substances within the body, as in the gall bladder, kidneys, joints, and urinary bladder, but here we refer chiefly to them as they are found in the intestines. Persons who have been in the habit of taking large and repeated doses of magnesia, have not unfrequently suffered from its concretion into hard lumps or balls in the stomach or intestines. Any substance which possesses the power of felting or matting together, is liable to form a concretion in the bowels; one has been found of ends of thread matted together, another of human hair, which the female had been in the habit of biting off and swallowing when at work; but perhaps the most common cause of the intestinal concretion is the felting of the bran of the oatmeal as used in Scotland, when too exclusively employed as food, and in too dry a state. Well boiling and diluting, and mingling with other articles of food, particularly of an oily nature, is the best preventative. Intestinal concretions are frequently found in the bowels of cattle, caused by their licking each other's backs .- See Biliary and Urinary Calculi

CONCUSSION.—A term applied in medicine to the effects of a severe blow, over some of the more important organs of the body, especiof the head and spine.

For concussion of the brain see Brain.

Severe concussion of the chest affecting the heart, or over the region of the stomach, may prove fatal immediately, or at least produce much alarming faintness and collapse; in the latter case, the use of stimulants, such as ammonia or spirit, internally, or stimulant injections, and the dashing of a jug of cold water over the chest and face, immediately following it by hot applications, mustard, &c., would be the most appropriate treatment. -See

CONDIMENTS are substances which are not of themselves nourishing, but which are taken along with food as seasoning, and to promote its digestion. Salt is the most extensively used, and also the most necessary condiment, if indeed it can be classed as a condiment, seeing the important uses it serves as a mineral food. Many of the lower animals are not only fond of it, but seek it instinctively as a necessity, and improve in health and appearance when they have access to it. Other condiments are obtained from the vegetable kingdom, and owe their properties to certain vegetable oils which they contain. The vegetable acids, vinegar, &c., are useful and wholesome in moderation, particularly with oily food. The aromatics and spices, such as cayenne, white or black pepper, ginger, mustard, &c., are all useful when used in moderation by healthy individuals; in debility of the stomach they are often of service, and they seem especially adapted to counteract the effects of a warm

climate upon the digestive organs, and also to the constitution, acquired or otherwise, of the inhabitants. They are, however, generally used along with other vegetable productions.

Refer to—Salt—Vinegar—Aromatics, &c. CONDYLE—the extended extremity of

a bone which forms the joint.

CONFECTION—a term applied to medicinal preparations generally made with sugar or honey. The most common are almond confection, aromatic confection, cassia, rose, and senna confections. Of these the most useful is the confection of senna, prepared as it is with numerous fruits and aromatics, combined with senna in fine powder and sugar. Dose for a child one or two teaspoonfuls.

Refer to—Almond—Rose—Senna, &c.
CONFECTIONERY, literally, "things made up," is not necessarily unwholesome, if used in moderation; it is, however, too often deleterious if made with much butter, of bad materials, or mingled with poisonous ingredients.

Baked Confectionery, in which the butter or grease, is rendered empyreumatic and acrid by the heat employed in its preparation, is always liable to disagree, and especially so when, as often happens, bad materials are made up and disguised with flavours of various kinds, which are often in themselves unwholesome, particularly those so largely used, such as the oil of bitter almond, peach, kernel, and laurel flavouring, which are actual poisons, when

taken even in not very large quantity.

In reference to sweetmeats, a recent writer (Wynter Blyth on Foods), says, -"A large proportion of those most commonly sold contain nothing but sugar, for the manufacturer, by careful heating, is able to impart a quite surprising scale of colours from the purest white to fawn colour, straw colour, reddish brown, or brown, to almost a jet black, by this agent alone. Sugar-candy is simply crystals of sugar obtained in a particular way.

The ice-coating of cakes is composed of white sugar and albumen. A great many sweets are acidulated with citric acid, and a few have cavities within them supposed to contain alcohol, but really a little syrup. Gum tragacanth, citric acid, fruit sugar, gelatine, albumen, fatty and flavouring matters, with the following colouring matters, make up the usual harmless ingredients of the confectioner's shop :-

"Red .- Cochineal, carmine, the juice of beet, and of red berries, such as cherries, currants, &c.

"Yellow. - Saffron, safflower, turmeric, marigold, Persian berries.

"Blue. - Indigo, litmus, saffron blue.

"Green .- Spinach juice and mixtures of yellow colours with blue.

"Black .- Chinese ink.

"Besides these there are the aniline colours which, when pure, have not been proved to be injurious."

Cases of injury, however, have arisen from coloured confectionery and sweetmeats having been tinged with deleterious substances; the greens with arsenite of copper or Scheele's green, verdigris, or a mixture of chrome and Prussian blue; the yellows by chromate of lead; the reds by vermillion, a compound of mercury, or by oxide of iron; and the whites by carbonate of lead, oxide or carbonate of zinc, chalk, or sulphate of baryta. These facts ought to be sufficient to make people cautious in the use of such articles, particularly with children; and in case of sudden unaccountable illnesses, they should not forget the possibility of such causes. The colour of a sweetmeat would afford some clue to the nature of the poison, and reference to the proper article in this work will show the measures proper to be adopted in the interval of procuring medical assistance.

CONGESTION - a morbid accumulation of fluid, such as blood, in its own proper vessels. Such a condition usually precedes inflammation, and is marked by heat, pain and swelling of the part, caused in the first instance by activity, and afterwards by a passive condition of the circulation giving rise to obstruction. This retardation of the natural current occurs mainly in the venous capillaries, is dependant on the various causes which give rise to inflammation, and is to be dealt with locally by the application of leeches and hot fomentations, and constitutionally by attention to the general health and the employment of those measures which are necessary in cases of inflammation.

CONJUNCTIVA is the membrane which lines the eyelids, and is folded from them upon the fore part of the eyeball, which it covers, extending over both the white and the clear portion, or cornea. In its ordinary healthy condition, the conjunctiva is a transparent membrane, with perhaps one or two tortuous vessels seen upon it.

Refer to—Cornea—Eye, &c.

CONSERVE is a compound of some fresh vegetable substance with sugar. The conserves are now classed with the confections.

CONSTIPATION, or COSTIVENESS, is due to a sluggish or torpid action of the bowels, and consists in the retention of the fæcal contents, and their evacuation in a harder and drier condition than natural. The state is one, in great degree dependent upon habit and constitution, for that which would be considered constipation in one person, would not be so in another, and vice versa. As a general rule, however, the bowels ought to relieve themselves thoroughly, once in the twenty-four hours; when such is not the case, the condition may be said to be one of constipation.

With some individuals, a single evacuation of the bowels, once every three or four days, seems to be sufficient, and perfectly compatible with their enjoyment of perfect health; and,

when such is the case, it is of course super- | means is preferable to the constant taking of fluous to endeavour to correct it, and it is better to let well alone. If, however, in conjunction with this condition of the bowels, the persons suffer from headache, from languor, from distention of the abdomen, if the breath is disagreeable, and the tongue furred, the state is not compatible with health, and should be corrected.

The causes of costiveness are very numerous, the nature of the food, as might be expected, exerts considerable influence; bread badly made, and especially if alum be mixed with it, cheese, milk with some persons, farinaceous articles, such as arrow-root or ground rice, and food of too concentrated a character, all tend to con-Deficient exercise, particularly if combined with much exertion of mind; any drain upon the system, as in suckling, abundant perspirations, loss of nervous power, and old age, have the same effects. Pregnancy, and tumours in the abdomen, constipate by mechanical obstruction, and in the same way, contraction of any portion of the alimentary canal. The colon or large bowel is very frequently the seat of the constipation, it loses tone, allows itself to be distended, sometimes to an enormous extent, or contracts to a very narrow calibre in some portion of its course. Lastly, a very common inducing cause of cos- by an attendant, from the nape of the neck tiveness, particularly in females, is inatten- downwards, with a little olive oil daily for ten tion to the intimation of nature to relieve the minutes, as recommended under Circulation.

Porhaps there is no ailment to which the human body is subject, which is more fre-quently mis-managed than constipation. Every effort should be made to correct the disorder without the aid of medicine. In the food, all those articles which have been enumerated, or which are known to constipate, must be avoided; the bread used should be made of coarse flour or whole meal; if vegetables and fruits agree in other respects, they may be freely consumed, and cocoa substituted for tea or coffee: food is not to be taken in a state of too great concentration, but so that, by the bulk of its refuse, it may afford substance to stimulate the action of the bowels. In addition, there are various articles of diet which exert an aperient effect, and which may be used or not according to the taste of the person: such as Scotch oatmeal in the form of porridge, honey, prunes, &c. Exercise, whether on foot or horseback, is another valuable aid in the removal of the costive state; it not only quickens all the functions, but it assists by the mechanical motion it communicates to the muscles of the abdomen; a similar effect may be produced by frequent flexion of the thighs, calling into play the same muscles, as in the action of moving up and down stairs. Prisoners who have a certain amount of work to do daily on the tread-mill rarely suffer from constipa-Glycerin Suppositories\* often afford great relief, and the use of such mechanical the treatment of costiveness is, that it is more

medicine. They can be safely employed (cut to a proper size) even for infants, and are helpful in the constipation of old age, producing easy evacuations. Another very important point is regularity in the time of evacuating the bowels; not waiting for the urgent sensation, but retiring for the purpose at one set period of the day, when time can be given. The bowels are greatly influenced by habit, and they can be trained to act periodically by persisting to make them act at a stated time each day. Persons who are liable to costiveness should give themselves at least a quarter of an hour, or even longer for the daily evacuation of the bowels. Lastly, as constipation is so frequent an attendant upon the sedentary life of the student, and upon the anxious-minded man of business, a holiday both from books or desk, and change of air and scene, is both a good and pleasant remedy.

In children, who occasionally suffer from constipation, a little fluid magnesia mixed with their milk, or a tea-spoonful or two of confection of senna, or the same amount of castor oil will Further, a usually meet the requirements. very good remedy, which often supersedes the use of medicine, is friction of the back and limbs-the spine being rubbed gent y

When neither diet nor regimen will effect the cure, other means must be had recourse to. If there is simple costiveness, without disorder of the digestive functions, the best remedy will be the regular use of a harmless aperient, as cascara tabloids, the colocynth and hyoscyamus pill, or saline mineral water, such as Hunyadi or Friedrichshall; if, on the other hand, furred tongue, with acidity of stomach, flatulence, pain between the shoulders, headache, &c., betoken deranged digestion, special medicine to meet the case will be required, at all events in the first instance; the liver is probably at fault, and five or six grains of blue pill, or of compound colocynth and calomel pill, followed in the morning by the black draught, or by castor oil, will be requisite.

When the bowels have been well cleared by the above medicines, it is requisite to keep them open, otherwise a few days will see all the symptoms return, and, in fact, such is too often the case: persons are content with taking a dose of strong opening medicine every few days, or once a week, as the case may be, and rest content with this, as it is called, having a good clearing out-albeit they are under the necessity of increasing the strength of the doses. The practice is one incompatible with sound health, and is most injurious to the stomach and bowels themselves; many cases of obstruction, and even inflammation of the bowels, are produced by it. The principle to be proceeded upon in

easy to keep the bowels in action than to excite | other aperients. As age advances, the bowels them to it when they have become thoroughly torpid, and therefore the individual should not rest content without the daily evacuation. If simple constipation, depending upon inaction of the lower bowel, exists, the use of a salt water enema will in all probability be sufficient; but medicine may be required, perhaps daily, for some time, or it may be used alternately with the enema. Some medicines are more than others adapted to the treatment of habitual costiveness, and of these castor oil, aloes (alone, or in its combinations), senna, and Epsom salts are the principal; their great advantage is-not losing their effect by continued use. castor oil can be taken regularly, in most cases it answers extremely well, and if taken regularly, the dose requires rather diminution than increase; it is a medicine, moreover, which never seems to injure the tone or the mucous coat of the bowels. In the constipation of pregnancy, castor oil is so well known as the best and safest aperient, that it scarcely requires mention. Aloes is peculiarly well adapted to relieve certain forms of costiveness, particularly that of the sedentary, and may be taken in the form of pill, in combination with soap, in the compound rhubarb pill or compound colocynth pill; any of these are most excellent combinations. If there is debility of stomach, the addition of a quarter or half a grain of quinine to each pill increases the efficiency of the medicine and gives tone to the stomach. The quinine must not be continued for more than a fortnight at a time. The dose of aloes when regularly taken does not require to be aug-When quicker action is required, the compound decoction of aloes may be taken with advantage instead of pills, or a pill containing one sixth of a grain of the extract of nux vomica and five grains of the compound colocynth pill. The principal contra-indication to the use of aloes is the occurence of piles, which, if inflamed, or if the dose be too strong, are apt to be aggravated by the medicine; in this case, castor oil, or infusion of senna, or the enema, should be substituted, for a time at least. In some cases, on the other hand, when the piles are not inflamed, aloes taken regularly in small doses, seem to exert a beneficial and curative action upon them; probably in consequence of keeping the intestinal veins from becoming over-loaded with blood. Senna, either in infusion or electuary, is a medicine well adapted for the relief of costiveness; it is perfectly safe, and does not seem soon to lose its effect. Ipecacuanha, not alone, but in quarter or halfgrain doses, added to the aloetic pills, exerts a most beneficial effect in cases of habitually confined bowels. A weak solution of Epsom salts, a drachm to the half-pint of water, with or without the addition of five or ten drops of dilute sulphuric acid, when taken on first rising in the morning, will prove effectual with

become more sluggish, and require to be assisted in their action by aperients. When the ordinary remedies mentioned above fail, large enemas of warm water, or of thin gruel with which three or four ounces of olive oil have been mixed, are frequently effective. Again, it is repeated, keep the bowels free, by food, by exercise, by habit. if possible; by injection or medicines, if necessary; but do not let them become costive.

In some individuals, in whom the walls of the abdomen are very flaccid, and do not afford sufficient tonic support to the contained bowels, costiveness frequently exists, and is much remedied by the use of an elastic or other belt, worn to support the entire abdomen.

-Digestion - Laxatives - Suppositories, &c.
CONSUMPTION, or PULMONARY CON-SUMPTION, as its name implies, is a disease of the lungs, or at least one in which the lungs are more prominently affected than any other organ. It is rightly termed consumption, as the vital process of combustion or consuming, goes on rapidly at the expense of all the tissues of the body, and cannot be counteracted by ordinary means. In Britain, its fatality and frequency render it but too familiar, as year by year it numbers for its victims, the young, the good, and the fairest in the land. The registration of deaths from all causes, shows that in England it accounts for one-tenth part, or about the same proportion as small-pox a century ago.

Consumption is a portion only of a constitutional malady, which very frequently develops its intensity in the organs of respiration, but may do so in other modes, and in other organs of the body. Its constitutional nature requires to be impressed upon the mind of people in general; for regarded only as a disease of the lungs, alarm is not taken, nor are remedies generally resorted to, until its effect upon these organs becomes manifest; the antecedent period, in which the constitution is giving way, is overlooked, and that time is lost in which the first indications of disease might have been successfully attended to. Consumption owes its origin to a deposit of new matter called tubercle, in the substance of the lung texture, which is infiltrated or studded over the organ in minute granules, like millet seeds or of larger size, but rarely larger than peas. These deposits are most frequently found in the upper parts of the lungs immediately under the collar bone, and after lying dormant for a while, become converted into yellow cheesy masses, which breaking down in the substance, involve the surrounding healthy tissues, giving rise to rupture of some of the small blood vessels, and to abscess, and accounting for the cough being accompanied in most cases with expectoration of blood and purulent matter. A similar tubercular deposit occurs some, and forms a change from the use of the glands connected with the intestines, causing

tion has its acute and chronic features; it may carry off its victim in a few weeks (rapid consumption), but it is more likely to continue for

years with intermissions.

Causes.-In 1881, Koch discovered that a special micro-organism, Tubercle bacillus, is to befound in tuberculous material. This bacillus is the essential factor in the disease. The development of consumption, however, is favoured by all the causes which occasion debility, not excepting the most frequent of all, hereditary predisposition, that tendency to the disease which exists so strongly in some families, that no care or precaution can ward it off, nor prevent it seizing in succession member after member of a household. Fortunately, this intensity of hereditary transmission is not so very frequent, but there are few families in this country in which the tendency does not more or less exist; there are few which cannot number amid their deceased relatives some victim of consumption. With a susceptibility so widely diffused, it becomes a serious con-sideration with all by what means this tendency is encouraged, and how it may be diminished. The first consideration that presents, is marriage. There can be no question, that from errors in the contraction of this great engagement of life, much of the hereditary tendency to consumption is developed, and especially when the union is between parties nearly related by blood; doubly so if the predisposi-tion already exists in the family. Delicacy of either parent, particularly of the father, is very apt to entail consumptive tendencies upon the children; and the same follows if the parents are either too young, or if the father be advanced in life. The mistake is a very common one, that marriage and child-bearing act as a check upon the progress of consumption, and the step is often advised, even to the comparatively young, with this view. The error is a serious one; nothing can be more trying even to a healthy female, in this country, than having a family before the constitution is formed; and most certainly it is so to the weak. It is true, apparent temporary amendment of consumptive symptoms sometimes occurs, but the powers of life are sapped by the too early call on their exertions. In the management of the children of even the most healthy parents, doubly so of those who are the reverse, much may be done either to weaken or to fortify the constitution, to pull down the one to the level of the scrofulous diathesis, which ripens into consumption, or to infuse into the other such strength and vigour that it may resist during a long life any development of the disease. For information respecting the management of children, the reader is referred to the article itself.

As the period of puberty approaches, care is required with all, but doubly so in the case of those who have displayed any scrofulous or patient is the last to take the alarm, the last

abdominal or intestinal phthisis. Consump- | consumptive tendency. The development of the body which is going on, requires a full supply of the most nutritious food, animal food particularly. The secretions should, if possible, be kept in healthy activity, and more especially, all sources of exhaustion most strictly avoided; youths, especially, must be warned against the evil of prolonged physical exertion, and not less so against the mental efforts, which those, especially, who partake of the nervous and excitable constitution of the hereditary consumptive, are apt to give way to in competitions at school or college.

At any period of life, mental anxiety or over-exertion, intemperance, or dissipation, the habitual breathing of vitiated air, a low damp situation, insufficient clothing, and exposure to the weather, or peculiarity of employment, particularly that which necessitates the inhalation of irritating matters, or any continued drain upon the powers of the constitution, such as suckling, may any of them develop or

induce consumption.

Two very opposite conditions of physical development are found to exist along with the scrofulous and consumptive tendency; in the one, there is the fair fine skin and bright red complexion, the fair hair, the light eye, with its pearly-looking white, and the tapering fingers; in the other, the dark hair and skin, the latter almost dirty-looking, and the swollenlooking upper lip. Consumption varies much in its initiatory stage; sometimes it steals upon the patient most slowly and imperceptibly; at others, developed probably by some acute attack, it appears to start at once into activity. Generally, for a considerable period before marked symptoms — or at least symptoms which attract general attention—show themselves, the person has felt weak, languid, and complained much of cold, probably has lost flesh, and short dry cough has come on, apparently without cause, or there has been continued dyspepsia; if the patient is a female, the monthly discharge has become irregular, or stopped; it may be that these symptoms have been aggravated during winter, and disappeared partially or entirely with the advent of warm weather. Such symptoms may go on for a longer or shorter period, ebbing and flowing, but still gaining ground, or they may progress more unremittingly, though still slowly, or become suddenly aggravated by some adventitious circumstance, such as cold taken, some unusual fatigue, or the like. The emaciation becomes too evident to escape notice, the cough is unabated and becomes troublesome, the voice assumes a peculiar hollow sound, the breathing is quickened, and it may be that spitting of blood, profuse night perspirations, or even diarrhoea, have set in before the patient's condition excites either alarm in his own mind or in that of his friends; indeed, it very frequently happens that the

to entertain the idea of the fatality of the dis- all less likely to be the victime of the disease. ease, of which this hopefulness of recovery is

a well-marked symptom.

Threatened consumption is no disease for domestic treatment. On the first suspicion of its presence, the person should at once be examined medically: the above symptoms may excite alarm, may afford most grave ground for suspicion, not only to the friends, but also in the mind of any medical man, but their certainty cannot possibly be pronounced upon, without the examination which educated medical skill alone can conduct.

As regards the prospect of recovery from consumption-for recovery does undoubtedly take place-much depends upon the original and existing constitution and the habits, past or present, of the individual, and the worldly means within his power.

Prevention.—The prevention of so fatal a disease is a more important subject, in a work like the present, than its treatment; and in those predisposed, the preventive or prophylactic system must be continued life through, even into old age. It is a popular error, that by the time middle life is reached, the liability to consumption is over. Such is not the case, for even the "three-score and ten" is sometimes

terminated by the disease.

Climate. — When the children in a family evidently inherit or display consumptive tendencies, it should become a question, how far permanent removal to a more genial and drier climate than that of Britain, might be desirable. To the rich, who have it in their power to change their residence as and when they may, the consideration is perhaps of less immediate consequence; but to the labourer, the mechanic, or the man of small income, it must be a question of paramount importance, whether, by emigration to such a climate as that of Australia, he may not only save himself the constant sorrow, of seeing his family drop one by one into their early graves, but also save the constant drain upon his resources, which a sickly family necessarily entails.

Occupation. - But in any condition of life, the question of tendency or not, to consumptive disease, should always influence the choice of field for exertion, and also of the nature of the business of life. Any occupation which renders the inhalation of irritating substances unavoidable, is to be eschewed by the consumptively inclined man, and not less so that which involves confinement in a constrained position, or in a close room. Of the former class, grinding or polishing of metal or stone, especially if dry, flour-grinding, &c., are examples; of the latter, the occupation of the tailor, the shoemaker, the seamstress, or the compositor. The most eligible employments are those which require muscular exertion of not too exhausting a kind, and without too great exposure to the weather; the gardener, the carpenter, the butcher, the farm servant, are

Hygiene. - In whatever situation or grade of life, however, a person may be placed who is predisposed to consumption, much may be done to maintain the powers of resistance, by keeping up the general health to the highest possible standard, by diet, early hours, attention to the skin, and avoidance of all kinds of dissipation and intemperance; smoking too much tobacco should be shunned as particularly injurious. Regular exercise is to be taken - the chest and shoulders should be bathed every morning with cold salt water, and rubbed afterwards to promote reaction. Cheerfulness of mind, and moderate mental exertion are important, whilst perfect temperance in the use of alcoholic stimuli is indispensable. Above all, emphasis must be placed on the importance of thorough ventilation of the residence, and a plentiful supply of fresh air to the rooms occupied as well during the night as in the daytime; and the habit of sleeping both summer and winter with windows freely opened should be cultivated. Where a choice of occupation is possible, an out-door life should

always be preferred.

Diet and Treatment.—As regards diet, there is the greatest variation, some being most comfortable with a milk or farinaceous diet alone, whilst others require the constant use of wine or porter, and consume animal food in good quantity. Cod-liver oil should be given from the first appearance of the disease, and should be continued unremittedly. Some persons, however, cannot take cod-liver oil in any form, and then the various forms of maltine will be found most useful, especially in combination with the various hypophosphites. For allaying the troublesome cough, demulcents of various kinds may be tried with or without the addition of small doses of morphia, laudanum, paregoric, or chlorodyne. When tendency to perspiration exists, and there is no diarrhea, the following is a very useful and palatable mixture, which allays both nervous irritability and cough:- Take of dilute hydrochloric acid thirty drops, muriate of morphia one grain, refined sugar two drachms, water six ounces; of this mixture a tablespoonful may be given every few hours. In the latter stages, when the cough is partly spasmodic, and expectoration difficult, much relief is often experienced by the inhalation of steam, along with the vapour from a few drops of sulphuric ether, put in the boiling water. The perspirations may be kept in check by fifteen drop doses of dilute sulphuric acid in a wine-glassful of water; but when diarrhoea is present, this cannot be persevered with. T $\sigma$ relieve diarrhea, the abundant use of isinglass or gelatine will be found serviceable, also chalk mixture with opium; five-grain doses of the sub-nitrate of bismuth, with a quarter of a grain of powdered opium, is often a useful remedy. Acetate of lead, gallic acid, &c., are

also used, but mainly with the view of arresting hæmorrhage from the lungs. Inhalations of various kinds have now come largely into use in the treatment of pulmonary consumptions, and many forms of inhalers have been used; but in point of convenience, efficiency, and comfort, the small respirator form recently introduced by Dr. Coghill, is the best.

CON

Infection. - Consumption is now regarded as a communicable disease, but the risk of infec-tion to healthy persons is slight. As has been well said by a recent writer (Dr. J. Ed. Squire, Hygienic Prevention of Consumption): "Let us thoroughly understand that sufferers from consumption need not be shunned as dangerous to their neighbours, nor isolated like small-pox patients. Direct infection is rare, and only possible under certain easily avoided conditions. . . . The experience of the nurses at the Brompton and other large consumption hospitals may be taken as a proof of the small risk of direct infection to healthy persons in continued residence amongst consumptive patients, so long as due hygienic

precautions are followed out.'

What these precautions are, and wherein the danger lies, will be easily seen from the following extract, also from Dr. Squire's work: "Almost all authorities seem to agree that the most potent cause of tubercular infection, and certainly the most frequent source of consumption or pulmonary tuberculosis, is to be found in the dust derived from the dried expectoration of phthisical persons. It seems probable that such infection may cling about rooms which have been occupied by consumptive persons, and retain its virulence for a considerable time. There is evidence pointing to the existence of infected houses and infected workshops; and our knowledge of the infective power of dried sputum dust, shows how indiscriminate expectoration may be a source of danger. Amongst the more careful and more cleanly portion of the community the danger is minimised by the use of spittoons for the patient, and by the frequent removal of dust from the rooms. But there are persons who are less cleanly in their habits. . . . For such persons it is necessary to seize any opportunities which may present themselves to instruct them as to the danger to others of indiscriminate expectoration by consumptives, and to teach them how this danger may be avoided. With this object the North London Consumption Hospital has adopted the following regulations, based upon suggestions by the author :-

Directions to Out-Patients .- As it is now known that the phlegm coughed up in consumption contains the seeds of disease-

'Do not swallow your expectorations. This habit may lead to consumption of the bowels. Do not spit about the floor, nor into any

utensil unless it contains a disinfectant.

' Do not spit about the streets.

'Indoors, use a special spitting-cup or other vessel in which is some disinfectant.

'Outdoors, use a pocket handkerchief, or else use a piece of rag or paper, which must be burned as soon as you get home.

'You can get some disinfectant from the

dispenser for use in the spittoon.

The contents of this spittoon should be mixed with some more disinfectant before being emptied.

'The spittoon should be emptied into the pan of the w.c. or into a bright fire, but never anywhere else, not even into the dustheap.

If you spit into a pocket handkerchief, it must be boiled for five minutes as soon as it

is done with.

'Keep your room well aired, throw the window wide open when you leave the room, and keep it open a little at the top all night.

'If there is a fireplace in the room, do not stop up the chimney, but always keep it free for the passage of air.

' Keep your room clean; do not allow dust

to remain on the floor.

'Consumptive patients should sleep alone. 'Consumptive mothers should not suckle

their children." The clergy, nurses, district visitors, and

others who come much in contact with the poor, might do excellent service by making Dr. Squire's simple rules widely known.

Refer to-Chest-Children-Inhalation-

Lungs-Respiration-Scrofula.

CONTAGION is sometimes used to express the actual agent by which disease is propagated; but more generally the propaga-Properly speaking, the term ought tion itself. to be confined to the propagation of disease by actual contact, in contradistinction to infection; but it is now used in the more extended sense of "infection" likewise. Contagious diseases may be communicated only by actual contact of individuals, as in the case of itch; by inoculation, as in the case of small pox; or through the direct medium of the atmosphere, as scarlet fever, small-pox, typhus, &c.

This power of propagation through the atmosphere, however, does not (independent of epidemic and endemic influences) extend far from the patient. Certain circumstances influence the extent of contagious diffusion these, the most distinctly ascertained are atmospheric impurities; for it is ever observed, and we believe it may be predicated of every disease possessing the property of remote contagion, that its contagious matter is propagated more readily in a dirty, crowded, and ill-ventilated apartment, than in one of which the air is pure. The same principle applies to articles of dress and furniture; those which are contaminated by animal secretions and effluvia being much more readily impregnated with contagious matter than those which are clean. Peculiar atmospheric conditions, certainly, also favour the propagation of disease by con-

ciable, at others they are evidently connected | with a superabundance of warmth and moisture; and also we have good reason to conclude, with certain states of electrical disturbance. Actual contact, however, or even immediate vicinage, to a person labouring under a contagious disease, is not requisite for its propagation to others; this may be effected by means of substances to which the contagious matter clings; these substances are more generally clothing and stuff furniture, which have been about or near the bodies of those labouring under the They are apt to be impregnated with the poison in a very concentrated condition, and are capable, not only of retaining it for a long period, but of transporting it from place to place. A sofa, on which a patient labouring under scarlet fever had lain, has been known to propagate the disease six months afterwards; and clothes which have been about the sick are constantly ascertained to have been the media of conveying fever, &c., to distant localities. Wool and cotton seem particularly apt to attract and retain contagious emanations; but, indeed, all loose textures appear to have the property; whilst, on the other hand, polished and hard surfaces and substances are much less likely to act as matrices, if they do so at all. Everything of unnecessary drapery or clothing should be removed from the chambers of those sick of contagious maladies, or, indeed, of any malady; for a sick chamber must always, in a lesser or greater degree, have an atmosphere containing unhealthy emanations, which it is expedient, both for the good of the patient and of others, should find no unnecessary attractions or lodg-ments. Further, it is advisable to have the furniture as much as possible of hard and polished substances; and the dresses of those in attendance upon the sick, especially if habitually so, might with advantage be made of cotton with a glazed surface. Those substances which have necessarily become the harbour of contagious matter, ought to be scrupulously freed from it by complete and lengthened exposure to the open air, by boiling or by exposure to the fumes of chlorine or of sulphur vapour, in a close apartment. Indeed, those persons under whose management a case of contagious disease has occurred, ought, as a Christian duty, to make sure that every article of stuff furni-ture, clothing, &c., has been fully and carefully purified, before others, either in the way of social intercourse, or in occupation, particularly that of the washerwoman, come into contact with them. The following is the most systematic course of action when the generation of contagious matter has ceased in an apartment, either by the death or recovery of the patient, premising of course, that throughout the illness,

tagion; sometimes these conditions are inappre- | be open to their full extent, and the infected articles freely exposed to the air. After this the windows and doors and every chink and crevice of the room being thoroughly closed, a pound of sulphur placed in a shovel over a chauffer or stove in the centre of the room, should be allowed to burn slowly until every corner of the apartment is thoroughly impregnated with the sulphurous vapour. A more convenient plan of generating sulphurous acid, is adopted in many places. Instead of the pure sulphur, a compound of sulphur and carbon, the bisulphide of carbon, is employed for the purposes of fumigation. This is an inflammable liquid, which when put into a cup (it had better be made of iron) and placed on a tripod at a safe distance from the floor, in the middle of the apartment and lighted, throws off, according to requirement and quantity, sufficient sulphur-vapour to destroy every particle of contagion in the atmosphere. All textile fabrics and the like should be removed; those that are capable of being washed put into boiling water, others placed in the open air. All articles of furniture left in the room, also the floor and oil-painted wood-work, should be well scoured. If the chamber be a whitewashed or coloured one, it should be "re-done;" if papered, it is only a safe precaution to repaper it. The bed requires the greatest amount of care; if of wool, it is better destroyed altogether; if of hair or feathers, these should be exposed to the heat of re-baking, that is, at least to a temperature of 230° Fahr.; and the ticking either thoroughly fumigated and washed, or entirely renewed. These directions may appear minute and troublesome, but they are far from being too much so when put in comparison with the fearful scourge of a contagious disease which has established itself in a household or community, and which perhaps might have been checked at the outset by the adoption of prompt and vigorous measures. poor and the ignorant cannot or will not adopt, in most instances, effective precautions; it remains for the rich, for the well-informed, to point out their necessity, and lend a helping hand to their fulfilment, not only as an act of Christian charity, but as a means of safety for themselves; the disease which takes its origin in the cellar of Lazarus, not unfrequently ends by establishing itself in the mansion of Dives. It is not a necessary character of contagious disease that it has itself sprung from contagion-some of the most virulent and spreading fevers, such as those of the ship, or of the old jails, had no such commencement; but had their origin in the decomposing emanations from the bodies of numbers of individuals confined in unventilated and insufficient spaces. In addition to the disinfectants already mentioned, air, boiling water, measures have been, or ought to have been, resorted to, to preserve purity. During the day, the door being shut, the windows should slice used, such as the vapour of vinegar, of pitch, or of tobacco, or camphor; large fires also used to be a favourite method; none of

Chlorine gas, generated from chlorinated lime to which some hydrochloric acid has been added, may be used instead of sulphur, but the latter does not require repetition, which the former does. In many instances, particularly in the case of clothes, and other textures which will not wash, dry heat might be used more extensively than it is at present by means of the disinfecting oven. Refer to Air, Bedroom, Disinfection.

CONTUSION .- See BRUISE and CONCUS-

CONVALESCENCE is the transition period between the care or cessation of severe disease, whether acute or chronic, and the re-establishment of health. The commencement of convalescence, or the point at which the characteristic symptoms of disease cease, is sometimes distinctly marked, more especially after acute disorders; frequently, however, the tendency towards health, particularly after chronic disease, is much more insensibly established; in the latter case, too, the progress of the convalescence is slower than it is in the former. Its rapidity or protraction, moreover, is much influenced by age, and the nature and treatment of the previous malady. Children convalesce rapidly, old people the reverse; but in all cases the natural power or resiliency of the constitution exerts much effect. In no case, perhaps, is convalescence more tardy and unsatisfactory than after illness in which much loss of blood, or of its constituents, has taken place, either as a consequence of the disease, or of accidental hæmorrhage.

When convalescence from acute disease commences, the previously quick pulse falls to the natural standard, the tongue begins to clear, the skin becomes cool, sleep is refreshing, the mind acquires a more healthy and hopeful tone, and the person looks better. There is nothing which more assures a medical man of the condition of his patients, than the look, the expression of the countenance, to which the first glance, as he enters the room of sickness, is almost instinctively directed. The look of convalescence is tranquil, placid, not the heightened colour and bright eye of hectic, which so often deceives the inexperienced with When the brain has been delusive hopes. much affected, however, the condition of the mind, and consequently the countenance, assumes its natural look more slowly.

The management of convalescence is extremely important; errors in this respect frequently expose the already weakened patient to attacks of other disorders, or induce relapses to the diseased actions which had just been cast off. The convalescence after some particular diseases is more liable to such accidents than it is in others. That after fever is peculiarly so; and after scarlet fever, the tendency to cold and its consequences, dropsical swelling, and affection of the kidneys, is so very common,

these last mentioned are to be depended upon. | and so frequently fatal, that the greatest possible care is requisite. During convalescence from acute disease, and especially of an eruptive character, many of the disorders characteristic of the scrofulous constitution show themselves: the eyes become the seat of chronic inflammation, purulent discharge from the ears occurs, and chronic eruptions show themselves upon the skin, of the head especially. Moreover, these disorders, now, perhaps, for the first time apparent, are apt to continue even after convalescence, properly so called, is Further, relapse in convalescence often occurs from too soon employing actively the previously affected organ; the liability to this mishap must be evident to the common sense of every one. In the case of the eye, it is evident to the senses, after inflammation of that organ, its undue exercise, or even its exposure to full daylight, will often be followed by a return of the disease. Such is the case elsewhere, and whether it be the eye, or the brain, or the stomach, which has been affected, return to the ordinary exertions of health must

be made with the greatest caution. The clothing of a convalescent patient requires particular attention; there is much susceptibility to cold and to atmospheric vicissitudes. For the requisite information, the reader is referred to the article Clothing. General exercise is to be resumed cautiously, and should never be carried to the extent of fatigue. Diet, however, is the great source both of error and mischief, the greatest difficulty which the medical man has to contend with; that is, in getting it properly attended to, and his orders properly carried out, parti-cularly among the poor. Whilst disease is in progress, and alarm is felt, directions are tolerably well, or indeed strictly obeyed; but no sooner does the patient begin to get better, than irregularities commence. The popular idea seems to be that convalescence must advance in proportion to the amount, and often to the stimulant qualities of the food given; and many a hopeful case sinks back into fatal relapse, from the wilful and injudi-cious kindness of friends. The point is one which requires to be strongly enforced, not only on the minds of the poorer and more ignorant, but on those of people generally, that in diet, as in everything else, convalescence must be gradual, and that nothing is more dangerous, more likely to induce relapse, than the injudicious use of solid animal food, or of stimulants. Milk, and the various farinaceous preparations with which it is usually combined, such as arrow-root, sago, rice, bread, &c., is perhaps the most generally useful article of diet in convalescence; next come the broths made from fowl, mutton, veal, or beef, alone, or mixed with some of the farinacea; next in succession, eggs lightly boiled; and lastly, solid meats, of which tender mutton is probably the best, are to be permitted. Ripe fruits in

their season, if not contra-indicated by the | vulsion, but in this case the term spasm is nature of the previous disease, and if they do not occasion flatulence or diarrhœa, are both grateful and serviceable. If alcoholic stimulants can be dispensed with, it is the safer plan, and when requisite, the time of their employment, and the kind used, are best left to a medical attendant. A good deal must depend upon the previous habits of the person. Gin, in cases in which the urinary secretion is deficient, is most suitable; or light sherry, if the circulation is excitable; and port wine or porter in extreme debility. One of the most useful of the alcoholic stimuli, in convalescence, is the bitter beer or pale ale; the amount of alcohol it contains is not large, its bitter exerts a beneficial tonic effect upon the stomach, whilst the narcotic principle of the hop tranquillises the nervous system, often so painfully irritable. In whatever form nourishment is given to the convalescent, it should be in small quantity at a time, but as frequently repeated as natural appetite requires. The atmospheric purity of the chamoers occupied by persons recovering from sickness requires great attention, and the temperature ought to be kept as nearly as possible about 608 Fahr. Lastly, when convalescence has reached a certain point, there is no remedy which so surely promotes perfect recovery, and confirms health, as change of air. Almost any change is beneficial, but in many cases much more advantage would be derived, if persons thus seeking health acted upon competent medical advice. It is to be regretted, that so many of the accessories which promote speedy and certain conval-escence, have hitherto been unattainable by the majority of the poorer classes in this country. Care, and good nursing, and the highest medical skill in the country are bestowed upon the poor inmate of the hospital up to a certain point, and convalescence is barely established, when too often the patient has to return to his home and his work, to help to make due provision for his family. Convalescent homes are now established in many parts of the country, where, on the recommendation of a subscriber, or by a small payment, patients may be accommodated for a limited time. These are excellent institutions, and are doing an infinite amount of good, but much more requires to be done to render them universally accessible. Their extension in larger numbers at the sea side is especially desirable, and charitable bequests and donations might be worse directed than into this channel.

CONVULSION is a state of alternate violent contraction and relaxation of the muscles, independent of the influence of the will; those under its direct control are most frequently affected, but not invariably so; the muscular fibres of the stomach, and other

generally applied to the disorder. Convulsions are classed by medical men as "tonic," or those in which the state of contraction is maintained for a considerable period without alternation with relaxation; and as "clonic," or those in which the two states succeed one another with more or less rapidity. When the relaxations and contractions are very slight, and very rapid, the condition is tremor. The first of these, or the tonic convulsion, occurs in lockjaw, in cramp, and in cholera; the second, or clonic, in epilepsy, chorea, and hysteria; the third is seen in the persons of hard drinkers, when not under the influence of their stimulant.

Convulsions may be either general or partial, affecting only the muscles of the eyes or eyelids, of the face, or of one of the extremities, or of one side of the body, or they may shake the whole frame in convulsive agitation, such as occurs in epilepsy. Some of the most characteristic local convulsive actions occur in the muscles of the face and orbit, causing squinting, &c., or the peculiar "sardonic smile," or grin, which is caused by forcible retraction of the corners of the mouth, exposing the teeth.

Sometimes an attack of general convulsion is forewarned by a local affection, the eye is unnaturally turned, or the thumbs, as often occurs in children, drawn across the palm of the hand; or hiccup, which is a convulsive affection of the diaphragm, precedes the more widely diffused affection. In partial convulsion, the mind is probably unaffected; but when the affection is widely distributed, or general, there is frequently no outward sign of consciousness, and when the convulsion ceases, and consciousness does return, there is no

recollection of the past paroxysm.

In children convulsions usually affect the whole body, and often occur without warning. The child becomes suddenly stiff, with eyes staring, head thrown back, limbs stretched out rigid, hands clenched, and breathing temporarily arrested. The eyes are often turned upwards, and little more than the whites are seen; sometimes they diverge or converge, and appear to squint. After a few seconds, convulsive movements of the face, arms, and legs commence. The face, usually livid, is twitched in different directions. The mouth is moved irregularly, and, if the child has teeth, the tongue may be bitten, and froth mixed with blood appear. The eyes usually roll from side to side, the eyelids being widely opened. The arms and legs twitch usually in a marked manner, every part of the limbs being so affected. The child is unconscious throughout the attack, and often for some little time after it. When the spasms cease the muscles relax, the child becomes pale, and may draw a long sigh, and gradually recovers. A slight attack lasts one or two minutes only, a severe one some hours.

involuntary muscles, are often the seat of con- ness, are the more frequent, unless due to

the spinal cord. In such cases the convulsive movements of the limbs, and the distortion of is, in many instances, heralded by an attack. the features are truly terrible to witness; but In fact, with those who are susceptible, there is there is every reason to suppose that in many instances, and it is a great consolation to do so, the trial is mainly to the spectators, and that the cerebral disorder which causes such violent commotion of the body, extinguishes for the time any consciousness of suffering. Of course, when the mind is unaffected, as it is in lockjaw or tetanus, or in hydrophobia and other cases, the pain of the convulsion is severely felt. The length of time a convulsion continues may vary from a few minutes to many hours, but generally the period is short, the paroxysms returning after intervals of cessation. The fit of convulsions may terminate in apoplectic stupor, in a state of extreme nervous exhaustion, in lethargy, or in prolonged sleep. For some time after, there is usually much languor, both physical and mental, and the faculties of the mind are confused and incapable of being exerted. There may remain permanent lesion of the nervous functions, such as paralysis, or disordered nervous action, such as St. Vitus's dance; a squint often dates from an attack of convulsions in childhood. In some cases bleeding from the nose or ears, or vomiting, or diarrhœa, appear to terminate the attack.

Convulsions are the most frequent and fatal of the diseases to which the nervous system is liable, and childhood suffers in a higher ratio than in after life, the disease appearing as a common cause of death from birth up to the seventh or eighth year, boys suffering in larger numbers than girls. After the eighth year convulsions are less frequent as the nervous system becomes better organised and developed. They are the result of a great variety of causes. The brain itself may be the organ primarily affected; there may be disease of its structure, or pressure or irritation exerted upon it, by disease or accident; there may be too great determination of blood to the head, or the reverse condition may exist, and the sup-ply of blood to the brain may be inade-quate. But convulsions quite as frequently arise from irritation of distant organs affecting the brain and spinal cord; in childhood, the irritation of teething is a most prolific source of convulsions, and perhaps not less so, irritation of the stomach and bowels: causes which might, in the adult, produce transient head-ache, in the susceptible nervous system of the child may cause convulsion. In females, irritation connected with the generative system is a frequent source of convulsive action, and, indeed, one of the most formidable phases of the disorder occurs in the process of childbirth. Strong mental emotions of any kind, such as joy, fear, &c., are apt to cause convulsion. Suppression of accustomed discharges likewise are often followed by an attack of the malady. Worms in the intestinal canal cause about the head, and the symptoms remain un-

epilepsy or to organic disease of the brain or | it; and the onset of acute disease, small-pox in particular, but also febrile disease of any kind, scarcely an agent, from a carious tooth or the scent of a flower upwards, which has not the power of exciting convulsive action—or something nearly approaching it-of the human frame.

Some persons are much more liable to be affected than others, and children, as a general rule, especially so; it is therefore very important, that the premonitory symptoms, either in them or in individuals of excitable temperament, should be carefully noted and attended to, and the exciting cause, if possible, discovered and removed. In children, the state of the gums, and of the secretions from the bowels, are especially to be watched; the first may require lancing, or the second clearing out by an active purgative, such as calomel and scammony; but when, from the occurrence of warning symptoms, and especially if the child, or any other member of the family, have previously suffered from convulsions, an attack is supposed to be impending, medical advice should be procured. A point of great importance to be determined is, whether the disordered condition is connected with excess or deficiency of circulation in the vessels of the head and spine; for, if the former, it is evident that the lowering treatment which it requires must be injurious should the latter condition prevail, for this must be corrected by tonic medicines, or even by the exhibition of stimulants such as sal volatile, or brandy in minute quantity. It must be clear to all, how important it is, either in the preventive or in the actual treatment of convulsions, whether in children or adults, that this point should be clearly ascertained. And as it is one which sometimes requires considerable medical acumen and experience satisfactorily to determine, it must be equally clear, that it must render nonprofessional interference in such cases a matter of hazard, and not lightly to be undertaken. At the same time, the sudden and alarming nature of convulsive attacks, renders it necessary that some means of discrimination, and some safe rules of treatment, should be known to all who are likely to be appealed to in such cases, particularly if resident in places far removed from immediate medical assistance; and it is reiterated that the two opposite states must be kept in mind, the one arising from excess, the other from deficiency of vital energy, and the treatment modified accordingly.

If convulsions be threatened in a child of full habit, with firm flesh and good colour, if teething is going on, the gums must be looked to, and lanced if requisite, the bowels may be freely purged with calomel and scammony, or with grey powder at night, followed by senna in the morning, the diet being at the same time reduced; and should there be much heat

abated, leeches-one, two, or more, according | plethoric, it should not be immersed above the to age-may be applied to the temples, and cold to the head generally. If, on the contrary, the child, even though fat, be pale, and the flesh loose, and if it is of feeble habit, anything like lowering must be avoided; the gums ought, of course, to be attended to, and if the bowels are disordered, the secretions must be gradually corrected by a couple of grains of grey powder, given every night at bedtime, and, if requisite, a small dose of castor oil in the morning; likewise, in either of the above cases, an antacid will probably be of service, such as three or four drops of potash solution, or a tea-spoonful of fluid magnesia, in the milk food, given twice a day. In judging of the energy or weakness of the cerebral circulation in infancy, as long as the opening of the head is unclosed it affords a guide to judgment. When, at this point, the scalp and subjacent parts appear depressed, the condition is one in which anything like lowering measures are inadmissible. Keeping the already given cautions in view, and remembering how often, both in child and adult, convulsion is threatened in consequence of irritation, not in the brain or spine, but at a distance from them, when it is suspected that an attack is impending, and when medical assistance cannot be at once procured, attention should be directed to any possible source of irritation, and should any such be found, its removal should, if possible, be effected. If no appreciable source of irritation is discovered, to which symptoms of threatened convulsion can be referred, and if the brain itself be suspected to be in fault, the same cautions respecting excess or deficiency of vascular action must still be remembered. If plethora is undoubted, if the individual is of full habit, florid, and with a strong pulse, leeches and cold to the head, and free purging, with low diet, may be resorted to with every prospect of advantage; on the contrary, if the habit is feeble, the more negative system will be most safely pursued; the bowels must be regulated but not purged, the diet attended to as regards digestibility, not lowered, and every source of nervous exhaustion, either fatigue of body or mind, or of a sexual character, most scrupulously avoided. If the extremities are cold, as they often are, their warmth must be preserved; if the head is hot, the moderate use of cold will allay nervous excitement, as well as vascular action. Provisional measures like the above, will, if used with judgment, be most valuable even in unprofessional hands, but they are not to supersede medical examination, which must be submitted to.

In the treatment of an attack of convulsions the above directions must equally be borne in mind and acted upon. When a child is seized with convulsions the most generally available remedy is the warm bath, and if used with judgment it is a good one; the temperature should be about 98°. If the child is strong and

waist, and while in the bath, cold should be applied to the head; if the child is weak, it may be put in the water above the shoulders; in either case the immersion is to be continued for twenty minutes. The gums are to be lanced if requisite, and leeches applied to the head, under the cautions already given as to the abstraction of blood, and under the same cautions, purgatives are to be resorted to, either the more powerful ones of calomel and scammony, or calomel and jalap, or senna, or indeed the first efficient medicines of the class at hand, or the milder agency of castor oil; in addition, an aperient injection may be administered with advantage. In many cases of convulsions, especially in children, it is impossible to get remedies swallowed. When this occurs, chloroform may be given carefully by inhalation, or a small dose of chloral hydrate by injection. In the former case, for a child three years old, fifteen minims on a piece of lint will suffice at first for inhalation; or, fifteen drops of syrup of chloral injected into the bowel in an ounce of thin gruel for an enema. Should there be great depression, a few drops of aromatic spirits of ammonia combined with the same amount of ether, may be administered on sugar. When the child is taken out of the bath, it should at once be wrapped up in warm blankets, and laid in its cradle, or in bed, and cold used to the head, or not, as thought well; and if the fits still continue, mustard plasters, made with half oatmeal, may be applied to the legs, but must be removed as soon as the skin is well reddened.

When an adult is seized with convulsions, the treatment, conducted upon the same principles, must be very similar to that recommended for a child, with exception of the bath, which cannot be conveniently used; in its stead, a warm bed, with hot applications to the feet, limbs, &c., must be substituted, and mustard-plasters may be used more freely. If there is much heat or excited action about the head, it should be shaved, or the hair cut close off, and cold or iced applications freely en ployed. In following out these directions, the non-professional will be doing much, indeed all they can legitimately, to relieve during the longer or shorter interval that must necessarily elapse before the case is seen by a medical man. Lastly, it must be borne in mind that convulsions are not unfrequent in extreme intoxication, and also in poisoning from narcotics, such as opium; their occurrence from such causes would of course materially modify the treatment. In children particularly, they are unquestionably the frequent result of the administration of laudanum, and more frequently still of quack soothing and carminative medicines and elixirs.

COO COO

The best methods of preparing suitable nourishment for the sick is a matter of so much consequence, that its consideration here cannot be out of place. Its importance is, perhaps, scarcely sufficiently appreciated by any class; and amongst the poor almost fatal ignorance prevails respecting it. Even when the needful materials are abundantly provided, they are prepared in such a barbarous and uninviting fashion, that the fastidious appetite of an invalid turns loathing from them, simply from lack of knowledge, or of attention in the process of cooking. Constantly is the medical man told,-"I could eat, but I cannot fancy such food as we have here,"—and this, when material is amply provided, but nicety wanting. For example there is no disease which requires more careful dieting than dyspepsia, and yet there is none on which people are so much "at sea." When a person complains that fat, potatoes, meat, and every conceivable food-stuff disagrees with him, it is a difficult matter for the doctor or the nurse to discover what is the best remedy. As a rule the only device is to fall back on the simplest food containing the two essential elements of heat-giving and flesh-forming material, such as we know to be the most nutritious, and to be taken without unduly taxing the stomach. Milk, all the better for being boiled, farinaceous substances, arrow-root, tapioca, and groundrice do not remain long in the stomach, and are quickly absorbed into the circulation; all supply the kind of food necessary for warmth and energy; while (when they can be borne with impunity) chicken or roast mutton will supply the nitrogenous element necessary for the repair of the wasted tissues. Then again in fevers, and in fact in all inflammatory disorders, there is great diminution of assimilative function in the stomach and bowels, and fluid food is the only aliment that can be indulged in. Even the simplest forms of fluid are rejected at times, in numerous dyspeptic disorders, and then there is no other resource than to fall back almost haphazard on the numerous modifications of farinaceous diet at our disposal, and carefully to avoid such as, after trial, are found to disagree. To tempt a sickly appetite is the province of both doctor and nurse, and in no way can this be better done than by attention to the minor details of cookery for the invalid. It is perhaps better to be perfect in the preparation of a few articles of domestic use rather than to be ruler over many, and the reader is referred to the separate articles which treat of the various forms of food for further information; but the following recipes are a few of the most directly useful:-

Sick-Room Articles of Diet-and here, it may just be hinted, that neatness in serving up, as well as care and perfect cleanliness in preparing, makes sick-room cookery more likely to be attractive to an easily-offended appetite.

Arrow-Root. - Not quite a table-spoonful of flavour of one or other.

COOKERY for the sick and convalescent. | arrow-root powder is to be mixed slowly and smoothly in a basin with a little cold waterand when done, a pint of boiling water added; it should then be sweetened to taste, and put on the fire to boil for five minutes, stirring well the whole time. If wine is permitted, it should be put to it after the arrow-root is poured into the basin. The same quantity of arrow-root is used when it is prepared with milk instead of water.

Oatmeal Gruel. - A dessert-spoonful of meal must be mixed smoothly with two of cold water -a pint of boiling water poured on, and the whole boiled on the fire for ten minutes, well stirring for the time-sugar, or pepper and salt being added, as may be agreeable to or proper

for the sick person.

Sago requires thorough washing in cold water, to take away its earthy taste; after doing so (a table-spoonful will be a suitable quantity) put it in a pint of milk, and boil it slowly till it is quite soft and has thickened the milk-ten minutes, or a quarter of an hour, is sufficient time-sweeten to taste, and add wine, or flavour with lemon peel, according to circumstances. Some invalids prefer tapioca to sago. It is prepared in the same quantity as the other, but does not require the previous washing, and takes only half the time for softening on the fire.

In all preparations for the sick, let the constant stirring whilst on the fire be attended to, whether directed or not. A burnt flavour renders sick-cookery perfectly abominable.

Ground Rice Milk .- A table-spoonful of ground rice, a pint and a half of milk, and half-an-ounce of candied lemon peel. Mix the rice very smoothly with the milk, then add the lemon peel cut into very small pieces; boil for half-an-hour; and strain as soon as off the

This is an excellent nutritious beverage for the sick when strict abstinence is not required,

and for early convalescence.

Simple Bread Panada.—Put a moderate quantity of grated or soft stale bread into enough boiling water to form a moderately thick pulp; cover it up, and leave it to soak for an hourthen beat it up with two or three table-spoonfuls of milk, and fine sugar to sweeten-boil the whole for ten minutes. This preparation is occasionally acceptable to the invalid, when milk dietary alone is rejected.

Carrageen or Irish Moss .- One ounce of it, boiled in a pint and a half of water, is sufficient to form a semi-transparent, moderately consistent, nearly tasteless jelly, which, when sweetened and acidulated, or when mixed with milk, forms an excellent diet for invalids who require to have the strength supported. The gelatine, now so commonly used, is a very palatable preparation, combined with either water or milk, and may be taken dissolved in tea, coffee, or broth, without impairing the

COO coo

Jelly from Gelatine .- To rather more than | acid, and consequently feels oppressed by milk an ounce of gelatine, add half a pint of cold water to soften it, then pour over a pint of boiling water, and stir till the gelatine is dissolved; pare very thinly the rind of one lemon, and add, with the juice of three or four (if acids are permitted), one pound of loaf sugar, the whites and shells of three or four eggs, thoroughly well whisked together, and stirred into the whole: let it come to the boil upon the fire without more stirring,—if wine is ordered with it, it should be added after coming off the fire; pour it through a thick flannel jelly bag, -what runs through at first will not be clear, and should be returned to the bag again; let it stand till cold, and you will have a clear, sparkling jelly, which few invalids will

Gelatine with Milk. - An ounce of gelatine is to be soaked in half-a-pint of cold milk; when softened, a pint of boiling milk stirred well with it, till it is quite dissolved, it may be sweetened to taste, and put upon the fire to boil up altogether. It may be flavoured with lemon peel, or cinnamon, or brandy, as is most liked, or most suitable. It will be quite solid when cold.

White Wine Whey.—Boil a pint of milk; add to it one or two glasses of sherry wine, and sugar enough to sweeten; let it boil till the curd has separated, then strain through muslin. If the wine does not possess sufficient acid to turn the milk, a little rennet, or a teaspoonful of lemon juice, or three or four grains

of tartaric acid may be added.

Barley-Water.—See Barley. Lemonade. - The juice of two lemons, the rind of one, added to a quart of boiling water, sweetened moderately, and kept in a covered jar or jug, is a useful drink for those suffering

from cold or slight fever.

Toast-Water.—This simple beverage is seldom well prepared. Let the water with which it is made have been boiled and become cold. Toast thoroughly of a fine deep brown, but not black, half-a-slice of a stale quartern loaf; put it into a jug, and pour a quart of the water over it; let it stand two hours, and decant the water from the bread. A small piece of either orange or lemon peel added with the bread is an improvement to toast water.

Linseed Tea. - One ounce of linseed not bruised, two drachms of liquorice-root bruised; pour over one pint of boiling water; place the jug-covered jugs with perforated spouts should always be used for drinks for sick people-near the fire for three or four hours, then strain When linseed tea is ordered to be continued it should be made fresh every day.

"Milk and Soda Water .- Heat, nearly to boiling, a tea-cupful of milk; dissolve in it a tea-spoonful of fine sugar, put it into a large tumbler, and pour over it two thirds of a bottle of soda water. This is an excellent mode of taking milk when the stomach is charged with alone.

"Rice and Gravy .- Let the rich gravy from a leg of roasted mutton, or sirloin of beef, stand till the fat forms a cake on the surface, remove it, and heat the gravy with as much well-boiled rice as will make it thick. A teacupful of this is very strengthening in the early convalescence of delicate children."-Dr. A. T. Thomson.

Concentrated essence of beef or beef tea is the most nourishing beverage of the sick-room. It gets its name from the supposition that it is an infusion of beef, but in nine cases out of ten when made, it is a decoction (see Beef tea). There are numerous beef essences for sale prepared in various ways, some containing all the essential elements of the meat, very costly but very good, and there are others such as Liebig's Extractum carnis and Whitehead's extract, made by chemical processes in countries where meat is excessively cheap, and by which the meaty flavour and the salts of the meat are retained, but not a particle of the albumen, fibrin, or fat so necessary for forming flesh and making heat. Notwithstanding this serious drawback, Liebig's extract is very much used, and beneficially so, for invalids, as it is both invigorating and refreshing, and can be made ready at a moment's notice. Its action as a nervous stimulant and restorative is not unlike tea or coffee, and when farinaceous vegetable substances are added to it, or when it is mixed with wine or brandy, its virtue is greatly enhanced.

There is a good method of making essence of beef with vegetable juice:- Take slices of undressed beef, free from fat and skin, and slices of turnips pared. Lay them alternately in an earthen pipkin till it is half filled. Then cover the pipkin with a bladder, tied so close down as to exclude water and air; then put the pipkin into a large vessel full of water, and let it boil two or three hours. Half a cupful of this very strong essence may be given at a time to a delicate person, or a smaller quantity of it may be given to a child.

Strong Veal Broth .- Take two pounds of veal, free from fat, and a quarter of a pound of pearl-barley. Boil them till they become like a cream, and can pass through a sieve. It may be taken warm or cold, with salt.

Charvil Broth. - Take a liver quite fresh, cut it into slices, add to it two good handfuls of charvil, and boil them in two quarts of water till reduced to one quart; strain. A tea-cupful may be taken warm every day.

Gloucester Jelly .- Take one ounce of sago, one of rice, one of pearl-barley, and one of candied eryngo root; put them into a small pan, with two quarts of water; let it boil till it is reduced to one quart; strain it through a sieve, and give the patient a tea-cupful three or four times a day, with wine and lemon peel if desired.

Strengthening Jelly .- Take two calves' feet,

well cleaned; put them into a jar; to which | ing excellent form:-Take two ounces of isadd one ounce of isinglass, two ounces of sugar candy, with two quarts of new milk. When bake it with some bread over the jar. When done, strain it off, and take a tea-cupful, just warmed before the fire, twice or three times a day.

Egg Soup.—Take some very strong stock, make it quite hot; mix the yolk of an egg to about the quantity of a wine-glassful of the stock. Put it in small cups, and steam it as you would a pudding for ten minutes. Serve

it very hot.

Cow Heel Jelly .- Put one cow heel into a pan, with three quarts of milk, and a little sugar, mace, and cinnamon. Let it bake for six hours, then strain off, and let it cool.

Pounded Meat.—Take a piece of raw mutton, quite free from skin and fat; cut it into small pieces, and pound it in a mortar. Then put it into a saucepan, and warm it over the fire for ten minutes or less in its own gravy (of course without water). If too dry, add a spoonful of *clear* gravy (not stock), or a little beef tea. It should be served very hot.

Toasted Mutton. - Cut slices as thin as possible from the prime part of a fresh loin of mutton, toast them with a toasting fork before the fire. It is very light of digestion when

prepared after this most simple fashion.

Chicken Panada.—Cut up a chicken or young fowl, take off the skin, put it into a stewpan with a table-spoonful of water, and cook on a slow fire. When the chicken is hot through, put in a tea-cupful more water. Stew it for half-an-hour or longer, till quite tender. Take the meat off the bones, pound it well in a mortar, and rub it through a sieve. Use the gravy to moisten the meat in the mortar.

Chicken Broth, with every particle of fat or grease carefully taken off by blotting paper when hot, may be drunk cold or iced, and will at times be retained when the stomach rejects everything else, especially in sea-sickness, or the sickness of pregnancy. It should be seasoned with a little salt, and taken from a glass feeder, when the patient is lying down. It is a refreshing and supporting drink even in cases of fever, and should be given quite cold or iced, not lukewarm.

Concentrated Fowl .- Take an old fowl, split it, and wash thoroughly under the pump, till all traces of blood have disappeared, then put it into a covered preserve jar, add three pints of water, let it stew in the pan till the meat comes off the bones, and the water is reduced

to a quart.

Calf's Foot Custard.—Take one calf's foot, put it into a quart of new milk, let it simmer till reduced to a pint, beat up the yolks of two eggs with a little pounded sugar, mix all together, boil for a few minutes, let it stand, and skim well. It should have the chill taken olf before eating it.

Port Wine Jelly. - Port wine may be given in the form of a jelly, according to the follow- the fluids which are administered. After the

inglass, one ounce of gum arabic, a bottle of port wine, loaf sugar and spices according to taste. Let it simmer until it is perfectly dissolved. Then put it in a shape. To be eaten when cold, two or three times a day, in cases of great debility where port wine is ordered.

COPAIBA, or COPAIVA, or BALSAM OF CO-PAIVA-is a fluid resin obtained from trees native to Brazil. It is principally used in the treatment of chest and venereal diseases.—See

Balsam

COPPER, the well known metal, is used in medicine, principally in the form of its sulphate, better known by the name of "Blue-vitriol," which occurs in crystals of a beautiful blue colour. It may be used internally as an emetic, and in small doses as a tonic; and externally as a caustic for wounds. As an emetic its action is quick and violent, but sulphate of zinc in emetic doses is preferred to it in cases of narcotic poisoning. As an astringent, for indolent sores, a lotion composed of two grains of the sulphate to an ounce of water will be found a good application. It may also be used without water as a caustic application to flabby and bleeding granulations, though its use in this and other ways is being superseded by other remedies.

All the salts of copper are poisonous, but those which are most generally known and used as poisons are, blue vitriol and verdigris; another combination, the arsenite of copper (a compound of arsenic and copper), also known as Scheele's green, is a deadly poison, and has already been noticed under the head of arsenic. In addition to the above, poisoning by copper frequently occurs in consequence of the use of

copper vessels in cooking, &c.

Blue vitriol is sometimes taken to procure abortion; its strong metallic taste, however, would prevent its being administered without the knowledge of the person taking it. It has been taken for the purpose of suicide, and the author has witnessed one case of the kind which proved fatal in ten hours, to a woman above seventy years of age, who swallowed a large dose in order to commit self-destruction. The poison produces, in the first instance, violent vomiting, and in this way life may be saved by the emetic action of the salt itself; purging succeeds, followed by extreme depression of the vital powers, cramps in the limbs and severe pain in the bowels; occasionally jaundice has occurred. The matters ejected are tinged with the blue colour of the poison. In a case of poisoning by a salt of copper, the object must, of course, be to get the stomach freed from it as quickly as possible. Its own emetic action should be assisted by warm drinks, warm water, or milk, or mucilaginous drinks of some kind, such as linseed tea or barley-water; sugar has been found useful in these cases as an antidote, and should be added in good quantity to

COR

raw eggs should be given largely; and if sickness does not recur, which it probably will, it should be reinduced by putting a feather down the throat, or by the administration of a scruple of white vitriol in a little water. Of course medical assistance should be obtained, but the above measures may advantageously be had recourse to in the interval. When poisoning by copper occurs in consequence of its presence in food which has been prepared improperly, or in badly cleaned copper vessels, the amount of the poison may not be sufficient to occasion death, but it produces severe symptoms similar to those above detailed. Copper vessels, unless protected by tinning, and even then, unless the protection is in a perfect state, cannot be considered desirable cooking utensils, and when they are used, the strictest cleanliness is requisite for safety; even if water is allowed to stand in a copper pan for any length of time, a poisonous salt is formed, but if the water contains an acid of any kind, such as vinegar, if it holds common salt in solution, or if there be oily or fatty matter present, poisonous compounds are quickly formed, consequently, food which contains any of these ingredients should never be prepared in copper vessels. The same objection, of course, holds good as regards preserving fruits, which all contain more or less acid, and are therefore liable to act upon copper. There is, however, less danger as long as the active operations of cooking are going on, than there is from allowing the articles above enumerated to stand for any length of time in a copper utensil, freely exposed to the air. Many of the cheaper pickles owed, formerly, their bright green colour to sulphate of copper, which was added to them to make the colour appear finer; the adulteration may be detected by introducing a perfectly clean plate of iron—a table knife—into the suspected article; if copper is present, it will be deposited upon the surface of the former metal, in the form of a fine metallic film or coating. It has been the practice, on the Continent, to add a small proportion of sulphate of copper to dough in the making of bread; the practice is not known to be followed in England. Copper has been detected in mussels which have caused symptoms of poisoning, but it is not considered to be the invariable cause of the injurious results which occasionally follow the use of this shell fish as food. It should be remembered that some of the green colouring matters and pigments, at present in general use, are compounds of copper, and therefore care should be observed in permitting children to have access to them. A child has been poisoned by a cake of green paint from a toy colour box. Copper coins are sometimes swallowed by children, and may pass away by stool without any apparent bad consequences; but this is not always the case, and severe epileptic fits have ensued in consequence of the

stomach has been well cleared by the vomiting, raw eggs should be given largely; and if sickness does not recur, which it probably will, it should be reinduced by putting a feather down the throat, or by the administration of a scruple of white vitriol in a little water. Of course medical assistance should be obtained, but the above measures may advantageously be had to have swallowed a piece of copper, salt, acids, and fatty matters should be excluded from its food, which ought to consist of thick milky preparations, such as hasty pudding and the like, well sweetened with sugar, gentle doses of aperients being administered. The thickened food should be given as soon as possible after the accident.

Refer to—Arsenite of Copper.

cordials are stimulants generally of an alcoholic nature, the name is derived from the old idea that they "strengthened the heart." They certainly stimulate the circulation, and are useful in cases of depression from any cause, where such an effect is required. Brandy is, perhaps, as good and as generally attainable a cordial as any; the compound tincture of cardamoms, and the aromatic spirit of ammonia, constitute two of the best medicinal cordials.

Refer to—Excitants.

CORIANDER SEEDS are produced by a plant, a native of southern Europe; it now grows wild in Britain. They are a pleasant and powerful carminative, the property depending upon the volatile oil which they contain. In medicine, coriander is principally used to correct the griping properties of senna. Coriander seeds, roasted and ground like coffee, and afterwards infused and drunk with cream and sugar, are employed in South

America as a soporific.

CORN .- A corn is a thickened state of the epidermis, or outer or scarf skin, caused by irritation, such as pressure or friction, acting upon the true or sensitive skin, which causes an increased growth of the flattened cells of which the epidermis is composed. The corn, produced in the first place by external pressure or friction, soon becomes, in itself, an additional source of irritation, and, by its hardness, increases proportionally the inflamed and sensitive condition of the true skin underneath. If the causes are removed, the disease gets well, as any one who has suffered from corns can testify, after having been confined by illness for any time. Tight shoes are undoubtedly the most general originators of corns, but badly-made, ill-fitting ones, also give rise to the affection, not by pressure, but by friction. Soft corns generally form between the toes, and are very troublesome and painful: they are kept soft by the continued perspiration of the part.

colouring matters and pigments, at present in general use, are compounds of copper, and therefore care should be observed in permitting children to have access to them. A child has been poisoned by a cake of green paint from a toy colour box. thick, and have a hole cut in the centre for the | small hospitals surrounded by open spaces and corn, which is thus preserved from pressure. Soft corns should be cut with scissors and the roots touched with strong acetic acid, and cotton wool placed over them afterwards to protect the adjoining toe from the effects of the acid, and the strictest cleanliness observed. A peculiar kind of corn occasionally forms under the corner of the nail of the great toe, and causes much pain and irritation; if discovered, by slightly elevating the nail, the thickened mass may be turned out.

CORN.—See GRAINS.

CORNEA.—The transparent, glass-like

portion of the eye.—See Eye.

CORROSION .- The term, when applied to the living body, means the gradual destruction of any of its tissues by chemical action.

CORROSIVE SUBLIMATE. — See

MERCURY.

COSMETICS are external applications used to alter and improve the appearance of the skin and the hair. Their employment is always to be condemned: moreover they frequently contain deleterious matters, such as corrosive sublimate of mercury, salts of lead, &c. Indirectly they are injurious, by leading the mind from the only true cosmetics, obedience to the laws for the maintenance of physical health, which the Almighty has linked with our existence-cleanliness, temperance, abundant fresh air and exercise, and early hours, and the cheerfulness which results from the healthful occupation of the mind in legitimate pursuits, are cosmetics which no art can imitate or supply

COTTAGE HOSPITALS, or VILLAGE HOSPITALS, as they are sometimes called, have been set in operation within the last few years in many of our populous neighbourhoods, and have met with such a measure of success as to make it probable that very many more will shortly be founded throughout the length and

breadth of the country.

To appreciate the advantages intended to be conferred on the poor by their introduction, it must be reflected that many of our most populous villages and neighbourhoods, in fact, many of our thriving towns, are at a considerable distance from an hospital, rendering it perhaps dangerous for the patient to be removed so far, and even if not dangerous, very disagreeable, inasmuch as he is removed from his friends who, possibly, may not be able to afford the time or expense necessary for visiting him. Again, many have a great objection to going into a large hospital, where their imagination paints to them all the horrors so generally and so falsely believed by the vulgar to obtain with regard to many of our charitable institutions. It is also a well-known fact that hospitals in large towns have not kept pace in numbers or accommodation with the great increase of populetion, and it is now generally understood that be said that they are attended with the best

placed in healthy situations, are attended with better results to their inmates, than those placed in the midst of a dense population. It will, then, probably be admitted by all, that a cottage hospital, small in extent, not situated in a crowded district, but, if possible, in the country, not overworked as to its staff, and not likely to be much abused or imposed upon, presents many advantages over those conducted in the midst of our most crowded cities. Of course, it is quite necessary that hospitals should exist in the last mentioned localities, especially since they are the seat of the occurrence of severe accidents; but what we wish to contend for is, that it is hard that these should be the only places where a poor man can go to, especially when he has to make the sacrifice of fresh air, and many of the conditions

necessary to health.

It is incalculable how much advantage might accrue to a district, and how much good might be done by establishing such an institution as a cottage or village hospital, where the poor might receive all the benefit attending upon first-rate nursing and lodging, and, in short, all the benefits of hospital treatment, without its disadvantages. In most places a cottage or house, with sufficient accommodation for six to twelve beds, can be rented at a moderate rate. Further, if good cause were shown to any of the heads of the leading sisterhoods and nursing establishments in the country, it is probable that nursing of the very best description would be given by them, so that the required outlay would evidently not be large, and might in special cases be fabulously small. Such a plan affords facilities to all. The influential people of the district have the poor treated upon the spot, instead of having to subscribe to distant hospitals, the clergy also are enabled to visit the sick when they perhaps most require it, and the charitable and bountiful throughout the land have a better opportunity of immediately dispensing, to their poor and suffering brethren, some of the blessings with which they have been favoured.

These tiny hospitals have been found especially valuable in the treatment of diseases of children, and it is easy to conceive how much more agreeable to the feelings of both mother and child such a system is likely to be, than one necessitating a cruel separation, and that, too, just at a time when the tender heart of the child is yearning most towards home and its ties; while, on the other hand, the anxious parent is scarcely able to rest without seeing her poor, sick child.

Mr. Burdett in his book on Cottage Hospitals, gives a wealth of information on all details respecting their construction, organisation, and support. These useful institutions have grown immensely during the last twenty years, and are still on the increase, and it need scarcely

COT COU

results to the communities among which they | or by irritation of the throat and fauces, parti are planted. The first cottage hospital was instituted at Cranley, Surrey, through the exertions of Mr. Albert Napper, surgeon in the village. At the same time, the author of this Dictionary may here remark, that previous to Mr. Napper's successful attempt to establish the Cranley Village Hospital, he endeavoured to bring the subject of cottage hospitals to the notice of the public through the pages of the journal of the British Medical Association, but at that time the public was not alive to the importance of the measure, and he could not

obtain the requisite support.

COTTON WOOL is the hairy seed of various species of gossypium, much used either in its carded state or in sheets of wadding, for various purposes in medicine. It is one of the best means of protecting inflamed or injured surfaces from the air, and is largely employed in erysipelas, and in burns and scalds. It is also extensively used for wrapping round rheumatic joints to prevent pressure, and for padding splints and other apparatus for fractured limbs and diseased joints. Wool is sold by chemists medicated with chloralum or boracic acid for applying to offensive sores, and an absorbent wool is prepared which answers the purpose of sponges. Gun cotton is made with wool and nitric and sulphuric acid, and is used in medicine in the preparation of collodion.

Refer to-Lint-Burns, &c.

COTYLEDON UMBILICUS, OF NAVEL Wort, is the name given to a plant which grows in this country upon walls and rocky places. Various parts of the plant have been recently used in medicine.

The leaves have been applied to wounds and sores, to piles, and to inflamed parts of the skin, &c., owing to their soothing and emol-

lient properties.

The juice has been tried in the treatment of epilepsy, but the success obtained is, to say the least, doubtful. The flowers have been used in certain diseases of the urinary organs, connected with a tendency to the formation of stone, and it is also said that they are used with good effect in the treatment of dropsies.

COUCHING is an operation performed upon the eye, by which the lens, when it has become opaque from disease, is shifted or depressed to another part of the interior of the eye-ball, and thus removed from the axis of

vision which it obstructs.

Refer to—Eye.

COUGH consists in the violent expulsion of air from the lungs through the air passages. In most cases it must be regarded rather as a symptom of disease than as a disease itself. Cough may arise from a great variety of causes. From direct irritation of the air tubes themselves by the inhalation of cold and damp air or of irritating vapours, by the mechanical irritation of foreign substances accidentally in-

cularly when there is relaxation of the uvula, and also in consequence of disease, inflammatory or otherwise, of the lungs themselves. Further, cough may be sympathetic with disorder in the stomach, or liver, or with irritation in the bowels occasioned by worms or other irritant agents, or it may be the result of nervous derangement such as hysteria, or be spasmodic, like hooping-cough. So numerous are the ailments and diseases of which cough is a symptom, that it frequently requires considerable discrimination to determine the real cause of the irritation. Many of the acting causes are undoubtedly trivial, but many are deeply seated and fatal diseases; and therefore, whenever an individual becomes the subject of cough, which cannot be readily accounted for by cold or some other direct cause, a medical examination ought to be submitted to, and even if the cough has been in the first instance the result of cold, should it continue "hanging about" a person, without obvious reason, medical advice ought to be taken; mischief may be brewing, and be the cause of the irritation, or the cough, excited by some trivial and easily remedied cause, may itself be causing disease in the lungs of a predisposed person.

Cough is spoken of both medically and popularly as dry and moist. A dry cough may be the result of direct temporary irritation of the air-passages, but more generally it is symptomatic either of incipient disease connected with the chest, or of sympathetic nervous irritation, probably connected with the abdominal viscera. Moist cough is generally connected with direct affections of the chest, such as common catarrh, and with inflammatory affections, or with

asthma or consumption.

It has already been said, that a cough should never be allowed to continue for any length of time without the cause being ascertained by medical examination; till this is done, it can scarcely be expected that the proper remedy can be applied. In the first instance, however, simple remedies may be tried. If the cough be clearly traceable to cold or catarrh, it may be treated according to the directions given under these heads; if it be very dry, demulcent medicines, such as the mucilage and tolumixture, or barley-water, or linseed tea, may be taken freely, with from five to ten drops of ipecacuanha wine two or three times a day, to which may be added fifteen or twenty drops of tincture of henbane to allay irritation. Opium and its preparations are not generally desirable in dry cough—unless, indeed, it be spasmodic as the drug itself exerts a drying effect upon the mucous membrane of the lungs. The inhalation of the steam from boiling water is sometimes highly beneficial. In dry, and also in moist cough, counter-irritation, by rubbing with hartshorn and oil, or some other stimulating embrocation, on the anterior part of the troduced into them, by the pressure of tumours, chest, or between the shoulders, is often of

much service, sometimes great benefit is derived from the application of a mustard poultice or a mustard leaf to the chest. The surface of the chest should be well protected by flannel next the skin, by a dressed hare skin, or by a warm plaster, either in front or behind. In moist coughs, the amount of fluids, and of demulcents, must be somewhat more restricted than in the above. The preparations of opium may be given in small quantity, either alone or in cough mixtures, but none answers better than paregoric, taken in one or two tea-spoonful doses in water; this allays the irritation and teazing frequency of the cough, and to each dose, if expectoration is difficult, five or ten drops of ipecacuanha wine, and the same of tincture of squill may be added. The author has found the following pill most extensively useful in coughs depending upon irritation in the bronchi or air passages :- Take of powdered opium five grains, of powdered squill sixteen grains, of powdered ipecacuanha twelve grains, of powdered camphor eighteen grains, of powdered gum ammoniac twenty-four grains, of powdered rhubarb twelve grains; make into a mass with syrup, and divide into thirty pills: of these, one or two may be taken for a dose.

The foregoing remarks apply only to mild cases of catarrhal cough; of course the treatment of the affection, as it arises in connection with other disease, either acute, such as inflammation of the lungs, or chronic, falls under the general management of these disorders. When feverish symptoms occur along with cough, all stimulation, either in diet, or by stimulant expectorants, is to be avoided; indeed, as a general rule, when cough exists, the diet should be as little stimulating as circumstances will permit, and the usual allowance of animal food curtailed; but in old people, and those who have lived freely, the lowering system must not be carried too far; it may be requisite even, at times, to stimulate, and to support strength by strong meat soups.

Again, it is repeated, a cough ought not to be allowed to continue; if not relieved by some of the simple remedies mentioned above, medical advice should be sought, particularly in the case of the aged, and if there is much secretion of phlegm or mucus, the least continued impediment to the expectoration of which, in an old person, may rapidly induce dangerous or fatal embarrassment of the lungs, often most unexpectedly.

The possibility of a relaxed or elongated uvula being the cause of cough must not be forgotten; an examination of the throat will detect it, and the state may be relieved by the use of some astringent gargle, by a small fragment of catechu allowed to dissolve in the mouth, or by touching the uvula once or twice a day with a camel's hair brush dipped in a

Refer to—Catarrh—Cold—Counter-irritation -Expectorants-Lungs, &c

solution of perchloride of iron.

COUNTENANCE. The expression and aspect of the human face is much and peculiarly affected by the various diseases which affect the body, and the first view of a countenance often conveys to a physician who has studied the subject, immediate, valuable, and certain prescience as to the nature of the disease for which his patient is about to ask advice. The indications are partly due to the changes of complexion which are associated with different forms of disease; but expression

is equally significant.

Physiognomical indications of different varieties of disease have indeed been classified in connection with the various organs of the body, but it is impossible to define the conditions in too rigid a manner, as many circumstances may combine to render a first impression erroneous. Some general facts relating to the appearance of the countenance and expression are, however, well ascertained guides in diagnosis. Pallor, as it occurs in anæmia and chlorosis. presents a different appearance from the same symptom when it is preceded by the shock of an accident, or when it accompanies consumption or scrofula; and the pallor of Bright's disease and some affections of the heart is peculiar on account of the glazed look and puffiness about the eyes, characteristic of dropsy. The expression of features sugges-tive of fear and anxiety is marked in heart disease, in croup and diphtheria, in persons liable to periodic attacks of epilepsy or asthma, or who may be suffering from malignant disease of some kind. A morbid indifference to external objects is the common expression of persons suffering from melancholia; while a reverse condition is peculiar to those about to suffer from delirium. The red mark on the cheek, "the spot which autumn makes upon the faded leaf," is characteristic of the hectic of consumption, or the hectic fever accompanying any other complaint of a severe type. A dull expression on one side of the face, while the other is marked, it may be, with a sardonic grin, is peculiar to some forms of paralysis. The purple or blue colour of the lips and cheeks is noticed in cyanosis or the blue disease, and in other affections of the heart and blood-vessels in which the blood is not sufficiently aerated. A sunken pinched expression of the features is peculiar to peritonitis in its last stage, and also to cholera; and is often premonitory of approaching death in other diseases. The Facies hippocratica is marked with a dry, livid, and dark skin, hollow eyes, the skin of the forehead rough and distended, and the ears abnormally cold. There is little difficulty in tracing jaundice and other irregularities in the biliary secretion from the marked yellow hue of the skin, and children and others suffering from scrofula are marked with the thick upper lip, delicate skin and fair complexion, peculiar to that disease.

COUNTER-IRRITATION is irritation

or excited action in one portion of the body, which counteracts or withdraws analogous action going on in another portion. It may be naturally or artificially established, and it may be called into action within the body, as well as without; but the term is now generally applied solely to counter-irritant action artificially excited upon the skin. There are many various modes of exciting counter-irritation; some may be, and are used, popularly, with perfect safety, others are only admissible in medical hands.

Counter-irritants may simply produce reddening of the skin, or they may blister, or they may cause discharge of purulent matter, or even mortification of the surface. Heat, according to the temperature at which it is used, may give rise to any or all of these effects: mustard will redden smartly, and may blister; ammonia will do the same, according to strength; camphor in solution, either in spirit

or oil, will redden.

Of the blistering counter-irritants the Spanish fly is the best, and almost universally employed. Steam, or metal heated in boiling water, have all been used for the purpose, and might be, on emergency. Counter-irritation by croton oil, or tartarised antimony, takes the form of pustules or pimples. The salt is applied either in the form of ointment, or as a saturated solution, used as hot as can be borne, and rubbed upon the skin by means of a piece of flannel. The pustules formed by the latter mode are said to heal speedily, and to leave no scar, which sometimes happens after the ointment. When a common blister is irritated, "kept open," secretion of purulent matter takes place; but the system is a bad one, and is productive of much unnecessary pain and irritation.

Issues and setons cause discharge of matter. The seton, though not so much adopted as formerly, is still occasionally employed in cases of Ophthalmia and in chronic diseases of the head. It is usually introduced through the skin of the nape of the neck, and irritation and discharge from the part are kept up by the skein of cotton threads carried through the part with the seton needle, and retained there.

Iron heated to a red or white heat, moxas, and other applications which destroy the texture to which they are applied, fall under the head of cauterants, and can never be used as domestic remedies. There is, however, one application of the hot iron, introduced by Dr. Corrigan, of Dublin, which might safely be used by the non-professional, and as the instrument can be made by any blacksmith, might prove a valuable resource in remote districts, for the relief of nervous and rheumatic pains, such as lumbago, sciatica, &c., in which it is often of essential service.

The instrument (fig. 59) consists of an iron portion (1) about four inches and a half long, which ends in a disk (2) half an inch in diatively mild,

meter, and quarter of an inch thick, and a wooden handle (3). When it is used, it is grasped so that the point of the fore-finger

Fig. 59.

may rest upon the bend at 4. The disk is then to be introduced in the flame of a spirit lamp, or of a piece of burning paper, and held till the metal (at 4) becomes uncomfortably hot; the handle is then to be grasped, and the disk applied lightly, and momentarily, and at short intervals, to the skin over the affected part. Each touch of the disk produces a shining mark on the skin, and very shortly the surface becomes reddened and slightly inflamed.

As regards the use of counter-irritants generally, it is often serviceable to excite the skin by friction or heat, before using them. When fever is present and inflammation is going on, non-professional persons will do quite as much, if not more good, and be much less likely to do harm, by using the mild counter-irritation of moist heat, than by applying blisters, mustard, &c., particularly close upon the seat of the disease. If a blister is put on in these cases, it should be done through medical advice. For further information respecting the counter-irritants individually, the reader is referred to the various articles — Antimony — Blister—Mustard, &c.

COUP DE SOLEIL, or SUN-STROKE.

-See HEAT, EFFECTS OF.

COW POX is the disease affecting the cow, which, transferred to the human subject, confers in the majority of cases immunity from attacks of small pox, and in those in which it does not give complete protection, renders the attack of that usually virulent disease comparatively mild.

Cow pox shows itself upon the teats of the | connected with disease of the heart and great cow in the form of blueish or livid-looking vesicles, surrounded by a ring of inflammation ; whilst at the same time, the animals are feverish, and the milk diminished. At first the vesicles contain clear fluid, but ultimately become pustular, or filled with matter. The cow is liable to other forms of pustular disease affecting the teats, but they do not present the same characters, nor follow the same course as the genuine cow pox, which is, moreover, a constitutional disease, sometimes extremely severe, and even fatal to the animals.-See Vaccination.

CRAB, the well known shell fish, is an article of diet unsuited for those of weak digestion. In some constitutions it causes griping when eaten, and in others a cutaneous eruption.

CRAB LOUSE, the vulgar name of the insect which infests the pubes of dirty people, and which gives rise to intolerable itching and sometimes to sores on the part. The insect is easily destroyed by some mercurial preparation, or by rubbing the parts with carbolic oil, and afterwards keeping them clean with soap and

CRADLE.—The old form of child's bed, is now nearly superseded by the more convenient swinging cot or bassinette. Either, if well arranged, should have a tolerably firm mattress, Either, if well a firm pillow, a piece of protective waterproof cloth over the mattress, and soft blankets, but no curtains, which are quite incompatible with the health of the child. Rockers beneath, if they allow only very gentle motion, are admissible, but not otherwise. An eider down quilt is the best covering for a child's cot.

Refer to-Children.

CRAMP is a spasmodic, involuntary, and painful contraction of the muscular fibres. The term is generally applied to the affection of the voluntary muscles, in contra-distinction to spasm, applied to that of the involuntary. Any muscles may become affected with cramp, but those of the legs and arms, of the former especially, are most liable to be so, doubtless from the greater liability of the nerves supplying the lower extremities, to irritation and pressure, two great exciting causes of the dis-order. The cramp may be confined to one or two muscles, such as those of the calves of the legs, or may be more general, as happens in cholera. The affected fibres are drawn in hard knotty contractions, and maintain this condition for a longer or shorter time. The most frequent causes of cramp, are the presence of indigestible food in the stomach, or of acid in the bowels, or the pressure exerted on the nerves by overloaded bowels. A similar acting cause in pregnancy and labour, the weight and pressure of the child, also occasions painful and troublesome cramp. The disorder is often associated with the presence of worms. When For allaying the pain of toothache, its power is

blood vessels of the chest. The power of the application of sudden and prolonged cold in producing cramp, is often sadly exemplified in the case of bathers. The best immediate remedy for cramp is friction with the hand, or better still, with the soap, chloroform, or opium lini-When the legs are affected, it is always expedient to take medicine, rhubarb and magnesia, with a tea-spoonful of sal volatile, or fifteen grains of carbonate of soda, with sal volatile, or a little ginger; and afterwards to clear out the bowels with some active aperient, such as castor oil, especially if there is any existing constipation, or a possibility of their being loaded. Any other disorder of the digestive organs ought of course to be attended to. Some persons find relief to the immediate attack of cramp, by tying a band of some kind tightly round the limb, between the affected part and the body, whilst others are in the habit of standing upon some cold substance. The first process is perfectly safe, and may be tried; the second certainly is often effectual, but it is not devoid of danger. Active friction is quite the best temporary remedy. Cramp affecting the arms is always to be regarded with suspicion; if it recurs, a medical opinion should

CRANIUM .- The skull containing the brain.

CREAM is that bland oily portion of the milk which separates and floats on the top as the liquor cools; its composition is akin to that of fat. It is a constituent of the milk of all animals. As the amount of cream contained in cows' milk, especially, varies considerably, the proportion may be ascertained by allowing the milk to repose in tall cylindrical glasses. Good milk should contain not less than twelve per cent. of cream, and 100 parts of cream ought to consist of thirty-six parts of milk fat, six of casein, two and a half of sugar of milk, and fifty-five parts of water.

Cream is consequently highly nourishing, but not suited for weak stomachs, except in small quantity, mixed with other articles of diet, such as arrow-root mucilage, when it may sometimes be advantageously substituted for a larger proportion of milk. It is often used as a substitute for cod-liver oil when the latter

disagrees with the stomach.

CREAM OF TARTAR, or BI-TARTRATI

OF POTASH. - See POTASH.

CREASOTE obtains its name from its powerful antiseptic properties. When pure, it is a colourless fluid, of a strong penetrating odour, which is known to most persons from its being extensively used as a palliative in toothache. It is obtained from tar, and, for that reason, is sometimes called "spirit of tar ramp affects the arms and fingers, it may be superior to that of most remedies. A single

CRE CRO

drop of creasote, rubbed up with a little sugar | ence is exerted upon the development of the or gum, in an ounce of water, will often allay obstinate vomiting. In cases of consumption or of chronic bronchitis, inhalations of creasote

are especially useful. - See Inhalers.

It makes into pill very nicely with crumb of bread; but the pills should not be kept for more than three or four days; it may also be given with spirit of juniper, or with acetic acid —vinegar—which dissolves it. It disgusts some patients, but others like the smoky flavour; it is a specific against sea-sickness, and rarely fails in the vomiting of pregnancy. It is an admirable ingredient for pomades for chilblains, threatening, incipient, or ulcerated, five or six drops being rubbed up with the ounce of lard. The late Sir J. R. Cormack, in his treatise on creasote, brought forward many arguments and facts to prove that the Egyptian mummies owed their preservation, as well as their medical virtues to creasote; and upon the occasion of the unrolling of an Egyptian mummy in 1850, the same author addressed a very interesting communication to the Athenœum of June 15, 1850, in which he seemed to establish beyond doubt that the essential part of the mummifying process was the application of heat to bodies filled with bitumen. He showed, upon the authority of Royer and others, that large quantities of bituminous substances were always introduced into the body, and that the strong heat was then always applied. Creasote is the basis of an extensively sold antiseptic agent known by the name of "Jeye's perfect purifier." It is a convenient liquid for household use, as it is said to have no poisonous properties, and is certainly an excellent deodoriser.

CREATINE, or KREATINE, is a crystallisable, highly organised substance, existing in

the flesh of all animals.

CRESSES in the various forms of land and water cresses, are wholesome salads, but like other vegetables which are eaten uncooked, are not likely to agree with those of weak

digestion.

CRETINS are individuals in whom deficient development of the brain, and of the body generally, is associated with mental Cretins are met with in various quarters of the world, and even in this country, but their peculiar location is in the dark, deep valleys of Switzerland. The condition is often associated with the existence of bronchocele, and there exists apparently some connection between cretinism and an imperfect or diseased condition of the thyroid gland.

The most characteristic features of cretinism are, the stunted stature, which seldom exceeds four and a half feet, the deformed head, large belly, and distorted limbs, the countenance being an index of the imbecile or idiotic condition of the mind. There are, of course, various grades of cretinism. The malady is dition of the mind.

human frame, by circumstances such as surround these unfortunate beings in their childhood; deficiency of light, and living in the damp malarious atmosphere of the deep valley. It is also to be feared, that it exemplifies the power exerted by the habits of the parents upon their offspring, and that drunkenness and debauchery of the former often entail cretinism upon the latter. There is no chance of amelioration, either physical or mental, unless the cretin is removed from his native home to the free air of the mountains above. various grades of cretinism run from a state of comparative intelligence to complete idiocy, and the physical deformity usually accords with the mental degradation. Many cretins are amenable to patient and careful training, and improve considerably. In some cases the administration of the thyroid glands of sheep has been useful. It is to be feared that frequent intermarriage among those predisposed to the malady is the prolific factor in its continuance.

CRISIS in disease, means a sudden change, tending either to recovery or death. Much more importance used formerly to be attached to the critical periods of diseases than there is at present, although, in some, undoubted periodical changes do take place, but not with sufficient certainty or regularity to admit of much calculation. A crisis has generally been considered to be denoted by some well-marked circumstance, such as profuse perspiration, discharge of blood, cutaneous eruptions, boils, abscesses, or the like, or by the appearance of copious deposits or sediment in the urine; and there can be no question, that decided and persistent improvement in the character of a disease does often follow immediately upon the occurrence of these "critical" ejec-

Refer to-Fever, &c.

CROTON OIL-is obtained by pressure from the seeds of a shrub, the Croton tiglium, a native of Hindostan, Ceylon, &c. The oil, when good, should be of a pale amber colour, about as thick as castor oil. It is very acrid, and so powerfully cathartic as to be a very unsafe remedy for domestic use internally, and, indeed, should never be so resorted to, except in the one case of apoplectic seizure, when medical assistance is at a distance. In such a case, a single drop of croton oil—if it is procurable — mingled with a little sugar, might be placed on the tongue, as far back as possible.

As a counter-irritant, croton oil is extremely useful; it may be made into a liniment, with equal parts of the strong solution of ammonia and water, or it may be used alone. It brings out a thick crop of pustules, when rubbed on the skin in small quantity; it sometimes, however, affects not only the part to which it is instructive in showing how strong an influ- tion, with swelling of the eye-lids, and applied, but causes a general cutaneous erupCRO

persons who happen to be near whilst the oil is neglected at this time, or go on uncontrolled, used. As the eruption produced by croton oil the cough, still retaining its peculiar character,

CRO

the upper portion of the windpipe. peculiar to children-males are more liable to it than females-and when one in a family suffers from the disease, the rest almost certainly have a tendency to it. The malady seldom occurs during the first year of life, but is more frequent from the second to the seventh year; at puberty the tendency to it ceases, although cases of genuine croup have occurred after that period. The rapidity with which croup at times progresses to a fatal termination, and the distressing character of the malady, always render it a dreaded disease; fortunately, it is one which, if taken in time, is greatly under the control of well-directed treatment. Its dangerous nature must ever make proper medical advice a necessity, but the importance of early active remedial measures renders it at the same time highly desirable that treatment should be resorted to without the slightest delay. Croup is not readily distinguishable from diphtheria, and medical men still differ much as to whether they are not really different phases of the same disease. The probable explanation of this is that there are two forms of croup, one, which is purely inflammatory, in which the hoarseness, stridulous breathing, hoarse cough, and paroxysms of breathlessness are due solely to inflammatory thickening of the mucous membrane lining the interior of the thickening of this is that there are two totals hard quick beat to one of a softer and a slower character.

Diphtheritic croup usually commences more gradually than inflammatory croup, being often the mucous membrane lining the interior of the thickening of the preceded for two or three days by general lassitude and maleise, with perhaps slight fever. larynx and windpipe, and to spasmodic action of the small muscles underlying that membrane; the other in which there is present on the surface of the inflamed lining a false membrane resembling thin leather of an ash colour, such as is found in the throat in cases of diphtheria, which aggravates and intensifies the symptoms mentioned above, and makes the disease in every respect more serious. That the latter every respect more serious. That the latter form is truly diphtheritic is evidenced not only by the similarity of the constitutional symptoms, if the patient survive long enough to exhibit them, but also by the presence of the true diphtheria bacilli in the membrane coughed

Inflammatory croup may begin apparently suddenly; a child goes to bed to all appearance perfectly well, and in the course of two or three hours comes a cough, which strikes even the most unobservant as peculiar, and falling upon the ear of the anxious parent, who has never heard it before, tells at once of danger. The child seems as if it coughed through a brazen tube. Perhaps, at first, the little invalid is not awakened, and if now visited, is found flushed and fevered, moaning slightly perhaps, and restless, the breathing slightly quickened; the cough comes again, the child awakes or is awakened; if it speaks, the voice is hoarse, if it

occasionally will exert the latter effect upon | cries, hoarser still. Should the disease be sometimes leaves permanent marks, it should becomes more frequent, the breathing quickened, not be used for the face or chest.

CROUP is an inflammatory affection of the windpipe. It is also accompanied by the characteristic distribution of the windpipe. It is the passage through which the air is drawn, and frequent paroxysms of spasmodic coughing of a suffocating character, followed by exhaus-tion, occur. These paroxysms are attended with risk of fatal collapse; but, except for this risk, inflammatory croup, although a serious disease, is not often a fatal one. Symptoms of improvement first present themselves in greater ease in breathing and a modification of the hoarse character of the cough, which becomes looser and more moist. The spasmodic attacks become slighter and less frequent, the fever diminishes, and the voice becomes less hoarse. There may, however, in the progress of the disease be intervals of comparative ease, alternating with paroxysms of spasmodic obstruction to the breathing, threatening, and sometimes causing, immediate suffocation. The average duration of a fatal attack of croup is from three to four days, but it may, and does, terminate much more speedily. When, under proper treatment, the disease is checked, the first best sign is the cough beginning to "loosen," the breathing at the same time becoming tranquil, and the skin moist; the pulse changes from its hard quick beat to one of a softer and a slower

> tude and malaise, with, perhaps, slight fever. The early local symptoms are similar to those of inflammatory croup, but the spasmodic attacks are not so severe; while, on the other hand, the continuous obstruction of the breathing tends to become more marked as the false membrane increases, and gradually narrows the larynx; the lips, consequently, become blue, the skin dusky, and the consciousness impaired. The pulse becomes quicker and feebler, and if the breathing is not relieved the child dies in a state of almost unconscious suffocation, and

frequently in convulsions.

The distinction between inflammatory croup and diphtheritic croup is not always easily made at the outset; but, as a rule, the former begins more suddenly. The small patches of glistening whitish-grey membrane sometimes observed on the tonsils or soft palate, or back of the throat, in diphtheritic croup, are never present in inflammatory croup. As the illness progresses, the severity of the symptoms, and especially the continued and increasing difficulty of breathing, affecting both inspiration and expiration, indicate the diphtheritic character

emetic given in tolerably full doses, either in As soon as diphtheritic croup is indicated, all the form of solution in water, or rubbed up with sugar, but never as antimonial wine. The form of a powder, one or two grains of sugar with the appropriate dose of the remedy, is the best form for keeping, as the solution decomgiven at once, to one of four years the sixth; produced. At the same time a warm bath may be got ready, into which the child is to be immersed for a quarter of an hour, as soon as possible; or what will in the author's opinion answer equally well, large poultices of linseed meal should be placed over the upper part of the chest and fore part of the throat, whilst the child is kept in a sufficiently warm situation. In the habitations of the poor, especially, the latter mode of treatment is certainly preferable to the bath, which cannot always be ing, the dose of tartar emetic is to be repeated, and vomiting again excited, and its subsequent repetition at the end of one, two, three, or more hours, must depend upon the continuance and urgency of the symptoms, the poultices being continued. The child may be allowed to drink freely of toast or barley water, or thin gruel, but not tea-which decomposes the tartar emetic-unless the infusion is extremely weak. If a case of incipient croup be thus treated, it will, in all probability, be subdued without medical assistance, though it is certainly safer to have it; but if the fever is extremely high, and if the breathing has any approach to a crowing sound, medical attendance must be procured if possible, and with the shortest possible delay. If it cannot be proeured, and if the attack does not seem to yield after the second or third dose of tartar emetic, leeches must be used-one, as a general rule, for each year of the child's life—not on the throat itself, but over the upper part of the breast bone, on each side of the throat, in which situations a blister may require to be placed, later in the disease. If, after tartar emetic has been used for four or five hours, the disease the disease of inflammatory croup are generally connected with cold and moisture, and each year of the child's life-not on the throat of laudanum. In the last stage, to prevent is given must now be diminished, and sickening doses given at longer intervals, otherwise there may be danger of depressing too much; but calomel must be begun, and to a child of two years of age, a grain is to be administered every four hours; the strength, if it seems to fail, should be supported with weak animal broththat made from veal or fowl is the most suitable of acute or debilitating disease.

—given in small quantity and at short intervals.

The prevention of croup is, of course, of the

depressing remedies must be stopped, and treatment suitable for, and described under Diphtheria be adopted. If any emetics are called for to assist in the removal of the membrane, they should be of a stimulating character, poses and becomes inert, and the latter is such as ten grains of sulphate of zinc, or thirty perhaps the most quickly efficient form of grains of sulphate of alum, in a little glycerine administration. In a house which contains a and water. The diet should be as nutritious as child liable to croup, six or eight of the powders ought to be ready at all times, and also means for the local application of heat. To a child of digestion will permit. Stimulants, as a rule, two years of age, the eighth of a grain is to be are required early, and are often of much value; port wine, diluted with a little water, or brandy and this dose is to be repeated every ten minutes in milk are the most eligible forms. For local or quarter of an hour, till full free vomiting is relief sprays of some antiseptic lotion, such as boracic acid, dissolved in water, of the strength of ten grains to one ounce, or Condy's fluid, diluted with twenty parts of water, may be used as frequently as can be done without overfatiguing the patient, perhaps once every two hours. As cases of diphtheritic croup are acutely infectious, all the precautions described under the article Contagion should be scrupulously observed; and, in addition, where possible, all other children should be removed from the house in which the patient is being procured without delay, nor managed without nursed. Such must be the general outline of danger of after chill. An hour after the vomitcroup, should it fall to be treated without the presence of a medical man; but again it is reiterated, the first twelve, nay the first eight hours, are the all-important period, which, if lost, can scarcely be recovered; for, though children do recover when the disease has advanced into its second stage, and even sometimes from such desperate circumstances as to make it a duty never to despair of saving life, the chances are but small compared with those which the first few hours hold out, that period, which in some situations must elapse before medical assistance can be procured, and which thus places the life of a child in the hands of a parent or guardian. If it is croup, even if it is suspected to be, let there be no temporising but let the treatment now laid down be promptly, actively, unsparingly, carried out. If the antimonials act strongly on the bowels, they should be checked with one or two drops

rally connected with cold and moisture, and particularly during east winds, hence, on the east side of Britain, the disease is considered to be more prevalent than on the other; but it may also be occasioned by the removal of wrappings from the throat, and exposure to a cool air, when a child is heated. Children

CUM CRO

of it, just enumerated, must be avoided in every way; slight colds should never be neglected in children or families predisposed, but should be treated by confinement to the house, or to bed if requisite, by milk diet, diluent drinks, and by the tolu and mucilage cough mixture, with the addition of ipecacuanha wine; paregoric should also be given to allay troublesome cough, and, in fact, those measures recommended in Cold carried out. The susceptibility may also be lessened, by not clothing the throat too warmly, and by the regular practice of bathing the throat and chest well with cold water every morning, rubbing afterwards with a rough towel till thorough reaction This practice is, of course, better commenced in warm weather, and not too soon after an attack of the disease. Flannel should always be worn next the skin, and care taken particularly, that bed chambers, and rooms children habitually live in, are not too warm, and never occupied whilst the floors are wet after washing. A residence at a distance from water is to be preferred.

Refer to—Antimony—Children—Diphtheria -Larynx—Trachea, &c.

CROUP-SPASMODIC, or CHILD-Crowing, is a species of convulsive or spasmodic affection of the muscles of the larynx, which, by narrowing and closing the chink in that organ through which the air passes, occasions the sound of the breathing to resemble that of the true inflammatory disease. spurious croup is often an alarming, and sometimes a fatal disease; it generally occurs before the end of the third year of life, and in consequence of irritations acting more or less at a distance from the affected larynx, which receives the impressions through its nerves. Enlargement of the glands of the neck, affections such as eruptions of the scalp, the irritation of teething more especially, or the presence of irritating matter in the bowels, may any of them give rise to the affection. It comes on suddenly, the child is seized in a moment with "catching at the breath," struggles, the face changes colour, and the veins are full; if the spasm be not relaxed, after a few ineffectual efforts at breathing, the child must die; but if the spasm gives way, the air is drawn into the thest with a crowing, croupy sound. It is of much importance that this spasmodic disease should be distinguished from real inflammatory croup, on account of the very different treat-ment required; it may be known by the absence of fever, the cessation of breathing being much more instantaneous than that which occurs in the real disease. In the affection presenting symptoms so sudden and so alarming, immediate remedies must be used; a little cold water should be dashed on the face at once, and, as recommended by Sir Thomas Watson, a sponge dipped in hot water useful in cases in which very active excitant applied to the fore-part of the throat; a few action is uncalled for.

highest importance, and, therefore, the causes drops of ether or chloroform on a handkerchief and applied loosely over the face to allow of inhalation, will often relieve the spasm, medical assistance, being, of course, procured quickly. Smelling salts should always be carried by the attendant of a child prone to such attacks. After one of these attacks have occurred, the strictest examination as to the probable cause should be instituted by a medical man; the gums lanced if requisite, the bowels cleared with a purgative, and the glands of the neck specially observed, and if enlarged, the cause ascertained and removed.

Refer to-Convulsion-Glands, &c.

CRY OF CHILDREN.—The principal distinctive difference in the cry of children is, whether it be that of expiration from, or inspiration into, the lungs. The cry of a strong child, suffering pain, is more of the expiratory; that of a weak exhausted child, of the inspiratory or sobbing character.

CRYSTALLINE LENS.—See Eye.

CUBEBS, or CUBEB PEPPER, is the fruit of a climbing plant, a native of the islands of the Indian Ocean. It is used as a means of arresting discharge and in affections of the urinary organs. The dose from a half to a whole tea-spoonful.

CUBIC SPACE—a term much in use in

connexion with ventilation, to ascertain with exactitude the amount of air which a person is at liberty to utilise under certain conditions of In building a hospital, school, barrack, or any public institution intended for the permanent residence of a large number of persons, it is usual to instruct the architect to provide a certain fixed amount of space for each individual. This is called cubic space, because it includes the length, width, and height of the school room or dormitory, and can easily be arrived at by multiplying the length by the width and the product by the height, and then dividing the whole by the number of persons likely to occupy the room. The Local Government Board requires that each sick pauper should not have less than 800 cubic feet of space; and by the army regulations 1200 feet are allotted to each soldier; while in civil hospitals, 1000 cubic feet are generally recognised as being essentially necessary. Of course the larger the amount of space in a sick room the better for the patient, but it matters little whether the space is 500 or 1000 cubic feet, if means are not provided for the continuous renewal of the air in the apartment. - See Ventilation.

CUCUMBER -a pleasant article of diet for the strong, but a very unwholesome one for

invalids.

CUMIN is the fruit of an umbelliferous plant, a native of Greece and Egypt. seeds contain an aromatic volatile oil, and are much used in the preparation of curry powders. Cumin plaster is stimulant to the skin, and

CUPPING is a process of blood-letting, ment get practical instruction, which there by which blood is drawn from wounds made for the purpose, by the agency of suction, exerted by a cup or other vessel exhausted of air, or nearly so. It is a very old surgical expedient, and in former times it was, and, indeed among uncivilised nations at the present time, it is still effected by the primitive agency of a sharp flint or knife, and a cow's horn with the tip removed, suction being made by the mouth of the operator. In modern surgery, cupping, when well performed, is at once one of the most elegant and most useful of our methods of treatment. For the purpose of wounding the skin, a metallic box, containing a set of lancets, varying in number, is provided; in the box (fig. 60) which is called the scarificator, the

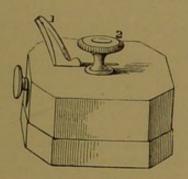

Fig. 60.

lancets are so fixed as to be discharged, when set or cocked, by a trigger (1) and spring, which cause them to pass rapidly through the skin in a semi-circular sweep, so rapidly indeed, that the usual sensation of cutting is not felt. The most convenient number of lancets is twelve, and the depth of the wound made by them can be increased or diminished by turning the screw (2); this must be done while they are fixed at half cock, and protruding from the instrument. The only other essentials for cupping are a vessel from which the air can be exhausted, and kept so when it is applied to the skin, and a flame of some kind, or some other means for exhausting the air. There are, however, sundry other little requisites convenient for the operation, to be mentioned hereafter.

Cupping is applicable in most instances where local abstraction of blood is called for, and may often be substituted for leeches, and even for general bleeding; it is a safe operation when used in proper situations, and most persons may be taught its performance by a few practical lessons; it is, moreover a most useful accomplishment for those who are far as it is for the application of the bell-shaped removed from medical assistance. It is hoped that the following details may be sufficiently burning spirits of wine, by means of a wick clear, to enable even those who have never which will afford a large flame.

Seen cupping performed to effect it in case of Cupping may be performed in

can be no difficulty in doing.

Cupping glasses of various kinds are, and have been used, but the most general is the bell-shaped form (fig. 61) of various sizes;

Fig. 61.

some of these are made with brass fittings at the top for the attachment of an exhausting syringe, or an india rubber suction ball; but the most useful form of all, and that most easily applicable by an unpractised or an unprofessional hand, is the leech cupping glass (fig. 62), which is the invention of Dr. Fox,

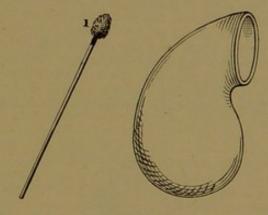

Fig. 62.

of Derby. When this is used, the next instrument, the lamp or torch (fig. 63), is not required,

Fig. 63.

need; but by all means, let every one who on which it is possible to fix a glass, by a procontemplates the possibility of such a require- ficient, but the range of unprofessional oper-

CUP CUP

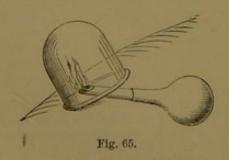

the score of safety, but also for the reason, that in some situations they are not likely to draw blood sufficient to effect any good object. As a general definition, an unprofessional person may cup anywhere upon the back of the trunk of the body, from and including the nape of the neck, to the bottom of the spine, and also on the fore part of the chest. In selecting a place within the above limit, it should always be ascertained that there is room for the rim of the glass to be in contact with the skin throughout its entire circle. It being presupposed that the abstraction of blood is called for, and it being also pre-supposed that the intending operator is provided with the necessary instruments, he should also have some warm water, a good-sized piece of sponge, or, in lieu of it, a piece of flannel, a light, and some plaster.

The person to be operated upon being conveniently placed, and the skin bared, it should be moistened with warm water, or the circulation of the part excited by means of hot water fomentation applied for some time; an exhausted glass is then to be applied for a few minutes, removed, the scarificator placed upon the portion of the skin which had been drawn up by the glass, and the lancets, which have been put on full cock, discharged. The scari-ficator being removed, the exhausted glass is again to be applied over the wounds made by the lancets (fig. 64); the blood ought immedi-

Fig. 64.

ately to commence flowing. If the bell-shaped glass is used, when applied, one edge should be made to rest upon the skin (fig. 65), the flame

withdrawn, and the glass at the same instant place to dry cupping, a most useful remedy;

ators must be much more limited, partly on pressed entirely down upon the skin. This is the point of the operation most difficult to perform well and efficiently by the unpractised; for if the exhaustion is complete, suction, and consequently the abstraction of blood, are so likewise; and in endeavouring to make the movements quickly, there is a liability of burning the skin. Fortunately, an individual can practise the manœuvre upon the skin of his own thigh at any time. Much of this is avoided by the use of the leech cupping-glass, from which the air is exhausted by simply putting into it a small fragment of paper, halfan-inch square, dipped in spirits of wine, or spirit of some sort. A short piece of wire (fig. 65) with a small portion of tow tied to the end of it, and dipped in the spirit, is used to ignite the paper in the glass, the latter being applied to the skin the moment this is done, and the wire withdrawn, the confined air extinguishes the lighted paper in the cupping-glass at once.

In addition to simplicity in application, the leech glass has also the advantage of taking at once a considerably larger quantity of blood than the other form, and thus of requiring to be less frequently re-applied; moreover, the blood, as it flows, gravitates to the bottom of the glass and does not clot over the wounds, as it does with the bell-shaped instrument. These remarks do not refer to the quick, elegant, and efficient manipulation of a professed cupper, but as the operation must be in the hands of the unskilled. When an applied cupping-glass is to be removed, it must be done by pressing down a portion of the skin at its edge with the point of the finger, so as to admit the air, which enters with a hiss. If, after a cuppingglass has been on some time, the blood does not flow freely, but clots upon the wounds, and if it is desirable that more blood be drawn, the glass should be taken off, and-when the wounds have been cleansed with warm waterre-applied. When the operation is concluded, it is only necessary to cleanse the wounds, which will not continue to bleed in the situations indicated for cupping in this article, and to put a little adhesive plaster upon them.

Such is the operation, under the pre-supposition that the operator is provided with the requisite instruments, but in the absence of these, very good substitutes may often be made. To make the incisions, which should be about the eighth of an inch in depth, any sharp instrument will suffice; for the cup, a tumbler or any similar vessel with a uniform rim, will do; and to exhaust the air, whatever will blaze freely. In cases of poisoned wounds, the application of a cupping-glass, where it can be done, either with or without enlargement of the original wound, is a good precaution, and will retard the absorption of the poison during the interval of precaution medical existence. of the spirit torch passed rapidly under it, and is called, has of late years been gradually giving

166

CUR CYC

this is the application of the cupping-glass for from blood finding its way into the windpipe. from ten to twenty minutes, without any previous scarification. The blood is thus withdrawn from parts in the vicinity of that operated on; and relief afforded, without weakening by actual abstraction of blood. In local congestions of blood, in local pain, &c., it is often of much service.

Cupping is certainly a most useful accomplishment for the emigrant. It is a safe method, and when once practised, an easy one, of blood-letting; but, by all means, let it be practically learned if possible, and then the above, though meant for all, will be more certainly useful in bringing back to the memory the minutiæ which so often escape it.

CURD.—See CHEESE.

CURRANTS - the well-known fruit, either black, red, or white—are extremely wholesome, disagree with few, and are particularly well adapted, either fresh or cooked, to form part of the cooling diet requisite for health in very hot weather. Moreover, the mechanical action of their seeds has a most beneficial effect in exciting the bowels. Some bilious persons say they find benefit from eating a few ripe red currants a short time before breakfast, and that the practice tends to keep off the increased liability to bilious attacks during the hot weather, when currants are in season.

The black current possesses more astringency than the other varieties, and when preserved, is much domestically used in sore throats, &c. ; it also acts upon the bowels. Boiling water poured upon a portion of currant preserve, and the infusion allowed to cool, forms one of the pleasantest and most useful of our fever beverages. Black current leaves are used, in infusion, as a domestic diuretic. What usually goes by the name of the dried black current, is no currant at all, but a species of small grape. It is brought almost solely from the islands of the Levant. It is a favourite domestic aperient-particularly in the lying-in chamber -mixed with gruel. It probably acts mechani-

CURRY is food of any kind prepared with the well-known condiment, curry powder, which is composed of turmeric, cumin, cayenne and black pepper, mustard, ginger, and other

spices.

The preparation is not adapted for invalids, and should only be used sparingly by those in health, especially if they have any tendency to irritation of the stomach and bowels, or to head affections. It is probably better adapted, as regards wholesomeness, to give requisite stimulating power to the rice and other foods of hot climates, than as an addition to an animal diet.

CUT.—See Wounds.

CUT THROAT .- In this horrible casualty two dangers chiefly threaten life immediately; the one, death from immediate bleeding, if any

In the first, few unprofessional persons could possess on the instant either sufficient knowledge or presence of mind to render much efficient assistance, certainly not in the case of the large arteries; but bleeding from a small branch might be arrested by the means suggested in article Artery. Should a superficial vein be wounded, and pouring out dark blood, gentle pressure in its course, between the wound and the head, might be of service. To prevent the danger of suffocation, when the windpipe is opened, and when the bleeding does not immediately threaten life, the position of the person is the principal thing to be attended to; this should be either on the side, or on the face, in whichever situation fluids may most easily run off without entering the tube. This being done, and some light gauze material thrown loosely over the wound, nothing more should be attempted before the arrival of that medical assistance which must as speedily as possible be procured. Above all things, no attempt should be made to close the wound.

Refer to—Artery—Hæmorrhage—Wounds. CUTANEOUS .- Belonging to the skin. CUTICLE.—The epidermis or scarf skin. -See Skin.

CYANOSIS, or the BLUE DISEASE, depends on a congenital malformation of the valves of the heart, and the symptoms arise from an obstruction to the natural current of the circulation, causing the lips, face, and hands to present a bluish appearance, due to the presence of an abnormal amount of venous blood in the smaller vessels.—See Heart.

CYCLING.—The invention of the safety bicycle has introduced a means of recreation and exercise at once useful, beneficial to health, and economical. It is suitable for persons of all ages, from childhood to mature age; and if enjoyed discreetly is as free from any risk of injury as any of the out-door recreations which conduce so largely to health and vigour in the

present day.

The Saddle.—Of the conditions desirable for its safe enjoyment among the most important are that the cycle and the saddle should be suitably adjusted to the rider. The cycle should be of convenient height, with the saddle so adjusted that in sitting on it the ball of the great toe can rest easily on the treadle at its lowest point without any leaning of the body towards one side. The handles should be arranged at a height and distance from the body allowing of them being held easily and lightly, or being left unheld, without any alteration in the position of the body. This condition insures that the rider sits in the saddle in proper relation to the treadles be-neath. The saddle should be of such a shape as not to press injuriously on any one place. It is impossible to suggest any particular saddle as of the large vessels of the neck have been suitable for all riders; the different types of divided; or if this has not been the case, death saddle are almost innumerable; but the general

CYS CYC

condition can be laid down that every saddle thoroughly with a dry towel. The risk of chill which gives rise to discomfort after a ride of moderate distance is unsuitable for the rider, and should be changed. Much injury may result from a badly fitting saddle. Local inflammation may be set up, followed even by abscess; in other cases painful neuralgic affections result, which may give rise to prolonged discomfort.

Curving of the Body.—The most common defect in adjustment among male riders is the tendency to lower the handles in such a way as to render it necessary to curve forward the body. This attitude acts injuriously in two directions. In the first place, it is impossible to bend forward the body in the manner described without reducing considerably the size of the chest, and thus limiting the breathing space. As a result of impaired breathing power much additional strain is put upon the heart, which has to pump the blood at a more rapid pace through a decreased area of lungs; the consequence is that the heart becomes overstrained, and severe palpitation and even sudden fainting may occur, not unattended with danger to life. In the second place, the position referred to puts pressure upon a part of the body which is unfitted to bear it without injury, and much discomfort and some risk of in a fluid and at other times in a semi-solid actual disease is incurred.

Too high a Saddle.—In women the chief error of adjustment is in riding with too high a saddle, so that the thigh and leg are somewhat strained to reach the lowest point of the treadle. A high saddle undoubtedly adds to graceful appearance, but this is somewhat dearly bought at the cost of strain of the muscles of the upper part of the thigh, and of injury to the organs

which lie in close proximity to them.

Cautions.—Of the risks to be guarded against in cycling the most noticeable are those of overfatigue and of chill. The exercise is pleasant and stimulating, and there is a tendency to persist even after some sensations of exhaustion manifest themselves. Breathlessness and palpitation are always indications that danger of excess is incurred, and should call for caution and rest. The slightest sensation of giddiness or faintness demands imperatively that one should dismount and walk slowly until per-fectly recovered. It is not well on such occasions to sit down for a time to rest, as there is considerable risk of taking chill after being over-heated by exertion; a few minutes perinæum and by the internal administration quiet walk beside the cycle is usually sufficient of camphor and extract of hyoscyamus. Alkato restore the breathing and to quiet the line drinks composed of the carbonates of soda excited heart.

Chill is apt to occur from resting in the open air or in a cool room after a long ride when the linseed tea. Various other remedies have found skin is relaxed with perspiration and the favour in cystitis, particularly infusions of muscles fatigued with exercise. It is a wise pareira, uva ursi, and buchu. Sir B. Brodie precaution, if such a condition is likely to used with much success a decoction made of an occur, to carry with one a light silk or thin ounce of uva ursi to eighteen ounces of water, woollen undervest, and to change when one's boiled down to sixteen ounces, and taken daily destination is reached, drying at the same time as a drink.

from evaporation is thus avoided. women should avoid long rides during the menstrual period, as at that time both the risk of strain and of chill are increased. Throughout pregnancy cycling should be given up entirely, and should not be resumed for at least three months after confinement.

Diet when Cycling.—When cycling for long distances it is best to abstain from heavy meals unless a rest of two or three hours can be taken in the middle of the day, during which a solid meal may be enjoyed. Much fluid of any kind should be avoided, and no stimulants should be taken except with a meal. In warm weather thirst is apt to be troublesome; this is best relieved by carrying a small flask of cold tea flavoured with lemon juice, of which a sip may be taken frequently; small quantities of aerated waters also are grateful and harmless. Water from wells and springs on the roadside should always be avoided; it is frequently impure and may give rise to serious illness.

CYNANCHE.—A term applied to affections about the throat, which tend to produce

suffocation.

CYST .- A membraneous-like bag, within the body, containing morbid matter, sometimes The matter varies much in concondition. sistence and appearance. Cysts frequently form just beneath the skin, and some persons are peculiarly liable to them. In aged people, cysts often form, and are conspicuous upon the head. Cysts, in superficial situations, are generally quickly and easily removable by the surgeon. The upper eyelid is often the site of a small cyst. Cystic tumours are common to most parts of the body, and they are often found in internal organs, as the liver and kidneys, and attain a large size in the ovary of the female.

CYSTITIS, OF INFLAMMATION OF THE BLADDER, is attended with great pain and frequent attempts to make water, which comes away in small quantities; or the person may suffer from a total retention of urine, with a strong desire to void it. Chronic cystitis, which is also termed catarrh of the bladder, is a serious malady, often of long duration. The treatment of the acute stage consists in the hot bath with opiates and demulcent drinks. Much relief is given by hot fomentations to the or potash are also much employed, with the free use of demulcents, such as barley-water and

compound of carbonate of magnesia, with various essential oils. It also contains opium, and this fact alone ought to be sufficient to exclude it from use. Magnesia, carminative distilled waters, and opium likewise, are all, unquestionably, when properly employed, useful even for infants; but in the majority of cases, the latter drug is quite uncalled for, and when it is necessary, its administration requires the utmost care and circumspection of the medical man; it cannot, therefore, be a matter of indifference, whether a medicine sold and kept for general use contains so powerful an ingredient as opium, or whether, when a simple mixture of magnesia, or chalk and dill water, will answer every purpose, a medicine—that is opium-is given, which cannot fail to act injuriously, unless positively indicated by the peculiar circumstances of the case. A dose of "Dalby" will undoubtedly "still" a child, perhaps more quickly than a simpler or more cautiously combined preparation; but its very power of action in this respect, indicates its power likewise of inflicting evil consequences. If a carminative simply is required, a simple carminative should be given, in some such mode as that recommended in the article Children. If opium is called for, let it be givenunder medical sanction—as opium, in known and graduated doses; but it is criminal folly to use it in the indefinite hap-hazard way in which such productions as the one in question are used. "According to Dr. Paris, there are five drops of the tincture of opium to two ounces of this mixture; but in another formula it is stated that this tincture forms one eighteenth part of the liquid. Like most of these quack preparations, it probably varies in strength. An infant is reported to have been destroyed by forty drops of this preparationa quantity equivalent to little more than two lrops of the tincture of opium."-Taylor's Jurisprudence.

The possibility of any preparation intended for children, containing a variable proportion of opium, ought to be sufficient to deter those who have the care of the young from hazarding either the lives of the latter, or their own peace of mind, by its administration. Moreover, it is impossible, habitually, to give opium, even in small doses, to children without injury, even if fatal consequences do not result.

Refer to-Opium, Quack Medicines, &c. DAMP .- Moisture is one of the most prolific and most generally acknowledged sources of disease; in whatever way applied to the body, whether in atmosphere, or clothing, or bed, it is alike apt to be productive of bad consequences, often of the most serious character. When combined with decaying vegetable matter, and more especially when favoured by heat, the condition which acclimatises the mosquito distributing ague may present itself; when cold and damp

DALBY'S CARMINATIVE is a quack | kind, inflammatory attacks, scrofula and consumption, rheumatism and neuralgia ensue.

Dampness, or injurious excess of moisture, may depend upon the natural formation of the country, or character of the soil, or upon a superabundant growth of timber, which obstructs the drying effect of the sun's rays, and of a free circulation of air The effects of these conditions are evidenced by the agues of the marsh districts, the cretinism of the low, dark, damp valleys of the Alps, the fevers of the tropical forests and African rivers, or in a lesser degree by the relaxing effect of a damp and somewhat mild climate, like that of Devon-shire. The advance of the improvements of civilisation does much, if it cannot do all, to rectify these sources of disease; the cutting of water courses, the clearing of timber, are for the most part attended with increased salubrity of the district. The latter, of course, requires circumspection; for much harm may be and has been done by the injudicious removal of protecting belts of trees; neither must it be forgot, as mentioned in article Ague, that the intervention of a wood may prevent the extension of the malaria of a marsh, and that trees and shrubs judiciously planted, besides adding beauty to the landscape, absorb moisture from the earth, and help to keep it dry. The now well-known Eucalyptus has special repute as both a preventive and absorbent of moisture, when planted in damp localities. But the shelter of trees is a different thing from closely encircling a house with them; they will retain moisture around more or less, according to the nature of the soil and the denseness of their growth, and in a way which is not compatible with health.

Dampness and moisture, in excess, cannot of course be prevented, when owing to the vicinity of large bodies of water, but in such a case the chief evils to be dreaded are the cold winds which "come off the water," laden with vapour, and which, as happens in many situations, are liable to produce croup in children, and catarrhal affections in the predisposed. If these influences cannot be guarded against, of course,

removal is the only remedy.

Damp houses must be unwholesome; it occupied too soon after building, disease, especially of a rheumatic character, is the frequent consequence, and no house should be occupied until fully a year has elapsed from the date of its completion. There are two causes which give rise to permanent dampness in a house; one is due to the influence of the soil, which may be within a very few feet of the ground water, and the other may arise from defective drainage—or both conditions may co-exist in the same building. It has been found that in houses built on alluvial soil, from which water is readily obtained, there is always a greater tendency to consumption, than in those of higher level and on a gravel foundaunite their depressing influences, colds of every tion. The evil may be partially remedied, in

the first instance, in the construction of the | its abuse and associations, in some instances, house, by having it thoroughly isolated from injury from damp, by a concrete and impervious foundation, and the introduction of what are termed damp-proof courses in the walls, to prevent the moisture being absorbed upwards. The damp-proof course may be made of slate or concrete, or what is better, perforated bricks, or vitrified tiles, with holes in them. Occasionally these tiles are inserted in the walls above the ground-floor level, for the purpose of admitting air into the spaces between the ceilings and floors above, for the prevention of dry-rot. —See Drainage—House, &c.

Damp clothes and beds are so generally recognised as causes of disease, that the fact scarcely requires to be insisted on, or indeed the additional one, that when the former are unavoidable, the danger is much if not wholly done away with by continued active motion, which keeps up the animal temperature, and it is probable that this preventive, not being available in the case of the latter, renders a damp bed almost synonymous with disease and

Damp, in most instances, acts undoubtedly, by abstracting, either by evaporation or otherwise, heat from the body; but as dry cold does this likewise without producing the same certain injurious consequences, it is probable that moisture also calls into action changes connected with certain conditions of the body, of the precise nature of which we are not at present cognizant. One thing is certain, that moisture is always more apt to act injuriously upon the system when the nervous power is either depressed, or not in its full state of activity, as it is during sleep, or for the first hour or more in the morning, after rising, and before food of some kind has been taken; hence it is always found that fogs and moisture are much more likely to injure during the first morning period, and that the best protection is some warm food or drink, which may support or gently stimulate the system.

Scrofula.

DAMSON, the well known fruit, is wholesome when ripe; but for invalids should be

cooked. It is slightly aperient.

DANCING, properly so-called, is the active exertion of the body in sprightly graceful movement, accompanied with exhilaration of mind, and when thus indulged in by the young, is a most beneficial and healthful recreation. It is no argument against dancing in itself, that it is too often connected with many things that are injurious, such as heated rooms, late hours, and the like-these belong to other considerations; but as an exercise congenial both to the mind and the physical requirements of the young, it is, as every exercise in which the mind enters with pleasure and interest into the exercises of the body, a most efficient promoter of health, and it is much to be regretted, that | scalp; but in persons of delicate skin, occurs

both with physical and moral evil, should cause its abandonment in any place where there

are young people.

DANDELION, or LEONTODON TARAX-ACUM, the plant native to this country, is too universally known to require description. Its leaves, when blanched, are used as a salad in some parts of the Continent, and the root is sometimes roasted, and mixed with coffee. As a medicinal agent, taraxacum is too much neglected; to be found by every hedge side, it is one of the most certain and active diuretics we possess, whether native or foreign; and perhaps no better proof of its utility can be cited, than that the author always finds patients who have once taken the medicine, recurring to it again and again of their own accord. No doubt something is due to the fact—and it is a consideration of some weight -that it is procurable without expense; it rarely fails to increase very considerably the flow of urine. Various preparations, extracts, &c., of dandelion are recommended and are employed, and are undoubtedly efficient, but the fresh infusion of the recent root is quite the best mode of administration. For this, roots of not less thickness than the little finger should, if possible, be used, and after being washed from the soil, sliced transversely in pieces a quarter of an inch thick. Of these a good double handful, or from two ounces and a half to three ounces, are to be put into a jug, a pint of boiling water poured upon them, and the whole allowed to infuse for an hour or two beside the fire, but not boiled. The infusion will have a greenish brown colour, and two or three cupfuls should be taken during the day, until the desired effect is produced. is not very unpleasant, is slightly bitter, and to some mawkish, but may be improved by the addition of a little orange peel. In addition to its action in increasing the flow of urine, taraxacum improves the tone of the digestive organs, and most certainly exerts a stimulant action upon the liver; indeed, it is in disorders of the digestive organs accompanied with deficient action of the kidneys, the urine being scanty, high coloured, and depositing a pink sediment, that dandelion exhibits its beneficial influence most apparently. It may advantageously be combined with broom, as a diuretic, and of course with other medicines, such as the tincture of calumba, with potassa, &c. A decoction (a faulty preparation), an extract, and a juice of taraxacum are admitted into the pharmacopæia. The juice is much employed; it is expressed from the root, and to every three parts one part of spirit is added. The dose of the juice is one or two tea-spoonfuls.

Refer to—Broom—Liver—Kidneys.

DANDRIFF is the formation and separation of numerous thin white scales, or scurf, from the skin, and is most usual upon the

also upon the face. In infancy it is very common upon the head, and among the poor there is a prejudice against its removal "for fear of cold," so that it is allowed to accumulate along with the dirt, and presents a most filthy appearance. Generally, the skin underneath, at the seat of dandriff, is not much changed, but sometimes it becomes reddened, and slightly irritable. It is common among scrofulous children, and is favoured by their constantly wearing the same flannel until the fabric is worn out. Numerous instances are related of its propagation from one person to another.

In adults, the disease is troublesome, from the quantity of scales, or scurf, which mingle with the hair, and shake from it upon the clothes.

In any case, care should be taken to avoid irritating the skin, the hair-brushes should be soft, and the small-tooth comb-at all times a doubtful substitute for thorough washingmust never be used.

In the case of infants, washing regularly with soap and water, and the use of some simple pomatum, or of an ointment composed of ten grains of red oxide of mercury to the ounce of lard, or vaseline, will remove the inconvenience; and either in their case, or in that of adults, an alkaline wash will be found useful. Sir Erasmus Wilson recommends two drachms of solution of caustic potash to eight ounces of soft or rose water.

DANGER .- See DEATH.

DARNEL GRASS is a species of rye-grass, the seed of which has a beard, or awn, like barley, and which, unlike the grasses generally, is poisonous. It is more common on the Continent than in Britain, and the seeds are occasionally so abundantly mingled with those of barley, or other grain, as to cause symptoms of poisoning in those consuming articles of food made from the meal. Several instances of accidental poisoning have occurred in consequence; these have been more common, however, on the Continent than in this country. When chewed, meal containing darnel grass causes a burning sensation in the throat, and giddiness, headache, and lethargy follow, with great intestinal irritation. An emetic would probably be the best remedy.

DATE.—The fruit of the date palm constitutes a considerable portion of the food of the people of Egypt and Northern Africa, Arabia, and Persia. The nutritive material is chiefly sugar. As imported into this country, dates

are not a digestible article of diet.

DATURA STRAMONIUM. - See

DAWLISH, in Devonshire, occupies a narrow valley opening upon the sea. The environs abound in walks and rides, and the sea-bathing is good. Dr. Shapter speaks highly of the houses up the valley as a winter residence in pulmonary complaints; "so entirely is season. During spring, however, this locality is not so favourable, on account of the east winds which then prevail, and to which, from

its aspect, it is exposed."

DEAD, DISPOSAL OF THE. - The instincts of mankind in all ages have led them to reverence the dead, but the various methods employed to find them a last resting place have not partaken of much uniformity. The Egyptians embalmed their dead, the Greeks and Romans cremated them, a practice which has many advocates, but few followers, at the present time; the Hindoos still float their dead on the sacred waters or expose them in the silent towers to be despatched by vultures. Nearly all civilised nations bury their dead. The objections to inhumation are that graveyards exhale noxious vapours, and that they pollute the waters in their neighbourhood, and for these reasons burying-grounds and church-yards in large towns have been nearly all closed by the legislature. There is no question that in the course of time, the garden cemeteries which have taken the place of the old burying grounds, will also be filled to repletion, and sanitarians of the future will discuss again the best means of disposing of human ashes. Public opinion is growing slowly in favour of cremation; as a sanitary measure it is much the most eligible method and if properly carried out equally reverend. The speedy removal of a dead person from an inhabited house, especially amongst the poor, and in epidemic seasons, is always advisable. In case of a person dying of contagious disease or of a malignant disease of any kind, it is desirable (to prevent any bad effects which might arise from exhalations from the body) to have it at once secured in a shell or coffin, well pitched inside, and partially filled with saw dust mixed with chlorinated lime, or moistened with a solution of carbolic acid, terebene, or other disinfectant. Care should be taken that the lid of the coffin is also well adjusted, otherwise these precautions are of little avail.

DEADLY NIGHTSHADE.—See Bel-LADONNA

DEAFNESS, or deficiency in the sense of hearing, may be either partial or complete, and it may be accompanied with dumbness. The causes of deafness may be temporary or permanent, and the affection may be due to disorder in the brain and nervous system, to disease and disorganisation of the essential portions of the organ of hearing itself, or to causes which interfere with the transmission of sound.

The temporary causes of deafness may be such as have their origin in temporary disorder of the brain, resulting from external violence, or from disorder either local or general, more particularly some forms of fever, of which deafness is a frequent concomitant. drugs, quinine particularly, given in too large it protected from the prevailing winds at this | doses, also give rise to the affection.

170

by common cold, which seems to cause tume- tumefaction resulting from the presence of the faction of the membranes lining the passage growths may be diminished by douching or of the external ear, or when the throat is spraying through the nostrils, with a syringe affected, obstruction of the Eustachian tube- or spray-producer, a solution of salt with biwhich extends between the middle ear and the carbonate of soda in water, of the strength of throat-either by swelling, or accumulated five grains of each to an ounce of water. The mucus. These causes often continue in action, and keep up the deafness long after the cold

has disappeared.

Permanent deafness may result from disease of the brain, such as paralysis, or from violence, such as severe blows or falls upon the head. The author had one patient, a gentleman afflicted with permanent partial deafness, the result of a dangerous fall when hunting, the effect upon the brain being evidenced by the fact, that his pulse, which formerly ranged at seventy-two, has never since exceeded, in health, which is perfect, forty in the minute. Disease of the ear itself, or its effects, can scarcely fail to cause deafness. The internal portions of the ear are liable to a variety of disorders or diseases, which it would be useless and out of place to notice in this work. Many of these take their origin during attacks of acute disease, particularly measles or scarlet fever. Discharges occur from the ears, and the minute bones contained in the cavity are sometimes discharged. To allow of this, of course, the membrane of the tympanum, or drum of the ear, must be wholly or partially destroyed. This important membrane of the ear being diseased, is often the occasion of deafness. mentioned above, the obstructions, either in the outer ear passage, or in the Eustachian tube, first arising from common cold, may become permanent; in the case of the latter, when the swelling subsides, thick mucus may block it up; in that of the former, hardened wax, or cerumen. This last mentioned cause of deafness is very frequent, is easily discoverable, and no less easily removed, affording most striking relief to an almost total defect of hearing. It is perhaps the only affection of the organ causing deafness, which is likely to be well or safely treated domestically.—See mediate relief will result. Before repeating the Cerumen.

One of the commonest causes of slight permanent deafness is adenoid growths behind the This affection occurs often in young children, particularly in the strumous, and may be known by the peculiar thick sound of the voice, the noisy breathing at night, and the constant liability to cold in the head and quinsy. These people always breathe through the mouth, so that in time the nose becomes flattened from side to side, and the nostrils small. The deafness is due to the swollen membrane blocking up the Eustachian tube. In mild cases of this character, so long as the A person affected with temporary deal In mild cases of this character, so long as the A person affected with temporary deafness, hearing is unaffected, considerable improvement if it is traceable to an assignable cause, such can be obtained by attention to the general as cold, should wait the effect of time for health, occasional change to a drier and more its alleviation. A blister applied behind the bracing air, and the administration of cod-liver affected ear, or, better still, an eruption brought

Temporary deafness is frequently occasioned oil and steel wine. Locally the catarrh and child should also be trained to breathe as much as possible through the nose. As soon, however, as any deafness becomes apparent, the growths should be removed at once by a competent surgeon. If the tonsils are enlarged, as is not unusual, they should be excised at the same time.

The most common cause of deafness is closure of the Eustachian tube, which connects the cavity of the middle ear with the throat, from neglected cold or from any other form of chronic irritation of the throat. The catarrhal irrita-tion causes, first, swelling and narrowing of the tube, and afterwards complete closure, and as a result disease attacks the cavity of the ear and the minute bones in it which convey vibrations from the drum to the nerve of the ear. The deafness resulting is very likely to be overlooked at first, as it usually comes on gradually and insidiously, often without any discomfort whatever in the ear, although sometimes it may be attended by singing or murmuring noises. When it affects only one ear it is seldom noticed until the other ear is temporarily affected. In such cases irretrievable damage often results before deafness is even suspected. Children thus suffering are often unfairly blamed for inattention at school; when complaint is made of this, an examination should always be made of the hearing powers of each ear separately; and if any deficiency is detected, medical advice should be resorted to at once. In the early stages of this affection, relief is afforded by forcing air up the Eustachian tube from the throat, in the following way :- Close the mouth, hold the nose so that no air can escape, and make a forcible effort to blow. The air is forced into the nose, and, if the tube is free, into the ear, when a slight movement will be felt and improcess it is necessary to swallow. This should not be done more than twice in the day. In descending a coal mine, often some fulness is experienced in the ear, owing to the atmospheric pressure; this is immediately relieved by swallowing, which, by opening the Eustachian tube admits air to the ear, thus equalising the pressure on each side of the tympanic membrane.

Among the most common causes of temporary deafness is the accumulation of wax in the outer passage. Those with coarse skins are more liable to this affection, and the tendency is

croton oil, may probably give some relief. If wax be suspected or ascertained to have accumulated, it should be removed, as directed under article Cerumen, but never by earpicks or such like dangerous weapons. When no assignable cause for the deafness, whether permanent or temporary, can be discovered, a medical man should be consulted—if he has given special educated attention to aural surgery, so much the better-but unqualified quacks, with nostrums and never-failing cures, must be shunned. No one, surely, can be so credulous as to believe that any application, or variety of applications, put into the outer ear—and strong stimulants are often used in this way-can be remedial for a symptom owing to causes so varied. Some varieties of deafness, are alleviated by appliances to the external ear passage, and some remarkable cases have been published of great improvement in hearing resulting from small pellets of cotton wool, or other substances, moistened and introduced so far into the ear, as to be in contact with the tympanic membrane, which had been perforated by disease. For moistening these, and indeed for moistening the passage of the external ear, when too dry-an occasional cause of deafness-or for moistening hardened wax previous to syringing, glycerine is better adapted than the oil generally in use. Various other modes of treating deafness, with reference to its various causes, have been, and are employed. Its dependence upon obstruction of the eustachian tubes, has originated the practice of passing an instrument, or eustachian catheter, up these passages, for the purpose of clearing them. The operation is one which requires both practice and tact for its safe and efficient performance. While the swelling is slight, air can be forced into the ear as recommended above.

When deafness is confirmed, and cure cannot be obtained, relief must be sought in the various artificial methods-ear cornets, and the like-for collecting and conveying to the ear as large a body of sound as possible. Conversation tubes, ear trumpets and cornets of various designs are made for the purpose, and are usually manufactured either of metal or vulcanite. In numerous cases, where hearing in the ordinary manner is lost, sound can be detected when any vibrating body is brought in contact with the bones of the head. This fact might be taken advantage of in the construction of an instrument for improv-

ing the hearing.

With respect to the deaf and dumb, or "deaf mutes," as they are now called, whatever the cause, whether congenital deficiency, or complete deafness brought on by disease or accident before the power of speech had been thoroughly acquired, the education should be conducted in an establishment for the purpose. There are two methods adopted for teaching deaf

out just below the ear, by tartar emetic or | the fingers, which is the plan most commonly employed in England, and the other the so-called "German" system. This latter plan has recently been largely developed, and a society for the education of teachers has been formed, and is now established at Ealing. The object in the system is to make the person speak, for in deaf mutes there is no impairment of the voice. The child is shown how to place its tongue and lips so as to form certain letters, and gets some notion of the sound, by placing the hand upon the throat of the teacher. So accurately may the sound be imitated by this means, that even a nasal twang has been communicated to a pupil, the teacher being an American. The deaf mute learns to understand others by watching the lips. It cannot be done at home, but much may be done by the philanthropic and earnest endeavours which have devised, and are now daily devising, new methods for imparting to these unfortunate individuals, the blessings of knowledge. It has probably been an error in the education of the deaf mutes hitherto, that they have been brought up in establishments by themselves, a plan it would seem less likely to fit them for mingling usefully with the world in general in after life, than commingling them with children who have the power of speech. Though a deaf mute can be perfectly educated only in a special school, much may be done at home, by inculcating habits of industry, and by teaching them the alphabet. Great patience is necessary, as the unfortunate child is unable to explain itself and is liable to be misunderstood.

> The affection, when it is itself hereditary, is transmitted to the offspring, hence intermar-

riage is to be avoided.

Dr. Allen Thomson remarks:-"Dumbness is known usually to proceed from deafness, either existing from birth, or arising early in life. The exceptions to this are very rare, and occur only from defective formation of the organs of voice and speech, or from disease of the brain. In the case of dumbness arising from total congenital deafness, sounds can never be associated with ideas, and consequently feelings, emotions, actions, and the names of objects or description of their qualities and states, must find a language in natural gesture, or in conventional written and manual signs. In the second case, that, viz., of total deafness coming on later in life, even if speech shall already have been acquired, it may be gradually lost, in consequence of the want of habit in associating sounds with speech. This occurs, however, only in early life, when the habit of speech has not been fully impressed on the memory. I was informed by the late Mr. Kiniburgh, Superintendent of the Deaf and Dumb Asylum in Edinburgh, that it rarely happens that dumbness is entailed by deafness so late as the tenth or eleventh year, and that the extent to which this may occur, depends mutes, one by means of an alphabet made upon | very much on the circumstances in which the

individual is placed. In those who become | connected with this world; but these are, it only partially deaf, but to such an extent as to incur the risk of becoming also mutes, it seems probable that much of the power of retaining voice and speech, or of regaining it, may depend on a very small difference in the amount of hearing; and I am inclined to think that much more might be done than has yet been attempted, in a certain proportion of such cases, by assisting the hearing through the hard parts of the head, or by other means.

Refer to—Ear—Glycerine, &c.

**DEATH.**—The departure of the animating spirit from the material body, the separation of the living soul from the frame so "fearfully and wonderfully made," which is no longer fitted to be its habitation or medium of communication with earth and earthly things, is a subject which few can approach without awe and fear, none without interest, though it may be of a solemn kind, as the one event from which no child of Adam is exempt. The possibility or the probability of illness having a fatal termination, devolves a great responsibility, and much anxiety, upon the mind of a medical man, as regards the patient more particularly. There is the preparation of the mind for the great change to be considered; the settlement of worldly affairs, on which may depend the future welfare of others, to be thought of; but there is also the effect of the announcement, nay, of the slightest hint of danger upon some individuals, to be duly pondered, lest the mental shock may put the finishing stroke to what disease has begun, and extinguish the last faint chance of recovery. None but those who have had to bear it, know the weight of anxious thought that such considerations press upon a conscientious mind. It is a position for which no stated rule can be framed, and in which the judgment must be guided by the many contingencies and considerations which surround every case of the kind. It may be requisite on the first symptoms of danger occurring in some diseases, particularly in those likely to affect the powers of the mind, to make the announcement early; in others it may be delayed for some time after the physician has decided in his own mind that the case can have none but a fatal issue, till, indeed, the idea, without being actually imparted, has gradually dawned upon, or been gently awakened in the mind of the patient, and has by degrees ripened into conviction.

The question of encouraging hope of recovery, depends upon considerations similar to those which influence the announcement of necessary death; many of these rest upon religious grounds, which it would be out of place to touch upon here, but in a medical point of view, the tonic influence of this powerful emotion of the human heart must never be forgotten. With some, the hopes of a blissful future may unchanged, or it might be called poisonous be so strong that they overpower all wishes blood upon the brain. Nearly all cases of

must be said, exceptional cases; the love of life is strong, the majority hope to get well; this hope is as it were an anchor and cable, linking them with the life and activity of earth-destroy it, and they sink at once; the emotion is a sustaining tonic which no remedy can supply. It is for this reason that the office of announcing the possibility or probability of death should not be devolved upon the medical attendant, except in certain cases. Coming from him, it takes too much the form of a final sentence; there are, it is true, various ways of breaking the subject, but softened down as it may be, it comes with a depressing force which it has not when friends or ministers breathe the possibility of such an occurrence. To the poor, and even to those who might know better, an important caution is required. Too frequently it happens, that whilst a medical man is examining his patient, or still within hearing, questions relative to that patient's state are put, whether "there is any danger?" whether the person will "get better?" and other interrogatories, which he can scarcely either answer or refuse to reply to, without conveying to the patient information he may not wish to communicate. Every medical man must have felt himself at times thus unfairly embarrassed.

The symptoms of approaching death must of

course be liable to great variation, depending upon the cause of the fatal event, and the peculiar constitution and temperament of the

patient.

Sudden death is usually considered to be that which occurs without immediate previous warning, for there are few cases in which some indications have not been developed of the disorder of the organ, or structure, which at last gives way and snaps the thread, unless, of course, life has been quickly destroyed by some external acci-

dental agency. Dr. Alison says, "All causes of sudden or violent death operate either by directly depressing or suspending the vital actions of the organs of circulation, or by obstructing the arterialisation of the blood, and thence arresting the circulation at the lungs." The action of the organs of circulation, that is, of the heart and blood vessels, may be fatally depressed by a sudden shock, communicated to the brain and nervous system, and death quickly produced, as in the case of severe blows, extensive burns, and the like; or the depression may be caused by abstraction of the blood itself by hæmorrhage; in such cases, death is the result of faintness. The arterialisation of the blood may be fatally interfered with, and speedy death ensue, from injuries to the nervous system, which interfere with the process of respiration, or by causes which impede directly the access of air to the lungs, causing asphyxia, or suffocation, death being the result of the influence of the

death are, indeed, referable to the above direct | is quite independent of the supply of blood, causes; but many cases of sudden death are most obviously so. Neither is death always owing to one or other of these causes distinctly acting by itself, for they may be variously commingled. The premonitions of approaching dissolution are often strongly marked. Independent of these authenticated cases, in which the mind has been powerfully impressed with the conviction of impending death, independent of, or not directly connected with physical causes, there are others which come under the notice of the physician; such are strange and sudden impulses of the mind, longing after familiar friends or scenes suddenly acquiring unusual force, to be indulged in before the eyes are sealed to the things of this world. As the closing scene draws near, most appear conscious of the coming change; but some hope on to the last, and cherish the idea of a return to earthly joys and sorrows and business, till the latest breath is drawn.

These signs of approaching dissolution are often terrible and distressing to witness in those we have loved, and though, undoubtedly, existence is sometimes terminated in a paroxysmal agony of pain, in slowly approaching death, such as has been described, the sensations are much blunted in consequence of the insufficient

change of the blood.

Whether death is slow or quick in its approaches, we usually recognise it as beginning at one of the three vital organs, the brain, the heart, or the lungs, which Sir T. Watson likens to a tripod on which life rests. Of course life ceases when the heart ceases to beat, but the immediate cause of death, the cessation of the heart's action, may be brought about in the

three following ways.

(1st.) By arrest of the brain function, causing unconsciousness or coma, as observed in severe injuries of the brain or nervous system; or in the effects of the narcotic poisons, and from loss of blood, acting on the nervous system apart from mere fainting. Such a condition of depression acts on the circulation by impeding the flow of blood and preventing its reaction, and finally by checking the heart's action, the characteristic changes being marked by total loss of sensibility, stertorous breathing, with purpling of the lips and increasing lividity of the countenance.

(2nd.) Death is said to begin at the heart by what is termed syncope or dead faint, in which there is a sudden or continuous withdrawal of blood from the circulation, depriving the heart of its stimulus to contract. Such a condition, though rare, is occasionally met with in persons who die from great loss of blood and of exhausting discharges, and is attended with extreme and uniform pallor of the skin, cold sweats, together with a small and almost inperceptible pulse, and later on, insensibility to all external impressions. A similar condition,

occurs in cholera, or may result from a severe blow on the pit of the stomach, in injury of the brain or spinal cord, in cases of death after the inhalation of chloroform, in all of which the supply of blood may be abundant, but there is a paralysis or inability of the heart to fulfil its proper function. Hence, death beginning at the heart may be divided into the two causes, one arising from anæmia or want of blood, and the other from want of power in the heart to contract, a condition termed asthenia. Intermediate between these two opposite conditions, we have deaths from privation, cold and hunger, which may properly be said to involve the heart in the first instance, and are characterised by languor, faintness, great nervous depression, disinclination to be roused, finishing with delirium, coma, and death. Such cases occur among shipwrecked seamen, and others exposed for days and nights to cold, without food or water, and may be classified as deaths beginning at the heart from an arrest of nutrition.

(3rd.) Death beginning at the lungs is a far more common mode of death; it is often termed asphyxia, but this word is now very properly replaced by the term apnæa, which literally signifies want of breath. In its acutest form this mode of death occurs in suffocation produced by hanging, drowning, or by any other mechanical means which stops the process of respiration beyond three or four minutes, at the end of which interval, life can no longer be Similar effects are produced by sustained. diseases which affect the air passages, especially the glottis, as in croup and diphtheria, when the passage closes on account of a mechanical obstruction; but in the vast majority of deaths from apnœa, the end approaches with the gradual failure of the powers of respiration consequent on the general prostration, and the absence of the inspiratory force requisite to ærate the blood and inflate the lungs.

Such are the modes of death as they apply separately to the functions of the three organs enumerated, but it must always be remembered that the heart, brain, and lungs are so mutually dependant on each other, that the more immediate way in which death approaches will in most cases be exhibited by an impairment of the functions of all three. In no class of persons does this hold better than amongst the old and enfeebled, where, as a rule, all the vital powers are implicated and death arrives in so imperceptible a manner, that it often takes the semblance of a quiet

The symptoms which indicate that death has actually taken place are, in the majority of instances, perhaps too unequivocal to be mistaken; but sometimes it is not so, and there is a difficulty in determining whether life actually causing collapse of the heart's action, but which | has departed, even hours after any appreciable

The signs of death may be divided into those which precede putrefaction, and the occurrence of that unequivocal evidence itself. indeed, have contended that it alone should be received as evidence of death; but there are obviously many circumstances under which it is impossible to await its occurrence, nor is it necessary to do so.

The absence of apparent respiration is a generally received symptom of death, and a looking glass, or light feather or down, placed before the lips are used as tests. Mr. Harrison, who writes on the medical aspects of death, says both are fallacious, and instances the circumstance represented by Shakespeare, of Prince Henry having been deceived when he carried off the crown from his father's pillow:-

"By his gates of breath
There lies a downy feather which stirs not;
Did he suspire, that light and weightless down
Perchance must move."

The light down may be stirred by any passing current, or the mirror may be dimmed by some exhalation from the body, and either

prove deceptive.

The most convincing signs of recent death are (1st) the cessation of the pulse and respiration, (2nd) the stiffening or cadaveric rigidity, and (3rd) the cooling of the body. The finger on the pulse at the wrist, or the hand placed over the region of the heart, will usually detect any movement in the circulation, and exposure of the naked chest for a period of two or three minutes, will satisfy a careful observer whether

any motion in the lungs remains.

Stiffening or rigidity is a generally received sign of death, on which much dependence is placed. A false rigidity may be present immediately after dissolution, in consequence of death from some nervous affection. It was formerly thought that persons killed by lightning did not become rigid, but the examinations of recent cases have proved this to be erroneous. "The rigidity of death appears to come on with various degrees of rapidity, and its duration is also various. It usually commences in about five or six hours, but it may be deferred considerably longer, even from twenty to thirty When the body is greatly weakened by disease, the rigidity comes on much sooner, but is much more evanescent. It has been known to arise in fifteen or twenty minutes. Its duration varies from twenty-four to thirtysix hours, but may continue many days. In some nervous diseases affecting the living body, rigidity occurs, but scarcely in a way to deceive. When the limbs have become rigid, and the rigidity has been succeeded by flexibility, the fact of death having occurred can never be doubted." Professor Louis, from observations made upon more than five hundred subjects after death, found that the articulations began to stiffen even before the loss of animal officious friends are heat. Foderé, another authority, has verified the last moments!

sign of conscious existence has been given. | the justness of this observation several times in hospitals, and concludes that the flexibility of the limbs is one of the principal signs by which we may judge that a person is not dead, although there is no other sign of life.

The cooling of the body after death from a temperature of 98° Fahr, to that of the surrounding atmosphere, is one of the most marked signs of death. The time occupied in diminishing the temperature is from fifteen to twenty hours, but it varies according to the state of the atmosphere, the amount of clothing on the body, and the mode of death. In cases of sudden death the body has been known to retain its heat for a considerable time longer, than when the person dies of lingering disease.

The occurrence of discolorations on various parts of the body, particularly the most de-pendent portions, are frequent sequents to death, and the darkening of that portion of the white of the eye which is exposed to light, has also been pointed out as a symptom to be depended upon, and along with it, dilatation of the pupil. The above symptoms, singly, might not perhaps convince of the occurrence of death, but more or less combined, they cannot be doubted. Putrefaction commencing, of

course, does away with all doubt.

It may seem to some that it is unnecessary to dwell so minutely upon the evidences of the last great change, but it is a subject on which many entertain great anxiety, and from the fact that a considerable number of ascertained cases have occurred, in which mistakes have been made with respect to death, it is desirable that accurate information upon the subject should be generally diffused. It ought to be remembered that the corpse of a person who has died of a contagious disorder, particularly one of the eruptive fevers, may propagate the disease. The influence of season in causing death is well marked. The sudden accession of cold after comparatively mild weather, invariably raises the death-rate of a community, and the effect of great heat in summer tells in a similar way. These effects are illustrated by the weekly tables of mortality, issued by the Registrar-General, and the meteorological changes are more marked in their results on the aged and the very young, than in persons of adult life. It would appear from carefully prepared statistics, that though the hours at which death occurs cannot be specialised, yet on the average, more deaths occur between 6 a.m. and noon, than on any other quarterly division of the day and night.

Lastly, one word as to the treatment of the dying: let quiet attention to every sign, the moistening of the lips, the gently shifted positions, be the attentions; but who can tell how painful the disturbance of the forced stimulant or medicine, the noisy lamentation, or the pulling about or pulling away of pillows, which officious friends are apt to practise, may be to

In persons found dead, or apparently so, the | limbs. first thing is of course to ascertain the real state of the case. If death is doubtful, judging by the signs stated in the early part of this article, the first object must be to ascertain, if possible, the cause of the condition which so nearly approaches to it; this must be the first step, but it must be taken with all possible speed, in order that proper measures for resuscitation may be adopted. The causes may either be natural or violent; of the former, diseased heart, apoplexy, sudden fainting, or suffocation from internal affections, may be in operation; of the latter, suffocation from unnatural causes, poison, wounds, burns, cold, starvation, lightning, include the most probable influences. Some of these, such as burns, wounds, the action of lightning, cold, and many of the usual modes of suffocation, such as hanging, drowning, &c., are too evident, either in themselves or from concomitant circumstances, to be overlooked; but others, particularly those cases of apparent death resulting from natural causes, from some forms of suffocation, and from poisons, are almost beyond the power of the unprofessional to investigate. For the mode of distinguishing, and for the subsequent treatment, the reader is referred to the articles devoted to these subjects. It is repeated, when a person is found apparently dead, do not let the fact be assumed without investigation; the spark of life may yet linger in its earthly tenement, may yet be not past recall, beyond which, the loss of even a short time, or the total abandonment of care may quickly place it. If there is the faintest hope that life is not quite gone, whilst the causes of the mishap are investigated, means, such as are recommended under the peculiar circumstances, should be at once adopted, and vigorously-no half measures will turn the scale between life and death. These things are peculiarly important, for often it can only be a fortunate chance that places a medical man on the spot where cases such as the above have occurred. Of course, where it is possible, medical assistance ought to be as quickly procured as may be, but time may or must necessarily elapse, and while it slips by, life slips away, which might be preserved by the knowledge possessed by some intelligent bystander, which might lead him to think that there was still hope-often too readily given up by the crowd-and lead him to direct the adoption of rational and really efficient measures, instead of the useless, or worse than useless, treatment followed, where there is no information to guide, or head to direct.

When persons are found who are undoubtedly dead, there yet remains something to be done, for the cause may be natural, or unnatural, and in the latter case the ends of justice may either be forwarded or retarded by those who first discover the body. The exact position

The presence or absence of warmth about the chest or abdomen particularly. The state of the clothes. Whether there are signs of vomited or other matters discharged from the body. Wounds noticed, and the state of the blood upon them, whether fresh, coagulated, but yet soft, or hardened. And, indeed, whatever the circumstances connected with the finding of the body can suggest to the intelligent mind, should be written down. On the arrival of the judicial and medical authorities, there are other matters of course to be investigated, which only they can undertake, but as most of those above mentioned are evanescent, the persons first on the spot can best, or only, testify to them, and facts which may appear trivial to note at the moment, may, in criminal cases, be the turning point on which conviction hinges.

Refer to-Apoplexy-To causes of unexpected

death generally DEATH-RATE.—To obtain accurate ideas concerning the health of a community, several methods of calculation have been suggested, but that adopted by the Registrar General in this country appears to answer its purpose as well as any. It is based on the principle of limited districts, either of town or country, and comparing the number of deaths which occur in each, with the population then living in the district, allowance being made from time to time for increase, or, if necessary, for a diminution of the population. Such calculations are of much interest and importance, as they throw light on many questions connected with disease, and the salubrity or otherwise of the town or district of country. The deathrate in England and Wales is thus shown, by lumping town and country together, to amount to 22 in 1000, that is to say, there is an average annual mortality of 22 persons, among every 1000 living, or 1 death in every 45 persons, in the course of the year. The range of the various districts runs from 15, the minimum, to 31, the maximum, per 1000, the larger rates occuring among the dense population of the large towns. London is better off in this respect than most large cities, the death-rate of London, averaging 22 per 1000, while Blackburn, Preston, and other manufacturing places, have a death-rate as high as 30 per 1000. Numerous foreign cities have a death-rate even higher than these. Turin, Naples, Trieste, all range between 30 and 40 per 1000; and St. Petersburg, in the same year that these calculations were made, rose as high as 47 in 1000; but these taken together are the worst figures which Europe supplies. The best figures, as showing a small death-rate in towns in this country, were for the year under consideration, those of Dover and Rochester, which were respectively 15 and 18 per 1000.

DEBILITY, or WEAKNESS, is a falling

should be noted. The stiffening or not of the perform those exertions, whether of duty or

and which, judging from the constitution, mode of life, &c., he might naturally be expected to

perform.

Illness and debility may also be said to be synonymous, for it is difficult to imagine the former unaccompanied or not followed by weakness, except in the few exceptional instances, in which apparent debility, caused by the presence of morbid matter in the blood, is relieved by the disorder which carries off the dangerous character. cause of the depression. Such is seen to be the case in mild attacks of bilious diarrhoea, which do not go far enough to affect the general strength, and which are immediately followed by relief to the feelings of languor and weakness which preceded them; indeed, unwonted discharges of any kind, whether in the urine, or from the skin, or even of blood in small quantity, if they do not go too far, are often followed by feelings of strength rather than of debility. In these cases, however, the debility was apparent, not real; that of oppression, rather than of depression. To these and similar sources, then, may be referred all those causes of apparent debility, or in other words of languor or torpor, which arise from impurity of the blood, consequent upon the retention of noxious matters in that fluid, which are from some cause unremoved, as they ought to be, by the agency either of lungs, liver, kidneys, bowels, or skin, or which have been absorbed into the vital fluid from without.

It may be said that these are not cases of debility at all, and perhaps by medical men, understanding and strictly investigating their causes, they would not be considered so; nevertheless they give rise to an appearance of weakness, of which the unprofessional only can judge, and under these circumstances, it is requisite plainly to point out the distinction, which is of no light importance in the modes of treatment and management usually resorted to. A person from some cause or other gets his blood loaded with morbid matter; either he has indulged in too full living, animal diet and alcoholic dripks especially, or he has neglected to take exercise, or to keep the skin in active operation; or the lungs, liver, kidneys, or bowels are oppressed or inactive; he has, in fact, more or less poisonous matter circulating throughout his frame, -he feels low, both in body and mind, languid and listless, thinks himself weak, and takes, perhaps, a little extra animal food, a little more wine or malt liquor, to correct the supposed debility. The consequence must be a fit of illness of some kind, "a bilious attack," a fit of gout or gravel, of piles or of some cutaneous eruption, which the system makes a safety valve; or it may be that apoplexy or some other congestive disease is induced. It is surely superfluous to say more respecting the serious tendency of such an error as that which mistakes false debility for real, and induces the individual, instead of seeking

pleasure, in which he has habitually engaged, | strength by the reduction and alteration of his diet, and by the regulation of the excreting functions of the body, either by general or medicinal means, to rush to the other extreme, and, in the endeavour to get rid of the disorder, to add to the causes of it. Of course real debility may co-exist with apparent, the result of impure blood; such happens in acute or exhausting affections of the liver, lungs, &c., and the case assumes a complicated and highly

As apparent debility is referred to impurity of blood, so the cause of real debility must be looked for, in many cases, in its deterioration or deficiency. The vital fluid, which is the medium for supporting our animal temperature, and for supplying plastic elements to the ever-wearing textures of the body, may be deficient in all or any of the elements required for these purposes, or it may itself have been drained away by hæmorrhage. The first office of the blood, the maintenance of animal heat, is so essential, that it seems arranged by the Author and Supporter of our life, that to carry on this, the soft constituents of the body may be sacrificed almost to the extreme limit, but this very circumstance must be a cause of debility during illness, when, to obtain fuel as it were muscular substance is consumed away, whilst muscular motion is unexercised. Again, whatever plastic elements the blood may be deficient in, the organs to which those elements should be supplied become debilitated. This is most strikingly exemplified in the case of the bones in childhood, where food is deficient, which become soft-rickety-for want of the due supply of earthy matter; still more generally is it exemplified in those cases so often quoted, of animals fed, or rather starved, upon certain kinds of food, such as arrow-root, white sugar, bread made of fine flour, &c., which, however wholesome as articles of diet in themselves, do not contain plastic elements sufficient for the building up or sustaining the bodily tissues in strength and healthy active operation; to defi-ciency, therefore, of the blood, as regards those elements required in the unceasing operations of the living frame, must we look for the most generally operating and palpable cause of debility. But this cause is itself only an effect of other causes. If the blood is to nourish well, it must be nourished well itself; the supplies it is ever yielding to the system must be rendered to it from without; the food must not only be in quantity and quality sufficient to preserve the balance of nutrient materials in the blood, but it must be properly digested, properly fitted for its commixture with the vital fluid; if either food or digestion be deficient, debility, more or less, must be the result.

Many causes, of course, may operate to diminish, or totally prevent, the supplies of food taken; febrile disease of any kind, accident, disorders of the digestive organs, and numberless others do this, and so surely as they do-except,

DEB DEB

to be sure, where a little wholesome starvation | strength. To use a simile, the machine must is required-so surely does debility follow; for although food may neither be taken nor digested, the bodily requirements, heat, movement, and even the power of thought, must be kept going, and if the materials are not furnished from without, they will be taken from within; the body preys upon itself as it were, lives upon its capital, and it is needless to say that debility must result. The body, in such a case, might well be compared to a steamer at sea run short of coal, the inner wood-work of which, even at the risk of weakening the hull, is necessarily broken up to supply the engine, and to enable the vessel to reach the harbour of safety; so the body, suffering under acute disease, and unsupplied with food, must make use of that which constitutes its internal structure, although it may be fearfully weakened, or perhaps destroyed by the process. The supply of proper nutriment, and its presence in the blood, are so intimately connected, that they may be regarded as one and the great source of real strength. Without good blood, neither muscle, nerve, nor any other constituent of the body, can be in its best state of healthy efficiency. Of course, deficiency of the circulating fluid, caused either by loss from hæmorrhage, or any other drain which abstracts all or part of its constituents, must act as a cause of debility equally with those previously mentioned.

Again, the blood may be adequate to fulfil all that is required of it, but some organ fails; it seems to lose its power of appropriating to itself elements fitted for its nutrition, although brought to it in the circulation, even in sufficient proportion to maintain moderate healthy action, or the individual organ may be over-tasked and debilitated, its tissues used up more rapidly than they can be repaired, or its nervous power exhausted. Here we have another source of strength or weakness, real or apparent, the nervous power, the agent through which movement is communicated. The action of the nervous system, as regards strength or debility, must be looked at in connection with its healthy or its morbid operation; in other words, its strength consists in the amount of exertion it is capable of stimulating and maintaining, either generally or partially, without subsequent exhaustion. This limitation is requisite, for were it not drawn, it would make the excitement of the nervous system the measure of strength, it would make the transitory exertions of enormous power exhibited at times by patients in the last stages of real debility from fever, or the almost resistless struggles of the delicate hysterical girl, tests of real strength, instead of paroxysms of morbid excitement, which terminate in the most exhausting, or it may be, fatal debility and

In the healthy constitution, all the tissues of the body, including the blood, receive and utilise nutriment sufficient for their requirebe strong in all its parts, and its moving power adequate to its requirements, to constitute real well-balanced strength.

When the central organ of the nervous system, the brain itself, becomes debilitated, the condition may be manifested by affections of the body, partial or general, or by disorders of the The brain may be debilitated or exhausted by the excessive stimulation of alcohol, opium, and other agents which act upon it peculiarly, also by sensual excesses, over-nursing and the like; but perhaps the most frequent source of weakened brain, is undue exertion of it as the agent of the mind; it is tasked till it gives way, is used up. Such is not unfrequently the case among persons who overstrain their minds by occasional fits of hard mental work, and especially among men engaged largely in mercantile speculations, and subject in consequence to alternating fits of excitement and depression, producing irregularity of action in the nerve fibres, and ultimately functional derangement. In persons of irritable and nervous temperament it is not uncommon to find deposits of phosphatic salts in the urine after the mind has been strained, and we can only look to the nervous system and brain as the most probable source of the additional excretion of phosphorus. The subject is undoubtedly an obscure one at present, but it is deserving of notice, from bringing directly and sensibly to the mind, and in a physical point of view, the possible and probable manner in which this wonderful agent of man's intellect may be, and is exhausted.

Having then seen that debility may either be apparent or real, and that in the latter case it may depend upon deficient nutriment or deficient healthy supply of nervous power, it remains to consider the causes which most generally tend to bring about these conditions.

Debility has been divided into original and acquired. The former is witnessed in the children of parents whose constitutions have been weakened by any cause, such as dissi-pation, advanced life, &c., and also in the children of scrofulous families. The latter or acquired debility, may, of course, be caused by whatever lowers the standard of health. As already mentioned, insufficient nourishment is one great source of debility; likewise, the absence of the usual stimuli of solar heat and light, deficiency of fresh air and exercise, and of stimulation to the mind by a proper amount of healthy active exertion. Again, there is the debility produced by the direct action of injurious agents, a continued damp climate, either warm or cold, poisons gradually absorbed in necessary employment, or accidentally but continually taken into the system, and such like; and also by depressing passions of the mind, such as anxiety, fear, &c.

Lastly, there is debility, the result of direct

ments, and in this lies the true element of habitual loss of blood, or drain, or discharge

collapse.

DEC

One especial cause of debility requires notice, it is that occasioned in young children or people who sleep with the aged; for the fact is an undoubted one, that the practice has an extremely debilitating effect upon the former. It is one which should never be followed or permitted. The withdrawal of accustomed excitements often occasions debility of an alarming and even fatal character. The debilitated drunkard or the opium eater cannot without danger be deprived of his usual stimulant, and even the man who has lived in the most perfect moderation, cannot always, without danger of inducing great debility, leave off an accustomed stimulus. It is not said that in many instances this may not be done with impunity, or even benefit, but there are cases in which it is hazardous. The effect is not manifested, perhaps, for a considerable time, it may be weeks or months, but it is manifested some time; and the author has met with some cases of extreme depression and general weakness, traceable to no other cause than an unadvised and rigid adherence to the strict rule of teetotalism. It matters not what the longaccustomed stimulant may have been, that of alcohol, of fresh air, of mental exertion, it cannot be withdrawn without danger of inducing weakness.

In the treatment of debility, whether simple, or complicated with disease, it must be obvious to all that it must be adopted with due reference to the cause. This must, if persistent, be removed or rectified as quickly as possible; if the mischief, as occurs in original debility, or in that produced by causes which have ceased to operate, cannot be prevented, of course nothing remains but to build up or restore strength by nourishment, tonic medicines, change of air and scene, especially to the sea side when that is practicable. In every case, however, of marked debility, the medical man should be consulted; he only is likely to detect with certainty the cause or causes, and to direct the adoption of appropriate remedies.

It may seem that too much space has been devoted to this subject, but it is one which is so erroneously regarded by the public in general, particularly by the lower classes, that it is a matter of importance for juster views to be imparted, that there should be a more enlightened understanding of the subject, of the principles by which debility is to be judged and treated. The case of apparent debility was disposed of in the first portion of this article. In the weakness which accompanies fever and acute inflammatory attacks, nothing is at times more difficult than to convince people, not only of the utter uselessness, but of the injuriousness, of administering any food but that of the mildest and most unstimulating character, such as the appetite alone desires, if it desires it at all; and notwithstanding that nature herself points instinctively to the proper old age or of decay commences; the descent has

of any kind, over-nursing, or sexual excesses. | course, they will persist in the idea, that if the person "would eat he would be better." doubtedly if he would and could eat, and digest the food taken, he would be better, for he must be better beforehand to do so; but the popular idea is, that if food be but got into the stomach, it must give strength, and foolish friends foster the same impression in the mind of the invalid, till he forces himself to take food; and many a promising case is thrown back in this way, although the medical attendant is never informed of and can only guess at the cause. Fortunately, nature often resents the error, and vomiting relieves the stomach of its injurious load; if not, fever, headache, &c., and relapse are too frequent consequences.

It is repeated, in the treatment of debility, whatever may be the cause, if still in operation, that must be rectified, but the weakness itself is only to be repaired by a sufficiently ample supply and circulation of healthy blood. The latter must be procured by every means which tend to enrich and purify the vital fluid: good food well digested, air, exercise, and the use of all accessories to health, and assisted when suitable by such regular and regulated exercise of the debilitated parts themselves, as will increase the circulation of blood through them, without exhausting either their constituent tissues or nervous power; but it is useless, and worse than useless, to load a stomach which cannot digest it, with food and drink, in the vain hope of giving strength, as people too often do, or wish to do, in cases of febrile or other disease. To resume the simile of the steamer, although the seasoned wood-work within may be broken up to feed the engine, and to carry the vessel safely into port, it would be no slight hindrance, and no small aggravation of her danger, were she to be loaded with water-logged or green wood, which would not burn when it was wanted; so it is with the body in fever: the already prepared and digested components stored up in its tissues, though not perhaps accumulated for the special purpose, will yet answer well to keep its works in movement; but crude food is like the green wet wood, useless for good, and fitted only to overload and retard. When increase of nourishment is called for in cases of debility, care must always be taken to adapt it to the condition of the digestive organs; these are generally weakened, and while the food given contains much nutriment, it should be as easily soluble in the stomach as possible. For information on this head, however, the reader is referred to the articles on Digestion, Food, &c.

Refer to-Animal Heat-Bilious Cholera-Blood-Fever-Nerves-Cookery, &c.

DECAY, or the gradual giving way of the

DEC DEF

begun, imperceptibly perhaps at first, but it is mother can assign no cause; in other cases the progressive. There may be no positive disease, deformity appears hereditary." "In non-conbut the circulatory powers fail, the arteries lose their elasticity and tone, and in this, perhaps, lies one great cause of the decay of the body generally, the deficient circulation of the blood; the brain, the muscles, the whole body becomes smaller, shrinks, and if there is no disease, the powers of material life are gradually extinguished; a fall of a few degrees in the thermometer may be all that is required to put out the flickering flame. For the management of this stage of life the reader is referred to the article on Old Age.

DECIDUA, or Deciduous Membranes, are those which line the uterus during pregnancy, and which are cast off shortly after the

birth of the child.

DECLINE.—See Consumption.

DECOCTION literally means a prepara. tion which has been boiled; but in medicine, by the term is understood that which has been boiled for a certain length of time for the purpose of extracting matters from crude materials, which cannot otherwise be obtained. Moreover, when improperly employed as a process, it drives off volatile matters, which ought to be retained. The most useful decoctions used in medicines are-

Compound decoction of aloes. Decoction of cinchona bark. Decoction of oak bark. Decoction of sarsaparilla.

Decoction of log wood. Decoction of senega or snake root. Decoction of elm bark.

Decoction of poppy.

And the preparations, gruel, barley-water, &c., are also classed with the decoctions.

There are many other medicinal decoctions, but they either do not require mention in this work, or the preparation, as in the case of dandelion, broom, &c., is better made as infusion. For information respecting those mentioned, the reader is referred to the respective articles.

**DECOMPOSITION** is the separation of the component principles or elements of compound bodies from each other, the process being either naturally or artificially excited .-See Antiseptics—Fermentation—Putrefaction.

DEFORMITY means "any and every

deviation from the recognised symmetrical pro-portions of the human frame;" but the word is more definitively applied to those irregularities of form which consist in partial deviation from the natural position of the body, unaccompanied by malformation of the general original structure. Deformities are either congenitalthat is, dating from birth-or acquired. With respect to the causes of congenital deformities, "some are at present inclined to attribute

genital cases, teething, worms, irritation of the spinal cord, and infantile paralysis, are frequent causes. Certain occupations, such as much standing, or carrying heavy loads; position also may be regarded as a cause, especially in lateral curvature of the spine; but occasionally we are at a loss to discover any cause, the deformity coming on insensibly, while the patient is apparently in perfect health." These cases, if attended to at their commencement, might certainly be relieved and prevented, but it often unfortunately happens that there is little interference with the general health; the deformity, as in the foot for instance, coming on insidiously, no attention is paid to the circumstance; a weakness, as it is termed, of the ankle is felt, and the foot deviates occasionally from its natural position, and thus, if the case be neglected, the foundation is laid for a permanent deformity, or at all events a permanent weakness of one or, both limbs, which may involve their being disabled for life.—See

The most simple form of distortion is the horse foot, which consists of complete elevation of the heel, so that the patient in walking rests entirely on the toes (fig. 66). This deformity

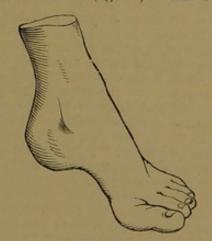

Fig. 66.

is rarely met with as a congenital affection, but as explained by Mr. Tamplin, it arises as a consequence of disorder of the system, and more especially of nervous irritation, such as that caused by teething, worms, &c. It may also be occasioned by wounds or local irrita-tions, such as ulcers, affecting the calf of the leg, or "it may arise spontaneously, the patient experiencing no pain or inconvenience beyond the inability to bend the foot or ankle joint in the act of walking, and retaining at the same time power over all the muscles. When weakness of the ligaments of the ankle joint is conjoined with the above deformity, in the course them to a mental impression, generally a distorted, that the person at length comes to sudden one, received by the mother during rest on its outer edge in walking.

Another deformity of the foot, that in which

DEL DEF

and frequently does, but it may also be induced by various causes of irritation affecting the nervous system. The flat or splay foot, although it may be a congenital formation, is also liable to be caused, where previous debility exists, by the carrying of heavy loads, and other things which necessitate much pressure upon the arch of the foot. "The first thing which attracts the attention of patients to this deformity in its incipient state, is a sense of weakness, more especially on the outer side of the ankle joint;" they then observe the flat appearance of the sole of the foot, and the tendency of the inner ankle to approach the ground in walking; as the deformity increases, the pain in the joint, and the sense of weakness increase to such an extent, that the patient becomes totally unable to follow his ordinary

occupation. It would be superfluous waste of time and space here to enter further into a consideration of the various deviations from the natural formation to which the limbs are liable. Suffice it, that whether the infant is born with these deformities, or whether it becomes the subject of them as life advances, they cannot too soon be submitted to medical management; modern surgery has demonstrated that they are remediable so far, that all striking deformity is removed, and that an otherwise almost useless member is adapted to perform its natural offices, if not with grace, at least with comfort. The great improvement in the treatment of these defects consists in division of the tendons which occasion the distortion. This practice Mr. Tamplin and other orthopædic surgeons recommended as the preferable one, whether for infants at the earliest age, or later in life, for the following reasons: "First, from the facility with which it is accomplished; secondly, because it incurs comparatively no risk, and scarcely any inconvenience; thirdly, because you at once overcome the principal resistance, and render the after-treatment painless to the patient, and comparatively easy to the attendant, independently of which, the child is not subjected to such constant confinement of the limb as is absolutely necessary when you do not have recourse to an operation; you can allow exercise to be taken for a certain time during the day, and that, even in infants, must have a most beneficial effect." Much benefit, however, is derived from wearing supporting apparatus suitable for each particular deformity. Boots with leg irons and bands made to grasp the limb, either above or below the knee, are now universally made use of for weak knees or ankles, and for other deformities arising from softening of the bones.

The above remarks have been brought forward in the hope that parents, and others having the care of children, may not, knowing the general causes of non-congenital deformity, leeches, or by cupping, cannot fail to be of neglect the first warning symptoms of its service; along with bleeding, free purging with

it is simply bent inwards, may date from birth | insidious approach, and in the case of children born with distortions, may place them at the earliest possible period under efficient surgical management, and not be deterred by the fear of an operation, which, in proper hands, is perfectly safe, comparatively painless, and unattended with loss of blood.

Deformity occurs from the softened condition of the bones in the disease of childhood named rickets, and also from softening of the bones in adults, but these cases are the effect of distinct and well-marked diseases. - See Rickets - Soften-

ing of Bones, &c.

Deformities and contractions of the shoulder and elbow joint are very generally the result of injury or disease. The wrist joint and the joints of the fingers are also liable to distortion from the same cause; in some cases the contraction is seated in the skin, as in cicatrices from burns, in others the joints are deformed and perhaps displaced by rheumatic disease. Deformity of the fingers may also be congenital. Such cases should be put at once under the management of the surgeon.

Refer to-Neck-Rickets-Spine, &c.

**DELIRIUM** is a temporary disordered condition of the mental faculties, occurring during illness, either of a febrile or of an exhausting character. It is generally a symptom of serious import, but not always; many children, and some adults, become partially delirious, or "wandering," from very slight causes, even a simple feverish cold being sufficient to produce the effect; in such cases, of course, judgment must be formed with some reservation. In fever, and febrile diseases generally, delirium may be no more than slight confusion of ideas on waking from sleep, or it may amount to furious and dangerous excitement, or merge in low muttering, or terminate in confirmed coma or stupor.

Delirium may be the effect of disordered or inflammatory action affecting the brain itself, or it may be sympathetic with active disease in other parts of the body, such as the heart or kidneys, or it may be caused by long-continued and exhausting pain, and by a state of inanition of the nervous system. In the treatment and alleviation of the symptom, it is of the highest importance that it should be ascertained to which of the above conditions it is owing, and from this circumstance, any attempts to remedy it by the unprofessional-who must be liable to error on this head-cannot but be attended with great risk. It may, however, at times, be requisite even to run this risk, for the chance of doing good, and then the following directions may serve as some guide:-

When delirium occurs in a person of full habit of body, accompanied with inflammatory fever, with quick strong pulse, bloodshot eye, and flushed countenance, abstraction of blood in the first instance, either from the arm, by

DEL DEL

calomel, combined with compound colocynth | sedative solution; the dose for an adult fifteen pill, with jalap or scammony, or followed by senna and Epsom salts, should be resorted to; the head should be shaved and kept cool, with the coldest applications to be procured, the feet should be kept warm, the room darkened, and every source of excitement removed. If there is violent effort, and unruly conduct, the limbs must be restrained firmly, but gently, whenever attempts to exercise them in an improper manner are made. In this case a broad belt passed loosely over the bed, and fastened at each side, so as to confine only when any attempt at rising is made, is of considerable assistance. In this form of delirium, it is of the most essential import that watch should be kept without one moment's interval, night and day; there must be no risk run of sleepy attendants, and there must be sufficient physical power to restrain the almost superhuman, though transient, efforts made by delirious patients. Some of the most painfully distressing accidents of illness have occured in consequence of neglect of these precautions; one unguarded moment, one five minutes' sleep, have neutralised days and nights of anxious care and watching; in the brief interval of remitted surveillance, the patient has escaped from bed, from room, even from house, by the usual modes of egress, or has dashed madly through the first window in his way, or laid hold of the first means of self-destruction. The force of the excitement, it is true, is generally soon over, but it lasts long enough for serious or fatal mischief; no apparent quiet for some time is to be trusted; unceasing care must be exercised till intelligence returns.

In the low forms of delirium, the mental disturbance is equally complete as in the acute forms, but the violence of the inflammatory fever is absent; generally, the person lies in a dreamy state of incoherent thought; but even in this form, occasional fits of excitement, and attempts to get out of bed, and the like, occur, and must be guarded against. It is this form of delirium which generally becomes developed in the progress of typhus and typhoid fever. The temperature is scarcely so high as in the inflammatory attack, the vessels do not throb in the same manner, and the eyes are not blood-shot, the pulse is feebler and more easily extinguished, the tongue and the hands are tremulous, the former when protruded, and the hands are perhaps affected with convulsive startings. When these symptoms are at all marked, there can be but little doubt as to the nature of the case. To take away blood is to kill; the head is to be kept cool, the bowels moderately but sufficiently opened, and the warmth of the feet attended to, perfect quiet being observed around the patient. In such a condition, particularly if there is tendency to nervous or convulsive twitching of the fingers or of the tendons at the wrist, opium may certainly

drops in the evening, five drops additional being given every two hours till sleep is procured, or till thirty drops have been administered in all; or the muriate of morphia may be given, in half or quarter grain doses, in the same manner; or in the absence of these, any other preparation of opium in corresponding quantity. The hydrate of chloral in doses of ten or liftcen grains may be given often with advantage to procure sleep, when it is not advisable to use opium. Sleep is the only remedy for the irritation and irritable exhaustion of the nervous system which is attended with this form of delirium, and opium is mainly to be trusted to for procuring its benefits. Strong meat soups, and wine, may also be requisite, but the consideration of these matters rather belongs to the subject of

A form of delirium, accompanied with much nervous irritation, is apt to be developed in the course of scarlet fever, towards the third day of the eruption, or when it is beginning to fade. In the progress of rheumatic fever, this same delirium of exhaustion may occur, and, like the others already mentioned, requires the treatment by opium.

Traumatic delirium takes either of the above forms, according to circumstances, but it is more generally the low type, especially when consecutive to severe accident or operation, or during protracted child-birth; generally, therefore, opiates and supporting measures, meat, broth, wine, and bark, &c., are required,

rather than the reverse. It is of consequence that delirium should not be mistaken for insanity, as it might be and has been, but scarcely ought to be by a medical man. The concomitant circumstances of disease, &c., will generally guide. In true delirium the presence of fever more or less, the acute disorder of the functions generally, such as digestion, &c., and the disorder of the whole mind, generally sufficiently indicate its distinctness from insanity, in which the faculties of the mind are only perhaps partly affected or perverted, and disconnected. The insane, moreover, do not exhibit the appearance of illness which accompanies true delirium, and the functions are not usually impaired in the same way. Still the two affections may nearly approach one another, and in the form of delirium which follows child-birth or the delirium tremens of the drunkard, it may often be difficult to make the definition as to which the case belongs. Still more difficult of discrimination are some cases of hysterical delirium, which, when long continued, might well be mistaken for insanity, unless submitted to medical judgment; indeed, in every case of delirium, medical assistance should be procured as early as possible. No unprofessional person in his senses would think of treating a case of be given with benefit—the best form is Battley's delirium, when professional assistance is at

DEL DEL

hand. In its absence, the foregoing article | stomach is in so irritable a condition that it

should be useful.—See *Insanity*. **DELIRIUM TREMENS** consists of a peculiar exhausted condition of the nervous system, which is accompanied with more or less mental disorder of a peculiar kind. This disease is generally the result of excessive continued intoxication with alcoholic liquors, or of their withdrawal when they have been habitually consumed in considerable quantity; it may also, however, be produced by the continued use of opium, and has been known to arise from other causes of cerebral exhaustion. The first symptom of delirium tremens is a state of restless nervous irritation, if the exciting cause be continued, sleeplessness follows, there is no rest, and if there is any approach to sleep, it is haunted by dreams and figures, which seem to excite the greatest terror; the mind is more collected than in most other forms of delirium, but seems always to be more or less haunted with suspicions of hose around. The entire frame is in a state of tremor, the closed eyelids and the protruded tongue are tremulous; the hand which attempts to perform any action requiring exact-ness, cannot execute it for shaking; the patient is exhausted, and still sleep does not come. Succeeding the above condition, the nervous excitement becomes so great that the person cannot be kept in bed, the mind becomes more disordered, a state of temporary insanity ensues, and convulsions, epilepsy, or apoplectic stupor close the scene; a scene of the most painful nature, perhaps, which the physician is called to witness—the death-bed of the drunkard-of the man slain by his own suicidal act, by the poison of alcohol.

Delirium tremens often supervenes in cases of injury to persons accustomed to the excessive use of alcohol, and tends greatly to complicate the recovery. It may continue for three or four days or even longer, though it usually succumbs to the remedies prescribed by the doctor.

It can rarely happen that an unprofessional person could have to undertake, unassisted, the management of a case of delirium tremens, and never should do so, except under extreme necessity. The nature of the disease is, un-happily, in almost all cases too palpable, from its exciting cause. It is an exhausted condition of the brain and nervous system, and the great effort must be to alleviate this exhaustion, too great even for sleep. Opium is the remedy among others, and must be given in full doses. A medical man will of course give it more freely at once than another person; but in a confirmed case of delirium tremens, twenty-five drops of Battley's solution, or thirty of laudanum should be given at once, and repeated until sleep has been procured. Should the opium fail to give relief, twenty grains of chloral, either alone or combined with some at intervals. It often happens that the continues to take food freely, he is not likely

will retain neither food nor medicine; in such a case, the opium is better given by hypodermic injection, and repeated should the occasion require it, but the person should be carefully watched, lest the narcotic should produce a too powerful effect. In some cases of delirium tremens, the liver is more or less affected, it is loaded with dark unhealthy bile, and so much is this the case, that some have been inclined to attribute many of the symptoms of delirium tremens to the liver disorder, and to recommend a purgative treatment, in preference to that by opium. The author has generally found the medium course the best, that is the combination of opium with calomel, and the compound colocynth pill. Five grains of powdered opium, ten grains of calomel, and twenty of compound colocynth pill, are to be compounded together and divided into twelve pills; of these, two or three should be given for the first dose, and one at intervals of an hour between each, till six have been given. Under this treatment, after sleep has continued for some time, the bowels are generally acted upon, with immense discharge of dark black-looking bile, much to the relief of the patient. After this, the remaining pills may be given, two every night, and castor oil in the morning, if required; five, ten, or fifteen drop doses of laudanum, or two teaspoonful doses of paregoric being given if the nervous irritation is unsubdued, or threatens to return. After the nervous irritation is tolerably well subsided, the next object must be to restore the tone of the stomach. Eight-grain doses of the carbonates of soda, or potash, combined with a tonic bitter, calumba, gentian or chamomile, may be given for this purpose, every eight hours, or quinine or bark, in some form, will be found useful. Bitter beer, with ten drops of potash solution, may be very serviceable. During the whole treatment, it may be necessary to allow the unfortunate subject of the disease a certain regulated portion of alcoholic stimulant, such as brandy and water, in some degree proportioned to the previous habits, and as soon as the stomach will bear it, the nourishment of strong meat broths, yolk of raw egg, beat up with a little brandy, or gruel or arrow-root, with brandy, should be given. If the tongue is very red at the tip, and if the pit of the stomach is very tender, milk, with or without the addition of a little brandy, should be substituted for the above; fifteen drops of solution of potash, or one or two tablespoonfuls of fluid magnesia or of lime-water, may be added to the milk with advantage. In cases of persistent sickness, effervescing draughts, and ice given in small, frequently repeated fragments, are often useful. The reception of nourishment by the system is of the highest importance in this disease; so much aromatic stimulant, may be given and repeated | indeed, is this the case, that as long as a man

DEL DEL

to become the subject of delirium tremens. The necessity for the continuance, in reduced quantity, during the treatment, of the stimulant which has produced the disease, is evidenced by the fact, that many cases of delirium tremens are precipitated at least, by the sudden withdrawal of the accustomed excitement, and relieved by its renewal; and for the same reason the radical removal of this fearful disease, or indeed of intemperance generally, though it can only be effected by the abandonment of the pernicious habit, must in many cases be conducted with extreme caution, otherwise dangerous or fatal consequences may result. Undoubtedly, men of naturally good nervous power, whose stomachs still retain some of their pristine tone, and can receive and digest food in tolerable quantity, and where the constitution has not been thoroughly sapped by intemperance, may, and do with impunity and benefit abandon at once their habits of drinking, and when this can be done, it is the safest and most certain plan; but many cannot do this without risk, and must go more cautiously to work. Where spirits have been consumed, let them be exchanged for wine or malt liquor, in reduced and reducing quantities. At the same time, with all who are endeavouring to break through the evil habits of intemperance, some innocent and rational excitement ought to be substituted for the pernicious one; excitement of mind or body of some kind must take the place of that which has been abandoned, if the full benefit of the change is to be

Many methods have been devised for gradually weaning the intemperate from the craved excitement: perhaps one of the most feasible is that of commencing with a certain quantity of the accustomed stimulant, taking from it a measured proportion only every day, and for every measure withdrawn, substituting an equal quantity of water. The plan is a good one, but no plan will succeed without the firmest determination of the drinker to conquer the vice which is dragging him to ruin in this world and the next. If he will make this resolve, and pray to Him who alone can strengthen and uphold man's feeble will, then may he hope to overcome. Again it is repeated, the intemperate man, whose constitutional powers will enable him at once and without compromise to cast aside the vice, has the easiest task; but no man should do so except by medical sanction, and the further advanced in life, and the more confirmed the habits of the patient, the more necessary does the precaution become. But in any case in which a person, who has been in the habit of taking alcoholic stimuli, abandons the custom, he should be under medical surveillance for a considerable time after; otherwise, formidable depression of some or all of the vital functions may be the result.

The question of restraint in cases of delirium

tremens is one of much importance; at times it becomes absolutely necessary to exercise it, for the preservation both of the patient and of those around. When the necessity does arise, it must be put in force with as much gentleness as may be compatible with firm command. The individual suffering should be kept in a bed where there is room for persons to be on each side, and all efforts at violence should be restrained by perfectly adequate physical power in the attendants. It is not necessary to keep the hands constantly upon the patient; if he knows-and he is generally conscious enough for this-and feels that he is mastered, he will remain quiet; but if by the temporary absence of an attendant, he thinks he can overpower the others, he again becomes unruly. This consciousness of hopeless effort on the part of the patient is in many cases the most powerful means of restraint. A strong webbing band made to cross over the bed about the middle, and to buckle at one side, is often extremely useful in checking sudden violence, whilst it ought to be sufficiently loose to prevent any feeling of restraint, such as the straight waistcoat gives rise to, thereby irritating the patient to a great degree, and inciting him to ceaseless and exhausting efforts to get free; the latter should never be used except under great necessity. The question of permanent restraint, where repeated attacks of delirium tremens occur, and where the patient is continually in a condition verging upon insanity, is a very puzzling one, in consequence of there being no asylum adapted for such cases. The person when at liberty will drink, and when he drinks he is mad; but when sober, or nearly so, his mind is not sufficiently affected to class him with the insane.

The difficulty of dealing with such cases is often extreme, both to the family of the patient and to the medical attendant. There may, it is true, be procured a keeper or guardian, but comparatively few can incur this expense, and it is but an insufficient safeguard after all; the consequence is, that numbers of such patients are kept at home; they cannot be prevented from indulging their irresistible propensity to intoxication, and so, for a longer or shorter time, they are a source of danger and of terror to their family, and to every one around, and run hourly risk of terminating their own miserable existence by a more speedy description of suicide than the one they are following. Such cases can sometimes be dealt with under the Inebriates' Acts, which allow a patient to be confined in a licensed Inebriates' Home for not more than two years, if his consent to the confinement is previously given. When there is a real desire for reformation this assent can usually be obtained, and the patient sent to one of the Homes now established throughout Great Britain.—Refer to—Alcohol—Intemperance— Dinsomania.

DELIVERY .- See CHILD-BED.

DEO DEM

medicine, is applied to remedies which exercise a soothing influence, more especially upon the mucous membranes and upon the skin, when substances, which disguise or destroy feetid and these are from any cause in a state of irritation. The demulcent may either be applied directly to the irritated and irritable surface, as in the case of the stomach and bowels, or indirectly, applied to various agents of a volatile character, as in the case of irritation of the urinary passages, and of the bronchi or air tubes.

The principal demulcents are:-

Almond (sweet). Arrow-root. Carrageen moss.

Eggs, in the form of emulsion.

Gelatine and isinglass.

Grains, in their preparations: barley-water

gruel, &c. Gum arabic.

Lard. Linseed. Liquorice. Marsh mallow

Sago. Spermaceti. Tapioca

Tragacanth gum.

Wax.

It cannot be said that any of the above substances act as medicines in the proper sense of the word; nevertheless, they constitute a class of remedies peculiarly valuable for domestic use. They are perfectly safe, and certainly most beneficial; at the same time, it is a necessary caution that the prolonged use of demulcent remedies is liable in some persons to occasion a relaxed and debilitated condition of the system. For further information respecting individuals of the class, the reader is referred to the separate articles.

DENGUE, or DANDY FEVER, is the name of a fever which has occurred in an epidemic form in the East and West Indies, and also in North America. The disease presents many of the characters of an eruptive fever, like measles or scarlatina, combined with pain and swelling of the joints, and the symptoms of acute rheumatism. It is liable to frequent remissions or relapses, and must be treated in a similar way to other fevers. The disease is scarcely known in this country.

DENTIFRICE.—See TEETH. DENTITION.—See TEETH.

DEOBSTRUENTS are medicines which have, or are supposed to have, the power of removing unnatural thickenings or formations from any portions of the body. Such medicines were formerly much more used and depended upon, particularly as external applications, than they are now. That is, there were many substances employed for a sort of mysterious deobstruent action, which probably possessed no such action at all. iodine, cod-liver oil, and friction are, however,

DEMULCENTS.—The name, as used in | deobstruents to be trusted, and are much em-

ployed as such in the present day.

DEODORANTS are chemical or vegetable offensive odours. In its largest sense the word would include most antiseptics and disinfectwhich are employed to impregnate the atmosphere of a sick room or other inhabited apartment, and to remove from them any faint or disagreeable odour. Chlorine and sulphurous acid being irrespirable gases, and the best deodorisers we possess, cannot be safely employed for this purpose, and recourse is had to scents of various kinds, balsamic and resinous substances burned in the form of pastilles, lavender twigs, cascarilla bark, and other aromatic vegetable matters, which are usually thrown on some hot cinders on a shovel, and volatilised. Coffee berries placed upon a very hot shovel, are both agreeable and effective as a deodorant, and according to some are disinfectant. The oil of the Eucalyptus is a valuable addition to our fragrant deodorants. Indeed, almost all essential oils, that of the common wild thyme especially, are recognised as beneficial air purifiers, although for a time they were supplanted by mineral products. Our forefathers were wise when they cultivated aromatic plants near their dwellings. Aromatic vinegar, Condy's fluid, solutions of chlorinated lime, chlorinated soda, and carbolic acid, may be all volatilised by means of the spray producer, and are most effective deodorants, as well as antiseptics. To remove fector from uninhabited places, the more powerful oxidising agents, chlorine, sulphur, nitrous acid, and ammonia, can of course be used with advantage, and their action may be kept up till the cause of the smell is removed; but it is well to bear in mind (especially in connection with the sick room) that the best deodorant is fresh air, and that the best means of obtaining it is by the occasional opening of the windows. Another important use to which deodorants are applied, is that of absorbing and destroying effluvia from sewage. Charcoal is much employed to destroy the smell of sewage gas, by filtering the gas through a charcoal layer on its passage through drains or sewers, which communicate with the external air, but the mixture of charcoal, clay, blood, and alumina, known by the name of the A.B.C. process, has become the most general plan of dealing with sewage on a large scale in tanks and cesspools. For privies, outhouses, and dung-heaps, no agent possesses greater powers of deodorisation than carbolic acid. When mingled with lime in the form of carbolate of lime, it can be sprinkled about or thrown down foul places, without blocking up the drains like chloride of lime.

Though we have thought it necessary to recommend the removal of all bad smells, it does not follow from experience that they are

DIA DEP

that gases which are not offensive or even perceptible to the sense of smell are wholesome; all that we wish to call attention to is the importance of discovering the cause of any odour, however slight, for until that is done it must

always be regarded with suspicion. **DEPILATORY** is an application which removes the hair from the skin. Pitch applied to the surface to be denuded, and then forcibly pulled off, so as to bring the hairs with it, was former 7 used for this purpose, but has, deservedly, with other barbarous customs of another age, fallen into disuse. Preparations of quicklime and of arsenic have also been used for the same purpose. In the few cases, such as some kinds of skin disease, in which it may be thought necessary to detach the hairs by the roots, they often come out easily, and the process is better effected by means of tweezers, than by the wholesale, painful, and it may be dangerous, though perhaps quicker methods above mentioned.

DERBYSHIRE NECK .- See BRONCHO-

DERIVATIVE -a term not so much used as it formerly was in medicine, signifies whatever tends to withdraw diseased action from any part of the body, by establishing a counter action in some other part. Thus, bleeding from the lungs may be stopped by the derivative action exerted by the flow of blood from a vein opened in the arm, or inflammation affecting the eyes may be relieved by a blister, or seton, at the back of the neck.

Derivatives may be either natural or artificial. The principal natural derivatives are, either the discharge of blood, or the increase of natural secretions; thus, bleeding from the nose may act derivatively, as regards the brain; or the bleeding from piles, as regards the liver or parts within the abdomen; or an attack of diarrhoea may also relieve in the same way. Boils, cutaneous eruptions, ulcers, &c., also act. as derivatives, but in many cases approach the class of counter-irritants. The great principle involved in the existence of natural derivatives is, that they must be the effect of some cause, and in many cases, of some internal disorder which has thus formed for itself a safety-valve, through less important channels, for the protection of more important organs. Much caution is requisite in stopping, or permitting to be stopped, incautiously and blindly, what is to be regarded as a natural derivative. The symptom itself should be regarded only as the outward sign of something which requires rectification within, and the efforts should be directed to the discovery of this inward acting cause, and to its removal when discovered; this being done, the external symptom will possibly disappear; but even should it not do o quickly, in consequence of having established a habitual local tendency, it may be much

all positively injurious, nor on the other hand, | the constitution has been relieved. Not only, however, must the constitution be relieved at the time, but if the natural derivative is done away with, it must be kept, if possible, free from the primary disorder; otherwise, should this recur, and should the constitution fail to re-establish the natural derivation in time, serious or fatal consequences may be the result. It not unfrequently happens that, some months after an old ulcer has been healed, or cutaneous eruption removed, the individual is seized with some dangerous internal malady, perhaps apoplexy, which might have been prevented, if, after the natural drain had been closed, strict attention had been paid to the regulation of the general health. This is a cogent reason why persons in whom some natural derivative action, such as any of those named above, has stopped, or been stopped, should pay the greatest attention to diet generally, to the regulation of the bowels, to the functions of the skin by cleanliness, of the lungs by fresh pure air, and of the system generally by exercise, and why on the slightest symptoms of indisposition they should subject themselves to medical treatment. A still more cogent reason is it why such persons should beware of tampering with themselves with quack ointments, lotions, and outward appliances, which if they do cure sores, as they profess, without constitutional treatment, must do mischief, for they would merely obliterate the outward symptom of disease, and send the latter to attack perhaps some vital organ.

Artificial derivatives, such as blood-letting, blisters, &c., may be referred to under their

proper heads.

DESQUAMATION is the separation, in scales or flakes, of the outward or scarf skin. Strictly speaking, desquamation is constantly going on upon the surface of the body, and scales or scurf are constantly being separated in small and almost insensible quantity; but after some inflammatory diseases, particularly those of an eruptive character, such as scarlet fever, measles, &c., a much more copious desquamation takes place, and the scarf skin separates in large pieces. The same thing occurs after irritants, such as mustard plasters, blisters, &c., have been applied to the skin. Desquamation, whether natural or the consequence of disease, is always facilitated by the use of the tepid or warm bath.

Refer to-Skin-Scarlet Fever.

DIABETES is a disease in which the urine is discharged in unusually large, often in enormous quantity, and for the most part contains a large amount of saccharine matter. The serious nature of the affection renders it one of those which should be trusted for treatment only to medical hands; the same reason renders it important that its first symptoms should be known, that they may not be neglected. It may creep on a person insidiously, or be suddenly developed. The first and most promore safely attended to as a local disease, after | minent symptom which usually awakens attenantly; at the same time, the thirst is extreme, and the appetite voracious. As Sir T. Watson remarks, some persons, especially among the lower orders, are apt to think, that as they eat and drink so well, there cannot be much the matter, and are thus lulled into security, whilst a fatal disease is undermining their constitution. In addition to the symptoms already mentioned, the mouth is dry, and the tongue clammy and sticky, often very red; there is flatulence and indigestion, and the bowels are generally constipated. Emaciation and general debility also occur; pain and weakness in the loins, and feebleness of the limbs. The leading symptom, however, is the discharge of urine, which has been authentically known to exceed forty pints in the twenty-four hours, the average in health amounting to two or three pints. At the commencement of the disease, the urine may still retain the urinous properties of the diluted secretion; but this passes into the saccharine condition, and sugar, which may be obtained in a crystalline state, is largely discharged. The specific gravity of healthy urine averages 1020° but in diabetes it rises as high as 1040° and 1050°. Among other means of detecting the existence of sugar in urine, take a test tube filled with the suspected fluid and add to it a few drops of a strong solution of sulphate of copper, and rather more than the same amount of liquor potassæ. The mixture will display a dirty bluish look, and when afterwards boiled over a spirit lamp, it will let fall an orange precipitate.

A disease of the nature of diabetes can never with propriety be treated domestically, and an individual who may detect in himself the occurrence of the symptoms detailed above, should at once seek competent medical assistance. The dietetic treatment of diabetes is of more importance than the medicinal; the chief precaution being the avoidance of whatever (either sugar of any kind, or vegetable starchy matter) is capable of being converted into grape or fermentable sugar. This of course involves the prohibition of potatoes, and bread made from ordinary flour, which contains all the starchy matter of the grain. This privation is always much felt and com-plained of, and various substitutes have been proposed. Bread made from bran, thoroughly ground and freed from as much starchy material as possible, is now in general use; so also is a species of bread sold in slices and prepared mainly from the gluten of flour. Biscuits and rusks made of ground almond powder, to which eggs are added, are also much in request. If only ordinary bread is to be used it ought to be much toasted, and green vegetables should always be used instead of potatoes. Skimmed and butter milk have been advocated to the exclusion of other aliment as a diet, and it is said with good results.

The tepid bath, to induce perspiration, is

tion, is the frequent call to pass urine abund- | prescription must be left to the medical man, Persons who suffer from any suspected tendency to diabetes cannot attend too strictly to the state of the digestive organs. Wet feet must be particularly avoided, and flannel should be worn next the skin. The constant drain on the system causes excessive emaciation, and diabetic people suffer from the slightest exposure to cold; it is calculated that one half of them die in the end from consumption. The complaint may be very acute and run its course in a few months, but it is more likely to continue for years: two years is about its average extent, but it may go on for eight or ten years. Codeia, one of the constituents of opium, has of late years been used successfully in the treatment of diabetes, but it requires careful medical supervision.

DIACHYLON PLASTER is the commonly used adhesive plaster spread on calico or leather. It was formerly prepared by hand, but as now made by machinery, is a beautifully uniform preparation, and notwithstanding many substitutes, is still the most firmly adhering, and most to be depended upon of the plasters for retaining the edges of wounds in apposition. People in general have a very false idea of the nature and uses of this and of other plasters. They attribute to them some healing power over the wound, whereas their only use is, by keeping the edges of the wound in perfect apposition, to permit them to heal by the natural power with which the living tissues are endowed. This idea of the healing properties of diachylon, however, often leads to mischief, from inducing persons to apply the plaster to abrasions and sores, which it seriously irritates, causing in some cases, much increase of inflammation, and troublesome ulceration. The practice is most hurtful, and should never be followed. This idea of the healing powers of diachylon has, too, been probably magnified by its known use by surgeons in the treatment of, and for the healing of ulcers. In such cases, used as a strapping round the leg, and over the sore, the latter quickly gets well, and apparently under the influence of the diachylon plaster, which, however, is used only as a convenient mechanical agent, to closely envelop the limb, and give support to the weakened vessels and infiltrated tissues, which have encouraged, and which surround the sore. The diachylon, it is true, passes over the ulcer, but it is prevented exerting any effect upon its surface by the intervening discharge. Sometimes, even when applied to the sound skin, diachylon is found too irritating, in which case soap or lead plaster must be substituted. If diachylon plaster is kept folded up in too warm a situation, it adheres together and becomes useless.

DIAGNOSIS is a frequently used medical often of service. As regards medicine, its term, which may be applied either to the "art

of discovering the nature of diseases, and of | for, but the child will not bear it from the arm, distinguishing them from each other," or to the conclusion arrived at by the exercise of the art. In other words, when a medical man, after investigating a disease, expresses his opinion respecting its nature, it is called his "diagnosis" of the disease. It must be evident to all how much, indeed how everything depends upon a correct diagnosis of the existing disorder; for unless correctness on this point be attained, treatment can scarcely be of much service, and if active, may be worse than no treatment at all. It is true that there are certair general symptoms of disease which may be treated, perhaps with benefit, in a general sort of way, without the medical attendant having any definite idea of the existing derangement. Such is the case with most febrile diseases, and many others, and as the natural powers do much towards the removal of the malady, and to promote restoration to health, a practitioner may practise in this loose sort of way with apparent success; he treats prominent symptoms, attends to diet, &c., and his patients get well. But this is not the true practice of medicine, it is very different from the active, well directed, and energetic measures of the man who, having both the knowledge and the will to truly investigate his case, and having done so, strikes home at once. The man who does not or cannot make a correct diagnosis is working in the dark; and if he uses edged tools, so much the worse for his patients, whose safety must in some measure depend upon the treatment of their cases being conducted upon the same inert plan as their investigation. At the same time, if there be any efficiency in medical treatment at all,—and no man who knows his profession and practises it conscientiously can doubt it,-how much passive evil must result from insufficient and slovenly investigation of disease; how much must be and is every day overlooked, which ought not to be so; how often are germs of fatal disease undetected, which ought to be detected, until they have ripened into active growth that is not to be repressed! One or two cases will more forcibly illustrate the difference between a loose and illdefined treatment of disease, and that which is the result of accurate diagnosis. A child is taken ill, becomes feverish, the breathing quickened, and there is frequent cough, along with other symptoms, indicating in a general way inflammatory affection of the lungs, and so far, perhaps, the diagnosis is too plain to be overlooked, even by a very cursory examination. Tartar emetic, mercurials, &c., are remedies so generally useful in the treatment of such cases, that they will be prescribed with probable success, and it may be that the little patient will get well under their use; but it may not so happen -the disease evidently does not yield, the feverish condition, the quick breathing, and the cough, all show that it is still active. It is evident that abstraction of blood is called ing from disease which tends to the formation

and it must be effected by leeches-where !-o! course on the chest. But on what part of the chest? Here comes the point of diagnosis; the careless or slovenly practitioner will be content with the general indication of the fore part of the chest, unless indeed there is complaint of pain-which may mislead as well as lead-to direct his aim elsewhere, and the chances are, that blood is taken away, comparatively little good is affected, and the child, not the disease, is weakened. The error may be a fatal one, which a correct diagnosis would have prevented. It may be that the anterior portions of the lungs are free from disease, which is confined to the posterior and lower portion of one or both. If a correct diagnosis has been made, this should be known; the practitioner, by the percussion of his fingers and the application of his ear to the chest, will probably be able to lay his hand upon the skin over the seat of disease, and to mark out with confidence the limits within which blood may be abstracted

with the greatest certainty of benefit.

Again, a patient suffers from indigestion, from weakness, pain in the back, and general symptoms of bad health-the spirits are depressed—a general diagnosis is perhaps made, and the round gone of various tonic medicines, alterative remedies, &c.; but the urine, if thought of at all, is passed over with a cursory glance: to the unassisted eye it looks all right, and perhaps is proclaimed so, but a simple chemical test may show the presence of albumen in solution, and indicate the commencement of Bright's disease of the kidneys. The correct method of diagnosis affords at once the key to the main points of the disorder, and probably to its successful treatment, which might have been groped after in vain; or if stumbled upon by accident, and found successful, the success would give but little clue in the next case of the kind which might occur; or it may be that false ideas of the nature of the disease, a false diagnosis having been formed, the success itself will constitute an abundant source of evil and error, not only to the individual practi-tioner, but to others. The fact being a false one, leads to false conclusions. The above cases-which might be multiplied to any extent-have been brought forward to show how much success in treatment must depend upon the correctness of the diagnosis which the attendant practitioner forms of the disease of his patient. They have also been brought forward to show that this correct diagnosis can only be attained by time and patient attention and investigation, even by the greatest in science. In many cases, no extent of knowledge will enable a physician to say what portion of a lung is affected, unless his sense of hearing conveys the exact information to his mind in a physical examination. A physician may suspect from symptoms that his patient is suffer-

of oxalic gravel, but he cannot positively | disease, and this is, perfect candour on the part assure either himself or others that such is the of the patient towards the medical man consulted; case, unless he actually see with his eyethrough the microscope—the peculiar crystal which marks the disease. From what has now been said, it must be evident that the highest attainments in medical knowledge will not compensate for a hurried examination of cases; there must be time; people forget this: attracted by some great name, and in all probability a really and truly great one, they crowd the reception rooms, and are passed in quick succession through the consulting room of the fashionable practitioner, who cannot give time to the full investigation of the cases which come before him. Few, perhaps, attain the meed of popularity without having well deserved it, or retain it without deserving to retain it by their progressive attainments; but, withal, they are not gifted with intuition, and if the public will compel them to see ten cases in the time they ought to take to two or three, the public must suffer, and they do suffer, for many a case overlooked is unravelled by the patient investigation of some less occupied practitioner. It must not, however, be supposed that it is here insinuated, that time and patience alone are sufficient for the proper investigation of disease in the living body; the man of experience, and who to his experience has added accurate observation, will undoubtedly seize more quickly than one less informed, the most distinctive features of the case before him; even at a single glance, in some cases, he may form a conclusion-and it may, probably, be a correct one-in his own mind respecting the nature of a case, and this conclusion will lead him at once to use the means of diagnosis best adapted quickly and surely to satisfy his mind; but even with all this, with abundant knowledge and ready tact, some time is required in all cases, often much more than is given by some in the full tide of practice. Nothing will compensate for a hasty and imperfect diagnosis, and evils innumerable spring from it. On this head Sir Thomas Watson, one of the ablest writers on medicine, remarks :- "It is mainly to the uncertainty in the diagnostic part of medicine, that we must attribute the uncertainty and variation both of doctrine and practice, which have brought so much suspicion, and reproach, and ridicule, upon the science we profess." The case of the fashionable physician has been alluded to; but there are other members of the profession equally overwhelmed with work, but of a far less remunerative character. These are the union and club surgeons, who have not the time, in the midst of their numerous avocations, to devote an adequate amount of it to a careful investigation of the special features of every case brought under their notice. There is yet, however, another essential—in many cases at least-either to facilitate or enable the men of Christian character and of high honour, formation of an accurate opinion of a case of make a parade of their diagnosis of disease, and

and not only candour, but thoughtful consideration and communication of every circumstance which is, or may appear to be, connected with the illness. Whether it be hereditary predisposition, or personal transgression, no-thing should be concealed. Females often permit prudery or mistaken feeling to interfere with their communications with a medical adviser; but one thing can be said upon this matter, if they cannot confide in him on these points, he is unworthy of their confidence at all, but the same resolution which induces the consultation, ought at the same time to give this resolve, to leave nothing untold connected with the state of health.

So much has been said with regard to the necessity for a well-defined diagnosis, that it may lead some to suppose that this can be made out in all cases, which is not possible; many diseases are, it is true, so distinctively marked, that there is no difficulty in assigning them their true name and character, but there are many diseased conditions of the human frame which will not fall under any classification, and which baffle the best directed efforts of our present knowledge for their elucidation. In this case, the diagnosis must be what has been called "empirical;" it is imperfect, because the science of medicine is yet an imperfect one, and in the absence of knowledge of the cause of the disease, experience of the use of medicines in similar cases must be used as a guide to treat-ment. These observations are made, that too much may not be expected from medical men by the public, and to show, that because a medical man will not, or cannot, give a defined diagnosis of a disease, he is not necessarily ignorant of its proper, or, at all events, best ascertained mode of treatment. Further, when it is reflected how strict an investigation is required at the hands of those whose lives are and have been devoted to the subject, it ought to make unprofessional persons doubly cautious in dealing with disease. To quote from the "prefatory address" to this work:- "When it is remembered, how the nicest judgment that observation and experience can form, the most patient attention, aided by practised ear and eye, by microscope and test tube, are frequently necessary, to enable the conscientious physician to judge of his case before he can apply the remedy, it is evident how great must be the responsibility of those who, in rashness or ignorance, venture upon the treatment of serious disease, either in their own persons or in those of others;" this is not meant as a discouragement, but as a caution, for the real object of a work like the present can only be fulfilled when the good it offers is safely and judiciously em-

ployed.

Lastly, either our physicians, most of them

devote their lives of labour to deceive the in the form of acetate or Spirit of Mindererus, public, or are themselves deceived; or quackery and quack medicine must be impudent lies and wicked deceits. The individual who purchases a quack nostrum can either have no idea of the disease-if he has one-under which he is suffering, or only the crude idea-diagnosis-—of his own judgment; and upon the faith of this, he prescribes for himself the unknown compound of an unknown—to him at least individual, on the faith of some lying advertisement. Is the diagnosis of the physician a delusion and a snare, or does the patroniser of the quack remedy exercise the same judgment in the treatment of his body that he would in his worldly business? To our readers we leave

Refer to—Advice, Medical—Disease, &c.

DIAPHORETICS, or Sudorifics, are agents used in the practice of medicine which "determine to the skin," or produce perspiration or sweating. When it is considered how extensive the surface of the skin is, how largely it is supplied with blood, and how abundantly with means for exhaling moisture (see Skin), it must be evident how powerful an influence its excitation or depression must exert upon the condition and functions of the body. influence is so undoubted, and so marked, that in all ages, and in almost all nations, even the most uncivilised, the cure, by promoting the flow of the sweat, has been a common and favourite mode of treatment. Among the tribes of North American Indians, it is employed, both as a curative and as a sanitary agent. The most general mode of exciting perspiration, particularly among the more uncivilised portions of mankind, is by means of hot vapour or the vapour bath, but they also employ abundantly decoctions of various herbs, to assist the process.

The effect which the constant insensible perspiration from the body exerts in regulating its temperature must, of course, be augmented as the excretion and evaporation of fluid from the surface is increased, thus furnishing an active medium for lowering the temperature of the body in states of fever. Every one knows how much and distressingly the dry heat of the skin is felt, and how grateful the sensation of moisture upon the surface. In addition to the reduction of temperature, however, the action of diaphoretics must tend powerfully to relieve congestion or collection of blood, or inflammatory action in internal organs; and, indeed, the fact is every day manifest in the treatment of disease, not as regards general perspiration only, but also as a consequence of the effect of local agents-such as the poultice, fomentation, or hot vapour to the skin, which produce sweating of the part to which they are applied. The most useful diaphoretics for domestic purposes are :-

Ammonia. - In the form of carbonate, when stimulation is required at the same time, and | ance occasioned thereby will not only effectu-

which is one of our most certain and safest

Antimony. - In the form of the tartarised antimony, in small doses, when fever is excessive, and the true James's powder, which is the safest form for children.

Baths.—Tepid, warm, or vapour, or used as in hydropathic establishments by means of the wet sheet and blankets.

Ipecacuanha. —In any of its combinations. Opium.—Particularly in its combination with ipecacuanha, named Dover's powder. There are others, such as aconite and pylocarpin, but these are too dangerous for any but medical hands.

To the above may be added, ethers, camphor, spirits of various kinds, and diluent drinks of a stimulating character, sometimes cold, but generally warm, and exercise. There are many other agents employed in medicine as diaphoretics, but they are not likely to be used domestically, unless, indeed, we except the dulcamara, or bitter-sweet, also called woody night-shade, which, being a common native plant, might be used in the absence of other remedies of the class (see Dulcamara). For information respecting the other diaphoretics mentioned, the reader is referred to their respective articles.

When perspiration is thought to be required, the most suitable agent to produce it should be selected; thus, if there is very hot dry skin, and quick hard pulse, antimony will generally be most useful; if there is depression, spirit of Mindererus, sweet spirit of nitre, or carbonate of ammonia will be most suitable, and with any of these ipecacuanha or opium may be To form one of the most useful and combined. certain sweating draughts, take of spirit of mindererus half an ounce, of antimonial or ipecacuanha wine fifteen to thirty drops, and water four table-spoonfuls, adding or not, as circumstances dictate, ten drops of laudanum,

or a tea-spoonful of paregoric. As there is always a degree of uncertainty, especially in some constitutions, in the action of diaphoretic medicines, when they are taken, every means should be used to assist and promote the desired effect. Confinement to bed is absolutely necessary, and before retiring there, it is always well to put the feet in hot water for twenty minutes; the diaphoretic medicine should be used on getting into bed, and nothing more for three quarters of an hour, when the warm diluent drinks are to be commenced with, and may after that be taken very freely, and continued as long as the sweating process is kept up. If the warm diluent drinks are taken too soon after the medicine, sickness will probably ensue, and so the object in view be defeated: purgative medicine, which is likely to act during the operation of a diaphoretic, should be avoided, for the disturb-

DIA DIA

ally counteract the desired process, but may, | by checking it, aggravate the disease it was intended to benefit. Some persons promote the action of sweating by cold instead of warm drinks; in cases of much febrile heat and excitement they may be useful, but as a general rule, it is the safer plan to keep to the warm fluid. When sweating is produced, the person should always have flannel next the skin, never linen, and of course there must be sufficient covering to maintain the requisite temperature; if the person is labouring under infectious disease, additional care is, of course, requisite in the after disposal and purification of the woollen clothing. When it is thought desirable to check the sweating process, every source of chill must be avoided, the skin is to be dried with warm towels, and fresh clothing previously slightly warmed, put on, the cover-ings lightened, and the hands and arms particularly seen in some cases of chest disease,

gradually exposed. There is sometimes great difficulty in producing perspiration in certain constitutions; when such is the case, the medicines should be given, and other means resorted to, towards four o'clock in the morning, that is, just previous to the time in the four-andtwenty hours, when the body, either in health or disease, appears most liable to perspiration.

Refer to-Skin.

DIAPHRAGM, or MIDRIFF, is the partly muscular and partly tendonous and membranous partition, which separates the cavities of the chest and the abdomen, the heart and lungs being on one side, while the liver, stomach, and intestines are on the other. The diaphragm assists materially in the process of respiration, descending and pressing downwards upon the contents of the abdominal cavity each time a breath is drawn; this is more

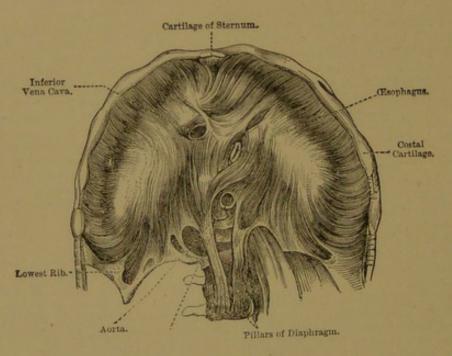

Fig. 67.

dependent upon this action of the diaphragm. From this it must be evident to all, how important it is that this muscle should have free play, and how much its essential movements must be impeded by anything, such as tight lacing, which presses the contents of the abdomen upwards.

Refer to—Lungs—Respiration, &c.

DIARRHŒA consists in frequent and urgent calls to relieve the bowels, the evacuations being for the most part more liquid than usual. The causes of diarrhœa are very numerous, but may, perhaps, be classed under three heads, nervous causes, causes which act upon the surface of the body, and irritating causes which act directly upon the bowels themselves.

when the respiration becomes almost entirely | Perhaps the simplest form of diarrhœa is that arising from nervous causes, such as some experience on the approach of thunder, or from electrical disturbance generally, or such as arises from emotions of the mind, as for example-fear. In these cases the bowels would appear to be simply "relaxed," the evacuations being healthy with the exception of being thinner, from their more rapid passage through the bowels. The simple salutary diarrhea, in teething children, is an example of the same

Influences affecting the body, particularly cold, and especially cold feet, often produce

DIA DIA

the breaking up of a long frost, indeed, to be | substance has been removed by the action, epidemic, that is, of general prevalence.

By far the most frequent cause of diarrhœa, however, is irritation in the bowels themselves, caused either by undigested or indigestible food, by biliary and gastro-intestinal derangement; it may also be caused by an accumulation of hardened feculent masses, or, as they are called in medical language, "scybalae;" or by the lodgment of such matters as the skins of old peas or beans or of raisins, in the folds of the large bowel; the above are frequent causes of teasing diarrhea in children. Lastly, diarrhœa may be dependent upon disease of the bowels themselves, such as inflammation of the mucous membrane of the intestines, ulceration or disease of the large intestine, when it constitutes dysentery, or ulceration of the glands and of the lining membrane such as occurs in

typhoid fever and consumption.

It must be remembered, however, that to some persons a habitually relaxed condition of the bowels is natural, and at the same time essential for health, and that to check it is dangerous. It is evident, that in a disease depending upon so many and various causes, a due discrimination of these is requisite for proper treatment. It must not, either, be lost sight of, that diarrhoea is in many cases salutary, an effort of nature to free the constitution from some morbid matter which, if retained, would produce disorder or disease. On this account, the simple forms of diarrhea are better left to right themselves so long as they keep within moderate bounds; this caution is particularly to be observed with regard to that which occurs in the teething of children, which, when moderate, is a safeguard. when the diarrhea becomes so frequent that the child is evidently weakened by it, and especially if the evacuations appear to be losing their feculent character and become like shreds of skin, or streaked with blood, then a warm bath for six or eight minutes, temperature 92°, should be used for two or three evenings in succession; isinglass or gelatine given in the milk food, and the castor oil emulsion with yolk of egg (see Castor oil) given three or four times a day, each dose containing from a quarter to half a drop of laudanum. Of course medical assistance should be procured if the complaint is not quickly moderated, for checked entirely it should not be.

In diarrhœa resulting from exposure to cold, the best plan of treatment is to moderately reexcite the skin according to the system recommended in the article Diaphoretics, and also, if requisite, to administer the remedies prescribed for continued diarrhea generally.

When diarrhoea is caused by irritating matters in the bowels, one thing is evident it cannot be properly relieved unless the bowels are freed from the irritant matters; it may, it is true, be stopped under these circumstances,

previous to the use of the astringent medicine, and the continuance of the diarrhoa is merely the consequence of the previous irritation. In many cases in which the diarrhœa is owing to irritant matters in the bowels, all that is requisite is to relieve the bowels by a dose of castor oil or by some saline aperient followed up by demulcent drinks, to which, if there is acid in the stomach, a little carbonate of soda is to be added. In other cases, when the action of the bowels is constant, painful, and exhausting, it is absolutely necessary to check these symptoms in the first place, and to soothe the bowels, before means are resorted to for freeing them from the irritant cause. For the former purpose, the common chalk mixture in three table-spoonful doses, with the addition of five drops of laudanum to each, may be given at short intervals till the disease is checked; or the compound chalk powder-dose thirty to sixty grains-and the same powder, with opium -dose, five to twenty grains-are both useful. Or aromatic confection may be given in half drachm doses in water, with or without laudanum. If the active diarrhea does not, from its comparative mildness, require these remedies at first, or when it is sufficiently moderated, the bowels should be thoroughly cleared out with a table-spoonful dose of castor oil, to which ten drops of laudanum have been added; this will probably clear away the irritating matters, if they consist of indigestible substances, hard feculent matter, or the like. When castor oil cannot be, or is not taken, the best substitute is ten grains of rhubarb and six of calcined magnesia, with some aromatic, such as half a tea-spoonful of sal volatile, or a teaspoonful of tincture of rhubarb, and if there is much pain, five to ten drops of laudanum, the dose being repeated, if requisite. After the action of the opening medicine one or two doses of astringent may again be required, as the bowels are apt to keep up acting, simply from irritability. Medical men sometimes give more active purgatives to clear away irritant matter; but the practice is not safe in the hands of the non-professional.

When diarrhoea has been permitted to pass into the stage of irritation, when there is tendency to fever, the belly tender, the tongue red, and the motions resemble shreds of skin, or pieces of jelly, and are mixed with blood, the case is of that serious nature that medical assistance should at once be obtained, if it has not been so before. In the meantime, the emulsion of castor oil with yolk of egg will be found the safest and most effectual medicine; two table-spoonfuls, with five drops of laudanum, being given every four hours, and starch and laudanum injections; the diet being as unirritating as possible, and containing abundance of gelatine. A most excellent drink in but it will recur, unless indeed the irritating from a quarter to a whole ounce of gelatine or these cases is rice water, in each pint of which

DIE DIA

isinglass is dissolved, with a piece of toasted bread | If the stomach will not retain liquid of any introduced to flavour it, or a little cinnamon.

In the more severe forms of diarrhea, such as that connected with consumption or fever, or when fever is present, medical attendance should alone be trusted to, but when unattainable, the disorder must be treated according to such of the methods above detailed as may appear most suitable. In all probability the soothing and astringent plan, such as chalk with opium, will answer best. The author has found bismuth of much service in some of these cases. In case of much tenderness of the bowels, a few leeches might be used, but pain generally should be treated with warm fomentations, or the hot bran poultice. The use of diluted sulphuric acid in frequently repeated doses of ten to twenty drops, of the diluted nitro-muriatic acid, in similar doses, in pure water, or combined with a tea-spoonful of the compound tincture of gentian, are remedies which have been found serviceable in obstinate diarrhœa.

During the late summer or early autumn persons are liable to suffer from a form of aggravated diarrhœa occurring epidemically, often attended with nausea and vomiting, and always with profuse watery evacuations. There is great thirst, accompanied with pains in the stomach and bowels, often amounting to cramp, the pulse is rapid and feeble, the voice becomes weak, and the countenance sunken and anxious. The skin at the same time is cold and damp, and the urine scanty and suppressed. The marked resemblance of these symptoms to those of Asiatic cholera has given the disease the name of British or summer cholera, and the treatment to be pursued partakes much of the same character as that employed in Asiatic cholera. Between the severe form and the mildest, the disease occurs in every degree of severity; if severe, the attack is always painful and alarming, and may be dangerous; and in the country, or at a distance from medical aid, requires to be quickly dealt with. The first thing to be kept in mind is, that the manifestations are not the disease; that the actual outbreak is only an effort of nature to free the system of morbid matter; that we may guide, control, and stop, if matters go too fast, but must not thwart. A mild attack of British cholera is better left alone as far as medicine is concerned, diluent drinks, such as barley or rice water, &c., being given. In a severer attack, when pain, purging, and other symptoms become urgent, it is time to interfere. The patient, if not in bed-which, however, frequently happens, from the attacks coming on in the night-should go there at once, and hot applications, and such like, used to the bowels to relieve the pain; or more extensively to the limbs, back, &c., if there is much coldness or cramp. Twenty to five-and-twenty drops of laudanum should be given to allay pain and moderate purging, and repeated if necessary.

DIETARIES.—During recent years, the united labours of physiologists, chemists, and medical men generally, have added much to

kind, chloric ether in the dose of fifteen or twenty drops should be given, either in combination with laudanum, or in the form of chlorodyne. Sometimes the vomiting is so obstinate that no ordinary means will stop it. Dilute hydrocyanic acid in the dose of five drops at a time may be employed; or four to eight drops of chloroform in a little sugar and water, or brandy and water, might have the desired Two table-spoonful doses of the ordinary chalk mixture, either with or without the laudanum, or half drachm doses of aromatic confection, will be useful when purging continues. In addition to these means, ice, cold water, diluent demulcent drinks, barley and rice water, with isinglass or gelatine dissolved in them, are to be taken. In case of extreme depression, stimulants, hot brandy and water, &c., are to be administered. The attack of British cholera is so sudden and its course so rapid, that if there is any great distance to send for medical assistance, there will be full time for the employment of the above means, not only to the relief, but also to the safety of the patient.

Diarrhœa may occur as a chronic, or longcontinued affection, lasting months or years; but these cases depend on such a variety of causes and influences, and require so much care in treatment, that they can only be advan-tageously managed by a medical adviser, and ought as soon as possible to be put under the care of one. In these and in all cases of bowel complaint, diet exerts great influence; generally speaking, the preparations of milk and of the grains are most suitable, such as arrow-root, sago, tapioca, rice, &c. When broth is given, it should be in small quantity and of tolerable strength; it is improved by the addition of gelatine, and of well-boiled rice. Alum whey is sometimes found useful in these cases.

Biliary Disorder—Digestion, &c.

DIASTASE, according to Liebig, is a portion of vegetable gluten in a state of decomposition, which possesses the power of converting starch into grape sugar; in fact, of acting as a sort of yeast or ferment.

DIASTOLE is the dilating action of the heart, or that by which its cavities are opened to attract and receive a portion of the current of blood, after a previous portion has been expelled by the systole or contracting action of the organ.

Refer to-Circulation-Heart.

DIATHESIS is a term used in medicine to indicate states of constitution peculiarly predisposed to certain diseases, such as scrofula, cancer, gout, &c. Peculiar diathesis is for the most part hereditary.

DIET .- See Food.

DIETARIES.—During recent years, the united labours of physiologists, chemists, and

our knowledge as to the relative value of different kinds of food, and have even furnished us with pretty accurate data from which we are enabled to draw up tables of diet suitable for people in various conditions of life, in health and in disease, during repose and during severe exertion, for the hospital patient, for the soldier, for the prisoner, for the valetudinarian, and for the athlete.

It will be seen from a reference to the article Food, and to the following tables, what are the general principles upon which dietaries ought to be drawn up; that is to say, what are the different classes of constituents into which our food may be sub-divided; and every one knows that unless certain proportions of these constituents enter into a diet, it is to all intents and purposes imperfect, whereas the proportions can, by a proper knowledge of the subject, be so adjusted as to afford the greatest amount of nutriment and sustenance to the frame, with the least possible amount of waste.

The late Dr. Parkes, has published in his work on *Practical Hygiene*, a table by which the amount of different aliments in any given diet may be accurately estimated,—a table calculated to be very useful, not only to the army medical officer, but to the officers of institutions of different kinds throughout the country, and to the public generally. The same authority states that a full-grown man of average weight (140 to 150 lbs.) and height (5 feet 7 in.) requires one twentieth part of his weight in food during the twenty-four hours. This would amount to about 7 lbs. of food, one

rest water.

In all calculations upon diet it must be borne in mind that the daily amount of nutriment must be increased with exercise and exposure, else the body quickly loses weight or becomes diseased; and that while a person at rest (such as a prisoner) may require 17 oz. of a properly proportioned diet, another, such as a hard working navvy, would require as much as 36 oz., or more than double the quantity.

to one and a half pound being solids, and the

It is a curious reflection, that our instincts and habits, as illustrated in our daily practice, have exactly adapted themselves to the demands of science and theory on the question of proper variation of diet. Thus we eat pork with pease pudding, bacon with veal and chicken, butter with fish, rice, sago, &c., cheese with maccaroni and bread; and it is well known that health cannot be maintained without proper variety in diet, and indeed that life itself cannot be preserved without a certain amount of it.

Salted meat is not equal to fresh in nutritive value, as some of the albumen and aromatic principles are lost in the process of curing, neither is it so digestible. It is desirable to add to a diet which must consist of salted meat, such substances as peas, dried fruits, butter, or oil, in order to make up for the deficient nutritive elements.

Tea and coffee, and such like articles of food, though not directly nourishing in themselves, are yet, according to all authors on dietetics, of great value, owing to their power of preventing the wear and tear of the tissues of the body; hence, in classifications, the name of "paratriptics" has been given to them. In all other parts of the world the same practice exists, and it has been proved that men do not feel the effects of hard work so much when tea, coffee, cocoa, chocolate, and the like are added to their diet.

Dietaries, or diet tables, must be used in many public institutions for the sake of order and convenience; also in hospitals for the sick, although it is well known that the innumerable wants of the sick in this respect can never be tabulated, and that a certain amount of extras will always be provided in any well-regulated hospital. It is matter of congratulation that our knowledge as to what does or what does not constitute a sufficient diet for people, under different conditions, is now so much more accurate than formerly, that we may hope to hear no more of outbreaks of scurvy in our jails and reformatories, or still worse, among our soldiers and sailors.

It will be seen at a glance how easily the following table may be employed to calculate the different proportions of the essential elements of food contained in any quantity of any of the articles mentioned. Every public institution, school, college, prison, workhouse, or hospital, has a diet of its own, and it would be an endless task to give even a selection of the best.

The dietaries now in use in all state establishments, are calculated on what may be termed a liberal scale, since they are proportioned to meet the requirements of the persons concerned, whether they are employed in idle or laborious work. The following figures, from the Science Hand-book of the food collection atthe Museum, Bethnal Green, give a summary of the essential dietetic elements of food, supplied to the following classes, in the shape of nitrogenous or flesh-forming, and in the amount of carbon, or heat and force-producing constituents. The British soldier and sailor receive each 5 oz. of flesh-formers and 10 oz. of carbon, a distinction being made in the case of the sailor, when he is placed on a salt meat diet, when he receives 6 oz. of flesh-formers and 12 oz. of carbon, on account of the less digestible nature of the latter diet. The French soldier, though his diet is made up with many articles different from the English soldier, is kept in good fighting condition on a diet composed of 43 oz. of flesh-formers, with 12 oz. of carbon. When not employed in active work, a smaller amount of nitrogen and carbon will suffice for the wants of the system; accordingly, we find that the Chelsea pensioner must content himself with  $3\frac{1}{2}$  oz. of flesh-formers and 10 oz. of carbon, and the workhouse pauper with 31 oz. of flesh-formers and 81 oz. of carbon.

DIE DIE

In estimating, however, the nutritive quality | reserve purposes, cannot be applied to the forof all diets, it is well to bear in mind that the mation of flesh. nitrogenous elements of food, besides making flesh, are to a limited extent employed in producing force; while, on the other hand, what for convenience we term heat-givers or forceproducers, though stored up in the body for de Chaumont):-

The following table, referred to above, for calculating the nutritive value of different articles of food, is extracted from Professor Parkes' work on Hygiene (the edition by Dr.

In estimating the requirements of the sick, | there are numerous difficulties to contend with, which are not met with in other spheres, and which must always complicate, to a greater or less extent, any attempt to provide a diet table on a purely scientific basis. Granted that the waste of tissue involved by disease must be replaced, there are numerous conditions that are to be considered with reference to each individual. The disease or injury from which the person is suffering, the age, sex, and previous habits of life of the person, all point to the necessity of a thorough understanding of the normal requirements of the body in its healthy state, so as better to appreciate its needs in disease. A person in fair health, and doing a moderate amount of exercise, is generally understood to require daily about 27 oz. of water-free food, one sixth part of which should be made up of nitrogenous, and the remaining five-sixths of carbonaceous be wholly impossible for medical authorities to

materials; while a man or woman at rest, with no physical exertion whatever, will require little more than half that amount. The condition of a person in sickness is essentially one of rest and quiescence; the wants of the body are diminished, so far as assimilation is concerned, and the amount of aliment required must depend on the nature of the disease, and the best means of remedying it. As a rule, persons suffering from chronic illness are for the most part confined to bed, and, being usually in a depressed condition, their diet, though select, must necessarily be of low nutritive value, somewhere between that of mere subsistence and the diet of rest. In acute diseases fluid food in a concentrated form, such as milk or beef tea, with the addition perhaps of some farinaceous material, is probably all that is required until the digestive organs return to their normal condition, and it would

average of the full diet daily allowance at most hospitals for the sick, and though it may not present much variety of fare, it is to be remembered that the cooked meat may be replaced or alternated with fish or chicken, chop or occasionally beef steak. In all hospitals, also, provision is made for those who have no appetite for solid food, and whose cases are met with oysters, beef tea, and other articles, which are comprised under the exceptional class of extras for the sick. In most books on nursing the sick, and in nearly all books on diet and cookery, numerous receipts are given, which may advantageously be prepared for the sick room; but it is better for the female attendant on the sick to be perfect in the preparation of a few articles of recognised merit, than to attempt too much .- See Cookery for the Sick-Food.

In connection with this subject, one word of advice to those who are under medical treatment, or their friends, as to dietetics. It is much more comfortable both for them and for the medical attendant to have the prescribed diet in "black and white," in all cases where it is necessary to adhere to a particular system, and where it is desirable to include certain articles, and as necessary peremptorily to exclude others. It saves a great deal of trouble and talk upon the subject, and nothing can be more simple than under the heads of the different meals to write down a list of various articles from which the patient or his friends may make a choice.

DIGESTER is a strong iron pot, the lid of which is fastened or screwed down, so as to be steam-tight, and is provided with a valve. By these arrangements, when the digester is placed near to or over the fire in cooking, the steam is confined, and by its pressure prevents the contents from boiling at the ordinary boiling temperature of 212°, consequently it is possible to raise the temperature above this point, or that at which the amount of heat carried off by the evaporated steam, balances that received by the fluid. This power of elevating temperature confers, of course, upon the water which must be used in the vessel increased power of acting upon bones, or any other substances immersed in it. The use of the digester, either in an economical or dietetic point of view is to be strongly recommended. The valve, of course, prevents all danger from bursting. The price is moderate. Bones which have been well acted upon in a digester, have their animal matter so thoroughly exhausted that, when taken out, they fall in pieces, little being left except the earthy constituents. The amount of animal nourishment in the form of gelatine thus extracted from bones is very considerable, quite sufficiently so to make it an object to the poor in their own homes, and in the houses of the rich, as the foundation of soup for distribution.

Refer to—Heat—Gelatine, &c.

DIGESTION is the process by which food of the esophagus, or gullet, by the same power

The foregoing will be found to be about the is fitted for the nourishment of the animal body. erage of the full diet daily allowance at most The whole process may be divided into:—

The mastication or chewing of the food, and its mingling with the saliva or spittle.

The swallowing of the food.

The digestion of the food in the stomach, by means of the gastric juice.

The mixture of the food with the bile and juice from the pancreas, and its conveyance through the small intestines.

The passage of the remains of the food into and through the large intestine, or colon, during which it becomes acid, and mixed with the feculent excretions from glands of that bowel.

The discharge of the remnants of the food from the body along with other excrementitious matters.

To the above must be added the absorption of the digested and nutritious part of the food into the blood.

The first process of digestion, the mastication or breaking down of the food by the teeth, and its mixture with the saliva, is one of extreme importance. The teeth of man are evidently adapted for the two processes of cutting and bruising; the front or incisor teeth being con-structed for the former purpose, the back or molar, for the latter. These adaptations are well seconded by the action of the powerful muscles of the lower jaw, which give it a direct cutting, and a side to side or grinding motion; the morsel of food submitted to this mechanical action being at the same time kept admirably under it by means of the extraordinary mobility and sensibility of the tongue, whilst it is at the same time thoroughly moistened by the saliva or spittle, which is poured out abundantly from the salivary glands, which lie imbedded around the mouth and jaws; the same mechanical action which grinds the food, serving at the same time to press out the secreted saliva. This fluid, however, does not act simply as a moistener of the food; it exerts a distinct chemical or digestive power upon its starchy components, acting in the same manner as the Diastase mentioned a few articles back, and converting them into sugar, in which state they become fitted for absorption into the blood, a capability which starch does not possess. When the food morsel has been masticated, and moistened sufficiently-at least such ought to be the case -it is collected by the action of the tongue into a ball, and conveyed to the back of the throat or fauces, where it is consigned to the care of involuntary muscles, and passes for the most part from under man's direct control. Passing from the throat into the gullet, it is carried by the wave-like action of that tube into the stomach. This action is not, as some might imagine, a simply mechanical one; that is, the food does not drop into the stomach as it would into a bag, by means of its own weight, but it is carried thither by the muscular movements DIG

that water is conveyed upwards through the gullet of the drinking horse or cow, or indeed in ourselves, as any one can testify who has drunk from a spring by stooping down to the water. The entire process of swallowing, particularly that part of it by which the top of the windpipe is protected during the passage of the food over it, is a series of beautifully connected actions.

When the food has been passed down the

gullet, and has reached the stomach, it lodges in its left or larger extremity. As soon as the lining membrane of the organ feels the contact of nutriment, it becomes reddened, there is evidently increased flow of blood to it, and quickly its peculiar secretion, the "gastric juice," or solvent fluid of the stomach, begins to be poured out. This fluid is "clear, transparent, and viscid, without smell, slightly saltish, and very perceptibly acid," its characteristic power being that of dissolving the chief components of the food, and reducing the varied ingredients of a common meal to one homogeneous, grey-looking, pulpy, acid fluid, which is called the "chyme." This uniform mass, when formed, varies but slightly in perceptible character; when the food has been farinaceous and albuminous, it is like gruel, but when much oily or fat nutriment is mixed with it, it has more of a creamy appearance, on account of the oily matter being as yet undigested.

The solution of the food, and its formation into chyme by the powers of the gastric juice, is much assisted by the muscular movements alternate contractions and relaxations-of the stomach, which turn the mass over and over, and thoroughly incorporate it with the solvent When the chyme is fully formed, it is probable that the albuminous, some part of the starchy, and all the saccharine components of the food have been dissolved, and fitted for absorption into the system. The action of the acid gastric juice, however, puts a stop to the conversion of the starchy ingredients of the food into sugar by the saliva; but this is resumed in the small intestines, when the acidity of the chyme has been neutralised by the alkalinity of the bile and juice of the pancreas or sweetbread, with which it becomes mingled, immediately after it passes or is passed through the opening at the right or smaller extremity of the stomach, into the duodenum, or first portion of the small intestines. This passage of the chyme from the stomach into the intestines, is effected as each successive portion is perfectly formed, that is, has become of semi-fluid, perfectly smooth consistence; for in a healthy condition of the digestive organs, should a portion of solid food attempt to pass the muscular valve at the "pylorus," or place of exit, it is immediately closed against it, and the morsel passed back into the stomach. As already mentioned, the chyme has no sooner passed from the stomach

effect of this admixture is to neutralise the acidity of the chyme. The action of the saliva in converting the starchy matters into sugar is now resumed, and is probably assisted by the fluid from the pancreas, and the oily principles of the food are converted into a milky-looking emulsion, in which state they are fit for absorption into the system. The digested and altered food mass is now passed slowly through the small intestines by their muscular, "vermicular," or wave-like movements; during this passage, the nutrient portions are absorbed, partly by the blood vessels, and partly—more par-ticularly the oily emulsion portion—by the lacteal absorbent vessels, until the now almost exhausted food, reaching the valve-like opening into the large bowel, or colon, is discharged into it. Here the food mass again becomes acid, and this change is supposed by some, and not improbably so, to be of the nature of a second digestion, to ensure the perfect solution of any matters which may have escaped the first acid digestion in the stomach. A more striking change, however, is effected, for here the contents of the bowels assume their natural fæcal or excrementitious character, and acquire their characteristic odour from being mingled with used-up matters thrown out or excreted from the system at large, and from the small glands with which the lining membrane of the large bowel is studded. The absorption of the nutrient matters from the chyme requires a little explanation.

The process is now considered to be largely shared in by the blood vessels, but much of it is doubtless effected by the lacteal vessels, which, indeed, were at one time considered to be the sole agents for the purpose. These little vessels (fig. 68—1) are abundantly distri-

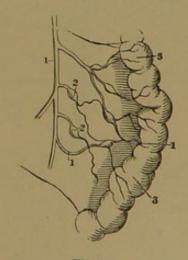

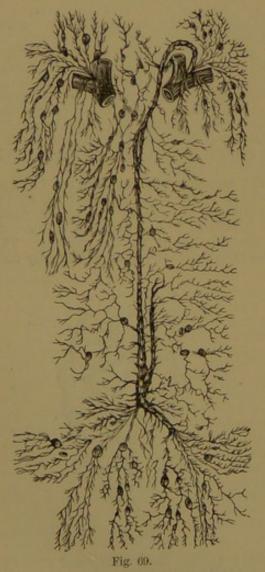

Fig. 68.

chyme has no sooner passed from the stomach into the small intestines, than it becomes mingled with the bile, which is continually distilling into them from the liver, and with 198

DIG DIG

from innumerable small elevated points, or junction of the large veins of the left side of "villi," which cover it—each of these villi the head and neck with that from the arm. contains a small lacteal vessel. These vessels The illustration gives a representation of the were formerly thought to absorb the nutrient portion of the food or "chyle" by means of open mouths, but it is now ascertained that the absorption is effected in the first place by minute cells, which burst, when full, and deliver up their contents to the lacteal twigs in contact with them. By the lacteals, the "chyle" or milky-looking fluid absorbed from the intestines, is conveyed through a set of small glands—the mesenteric (fig. 68-2), after passing through which, the chyle, this extract from the digested food, seems—if we may so speak to become in some degree vitalised; it acquires the power of coagulating, and assumes a red tinge when exposed to the air. The chyle from the various smaller lacteal vessels is now collected in the larger trunks, which coalesce at one point, and form one main vessel, the "thoracic duct" (fig. 69), which runs up and lies close upon

the spine, till, arriving at the neck, it turns down and opens to discharge its contents into the general current of the circulation at the the slight sensation of cold which generally

The illustration gives a representation of the thoracic duct and its tributaries as seen when

injected with mercury.

Such is the marvellous process by which man's material body is daily nourished, and its strength preserved and renewed; such, at least, is the healthy process, as it ought to be: the most generally prevalent causes of its disorder, and they are very general and very prevalent, it remains now to point out. Of course the nature of the food must exert great influence, for good or evil, over digestion; but as that will be fully discussed under the article Food, it need not be entered into here.

One of the most frequent causes of disorder of the digestive function is insufficient mastication, either from want of teeth, from a habit of hurried eating, or from carelessness; many persons but half, or indeed scarcely at all, chew their food, which is swallowed in lumps, and of course, not being broken down, is unmixed with the due proportion of saliva. Fortunately, the solvent powers of the gastric juice are sufficiently active to compensate in the course of time for the imperfect performance of the first of the digestive operations; but it must be evident to all, how much longer and more laborious the process must be of dissolving a solid lump of meat or potato, than of one well broken down and opened up to the operations of the gastric juice; it must also be evident, that in the case of farinaceous and vegetable food, insufficient admixture of saliva must occasion insufficient digestion, or conversion of the starchy matter into sugar, and that, therefore, a portion of the food consumed may become useless. When a difficulty of mastication is experienced, it is always advisable to have the solid food, especially meat, well cut up or minced before partaking of it. Mincing instruments are now sold for the purpose, made on the principle of the sausage-making machine.

Another evil resulting from imperfect mastication, is the rapidity with which food is introduced into the stomach, so that, probably, the organ is over-loaded before the natural sensation of appeased hunger can make itself felt.

Many persons, again, hurry over their meals, with minds intently engaged on something else; the food is swallowed as quickly as possible, and the scarcely interrupted mental effort or business anxiety is resumed, or it may be active exertion at once engaged in. Now, it is a law of the animal economy, that all the functions of the living body, and those which are only periodically called into exercise more than others, require for their perfect performance, some additional access of nervous power, and some increase in their usual supply of blood, whilst the peculiar function is in active operation. With the stomach this is peculiarly the case; the disinclination for exertion, and

DIG DIG

made upon the nervous energies, and upon the circulating blood, by the stomach, during the first stages of digestion. These sensations are more felt if the individual remains quiet after a meal, less so or not at all, if active exertion, either of mind or body, is at once engaged in, and the reason for this is evident; in the first instance, the person who remains quiet, permits the nervous power and the blood to be, as they ought, directed to the performance of the digestive function, and consequently, their supply to the other portions of the body being diminished, incapacity for exertion, both of mind and body, is experienced; if, however, before the nervous and circulating energies have become fully directed towards the stomach (or, indeed, if after they have, exertion is made by a strong effort of the will), they are attracted by a still stronger power, either of muscular movement or mental exercise, the inclination for rest is not experienced; but as this is attained at the expense of the stomach and of its digestive powers, the food is more slowly and perhaps imperfectly digested. It is true that many persons go on for a great length of time without apparent bad results, violating the laws of their own constitution, snatching hurried meals, and running off to business, or study, or exertion, immediately after; but the practice tells in the course of time, and the extreme prevalence of disorder of the digestive organs, amid the commercial and professional classes in this country, is evidence sufficient of the hurtful tendency of such practices. There is, of course, much variation in the injury which the digestive powers sustain, for some have these naturally much more active than others, and can with much more impunity impose upon them; but, as a general rule, moderate rest, both of body and mind, is requisite for a short period after a full meal has been taken, to ensure the perfection and the continued healthy operation of the digestive powers. If exertion is requisite, the meal should be made a light one, and the full supply of food delayed till rest can be taken. Somewhat similar consequences and enfeeblement of the function of digestion are apt to occur, if an individual makes a hearty meal when in a state of fatigue or exhaustion from exertion previous to the taking food, even though quiet is observed after it; the nervous power being exhausted, cannot be sufficiently supplied to the stomach to support its efficient

Another frequent cause of disordered digestion is excess of food, either at once, or by its too frequent repetition. It would seem that the healthy digestive power, and secretion of the gastric juice, is dependent in some degree upon the requirements of the system, and as the gastric juice can only dissolve a certain proportionate quantity of aliment, if more is taken than there is gastric juice to act upon it, it must be imperfectly or not all digested, and

follow a full meal, are the results of the call | if it is not, it becomes subject to the same chemical laws as if exposed to heat and moisture out of the living body; fermentation takes place, gas—"wind"—is generated, acids are formed both in the aliment itself, and thrown out, probably by the efforts of the irritated stomach, and heartburn, pain, and the many other uneasy sensations connected with indigestion are developed. Many of the causes of indigestion are undoubtedly traceable to other sources, but the consideration of those will be taken up in the article devoted to the subject. The digestive power of the stomach is remarkably interfered with, or even negatived, in many diseases, especially those of an acute or febrile character; it seems to lose almost its power of secreting the gastric juice, and with it, of course, all power of digesting; if food is put into it, it is unacted upon, and is probably vomited after many hours, almost unchanged. There can be no question that this instinctive sympathy, as we may call it, of the stomach with the constitution at large, is wisely intended to prevent nutriment being introduced into the system, and into the blood, when it would either only tend to embarrass the curative powers of nature, or to aggravate the disease.

From the review now taken of the nature of the process of digestion, and of the more general causes of its disorder, the reader must have been made rationally aware of the necessity and reasons for attending to these requirements, which have been pointed out as imperative, for the immediate proper performance, or for the continued health of the function. The food must be prepared for the stomach in the mouth, and the stomach must not have the nervous energy and blood supply, requisite for the important office it performs for the system at large, abstracted from it by unseasonable exertion. The food must, too, be proportioned to the wants of the system. If a man will be sedentary, if he will not use up his blood, his muscle and nerve, in active exertion, he must not expect to enjoy food like one who does; he may eat the food, and, if he possess naturally strong digestive powers, his stomach may dispose of it without giving him much inconvenience; but when the excess of nutriment reaches the blood, it must either be deposited as fatitself, when in excess, a disease-or it must be developed in the poison of gout, gravel, or biliary or other disorders.

Hitherto, the processes of the first or primary digestion have been considered, being the changes of the food from its introduction into the mouth, to the discharge of its refuse on the one hand, and the passage of its nutrient materials into the blood on the other. Physiologists, however, recognise a secondary digestion, embracing the changes undergone by the blood and tissues in the performance of the various functions of the living body, and the final discharge of their components after they

DIL DIG

tion of these changes is entered into in various articles, such as Animal Heat, Nutrition, Respiration, Motor Change, &c., it is unnecessary to pursue it further in this place.

It may, perhaps, have puzzled the unprofessional reader, that at times the digestive operations have been alluded to as if they had actually been witnessed by the eye, and such is the fact; for it happened that, between forty and fifty years ago, an American physician, Dr. Beaumont, enjoyed the rare opportunity of experimenting upon, and witnessing with his eyes, the results of his experiments upon the healthy stomach of a living

healthy man.

The subject of Dr. Beaumont's experiments was Alexis St. Martin, a young Canadian of good constitution and robust health, who was accidentally wounded by the discharge of a musket, which carried away a portion of the skin and muscles covering the stomach, and perforated the organ: by good treatment, St. Martin recovered from the injury, but the opening into the stomach never closed. The case coming under the notice of Dr. Beaumont, he, fortunately for science, availed himself most fully and intelligently of the unique opportunity it afforded, and, by numerous wellconducted and accurately-recorded experiments, he cast light upon many unascertained points connected with the process of digestion, to some of which allusion will be made in future articles, particularly in that upon Food. Those who wish further information respecting the case will find all its details in Dr. Beaumont's work, re-edited in this country by the late Dr. Andrew Combe.

DIGITALIS, or Fox-GLOVE, is well known, and one of the handsomest of our native plants. It is biennial, that is, the first year a tuft of leaves only is formed, and the flowers do not appear till the second summer. About the middle of June, the wand-like stem, rising from two to four feet high from the centre of the root leaves, begins to expand its purple blossoms, resembling in some degree, in shape, the finger of a glove, from which resemblance the plant is named.

Digitalis is a very powerful medicine, and, except in skilled and careful hands, a dangerous one, and can never be employed with propriety as a domestic remedy; although in Ireland it is used by the peasantry for the cure of epilepsy. The infusion and tincture as well as the active principle of the leaf, named digitaline, are used in medicine; the dose of the tincture is from five to thirty minims, that of the infusion from

two tea-spoonfuls to half an ounce.

Fox-glove acts powerfully upon the kidneys in many cases, but its most marked, and, at the same time, most dangerous property, is that which it possesses of depressing the action amount is taken along with food; the gastric

have fulfilled their offices. As the considera- | of the heart, the hazard being increased from the tendency of the medicine to accumulate in the system, and suddenly to develop its depressing or poisonous effects. Properly administered, nevertheless, digitalis is a heart tonic, toning down tumultuous and irregular action. There are but few cases of direct poisoning by fox-glove recorded, but accidents sometimes happen from the incautious administration of it as a medicine; in these cases, great languor and depression of the action of the heart, yawning, giddiness, nausea, and a sense of anxiety, are the usual symptoms. The best antidotes would be wine or brandy, small doses of opium, ammonia, and strong infusion of green tea.

DILL, or DILL-SEED, is the fruit of an umbelliferous plant, the Anethum graveolens. It is a native of South Europe, but is cultivated in Britain, The distilled water, or "dill water, is one of our best carminatives for infants when suffering from flatulence, in one or two teaspoonful doses, either alone or combined with

magnesia.

DILUENTS are agents used medicinally for diluting the fluids of the body, and in many diseases their employment is a subject of much practical importance. In most cases, either in health or disease, the necessity for the use of diluents is made known by the occurrence of thirst. This sensation, which is perceived in the mouth and throat principally, is evidently only felt from sympathy with the body generally, for it is not relieved by the mere moistening of these parts, but only by a supply of fluid afforded to the system at large, either, as in most cases, by the stomach, or through the medium of the skin. Diluents may, however, be very serviceable in the treatment of some diseases when thirst is not felt, as in gravel; they are much more largely used, and perhaps abused, as medicinal agents, on the Continent, than they are in this country. Many reputed mineral waters act most beneficially by their diluting effects; under the hydropathic system, the treatment is carried to a most unlimited, and often injurious extent.

In health, a large amount of fluid, or of diluent, is required periodically by the body to supply the waste continually going on by the discharge of moisture from the lungs and skin, and by the excretions from the kidneys and bowels. The amount must, of course, vary somewhat according to the conditions of the surrounding atmosphere as to temperature and dryness, and also according to the amount of exercise taken; a man making much active exertion, and perspiring profusely, requiring a much larger supply of diluent than one who is Stokers, ironfounders, and others who work hard under great heat, consume an almost incredible amount of fluid. The unnecessary use of diluents by persons in health is undoubtedly hurtful, particularly when the

juice is thereby diluted too greatly, and its eases in which thirst exists, and especially if digestive powers impaired; moreover, persons who drink largely with their food, are apt to wash it down in a half masticated condition, and to take more than is necessary. A certain amount of dilution is, nevertheless, requisite for digestion, and error on this side, also, is undoubtedly committed; but these are points connected with individual constitution, which every man's sense and experience ought, as far as he himself is concerned, to determine better than another can do for him.

All dilution must, of course, be due to water, and the various forms of diluents used in illness are but varied modes of administering the pure element disguised. In many cases this is too largely practised, and patients, very commonly, after having gone the round of the various artificial drinks, are found to prefer, and to adhere to the simple water, as their most grateful and only drink. How often does the child with fever ask for "water from the pump" in

preference to everything else!

Water may be used as a diluent in its purest condition, that of distilled water, or rain water, or as procured from the various sources of spring, well, river, or lake, in which cases it is more or less impregnated with foreign matters. Its temperature may be modified, for it may be used either ice cold, or tepid, or warm; or it may be administered in the form of some of the artificial drinks, such as toast-water, barleywater, thin gruel, or, as on the Continent, as tisane of various kinds. Weak tea is a common and favourite diluent with many. But diluents are not necessarily unstimulating, though most generally so; as a dietetic diluent, oatmeal and water may be more serviceable than any other form, and the same may be the case on occasion where there is intense thirst, along with nervous exhaustion. Persons who have become exhausted by severe labour, having at the same time been exposed to heat, may often with greater benefit and safety take a small quantity of slightly stimulating diluent, than a larger, or even the same amount of plain water. This must not be understood as a recommendation of stimulants under circumstances of ordinary labour, but as applying to cases of exhaustion, and even in these the stimulant must be in very moderate proportion,

The instinctive desire for fluid in cholera, and in diseases generally which are attended with fever, ought not to be neglected. There appears to be almost a superstitious fear with many, particularly of the poorer classes, of allowing the sick to "drink cold water," and many a sufferer regards most gratefully the permission of the medical attendant to take it freely, after it had perhaps been begged for, but withheld by mistaken friends. There are few safer prescriptions, none perhaps which may be more freely carried out by unprofessional persons, than the moderate allowance of simple, unstimulating drink, in all acute dis-

fever be present.

As mentioned in the first part of this article, diluents may be administered through the medium of the skin, and thirst and distress allayed in this way, when the power of swallow-ing is impaired or lost, either temporarily or permanently, or when the only diluent at command, such as sea water, is unfit for drinking. Diluents may also be administered by injection into the bowels.

Water, &c.

DINNER is the meal of the twenty-four hours, the principal occasion on which the daily waste of the body is restored by food. At dinner, for the most part, the articles either of food or drink taken are stronger and more stimulating that at any other meal, consequently its disposal makes the greatest demand upon the digestive powers. It matters not that what some persons call dinner, others would call supper, for by the designation is here meant the principal meal of the day. The regulation of the meal as to time and circumstances often requires more attention and care, in relation to health, than is bestowed upon it, either by medical men or the public. In more primitive times, and where primitive habits prevail at the present day, the timing of this principal meal, must obviously be very different from what it should be when taken in connexion with the habits and modes of life of many in this country, particularly in our large cities. When persons, such as those engaged in country and agricultural work, rise very early, breakfast early, and are engaged in active muscular exertion in the open air, there can be no question, that by the time of noon, the system is ready for, and requires a full supply of good nourishment; and the powers of digestion are fully equal to the task, even though the interval of rest be not very great. Further, half-a-dozen hours' work afterwards, pave the way for another substantial meal; and such being the case with our agriculturists, the healthiest and strongest, probably, of our population, people seeing this, have jumped somewhat hastily to the conclusion, that the early dinner is the secret of health, forgetting the other accessories of fresh air and exercise, and, in the case of the labourer, not over-active minds. The case of mechanics and artizans generally, who begin the day early, is nearly, but not quite similar to that of the labourer; they require a good meal tolerably early in the day, but not having the advantage in many cases of the fresh air of the agriculturist, many of them might with advantage divide the meals a little more equally; diminish the dinner, and add to the meal made after work is concluded, more particularly when the dinner hour is short, or shortened by the necessity of walking home from the place of employment to the meal.

When the case of the higher classes is con-

DIP DIN

sidered, it must be evident how completely the | tend frequently to make even this principal time for their principal meal must be altered by circumstances; beginning the day, for the most part, some hours later than the operatives, making, generally, much less physical exertion, and working the head more, there is not the necessity for the principal meal being early in the day. Moreover, the employments generally of the class in question, being more of the mind than of the body, and often of an anxious and thought-engrossing nature, they cannot in the midst of them cast loose the mind, or place it in the same careless ease as the physical labourer can do, consequently the digestive powers are interfered with. If these observations are taken in connection with those upon Digestion, in the article devoted to that subject, their force will be seen. From them the following deductions may be drawn:-That although those engaged in physical exertion, either of business or pleasure, particularly if early hours are observed generally, require and ought to have the principal meal of the day early; those engaged in occupations of mental rather than of bodily exertion ought to delay it till the necessity for the mental stretch is passed over. This subject has been more dwelt upon from its so frequently being the case, that early dining is prescribed in cases of stomach disorder as a sort of panacea, which it does not prove. It is not counselled that the dinner hour should be thrown too late in the evening,-probably six o'clock should be the limit, but it is far better that it should be late, than interpolated in the midst of the turmoil and anxieties of business, or mental strain of study. It is objected that a late dinner involves either too long an interval between breakfast and dinner, or a luncheon. This is matter of constitution simply; some persons of good constitutional powers, who can make a substantial breakfast between eight and nine in the morning, do not require food between that meal and a five or six o'clock dinner; those who cannot take so much at a time, are much more likely to do well with a light luncheon, not necessarily a meat one, in the midst of their work, than with a heavy meal, as even the lightest dinner must be. It is no real objec-tion against a late dinner, that its being made after work, induces people to indulge in the pleasures of the table more than if they dined early; abuse will neutralise the good of anything, however beneficial, but it is not an argument against its use. Further, there are undoubtedly invalids, and certain impaired states of health, in which an early hour for dinner is found beneficial, but these must be cases in which either the state of health, or circumstances, require or permit all arrangements to be made conformable to the one object-health. An early dinner almost certainly involves supper of some kind, and this may or may not be an objection according to circumstances.

meal a much too abundant one, chiefly by tempting the appetite with a variety of food, and it is impossible to lay down any set rules on this head beyond that which every rational man must be well aware of, that none can perseveringly transgress the bounds of temperance, either in eating or drinking, without, sooner or later, disease being the result.

Sleeping after dinner may suit a few persons, but it is not advisable for those of full habit of body. For the reasons already mentioned, the time immediately succeeding dinner should be one of easy relaxation, to the man of mental toil in particular. The use of wine, beer, or any stimulant falls of course to be considered under the other articles more directly bearing on these subjects. A cup of coffee is sometimes taken shortly after dinner; opinions differ as to the propriety or not of the practice; it will probably be found to be best regulated by individual experience; the practice, however, of taking tea or coffee, either immediately or two or three hours after the meal, is unquestionably a serviceable one amid the usages of civilised life, and assists the perfection of the latter stages of digestion. These diluents, however, ought not to be taken too strong, or too late in the evening, otherwise their effect upon the nervous

system will interfere with sleep.

Some individuals of weak digestive powers are in the habit of taking a "dinner pill," for the purpose either of exciting the appetite, of stimulating the digestion, or of both. As a habit, the practice is bad, because it must be a substitute for more efficient and permanent means of improving appetite and digestion; occasionally, however, in some cases the dinner pill is useful as a temporary remedy. Eighteen grains of compound rhubarb pill, six grains of cayenne pepper, and twelve grains of extract of gentian, made up into twelve pills, of which one or two may be taken a quarter of an hour before dinner, will be found useful. The practice of taking spirits, or stimulant cordials, or bitters, before dinner, is highly injurious to the stomach, exhausting and irritating in a way that must interfere with digestion. A draught of cold water is a much better preparative; with persons of very weak powers, however, cold water, either before or during the meal, depresses too much. Many persons find that a glass of warm water agrees better with them than cold, and it is certainly quite as efficacious in quenching thirst.

Refer to—Digestion—Food—Stimulants.

DIPHTHERIA.—There prevails throughout this country a very general, though an entirely erroneous impression, that diphtheria is a new disease. It cannot be doubted, however, that it had been observed at different times in France, in Scotland, and in England during the last two or three hundred years.

an objection according to circumstances.

Undoubtedly, modern habits and luxury specific infectious disease characterised by

DIP

brane (Greek, diphthera, a membrane) on the throat (tonsils, pharynx, and upper air-passages), attended by great prostration of vital power, and not unfrequently followed by a remarkable form of paralysis of certain muscles, of which more will be said hereafter. It is caused by a rod-shaped bacterium, known as the Bacillus diphtheriæ, or, from its discoverers, the Klebs-Loeffler bacillus.

It mainly attacks children and young people, and it may occur more than once in

the same individual.

Symptoms. — The disease generally commences with a feeling of languor and debility, sickness, headache, and not unfrequently shiverings or chilly sensations. It is very remarkable that, in a short time after the commencement of the symptoms, the strongest man may feel as weak as a child, and require to be supported in walking to his bedroom. The throat affection comes on in different ways. Some patients awake in the middle of the night, and find the throat sore for the first time. In others it is preceded by a slight feeling of stiffness in the neck, and general uneasiness in the region of the throat. The tonsils and glands of the neck become tender and inflamed, there is difficulty of breathing, and sooner or later there appears the leathery membrane spoken of above. This does not, of course, present itself fully formed all at once, but in the form of little patches, which coalesce to form one continuous skin or membrane, which certainly resembles damp white leather. It is this skin or membrane which is so eminently characteristic of diphtheria, whether it occurs in the throat, or, as it sometimes does, in other parts of the body. In this membrane about the throat or mouth, there is always a great amount of sloughing, accompanied with feetor of the breath while the membrane is being detached and separated, leaving a raw, ulcerated surface underneath, which is often very painful during swallowing, pulse is generally quick and very feeble, and the skin dry and hot. The tongue is generally furred; and there is great disinclination to liquid, passing down the nostrils, to the great inconvenience and pain of the sufferer.

Paralysis of the legs and arms may supertake food, both on account of the difficulty of

the presence of a whitish leather-like mem- | may cause death to those already weakened by the disease. Most commonly death takes place from exhaustion. It may, however, take place suddenly, owing to the formation of clots of the diseased blood in the heart or large bloodvessels. It not unfrequently happens, too, that the patient is choked by the membrane extending down into and blocking up the air passages; death being either gradual or sudden from this cause.

The Bacillus of Diphtheria.—The bacillus is found only locally, as a rule, although, according to some authorities, it may invade the general system. But it produces an extremely powerful poison, or toxine, which is rapidly absorbed, and it is this toxine which gives rise to most of the symptoms characteristic of the disease. One of the most remarkable discoveries in medicine is that of Behring and Kitasato that, if animals (horses) are subjected to inoculations of this diphtheria toxine in repeated and increasing doses, their blood, after a shorter or longer period, contains a substance which can neutralise the toxine, and so destroy it. This "antitoxine," or "antitoxic serum," has become a specific in the treatment of the disease, and better results have probably been obtained with it than by any other method. However, as in the case of other "specifics," it does not always effect a cure. The serum is injected into the subcutaneous tissue of the abdominal wall, and the earlier in the disease the injection is made, the better are the results.

Local Treatment.—Mild antiseptic solutions of boracic acid are most in favour, or chlorinated soda in the proportion of one part to eight of water. Warm sprays to the throat of carbonate of soda (20 grs. to 1 oz. of water) bad cases of the disease, the membrane increases afford great relief. Strong beef tea and in extent, and spreads to the surrounding parts wine should be given at regular intervals, —to the palate, uvula, gullet, and nostrils, the cheek and gums, or even—in which case it is of course extremely perilous, to the larynx and given instead of wine. Where there is in wind-pipe. In cases where there is much of ability to swallow, enemata of brandy, beef tea, and quinine should be administered.

After Effects.—It now remains to speak of the very remarkable consequences which often attend upon an attack of diphtheria. During convalescence from this disease, the patient is sometimes affected by paralysis of certain especially if any irritating substance is used muscles, especially those concerned in the with the food which the patient takes. The act of swallowing; the food, both solid and

Paralysis of the legs and arms may supervene quite suddenly. Paralysis of the muscles swallowing, and the want of appetite. In very of the trunk is much less frequent, but parbad cases, occurring for the most part in those alysis of the heart may come on, and cause who live in dark and damp, ill-ventilated and death. The eyesight may be affected, or the ill-drained dwellings, the patient very soon tone of the voice altered for a time. But it sinks into what is called a typhoid state, mor- is fortunate that, as a rule, none of the abovetification sets in in the affected parts, and mentioned conditions continue permanent. On there is not unfrequently hæmorrhage occa- the contrary, after a few weeks, they generally sioned by the separation of the sloughs, which | begin, under proper treatment, to improve

steadily, and progress gradually towards a perfect cure. The nervous sequelæ are best treated by the internal administration of The citrate of nux vomica or strychnine. quinine and iron, in doses of from three to five grains, three times a day, may be prescribed with advantage; while bathing, rubbing, and shampooing the limbs may be practised with the employment of electricity. A liberal diet, with a moderate allowance of sherry or pale ale, should be given; while, at the same time, if the patient is unable to take walking exercise, it will be well to substitute daily drives in an open carriage, if the weather be fine enough to admit of it.

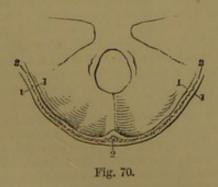

Isolation. — Precautionary Measures. — As the disease is contagious, it is absolutely necessary that the patient should be isolated, and the attendant should protect herself by avoiding the breath and cough of the patient, and by disinfecting the vessels into which he expectorates. Unless perfect isolation is insisted on, the disease usually spreads to other members of the household, and especially to

the children.

To arrest the spread of diphtheria, the disease should be recognised as early as possible. precise diagnosis can be made from the examination of the false membranes, by the microscope, or by the cultivation of the germ. must be remembered that the bacillus can remain active in the mouth for weeks after the disease is cured. Consequently, diphtheritic patients should be kept isolated for some time after the disease subsides. Linen and all articles which have been in contact with diphtheritic patients should be disinfected by boiling for at least five minutes.

Of course, it is not expected that any unprofessional person would attempt to carry out the treatment of so formidable and fatal a disease as diphtheria, when the aid of a medical man can be procured; but, as diphtheria now prevails in almost every quarter of the globe, and under every variety of circumstances, it is well that all should know the symptoms of the malady, and the measures most likely to be successful in

**DIPLOE** is the name given by anatomists

the more condensed and solid, but thinner, outer and inner "tables," or plates (1,1,) of the skull.

Refer to-Skull.

DIPSOMANIA is a state when habits of intemperance have reached such a height, that the unfortunate victim becomes partly insane, or at least so much so, as to lose all self-control on the one point, and to become affected with the species of monomania to which the term Dipsomania, has been applied. Sir Alexander Morrison describes it as a "morbid craving for drink which generally occurs at intervals, in which persons are seized with an irresistible propensity to drink to excess, although conscious at the time of their misconduct, but

are unable to control themselves.'

The employment of the term dipsomania has been rendered necessary by the now well-known fact, that there are numbers of individuals whose desire for intoxicating liquors is so strong, and their ability to resist it so feeble, that they are in a manner obliged to give way to it, or, at all events, are so little under the control of reason, that they are for the time being maniacs, in one sense of the word. It is a remarkable and at the same time a most melancholy reflection, that those persons who have for a length of time indulged a craving for intoxicating drinks, sooner or later, are apt to lose all power of control over themselves, and, in fact, so conscious are they of this, that many of them would willingly submit to any kind of restraint which would deprive them of all opportunities of indulging in a vice, the pernicious consequences of which they are too well aware of. Continuance in such a degrading vice as drunkenness cannot fail to be followed by punishment, and those who are ignorant on the subject should not be left uninformed that the disease, if we may so call it, dipsomania, is a consequence of vicious habits unchecked, that it is one of the most dreadful punishments with which a poor human creature can be visited,—so dreadful, that the sufferer is often only too anxious to put himself under voluntary restraint, making the humiliating confession that his reason-that proudest faculty of man-has lost its ascendency over his evil passions, and that he has indeed sunk into a lower condition than the brutes that perish ! It must, however, be distinctly understood that there is no such disease as dipsomania, which has not been self-acquired or hereditarily transmitted, of which more hereafter; that is, there is no disease of the brain known to physicians which causes this morbid craving for drink that has not itself followed as a consequence of indulgence in the evil habit. In connection with this, it may be well to remark that there is in the present day too great a readiness on the part of the public mind to attribute the commission of the most revolting to the more cellular or porous portion of crimes to insanity, and to regard a drunkard bone (fig. 70-2) which intervenes between as an irresponsible being, a tendency which is

as much against common sense as it is detrimental to public safety. The welfare of society demands that there should be institutions throughout the country for the voluntary or compulsory restraint of habitual drunkards, where they might be subjected to proper treatment, under the care of duly qualified medical attendants. Proper treatment consists in the entire removal of stimulants and the substitution of good nourishing food, exercise in the open air, and healthful occupation both of body and mind. Medicine is only of use in so far as to correct that derangement of the digestive organs which almost invariably is present in the debauchee. Bitter tonics, the mineral acids, quinine, iron, &c., may be given to restore the tone of the system. To relieve the craving and to procure sleep, bromide of potassium in twenty-grain doses is frequently administered, and is often combined with twenty or thirty drops of tincture of capsicum. Ærated waters of various kinds, either alone, or with the addition of some agreeable fruit syrup, lemonade, soda water, potash water, &c., may be taken as drinks at meals.

It is matter of congratulation that at the present time the absurd custom of pressing people to drink, under the idea of being hospitable, no longer exists in the homes of the more educated and refined, and that any one, even the most wanting in moral courage, may abstain entirely, without any explanation being asked or given; or, if any is asked, it is quite sufficient to say that it is in accordance

with medical advice.

Dipsomania is now recognised as a disease, and provision is made by Act of Parliament for the licensing of Homes in which patients suffering from it may be confined and medically treated. Under the Habital Inebriates' Act victims of the malady with their own consent can be committed to a Home for a period of not more than one year, during which time they may be placed under any necessary restraint. The great want of such institutions is shown by the fact, that no class of persons are so convinced of the necessity for them as the patients proposed to be admitted to them for treatment. At present there are many persons abroad in the world who have acquired this disease, and who are unable to resist the sudden craving for drink when temptation offers, in spite of all the numerous good resolutions which they may previously have formed in perfectly good faith. Now, it is to such persons that asylums of this kind would afford a retreat, and a means of cure under proper and skilful medical treatment, both of body and mind, till the morbid propensity is overcome. It will be readily understood, upon a little reflection, how much misery might be spared to families, and to individuals, by the adoption of such a system, and how many an onward career to ruin might be opportunely checked, better account. The experience of medical paralysis: or on the other hand, to drag out a

men goes to prove that even the worst cases are capable of cure, if only time can be gained, and most are of opinion also that the time of probation should be as extended as possible, owing to the extreme proclivity which such cases manifest towards a relapse into former habits when restraint is withdrawn, and temptation suddenly presents itself in the shape of old familiar scenes, associates, and customs. No doubt the great difficulty will be to say when, in any given case, it will be safe to remove the patient from restraint. But the very experience upon this point, afforded from the treatment of such cases in public institutions, will be of the greatest value both to the medical profession and to the public at large. Meanwhile, it may be stated as a general rule, that those cases in which the habit has not been of long standing, will require much less and much shorter duration of treatment than those in which the vice has been acquired through a system of continued indulgence for many years, and in which partial reform has been only too surely followed

by a speedy relapse.

Dr. Aitken, in his work upon the Science and Practice of Medicine, very forcibly describes the effects of a long-continued and immoderate use of alcohol in giving rise to degeneration both of body and mind. He says, - "By far the most active sources of degeneracy are those direct and repeated influences upon the blood, the brain, and the nervous system, which give rise to morbid conditions, and which often place those who periodically expose themselves to the influence of toxic agents in a condition merging on, or equivalent to, insanity. The effects of chronic alcoholism, for instance, in giving rise surely and progressively to the degeneration of the individual, are mainly demonstrable by the production of the following states, namely:-Persistent loss of appetite, indigestion, nausea, occasional diarrhœa, progressive emaciation and cachexia, the appearance of pustular eruptions, the occurrence of eructations, associated with offensive breath, serious disturbance of the functions of the stomach, liver, kidneys, and heart, and the production of organic lesions in these organs, and in the structures of the blood-vessels, followed by fatal serous effusions, dropsy, hæmorrhages, extravasations, or apoplexies. Intercurrent with these morbid conditions, at variable periods, and otherwise contingently, 'fits of drunkenness,' with sexual incompetency, different forms of psychical aberration, delirium tremens, suicidal melancholy, and such like morbid phenomena, ensue. Finally, epileptiform seizures general paralysis, drivelling or form seizures, general paralysis, drivelling or slavering idiocy, may close the scene." The tendency of such unfortunate individuals, as described by Morel, is either to pass at length through a succession of stages marked by intellectual and physical deterioration of all and, perhaps, when the time came, turned to kinds, into a condition known as general

miserable existence, with a completely shattered | such an organisation than you can from that nervous system, a burden to themselves and their friends, depraved in body and mind, and not unfrequently exhibiting the most degrad-ing propensities. Dr. Aitken states that the degenerative effects of alcoholism above detailed do not stop here, but affect the procreative functions to such a degree, that not only is the standard of the offspring lowered materially, but the extinction of race follows as an almost invariable consequence. In speaking farther on this subject, he says :-- "When such results are coupled with the moral and the social aberration which ensue from bad example, misery and want in families and masses of men, they become ample sources of the degeneracy of the population, not only throughout the existing, but succeeding generation; and not only is the vice of alcoholic abuse transmissible, but it also frequently leads to insanity in the offspring of the drunkard, and in cases where the tendency to alcoholic excesses has a hereditary origin, the cure of the dipsomaniac is generally impossible." Morel gives the following example, in which a well-marked succession of morbid phenomena became developed in different descendants of a family throughout four generations :- "The great grandfather of the family was a dipsomaniac; and so complete was the transmission of the disease, that the race became totally extinct, under the well-marked form of alcoholic poisoning and degeneracy. The effects entailed were—in the first generation, alcoholic excesses, immorality, depravity, brutish disposition; in the second generation, hereditary drunkenness, attacks of mania, general paralysis; in the third generation sobriety prevailed, but hypochondriasis, lypomania, persistent ideas of persecution, homicidal tendencies were expressed; in the fourth generation intelligence was but feeble, mania became developed at sixteen years of age, stupidity running on to idiocy, and to a condition involving extinction of the race.

Dr. Gairdner, in his Clinical Medicine, gives the result of his very extended experience in the observation and treatment of cases of this nature. He mentions the case of one man, a clerk, who had been admitted upwards of twenty times to the hospital, and who was not likely to be long in seeking re-admission. After giving a very full and interesting description of what may be regarded as a typical case of dipsomania, the professor says:—"There is in all this evidence of long-continued and probably irreclaimable bad habits founded on a weakening of the moral sense, amounting to a kind of paralysis of it;" and, again, "It is a case not only of degradation, but of positive degeneration of the moral instinct; the degradation is probably both physical and moral by this time; the machinery of mind has suffered as well as the mind itself. This man, I believe, literally the mind itself. This man, I believe, literally cannot do good at present; you can no more four-and-twenty hours without some slight expect good conduct and high principle from twinge of pain, without some ache or weariness

of a gorilla. A long course of reformatory discipline might possibly, indeed, even now, do something to reverse the habits of forty years; but at the present moment of time this man is in a state of moral paralysis-powerless for good, and a prey to evil, in virtue of his physical and moral organisation — his craving appetites and deeply imprinted bad habits. Seeing that there are many such, and many worse cases, it remains an important question, What is to be done with them, how they are to be classified, and whether or not the medical man should be allowed more support from the public, and from the law, in dealing with them? And this manifestly becomes a question likely to excite much greater interest in the eyes of the public, when it is considered that all the cases are not met with in hospital patients only, but that unfortunately there are not a few, it may be, holding offices of trust and responsibility, heirs to large fortunes, or possessed of large estates.

DIS

Refer to—Alcohol—Delirium Tremens—Intoxication—Stimulants.

DISCHARGE, used as a medical term generally, means anything cast out from the body; it is often applied, however, in a more restricted sense to the excretion of purulent

matter solely

DISEASE is any departure from the naturally healthy actions of the system at large, or of any structure or organ in particular. The divisions and sub-divisions of diseases generally, according to their nature, causes, &c., are very numerous. A distinction is made into organic and functional diseases, the former being such as are accompanied with perceptible and appreciable change from the natural structure or composition of any component of the body; the latter those in which the actions are not healthy, but in which, as far as present means of investigation go, no appreciable departure from the ordinary structure can be detected. As, however, it may be doubted whether disordered action can take place without change of structure, temporary or permanent, its nondetection is probably owing to the deficiency of our present means of investigation; and, indeed, chemical analysis, and the use of the microscope, have demonstrated, and are daily demonstrating, the nature and tendencies of many alterations in the composition and structure of the bodily constituents which had previously escaped notice.

Perfect health consists in the uninterrupted action, and perfect balance of all the functions of the body; this involving, of course, perfection of structure, the slighest pain or ache must be indicative of a hitch somewhere in the machinery. In this view, perhaps, none are free from disease for a day, for few can boast

and from this slightest passing uneasiness, to the confirmed and fatal malady, disease passes through every gradation. Many of the most painful and deadly disorders are not more felt at their commencement than as a slight sense of discomfort, and perhaps numberless of the lesser pains felt during what is considered health, might pass on to real disease, were it not for the natural tendency to cure with which our bodies are endowed; that which is called the vis medicatrix nature-the same tendency which restores the fractured bone to soundness, and heals the wound. There can be no question that, but for this tendency towards health, this power of resisting and casting off disease, our bodies would quickly succumb to the innumerable causes of disorder to which they are hourly exposed. This power of resisting disease is without doubt much greater in some persons than others, and even in the same person at different times, often without any per-ceptible reason why it should be so. The power of the system in casting off disease, when forming or formed, is for the most part more plainly exercised, but of this more will be said hereafter.

Again, it must be remembered, that constitution and other causes occasion so much variation in the actions of the body, that what would be disease in one man is health in another. For instance, one man's pulse may average sixty in a minute, another's eighty; and it is certain that the former could not rise to the level of the latter, or the latter sink to that of the former, without disease or dis-order being present. Such considerations are important in judging of the real state of a person labouring under disease; to judge accurately of disorder, we must know the whereabouts of the level of health, and in this consists tle great advantage of the regular medical attendant over one who is casually consulted, and who first sees the patient when suffering under illness. In popular language, the regular attendant "knows the constitution" of his patient; the other has it in many respects to fearn. But if there is a tendency towards health, there is also a tendency, more or less, towards certain forms of disease existing with every one, this tendency being either hereditary or acquired. The power of hereditary tendency towards certain forms of disease, such as scrofula and consumption, gout, gravel, and rheumatism, paralysis, &c., is so generally recognised as to be a matter of popular information; that is to say, when these diseases have affected parents, or relatives of parents, they are regarded as hereditary in descendants; there is, however, a hereditary predisposition not so apparent, which requires more notice than it receives; it is that which devolves upon chil-

to remind them that their bodies are mortal, | age-especially if the father has been advanced in years, or if marriage has been contracted too early in life, or if either parents have lowered the standard of health by dissipation or by any other means, their sins, in obedience to those laws which the Almighty has connected with our being, are visited upon the children, in tendencies to certain diseases. The offspring of drunkards are very frequently the subjects of affection of the brain and nervous system; the child of the woman who gives way to indolence, or indulges in undue excitements, will in all probability fall below the standard of health. Tendency to disease may also be given, in persons previously healthy, by whatever lowers their own standard of health. Dissipation of any kind, deficient food or supply of pure air, exhaustion from whatever cause, depressing passions of the mind, &c., all give that tendency to disease which renders the constitution more susceptible of its attacks. Even the time of day exerts some influence, for it is well known that a person is much more liable to become affected with any malady, either of a contagious or malarious character, such as ague, if exposed to its influences in the early morning, before the powers of the constitution have been invigorated with food, especially with that, such as warm tea or coffee, which affords the gentle stimulation of heat. Further, individuals are never so liable to succumb to disease as they are during the stage of depression succeeding a debauch. Every day adds to our experience of the way in which the ill-ventilated and badly-drained dwelling gives the tendency to fever and to cholera, whilst at the same time it fosters their deadly germs into activity.\* Lastly, nothing predisposes more to disease, or increases the tendency to it, than the depressing passions, such as fear, despondency, &c. Those who give way to dread of taking any malady, open the readiest door for its incursion; and even without the fear of the disease itself being the cause of the depression, the fact of the mind being depressed, increases greatly the susceptibility to any causes of disorder in active operation at the time. This is often strikingly exemplified in the case of troops; it is always observed that sickness is more prevalent among the men of a retreating and desponding army than under the reverse circumstances. Perhaps, under no circumstances is the worldly advantage of a firm reliance upon Providence more palpable than when that reliance sustains the mind in cheerfulness, hope, and resignation, resistants to disease, which come to the aid of those who hold them, when other help seems to have vanished.

There is a kind of mixed tendency to disease, partly hereditary and partly excited by external circumstances: it is this from which dren in consequence of the habits, &c., of the the children born in India, and the other hot parents. The latter may be of healthy families, climates, of English parents, suffer, particularly but if there has existed much inequality of if the parents have been long resident. They

DIS DIS

cannot be retained in the clime of their birth, | the disease; the powers of a good constitution without the greatest risk to life before the age

of puberty is attained.

Most of those causes which give a tendency to disease, also, in themselves, when acting with increased intensity, tend to produce it, or to aggravate it when existing. The influences of climate, of air, whether pure or impure; of food, whether deficient in quantity or quality; of occupation, of habits, or mental influences, are all-powerful excitants of disease. The remittent fevers of the tropics, and the typhus of Britain, the scrofula, the rickets and cutaneous eruptions, the consumption of the metal grinders, the delirium of the drunkard, are all instances, which might be multiplied, of diseases produced by external influences. The diarrhaa of fear, the nostalgia or home sickness—which is actually accompanied with disease in the lungs—of the Highlander or of the Swiss, the diseases of the heart which result from the agitation of political or commercial excitement, are all examples of the production of disease by the internal agency of the

When disease has established itself in the constitution, were it not for the "tendency to health," it must run on to a fatal termination; the wound would remain unhealed, the inflammation would extend, or its effects remain unrepaired, were it not for these curative powers existing in the constitution itself. then, whatever tends to lower the standard of health, favours the inroads of disease, so the preservation of that standard, as far as may be consistent with the safety of the patient, and the reduction of his malady, ensures a more certain and speedy throwing off of the effects of the disorder, or in one word-convalescence. Patients who have suffered from hæmorrhage are often very long in recovering, and during the period of recovery are liable to relapse, and to be attacked by other forms of disease.

Moreover, during the progress of disease, nothing assists more the powers of the constitution which tend towards health, and to throw off the enemy, than a cheerful and hopeful mind; as the people call it, a "good spirit;" it may make all the difference between recovery or the reverse; indeed every medical man must have met with cases of illness, in which the patient seemed, as it were, resolved not to give in-seemed, even under unfavourable circumstances, determined not to die, if he could help it-and did not die; even when physical powers tended to death, the mind tended to life, and the mind succeeded. Were it not for the tendency to health, or to cure, existing in the body, our medicines would be in vain, and he is the best physician who can detect those tendencies to recovery, permit them to act when they seem strong enough, and assist them when they do not. The patient in the lowest stage of fever still has the tendency to health existing, and acting within, and battling with fied. But why quinine should cure neuralgia,

may of themselves be sufficient to conduct him over the crisis, but they may not, and unassisted, the patient must sink ere the tendency to throw off the disease gets the mastery; but the physician steps in—he gives his help to the constitution, his wine, and bark, and nourishment, and regulation of the functions, supports the frame till the struggle is over, and the disease is vanquished. This power of throwing off disease, this tendency to health with which the living body is endowed, requires to be impressed upon the mind of people generally, for they are too apt to attribute that to the action of medicine, which medicine only gives its assistance to, and to despise the simpler modes of treatment, which place the natural powers in the most favourable position for curing. The vulgar attribute the healing of the wound to the plaster which merely holds it together, and cold water is too simple to do good.

The aggravation of existing disease, both by physical influences and mental emotions, is one of the most serious enemies the physician has to contend with. The subject is sufficiently entered into in the various articles of this

work.

Lastly, disease is often established as a secondary affection, it occurs in consequence of some previously existing morbid condition of, or in some part of the body. Dropsy is a disease peculiarly of this class; affection of the heart, liver, kidneys, or other disorders, all tending to produce it; apoplexy may result from disease of the heart: in these cases, the secondary disease appears simply a result, without beneficial influence; but in many cases, it exerts a tendency to remove the primary one, and this fact is one of great importance in the treatment of all disorders of the body, for rash interference with the natural effort may throw the diseased action back upon the previously affected, or upon some more vital part. healed-up ulcer, or seemingly cured eruption, may occasion head disease, or the checked diarrhea may throw back upon the constitution, with serious or fatal effect, the blood poison of which the vital fluid was endeavouring to relieve itself. Even that alarming incident, spitting of blood, though in itself a grave symptom, may tend to relieve from worse evil. These efforts of the constitution, therefore, to cast off or cure disease, are to be cautiously interfered with.

In the treatment of disease, two very different methods have to be pursued; the one is that which exerts itself directly to cure by the direct action of certain medicines. Of this, the cure of ague, of neuralgia, and other periodical diseases, by quinine or iron, is an example; experience has unfolded to us, that in these and similar cases, the medicine has the power of curing by some relation established between it and the disease, by the Author of all things, and in nothing is His mercy more strikingly exempli-

DIS DIS

why opium should allay pain, we cannot tell, at least in the present state of our knowledge; the only approach to any explanation being one given by Liebig. The other method in the treatment of disease is not so much of the active as of the expectant or passive character. There are many-perhaps the majority belong to this class-forms of disease, for which we know of no cure such as quinine is to ague; the throwing off of the malady must be by the natural powers, and our only resource consists in putting and keeping those natural powers in as favourable a state for this purpose as possible. Of this, many forms of fever are examples; we cannot hope to cure, we can only hope to pilot the body through the rocks and untoward currents which arise in the course of the disorder, to allay secondary diseases which show themselves, to alleviate painful symptoms, and to support the constitution. These facts should be made plain to the minds of unprofessional persons generally, for the most erroneous notions prevail upon the points just alluded to, and often lead to dissatisfaction with medical men. One who is content with guiding the course of a fever, either with the gentlest treatment, or with what people may consider no treatment at all, is looked upon as inefficient; whilst the busy meddler, who interferes without aim or object, and probably thwarts, with uncalled-for medicine, the natural tendency to cure, is regarded as the "active"(?) practitioner.

The reference from this article must be to the work at large, for it bears upon the whole.

DISINFECTION, in the largest sense of the word, is a process which destroys the power or means of propagation of diseases which spread by infection or contagion. Purification of every kind, therefore, either by fresh air, cleanliness, or by chemical substances, is disinfection, these agents acting either by destroying, dispersing, or diluting the morbific germs emanating from the sick. In its less comprehensive, though more correct, sense, the term "disinfectant" is confined to substances we have at our command, which we know have the power, by their gaseous and chemical relation, of acting on clothing, &c., or the atmosphere of an enclosed space, such as a room or a house, and thoroughly destroying every vestige of contagious matter which may be present.

The recent advance in knowledge concerning the nature of contagion has led to greater precision in the measures adopted to destroy the infective agents which are the cause of zymotic or infectious diseases. The study of the life-history of the germs, or bacteria, to which these diseases owe their origin, and which are responsible for their propagation, has proved that many of the preventive measures hitherto relied upon have no claim to be classed as true disinfectants. Hence, the

by this means.

Dry Heat is also a disinfectant; but, for several reasons, it is not so reliable as moist heat. In the first place, a higher temperature is essential, and the articles require much longer exposure to it. Drs. Parsons and Klein have proved that it requires an term "disinfection" should be applied only over the temperature of boiling water to de exposure of four hours to a dry heat a little

to a process which effects the complete destruction of the poison; but, owing to the indiscriminate use of the terms disinfectant, antiseptic, and deodorant, much confusion exists, and, as a result, the public, by adopting inefficient precautions, are relying upon a false security, and thereby, owing to laxity in the use of other precautionary measures, the risk is increased rather than diminished. The following definitions may help towards a clearer understanding of the subject :-

(1) The terms disinfection and disinfectant should only be applied to processes or substances which are absolutely destructive of

the virus or poison of disease;

(2) The term antiseptic, to substances or processes which have the power of arresting the growth of the virus; and

(3) The term deodorant, to substances or

processes which correct offensive smells.

To appreciate the difference between "disinfectants" and "antiseptics," it is necessary to know something of the behaviour of disease germs. It has been proved that these germs, during certain stages of their existence, are more tenacious of life than at others, and that what may be destructive of mature germs is powerless as regards their spores or seeds. These have the power of lying dormant for indefinite periods, and as soon as the adverse conditions are removed, the process of development is continued, and the active virus is produced. It follows from this, that a substance which is a real disinfectant, if used in sufficient strength, may, by dilution, be reduced to the level of an antiseptic or even a deodorant, and, as a fact, this has been experimentally proved. The essential conditions then, in a true disinfectant are the following:-

(1) That it shall be capable of killing germs

and their spores;

(2) That it shall be applied to every part;

(3) In sufficient strength; (4) For a sufficient time.

It will be useful to consider here, shortly, the relative value of the means of disinfection now in use, and their method of application, so as to insure that they shall comply with the essential conditions named.

Moist Heat. - The best disinfectant we possess is moist heat. By boiling any infected liquid or article of clothing for ten minutes,

all disease germs and their spores are destroyed. All infected articles, therefore, which can be boiled will be rendered absolutely safe

stroy the spores of the germ of anthrax disease, but that one hour's exposure to a The latter temperature of 245° F. suffices. temperature, however, very closely approaches the scorching point. Until steam disinfecting apparatus were introduced, Sanitary Authorities had to depend upon dry heat disinfecting chambers, and the process, if carried out at all thoroughly, was a very tedious one, and frequently led to the destruction of articles of clothing or bedding. Steam, on the other hand, when used at a high pressure, and corresponding temperature, is a most reliable agent for disinfecting by heat, having great penetrating power, and being available for articles which do not admit of boiling. The steam disinfectors now in the market comply in every respect with the conditions laid down as essential to thorough disinfection, and although they cost more than the hot air apparatus, their efficiency more than justifies the extra outlay

incurred in their purchase.

Carbolic Acid has long been in popular favour as a disinfectant, but it is doubtful whether it is often used in a solution of sufficient strength to act otherwise than as a mere deodorant, or at best an antiseptic. Five per cent, is the weakest solution which can be credited with disinfecting properties, and even in this strength the solution must remain in contact with the disease poison for a length of time. It is obvious from this that the common practice of discharging carbolic acid into sewers is of little or no real value from the point of view of disinfection, as, owing to the great dilution which takes place in the sewer, the acid is rendered useless. It follows, therefore, in the case of diseases, such as enteric fever and cholera, that to properly disinfect the stools with carbolic acid, they should be kept for twenty-four hours in closed vessels containing the disinfectant in sufficient quantity to form, with the excreta, a mixture of 5 per cent.

Corrosive Sublimate (bichloride of mercury), which has lately come into great favour, is a very potent disinfecting agent, even when diluted to the strength recommended-viz., 1 in 1,000. Unfortunately, its extremely poisonous character greatly interferes with its usefulness in the hands of the public, but the risk may be much lessened by artificially colouring the solution, (which is naturally colourless), and keeping it in specially-shaped bottles, with a prominent poison-label attached .- See Mercury.

Condy's Fluid (potassic permanganate solution), which is in daily use, has, theoretically speaking, disinfecting properties when the strength of the solution used contains, at least, 5 per cent. of potassic permanganate. As, however, the disinfecting power is very much diminished, owing to the material being used up in oxidising the organic matter present in the intected fluid, to be of real value

it must be added in so concentrated a form as to forbid its use altogether on account of

Remembering the distinction between disinfectants and antiseptics, the three substances just mentioned will act in the latter capacity in the following relative proportions :-

Corrosive sublimate = 3 parts per 1,000,000. Potassic perman-= 700 ganate Carbolic acid =1200

Concerning the other so-called disinfectants, namely-chloride of lime, chloride of zinc, sulphate of copper, sulphate of iron, boracic acid, &c., experiment has proved that in practice they come short of what is required.

From what has been said, it will be understood that the popular custom of suspending about rooms sheets, &c., saturated with solution of carbolic acid and other substances, is useless, so far as disinfection is concerned. It is equally useless to place dishes about the house containing Condy's fluid, &c.; and, as already hinted, such practices are likely to do more harm than good, by encouraging a false security which may lead to valuable precautions being neglected.

How to Disinfect a Room.—Rooms are usually disinfected by burning sulphur in the proportion of 14 lb. per 1,000 cubic feet of The process is conducted as room space. follows :- Carefully seal all openings, such as the fireplace, defective window-sashes, and any ventilating apertures, by pasting brown paper over them; furniture and all articles which cannot be boiled or otherwise disin-fected, should be arranged so as to be as freely exposed as possible to the fumes. The sulphur should then be placed in one or more vessels (a sauce-pan answers very well) according to the size of the room, and, as a precaution against fire, each should be placed on two bricks standing in a tray containing water. Having added a little methylated spirit to facilitate lighting, the sulphur (which should be in small pieces) is then set fire to, and the operator must at once leave the room, close the door, and place paper all round it. The room must be left undisturbed for six hours, after which the windows should be left freely open for at least twenty-four hours. As it is doubtful to what extent, in practice, sulphur fumigation is effective, it should invariably be supplemented by further precautions. The rooms should undergo a thorough cleaning, the floors, and such articles of furniture as will permit of it, being well washed with soap and water. If the walls are papered, they should be re-papered after the old paper has been stripped off; painted walls, on the other hand, should be washed, and coloured walls should be scraped and re-limewashed. Any furniture which cannot be washed should be exposed in the open air for several days,

DIS DIS

methods of disinfection, is credited with greater powers than it possesses, hence the necessity for observing the precautions just mentioned. The penetrating power of sul-phurous acid into textile fabric is practically nil, one fold of blanket being sufficient to protect bacteria from its influence.

Sulphurous acid gas under pressure, in cylinders, is now often used as a convenient means

of applying this method of disinfection.

What is known as formic aldehyde gas is now coming into favour as a substitute for sulphurous acid gas. It is liberated from a substance called "paraform" by heat, in a special apparatus, and as the gas has the same density as air its power of diffusion is greater than that of the sulphur gas. When used in solution this is undoubtedly a valuable disinfectant, but opinions differ as regards its practical value in the form of a gas.—See Germs of Disease—Enteric Fever.

DISLOCATION, in medical, or rathe surgical language, means the displacement from their natural positions, of bones or portions of bones at the points where they are connected together by means of joints or "articulations." There is not, perhaps, a bone in the body which may not be displaced by violence, but some are much more liable to the accident than others. It would answer no good purpose, in a work of this kind, to enter into details respecting the varied dislocations which may and do occur: a few, therefore, only of the commonest, most easily recognisable, and most readily remediable will be noticed. There is some difficulty in treating the subject of dislocation in a popular work; for, although, from the nature of the accident, and of the circumstances in which it is apt to occur, it is highly desirable that some knowledge should be possessed by the unprofessional, both as regards the signs and symptoms of dislocation, and its more immediate treatment, the difficulty that occasionally presents itself, even to the skilled surgeon, in determining whether dislocation actually exists or not, or whether it is complicated with some other injury, such as fracture, renders the matter a delicate one for lay interference. With this caution, therefore, that unless tolerably clear upon the point, it will be better to wait even days for the arrival of skilled advice, than to make attempts to remedy an uncertainly-ascertained injury, the following hints may be useful, particularly in those cases in which the accident does not happen for the first time; and this will often be the case, for, having once occurred, it is very apt to do so again, even from slight causes. In such cases, the doubt as to the nature of the mishap will be most materially diminished; indeed, the patient himself is generally perfectly well aware of what has occurred, and can often give directions accordingly. The symptoms of disloca-

The process of sulphur fumigation, like other | are, pain with loss of power over the limb or member, and its becoming fixed in one position, so that it cannot be moved, either by the patient or by others, at least not without occasioning severe suffering; numbness is felt in the limb, the person becomes faint and sick, and if the joint be examined, it will be found

Whenever doubt exists as to whether dislocation has or has not happened, the case should be examined by a competent surgeon as early as possible, and no time wasted in fomentations and rubbings, which are perfectly use-less. If a bone is "out of place," it cannot be too soon restored to its proper position, and nothing will give relief, at least for a long period, if this is not effected. A bone certainly may remain permanently dislocated, and the member attain, in the course of time, a very considerable amount of motion, by the formation of a new joint; but it is long before it does so, the power of movement is never equal to what it was before, or would have been, had the injury to the joint been properly rectified, and much unnecessary pain is suffered. The necessity for the speedy reduction of a dislocation is great, from the fact that every day increases the difficulty of its performance, and when a certain time has elapsed, no force which can be exerted-consistent with safety to life and limb-will be adequate to return the displaced bone, partly owing to the resistance of the muscles, but also to obliteration or doing away with the cavity which formed the one portion of the joint. When dislocation occurs, two different actions take place; one, that by which the bone is driven from its usual position; the other, the action of the muscles, which tend still further to draw it from its proper site as soon as the balance of resistance of bone against bone is removed. It is, too, in most cases, the action of the muscles which tends to keep the bone displaced, and to resist the efforts made to replace it. This is evident from the fact, that if a person be seen immediately after a dislocation, and whilst suffering from the faintness which almost invariably accompanies the accident, and whilst the muscles are necessarily in a state of weakness and relaxation, the dislocation may often be reduced with the greatest possible ease, even by the unskilled. The inhalation of chloroform is now universally used by surgeons prior to attempts being made to reduce the dislocation. It relaxes the muscles round the joint better than any thing else, and while under its influence, there is seldom any difficulty in ascertaining the extent of the injury and its true character, or of reducing the dislocation, if it is of recent When a dislocation occurs, the bone is not simply pushed out of its place, but is drawn for the most part upwards, or towards the body; the dislocated bone of the finger is drawn upwards over its fellow; the arm bone, tion having occurred, after violence or accident, in dislocation of the shoulder, may be drawn

DIS DIS

upwards, or into the arm pit, in this case | tend by the same power to draw the head of downwards, it is true, as regards the joint, but still towards the body; and the same will be found to be the case in most forms of dislocation. The first object, therefore, in treating a dislocation, must be to draw it down from or out of the situation to and in which it has been drawn, and is retained by the muscles of the limb, and to get it as near the corresponding part of the joint, or in other words, as near the part from which it has been dislocated as possible. If the dislocated bone is thus drawn down to, or near to the level of the other portion of the joint from which it has been removed, the muscles will of themselves tend to draw it into its old position. A good deal is often said about the adjustment, &c., of the bone in reducing dislocations, and though, perhaps, useful in some cases, in many nothing of the kind is required, at least, unprofessional persons should not attempt it; all that is to be done is, give the muscles the chance of drawing the bone into its old place by bringing it to a position in which this can be effected. This is often exemplified in cases in which much force is used in the reduction of a dislocation; if the force be kept up strongly, the bone cannot be drawn into its socket, because the force is stronger than the muscles of the patient; but relax the external force for a moment, and without any fitting or adjustment, the bone is instantly drawn, or "sucked" into its proper position by the power of its own The above principles will be better muscles. understood by a reference to the annexed cut, for which the author is indebted to Professor Fergusson's Manual of Surgery. In this (fig. 72-1) is the shallow cup attached to the

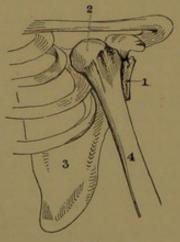

Fig. 72.

shoulder blade (3) in which the round extremity or head (2) of the arm bone (4) ought to rest, but from which it is represented as displaced or dislocated. The muscles are not here represented. It is evident, that before the round head (2) is replaced in the cavity (1) it must be forcibly drawn down to its level; this drawing down the muscles strongly resist, but also from an examination of the cut, than from any

the bone into its place, as soon as it is drawn down sufficiently for them to do so.

These principles respecting the nature and management of dislocations have been dwelt upon, from the author thinking that a knowledge of them would be more likely to lead an intelligent non-professional person to judge correctly and act efficiently on such emergencies, than the bare enumeration of certain sets of symptoms, often sufficiently obscure, which characterise the different forms of dislocation, and which he could not carry in his mind. There is, however, yet another important principle involved in the reduction of dislocations. It has been pointed out, how the bone farthest from the body-which is usually drawn up-is to be drawn down; but that this may be done properly, the bone above it must be fixed, otherwise it will be drawn down too. This is easily effected in such cases as the ankle or the wrist, by any one grasping and holding firmly either the leg or the fore arm; but in the case of the hip or the shoulder, more management is requisite. In the latter, which is the most likely to fall under non-professional treatment, the shoulder blade must be fixed or prevented from giving way with the "extending" force applied to the arm bone; how this is to be done will be pointed out when the particular dislocation is treated of. Again, in "making the extension," that is, using the forcible effort to return the dislocated bone to its place, the extending force will best be made in the direction in which the limb is fixed, and in the manner most likely to bring the joint portion, or "articulation," of the displaced bone as near to the old position as possible, and it must be applied directly to the bone which is displaced. Thus, in dislocation of the shoulder, the reducing force is applied to the arm bone; in dislocation of the hip to that of the thigh. This extending power may simply be by the hand, but a cloth, or band of some kind, put round the member to be replaced, is often more advantageous. In order to put this band on most efficiently, it is

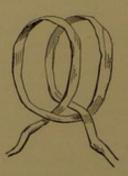

Fig. 73.

applied in the form of what is called the clove hitch (fig. 73) which will be better understood

description. This double noose, which may be formed of any suitable material, such as a large soft handkerchief, being fitted to the part to which force is to be used, with a piece of cloth interposed between it and the skin, is not liable to tighten when its loose ends are used to pull by. The particular dislocations most likely to be recognised and to be remedied by unprofessional persons, are those of the small joints, such as fingers and toes, of the wrist and ankle, of the elbow, shoulder, and lower jaw

Dislocations of fingers or toes may generally be made out by most, and should, if possible be reduced at once; the dislocated bone being grasped as represented (fig. 74, also taken

Fig. 74.

from Fergusson's Surgery), and forcibly pulled into place; or the clove hitch noose, made with a piece of tape, may be used. Dislocation of the thumb, it should be known, is extremely difficult of reduction, and should this not be effected at once, the attempt ought to be given up till the surgeon's arrival; it is, moreover, one of the dislocations which may be left unreduced with less subsequent inconvenience than many others. Dislocation of the ankle is very generally accompanied with fracture, but the distortion is often so great and evident, and the suffering so severe, that when the accident does occur far from proper aid, some attempt ought to be made to put the displaced parts in better position; for this purpose, whilst one individual grasps the leg firmly, another, putting one hand on the heel and the other on the instep, should endeavour, whilst steadily pulling downward, to bring the joint into its natural position.

Dislocation of the wrist is reduced by the fore arm being tightly grasped by one individual, the surgeon laying hold of the patient's hand in his, and endeavouring by steady traction downwards, and slight up and down movement, to bring the joint into its proper

Dislocation of the elbow, if attended to quickly after the accident, may often be easily reduced by seating the person in a chair, carrying the arm well behind the back, and pulling, not very forcibly, from the forearm; or by placing the knee in the hollow of the elbow and forcibly bending the forearm across it. This dislocation, like that of the wrist is extremely apt to be confounded with fracture of the bones close to the joint, and great caution is necessary in ascertaining the nature of the injury.

Both these dislocations - of the wrist and elbow-may be suspected, when, after violence - particularly such as is calculated to push either the hand or lower arm upwards-inability to use the limb below the seat of the injury, and distortion and impaired motion of the joint, are unaccompanied with any grating sensation, such as occurs when bone is fractured.

Dislocation of the shoulder is most generally occasioned by violence applied to the elbow, or by falls whilst the arm is not close down to the side of the body. Sometimes the exact dis-crimination of an injury to the shoulder-joint is a matter of much difficulty, for fracture alone, or fractures with dislocation, may occur. At other times, particularly in thin persons, it is tolerably easily made out, more so if the examination is made before swelling comes on. In addition to the general symptoms of dislocation already enumerated, the injured shoulder will be perceptibly altered in shape; it will appear more depressed and flatter than the sound one, and if the hand is placed upon the spot which ought to be occupied with the round head of the arm bone—and this may be discovered by examination of the uninjured shoulder-it will be found hollow, and further, if the arm be now gently moved about, and its bone traced up towards the shoulder, it will be found moving in some unusual position, most probably in the arm-pit. Supposing, therefore, that the case is sufficiently clear, and that the sufferer from the accident, in the absence of proper surgical assistance, is content to risk the matter to non-professional judgment, or that, from having been the subject of the accident on some previous occasion, he is tolerably certain of its present nature, the means for the reduction ought to set about as speedily as possible, if it can be, whilst faintness from the injuries continues. These means vary considerably; hanging over doors or gates, the arm-pit being placed on the edge, have been employed and recommended, and in persons who have been the subjects of frequent dislocations in the same shoulder, may be efficient, but in a first dislocation should never be resorted to. One frequently-used method of reducing dislocation of the arm bone into the arm-pit, is for both patient and surgeon to lie down upon the ground side by side, but with their heads different ways, and so that the surgeon, having previously taken off his boot, can place his heel in the arm pit of the patient, whilst he grasps the hand, or a towel fixed to the arm of the affected side; in this way, whilst the heel is used to push against the displaced bone in the arm-pit, it, combined with the traction exerted by the surgeon upon the limb of the patient, tends to give a leverage by which the bone is so placed, that it can be drawn into the socket by the muscles. This method may be a convenient one, when only one person is in company with the individual to whom the accident has happened. The following is the most generally

214

DOU DIS

dislocation of the shoulder:-The patient being seated on a chair, a large towel or a table cloth, folded broad, is to be passed round the chest, close under the arm pit of the affected side, crossed over the opposite shoulder, and held either by a strong assistant or fastened to some fixed point. By this application, the shoulder blade is fixed, the arm itself is then to be pulled, chiefly in the direction in which it has been fixed, firmly, steadily, and slowly; this being done, either directly by the hands of assistants, or by a towel fastened round the arm by the hitch-noose (fig. 73). If, when this steady pull has been persevered in for some time, the displaced bone does not get into place, the effect of suddenly taking off the attention of the patient may be tried, either by some sudden exclamation, or by dashing a little cold water in the face. By such a proceeding, the muscles which resist the reducing or pulling force applied to the arm, are for a moment, so to speak, thrown off their guard, and that moment may suffice to permit the bone to pass into its

Dislocation of the lower jaw is not a very unfrequent occurrence, and happens from persons opening the mouth very wide, either in laughing or gaping; the jaw slips, and its joint portions or articulations on both sides are drawn forward; the person cannot close the jaws, but remains with the mouth wide open, a most inconvenient position should skilled assistance be far distant; the accident, however, can scarcely be mistaken, and may be rectified without much difficulty by a bystander. It should be re-membered, however, that the unfortunate sufferer is quite unable in most cases to speak a word distinctly so as to explain the nature of the accident. To reduce it, the thumb or thumbs, according to whether the joint is en-tirely dislocated or only on one side, are to be placed by the acting party upon the upper portions of the back teeth, and strong pressure exerted downwards, whilst the chin is drawn upwards by the fingers at the same time. As the jaw returns to its place, its powerful muscles draw it upwards with a sudden snap, and if the fingers of the operator are not covered with a handkerchief or some other material, they may get smartly bitten.

After dislocation of any part has occurred and been reduced, a bandage or some application which will confine the injured members should be worn for two or three weeks, not simply from fear of the accident recurring at the time, but to keep the parts, which must have been more or less lacerated, quiet, and to permit the in-ternal traces of the injury to be as much as possible obliterated. In conclusion, although the subject of dislocation has been dwelt upon at some length, it is chiefly for the reason that these accidents, painful at the time, and, if unremedied, productive of deformity and impaired usefulness for the future, are often overlapped water in the difference mentioned.

DOUCHE is a stream of water directed upon a part of the body, and may range in temperature from cold to blood heat, or even warmer. Douches are of various kinds, as the descending—the water in the first kind falling from a reservative mentioned.

useful and most resorted to mode of reducing | looked, or are apt to occur at great distances from skilled assistance. In such cases, the information given in the foregoing article, may, either by directing attention to the importance of the injury and of its speedy rectification, or if acted upon with care and prudence, by pointing out the most effective treatment, prove a useful guide.

DISTILLED WATER.—See WATER. DIURETICS are medicines which increase the flow of urine. The class embraces very many substances, but it will be sufficient to notice only those which may be most safely and generally used; they are-

Broom. Dandelion. Fir Top, which contain turpentine. Juniper, Parsley. Potash-Solution, or Liquor Potassæ. Acetate.

Bitartrate, or Cream of Tartar. " Carbonate.

" Nitrate, or Saltpetre. Soda-Carbonate. Spirit of Sweet Nitre. Spirituous Liquors.

Squill. Turpentine.

There is always some degree of uncertainty in the action of diuretic medicines, but with some more than others. The author has found the two first on the list-broom and dandelion-as certain as, or more so, than any others, and, as domestic remedies, they have the advantage of being easily procurable in this country, and of being perfectly safe. Fluids should be given freely during the action of diuretic remedies. It sometimes happens, that diuretics, which would not act before, act after the administration of an active purgative. Similar effects are found in the hands of medical men, before and after bleeding. As mentioned under the article Coffee, the infusion of the raw berry is diuretic. Mental emotion such as fear, and nervous disorders such as hysteria, it is well known, give rise to great increase in the flow of urine.

uses, &c., of the diuretics mentioned.

DOUCHE is a stream of water directed upon

DOV DRA

voir, at a greater or lesser height, upon the | apply chiefly to temperate climates, but when patient in a single or divided stream, the size of which may be varied according to circumstances. The lateral douche is produced by a man's pressing the water through a tube, as with a fire engine, the stream being directed against any part of the body that is indicated. The strength of this can be regulated by the attendants pumping with a greater or less degree of force, and also by a finger placed over the aperture by which the stream is divided. In the ascending douche, the column of water is directed upwards, and is usually taken in a sitting posture; this douche being almost exclusively employed in complaints of the organs contained within the pelvis.

"Douches are directly exciting remedies, and are mostly used to produce a greater degree of vitality and activity in parts, as in cases of local debility, scrofulous swelling, muscular rigidity, paralysis, contracted joints, neuralgic They are mostly administered pains, &c. while the patient is in the bath, and are often advantageously combined with friction. employment of the douche requires to be carefully superintended."—Extracted from Lee's

Baths of England. Refer to—Bath.

DOVER'S POWDER is a compound of one grain of opium, one of ipecacuanha, and eight grains of sulphate of potass, powdered well together; ten grains consequently contain one of opium. It is much used as a remedy to produce perspiration, and frequently cuts short an attack of cold. A pill containing five grains of Dover's powder, that is to say, half a grain of opium, will be found generally sufficient for a dose.

Refer to-Opium.

DRAINAGE is the important process by which superfluous moisture is removed from the soil, through the soil itself, or by means of channels made in or through the earth. It may be either natural or artificial, to carry off the simple excess of fluid resulting from atmospheric moisture, such as rain, or to remove the impure and deteriorated fluids, which more or less result where man and the domestic animals

are congregated.

The salubrity of a district is always closely connected with its natural drainage; whenever moisture accumulates, either from position, that is, want of inclination or slope to run it off, or from the nature of the soil, disease is apt to prevail. Professor Ansted remarks:-"There can be no doubt that the district where sand and gravel allow the water to drain off at once beneath the surface, and that where hard and impermeable rock permits the rain to escape readily into the nearest running stream, will be on the whole the most healthy; while, on the other hand, that in which the tough clays retain the water in ponds on the surface will

the conditions of vegetation are taken into account, they are no less true than important for warm countries, where the rankness of the vegetation must no doubt be connected with the nature of the sub-soil over which it grows.

These considerations are important for all, and especially for the emigrant and settler in new districts, who ought always to fix, if possible, upon a site for his dwelling, where the water has, or may be made to have, an efficient drainage in every direction and way, and to exercise caution also, that the dwelling of himself and family is not so placed that any generally prevailing wind can blow upon it from a marshy or badly-drained tract of country. The effect of draining the soil, in rendering a country more salubrious, and in removing disease, is well exemplified in the disappearance of ague from many parts of Great Britain in which it formerly prevailed, a circumstance which can only be accounted for, by the increased attention to the drainage of those dis-

The drainage of houses or collections of houses, where day by day there must be removed the excretions, both solid and fluid of man and animals, is one of the most important points connected with the preservation of health—it might almost be added, and one of the most neglected ones. Both in town and country, the necessity for sufficient drainage, whether of the natural moisture of the soil, of the results of animal life or of domestic use, has been, if not entirely overlooked, most in-

sufficiently provided for.

It is generally thought, that in the country less necessity exists for perfect drainage than there does in large towns, and to some extent. the idea may be correct, in so far, as the less number of individuals collected in a given spot, and the freer circulation of air, must tend to preserve greater purity of atmosphere; but the idea, by fulling suspicion has proved a dangerous one, and the single homestead, or small isolated hamlet, has been desolated by the scourge of fever, which a little precaution might have prevented. One most striking instance has been recorded by the late Sir Robert. Christison, long before the true causes of fever were distinctly understood, which occurred in and close round a farm house occupied by an extensive farmer, in "a thinly-peopled rural district in Peeblesshire." With respect to situation, Dr. Christison, after describing it, concludes with, "A healthier locality could not well be chosen;" and yet, in and close to this healthily situated house, and in no other in the district, fifteen cases of a severe and peculiar form of fever (no doubt enteric) occurred within the space of a few weeks, and three proved fatal. Such a well-marked visitation could not well be exposed to marsh fevers and various disorders to light the fact, that the house was completely affecting the throat and lungs. These remarks surrounded by drains, which had, in the course

DRA DRA

of time, become filled up with the drainage of the farm-yard, of the necessaries, &c. Such cases are by no means uncommon, even in country situations, which would be at a first glance esteemed most salubrious, and indeed would be, but for the shameful neglect of the inhabitants.

It is not simply typhoid fever, cholera, and diphtheria which are associated with deficient drainage, but bad health generally; and whatever case of disease or accident may remain within the tainted locality, acquires a certain unfavourable tendency and type; even recovery from child-bed is affected by it: and perhaps more cases of child-bed fever and death than would be imagined, might be traced to the unhealthy influences originated by habitations situated in a badly-drained locality.

The contamination of wells which supply water used for drinking and cooking, by badly-arranged or imperfect drainage, is a very fertile source of disease; many invasions of typhoid fever, diarrhæa, and cholera have been traced to this disgusting source.

Whatever has been said respecting drainage in country places, applies with increased force to the provision in towns, with their dense populations. All large towns are bound to have systems of sewers and drains in connection with the houses, having an ultimate outlet into the sea or river, and it is the duty of all constituted authorities to see some

efficient system carried out.

Essentials of Proper Drainage.—The first essentials for proper drainage are-(1) well constructed sewers-that is, such as will not promote the deposition of solid matter in their interior. That the majority of the old sewers and drains do this has been proved by numerous parliamentary enquiries. It has been shown, that their unnecessary size and defective form (most of the old sewers being flat at the bottom) cause a retardation in the flow of their muddy contents, and thus, of necessity, produce a lodgment of putrefying animal and vegetable matter. Another source of deposit is the improper direction of these conduits, the sharp angles and curves of which, especially where the smaller sewers enter the main trunks, lead to obstruction; and to these must be added the various irregularities of surface connected with the masonry.

(2) In addition, however, to construction, a full supply of water is requisite, one that can thoroughly and periodically, at not too distant intervals, be sent in full volume-"flushed" -through the passages so as to sweep every-

thing before it.

It often happens, where a sufficient fall cannot be obtained between the house and the sewer, and there are no frequent facilities for flushing, that the drain pipes become choked with semi-fluid filth. To remedy this serious nuisance, no mechanical contrivance supersedes the self-acting flushing chamber, fitted

with Mr Rogers Field's annular syphon (fig. 76), which acts automatically, and affords a simple and effective means of flushing house drains and sewers at stated intervals during the day, thereby preventing dangerous deposits from accumulating.

In the case of private drains the usual capacity of such a tank is from 80 to 100 gallons, the diameter of the discharge pipe being 4 inches. A tap is connected with the tank, and the flow of water is regulated in accordance with the interval it is intended should elapse between each discharge. The action of the syphon is so perfect that even a drop supply is sufficient to insure the dis-

charge of the tank.

Construction and Laying of Drains .-There are certain principles with which all house drains must comply in order to come up to the modern standard. In the first place, they should be constructed with a view to the immediate and perfect removal of house sewage. Fresh sewage in itself is not oftensive; but when putrefaction starts, nuisance arises from the foul gases which are given off. To facilitate the flow of sewage, therefore, and prevent any deposit or obstruction are all-important considerations, and with these objects drains should have a perfectly smooth internal surface, and be absolutely free from any projections such as are often found, owing to cement being allowed to penetrate into the interior by a careless joint-maker.

The size of the pipes used in house drainage has also an important bearing upon the selfcleansing property of the drains. It is a mistake to suppose that the larger a drain is, the less likelihood is there of its becoming obstructed; the cause of obstruction, as a rule, is not large articles, but the gradual accumulation of deposit arising from the slow rate of flow of the sewage. Given an equal fall in two drains which carry an equal volume of sewage, and the respective diameters of which are 4 and 6 inches, the rate of travel, and, therefore, the flushing power, in the former, will be greater than in the latter, because the depth of fluid in the smaller pipe is greater than in the larger.

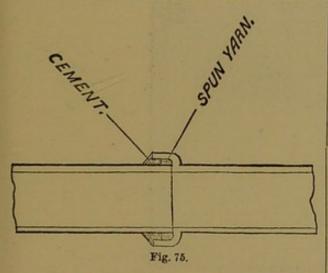

The tendency among sanitary engineers in recent years has been to diminish the size of In the case of private houses, of ordinary dimensions, no drain should exceed 4 inches in diameter, and the fall should not

be less than one in 30 or 40.

In laying drain pipes, certain points are essential to success. In the first place, in order that the pipes may rest on a firm bed, it is important not to dig the trench, in the first instance, deeper than is necessary, otherwise soil will have to be replaced, and this cannot well be done without the risk of impairing the solidity of the beds on which the pipes are laid. Again, a common practice among careless drain-layers is to rest the

pipes on their sockets, in place of removing a portion of the soil from the bed of the trench corresponding with the socket of each pipe, to allow the pipes to rest on their bodies. Unless this precaution is observed, the weight of soil which is replaced, instead of being uniformly distributed along the entire length of pipe, will be concentrated upon each joint, and will, in all probability, cause the recently introduced cement to be expelled from the sockets.

In making drain-joints the best Portland cement alone should be used. It is still a common practice to use clay, but such joints are never water-tight, and even if they can stand the test which should be applied to all new drains before the trench is filled in, their durability is only temporary. An excellent method of making ordinary drain-joints is shown in the accompanying sketch (fig. 75). Having laid the pipes in accordance with the above instructions, spun yarn, which has

previously been soaked in fluid cement, is rammed into the socket to a depth of about an inch, and the joint is then completed in the ordinary way with stiff cement. By this process, the risk of any cement penetrating into the interior is avoided; the whole sets firmly, and forms, if carefully made, a perfectly water-tight joint. In replacing the soil, the first portion should be packed well under and on either side of the pipes, so as to guard against after-displacement. Various patent joints have been invented from time to time. Perhaps the best of these is Hassall's, which has two rims of smooth and durable material cast on the spigot end of the pipe, thus leaving a groove between, while in the socket two corresponding rims are cast, so as to come in tight contact with the rims on the spigot end when it is introduced, thus forming, by means of the opposing grooves, a channel round the middle of the interior of the socket. Communicating with this channel, at the top of the socket, are two openings placed side by side; into one of these fluid cement is poured |

until it fills the whole of the interior of the channel, the displaced air escaping at the When the cement sets, a other opening. strong water-tight joint is formed. These pipes are expensive, but they are now frequently used, and are specially useful when drains have to be laid in a water-logged soil.

In laying drains in loose soils, they should rest on a bed of cement concrete; also all drains in close proximity to wells, and drains which must be carried under houses, should be completely embedded in the same ma-In the last case, however, it is terial. better to use iron pipes with caulked lead joints. No drain should be covered over until it has been thoroughly tested. This is best done by what is known as the hydraulic test. Having sealed up the terminal end, a short length of pipe with an easy bend is then temporarily fixed, with its curve directed upwards towards the surface, to the house end of the section of drain which is to be tested, and water is poured in until it completely fills the drain; by this means all imperfections will be detected by the water oozing through. The same test may be applied to existing drains by stopping them up at the manhole, or disconnecting chamber, and pouring the water in at one of the surface gullies until it reaches the surface; if after a time it is found that the water does not sink away, but remains at the same level, the integrity of

the drain is proved.

Caution !- The house connections with the drains should in every case be so arranged as not to communicate directly with the drains, the sink, bath, and other wastes being made to discharge on to outside traps; in addition to this a trap should invariably be placed at the top end of the waste pipe itself. In the case of many houses, which appear to a casual observer to be properly disconnected from the drains, all the precautions taken are found to be defeated owing to the existence of cellar connections with the drain, which under no circumstances should be allowed. They are introduced for one of two purposes - either to drain cellars which are liable to flooding from ground water, or as a convenience for swilling purposes. In the first case it is wrong that a cellar should exist at all unless measures are taken to render its floor and walls impervious, and in the latter, there is no reason why the cellar washings should not be mopped up, as is done daily in the case of back passages, &c. It may be asked: What is the objection to a cellar drain if it is properly trapped? The answer is, that a trap is not an absolute security, and in the case in point it is exceedingly likely to become dry from disuse, when sewer gas will have a free entry to the house. The above remarks apply only to cellars proper. In those cases where the kitchen premises are underground, the sink water is carried through the wall in

DRA DRA

the usual manner on to a disconnecting trap | preventer" (see Water-Closets). Unless this in the area.

Effluvia are very apt to escape from drains by the improper position of the gully gratings. By improper position is meant the top of an eminence, where no surface water can properly accumulate. Gratings and gullies are therefore injurious in such situations; and, indeed, should only be placed where absolutely necessary to carry off surface water, which will clear them out and maintain their water seal.

If the water-supply of a house should be stored in a cistern (as may be necessary in the country, and in towns where the supply is not on the "constant" system), it is essential that the supply to the water-closet should be cut off from direct communication with the house cistern by means of a special small flush-cistern which is termed a "water-waste

precaution is observed the water-supply will never be safe from pollution, as foul matter may be absorbed from the closet - a risk which is entirely prevented by the introduction of the special supply cistern.

The report of the Commission appointed to inquire into the best method of distributing the sewage of towns, shows that nothing is more to be deprecated than the opening of mains and sewers into a river, the water of which is used for drinking, and it is to be hoped that this will no longer be permitted by the law. The natural question is, Where is the sewage to be disposed of? It ought, if possible, to be conveyed by the drain into the sea, beyond low water mark. But what is to be done with the sewage of inland towns? In answer to this, it may be at once stated that

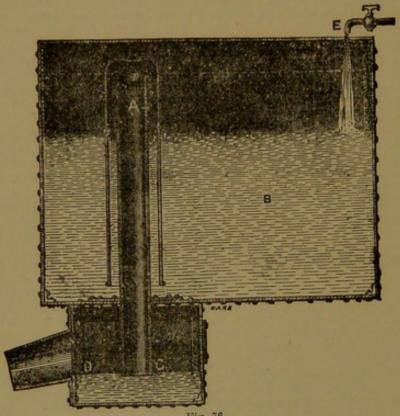

Fig. 76.

scientific men have not yet decided what is the best and most economical method of disposing of it, the great difficulty being that it is so diluted with water, as to render its collection and application to the soil very troublesome and unremunerative. The day, however, will assuredly come when all sewage will be utilised, and this is the more probable since there does not seem to be much fear of bad consequences, such as the production of disease, owing to the deodorant and disinfectant properties of most soils. The subject is one of great difficulty, because all attempts to improve the quality of the sewage, by diminishing the quantity of water to the drains, is immediately followed by undesirable results,

seeing that the drains are dependent upon a large supply of water for their adequate purification. Some idea of the amount of dilution of the sewage may be obtained, when it is known that upwards of 400,000,000 gallons of water are calculated to pass through the sewers of London on a daily average.

The reader is referred to the article Enteric or Typhoid fever, for an account of the disastrous effects likely to accrue from bad drainage.

It would be a wise precaution if, in every large establishment, and even in every house, especially in the country, an accurate plan of all the drains, &c., were kept, so that when it is necessary to have repairs executed, they may be done with as little trouble and ex-

DRE

pense as possible. Many days' unnecessary to the head alone, will be useful in such work in digging would thus be saved. In sur- cases. gical language, drainage is the continuous drawing off of fluid tending to collect in a cavity, such as an abscess, or a place from which a tumour has been removed. It is usually effected by fixing in the lowest point of the cavity an aseptic tube of india-rubber or glass, through which such fluid can pass into an absorbent dressing covering the outside of the wound through which the cavity has been emptied.

**DREAMING** is the wakeful and sentient condition of some of the faculties of the mind whilst the others are asleep. Few are so fortunate as to have escaped an attack of incubus, or nightmare, arising from disordered digestion; and all who have been much with children, know well how liable they are to suffer from disturbing dreams, whenever the stomach and bowels are disordered. It may be safely asserted that a large proportion of uncomfortable dreams are connected with disorder of the digestive functions—generally over-loading, but some-times the reverse. Some people always dream if they do not take some slight refreshment just before retiring to rest. Mental excitement during the previous day is of course a frequent cause of dreaming. Organic diseases, which give rise to oppression within the chest, such as diseases of the heart, are peculiarly liable to occasion uncomfortable dreams and nightmare. Uneasy and powerful sensations excited upon any portion of the body occasion what are called suggestive dreams; that is, the sensation seems to start some thought in relation to itself from which a train of incongruities, such as occur in dreams, appears to arise: a blister is the foundation for some dream of torture, or a loud sound for one of tumult.

Although made the subject of much credulity, dreaming, not only in its general character, but as regards the nature of the dreams, is not to be altogether disregarded with respect to the indications it affords of the bodily condition. When natural sleep is thus disturbed, particularly by dreams which cause alarm and uncomfortable sensations, or which occasion children to start and scream, the cause should be investigated; some error, simply as regards diet, either as to time, quantity, or quality, may be the reason; or disease may be forming. One or two smart purges will frequently remove the symptom. Whether in child or adult, should much mental exertion be going on, and sleep become unusually disturbed by dreaming, mental relaxation, and a greater amount of physical exercise, should be combined with

Refer to-Sleep.

DRESS .- See CLOTHING.

DRESSING is the application of various substances or agents to diseased or wounded parts to protect them from the action of the air, and from external injury, and, either by mechanical action or otherwise, to promote their healing or cure. It is of course also requisite both for cleanliness, and for the comfort of the

patient and of those around.

In former times, the process of dressing was DRASTIC—a medical term applied to a much more formidable and complicated affair than it is now under the modern, simpler, and more efficient practice of surgery-too simple to please patients sometimes. As the treatment of and mode of dressing burns, wounds, &c., is entered into in the articles on these and similar subjects, it is unnecessary to reiterate them here; and for what is requisite respecting the application of bandages, the reader is referred to the article itself. Here it is proposed to give the principle on which dressing generally should

be conducted rather than its details.

The first essential in dressing is gentleness Parts which require and lightness of hand. the process are generally in a state of greater or less inflammation, and consequently of increased sensitiveness; and the patient too, owing to the weakness which accompanies or follows disease or accident is most probably in an irritable and nervous condition. For these considerations, if for no other, the dressing, which is so often dreaded, should be conducted with the utmost gentle care. The next essential is to have at hand whatever is likely to be wanted; warm soft water, with sponge-or in its place some soft material-scissors, and lint, or linen. A piece of waterproof material to draw under the part is often useful. If plasters, bandages, &c., are required, they should not have to be sought for or cut when the wound is exposed, and the patient waiting. If the old dressings have become in the least hard or adherent, or if plasters form part of the applications, they should all be well softened by the warm water before the attempt is made to remove them; they should not require pulling away. When plasters are to be taken off a wound, the lips of which they hold together, they should be lifted at both ends, so that the detaching process meets just at the wound. The object of this proceeding is to prevent the newly healed and adhering surfaces being torn asunder, which they are more likely to be if the plaster is pulled off from end to end. For taking dressings off wounds, a pair of "dressing forceps" will be found useful. When the olddressings have been removed, the parts around the wound should be gently but thoroughly cleansed. If there are any loose, mortified, or "sloughing" substances attention to all the functions. The shower surface must not as is too frequently done, upon the wound, they may be lifted off, but its bath, either generally, or as a local application even by medical men—be washed and swilled

DRE DRO

the surface of a wound is the protective covering provided for it by nature, and if this be removed, it is much more likely to become irritable and painful, and to be longer in healing. When the proper cleansing has been effected, the requisite dressings should be put on without delay, leaving room, if there is likely to be much formation of matter, for its due discharge, and so placing the part when the dressing is finished, that the discharge can easily

The various dressings requisite for injuries will be mentioned in their proper places and articles; see specially Carbolic acid and Wounds. But one often recommended in this work requires notice here: it is the simple water dressing; which is at once the most convenient, agreeable, and universally applicable application to wounds of every kind. The popular fallacy that the applications have in all cases something to do with the healing of wounds, is very apt to make people, especially the poor, look suspiciously on so simple an agent as pure water. It is true, the interference of art is frequently requisite, either to stimulate or to repress action whilst wounds or diseases are in process of cure; but in the majority of instances, the cure is the work of the natural powers alone; all that has to be done is to place these in as favourable a position for exerting their agency as possible, and nothing answers this purpose so well as pure soft water. The application is made either by linen or lint soaked in the water-warm, tepid, or cold, as most agreeable to the sensations of the patient-and is in most cases covered over with some material which will prevent evaporation. Oiled silk has generally been used for the purpose, and oiled calico where economy is an object, but latterly thin sheet gutta percha has been employed, and answers extremely well. If linen is used, it will require folding at least double, to enable it to retain moisture sufficient. As a dressing, lint is a material better adapted than anything else. Water dressing is not necessarily covered with waterproof material; if the part requires keeping very cool, it is better not so; but then it will require much more frequent wetting, either by a nurse or by the system of irrigation recommended under article Cold. When waterproof material is put over the wet linen or lint, it of course prevents evaporation, and keeps in heat; it should always be larger than the lint. A mistake is very commonly made in this matter; a great piece of linen or lint is put on with its edges sticking out beyond the oiled silk, or whatever is used; and these edges, or even a very slight protrusion, are sufficient to drain be a most soothing dressing, a dry and irritating one. Among the poor the most complete ignorance respecting the use of water dressing sulphur, are useful as local remedies. Hot off the entire moisture, leaving what ought to prevails; it is too simple to get much of their | baths, with sulphur, or with the addition of a

over with water. The matter which covers | confidence; and very often, unless the most particular and repeated directions are given, the waterproof material-mistaken for a plaster -is put next the sore, and the wet lint on the top of it! Of course, when requisite, any description of lotion can be used as a dressing in this way, in place of the simple water. So universally applicable is the water dressing, and lotion applied in the same way, that they may almost entirely supersede ointment, to which there are many objections. A greasy application is seldom as pleasant, and never so cleanly as the fluid one; moreover, ointments are very often indeed used rancid, and thus become sources of irritation, rather than of benefit. When a simple greasy dressing is required, a little perfectly fresh lard, or oliveoil, is as good as any.

DRINKS .- Fluids taken by the mouth may be simple, medicated, nutrient, or stimu-The only simple drink is water. When agents which act medicinally upon the body are dissolved in that fluid, as in the case of mineral waters, either natural or artificial,when it is rendered alkaline, or is acidulated, or is impregnated with carbonic acid gas, as in the case of soda water, —it becomes a medicated drink. Barley water, toast-water, milk, &c., are examples of nutrient, and alcoholic liquors, tea, coffee, &c., of stimulant drinks. It is difficult, however, to draw the line between these classes. Many drinks which might be called medicated are in daily use; those which are stimulant are in many cases nutrient, and vice versa. As drinks come under the head of Diluents, the reader is referred to the article under that head.

DRIPPING.—As this article is often used for household purposes, or given away, it should be known that symptoms of lead-poisoning, or colic, have been induced by dripping from meat which had been baked in a newlyglazed earthen vessel; the lead-glaze being soluble in the fatty matter. Neither should it be forgotten, in connection with this subject, what was said of the power of fatty matters to act upon copper, when kept in vessels composed of that material, and especially if mixed with salt. Otherwise good roast-meat dripping is an excellent substitute for lard or butter in cooking, and many families, especially among the poor, use it instead of butter for their bread. It is sold in the shops at a third of the price of butter.

DROPPED WRIST, or wrist drop, as it is often called, is an affection frequently accompanying lead poisoning, and depending upon paralysis of the muscles which extend the hand, so that it falls, or drops. Galvanism

handful of sulphuret of potassium may be given every other day. These means, it is scarcely necessary to add, will be of little avail without the administration of medicines to aid in the elimination of lead from the system, and this should only be followed out under medical The affection is common among advice. painters, and all tradesmen who use lead (see article Lead), such as plumbers and workers in glass and putty powder, and among those engaged in the manufacture of preparations of lead. It is also occasionally the result of pro-

longed indulgence in alcohol.

DROPSY is the effusion or accumulation of the serous or watery portion of the bloodsuch as we see thrown out in a blister-in any of the tissues or cavities of the body. Thus the watery effusion may take place in the cellular tissue (see Cellular tissue) which connects the various portions of the body, and fills up their interstices, in which case it will show itself in the eye-lids and other portions of the face, or swell the feet and legs, hands and arms, or the body generally. This form of dropsy is called by medical men Anasarca. The effusion, on the other hand, may be into some of the larger cavities, as into the abdomen, when it is named Ascites; or into the cavity of the chest, between the lungs and ribs, when it is known as "Hydrothorax, or water in the chest." Again, effusion may take place into some of the smaller cavities, or rather "sacs," as into the bag which surrounds the heart. Whenever it occurs, dropsy is always to be regarded seriously. It is not, as the unprofessional generally regard it, a disease in itself, but it is almost invariably a symptom of disease, either constitutional or local, existing in the system. It is not here meant that dropsy is not a disease, but that it is generally a secondary one, not the original affection, which may, however, be so obscure, that nothing is left for the practitioner to treat but the dropsy, and that he must get rid of, if possible; for though in itself an effect only, it tends to produce other diseased actions, by impeding or stopping the functions of important or vital

Anasarca, or effusion into the cellular tissue under the skin, may be simply the result of general constitutional debility, of which the blood vessels, both large and small, and the heart partake. This form of dropsical swelling usually shows itself in the feet or ankles towards night, especially after long standing; many delicate persons are subject to it as a temporary ailment, when from any cause the general health has become impaired. When it shows itself and continues in the weakly, as in delicate girls, along with weakness generally, pallor, &c., it is only to be got rid of by measures which restore the tone and vigour of the system; such as good diet, with port wine and porter, tonic medicines, exercise, and change of air.

with an inflammatory condition of body--and the quick-irritable pulse might mislead--and lowering measures be resorted to, the disease will be greatly aggravated. Local anasarca, or dropsical swelling, may arise from any cause which impedes the return of the blood through the veins, and is a very common accompani-ment of disease of the liver or heart, or of tumours which press upon the great veins; of this, pregnancy, which often occasions swelling of the legs during its continuance, is an example, the effect passing off as soon as the cause is removed. The lower limbs are the most frequent seat of anasarcous, or as it is often called, "cedematous" swelling; but the hands, face, &c., are also occupied by it; indeed, swelling of the eye-lids in the morning, with stiffness on first trying to open them, is often one of the first symptoms of the tendency to dropsical effusion, whatever the cause. Again, anasarcous dropsical swelling may be occasioned by affection of the kidneys, which cannot carry off the fluid from the body with sufficient rapidity. The above are all instances of what are called "passive" dropsies; the cause generally acting slowly, and unaccompanied with a marked feverish state of the system. There are, however, forms of dropsy which are attended with this feverish state, and in which the watery effusion takes place rapidly, sometimes surprisingly so. The best instance of this is the acute form of dropsy, which is apt to happen in the later stages of scarlet fever as a complication of the disease. Whatever occasions "anasarca," or effusion of watery fluid into the cellular substance of the body generally, may also cause its occurrence in the cavities, as of the abdomen or chest; but it may also take place both in the large and small cavities, as a consequence of local inflammation. Their lining "serous" membrane becomes inflamed, and pours out a watery secretion in greater or less abundance. It is matter of popular information, that dropsy in the belly, or ascites, is apt to follow inflammation, and disease of the liver, and that water in the chest results from pleurisy.

From what has now been said in explanation of the nature and causes of dropsy, it must be evident that its serious treatment is not for the unprofessional; the causes are often too obscure, and the proper and efficient remedies too active, to be entrusted to non-medical hands, particularly as it can rarely be an emergency. A case of inflammatory dropsy, such as occurs after scarlet fever, might of course happen at a distance from medical aid, and for the measures to be adopted the reader

is referred to article Scarlet Fever.

Whatever form dropsy assumes, however, the case should at once be put under medical superintendence. As temporary palliative measures, the bowels should be kept either simply open or actively purged, according as the patient is of weak or strong habit of body; Should the error be made of confounding it and the effusion of water may be kept in check

DROWNING is death by suffocation from immersion in fluid. Few subjects treated of in this work are more important; accidental drowning is so frequent an occurrence, and it so often happens that no medical assistance is at hand during those first few precious moments after the body of a drowned person is recovered from the water, that some bystander, who is possessed of the knowledge, not only of what ought to be done, but of what ought to be avoided, may have the satisfaction of saving a life which must otherwise have been lost. When an individual falls into the water, especially from a height, there may or may not be considerable shock, from the body strik-ing the surface; or the head or other parts may have struck against a stone or some hard body, or there may have been fainting caused by the fright; all these circumstances must, of course, modify the effects. The last has been said to account for those cases which have been reported as recovered, after very long immersion,

that is, half an hour or longer.

The longest well-authenticated time of complete immersion, after which recovery has been effected, is fourteen minutes, and this case stands by itself. Other cases of ten minutes and even half an hour are recorded, but there is always doubt whether immersion has been complete during the whole time. This doubt, however, which must occur in most cases, is the very reason why hope should not be abandoned, even after persons may be thought to have been in the water a considerably longer period; and though it might be established, that none could be entirely under water for five minutes, and recover, this is not to be acted upon; half an hour's supposed immersion, or even longer, should be no barrier to When an individual efforts at restoration. falls into water, the body generally rises again to the surface, when an effort to breathe is made; air may be drawn in to some extent, and with it water, more or less, which passes into the stomach; this may be repeated two or three times, or efforts to breathe may be made beneath the surface; however it may be, the contact of the water in the breathing effort causes closure of the "glottis" or chink at the upper part of the windpipe; a small portion of fluid may pass in, but the principal effect is the exclusion of the air, and thus the drowned person is effectually suffocated, and the lungs in a considerable degree emptied of their air, which is pressed out in the vain respiratory efforts, and rises in bubbles to the surfacedeath in such cases occurring from apnœa, accompanied with a state of unconsciousness. The amount of water which may have been swallowed is comparatively of little moment, principles of the system, and the practical

the fatal consequence. A person, therefore, who is rescued from the water after immersion, if not dead beyond recall, -and here is the doubt of which he should be given the advantage,—is partially suffocated; the vital powers are also depressed by the action of cold, and probably also by the struggles and shock, both mental and bodily; but still the machinery is perfect, -the pendulum may be stopped, but the spring may yet be capable of action. In other words, vitality, though apparently suspended, may yet linger in a frame of which the structures are as capable as ever they were of acting as its agents; the mysterious link which binds them in action may be almost severed, but our efforts may restore it. If on the other hand life is extinct, the appearances on the body must vary according to the length of time the body has been in the water. If a long time has elapsed, a week or longer, signs of putre-faction will have commenced to show themselves in the skin, and the face will be swollen and livid; but if the person found drowned has been only a few hours in the water, the skin will be found pale and cold, and the mouth and nostrils will be covered with frothy mucus. The stomach and lungs will contain much water, and the latter organs will be found congested with venous blood.

Drowned, Treatment of the Apparently .-It may first of all be laid down as a general rule, never to be forgotten, that however discouraging apparent want of success may be, the attempt to restore a drowned person to animation should be continuously persevered with, as many cases are on record where a happy result was obtained long after many of the bystanders had given up the case as hopeless. When a body has been recovered from the water, it is well that those standing around should each provide a garment, so that the unfortunate person may at once be as much protected from cold as is possible under the circumstances. In addition to the measures which will be presently recommended, artificial respiration should at once be commenced, according to what is now generally known as "Marshall Hall's ready method;" that is to say, the patient should be laid upon a table upon his face, the forehead resting upon a book or some such thing, and every three or four seconds the body should be turned quite on one side, and then returned to the former position. Of course, all the while that this is being done, preparations should also be made for the other means necessary, such as constant chafing of the hands and feet, the application of warm blankets, hot bricks, or bags of salt, &c., when these can be ob-

tained. The Royal National Life-boat Institution has issued the following directions for restoring the apparently drowned. The leading

instructions, are founded on those of the late | of the body forces the air out; when turned on Dr. Marshall Hall, combined with those of Dr. H. R. Silvester, and are the result of extensive inquiries which were made by the Institution in 1863-4 amongst medical men, medical bodies, and coroners, throughout the United Kingdom:-

Send immediately for medical assistance, blankets, and dry clothing, but proceed to treat the patient instantly on the spot, in the open air, with the face downwards, whether on shore or afloat; exposing the face, neck, and chest to the wind, except in severe weather, and removing all tight clothing from the neck and chest, especially the braces.

The points to be aimed at are-first and immediately, the restoration of breathing; and secondly, after breathing is restored, the pro-

motion of warmth and circulation.

The efforts to restore breathing must be commenced immediately and energetically, and persevered in for one or two hours, or until a medical man has pronounced that life is extinct. Efforts to promote warmth and circulation, beyond removing the wet clothes and drying the skin, must not be made until the first appearance of natural breathing. For if circulation of the blood be induced before breathing has recommenced, the restoration to life will be endangered.

## II. -TO RESTORE BREATHING.

To Clear the Throat. -Place the patient on the floor or ground with the face downwards, and one of the arms under the forehead, in which position all fluids will more readily escape by the mouth, and the tongue itself will fall forward, leaving the entrance into the windpipe free. Assist this operation by wiping and cleansing the mouth.

If satisfactory breathing commences, use the treatment described below to promote warmth. If there be only slight breathing, or no breath-

ing, or if the breathing fail, then-

To Excite Breathing .- Turn the patient well and instantly on the side, supporting the head,

Excite the nostrils with snuff, hartshorn, and smelling salts, or tickle the throat with a feather, &c., if they are at hand. Rub the chest and face warm, and dash cold water, or cold and hot water alternately, on them.

If there be no success, lose not a moment,

but instantly

To Imitate Breathing .- Replace the patient on his face, raising and supporting the chest well on a folded coat or other article of dress.

Turn the body very gently on the side and a little beyond, and then briskly on the face, back again; repeating these measures cautiously, efficiently, and perseveringly, about fifteen times in the minute, or once every four or five seconds, occasionally varying the side.

the side, this pressure is removed, and air enters

On each occasion that the body is replaced on the face, make uniform but efficient pressure, with brisk movement, on the back, between and below the shoulder blades or bones on each side, removing the pressure immediately before turning the body on the side. During the whole of the operations, let one person attend solely to the movements of the head, and of the arm placed under it.

[The first measure increases the expiration,

the second commences inspiration.]

Should these efforts not prove successful in the course of from two to five minutes, proceed to imitate breathing by Dr. Silvester's method, as follows :-

Place the patient on his back on a flat surface, inclined a little upwards from the feet, raise and support the head and shoulders on a small firm cushion or folded article of dress placed under the shoulder blades, in the manner

represented in the engravings.

Draw forward the patient's tongue, and keep it projecting beyond the lips; an elastic band over the tongue and under the chin will answer this purpose, or a piece of string or tape may be tied round them, or by raising the lower jaw the teeth may be made to retain the tongue in that position. Remove all tight clothing from about the neck and chest, especially the braces.

To Imitate the Movements of Breathing .-Standing at the patient's head, grasp the arms just above the elbows, and draw the arms gently and steadily upwards above the head, and keep them stretched upwards for two seconds [by this means air is drawn into the lungs]. Then turn down the patient's arms, and press them gently and firmly for two seconds against the sides of the chest [by this means air is pressed out of the lungs].

Repeat these measures alternately, deliberately, and perseveringly, about fifteen times in a minute, until a spontaneous effort to respire is perceived, immediately upon which cease to imitate the movements of breathing, and pro-

ceed to induce circulation and warmth.

## IV .- TREATMENT AFTER NATURAL BREATHING HAS BEEN RESTORED.

To Promote Warmth and Circulation .-Commence rubbing the limbs upwards, with firm grasping pressure and energy, using handkerchiefs, flannels, &c. [by this measure the blood is assisted along the veins towards the

The friction must be continued under the

blanket or over the dry clothing.

Promote the warmth of the body by the application of hot flannels, bottles, or bladders of hot water, heated bricks, &c., to the pit of [By placing the patient on the chest, the weight | and to the soles of the feet the stomach, the arm-pits, between the thighs

## METHOD OF RESTORING RESPIRATION.

INSPIRATION.

Flg 77.

## EXPIRATION.

Fig. 78.

Treatment of the apparently drowned, as recommended by Dr. Silvester. Inserted by kind permission of the Royal Humane Society, Trafalgar Square.

If the patient has been carried to a house | be made to administer anything by the mouth after respiration has been restored, be careful

to let the air play freely about the room.

On the restoration of life, a tea-spoonful of warm water should be given; and then, if the power of swallowing have returned, small quantities of wine, warm brandy and water, or coffee, should be administered. The patient should be kept in bed, and a disposition to sleep encouraged.

General Observations. - The above treatment should be persevered in for some hours, as it is an erroneous opinion that persons are irrecoverable because life does not soon make its appearance, persons having been restored after

persevering for many hours.

Appearances which generally accompany Death. - Breathing and the heart's action cease entirely; the eye-lids are generally half closed; the pupils dilated; the jaws clenched; the fingers semi-contracted; the tongue approaches to the under edges of the lips, and these, as well as the nostrils, are covered with a frothy Coldness and pallor of surface increase.

Cautions .- Prevent unnecessary crowding of persons round the body, especially if in an

Avoid rough usage, and do not allow the body to remain on the back unless the tongue is secured.

Under no circumstances hold the body up by

On no account place the body in a warm bath, unless under medical direction, and even then it should only be employed as a momentary excitant.

Two other methods of imitating natural respiration and thus inducing its return, are known respectively as the Howard and the Schafer methods. In that suggested by Dr. Howard the patient is placed on his back as in the Silvester plan, while the operator kneels

over him and rhythmically compresses and relaxes the lower part of the chest through the ribs. Professor Schafer, on the other hand, places the patient on his face, with the forehead supported on the bent forearm, and then proceeds as in Dr. Howard's method to compress and relax alternately the lungs by pressure and relief of the lower ribs on each side. Both methods have some advantages over Dr. Silvester's, and are somewhat less fatiguing for a single operator. Some practice is required for making use effectively of any of the means described; and demonstrations are usually given

to those who attend ambulance classes. When no one is present who is conversant with any of the methods for restoring the apparently drowned, measures should be limited to restoring circulation and warmth by friction and warm blankets. If a medical man is present, and thinks well to use the stomach pump, quickly remove the water and replace it with a small quantity of hot brandy and water,

so long as unconsciousness continues.

In cases of drowning, the motto should benever despair: when all hope seems to have vanished, and no sign of life has been given for one, two, four, six, or even eight hours, the perseverance of those around has been at last

rewarded, and existence preserved.

After a person has been restored to consciousness, there may be considerable congestion of blood about the head, which may require leeches. In all cases of recovery, the greatest care must be taken to preserve the re-excited actions; if stimulants are thought requisite, they must be given most cautiously, and all sources of excitement, such as visits from friends or relatives, guarded against; hot fluids, tea, coffee, and the like, should be given moderately, and the strength supported by nourishing meat soups.

DRUG is the general term applied to medicinal agents used in the treatment of disease; it is, however, more generally employed with reference to the crude or commercial substances; after these have undergone preparation, they are usually called medicines. Although, undoubtedly, many medicines are largely adulterated in this country, many are impure in consequence of the adulteration of the drug in its collection or preparation by the natives of the country of which it is a product. Thus, senna is largely mixed with the leaves of other plants, opium with seeds and leaves, and sometimes with small stones, &c., to increase its weight; scammony is mixed with chalk. As, however, the adulterations to be guarded against are mentioned under the respective articles, to them the reader is referred.

DRUM OF THE EAR, or TYMPANUM, is an interior portion of the organ of hearing, which contains the small bones, and air .- See

DRUNKENNESS .- See Intoxication. DRY CUPPING. - See CUPPING.

**DUCT** is a medical term applied to a tube or "canal," adapted to convey fluid from one part of the body to another. Thus, the "hepatic duct" conveys the bile from the liver into the intestines; the "salivary ducts" carry the saliva into the mouth from the glands, by which it is secreted from the blood; the "thoracic duct" (see Digestion) conveys the chyle into the blood, &c.

DUGONG OIL.—For a very interesting account of this oil, the reader is referred to a pamphlet on the subject by Dr. M'Gregor Croft, of London, to whom we are indebted for

its introduction to this country.

Dr. Croft claims for it a superiority over codliver oil, on account of its being not disagreeable to the taste. It is true that the oil has this advantage, being almost like mutton fat to it may be of service; but no attempts should | the taste; but it is not proved as yet that it

DYS DUL

and as a medicinal agent, of cod-liver oil. The high price of the oil has prevented medical men from making the extensive trial that would be necessary to determine this question, although, owing to the praiseworthy efforts of Dr. Croft, the oil has been presented at as low a rate as possible. To medical men holding appointments in hospitals, who are in the best circumstances to try its effects, Dr. Croft has on many occasions provided a small quantity at his own The results, so far, have been most satisfactory, and one thing is certain, at all events, that the patients do not complain of the taste of the oil. The writer has made a trial of it, and was pleased to note a decided improvement in the patient during its use. The case was one of consumption, and the patient gained in weight, and did not suffer to the same degree as formerly from perspirations at night. It seemed to agree well with the stomach, and was said not to be at all disagreeable to the taste, even in the first trial.

DULCAMARA, or SOLANUM DULCA-MARA, or BITTER-SWEET, or WOODY NIGHT-SHADE,—are all names for the same native plant, which is, however, widely distributed over the temperate portion of the globe. It is a shrubby climbing plant, bearing clusters of flowers, closely resembling, but smaller than those of the potato, which belongs to the same family. Under its name of "bitter-sweet" it is well known in the country. It flowers in June, and in the autumn bears clusters of red, somewhat transparent, berries. The twigs are used in medicine, and are directed to be gathered when of the thickness of a goose quill. medicinal use of dulcamara is as a soothing diaphoretic, producing perspiration, and it might be used in the absence of other remedies for this purpose. To make the infusion, one ounce of the twigs, chopped, is to be infused in half a pint of boiling distilled water. Of this, the dose is two to six table-spoonfuls twice or thrice a day.

Refer to—Diaphoretics.

DUMBNESS, or inability to utter articulate sounds, may arise from absence of the tongue, or from defect in the formation of the organs of voice; probably also from causes affecting the nerves which supply the organs of speech; but most generally, from complete deafness, either congenital, that is dating from birth, or as the result of disease before the power of speech had been acquired and fixed in the memory.

DURA MATER is the term applied to a

possesses all the advantages, both as a nutrient | skull on the one hand, and invests the brain. Between it, however, and that organ, two other membranes lie: the "arachnoid membrane," so named from its extremely fine texture, which lines the dura mater, and also covers the brain, forming a double layer, or "shut sac," in the interior of which a watery fluid is secreted; and the "pia mater," or vascular membrane of the brain, which lies directly upon and covers the

organ itself, dipping between its convolutions.

The "dura mater" is prolonged into various "processes," or projections, which pass between and give support to the different portions of the cerebrum, or brain, and cerebellum, or little brain, which are in fact partially separated from each other by a fold of the dura mater. This membrane, and the others above mentioned, are continued from the interior of the skull down the spinal column.

Refer to-Brain-Spine, &c. DWELLINGS .- See Houses.

DYSENTERY, or as it has been popularly called "bloody flux," is a disease characterised by severe diarrhœa, fever, &c., the accompaniment of a peculiar inflammation of the mucous membrane lining the large intestines. It is much more frequent in tropical climates and marshy districts than it is in this country at the present day although formerly it was very prevalent, forming a large item in the bills of mortality of a hundred or a hundred and fifty years back; and at times showing itself in a fatal epidemic form. It is probable that the diminished occurrence of dysentery in Britain at the present day is owing to the increased comfort of the population, the drainage of the land, and some attention to sanitary influences; for, deficient as the regulations attached to these still are, they are certainly better than they were a century ago. A kind of dysenteric affection-that is, severe diarrhea, with fever, tenderness of the bowels, indicative of inflammation, and bloody stools—is frequently met with in autumn during the prevalence of the common British cholera. In some low-lying districts in our eastern counties, we have still a good deal of dysentery allied with ague. An ordinary attack commences with diarrhœa, and griping pains, which continue till the patient is scarcely able to pass anything but a little bloody mucus. The term "tenesmus" is given to the violent straining, and this constitutes one of the main features of the disease. After a time, the evacuations become more copious and are tinged with bile. Occasionally, and these are the most dangerous cases, we have high fever, furred tongue, with rapid and feeble pulse, and the urine becomes scanty and highly coloured. These symptoms often denote the approach of death, the patient retaining consciousness to the last. Dysentery appears to be engendered by exposure to cold, wet, to privations connected with food, and to impure and contaminated water; hence it has been one of the firm white fibrous membrane which lines the greatest scourges of our armies in all parts of DYS DYS

Indian possessions, and on the coast of Africa, we have still a good deal of dysentery along with ague. The same causes, and its connection with variations in climate, particularly with a hot one, must render dysentery a disease respecting which the emigrant ought to possess information; for it may happen, and it often does, that the disorder attacks those far removed from medical aid, and it is not one which brooks much delay in treatment. Medical men in this country have comparatively so little experience of the disease, that the author gladly avails himself of the valuable work of Dr. Parkes in the compilation of this article. By this author the symptoms of dysentery are thus succinctly described:-"Dysentery commences either gradually or suddenly; the general commencement is, however, by diarrhœa.

"First, as to the kind of stools.

"These are, first, simply numerous, perhaps feculent, in a few very rare instances scybalous. [That is, containing hard black-looking lumps about the size of beans or nuts, called by medi-

cal men scybalæ].

"After this the stools become numerous, slimy, gelatinous, bloody; blood in streaks, or mixed with a dark watery fluid; in another form pure, perhaps clotted. Afterwards, stools watery, muddy, like the washings of meat, or gelatinous-looking, shreddy, offensive in odour. Sometimes after this the stools present an appearance something like pus (matter), or this is mixed with mucous slime and blood, in such a way as to form a variously coloured stool, which causes great griping and tenesmus when passed.'

With respect to the causes of dysentery Dr. Parkes says: "We may admit as both predisposing and exciting causes, according to cir-

cumstances, the following agents:-

"1st. - All acrid agents, whether produced by irritating ingesta, or secretions: as bad or too rich food, bad water, fruits, or retained excretions, or derangement of the biliary secretions, &c.

"2nd.—Suppression of secretions rapidly accomplished: as that of the skin by cold, wet, sudden changes of temperature from hot to

cold, &c.

"3rd.—Epidemic states of the atmosphere, and probable alteration of the blood, either from food or its digestion."

The power of these causes to produce dysentery should be well fixed in the minds of all those whose lot it may be to be exposed to their influences; for by their avoidance the disease may probably be escaped; and there can be few misfortunes greater than for a new settler, whose welfare and that, perhaps, of a family depend upon his health and strength, to be attacked with dysentery.

The treatment of dysentery which may most safely be practised by an unprofessional person,

the world. On the coasts of our East and West | in the absence of a medical man, would be, in the first instance, if they were procurable, the application of leeches to the belly, a dozen or more at once, and repeated according to the strength of the patient, if the symptoms remained unrelieved. Should leeches not be obtainable, and even if they are, a warm bath once or twice-if it did not exhaust too much -in the twenty-four hours, would be found useful; and probably warm fomentations to the bowels. To allay pain and relieve the disease generally, opium is the most valuable remedy; but as there may be irritating matters in the bowels, they must not be confined, which the opium alone might do, and thus, though relieving apparently for a time, aggravate the disease ultimately. To avoid this, the opium should be combined with castor oil, or olive oil, either simply or in emulsion with yolk of egg. If castor oil is procurable, it should be trusted to; if not, Epsom salts, in tea-spoonful doses, each dissolved in from half a pint to a pint of gruel or barley-water, or some other demulcent, with four or five drops of laudanum added, may be given every four or five hours. Ten grains of Dover's powder, given once or twice in the twenty-four hours, may probably be of service, or a pill composed of half a grain of opium, a grain and a half of blue pill, and half a grain of ipecacuanha, may be given every six or eight hours. The safest course, however, will be the treatment by the oily aperients and laudanum. In addition, injections containing from ten to twenty drops of laudanum will give much relief. Sometimes the lower bowel is too irritable to bear the enema, or even the tube; in which case, a suppository, or pill, made with a grain of opium, mixed with a little flour and water, may be passed into the bowel. The food requires much attention, and should be of the mildest character: milk, and preparations of the grains, and sago, arrow-root, &c., combined with gelatine or isinglass, will be most suitable. If the strength is much reduced, strong concentrated animal soup will perhaps be required.

Of course so serious, and it may be fatal, a disease as dysentery should be put under medical care as shortly as possible; in the meantime the above directions may be of much service.

"The first appearance of recovery is evidenced by the stools becoming less slimy, perhaps copious and feculent, or bran-like, or dark and slightly beaten up; or while one part of the stool is slimy, the remainder consists of natural feculence." A person convalescent from dysentery will of course require the greatest possible care in diet; and also with respect to all exposure to the causes which originated it.

EAR .- This is the organ of hearing, by means of which man and animals are made sensible of what we call sound, that is, of certain vibrations communicated to the atmosphere, or surrounding medium, which give rise to the sensation of sound, by acting upon the organ fitted by structure to receive them, which organ is connected with the brain, or agent of the sentient mind, by nerves special to the purpose. The entire organ of hearing is called the ear; its anatomy and functions constitute a wide and interesting branch of study; but here it will be sufficient to explain just so much as is requisite to give the unprofessional reader some idea of the nature of the organ some rational view of the disorders to which it is subject, sufficient, it is trusted, to guard them against submitting so valuable an agent, of which the varied structures must give rise to varied forms of disease, to be tampered with by ignorant quackery. Any one who will for a moment consider in how many ways deafness may be produced, must see that there can be no specific to effect its cure, but that the means of cure must vary with the cause of the disease.

The human ear consists of an external, middle, and internal portion,—the external being composed of the flat folded organ attached to the head, usually called the ear (fig. 79-1), and of the ear passage, or "meatus"(2).

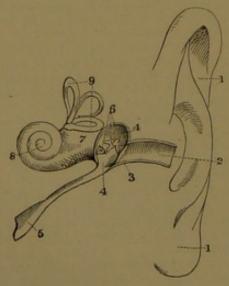

Fig. 79

The external flap of the ear is divided by anatomists into various parts, which it would answer no good purpose to go over here; its evident function is to collect as much as possible the body of sound. Its adaptation for nerves, abscess within the meatus, or in the

**DYSPHAGIA.**—Difficulty in swallowing, | this purpose is more plainly evidenced in the movable ears of the lower animals than it is in man. The air passage, or meatus, is oval in form, curved upon itself, and rather narrowest in the middle; it contains a few small hairs, and glands which secrete the peculiar bitter wax, or "cerumen," which is probably a provision to prevent insects entering the air passage.

The inner extremity of the ear passage is closed by a membrane (3), that of the tympanum, or drum of the ear; it is placed obliquely. The cavity of which it forms the external boundary is the portion of the middle ear named the drum, or tympanum (4); it contains air, and communicates with the atmosphere by means of the eustachian tube (5), which opens into the throat. The tympanum contains three very minute bones, articulated or jointed together so as to admit of slight motion; these which are represented magnified (fig. 80) extend across the cavity; the small

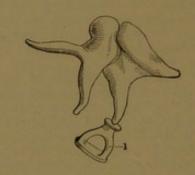

Fig. 80.

bone (1)—which resembles a stirrup in shape, and, indeed, derives its name, "stapes," from and, indeed, derives its name, "stapes," from that resemblance—being attached at a small opening to a portion of the membrane which lines the inner ear, or "labyrinth," as it is called from its complex construction. The labyrinth, or inner ear, is composed of three parts, the vestibule (fig. 79—7), the "cochlea" or shell-like portion (8), and the semicircular canals (9). Both the middle and inner ears, and indeed part of the external ear passage, are accommodated in a portion of the temporal are accommodated in a portion of the temporal or temple bone, excavated for the purpose. To the small bones of the tympanum are attached four minute muscles, which by their agency act upon the membrane of the drum; the office of these bones being evidently at the same time to conduct the vibrations of sound from the membrane of the tympanum, which is exposed to the external air, to the membrane of the vestibule, which, with the other parts of the labyrinth, constitutes the essential organ of hearing. Within the labyrinth, a watery-like fluid is the medium for conducting the vibrations of sound to the nervous expansions which are also contained within the cavity.

The disorders to which the organ of hearing is most liable, are loss of function, or deafness, noises in the ear, neuralgia, or affection of its

cavity of the tympanum, chronic discharges, polypus; and further, the meatus in children is very apt to be chosen as the receptacle for peas, small buttons, or indeed anything they can poke in easily, but which are often ex-

tremely difficult to get out again.

The subject of deafness has been already treated of, but the attention of the reader is again called to the many causes which may produce the one effect. The malformation at birth of the inner ear, as a cause of complete deafness, is also connected with dumbness; or accident may at any time of life injure the delicate structures contained within their cover of bone. The passage of the air through the external ear passage may be obstructed or prevented by an accumulation of wax or other matters; the membrane of the drum may be perforated; the bones may have been dis-charged by disease; or the eustachian tube blocked up by swelling temporarily, or permanently by thickened mucus. There are no diseases, perhaps, which require—as must be evident to all-more tact in their discovery and in their treatment, than those of the ear.

Noises in the ears, such as singings, ringing of bells, roaring as of the sea, &c., are often extremely troublesome, and may arise from many and different causes. Mere temporary derangement of the digestive organs will in some persons produce them; they are often indicative of determination of blood to the head, and when accompanied with symptoms of this tendency ought not to be neglected. Partial obstruction of the eustachian tube by cold, or accumulation of wax in the external ear passage, is apt to occasion these noises, and they are accompanied with some degree of deafness. Of course the remedy must vary with the cause; if the digestive organs are deranged, they must be regulated; if cold be the cause, the symptoms may be left to pass away with the temporary ailment. In some cases of chronic, or continued, noise in the ears, regularly bathing the head with cold water every morning will, after a time, remove

Earache, or neuralgia of the ear, is treated of under the head of Neuralgia generally. It is often relieved by the insertion of a piece of cotton wadding dipped in laudanum, or equal

parts of chloroform and laudanum.

Abscess in the meatus is often also called earache. It is one of the most painful disorders, and is generally the result of cold. It is characterised by intense throbbing pain in the ear, with, frequently, perceptible swelling externally, and more or less fever. There is no relief from pain till the abscess bursts, and this result is to be encouraged by the assiduous use of fomentations, poultices, &c. After the matter has discharged, the ear ought to be gently syringed out three or four times a day with warm water, till the discharge ceases.

very simple and ingenious apparatus may be had for a few pence from the instrument makers. This channel fastens with a spring round the head (fig. 81), and being thus maintained in place and projecting from the ear prevents the water from flowing over the patient's clothes as it is returned from the ear. As it

Fig. 81.

is not always convenient to get a second person to syringe the ears, a very neat and efficient instrument may be procured, by means of which any person can syringe for himself. The instrument is made of india rubber, and is somewhat like a small enema instrument. It will be advisable to give a few doses of aperient medicine during the progress of the case.

The abscess may form within the tympanum, and the membrane be perforated in giving exit to the matter. Inflammation of the ear ending in abscess, differs from true earache, or neuralgia, in the pain being comparatively slight at first, and gradually increasing in intensity as the disease progresses; whereas in neuralgia it commences with full severity.

When the discharge after an abscess does not disappear, or when running from the ears shows itself after acute diseases, such as measles, scarlet fever, &c., the symptom must not be neglected, and should be examined into by a medical man. It is most general in children of weak or scrofulous constitution, and may be with or without disease of the bone; in the former case the discharge is extremely feetid, and often stains the linen black. These discharges cannot be allowed to go on without risk; as the brain or its membranes may become affected by the gradual extension of the disease to them through the bones. Counter-irritation, by blisters, or tartar-emetic, behind the ears; strict attention to the bowels; the general tonic treatment recommended under the article Scrofula; the introduction of glycerine tannin into the internal ear, or syringing with slightly astringent washes, such as one grain of lunar caustic, or two of white vitriol, to the ounce of water, will constitute the most appropriate treatment To assist the operation of syringing the ear, a | The safest plan, however, is to submit the case

EAR EAR

to medical inspection. Bodies of various | changes which are probably influenced by atkinds are apt to be thrust into the external ear passage by children, or to find their way there by accident; and farm labourers sometimes get grain, peas, &c., projected in during threshing. If the introduced body is much smaller than the passage, its removal may be attempted by syringing freely, and with a strong syringe; but if the body fills up the meatus, or nearly so, this will not succeed; and in the event of its being a pea, or anything which will absorb fluid, and swell, will do mischief. Neither, in case of a large body, which the syringe will not disengage, is it well for friends to attempt the removal, in any other way; they never do any good, and only push the obstruction further in, rendering its extraction by the surgeon more difficult, particularly if it is passed beyond the middle and narrowest portion of the canal. Insects, which occasionally get into the ear, may be removed by inclining the head and pouring a little water into the external opening.

Note. - Discharges from the ear resulting from infectious diseases, such as scarlet fever and diphtheria, may retain the infection for many months, and convey it to others. Association with others is unsafe so long as

the discharge continues.

Refer to—Cerumen - Head—Indigestion, &c. EARLY RISING. — There can be no question, as a general rule, that the habit of early rising is conducive to health; but, like many other similar matters, the general application would, by many, be converted into a universal law, and much fallacy and no little mischief has been done by the propagation of the dogma. The poets have given their strains, the philosophers their aphorisms, and the hearty centenarian his experience, to eulogise early rising as a sort of elixir of life, and preventive of illness and disease. It is a

great good, but not a universal one. It is generally said that all those who have attained great and green old age have been early risers; therefore, say others, early rising is a promoter of health; therefore, it might be whispered, those whose constitutions have carried them through a long life have been able to be early risers. As in many other things, the truth probably lies between the two: there have been good vital powers on the one hand, and good habits, of which early rising is often an indication, on the other. The wrong deduction, however, that early rising is an unmixed good, has occasioned much erroneous practice; and many a delicate person, either in consequence of the false idea, or badly advised by others, has injured his health, materially, by perseverance in the practice; this, however, is more common among the young, than among the aged who require less sleep.

There is no question but that the bodily powers and constitution undergo marked and regular changes during the twenty-four hours, for a short time, the novelty; but shortly,

mospheric and other causes not at present understood. At all events, in disease, evening brings fever if it is present at all, and towards morning, excitement abates if it does so at all; further, in health, the body, it is well known, is more obnoxious to the causes of disease in early morning than it is at other times; and lastly, persons of weak nervous power, generally feel better towards evening than they do in the morning, even when the refreshment of a night's rest might be expected to have given strength. The reason of these differences it is perhaps not possible fully to explain, but we may reasonably conclude that the same influence which causes or aggravates the evening fever, and abstracts excitement towards morning, may also act as the elevator or depressor of the constitution generally, although only felt when it is not in full vigour; it may, or it may not, be owing to the presence or absence of solar influence, but still it is so, and the fact is one of general experience. The fact, too, explains why early rising is not only not good for all persons, but why to some it is positively hurtful, and why those who are able to practise it are generally of strong and good constitution. Moreover, the fact tells that the person who cannot rise early with impunity is not in full vigour, but requires means for attaining a better state of health: when the powers of life are raised to the proper level, then, by all means, let them be kept to it, and early rising used as one of the preservative

What is meant by early rising, is getting up from rest before the sun has exerted some power upon the earth; the exact period to suit the invalid it is impossible to specify; it ought to be matter of experience. As a general rule for a healthy adult, eight hours sleep, or a third part of the twenty-four hours, should be devoted to rest. That is to say, retiring to rest at a reasonable, early hour, such as ten o'clock, the person should rise as early as can be done without feelings of sleepiness, languor, &c., supervening during the day. There are certainly evils consequent upon continuance in bed in the morning, such as perspiration, &c., but they may be greatly obviated by the nonuse of feather beds, or too much clothing; they are less, however, than those which result from a nervous system exhausted at a period of the day before it had come into full activity. The same arguments which apply to early rising, also do so to exertions, or continuance without food, by weak individuals in the first part of the morning; they can practise neither with impunity. There is no time of the day so pleasant, and the hale and strong can enjoy it to perfection, and gather health in its fresh breezes, and their description will often tempt the unwary invalid to leave his couch and follow the example, and he really does enjoy,

EAR ECZ

disappears before the appetite of the strong morning walker, has no charms for his exhausted weaker companion, who pays with a day of listless languor for this ill-advised attempt. These hints will, it is trusted, not be taken as an encouragement to laziness, but as pointing out a very common error in popular belief and popular practice. The person of weak vital power, who cannot be an early riser, must guard well that he does not mistake sloth for inability, nor encourage the inability by indulging in late hours, which are often to him the most vigorous. Persons who suffer much from debility in the morning, and who are constrained to be up early, ought, as soon as possible, to have some warm refreshment, a cup of warm milk if it agrees, or tea, coffee, or cocoa. In some cases the popular addition of a tea-spoonful of rum or brandy to milk is undoubtedly useful, particularly where there is tendency to faintness; but the cordial must be taken as a medicine, and abandoned as soon as possible.

Refer to-Bed.

EARTH CLOSETS .- These are ingenious contrivances introduced by Mr. Moule, a Hampshire clergyman, to obviate some of the defects of the ordinary water closet, and especially to utilise the excreta for the purposes of manure. Their action is based on the well-

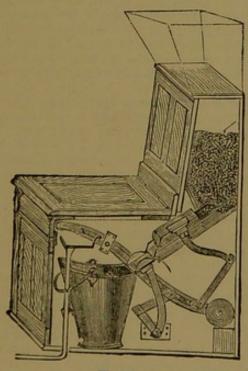

Fig. 82.

known disinfecting and deodorant property of dry earth, and they consist of an apparatus worked by a handle, which measures and delivers the requisite quantity each time the closet is used. Neither sand nor chalk can be employed for the purpose, and care is necessary

languor creeps over him; the breakfast which | hand, so that it may more readily be converted into mould. The invention has not met with much favour in private houses in towns, on account of the care and attention it requires to prevent its being a nuisance. We must, however, exempt from this condemnatory opinion Parker's portable earth closet (fig. 82), made for sick-room purposes and intended for persons unable to leave their rooms, but sufficiently well not to require a bed-pan; in such cases the earth closet is both a convenient and a sanitary arrangement.

In outside privies in country houses to which gardens are attached, in public schools in the country, in lunatic asylums, and in other establishments, the earth closet has been largely adopted, and appears to answer its purpose well. It has been much employed in warm countries, especially in India, where it has been introduced into numerous barracks and prisons; and Dr. Mouat, the late Inspector-General of Prisons, reports that "it has removed the greatest sanitary defect of the prisons, and has led to a remarkable change in the health of the prisoners, which, prior to its adoption, was in a very bad state."

EATING.—See FOOD—DIGESTION—INDI

ECCHYMOSIS is a medical term applied to discoloured swelling, caused by effusion of blood beneath the skin, or in the tissues of the body. A common bruise is the most familiar example.

ECTHYMA.—A disease of the skin in which pimple-like pustules containing matter

are developed. - See Skin.

ECZEMA is of more common occurrence than any other affection of the skin. It is not a contagious disease. Though considered vesicular (that is to say, attended by an eruption and exudation of watery fluid from the skin, which dries up into a scab or crust), it presents various appearances, being sometimes marked by pustules, sometimes by papules, while at other times, and not unfrequently, the inflamed skin has a smooth glazed look, without a trace of eruption. All parts of the body are liable to eczema, but its more frequent sites are the scalp and hairy parts of the face, where it is most liable to take on the pustular form; the hands, feet, and legs, as well as those parts of the skin liable to contact and friction with other parts, as the flexions of the joints, the nates, and the inside of the thighs, are also prone to be attacked. The disease is usually attended with much irritation and intolerable itching; and if scratching is indulged in by the patient, the symptoms are aggravated, and bleeding from the surface of the inflamed skin is most likely to ensue. Eczema is very common in infants and young children, and may be traced to want of cleanliness, or to vermin in the hair, or to not drying the tender parts that the earth used should be dried before- unhealthy children, it is an accompaniment of

ECZ EDU

various constitutional affections, and it is ex- | liquid pitch ointment, composed of five parts of tremely apt to supervene on measles. Among the aged, the circulation becoming languid, eczema is prone to be very troublesome; it usually attacks the legs in these cases, particularly the calves and shins, and resists most remedies except palliatives. The skin of those parts which have suffered from repeated attacks of the disease, undergoes sensible changes; it becomes permanently red and thickened, and when pinched up by the fingers, it changes its colour at the point of pressure to a dirty yellow hue. Eczema, as a rule, is not difficult to cure, but in adults it is liable to recur, and in

the aged it is very intractable.

The remedies employed for the removal of eczema are very numerous, and include those of a constitutional character, as well as local applications. In the case of infants and young children, carefully drying the parts after washing, and dusting them with the powder of zinc oxide and starch, morning and evening, combined with attention to the state of the bowels, will generally effect a cure. If the disease is the result of itch or vermin in the hair, it will be necessary to employ sulphur ointment, or ointment composed of ammoniated mercury (white precipitate), which should be smeared over the parts night and morning. If, on the other hand, the disease is the offspring of scrofula or other constitutional taint, it will be necessary to have recourse to steel wine, Parish's food, cod-liver oil, and to the class of remedies best suited for each individual case. When there is reason to suppose that the complaint is associated, as it very often is in adults, with derangement of the digestive organs, alterative and aperient medicines are indicated, such as rhubarb and carbonate of soda, combined with three grains of grey powder three times a day. Should the person be florid and robust, an occasional smart purge with calomel and scammony, or the mixture of magnesia and Epsom salts, will be found effective. The diet ought to be carefully attended to, and abstinence from alcoholic beverages of all kinds strictly In obstinate cases of eczema, no remedy has been found so serviceable as arsenic, but it is a powerful poison, and can only be administered under medical supervision. The arsenical solution (Fowler's) is given in five minim doses in water twice a day, and must be persevered with till the symptoms abate, or the constitution is affected by the drug.

With regard to external applications, those which soothe inflammation and itching are most in request. A bran or bread poultice applied over the affected part will often do this, or the lime water liniment, so serviceable in burns and scalds, will be found equally useful in allaying the irritation in eczema. The iodide of mercury ointment, glycerine tannin, a weak solution of nitrate of silver, are each employed with the view of producing a normal condition of the skin; another good local application is the

tar to two parts of wax, which has long had a deserved reputation in the treatment of this affection. Persons liable to attacks of eczema will find the continuous employment of the coal-tar soap for the ordinary purposes of ablution an excellent preventive; but while cleanliness is essential, it is a mistake to overdo it by incessant washing of the parts most liable to the disease with soap and water. In the obstinate eczema of the legs in old people, the solid rubber bandage, as made by Messrs. Hooper, of Pall Mall, has, in Dr. Thomson's hands, proved especially useful. In general eczema, an ointment, composed of ten grains of boracic acid to the ounce of vaseline, is the most generally efficacious application he has met with. For washing, Perkin's American woodtar soap is excellent.

EDUCATION, as applied to man, means literally the bringing forward, or encouraging and regulating the qualities or properties of which his whole being is capable. The natural division of the process is into mental and physical; the education of the mind and of the body. Strictly, in a work like the present, it is with the latter only we have to do; but the two are so intimately connected, that it is

impossible to separate them.

So much that is applicable to the subject of physical education is said in the article Childhood, and also in the various articles on Air, Clothing, Food, &c., that it leaves but little to be added here; and to the above mentioned articles, and to those bearing upon sanitary measures generally, the reader is referred for

information.

The great difference between the physical education of the male and female sex commences when children leave the nursery. boy, much less hampered by the mode of clothing, and permitted much more freedom in physical exertion than the girl, has, as far as these are concerned, a better chance of attaining his full measure of health, provided the mind be not overworked, and constitution and surrounding circumstances not absolutely deficient or adverse. The girl, on the other hand, is subjected to many artificial restraints and modes of education which militate strongly against the chance of her making a perfectly healthy woman. The diffusion of a knowledge of the principles on which health depends, has, of late years, tended to ameliorate many of the most injurious practices connected with the bringing up of girls, but many yet require to be corrected.

The bad results which are often brought about by the use of stays, have been so often exposed and condemned, that the subject has become almost hackneyed, and yet by a majority of the female sex the practice is still followed to an injurious extent. It seems as if people imagined that the Creator had made the body of the adult female so weak, that it can-

EFF

account, or without reason, they case it up in artificial supports. Even among the poorest the abuse extends; and girls of ten or twelve are kept from bending naturally by a stiff piece of steel stuck down the front of what, at least, stands instead of stays. True, these articles of dress do at last become indispensable, but it is only after the muscles of the frame have been weakened, in consequence of not being permitted to exert their appointed and regular action. Any muscle or set of muscles of the body, if not regularly exercised, become diminished both in substance and power; and the human framework or skeleton is so constructed, that the muscles with which it is furnished, and particularly those connected with the spine, preserve its equilibrium. Supersede these muscles by artificial support, and they become weakened; but as their artificial substitutes cannot act with the perfection of the natural supporters, the defect sooner or later shows itself; the unsupported spine gives way somewhere, and curvature, more or less, ensues. It would astonish most were they made aware how many curved spines there are; in how many, who even do not themselves suspect it, the deviation exists, and how often it is the occasion of impaired health, palpitation of the heart, hysterical and other affections. To the above assertion, it is only necessary to add the high testimony of Sir John Forbes, who says in a note to the article on "Physical Educa-tion," in the Cyclopædia of Practical Medicine: "We lately visited, in a large town, a boarding school containing forty girls; and we learnt on close and accurate inquiry, that there was not one of the girls who had been at the school two years—and the majority had been as long—that was not, more or less, crooked!" True, the whole of this enormous evil is not entirely due to the use of stays, but much of it is so, coupled with long-standing lessons, seats without backs, and too many hours devoted to the education of the mind, by which the constitutional powers, generally, are enfeebled. Moreover, the above spinal weakness is not the only evil consequence, for it is too often mixed up with disorders of the digestive and circulatory organs, originating in their compression by the clothing. The too prolonged hours of study inflicted upon girls have been alluded to, and are unquestionably a great evil, but they would be less so, were the hours of relaxation and exercise more rationally conducted. No exercise can be beneficial unless the mind be actively interested, or at least pleasantly occupied, during the time of exertion; but little good can result from demure walks, taken without interest, and almost without enjoyment.

Nothing perhaps is more certain than that, for the full development and healthy exercise of all the powers of the mind, a healthy body

not support its own weight; for either on this | mental manifestations in this world with a material organ, the brain, and this organ, like every other in the body, is dependent for its healthy action upon that of the other organs. It is evident then, that to preserve this wonderful instrument in the harmonious and vigorous exercise of its powers, the whole body must be in health; but modern fashion and fallacy, and many modern educationists, say no; let the body and instrument take care of themselves, our part is to elicit as many tones from the latter as possible, and elicit them they do, but they often sadly jar. Moral perceptions and acts, influenced by bodily disorder, often war with moral and religious precepts; the precept "slow to anger" cannot always control the irritabilities of a morbid nervous system, and the "not slothful in business" cannot at all times rouse the body oppressed by morbid and narcotising blood, to the active and vigorous discharge of its duties. As long as our abode is in this world, our bodies and minds must be in intimate relation, in action and re-action with one another; God has joined them, and man cannot dissolve the union, without paying the penalty of his transgression. A perfectly healthy mind is only compatible with a perfectly healthy body; and in civilised life, with its many causes of disorder, the latter can only be insured by attention to the laws of physical health and education. The mind, on the other hand, has its influences upon the physical health; but these will be considered in the article devoted to the subject.

EEL .- The eel, according to Letheby, contains fourteen per cent. of fat and nine of nitrogenous matter. It is much prized by epicures, but is hardly suitable for the sick.

EFFERVESCENCE is the rapid evolution of gas or vapour from a liquid; hence, boiling is effervescence; medically, however, the term is generally applied to the evolution of carbonic acid gas solely. Many mineral waters, such as Seltzer water, are effervescing, from containing the gas naturally; soda water and other effervescing drinks are impregnated with it by mechanical means, whilst in fermented liquors it is generated in the process of fermentation. In the practice of medicine, effervescing draughts are most frequently, perhaps, formed by the direct separation of the gas from one of the alkaline carbonates, such as the carbonate or bicarbonate-which latter contains the gas in greatest abundance-of potash, soda, or ammonia; the solution of bicarbonate of magnesia, or "fluid magnesia," is also used for the purpose. In many forms of illness, particularly those attended with thirst, no kind of medicine is so grateful to the patient, or so readily taken, as that which is given in a state of effervescence. If the stomach is irritable, and a tendency to sickness present, medicines given in this way are more likely to be retained, the carbonic acid apparently exertis required. The Almighty has connected our | ing a quieting and soothing effect upon the

EFF EGG

organ; at the same time, the taste of medicine one, the same precautions are not required. is considerably obscured by its administration by this method. When the tongue is much furred, and particularly in cases of sore throat, when medicine in any effervescing form can be swallowed, none appears to exert a more cleansing effect, in removing thick mucus and incrustations; and if it does this for the mucous membrane of the mouth, it will probably have the same effect on that of the stomach.

Some persons who are liable to suffer from difficulty of breathing, whether from asthmatic or other causes, and those who do not easily get rid of flatulence, cannot take effervescing drinks without inconvenience; this, too, occurs if patients to whom they are administered are confined to bed, and lie down too soon after taking the dose. A minute or two ought always to be allowed for the eructation of the gas, before a patient who has taken an effervescing draught resumes a recumbent position.

One of the alkaline carbonates above men-tioned being made of the effervescing agent, many medicines may of course be given in combination. The acids most generally and beneficially used to combine with the alkali, and set free the gas, are lemon juice, citric acid, and tartaric acid; they ought to be used in the following proportions: To thirty grains of bicarbonate of potash, a small table-spoonful of lemon juice, or twenty grains of either tartarie or citric acids. To thirty grains of bicarbonate of soda, about one fifth more of the above acids. To six grains of carbonate of ammonia, two tea-spoonfuls of lemon juice, or about eight grains of either citric or tartaric

So common has the use of effervescing draughts become, that the materials, soda and tartaric acid, and a measure for the purpose, are kept in many houses. The practice is not free from danger or injury, the continued use of soda being apt to impoverish the blood. the weakly it is of course more likely to prove

hurtful than to the strong.

The mode of mixing effervescing draughts which is commonly recommended is a bad one. The two powders are generally ordered to be quite dissolved in separate portions of water before mixing; the consequence is, the gas is evolved all at once; the violence of the effervescence-unless the glass is a very large one—is very liable to carry up and spill over a portion of the liquid, and the action subsides before the person can drink. All this may be avoided if the acid and alkali, in fine powder, are put dry into the glass, and the water poured slowly upon them from some little height. In this way the gas is more slowly extricated; there is no spilling, and, if properly done, full solution of the powders ought to be effected. If lemon juice is used, it should be mixed with the water, and poured upon the alkali in the same way. Of course, when the draught is a very small medicinal valuable. It may be combined with any

Soda and potash waters are now prepared domestically by means of the gazogene, a very convenient and useful appliance of the sickroom, by which the objections urged above can be easily avoided. A tea-spoonful of any of the fruit syrups added to the effervescent draught will prove in most cases agreeable. The use of effervescing forms of medicine has of late years become much more prevalent than formerly, and, as a consequence, we find many improvements introduced, by which various drugs are rendered not only more palatable if taken in the above state, but also more likely to sit easily upon the stomach. Thus, we have effervescing magnesia, iron, quinine, lithia, bismuth, &c.; also, the familiar lemon kali. Until these preparations were introduced, it was a necessity of effervescing preparations that the acid, whatever it might be, should be kept separate from the carbonated alkali until the moment the effervescing action was required, the water of crystallisation contained in salts, such as carbonate of soda, potash, &c., and also in tartaric or citric acid, being sufficient, though perhaps not apparent, moisture to cause slow decomposition and destruction of the effervescing quality. As in the well known lemon kali, this was overcome by depriving both alkali and acid, before mixing, of their water of crystallisation by heat; but even then moisture sufficient was attracted from the atmosphere to decompose the salts in time, owing to their being in fine powder. The process of "granulating," not long introduced, and now applied to many medicines, quite overcomes the defect, and, consequently, we have such medicines as the granulated effervescing citrate of magnesia, and others, which are found so convenient and so comparatively agreeable.—See Magnesia—Citrate of Ammonia
—Carbonic acid—Potash—Soda, &c.

EFFLUVIUM is a gaseous emanation or

exhalation from any body, generally of an offensive or noxious character. Effluvia is the plural. Refer to—Contagion—Disinfectant, &c.

EFFUSION is a medical term applied to the throwing out of an unnatural amount of fluid into cavities, or tissues, which ordinarily contain a small quantity only. Thus, the watery fluid which is thrown out into the chest in consequence of inflammation of the pleura or covering membrane of the lungs, is named an effusion. There are also effusions into the abdomen and in the head, also into joints and cellular tissue.

EGG of the domestic fowl, or of birds generally, as an article of diet, is one of the most nutritious; this is evident, indeed, from the

ELE

stimulant, such as brandy or wine, and sweet- | value as a curative agent has been generally ened with sugar, or it may be used with beef tea as a concentrated means of nourishment. The alimentary composition of the egg is not unlike that of butcher's meat. The white contains in 100 parts:

85 of Water. 12 of Albumen. 2 of Fat.

1 of Salts. While the yolk is constituted of-

511 of Water. of Albumen.
Of Oil and fat.

of Extractive matter.

11 of Salts.

The saline matter is rich in the various phos-

phates of lime, magnesia and iron.

The digestibility and nutritive conditions of the egg are considerably improved by its maceration in cold water for twelve or fourteen hours. The egg is broken into a basin as for poaching, cold water poured gently over it to some depth, and the whole allowed to stand for the above The egg may then be poached, fried, or beaten up. This form is very useful in diarrhœa.

In the preparation of medicines of an oily character, the yolk of egg is often advantageously employed, forming with them an emulsion which is miscible with water. Castor oil and turpentine are both advantageously given

by this method.

ELASTICITY is the power possessed by various bodies of returning quickly to the form from which they have been forcibly altered. India rubber, both in its natural and in its vulcanised condition, presents one of the most familiar and best examples. - See India rubber.

ELATERIUM is a medicine possessing most powerful drastic cathartic properties. It is obtained from the juice of the Momordica elaterium, or "squirting cucumber." plant is native to the south of Europe. It is a most valuable remedy in proper hands, but one much too powerful to be used with safety by unprofessional persons. The compound powder of elaterium is composed of one part of elaterium and nine parts of sugar of milk intimately mixed in a mortar. The dose is from three to five grains

ELBOW-JOINT.—See DISLOCATIONS—

JOINTS, &C.

ELECTRICITY and GALVANISM .-The employment of these agents in the investigation and treatment of disease has been greatly developed during the last twenty years. It had long been known that electricity pos-sessed properties allied in some degree with the manifestation of nervous force, but it was not till much new light was thrown on the subject by patient investigators, and by the construction of numerous new and ingenious instruments,

accepted.

The three forms in which electricity and

galvanism are employed are-

 Static, sometimes called Franklinic, after the name of its discoverer. This form of electricity is generated by means of a glass cylinder or plate, with a multiplying wheel, which with a handle is made to turn rapidly against a rubber of silk, and the electricity induced by the friction is conveyed to an insulated brass cylinder, called the prime conductor, and from thence to the person (who is seated on a chair with glass legs) by means of a chain or covered wire, the operator using a glass director fitted with a brass knob at its

extremity to administer the agent.

2. Faradisation, also named after its discoverer, but variously known as the induced, intermittent, interrupted and electro-magnetic current. The apparatus provided for its administration are various, and are furnished with means for breaking the continuous current from a galvanic battery, and producing a constant succession of shocks. A similar, though much slighter effect is produced with a horse shoe magnet, against which two coils of soft metal are made to revolve in a box worked from a handle outside, and which is known by the name of A better arthe magneto-electric machine. rangement was afterwards introduced in what is known as the galvano-magnetic machine, which for many years was, and is still employed for administering the induced or interrupted current. The battery, however, most in use by electricians for medical purposes, is that known as Stohrer's, as it is not liable to get out of order, and will retain its activity for a month or more without change. But perhaps the most convenient and certainly the most portable battery for private use, is one manufactured by Coxeter, of Grafton Street, which will remain good for a couple of years, with careful handling. The illustration (fig. 83) gives an idea of the construction of this battery, the leading feature of which is, that it is worked without acids, and is always ready for use.

3. The Galvanic, continuous, or silent current, is simply developed by the chemical decomposition of an acid upon two different metals. There are also many varieties of this battery; those best adapted for medical purposes are Daniell's, Muirhead's, Smee's and Leclanche's. The improved portable Leclanché battery is the best apparatus of its kind yet introduced. By the substitution of agglomerated cells in the battery in place of porous cells, the apparatus gains three or four times in activity, and is reduced proportionally in bulk, since the smallest size of the agglomerated cell is fully equal in strength to the largest size of the old porous cell. For the conduction either of the intermittent or the continuous current, copper wires of convenient length are attached for its administration, that its importance and | to the batteries, insulated from the operator by

wooden handles, to the extremities of which | under the direction of a medical man or sponges in direct communication with the wires are attached for topical application. When re-

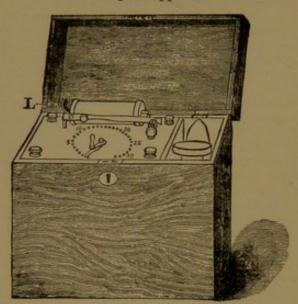

Fig. 83.

quired, the sponges are moistened with warm salt water, to aid the penetration of the electric current through the skin to the tissues beneath.

The medical uses to which electricity is applied, may be classified under those intended for the diagnosis or discovery of the true nature of nervous disease, and such as refer to its curative properties. In the former case, both currents are employed to discover the amount of loss of power in a muscle or group of muscles of any part, either from paralysis or injury, the constant current frequently responding by the manifestation of muscular action, when the induced current fails to elicit it. In cases of feigned disease or malingering, electricity is often of great service, especially where attempts are made to excite sympathy by simulating paralysis. In persons suffering from ideal influences, such as loss of voice, or aphonia, the application of electricity has often been known to restore speech in a miraculous manner. The diseases in which electricity has been found most useful, can only be enumerated They comprise infantile and local paralysis, the paralysis induced by lead, loss of sensation in the nerves of special sense, unless such is accompanied with organic lesion, neuralgia, especially that affecting the face and known by the name of tic-doloureux, sciatica, lumbago, and some forms of chronic rheumatism. In the majority of cases, the continuous galvanic current will be found more effective than that induced by faradisation, but it should always be remembered that electricity is one of the most powerful agents we possess, and that it must not be rashly tampered with. Its appli-cation requires considerable skill, as well as knowledge of the anatomy of the parts subjected

experienced electrician.

Other forms of electricity used in medicine are the high frequency current, the electro-cautery, and the Röntgen or X-rays. The various uses of these are too technical to be described in a work of this character. They form valuable additions to the resources of the physician and surgeon.

ELECTUARY.—a medicinal preparation

made of sugar. - See Confection.

ELEPHANTIASIS is a name applied to two very distinct forms of disease. One in which a limb (usually of the lower extremities) obtains gigantic proportions in consequence of the thickening of the skin and subjacent tissues; and the other the true leprosy of the ancients, of the Middle Ages, and of our own time. The first is often called Barbadoes leg, as it was frequently seen among the natives of Barbadoes; the other seems now to be limited to hot climates, where it is shown to be hereditary among the population. True leprosy, or elephantiasis of the Greeks, is characterised by a shining tubercular condition of the skin with a tendency to ulceration and sloughing. The disease is very chronic, and the victims of it are reduced to the most pitiable mental and physical

ELM-BARK, from the well-known tree, has been used as a remedy in skin diseases, especially in lepra and psoriasis; it is also slightly tonic and astringent. The decoction is made with two and a half ounces of the bark

and a pint of distilled water, and the dose is from three to four fluid ounces.

EMACIATION is wasting of the tissues so that the body becomes thin. The process of emaciation, however, is very different from simple diminution of bulk; the latter may take place whilst the appearance of health is still retained; but with true emaciation, the skin and aspect generally present an unhealthy appearance. There are few diseases which are not accompanied with loss of flesh or emaciation, and it is not unfrequently the first observable symptom. Sir Thomas Watson remarks:-"It occurs in complaints that are not commonly dangerous—as in dyspepsia, and in hypochondriasis, which is often connected with dyspepsia; and when it does occur, it marks the reality of the disease." It is a good plan, now often pursued by medical men, to weigh at stated intervals a patient, who complains chiefly of wasting, in order to test the effect of remedies and of the progress of the disease. This wasting happens in many fatal maladies — in pulmonary consumption, for example, and in dropsy, although the dropsical enlargement sometimes masks it. companies many acute diseases, and is reckoned an unfavourable symptom: for it shows that the body is not properly nourished. Sometimes to its influence, and it should only be employed | the emaciation is so extreme that the integu-

ments give way-the bones of the patient are | hæmorrhage great, it might even be advisable said to come through his skin.

Refer to-Atrophy

EMBROCATION .- A fluid applied with friction to any portion of the body. - See Lini-

EMERGENCIES.—We intend this term to denote such occasions as are liable to happen in the experience of every one, when it is necessary, in the absence of medical assistance, to use one's own judgment promptly and judiciously in rendering what aid one can in the circumstances. Such events arise in cases of injury from accidental causes, in persons subject to fits, in cases of sudden hæmorrhage, in drowning, poisoning, and in insensibility from a multiplicity of causes. It ought to be borne in mind, however, that more harm than good is often done by injudicious meddling in circumstances which might appear to warrant interference, and that he or she who has the courage to let well alone, and to persuade others to do the same, displays more medical skill and foresight than the industrious busybodies, armed with an infallible remedy for every ailment that afflicts humanity. As the occasions referred to are treated at length under separate articles, it is only necessary in this place to point out a few of the more prominent, and to indicate briefly the best course to adopt under the circumstances of each.

1. Injuries. - In the event of a person sustaining a serious injury, he should be laid flat on his back, with his head slightly raised; all constrictions in his clothing-such as necktie, shirt-collar, waistcoat, and trowser-band
—should be undone. If possible, the seat of
the injury should be sought for, and the clothing removed from it; and if there is less of ing removed from it; and if there is loss of power in one or more limbs, it may be assumed that the patient has sustained a fracture or dislocation of one or more bones, and it is advisable to retain him in the horizontal position in the course of his removal to his home

or the hospital. - See Ambulance.

2. Hamorrhage. - Supposing that the patient has received a wound from which the hæmorrhage is great, and there is no surgeon at hand to control it, it becomes the duty of the bystander to have recourse to his own ingenuity to check it, and this he can best do by planting the front surface of his thumb on the spot from which the blood is issuing, and retaining it there until a more efficient substitute for a compress can be had. The best and readiest form of compress would consist of a coin, say a penny, enveloped tightly in several folds of linen rag, placed over the mouth of the bleeding artery or vein, and kept firmly in its place by means of a handkerchief tied round the limb. Such an arrangement answers well in the case of a punctured wound which bleeds much, or in a ruptured varicose vein, and is usually successful in checking the hæmorrhage.

to extemporise a tourniquet by means of a handkerchief or bandage, in which case the compress above referred to must be placed over the main artery above the wound, and retained firmly there. This operation, however, could scarcely be had recourse to unless the operator was sufficiently conversant with the route of the vessel, and its anatomical relations. Hæmorrhage from an artery is always more to be dreaded than hæmorrhage from a vein. The blood in the former case is known by its bright red colour, and from its issuing from wounds in jerks corresponding to the beats of the pulse; while venous blood, on the other hand, is of a dark purple colour, and comes away in a full continuous stream. Should there be no fracture of the limb, it is advantageous in staying the hæmorrhage from a wound, to raise the part above the level of the body, to lessen the force of gravitation. This remedy is usually successful in bleeding from the nose, in which case both arms should be raised above the head, and retained there for several minutes, or until the hæmorrhage ceases.

3. Burns. - One of the most common accidents which an ordinary person has to en-counter is a burn or scald, and no time should be lost in discussing which is the best applica-tion. The main object is to exclude the air from the wound and to relieve pain, and this is best done by soaking a piece of lint in carron oil, spreading it over the surface of the burn, and laying a layer of cotton wool over the dressing, the whole being kept in its place by

a lightly applied bandage.

4. Collapse. - When there is much collapse or shock from the accident, or faintness from hæmorrhage, it is usually advisable to administer a table-spoonful of brandy and water from time to time; but in injuries to the head and insensibility from fits or other causes, stimulants should be avoided. The chief causes of sudden insensibility are due to injuries of the head, apoplexy, epilepsy, drunkenness, narcotic poison, and to heart disease; and unless the consequence of an accident, there is no single symptom in any of these occurrences which the bystander can rely on as indicative of the malady at fault. Nevertheless, something may be done before the doctor arrives, even if it be only to check injudicious meddling.

5. Convulsions. - In all cases of fits and convulsions, the patient should be allowed to remain on the spot where he has been smitten down, unless necessity renders his removal imperative, and all constrictions of clothing from the neck and chest should be at once undone, so as to give free play to the lungs. Means ought to be taken to prevent the person injuring himself, by the sudden contortions to which the body is subject in convulsions; and if there Should the wound be large or lacerated and the bite the tongue, a piece of wood, cork, leather, is much gnashing of the teeth and tendency to

EME EME

or handle of a spoon, if nothing better can be | into the circulation; thus, vomiting may be had, should be placed between the teeth, while all attempts to make the patient swallow any thing should be summarily condemned, as in all probability it would choke him. The case is different with children who may be suffering from the convulsions caused by teething, in which little harm, or rather, much good, may accrue from the child's being at once immersed in a hot bath, at a temperature of 98° Fahr., and retained there for ten minutes or a quarter of an hour.

6. Poisoning. - When there is little doubt of the insensibility being caused by drunkenness or a narcotic poison, such as opium or belladonna, or where there is no doubt poison of some kind has been swallowed, attempts to cause vomiting should be made at once. This can be most readily done in domestic life by administering about half a table-spoonful of mustard in half a tumbler of water, followed by copious

draughts of warm water.

7. Symptoms generally.—Violent fits are indicative of some injuries of the brain, of hysteria, of epilepsy, and sometimes of drunkenness; while convulsions of a less severe type are noticed in apoplexy, most head injuries, and in teething in children. The sudden cessation of the circulation in heart disease is so rapidly followed by death, that the condition may be looked on rather as one of fatal syncope than insensibility, and no action can be taken under the circumstances. Simple giddiness often precedes more violent symptoms, but it more frequently occurs alone, and indicates something amiss with the stomach and bowels which requires rectification. There are certain symptoms which, allied with others, help materially in aiding diagnosis in cases of insensibility—to wit, the condition of the pupil of the eye, and the pulse at the wrist. In apoplexy, the pupils are usually dilated and fixed; in disease or injury of one side of the brain, they are unequal in size; and in simple congestion, they are as a rule contracted. The pulse again is always weak and sometimes imperceptible in shock from injury, collapse, and in hæmorrhage, irregular in heart disease, and slow in cases of apoplexy, and in other diseases producing insensibility by pressure on the brain. In nearly all cases of insensibility, whether arising from disease or injury, the recumbent position, with the head slightly raised, is the best for the patient; cold applications to the head and warmth to the body, especially to the feet, are also indicated in the vast majority of cases. Drowning and other causes of insensibility and sudden death are noticed in separate articles .-See Ambulance—Wounds—Fractures—Burns and Scalds—Hæmorrhage—Emetics, &c.

EMETICS are substances which excite vomiting; that is, which cause the stomach to be forcibly emptied of its contents by the mouth, and which do this by a peculiar action, exerted either directly upon the organ itself, or in consequence of their having been taken emetic substance has come into action; if this

excited by the injection of some emetic substances into the veins.

Many agents are capable of exciting vomiting, which are not classed as emetics, such as nauseous tastes or smells, swinging motions, such as that which causes sea sickness, mechanical irritation of the throat, &c., but these causes are very different from the specific action of a true emetic, which acts indepen-dently of taste or smell. Emetics constitute a class of our most valuable remedies, although not so indiscriminately and extensively used as they were formerly. In ancient times, particularly among the luxurious Romans, emetics were commonly employed for the disgusting purpose of enabling them to disgorge one luxurious meal as soon as swallowed, that they might immediately begin with another. "Cicero, in describing a visit paid to Cæsar at a villa near Rome, states that Cæsar paid him the high compliment of taking an emetic before dinner, when he understood that Cicero intended to spend the day with him.'

The most generally used and most useful

emetics are-

Sulphate of alum. Antimony. Sulphate of zinc, Ipecacuanha. or white vitriol. Mustard.

Salt is sometimes used as an emetic; and the mechanical irritation of the throat with a feather or piece of rolled up paper is often resorted to with benefit, for the purpose of exciting vomiting. The reader will find further information respecting the above emetics under their individual articles.

Of sulphate of zinc thirty grains in a little water should be given to an adult; of sulphate of alum, a teaspoonful; of mustard, half a tablespoonful mixed with half a tumbler of water. For children one or two teaspoonfuls of ipecacuanha wine every ten minutes usually act. A little time, five to fifteen minutes, according as the state of the stomach is empty or full, often elapses before vomiting occurs. The first sensation is one of nausea, accompanied with flow of the saliva, slight faintness, and cold perspiration; at last, the effort of vomiting supervenes, and the contents of the stomach are ejected. As soon as actual vomiting commences, as a general rule, but not before, some tepid fluidwater, gruel, chamomile tea, or such like —should be given in moderate quantity, not exceeding half a pint at a time. A slight caution is requisite upon this head, for occasionally individuals, under the action of an emetic, are encouraged to drink very freely of fluid and to distend the stomach. This is not well, for it not only embarrasses the action of the organ, but might cause its being lacerated or burst. It is also requisite to caution against giving the diluent fluid too soon, that is before the specific power of the EME EMI

is done, the dilution will either delay, or altogether prevent the desired effect. When there is much debility of stomach, it is better to choose for the diluting fluid a bitter, such as chamomile tea, which has the additional advantage of being itself emetic. As a general rule, the mineral act more quickly and violently than the vegetable emetics; for this reason the former are generally selected in cases of poisoning, such as that by opium, in which there is some difficulty in rousing the stomach to action at all, and in which it is important that it should be relieved of its contents as speedily as possible. In such cases medical men may give the sulphate of copper; but for the unprofessional, the sulphate of zinc, or white vitrol, is the safest, and is a

nearly equally efficacious remedy.

When there is much fever, and in some forms of inflammation, the salts of antimony, particularly tartar emetic, are most generally used if emetic action is desirable. As a simple emetic to relieve the stomach, and also in cases of chest affections, ipecacuanha will be found the best. In diseases of depression, mustard is most useful; and carbonate of ammonia may also be employed alone, or combined with ipecacuanha. In cases where the power of swallowing is lost, medical men can excite vomiting by the injection of emetic substances into the veins. This practice, of course, cannot be followed by the unprofessional, yet they may safely, and with much certainty of success, have recourse to mechanical irritation of the back of the throat, either by the finger or by a feather. A few individuals possess the power of spontaneous vomiting, or at least of exciting regurgitation of the food from the stomach into the mouth; a process somewhat analogous to the rumination of animals. Such persons usually suffer from dyspepsia, and have recourse to the operation to free the stomach from food it cannot digest.

The evening is generally the most suitable time for administering an ordinary emetic, as the stomach has time to recover itself during the night, and the uncomfortable nausea which

often follows is less felt.

Emetics are used to fulfil various indications, the most direct and obvious being the emptying of the stomach of any noxious substances, either formed within the body, such as bile; or taken in by the mouth, as indigestible food or poison. Fortunately, these matters often of themselves excite vomiting, but in many instances they do not sufficiently empty the stomach, in which case the action must be kept up, or re-excited, either by a diluent or by some emetic medicine. It must be remembered, however, that in the case of some poisons it is not desirable to dilute largely. In addi-

mechanical effect, or "shock," of an emetic, was believed to have the power of checking fever and other diseases at their outset; it is not now, however, much trusted to by medical men, and if it does not do good, is apt to prove injurious, by causing an irritable condition of the organ, which may continue throughout the disease. In many cases of incipient disease, however, characterised by depression, coldness of the skin, &c., the mechanical action of a smart emetic of ipecacuanha, either alone, or with five to eight grains of carbonate of ammonia, is most beneficial, by rousing the system, and removing the tendency to internal congestion, or accumulation of blood. Another, and most beneficial, mechanical emetic effect, is in the case of children suffering from affections of the chest, with accumulation of mucus, or phlegm. Children cannot expectorate, and are liable to be suffocated if the phlegm is in large quantity, and cannot be removed; nothing ensures its removal so effectually as an emetic, or rather emetics, repeated from time to time-every few hours-according to circumstances. In cases of jaundice and overloaded liver, the mechanical action of emetics is often beneficially had recourse to. In chronic bronchitis and some forms of consumption, the periodical exhibition of emetics has been used with advantage. In spasmodic diseases, either general, as hysteria, or local, as in spasm of the stomach, emetics are beneficial; in the latter case, often, of course, by freeing the stomach from the offending cause of the disorder. In asthma, they often relieve when nothing else will.

Emetics are not always safe remedies; in pregnancy, in persons of very full habit, parti-cularly if there is determination to the head, in rupture, in falling down either of the bowel or of the womb, vomiting should, if possible, be avoided. The ancients held the opinion that emetics strengthened the stomach, and they were even used in the training of the athletæ; modern experience certainly does not uphold the fact, for the habitual use of these agents assuredly injures the tone of the organ,

and weakens its power.

An error is frequently committed in using antimonial, or, as it is called, "antimony wine, as an emetic; it is far too depressing for general purposes. For these, ipecacuanha is the safest agent of the class; an adult requires ten to twenty grains of the powdered root; a child one to four grains, mixed with a little water.

EMIGRATION .- For those who leave their native country and go to seek a home and fortune in other lands, one thing is essential to success. Invaluable to all, health is to the emigrant a necessity; it is to him a capital tion to their power of emptying the stomach, emetics are valuable from the mechanical effects, both general and local, which they exert upon the body. Formerly, the general Many are undoubtedly too poor and too ignorof more than money value; and yet this foundation of future fortune, nay even of existant to profit by counsel even when it is given, generally agreed upon, that, however good an but thousands annually leave the shores of Britain as emigrants, who are capable of acquiring and acting upon useful information concerning matters of health; and how few, comparatively, have even a slight acquaintance with the laws which regulate their being, on the observance of which their health and usefulness depend; how few are capable of acting intelligently and promptly under the occurrence of those accidents and contingencies which it must often fall to the lot of the emigrant to encounter! Into the hands of some who meditate emigration these pages may fall; to them the author more particularly addresses

The first thing to be considered must be, not whether gold is to be extracted from the river sands in one place, or corn is to be grown without exertion in another, but the question should be, What is my constitution? What are its tendencies, hereditary or acquired? To what climate is it most adapted? Will it endure the hot summers and severe winters of America, or will these probably develop the consumptive tendency I inherit? Is it not more suited for Australia or New Zealand?—are not my children more likely to be reared in the one climate than the other? These and numerous other considerations connected with the adaptation of constitution to climate and probable occupation, ought to hold the chief place in the decision as to emigration. That being decided, the next is the preservation of health during the voyage. As far as circumstances will permit, a vessel should be selected which guarantees sufficient room, ventilation, supply of water, and fresh food. The various Emigration Acts have done much to succour the friendless emigrant from numerous hardships and discomforts which at one time were notoriously associated with the passage out, whether to the old world or the new. The Emigration Commissioners are enabled to grant free passages to those colonies in want of labour, and which are willing to provide necessary funds for the purpose, and Boards of Guardians at home are at liberty to raise money for the same purpose under the authority of the Local Government. Space will not permit, in a work like the present, the detail of all those means and measures which the intending emigrant should adopt as regards health: much information on these points he may gather from the various *Emigrant's Guides*, particularly those of the Messrs. Chambers; and further, he is referred to the various articles in this Dictionary, which treat of matters connected with the preservation and regulation of health, more particularly Ague, Bed, Climate, Clothing, Consumption, Food, Medicines, Venti-lation, Water, &c. These and others contain many hints which will be found valuable, both in the selection of the future home, and of the mode and means of transit. One thing is at home, and the facilities and demand for

emigrant ship's dietary may be, it is always advisable for the passengers to add a private one, of such concentrated foods as means will allow-common cabbage will do, preserved in vinegar-which may afford a supply of the vegetable acids, the best counter-agents to the effects of the salted provisions which necessarily form a large proportion of the food on board ship: a few bottles of lemon juice are always a valuable addition to the sea store.

As regards clothing, it is unnecessary to repeat here what is said in the article on that subject, but it may be mentioned, that emigrants who probably have to encounter exposure on first landing in their adopted country, would do well to provide some cheap water-proof material to place beneath them at night. An attack of rheumatism is an unfortunate, and often, when once acquired, too constant companion of the emigrant, and may cripple him permanently. Those who have to undergo the confinement which a long voyage must entail, most especially require to attend to all the laws of health, and particularly exercise, which, from the small walking space on board ship, is often neglected; it should be a carefully observed rule to walk for a certain time daily.

The amusement of the mind is a matter of much importance, even in a health point of view, for those exposed to the monotony of a long sea voyage; happy are those to whom books afford their never-failing resource, and the time might be worse employed than in the perusal, or rather study, of works like the pre-sent. When the new scene of labour is reached, the opportunity will be past, but the man who has acquired for himself information which may enable him either personally to avoid, or, in the case of others, to counsel the avoidance of sources of disease, or to act intelligently and promptly in cases of sudden illness or accident, may have reason to bless the, perhaps otherwise wasted, time spent in the acquisition of the principles of Domestic Medicine, or of Household Surgery.

After landing in his new country, the emigrant ought to inform himself as far as possible respecting the occurrence and causes of illness, either in the one district of his residence, or in those he may have to pass through.

As said at the commencement of this article, health is, next to trust in God, the essential, and it cannot be too jealously guarded by the emigrant, to whom its loss is ruin and misery. For information respecting medicines, the emigrant reader is referred to the article.

"Although emigration is now universally looked upon as the best means of disposing of a surplus population, it is clear from the returns published by the Board of Trade, that its ebb and flow depend on other causes than the numerical increase of the people. The deficiency of employment, coupled with bad harvests,

fluence more than any other cause the stream of emigrants from the mother country. is especially the case with respect to emigration to the United States, which swallows up the larger proportion of the emigrants from the United Kingdom, and nearly all the Irish who leave their country. No incident connected with our history lent a greater impetus to emigration than the potato blight and consequent famine in Ireland, which occurred in the memorable years 1846-47. The same influence, though less severe, was felt in other parts of the United Kingdom, and raised the total annual emigration to a height which it had never reached before, averaging till about the close of the Crimean war 200,000 a year. After this time (1857) the exodus began to decrease steadily till it reached in the year 1861, a minimum of 65,197, the smallest return since the famine year. The year 1861 coincided with the beginning of the Civil War in North America, which no doubt deterred many from carrying out their intentions of emigrating there, but after a few years the flow kept pretty steadily increasing until 1873, when the numbers who left these shores for various quarters of the globe amounted to 228,345. After this time it diminished again, in consequence, it was thought, of the great American railway panic, until the year 1877, when the total emigrants from the mother country numbered 95,195. During the two years 1879-80 there has been again a very considerable increase in the number of emigrants from the ports of the United Kingdom, the number for 1879 having amounted to 164,274, and in 1880 to 227,542. The great labour market of the United States absorbed no less than 73 per cent. of the emigrants in 1880, induced there by a succession of good harvests and ample employment, and discouraged by a couple of years marked with bad harvests in Britain. The colonies of Australia and New Zealand come next in order of preference, after which our possessions in North America, which, doubtless, when they become further developed, will offer attractions to the emigrant equal to those of the United States."

EMMENAGOGUES are medicines which exert, or are supposed to exert, their action upon the womb, and to promote the menstrual discharge. The only well-known medicinal agent which exerts an undoubted specific action of the kind, is the Secale cornulum, or ergot of rye (see Ergot). The Actaa racemosa is akin somewhat in its action to ergot (see Actaa). Some medicines seem to exert their influence upon the womb by stimulating neighbouring organs, to this class aloes, colocynth, and other strong purgatives belong; others, such as valerian and assafætida, by their action on the nervous system; and another set, such as iron, by their tonic influence upon

labour abroad, at given intervals of time, in- | in which emmenagogues are required, a combination of iron with aloes, will prove the most effectual means of stimulating the womb.

Refer to-Menstruation.

EMOLLIENTS are remedies which possess the power of relaxing and softening parts to which they are applied. Heat and moisture, and oil or fatty matters, are the chief and best emollient remedies.

EMPHYSEMA means the presence of air in the cellular or connective tissue of any part of the body, and when the part is in fault it is said to be emphysematous, though the term is now almost entirely applied to a dilated or ruptured condition of the air cells of the lungs, which condition materially interferes with the natural process of respiration. The disease is brought on by repeated attacks of bronchitis, of which it forms afterwards a troublesome complication. It is also induced by violent respiratory efforts, and is a common consequence of asthma. The symptoms are shortness of breath on exertion, and much less chest movement in respiration, the lungs being unable to perform their proper complement of work, in consequence of the dilated condition of the air cells, the person affected becomes short-winded, and the blood is deprived of its free oxygena-The lips and face in consequence become livid, and the person is apt to have a tendency to lean forwards, and after a while to become round shouldered. Emphysema of the lungs is extremely common among cabmen and others addicted to drink, although it is not at all an unusual disease both among men and women who lead most abstemious lives.

The treatment to be pursued must be both general and medicinal. A person liable to emphysema will usually take care not to expose himself to the raw night air, and should have a fire in his bed-room in cold weather. He ought also to provide himself with a respirator, if he is forced to face cold foggy weather, and adopt the same means as those recommended generally for bronchitis, with which disease this complaint is closely allied. When it comes on in paroxysms, it is useful to employ one or other of the numerous antispasmodics recommended for asthma, as, spirits of chloroform in doses from twenty to thirty minims, ether spirit to the extent of thirty to forty minims, or the etherial tinctures of lobelia, belladonna, or conium.

Dr. Coghill's new inhaling respirator is now one of the most efficient aids in the treatment of bronchitis and bronchitic asthma, with emphysema. By its means a patient can, without fatigue or trouble, inhale for hours whatever medicament is considered best. Eucalyptus oil; compound tincture of benzoin, with or without henbane; or spirit of chloroform or creasote, and others, may all be inhaled in this

way with much advantage. - See Inhalers. the system at large. In the majority of cases subcutaneous tissues, sometimes follows upon

EMP ENE

the bone penetrates the lung. In this case, with every breath expired, air passes from the lung into the cavity of the chest, from whence it finds its way through the wound made in the walls of the cavity, and by this means becomes diffused through the cellular tissue; the features and the whole body become greatly swollen, and when the surface is indented by the finger, a crackling sensation is experienced. The mere distension of the cellular tissue is not a circumstance of so much importance as the accident which gives rise to it, but in those perfectly unaware of the possibility of such an occurrence, the appearance presented by the affection would cause much alarm: of course the broken rib itself should be attended to; the emphysema may be relieved by punctures made in the skin by a lancet, and by the application of bandages.

Refer to—Bronchitis—Fractured ribs, &c.

EMPYEMA is one of the results of inflammation of the pleura, in which suppuration occurs, and the matter has a tendency to gravitate towards the lower part of the chest walls. When there is reason to suppose from the results of a careful physical examination, and from other symptoms indicative of chronic pleurisy, that matter is confined in the space between the lung and the skin, the surgeon has recourse to the operation of tapping, or as it is called paracentesis thoracis, by which the imprisoned fluid may be allowed to escape; and after its discharge, he introduces a drainage tube into the wound to permit the escape of more matter. In severe empyema the surgeon (with aseptic precautions) usually makes a free opening into the pleural cavity, cutting out, if necessary, part of a rib; after the matter is removed a drainage tube is inserted, and kept in the opening covered with antiseptic dressings until the cavity heals by granulations or adhesions. - See Aspirator.

Refer to—Inflammation of the Lungs. EMPYREUMA is the peculiar and often offensive smell which many substances acquire after exposure to considerable heat in close ovens or vessels. The fact of an article of diet having an empyreumatic odour, renders it unwholesome and irritating to the stomach; on this account, baked meats, pastry, &c., are more apt to disagree than the same articles

roasted or boiled.

Refer to—Baking. EMULSION is a mixture of oil with water by the intervention of a third substance. This may be effected by means of gum mucilage, syrup, &c., but perhaps the best agent for forming emulsions, is the yolk of egg. The oil forming emulsions, is the yolk of egg. must first be rubbed up with the yolk, and then, distilled, rain, or perfectly soft water added gradually. Milk, which is itself a natural emulsion, is also a very good agent for uniting some oily, or such like matters resembling the oils in semposition with vector particular. uniting some oily, or such like matters resembling the oils in composition, with water, parti- formerly the only method used, is still em-

> ENAMEL.—The outer hard casing of the teeth. - See Teeth.

> ENCEPHALON—a medical term employed to designate the parts generally contained within the skull.

ENDEMIC is a term applied to diseases which are peculiar to, and persistent in, certain districts or countries. Thus, ague is endemic in marshy districts; bronchocele or goitre where the water is impregnated with magnesian limestone; and cretinism in the low dark valleys of Switzerland. These and other endemic affections are undoubtedly due to natural peculiarities of soil and climate; but their power is unquestionably much augmented by the privations attendant on poverty, and by the depressing influence of dirt and vice; or, as in

the case of bronchocele, by laborious lives.

Besides naturally caused endemic diseases, there are others which may equally be called endemic, though arising from the artificial circumstances which have hitherto been attendant on man when living in community; such are the fevers of our large towns, which are so constant in their operation in particular localities, as truly to merit the name of endemic.

In many situations, the constitutions of the natives of districts in which endemic influences prevail, appear to become habituated to, or proof against, the morbific causes, which are quickly productive of disease in strangers. Such is strikingly the case in the rivers of the African coast; and the Niger expedition afforded melancholy proof of how fatal to Europeans a climate may be, in which the natives live with comparative impunity. In many cases something is due to the adaptation of habits and modes of life by the inhabitants, which are either unknown to or neglected by strangers.

Refer to—Climate—Epidemic, &c. ENDERMIC .- See Hypodermic.

ENEMA, INJECTION, or CLYSTER, are all names for the same useful adjunct to medical treatment, the mechanical injection of fluid into the bowels by the rectum. Injections are most commonly employed as aperients, but they are also used as anodynes, or antispasmodics, for the purpose of dispelling wind, or as internal fomentations, or as styptics. One of their chief uses is the administration of nutriment when the passage to the stomach is obstructed. In illness they are generally administered to the patient by others, but instruments are constructed to facilitate their selfadministration, which is of course preferable when, as frequently occurs, they are often required in ordinary health.

The mechanical means used for the administration of injections are very numerous, one of the simplest is the vulcanised india rubber bag

ENE ENE

ployed in country districts, and though clumsy, may be had recourse to on an emer-Of late years the syringe most in favour has been Higginson's enema syphon, in

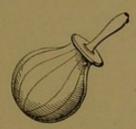

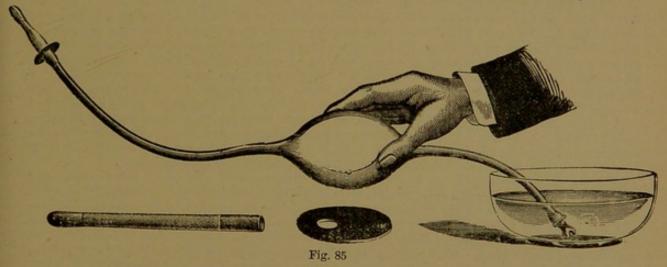

Fig. 84.

which a vulcanised india rubber ball takes the place of the metal syringe, and the fluid is forced by hand pressure through the tube into the rectum. is made in one piece.

the injection to be administered much exceeds half a pint in quantity, when it is used as an aperient, and requires to be forcibly injected. When the enema does not exceed half a pint, as in the case of children, or when used as an anodyne or styptic, the vulcanised india rubber bag (fig. 84) is quite the most convenient mechanical agent, from its simplicity and the ease with which any one may use it. Suitable instruments may be procured good from any respectable maker of surgical instruments, and directions are, or ought to be, given with them. When an enema is administered to the sick, the patient may either be laid on the face or on the left side, near the edge of the bed, with the knees drawn up. The bone or vulcanite pipe which is introduced into the bowels should be well oiled or greased, and its introduction Another useful form is that should be effected with perfect gentleness, not manufactured by Messrs. Ingram, figured in straight up, but in a direction slightly inclined the accompanying illustration (fig. 85), which towards the back bone, care being taken that made in one piece.

The injection syringe is most useful when occasioned; this is a most necessary caution

in all cases, but more especially in those in which repeated use of the remedy will probably be required. Even with the greatest care, the parts are liable to become sore, causing the patient both to dread and suffer each time the instrument is used, and even to be unable to bear a continuance of the practice. In all cases an enema should be given slowly and gently, and care taken that air is not thrown up into the bowel as well as fluid; with the syringe, this is to be avoided by pumping it full of fluid, before it is applied to the patient, and by not continuing the operation when the fluid used gets so low in the basin as to allow air to be drawn in; with the bag, care should be taken that it is quite full, and that the pipe end is held upwards until placed in the bowel. When self-administered, the sitting posture is the most convenient. When the syringe is used, if the flexible tubes have been kept bent in one position, they should be slightly wermed in one position, they should be slightly warmed before any attempt is made to straighten them

they are apt to crack. If an instrument has been used for anything but simple water, it ought always to be well washed out with warm water before putting by. When taken to pieces it must always be unscrewed by the hand holding the metal mountings.

Enemas, self-administered, can be done most

conveniently by means of the syringe.

Aperient injections may be simply mechanical, of water, gruel, and the like, either cold, tepid, or warm, or they may be medicated. There is an objection to enemas of simple water, that in some cases they are apt to wash off the natural protecting mucus of the bowel, and therefore it is perhaps better as a general rule, and where the remedy is often or habitu ally used, to employ a demulcent, such as gruel or barley-water. Cold enemas, sometimes use ful, ought never to be resorted to except by medical direction; the fluid about the temperature of 90° will generally be found most approfor use, otherwise, especially in cold weather, thrown up slowly, but with sufficient force, priate, and when used simply, about a quart

will be found a suitable amount for the generality of adults. Some use a much larger quantity, as much as two or three quarts; this, in certain cases of illness, may be a useful measure, but as a habitual thing is bad; the frequent over-distension with so large a quantity of warm fluid, produces want of tone, which aggravates the torpid tendency of the bowels, and favours fæcal accumulation. For a child of six years of age, half a pint of simple gruel injection is ample. These simple enemas act by stimulating the bowel by their mechanical bulk; when a medicinal injection is used, or when food such as beef tea is given by the rectum, the object is in some degree to avoid this, so that the agent may not be expelled before it has time to exert its peculiar agency. The medicinal or nutritive injection ought, therefore, as a general rule, to be small in quantity, not exceeding two or three ounces.

The most convenient medicated aperient enema is made, either with a table-spoonful of common salt in a pint of gruel, or with a piece of brown soap, the size of a hazel nut, rubbed down into a pint of warm water; or instead of these, from half an ounce to an ounce of Epsom salts, or two ounces of olive oil, or half that quantity of castor oil; or infusion of senna, half an ounce of leaves to the pint, may be employed. Stronger enemas, with turpentine, croton oil,

&c., are also used by medical men.

Anodyne injections ought always to be so small in bulk—not exceeding three fluid ounces -as not to stimulate the bowel to expel them, which, from the nature of the cases in which they are usually given, it is apt to do. In all cases, anodyne injections are most conveniently administered by means of the vulcanised bag, and the best form is from fifteen to twenty-five drops or more of laudanum in three ounces of moderately thin starch. This enema is of course to be retained in the bowel if possible. One of the most useful injections for dispersing flatulence, is made with two drachms of tincture of assafœtida to half a pint of gruel, to which, if there is much pain, ten or fifteen drops of laudanum may be added; or the same quantity of assafætida tincture may, if required, be added to an aperient injection. Injections used for the purposes of internal fomentation may be given to the amount of a quart, and of a temperature of 98° or 100°.

Nourishing injections are usually composed of strong beef tea with yolk of egg beat up in it, and to which port wine or brandy may be added. As it is an object to retain the fluid in the bowel as long as possible, not more than three or four ounces should be thrown up at one time, the operation being repeated every

few hours.

In hæmorrhage from the lower bowel, when it is proper to interfere with it, a two or three-ounce cold styptic injection may be used, made with sulphate of zinc four grains, or sulphate of iron one grain, to the ounce of fluid.

ENTERIC, TYPHOID, or GASTRIC FEVER.—These three names apply to one and the same disease, than which there is none more dangerous and subtle. It may run its course mildly, without the development of any bad symptoms whatsoever, beyond the ordinary manifestations of a slight feverish attack; it may be attended by the gravest symptoms, so as to threaten life, at any time during its course; or, lastly, it may appear to be running on to a favourable termination, when, suddenly, a relapse declares itself, and the patient is speedily again in the greatest Severe cases of this disease were formerly confounded with typhus fever; while mild cases were generally called gastric fever. Still later, its striking analogy to typhus, led some medical men to give it the name of typhoid fever, but it was reserved for Sir William Jenner, to prove thoroughly the nonidentity of the two diseases, and to give the latter the name of Enteric Fever. It is a circumstance of singular and melancholy interest, that it was this very disease which attacked the Prince of Wales, and which carried off our great and good Prince Albert, in the prime of life. The disease is attended, in many cases, by ulceration of the bowels, and sometimes by perforation (see article under that head); or fatal hæmorrhage may take place in consequence of the ulcerative process. There is usually diarrhea, the stools being generally of a pea-soup character. Any treatment beyond that generally recommended in ordinary fever, must be left to a medical man.

Management.—As in all other fevers, good nursing is here of the highest consequence. The patient is often delirious, and requires constant watching on this account. Again, the irritation of the bowels and diarrhœa are very troublesome, inasmuch as many patients who have never been accustomed to it cannot (in their half-delirious state, perhaps) be prevailed upon to make use of the bed-pan, and yet nothing is more dangerous when there is great prostration than to allow them to get up to the water-closet or to the night-chair; indeed, in some cases with hæmorrhage from the bowels, death has taken place suddenly, from this precaution having been overlooked; besides, it is dangerous to the public to allow non-disinfected stools to enter the drains,

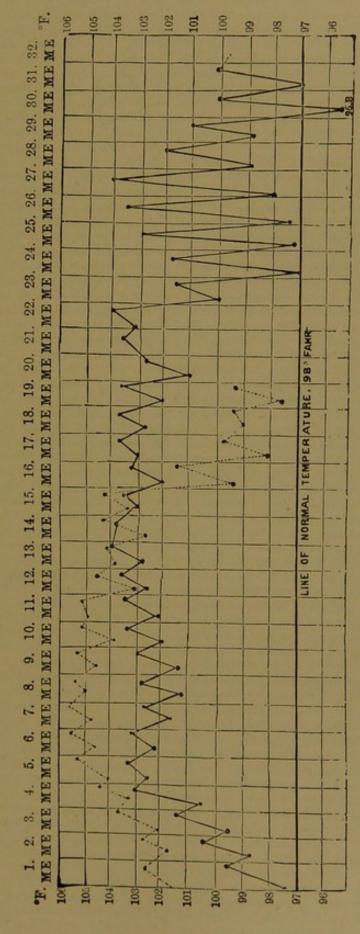

As medical science advances, it may be that we shall discover a method of treatment for this disease which will be successful in destroying or eliminating the poison. At present, however, the chief indication is to pay great attention to the state of the bowels, as it is the glands upon the surface of them which are chiefly affected. These glands are exceedingly liable to ulceration, during the fever, and this constitutes the prime danger of the disease.

From what has been already said, it will be believed that more than ordinary care is required in the nursing and general treatment

245

## RANGE OF TEMPERATURE DURING TYPHOID FEVER.

Evening (E.) observations. The dotted lines indicate the Typhus range; the continuous dark lines indicate the range TYPICAL RANGES OF TEMPERATURE IN CASES OF TYPHUS AND TYPHOID FEVER CONTRASTED WITH EACH OTHER THROUGHOUT THEIR COURSE, FROM THE BEGINNING TO THE END OF THE DISEASE. The Records indicate Morning (M.) and in Typhoid (WUNDERLICH and TRAUBE).

N.B.—The above table, taken from Dr. Aitken's work on the Science and Practice of Medicine, may appear unsuitable for the non-professional reader; still the subject of the range of the temperature of the body in different diseases engages so much of the attention of medical men, that we need offer no apology for its introduction.

ENT ENT

of cases of this disease, and at no time more than during convalescence. It happens, sometimes, that the diarrhea stops suddenly, and is succeeded by constipation. Now, it is well to know that by far the most efficient, and indeed, almost the only safe remedy to be used for this state of things is castor oil, given in a small dose. An ordinary dose of some more irritating and less bland purgative, often causes the purging to return with violence.—

See Castor oil.

If there is much thirst, a pleasant drink, and one likely to suit the peculiarities of the fever, may be given, by mixing equal parts of milk and lime water, either simple, or still better as the effervescing lime, or as it is called Carrara water. In the absence of a medical man, when there is severe hæmorrhage from the bowels, (this sometimes occurs to such an extent-several pints-as immediately to threaten life), gallic acid with opium, or acetate of lead with opium, may be given, or if these remedies are not at hand, at all events, cold or iced water should be applied over the abdomen, and above all, the patient should be made to continue in the recumbent posture. Should great faintness ensue, of course brandy must be given freely, and indeed, it is often necessary in this disease to adopt treatment of a highly stimulating and supporting nature.

An important point in the domestic management or nursing of cases of this disease, is to avoid the occurrence of bed-sores, which are often so distressing and dangerous, and which, in all cases, greatly retard convalescence, if they do not ultimately cause the patient to sink from exhaustion. They can be quite well avoided by proper attention to the state of the patient's back, in the general way re-commended for bed-sores, and it will be necessary, when the diarrhea is very troublesome, and the patient in a state of unconsciousness, perhaps, is passing everything under him, to sponge the body frequently, and to have abundance of drawsheets, in order that impurities may be at once removed. At the risk of being thought tiresome, we repeat that the greatest care is necessary during convalescence from this disease, because the bowels, let it be remembered, have been ulcerated, probably at several points, and are gradually healing, so that the least undue exertion on the part of the patient, or the least distention or irritation of the bowels, by improper food, may cause the cicatrising ulcers to give way, and fatal hæmorrhage, or still more likely, perforation of the bowel, may be the result.

Enteric fever, always endemic in this country, is most common during autumn, and at this time may attack whole villages or parts of towns where the drainage is bad, or where the drinking water is contaminated with sewage, which has made its way into the well.

This disease and typhus fever were at one time supposed to be identical, but now their distinctiveness is well recognised and admitted by all. Sir William Jenner first proved their non-identity, mainly from the fact that, after death, there is found ulceration of the bowels in enteric fever while these organs are not affected in typhus.

It would not serve any useful purpose, in a

book of this description, to detail the symptoms of each disease with the view of qualifying the reader to distinguish the one from the other, as medical knowledge is essential to

enable such a distinction to be made.

Causation.—As regards causation, enteric fever is undoubtedly a germ disease, and the introduction into the body of the specific germ is essential to its production. Formerly it was believed that sewer gas in itself, or the offensive gases given off by a collection of putrefying organic matter might give rise to the affection, but this theory is now exploded. It is true, the disease is generally associated with such conditions; but this arises from the fact that its germs are contained in the bowel discharges of patients, and thus gain entrance to sewers, cesspools, or privies, as the case may be. The most frequent channel by which the contagion is introduced is drinking water; but here, again, however much impurity a water may contain, and unwholesome though it may be in consequence, the specific ailment "Enteric Fever" will not result from its consumption unless the germs of that particular disease are present in it. At the same time, it must be remembered that the contaminating source of a water-supply is likely, sooner or later, to be the means of this particular virus being imparted to it. Bearing this in mind, it will be understood how unsafe it is to rely entirely upon chemical analysis in forming an opinion as to the safety of any water-supply. It is quite possible that a water may contain so little organic matter as to bring it well within the chemical standard of purity, and yet it may be fatally contaminated with enteric fever poison. The quantity of organic matter present is a small element if that which is present contains the specific poison.

The contagion of enteric fever, like that of other infectious diseases, can, apparently, retain its vitality, and exist in a dormant state for a long period until conditions favourable to its development arise, when it shows its presence by the disease making its appearance among those who are exposed to it. In this way, many cases which cannot be traced to antecedent cases may be accounted The following history illustrates this pretty conclusively:-In an isolated country village an imported case of enteric fever appeared, which terminated fatally without giving rise to any other cases. In the autumn of the following year, after an interval of ten months, seven cases of the disease occurred in four houses, among families whose water-supply was obtained from the well belonging to the

247

house in which the original case occurred, while other families in the village escaped. That the well water in question was responsible for all the cases was clearly proved, and there can be but little doubt that the imported case was responsible for the sowing of the seed which had germinated after so long an interval. Within a short distance of the well (a shallow one) was a privy with a sunk See Urine. cesspit, into which the excreta from the original case had been thrown. The surroundings forbade the conclusion that the contents of the cesspit had taken ten months to find their way to the well; and the outbreak being so long delayed after the introduction of the contagion, indicated that circumstances had not been favourable to the development of the germs, which, therefore, remained in a spore condition in the soil until, possibly, the temperature necessary for their growth was reached. These cases are recorded mainly to illustrate a theory in support of which many similar outbreaks might be men-tioned, and they also point to the necessity for the thorough disinfection of the excreta of enteric fever patients. To disinfect the excreta of enteric fever patients, the principles laid down in the section on Disinfection must be strictly adhered to; the disinfectant must be added in sufficient strength, not omitting to allow for the diluting effect of the excreta, and it must be allowed to remain in contact with the infected matter for, say, twenty-four hours. To allow of this it is desirable to make use of a special pail with a tight-fitting cover, in which the excreta may be retained until they are finally disposed of. The ultimate disposal of the excreta is best effected by burning, if circumstances will permit of this plan being carried out; failing this, and if land is available at a safe distance from any houses, the excreta may be disposed of by burying them well underground. If, on the other hand, the sewer is the only means of disposal, for reasons mentioned in the section on Disinfection, it is imperative that the di infectant used (perchloride of mercury by p eference) should be allowed ample time to do its work before the excreta are thrown away. If, as in many towns, and in most rural districts, the privy-midden system of excretal disposal is in operation, under no circumstances should the infected excreta be disposed of in that manner.

To insure success, all such cases should be isolated in hospital, and with proper observance of precautions as regards the disinfection of linen, excreta, &c., imported case of the disease need give rise to no anxiety Again, with thorough cleanliness, attention to house sanitation generally, and a water-sup ly which is beyond suspicion, the disease should become a thing of the past. The same remar sapply with equal force in the case of cholera and epidemic diarrhœa.—See Cholera—Disinfection-Germs of Disease-Water, &c.

ENURESIS. - Incontinency of urine .-

EPHEMERA. - A fever which does not

last more than twenty-four hours.

EPIDEMIC is a term applied to a disease which attacks a large number of individuals simultaneously, or at least in quick succession. Perhaps the best instance of an epidemic is the well-known influenza, which seems more independent of endemic, or local influences, than most others of the class. Cholera is an epidemic disease, but the liability to its visitation is evidently connected with local circumstances, which either assist in developing the activity of its mysterious germs, or at all events exert an attracting influence over them. Scarlet fever, measles, small pox, diphtheria, and other diseases of the class, most certainly prevail epidemically at times; for though they undoubtedly disseminate themselves by contagion, observation would show that the contagious influences are much more potent in different places at different times. The reason why this should be so is not always traceable; but as regards the greater and more pestilential epidemics, it has been observed that they have been preceded or accompanied by striking vicissitudes in the weather. It is well known that the first extensive diffusion of the Asiatic cholera dated from a swampy district at the mouth of the Ganges, after a very wet season, and it is matter of history, that the epidemics of plague were associated with unusual modifications of weather: the extremes of heat or cold, of drought or moisture. Neither are the epidemic influences always confined to man: the lower animals are also frequently and fatally subject to them. It is remarkable, as indicative of this influence, that birds have been observed to forsake districts in which an epidemic pestilence prevailed.

Epidemics were much more common and fatal in former times than they have been within the last hundred years. Such were the plague at Athens, 430 years before Christ, the black death or plague of the fourteenth century. the sweating sickness towards the end of the fifteenth, the great plague of London of the seventeenth; at the present day, the plague of eastern countries, of Egypt in particular, and the cholera, are the modern pestilences. All these, and many others, are undoubted epidemics; but equally certain is it, that they owed, and still owe, much of their potency for evil, to local and endemic causes, and to the entire want of attention to sanitary arrangements. However deficient these may be in this country, even at the present day, were it

248

not for such regulations as there are, we know | a fearful-cry, and, if unsupported, falls to of no reason why cholera, which still lingers around and sometimes decimates the neglected oriental city, should not again visit our shores. In view of a threatened outbreak, and during the prevalence of an epidemic, it is of paramount importance, that the general health of the individual, as well as of the community, should be strictly considered, and that every precaution should be taken that the drainage and water supply are in an efficient state. Poor and dirty neighbourhoods are almost certain to be the first affected, and there, if anywhere, thorough inspection should be made, and, if possible, overcrowding prevented. The ventilation of houses ought to be free and ample, and measures taken to have notoriously close and dirty rooms limewashed and purified. In the majority of epidemics it is impossible to prevent personal susceptibility to an attack of the prevalent distemper, but in the case of small-pox we know re-vaccination to be an excellent safeguard, and in the advent of cholera much may be done in the way of prevention by checking the premonitory diarrhea which is sure to prevail about the period. Measures of isolation for the affected, either in their own houses, or, when the disease occurs among the poor, in buildings arranged for their reception, should be strictly enforced; it is greatly to be regretted that so many obstacles to the establishment of these asylums should have been recently raised, for they unquestionably confer an enormous benefit on the public at large.

EPIGASTRIUM. — The pit of the

EPIGLOTTIS is a cartilage of an oval or heart-shaped figure, situated at the root of the tongue, which falls upon and covers the glottis or opening into the larynx, so as to protect it, particularly during the passage of food, in the act of swallowing.

Refer to—Larynx—Swallowing, &c.
EPILEPSY, or FALLING SICKNESS, is one of the very afflicting maladies to which man is subject, belonging to the class of convulsive diseases. It is also one of the most eminently characteristic, and at the same time terrible to witness, when it occurs in its severer

The fits, or convulsive seizures of epilepsy, are most varied as to occurrence; occasionally an individual has suffered from one paroxysm, and one only, the disease never again returning; in other cases, years have intervened; frequently the interval is one of months, but again, daily fits, or even two or three times a day, are the rule in the worst cases. The tion, which exists but for a few seconds, and is attack of epilepsy is for the most part sudden:
the individual in the midst of some accustomed
occupation, or whilst holding active communion
with persons around, suddenly utters a loud—
described by the patient as arising at some
particular part of the body, such as the extremity of a limb, and gradually ascending
upwards to the trunk or head, till the

the ground; the eyes are staring or rolling, the head, or rather chin, is drawn towards one shoulder, the colour becomes dark or livid, the veins of the face and temples turgid with blood, and the features are thrown into convulsive movement; there is froth at the mouth, whilst a kind of choking noise is often made in the throat; the limbs are also more or less convulsed, and the excretions are often expelled involuntarily. The tongue very often suffers from being bitten, and the teeth have even been fractured during the fit. Gradually, these convulsive movements diminish, and the person awakes to consciousness, with a heavy stupid look, or falls into a deep lethargic sleep which continues for some hours; but even when this is roused from, there often remains slight temporary suspension of the activity of the mental functions. Such are the phenomena of a severe epileptic paroxysm; the disease, however, occurs in much milder forms, even in those who at other times suffer from it in greater intensity. A slight temporary unconsciousness may be the only symptom, with or without the slightest approach to convulsive movement, as evidenced by the twitching of a finger, the roll of an eye, or slight spasmodic action of the muscles of the face; the patient may fall gently as in a faint, or remain standing as it were asleep for a few moments. As there is every variety in the nature of the attacks, so is there likewise in their duration: from a few moments, to the average period of from two to three minutes, but sometimes much longer.

The attack in many cases appears to bystanders to come on suddenly, and without warning; but most epileptic patients are sensible for some time previously of the approach of the paroxysm, and even for twenty-four hours are always aware that a fit is at least probable, although its direct accession may not be certainly known until just previous to its occurrence. It may, however, happen that these symptoms will pass off without a fit, either independent of any effort of the patient to ward off the attack, or in consequence of some of those measures found to be efficacious, and adopted by epileptic patients for the

The premonitory symptoms vary greatly: low spirits, or unusual irritability, sometimes

an increased energy, dizziness, noises in the ears, floating specks before the eyes, and many other signs connected with disorder of the nervous system, are the occasional precursors of the epileptic paroxsym; but the most generally marked, and remarked, precedent, is the epileptic "aura," a sort of creeping sensa-

EPI

Epileptic seizures are very frequent in the night time, just as the person is falling asleep; but they may occur at any period of the twentyfour hours, and may be induced by causes affecting the nervous system: the excitement of joy or passion, or the depression of grief, intoxication, and sexual excess are most frequent, not only actual exciters, but also pre-

disposers, to the attack of epilepsy.

Epilepsy may be a congenital disease, that is, the child is born with the tendency, and becomes subject to the fits, either with or without apparent cause, early in life, indeed, many of the convulsions of children occasioned by teething, &c., are in fact epilepsy, but as they arise from causes irritating the brain, and not from affection of the organ itself, they are possibly not repeated when the cause of irritation has subsided. If, however, the tendency exists strongly in the constitution, and has not developed itself before puberty, it is very apt to do so at that period, and more especially if favoured by circumstances which lower the tone of the body generally, or of the nervous system in particular; but no period of life is exempt from becoming the period of epileptic development, even to old age. From Dr. Gower's exhaustive analysis of the causes of epilepsy, hereditary disposition comes first on the list, then follow in order, dentition, fright, mental anxiety, and excitement, blows and falls on the head; but in a very large proportion of persons subject to the disease, it is difficult to trace the phenomena to their true cause, which may be of a more or less complex character. The following observations of Dr. Bright upon this point are generally instruc-tive, he says:—"There are leading periods in the evolution of the frame, and peculiar circumstances connected with certain periods, which may well be considered as influential in the production of the disease. In infancy, the nervous system is delicate, and easily acted upon by various causes of irritation. Then follows the trying period of teething. In a few years the second dentition occurs. In a few years later, all the great changes connected with the age of puberty. To this follow the excesses and exposures of manhood; and after the lapse of years the vigour of the system fails, and many causes act to derange the nice balance of the constitution: the bowels often become sluggish, &c.'

A person may die in an epileptic fit, even in the first, but this is seldom the case; more generally the disorder does not immediately threaten life, but the individual goes on from year to year, suffering more or less, and still lives; even when the fits occur daily, or two or three times a day, this is the case. When death does occur early in the disease, it is more probably due to suffocation arising from the

individual loses his consciousness in the con- | than to the brain affection. But if life is continued to the confirmed epileptic, too often intellect becomes affected. This may not be palpable after a first seizure, not even after many seizures for many years, not throughout a tolerably long life, but these are exceptions. The generality of epileptics become feebler in intellect, the memory fails, the power or continuous exertion of the mind is lost, and perhaps, at last, the condition ends in mental fatuity.

That epilepsy is due to disease or disorder of the brain and nervous system is unquestionable; the affection either directly originating from them, or through them, in consequence of irritation in some portion of the body. It is well ascertained that hereditary predisposi-tion gives greater effect to causes which have plainly exerted influence in the production of this distressing malady. Dating, either directly or indirectly, from the nervous system, whatever weakens that system tends to cause epi-From this it is evident how well lepsy. founded the observation is, that there is no more fertile source of epilepsy than the abuse of the sexual organs, particularly in the young. The subject is a painful one, but the direful consequences of vice, with which the merest children become imbued at school, is frequently coming before medical men; unaware of the sin and evil consequences of their acts, they ruin constitutions at the most critical period of life, and lay the foundations of epilepsy and other nervous diseases, which are either quickly developed, or do not show themselves till late in life. The subject is one to which parents and tutors cannot be too strongly alive. Intoxication is a cause of epilepsy, and delirium tremens may be complicated with it. Strong and prolonged mental exertion may induce epilepsy. Fright is another and very frequent existing cause. Worms and irritations in the bowels, indeed, whatever can irritate the nervous system, may induce the disease in question. Imitation, or at least the witnessing an individual in the epileptic paroxysm has been known to give rise to the fits in others, but they were most likely predisposed, or at all events of nervous and susceptible temperament; for this reason, such persons, young females and children especially, should never, if possible, be permitted to witness an epileptic fit; the premonitory cry is so terrifying that it has been known to affect even the lower animals.

Of the predisposing causes there is no question that hereditary tendency is a powerful one, and especially if the constitution of the family be scrofulous. Epilepsy in the offspring has been traceable to no other cause than dissipated, and especially drunken, habits in the father. It is frequently observed to be concomitant with malformation, or at least mis-shape, of the head of the sufferer. From what has now been said, it must be evident spasm of the muscles of the throat and neck, that epilepsy is no disease for domestic manage-

ment in a curative point of view, but that it | Those who are much in attendance upon the affords much room for preventive and other

In families in which a tendency to epilepsy is known to exist, the greatest care should be taken to guard the nervous system from all causes either of irritation or exhaustion. In infancy, the period of teething, and the condition of the bowels, will require special attention, and the tone of the system to be maintained as directed in article Childhood. The physical strength and health are to be cultivated in early life, even at some sacrifice of educational advancement; at puberty, the strictest eye must be kept upon the habits and tendencies, and whilst the constitution is developing, and growth going on, all exhaust-ing exercises prevented; indeed, during life the suspicion of a tendency to so terrible an affliction as epilepsy should be a salutary check upon excess in every way—a check upon the man who consumes his energies in the exertions of business or of study, as well as upon those who waste them in the pursuits of vice or sensualism. In addition to passive preventive means, all those measures which are fully laid down throughout this work for the pre-servation of health should be well attended to, particularly the use of cold water to the head, spine, and surface generally, if there is sufficient re-action to bear the application.

Care must be taken in the curing or suppression of accustomed or long-continued discharges, such as habitual diarrhoa, bleeding from piles, &c.; at the same time it must be borne in mind, that the discharge, by weakening the system, may be itself the cause of the disease; but this is a point which the medical attendant must determine.

Certain precautions are always requisite with those who suffer from epilepsy, and as a general rule it may be laid down that they should never, if possible, place themselves or be placed in situations in which a sudden seizure will expose them to danger. Thus, employments which necessitate riding on horseback, ascending heights, &c., ought never to be engaged in, neither such as those in which even momentary unconsciousness may involve the lives of others in danger. Even the suspicion of epilepsy in a railway official ought to be a disqualifying circumstance. Many, it is true, have sufficient warning to enable them to prepare for the attack, and to withdraw from danger, but this is not always possible; the worst case of burning-or rather roasting-the author ever witnessed, was in consequence of a fall into the fire in an epileptic paroxysm: when means will allow of it, the epileptic ought to have an attendant constantly with him. When an individual is seized with a fit of epilepsy, but little can be done for its immediate relief; the chief thing is to prevent the patient inflicting injury upon himself, by striking against sur-

epileptic, ought always to have at hand a piece of india rubber, or a thick india rubber ringsuch as is used for children teething-to insert. between the teeth. All fastening about the body, such as the neckcloth, &c., ought to be loosened, and air freely admitted; the head should be raised, and cold wet cloths may be applied to it if there is much heat. The person should be placed on the ground or floor, and the bystanders forbidden to give him any thing so long as the fit lasts. Much harm is done at times by good-natured attempts to make the patient swallow fluid, such as water or spirits during the fit, but all attempts of this kind should be postponed till after his recovery from the fit.

The treatment of an epileptic patient in the intervals of the fits, must be left to a medical man; it involves too many considerations to be advantageously managed by others: when well treated, there is a hope of cure, and this chance should be afforded to the patient, which can only be certainly done under efficient and educated management; for even with all that skill and attention can do, the disease often proves intractable. The various remedies which have been used in epilepsy, and they have been very numerous, it would serve no good purpose to enumerate here, further than to state, that in the severe headache which often accompanies the complaint, much benefit has frequently resulted from counter-irritation, such as the introduction of a seton in the neck. It sometimes happens that accidental counterirritating effects relieve epilepsy, at all events for as long as they are in action. In one case attended by the author, a man who was suffering from daily attacks of epileptic convulsion fractured his leg, and from that time, had no attack for five or six weeks, during the period the accident was being recovered from. The inhalation of nitrite of amyl sometimes prevents an epileptic seizure, and ammonia, ether or chloroform, used in the same way are often serviceable. Of late years bromides of potassium, of sodium, and ammonium, taken in large doses regularly, have been found very efficacious. Tonics such as steel and cod-liver oil, with attention to the general health and surroundings of the patient are very necessary. Epilepsy is often a feigned disease, particularly among soldiers and sailors, and also by mendicant impostors. The latter usually choose public places for the exhibition, throw their legs and arms about, foam at the mouth with a little soap mixed with the saliva, and continue their exertions for a much longer time, and with more expenditure of force, but with less active power than the real epileptic. A real epileptic is not susceptible to pain or sensation; where suspicion exists, therefore, some test of this kind which will not injure may well be injury upon himself, by striking against surtried. Snuff may be put up the nostrils, and tounding objects, and also to protect the tongue. if it produces sneezing there is no epilepsy:

EPIPHYSIS is the extremity of a long bone, such as of the arm or thigh, which is, in the young, connected with the shaft or main portion of the bone, by means of gristle. When such bones are boiled for some time, the epiphysis separates, as may be seen in the case of veal or chickens. In children the epiphysis is sometimes separated by accident attended with violence.

EPSOM SALTS are a compound of magnesia and sulphuric acid—sulphate of magnesia - and derive their name from having been first obtained by the evaporation of the water of a spring, situated near Epsom, in Surrey, which contains the salt in large quantity. They are now prepared largely by manufacturing chemists from magnesian limestone, and also from sea water. They are sold in the form of small, pure white, needle-like crystals, and from their cheapness are extensively, indeed too much so, used among the poor as a general aperient, and not unfrequently by all classes. Epsom salts are tolerably certain in their action, do not gripe much, and produce free watery evacuation of the bowels; on these accounts the medicine is a most valuable one in many diseases, particularly in fevers and in cases of torpor of the liver, also in persons of a full habit, but, as generally employed, it is not suitable for a common or frequently repeated aperient. From its being in many instances induces a discharge of the watery part of the blood into the bowels, and thus seriously

sometimes the proposal, within hearing of the | of Epsom salts, the bowels, in those liable to habitual constipation, are very apt to be left with a greater tendency to inaction than before; nevertheless, in persons of full strong habit, an occasional dose of the medicine is, without question, beneficial, but it should be taken in smaller quantity and much more largely diluted than is usually done. The question of dilution is a very important one in the administration of this salt, and if attended to, renders it safe and efficient even for the comparatively delicate. From half a drachm, or even less, to a drachm, should be dissolved in at least six ounces or half a pint of cold or tepid water, and taken on first rising in the morning, when the dose should be followed by the fluid breakfast: many persons liable to constipation find this method a simple and effectual remedy, which may be used for weeks together. From five to ten drops of dilute sulphuric acid are often a good addition to the dose, and one which at the same time corrects in some degree the bitterness of the salt. If there is debility, either of the stomach, or generally, from a quarter to half a grain, either of quinine or of some salt of iron may be added. The quinine appears to The most conincrease the aperient power. venient method of taking Epsom salts in this form is to dissolve one ounce in a pint-sixteen ounces-of water, adding the acid or other ingredients in proper proportion. Of the solution, from half to a whole wine-glassful may be taken the first thing in the morning, diluted with the proper quantity of water before taking, or if preferred, by the latter being drunk immediately after the medicine.

> The following method for the administration of Epsom salts has been recommended in France:—take of water about sixteen ounces, powder of roasted coffee two and a half drachms, Epsom salts one ounce; boil well for two minutes—not in a tinned vessel—remove from the fire, and let the mixture infuse for some minutes, so as to allow time for the development of the aroma; then filter, or merely strain off: it must be sweetened to taste. This fluid does not impart the slightest taste of the bitterness of the salt. It should be observed that the simple infusion of coffee is not capable of re-

moving the bitter taste.

Perhaps the most agreeable form in which the salts can be taken, is by using one or other of the numerous mineral waters which contain it in abundance, such as the Hunyadi Janos, Friedrichshall, or Pullna waters. A wine-glassful of Hunyadi water taken in the early morning, and afterwards supplemented with a breakfast-cupful of hot tea or coffee is almost certain to relieve the bowels.

The combination of Epsom salts with infusion of senna, constituting the common black taken in a state of too concentrated solution, it draught, is one of the best forms of active occasional purgative in common use. It is well to bear in mind, that there is considerable debilitates: moreover, after the action of a dose resemblance between oxalic acid in its crystai-

line commercial form and Epsom salts, and that | or THE ROSE, is an inflammatory affection of in consequence, fatal mistakes have occurred. The intensely acid taste of a single crystal of the former would at once clear up any doubt; perhaps it might be well always to use so simple

Refer to—Oxalic Acid—Purgatives—Senna. ERGOT OF RYE is a peculiar diseased or fungoid growth which is developed upon the seed of the common rye. The affected grain is sometimes called "spurred rye;" from the peculiar curvature of the growth, which varies from half an inch to an inch and a half in length, is about a quarter of an inch thick, slightly angular in shape, and black in colour. As a remedial adjunct in the hands of the accoucheur, ergot of rye is most valuable, but is scarce likely to form part of the domestic medicine chest. It is more commonly met with on the Continent, where much rye is grown, than in this country, and when the grain is largely infected with it, pestilential diseases have been ascribed to the use of the flour in which it has been mixed. It is certain that a peculiar kind of dry mortification of the extremities has followed the prolonged use of grain containing ergot.

Ergot of rye has been used in medicine in hæmorrhagic and other diseases, but chiefly on account of its undoubted action upon the womb. It is sometimes employed hypodermically to check hæmorrhage from any source, from its well-known power of producing vascular contraction, by its influence on the spinal cord and sympathetic nervous system. Of the beneficial effects of ergotine given hypodermically in hæmorrhages generally, it is impossible to speak too highly. It can only be safely used by medical men.

ERRHINES are medicinal substances used as snuff to excite discharge from the lining mucous membrane of the nostrils; they are, in fact, means of counter-irritation, but are not much employed by medical men. In some cases of headache they are useful, and common snuff may be used with as much effect as any of the class.

ERUCTATION is the rising, either of gas or fluid, into the mouth from the stomach. It is a common symptom in dyspepsia. Relief for this troublesome affection may generally be obtained by the following prescription:—nitrohydrochloric acid half an ounce, distilled water seven and a half ounces, of which a tea-spoonful may be taken three times a day; or subnitrate of bismuth and compound powder of tragacanth, of each ten grains with an ounce of water two or three times a day. Half a tea-spoonful of powdered charcoal taken in water once or twice a day, will greatly check eructations, especially of a fœtid character.

Refer to—Flatulence.

ERUPTION—a diseased appearance on the skin. - See Skin.

the skin, with or without vesication or blistering, sometimes extending to the cellular tissue beneath. It appears on various parts of the body, but most generally on the head and neck. Unless the attack is very slight indeed, the occurrence of erysipelas is generally ushered in by symptoms of fever, shivering, and headache, furred tongue, perhaps sickness, followed by thirst, hot skin, quick pulse, &c.; at the same time, the part first affected, such as the nose, cheek, or ear, becomes stiff, painful, red and swollen, the pain being of a burning character. If unchecked, this inflammation of the skin extends with more or less rapidity, and so rapid indeed is its progress at times, that in a very few hours the whole head and face become enormously swollen. As the disease progresses, blisters resembling these raised by a scald form over the surface, which is intensely hot and red, or purplish; the pain is severe, fever runs high; sore throat is a very frequent accompaniment, and delirium is common.

So serious a disease as erysipelas ought only to be treated by a medical man; but as it is important, if possible, to check it at its first onset, the following measures should be adopted if proper assistance cannot quickly be procured; a disease presenting the symptoms above detailed, must generally be recognisable even by unprofessional persons. In the general treatment of erysipelas, it is advisable to produce in the first instance free action of the bowels by means of the colocynth and hyoscyamus pill. Next, tincture of iron is to be given in doses of from fifteen to thirty drops to an adult, every four hours, and to a child, less in proportion. Fluid nourishment must be given in abundance, especially milk, and wine added if the fever be high and the patient delirious.

Flour is a very common and often a good and comfortable local remedy in erysipelas; hot fomentations, either of simple water or decoction of poppy heads, applied continuously for many hours, by means of flannel, give much relief in some cases; or a lotion composed of twenty grains of sugar of lead, a drachm of laudanum, and sixteen ounces of distilled or rain water may be used slightly warm, and applied by means of linen cloths, with much advantage; or the part may be covered with oil, and wrapped in cotton wool. Painting the erysipelatous surface with collodion, is another remedy in frequent use, and usually gives relief. It is thought by some medical men, that the application to the skin and around the inflamed part of a solution of lunar caustic, will arrest the disease. Either the solid stick of caustic may be used, or a lotion, containing two drachms of the nitrate of silver to an ounce of distilled water. When the scalp is affected with erysipelas, it is always advisable to cut off the hair. ERYSIPELAS, or St. Anthony's Fire, | Probably the best mode of using lunar caustic

ERY EUC

or nitrate of silver is that recommended by the | forms, and the parts slough or mortify. late Mr. Startin. It is a solution in pure nitric ether, of the strength of forty grains to the ounce. It has this great advantage that it spreads easily and evenly on the skin, and

dries quickly.

The remedial measures, both local and general, which have now been recommended, should and may, under intelligent unprofessional management, do much to keep this formidable disease in check until the medical man, whose presence must be necessary, can be got. over, there ought not to be much doubt as to the nature of the disease, if the distinctions pointed out in the first part of this article are attended to, and further, many attacks of erysipelas are secondary ones, as persons who have once suffered are liable to do so again.

Much confusion of ideas exists on the part of the public with regard to erysipelas, and many affections of the skin are imagined to be this disease, which do not in the least resemble it. It should be remembered that it is an affection which appears suddenly, tends to spread, and is accompanied with fever; that the affected skin is red, hot, tender, and often blistered.

The causes of erysipelas are numerous: cold and atmospheric vicissitudes, and peculiar conditions of the atmosphere, are all apt to excite an attack, and everything which tends to pro-

duce debility, predisposes to it. . Wounds and sores often appear to be the first originators of the malady, and in such cases, contagion has much to do with its diffusion through a hospital or a town; even the most trifling scratch being sufficient to become the attraction. For this reason, erysipelas is the most formidable enemy which can gain a footing in a surgical hospital, and for the same reason when the disease occurs in private houses, caution should be observed that persons suffering from wounds do not come into close contact with the affected; and, indeed, in any case, the same precautions should be adopted in erysipelas as in contagious diseases animal tissue which separates from the living generally. This is doubly requisite in a house in which a confinement is expected, or has recently taken place, for there is an undoubted close connection between erysipelas and fatal child-bed inflammation. The head and neck are the most frequent sites attacked by this applied. Refer to-Caustic, &c. disease, but any other portion of the body may be liable to it; the throat not uncommonly suffers, and is a dangerous complication, best treated by the free application of the caustic solution to the tonsils; it ought to be quickly attended to by a medical man, for death sometimes occurs most unexpectedly from suffocation, in consequence of swelling. Hot bran poultices and mustard plasters externally would perhaps relieve the throat in some

such cases it is usual for the surgeon to cut through the skin to give free exit to the matter, and by the proceeding much relief is afforded; this, of course, unprofessional persons cannot do, and poultices and fomentations must be their resource should it happen, which is not likely, since a case which has reached this stage has probably been visited by a medical attendant.

Refer to—Silver, Nitrate of—Skin, &c.

ERYTHEMA is a more superficial and evanescent inflammation of the skin than erysipelas. The most familiar instance of it is the inflammation produced by the chafing which occurs in stout children, or adults, between the folds of the skin, and which has a tendency to spread from its point of origin. The application of cloths dipped in tepid water, or in the sugar of lead and laudanum lotion, recommended in erysipelas, will allay the burning sensation. A few grains of grey power should be given at bedtime, followed by castor oil or senna in the morning, and then quinine administered in doses suited to the age of the Rapidly spreading crythema, even in an infant, quickly yields to small doses of quinine. There is a form of erythema, called by medical men Erythema nodosum, to which some persons are liable, and which appears chiefly on the legs or arms, in the form of red, flattened, somewhat hard and painful swellings. Rest with the limbs raised, and the use of the warm lead and opium lotion, are the best local means; as the disease frequently occurs in those of florid habit, the diet generally requires to be reduced: a five grain dose of Plummer's pill may be given at bedtime, for three or four nights in succession, and two table-spoonfuls of the soda and magnesia mixture (see Magnesia) thrice daily. If the bowels are confined, the colocynth and blue pill will be better than Plummer's for persons of strong habit.

EXCITEMENT-EXCITANTS, OF STIMU-LANTS.-To excite, to stimulate, is either to originate action where no action previously existed, or to give increased energy to powers Excitants or already in active operation. stimulants, therefore, are agents which are capable of producing such effects, and excitement is the effect produced. Excitants may be artificially divided into-

I. Ordinary excitants—the regular unceasing action of which is necessary for the pre-servation of sound health both of mind and

II. Extraordinary or occasional excitants, which produce a certain amount of temporary exalted action of mind, or of body, or of

III. Superfluous excitants, which are geneally those comprised in the second division abused.

Under the head of ordinary excitants we have

the following:-

A .- PHYSICAL EXCITANTS.

4. Atmospheric air. 1. Heat.

2. Light.

5. Aliment. 3 Electricity, Magne- | 6. Muscular action-Exercise. tism.

B.—MENTAL EXCITANTS.

Occupation of the mind with some definite

Under the head of extraordinary excitants we have-

A.—PHYSICAL EXCITANTS.

Alcoholic excitants.

2. Excitant ingesta generally: tea, coffee, spices, drugs, &c.

3. Atmospheric changes.

B.—MIXED EXCITANTS

Sexual stimuli.

2. Extra exercises: dancing and athletic sports.

3. Travelling, and exciting or novel scenes. C.—MENTAL EXCITANTS.

Hope, Joy, &c.

2. Love, Anger, &c.

3. Social intercourse.

6. Eloquence, written or spoken, exciting literature.

7. Religion.

For the more particular consideration of the above-cited agencies, both as excitants and otherwise, the reader is referred to the various articles in which they are treated of in this work. From these it will be seen that certain ordinary physical stimuli, or excitants, are necessary for the sustenance of human health and life, and that equally important for the preservation of vigour, not only of mind, but of body, is the stimulus resulting from the ordinary but regular action and reaction of the mind of man, originating either in daily intercourse with his fellows, or in pursuits which continuously engage the mental powers. And further, that the mental and bodily functions are at intervals acted upon by occasional or extraordinary stimuli, which temporarily occasion their exalted and increased action; not only without actual injury, but with positive benefit. And, lastly, that these extraordinary stimuli are not liable to lose their power of beneficial stimulation, unless exerted in a disorderly and unrestrained manner

EXCORIATION.—See ABRASION.

EXCRETION .- Anything either superfluous or noxious, separated and thrown out from the living body. Excretions may consist of noxious and superfluous matters which have been introduced into the circulation by the stomach-in the food-or through the lungs, or skin; but the bulk of the excretions consist of waste matters, that is of substances which, having fulfilled their part in the animal economy, cannot be retained in it without danger to health or life, and are therefore cast out by some of the outlets specially provided for the purpose. The urine is perhaps the best specimen of an excretion, and consists of water holding in solution mineral salts, and the used up elementary substances in various combinations. One of these compounds—the urea—is a narcotic poison, and if from disease of the kidneys, or other cause, it is retained in the blood, it acts as such, and kills. The chief constituents of excrement from the bowels are matters excreted by the large bowel, which cannot be retained in the body without danger. The kidneys, the bowels, including the liver, the skin, the lungs, are the excretory outlets of the body; and what has been said of the nature of excretions generally, must render

evident the paramount importance of keeping | which is not required, and which must consethese outlets in free operation.

Refer to-Alimentary Canal-Bile-Blood

-Lungs-Skin-Urine, &c.

EXERCISE - SPONTANEOUS MUSCULAR MOVEMENT.—The stimulus imparted to the system generally, and to every one of the vital processes particularly, by the excitant power of muscular movement which every healthy man is compelled or ought to undergo, is a fact generally recognised; it is one of those ordinary excitements the agency of which is linked with our happiness and health, and it may almost be said with our existence. A man engaged in active bodily exercise is undergoing a regular course of excitement; his will is stimulating the nervous system to rouse the muscles to action, and in this process both the rouser and the roused are using up their own substance; the acting muscles are sending the blood more quickly through the capillaries and large vessels, and the heart must move more actively to keep pace with them, and transmit the quickly returned blood loaded with effete matter to be purified in the lungs; to preserve the balance, the respirations are increased, and the stomach is stimulated to crave for nourishing food and unstimulating drink, fitted to keep in repair the ever wearing structures of man's body, and to supply the fluid waste. Baron Liebig and his successors have done much to give us clear views respecting the changes which take place within the body under the influence of muscular movements; and from them we learn, that in the expenditure of this force, there is a certain metamorphosis in the tissues which require renewal in proportion to the amount of physical exertion and consequent waste.

Exercise, therefore, is in the first place requisite as an ordinary excitant, to be brought into daily operation, that the vigour of all the functions of the body, whether of digestion, or of secretion or excretion, may be preserved; it is the merciful provision by which the decree, that man should earn his bread by the 'sweat of his brow," has been converted into a bless-ing; it is the great compensating balance which gives the labourer sound sleep and healthy appetite and vigour, instead of the wealth which too often seduces to indolence,

and palls every enjoyment of life.

Exercise, again, is requisite as an agent with reference to the food consumed. Food is taken to supply the waste of the body, which must go on more or less as long as man lives; more if actual exercise is taken, and vice versa. Man ought not, therefore, to expect, if neglecting muscular exercise—that is, to use up the substance of his body in exertion-to have the same appetite for and enjoyment of food as if he did; but man does expect this in many instances; he indulges in indolence, and then excites the appetite and stomach by artificial

quently produce disorder somewhere. If an individual's employments are of a kind which do not require muscular exertion, his food should be diminished either as regards quality or quantity in due proportion; but even under this regulation, none can be well or vigorous who do not take some amount of exercise in

the open air daily.

With regard to extra exercises, such as dancing, and athletic sports generally, which are only engaged in at intervals, it is certain that their beneficial effect upon the functions and health depends quite as much upon the excitement of the mind as upon that of the body; and every one's experience must tell him how much his favourite exercise owes its renovating influence to the mental stimulation which accompanies it.

Refer to-Blood-Excitement-Food, &c.

EXFOLIATION is the separation of a scale of dead bone from the living. The term is applied either to the process itself, or to the

separated portion of the bone.

EXHALATION applied to the body, means an excretion in a state of vapour, such as that from the lungs and skin. It is calculated that thirty-one ounces of water pass daily from the lungs in a state of vapour and that sixteen ounces of the same fluid is exhaled from the skin in the same time. It is obvious that these excretions cannot be checked without danger. The foolish practice of gilding the entire surface of the bodies of children, who took part in the Roman triumphal procession, was often attended with fatal results.

EXHAUSTION is the diminished or almost extinguished power, either of the body generally, or of one or more of its organs, to continue its natural active operations, until it has been recruited by a period of repose. Exhaustion may arise from two principal causes -failure of the nervous power, and deficiency of organised materials fitted to support the re-

quirements of the living body.

If every thought, every exertion of the will upon the body, occasions the consumption of nervous matter, exhaustion of nervous power must in all probability be due to using up of nervous substance. Sooner or later, according to circumstances, every exertion must come to an end, and repose must be taken, that the exhausted brain and nerves may be recruited, and if man acts wisely, he will, if possible, stop exertion either of mind or body at the first point of exhaustion. It is true that powerful exercise of the will can and does compel exertion beyond the point at which nature says "stop;" but the effort is not made with impunity, and the after exhaustion is proportionally increased. No permanent injury probably arises from those occasional exhaustions, either mental or physical, which all have at times to means and tempting food, to take nourishment exhausting his nervous power, whether in the

direct service of the mind, in the labours of the body, or in the less excusable requirements of vicious excess, without suffering eventually. The early paralysis and softened brain of the mental, the premature old age of the physical labourer, the wretched decrepitude of the debauchee, are all the results of continued nervous exhaustion. It is not, however, simply the brain and nervous system which suffer, but the other organs of the body, particularly those of nutrition, suffer also, if the supply of nervous power which ought to sustain their healthy actions is withdrawn to support the exhausting efforts either of mind or muscle. Those, therefore, who can, will do wisely to avoid the cause of these evils, but all cannot do this: in many situations of life continued exertions, which carry the individual to the extreme of exhaustion, become abso-lutely necessary; it becomes a question, there-fore, how the evil effects of the necessity may be most efficiently counteracted. This must be done by the proper management of the nourishment. The stomach in such cases is not receiving its full supply of nervous stimulation, and therefore its work must be made as light as possible, consistent with conveying good nourishment into the system; small quantities of food should be taken at once, and more frequently repeated, rather than anything like a meal made. In the majority of instances, the most efficient nourishment will be strong concentrated animal soup, either alone or mixed with some farinaceous material, and next in utility will be coffee or cocoa, along with bread or biscuit, or with the yolk of egg beaten with them. Of course, if these are unattainable, the next best substitute must be used; but the principle must be to keep the system supported by means of repeated small quantities of food, of as nourishing quality, and in as digestible a form as may be; the use of alco-holic stimulants being avoided as long as possible. At length, if the exhausting agencies are still in operation, a time comes when the stimulation of alcohol is eminently serviceable by virtue of its peculiar action upon the nervous system, when it does that to support the bodily powers which nothing else can; and then the draught of porter, or the dose of wine, or of diluted spirit, comes like an elixir of life to "him who is ready to perish."

EXOPHTHALMIC GOITRE. — See

BRONCHOCELE

EXPECTORANTS are a class of medicines which increase and alter the secretion from the mucous membrane of the air passages, and afterwards assist in its separation and expulsion. Very many substances are employed with this view; the most useful are-

Acids, which astringe and stimulate, Ammonia, which stimulates. Ammoniae, which stimulates, Antimonials, which relax.

Ipecacuanha, which relaxes. Squill, which stimulates. Stramonium, or Thorn Apple.
Tobacco. Tolu, which stimulates. Vapour, either simple or medicated.

The use of expectorant medicines by means of vapour, spray, &c., is coming more and more into favour, and will probably greatly supersede the old "cough mixture" under the use of improved instruments.—See Inhalation—Inhalers.

In whatever way these medicinal substances exert their action upon the body, the most important practical point is the division into relaxing and stimulant. In the first stages of affection of the bronchi with cough, when there is fever, and probably inflammation present, the relaxing expectorants only should be used, either antimony or ipecacuanha; the former may be given with solution of acetate of ammonia, the latter with carbonate of potash; when there is much debility, ammonia combined with camphor is generally employed, and probably squill added. In chronic cough, with difficult expectoration, the same combination may be used, and when there is a relaxed state of the system, with copious expectoration and tendency to perspiration, the acids, either vegetable or mineral, alone or combined with

squill, are most serviceable.

The combination of opium or some other anodyne with expectorants, is both a common and a useful practice; it allays the irritability of the bronchial membrane, and the frequency of the cough, and probably also relaxes spasm; opium, however, tends to check expectoration, and on this account ought in almost every case -in which it is given to allay cough-to be combined with some counteracting expecto rant. More mischief is, perhaps, done with squill, than with any other of this class of remedies; its syrup is much given domestically, and generally too early, whereby both irritation and cough are increased. Tolu syrup is a good and pleasant addition to cough mixtures. Many expectorants act also as emetics, and in so doing, especially in children, frequently assist most efficaciously their expectorant action. Tobacco or thorn apple smoked, or watery vapour inhaled, act directly upon the air tubes.

Refer to articles on various expectorant

medicines, to-Catarrh-Cough, &c.

EXPECTORATION is the term applied either to the act of coughing up matters from the lungs, or to the matters so coughed up. These vary greatly in consistence and appearance, and consequently are valuable guides in the investigation of disease affecting the chest; indeed, until the physical examination of the chest by the ear was introduced into practice, the expectorated matters were the most distinctive evidences attainable. Expectoration may be thin and frothy, as it is when the lining membrane of the air tubes is suffering from irritation or inflammation, or thick and almost solid as it becomes in the last stages of a cold; EXP EYE

it may be ropy, as it often is in old people, or viscid in inflammation of the true tissue of the lungs, when it generally becomes of a dull reddish brown or rust colour; it may consist more or less of purulent matter; or be tuberculous and semi-solid as in pulmonary consumption; it may be mixed more or less with blood, or pure blood may be expectorated, or it may be what is called the prune juice expectoration from its colour, as happens in certain cases of pneumonia. Generally, expectoration is inodorous, but sometimes it is abominably fætid, the odour being mostly but not invariably indicative of mortification of the lung itself: other matters, such as bile, blood, &c., are occasionally coughed up from the stomach.

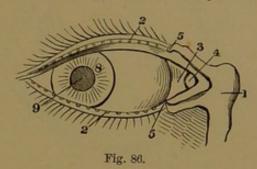

EXPIRATION is the act of expelling air from the chest after it has been inspired.

EXTRACTS are medicinal preparations made by separating the active portions of various drugs from the inert ones, this being effected by dissolving out the former, either by water, alcohol or ether, and evaporating the superfluous fluid, until a tolerably firm consistent mass of extract is left. Formerly, heat was used in the evaporation; but as this destroys in some measure the activity of the preparation, the best extracts are now all prepared without any heat whatever, and these should always be purchased in preference. The extracts of aloes, of colocynth, of hemlock, of henbane, of chamomile, of gentian, may be used by unprofessional persons. They are usually given in the form of pills, alone, or mixed with other drugs. There are many others, but they are either dangerous, or the medicine is better used in other forms.

EYE .- The organ of vision, not only in man but in the lower animals, is an instrument so wonderful, so replete with beautiful structure and admirable contrivance, that it is always alluded to as one of the most, if not the most splendid instance of the power and beneficence of God, as displayed in His physical creation. Its importance to man as an organ of sense, ought to render the study of its construction and adaptations one of intense interest, and must ever render its perfection and preservation an object of the greatest solicitude. The space which can be spared in a work like the present is too limited to do justice to the subject.

The whole apparatus of vision naturally divides itself into two sections—the globe of the eye and the appendages of the globe. The conical-shaped sockets, or orbits, in which the eye-globes are suspended, have projecting edges, especially superiorly, which protect the organ from injury; the pent-house of the eye-brow slightly shades from the light, and intercepts perspiration, which might trickle down and irritate; the fringed curtains of the lids are ever ready to close over and instinctively to protect their charge, and on their internal surface secrete a lubricating mucus; on their edges, a

secrete an unctuous matter. In the upper and outer angle of the socket lies the lachrymal gland, which furnishes the tears, and is always pouring out a watery fluid which is continually passing over and cleansing the exposed surface of the eye, being taken up at its inner angle, at the points 5 (fig. 86), and conveyed through

the lachrymal duct (1) into the nose, which it also supplies with moisture. Through this duct also, the membrane which lines the nose is continuous with that (the conjunctiva) which covers the fore part of the eye-globe and lines the lids.

In the socket, the eye-globe lies embedded in fat, but is also, as it were, slung in a kind of membrane; it is further both fixed and moved by means of its six muscles (fig. 87-1, 1)

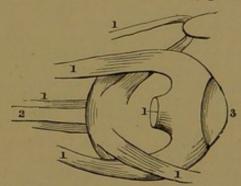

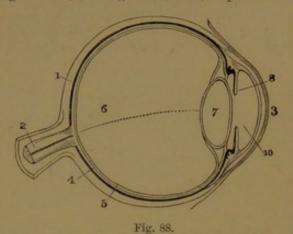

Fig. 87.

four of which pass forwards from the back or apex of the conical cavity to be attached to the globe. The optic nerve (2), and other nerves and blood-vessels, are also contained within the socket, the whole being arranged so as to afford the most facile, but at the same time steady, movement.

The globe of the eye itself is barely an inch in diameter, and measures longest from before backwards. Its outer coat, called the sclerotic, (fig. 88-1), is very firm and is composed of interlaced fibres; anteriorly a portion of it is, as it were, cut out to permit the insertion of the cornea (fig. 87—3; 88—3) or glass of the eye; posteriorly it gives passage to the optic nerve (fig. 87—2; 88—2). Within the outer coat is the choroid coat (fig. 88—4) of a dark chocolate colour, and within that, the retina or nervous coat (5), which forms the sensitive field eries of minute glands (fig. 86-2) open, which a remarkably transparent semi-fluid substance, of vision. The mass of the globe is filled with

EYE EYE

the vitreous humour, in the fore part of which | ing them together while the upper lid returns the crystalline lens (7) is imbedded. In front of this, and partly surrounding it, is the iris (fig. 88-8; 86-8), the circular aperture in

which (fig. 86-9) constitutes the pupil. front of the lens, between it and the cornea, is the chamber of the aqueous humour (fig. 88-10), so called from the watery fluid with which it is filled. It will be remembered, that the entire fore part of the globe, or white of the eye, and the clear cornea, are covered with the con-

junctiva, as already mentioned.

To give the sense of vision, the rays of light from surrounding objects penetrate the eye first by the cornea (fig. 88-3), pass through the aqueous humour, the lens, and the vitreous humour (10, 7, 6), and, in doing so, undergo a series of refractions, which bring them at last into focus in the retina (5), where the picture of external objects is formed, and where the impression is conveyed to the brain by the optic nerve (2). The object of the black or choroid coat (4) is to absorb the superfluous rays of light, which would otherwise be reflected within the eye, and confuse vision.

This rapid and necessarily imperfect sketch of the construction and functions of the organ of vision will, it is trusted, assist the unprofessional reader in gaining some rational idea of the dangers and diseases to which so important a portion of his frame is liable. The membrane (or conjunctiva) which covers the inside of the lids and white of the eye is, from its exposed situation, liable to become inflamed from various causes. Minute particles of dust, or other substances, getting into the eye, and becoming fixed in the lining of the upper eyelid, between it and the globe, cause an amount of pain and irritation, which could scarcely be credited from their size, but which is well accounted for by the accurate apposition of the two surfaces between which they lie. particle so situated, may be discovered without much difficulty, by a second party examining the sufferer with the head thrown back, whilst he slightly everts the upper lid with the thumb and finger; particles may also be removed by drawing the upper lid over the lower, and press- an inch square, made into a kind of small

to its normal position. The slightest speck of foreign matter must be removed, and no better instrument can be employed for the purpose than a piece of not over-stiff writing paper, twisted like a match. Those who work in metals are apt to get minute scales imbedded in the fore part of the ball; they cause much insist tiers and are of the ball; they cause much irritation, and are often so extremely difficult to remove, that a surgeon's assistance is required. The effect of these mechanical irritations is to cause inflammation of the conjunctiva (see description); this, however, may often arise, and frequently does, from cold, from disorder of the digestive organs, &c. The first symptom of inflammation is a sensation as if a particle of some kind had lodged in the eye, and if an examination be made, there will be seen, not only an enlargement of any small blood-vessels that may be generally visible on the white of the eye, but a new development of others, the appearance varying from the slightest apparent increase of vascularity, to the most intensely red inflammation; at the same time there is considerable increase in the mucous secretion-not in the tears, as is often supposed—and in bad cases this becomes purulent or mixed with matter. There is, sometimes, considerable swelling of the surface usually distinguished as the white of the eye. The above is the most superficial form of inflammation to which the eye is subject: if neglected, it may extend itself over the cornea and produce permanent blindness. It is distinguishable from the next form or inflammation of the sclerotic coat, by the size and winding character of the small blood-vessels, and by their being slightly movable, along with the conjunctiva itself, when the lids are drawn down. It is important that these distinctive characters should be attended to in the first place, that no error may be committed between this form and a more serious and deep-seated inflammation of the eye, but also that proper treatment may be used. A great error is committed in treating this form of inflammation by means of warm fomentations, &c., applications tending rather to keep up than to cure the disease, which is generally quickly removed by astring-A drop of laudanum or of Battley's solution in the eye, repeated two or three times, will often cure the disorder, or a lotion of sulphate of zinc from one to three grains to the ounce of water, will be found efficient; but the best of all is the solution of nitrate of silver, or lunar caustic, of the strength of two grains to the ounce of distilled water. Of this a few drops may be introduced into the inflamed eye, twice or three times in the twenty-four hours. The best plan of introducing drops into the eye, is to draw down the lower lid with the fingers, and turn the eye upwards. The operator then pours the drops into the affected eye from a quill, or from a piece of folded paper of about trough. The eye, of course, should be exercised as little as possible, and if the bowels are inability to open the eye, and bear the light, confined, or the stomach disordered, a few doses of the blue pill and colocynth will be found useful. If the disease is obstinate, a blister to the back of the neck may be applied with advantage.

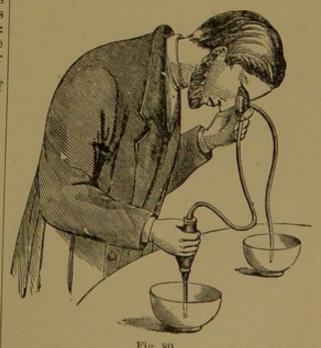

The disease which has just been treated of, is a comparatively mild disorder, but under certain circumstances it becomes much more virulent; the secretion of matter is very great, and acquires the power of propagating the disease by contagion from one person to another. The well-known Egyptian ophthalmia is of this nature, and among other means is carried from individual to individual by the flies, which, according to travellers, seem to have acquired an instinctive tendency to attack the eyes in that country. Newly-born and young infants frequently suffer from a severe form of purulent ophthalmia, which often shows itself within three days after birth. The inflammation is intense, and the matter often accumulates largely between the lids, gushing out when they are separated; in scrofulous children especially the affection is often obstinate. The nitrate of silver solution is the best application, and small doses of quinine the best internal remedy. Syringing between the lids with a solution of alum-four grains to the ounce of water, six or eight times a day, is also recommended; a little vaseline should be used on the edges to prevent them sticking together.

In inflammation of the sclerotic or outer coat of the ball itself, there is more actual pain, it is more deeply seated, the redness seen on the white of the eye is more of a pink hue than in the conjunctival affection, the vessels appear much smaller and straighter, radiate as it were from the cornea, and are not movable: the affection is, moreover, generally a more serious one than the other. The more interior structures of the eye may also become inflamed, and especially the iris; in all these cases of deep inflammation of the eye, the constitution is much affected, there is shivering, followed by thirst, fever, &c.; the pain in the organ itself is often most severe, and extends to the forehead; light cannot be borne. If the iris is the part affected its colour is changed, and often becomes of a dirty brick red; the pupil at the same time is irregular.

In these, and indeed in all affections of so precious an organ as the eye, whenever proper medical treatment is attainable, it should be taken advantage of. If this is impossible, the adoption of the following rules will, in judicious hands, prove beneficial. If the eye be very red, and the vessels large and full, with no pain on exposing the eye to the light and with at the same time some discharge, the use of astringent lotions, such as alum, in the proportion of four grains to an ounce of water, is indicated. If there is little redness, and what there is of it is confined to the portion around bag with nozzle in connection with an india

inability to open the eye, and bear the light, and if the pupil is sluggish, astringent washes will do harm. In such cases the eye must be bound up with belladonna lotion applied to it. In young children, especially of a scrofulous tendency, small ulcers often occur on the eye, which give rise to the symptoms mentioned. The belladonna lotion is best adapted for such, and in addition, an ointment containing two grains of yellow oxide of mercury to a drachm of lard or vaseline, should be applied to the eye at bedtime. Along with the local treatment, cod-liver oil and steel wine should be taken For information respecting the regularly. more chronic affections of the eye, the reader is referred to articles Amaurosis, Cataract, &c. In some eye affections the lids are apt to become glued together during sleep by the secretion; this is best prevented by smearing the edges with some simple oil or ointment. The edges of the lids, likewise, are apt to become affected with a succession of small pustules, or abscesses, which often continue to form in spite of treatment, depending probably on some disorder of the digestive organs, which should be attended to. The local treatment consists of alum lotion and the application to the edges of the lids, night and morning, of an ointment composed of one part of nitrate of mercury ointment to eleven parts of lard or vaseline.

In some exceptional cases of eye disease, there is needed a continuous application of lotion, fomentation or irrigation of the affected eye; this is best done by a simple apparatus (which may be obtained at the

FA1

rubber tube to which a small rose is attached, and which is represented in action in the illustration from Maw & Son's Catalogue (fig. 89).

The lachrymal sac, or some of its ducts (fig. 86) are apt to become the seat of inflammation, and to be blocked up in consequence; the tears, not escaping by their natural outlet, run over the cheek, causing painful excoriation, and the corresponding nostril is dry. The disorder is not only troublesome to bear, but often to manage, and should be seen by a surgeon.

A stye in the eye, or rather the eye-lid, is a small abscess, and often gives great pain; it is

best treated by fomentations.

Blows on the eye frequently give rise to effusion of blood beneath the conjunctiva, which occasions the white of the eye to become of a deep, almost black, red colour, and to present a very alarming appearance. The state of matters may be distinguished from inflammation by the uniformity of the redness, and by the absence of those characteristics. teristic symptoms enumerated above. effusions, the result of the rupture of a small blood-vessel, are harmless, and disappear without any treatment.

Disorded vision may be the result of causes, such as cataract, &c., which interfere with the transmission of the rays of light, it may also arise from disorder of the digestive organs, and not unfrequently from incipient disease of the Persons who become suddenly and unaccountably affected with disorded vision, should manage themselves as directed in article Amaurosis, and get medical advice as

speedily as possible.

FAINTING, or SYNCOPE, is a state of partial, or of total unconsciousness, in consequence of diminished circulation of blood through the brain, the result of depression of the heart's action. Some persons are much more liable to become faint than others, and there is often a good deal of peculiarity with respect to the acting cause. Certain objects of sight will cause some persons to become faint immediately, the most general, probably, being accidents or their consequences, which injure the human body, and cause effusion of blood; certain smells affect others, and cause immediate faintness; even the smell of a rose has been known to have this effect. Affections of the mind, and sudden emotions, debility, habitual or temporary, weakness of the heart judiced, a true faith in curative means,

itself, loss of blood, or, in fact, whatever depresses the acting power of the central organ of circulation is apt to produce faint-

A person about to faint becomes affected with ringing in the ears, the sight fails, the ideas are confused, and the mind incapable of exertion, the countenance becomes deadly pale, cold sweat breaks out over the forehead, the power over the limbs either becomes very unsteady or fails altogether, and if actual fainting happens, the individual sinks down, and is really in a condition which much resembles death, and might pass into death.

As said above, the direct cause of fainting is diminished circulation of blood through the brain; it must be obvious, that in the endeavours to restore a person who has fainted, this condition must be altered as quickly as possible; and for this purpose, the individual should be laid quite flat down, the head on a level with the body, so that the feebly acting heart may not have to propel the blood upward, but horizontally. The neck and chest should be exposed, fresh air admitted freely, a little water sprinkled on the face, and stimulant vapours, such as ammonia, held to the nostrils at intervals. Sal volatile or a little spirits or wine and water or from twenty to thirty minims of chloric ether, if the person is capable of swallowing, may be given. Stimulant vapours, such as those of ammonia and nitrite of amyl, are of much service, and convenient in application. Friction over the region of the heart with the hand or rough cloth should be vigorously employed with other means, when there is a difficulty in restoring animation.

It must be remembered that the first period of some apoplectic or paralytic seizures is one of faintness; and also, that where the affection is the consequence of loss of blood, its continuance to some extent may be the safety of the patient. In either case the use of stimulants must be a very cautious one.

Refer to-Apoplexy-Hamorrhage, &c.

FAITH in medicine is one of those strong emotions of the mind which, like hope and despondency, exert much influence upon the progress of a case of illness, whether it attaches itself to the medical attendant, or to the system of treatment pursued by him. The history of popular delusions connected with the treatment of diseases, is rich in illustration of how far simple faith in some method of treatment which has acquired reputation will add to the apparent curative powers of that method, in consequence of results which are due to that tendency to cure-vis medicatrix naturawhich has no more powerful assistant than the hopeful and trusting, even if mistaken, mind. It sometimes becomes a nice question in medical ethics how far medical men are justified in using this agent in the treatment of their patients. With the intelligent and unpre-

grounded in clear understanding of the nature | of their case, and the requisite treatment, is always to be preferred to a blind and unreasoning trust, however implicitly given; but amid the ignorant, if they will employ a fomentation more assiduously because it has a few chamomile flowers in it, or such like, and if it will ensure their greater faith in the treatment generally, it is a concession to prejudice at least, which ought to be made. Many persons err in placing too great reliance—faith—in mere medicines and drugging alone, to the neglect of the equally important general aids in the treatment of disease, so often alluded to in this work. Such persons are not content, and do not think themselves properly—"actively"—treated if they are not constantly swallowing physic. The error must in a great degree be ascribed, in England at least, to the foolish, absurd, and it may be said, degrading system, which has so long prevailed of making the remuneration for the time and skill of a medical attendant depend upon the price-and that a factitious one-of his drugs. The author cannot refrain from taking advantage of the opening afforded him by the present work to assure the public how gladly the whole body of the medical profession would change the system. Many are endeavouring -and, the author can speak from his own experience, successfully-to do so; but still a large proportion of the payments of medical accounts in England are upon the medicines, and disputes for attendance-charges are constantly being made. The man who will insist upon basing his medical attendant's just remuneration upon draughts and mixtures, must probably, in many cases, be content to swallow sufficient to remunerate. This system, in addition to other evils, has engendered a faith in mere drugging as necessary for the cure of disease, to the exclusion-and this is the main evil-of other essential aids. The public are in many places becoming alive to the absurdity of the old system, and medical men might by an effort overturn it entirely, and by so doing place both themselves and patients in a better and juster position.

FALLING SICKNESS, or EPILEPSY.— See EPILEPSY

FAMINE.—See STARVATION. FARCY.—See GLANDERS.

FARINA-derived from "far," cornmeans literally the meal or flour formed from grain, when ground, and consists, therefore, of starch, gluten, &c.; the word, however, is sometimes applied to the farinaceous matter contained in other vegetable products, such as the potato, when it consists almost entirely of starch or fecula; also in beans, peas, &c. The farinaceous matters, or particles, are contained in a network of cells.—See Fecula.

FARINACEA.—Articles of food generally which contain farina.

FARINACEOUS FOOD comprises such articles of diet as are prepared from one or other of the cereals or tuberous roots, in a way to render them easy of digestion. Articles of this kind are now so numerous, and appear every day with such rapidity, that a bare enumeration, even, would be impossible. One of the most celebrated and best known, is "Liebig's food," which contains all the elements of a nutritious food for infants or for invalids, when mixed and taken according to directions.

Brown & Polson's patent corn flour, pre-pared from maize or Indian corn, forms an excellent and firm jelly. It may also be used boiled with milk as a diet for children, and it is a useful article in the cookery of the sick-room,

for thickening beef tea, soups, &c.

Another superior corn flour is that known as Maizena, which received a prize medal, and was favourably spoken of by the judges at the International Exhibition. Semola, pearl semoule, cerealina, embden groats, patent groats, and patent foods of all kinds, have their advocates, and it must be remembered that one which will agree with some children, will cause purging, griping, and acidity, with others, so that we are often forced to try several, before we find out which agrees best with the delicate stomach of an infant. Sago, arrow-root, and tapioca are familiar to every one, and may be looked upon as the types of a large class of dried farinaceous foods which are imported into this country, but their use has been in some measure, at all events, supplanted by several of the preparations above noticed. All these kinds of food consist more or less entirely of starch; they have very little, if any, flavour of their own, requiring to be seasoned by condiments, and have a very low nutritive value, unless they are cooked with milk. They absorb a considerable quantity of water. By this means they increase greatly in bulk, and may be used either as puddings and jellies, or as drinks resembling gruel.

Dr. Edward Smith, in his Practical Dietary, highly recommends maize as a cheap farinaceous food for the poor. The great objection to its use is its rough taste, so that it is never a favourite article of diet with those who have been accustomed to wheaten flour. Since the potato famine in Ireland, it has been of the greatest service to the poor of that country. Dr. Smith says :- "When the 'col' or head of maize is yet young and the grain soft, it is commonly gathered whole, and boiled in milk, &c., is a delicious food; but when ripe, the grain must be ground before it is cooked. In the western parts of America, the grain is freshly ground in a handmill and mixed with water and a little salt, and sometimes a little soda is added; and when paste is made it is spread into a little cake, about one inch in thickness, and baked before or over the fire. When milk and eggs are allowable, they may be added, with great advantage to the flavour of the bread. In

FAS FAS

treland, it is generally made like the Scotch | dition to receive nourishment, it can scarcely be porridge, by scalding it and stirring it into boiling water, until a hasty pudding is prepared, when it is poured out and eaten with a little sugar or treacle, if obtainable, and with milk. This is called stirabout, and has a rough and not agreeable flavour. When prepared in a peculiar manner, as in the Oswego corn flour, it offers excellent and agreeable farinaceous material for puddings, but so prepared its cost

s much enhanced.

"The nutritive qualities of maize are very considerable, since it offers more carbon and nitrogen than is found in an equal weight of wheaten flour, viz., 2800 grains of carbon and 121 grains of nitrogen in each pound, besides a considerable quantity of free hydrogen, which is found in the fat, a substance in which the grain is somewhat rich. In point of economy it exceeds all other grains, since it is sold at a penny per pound, and offers the above large quantities of nutriment for that sum. It is, however, highly probable that it is not fully digested when taken in large quantities, for the amount which leaves the bodies of those using it daily is very considerable, much more than would be found with a bread dietary.

If at any future time food threatens to become expensive, it is not unlikely that maize, or Indian corn meal, may be more generally used in this country. We therefore give Dr. Smith's practical instructions to the poor, as to the best methods of preparing it.

"When you can buy it, you will find it a stronger and cheaper food than flour. Make

"1st.—Hasty pudding, by sprinkling it into boiling water, and boiling it for a short time. Eat it with milk, sugar, treacle, or butter.

"2nd. - Cakes, by stirring it well in hot water or skim milk, and then baking it in the frying pan or dutch oven, or upon the hot hearth; or spread upon a board, and lay near to the fire.

Eat them hot, with milk, butter, or treacle.
"3rd.—Puddings with milk, fat, or spice."
Among the many varieties of "farinaceous food," there are few which do not consist of flour highly baked, or subjected to some heating process. Sometimes a little lentil, or pea flour is added, or a little potato flour, or arrow-

Refer to—Cookery for the Sick—Food—Gluten

FASTING .- The remaining without food for a longer period than usual may sometimes be a useful proceeding, as a kind of negative remedy, for those who have been living too freely; but even then abstemiousness, that is, the partaking of a reduced quantity of very plain food, is better than complete denial of aliment. Fasting, as a term, is more properly applicable to a condition in which the desire for food exists. When the appetite fails, as it does in disease, and its failure is a natural indication that the system is not in a fit con- tremely small supplies of nourishment, when

said that a person fasts. The power of fasting depends greatly upon habit, constitution, climate, and other contingent circumstances. It has been, and still is, the custom of many nations to take but one meal in the twenty-four hours, but if into that meal must be crowded the entire nutriment required for the body during that space of time, it is needless to remark that for some time after, the individual can be fit for little beyond digesting his food, and that such a division of duties would but ill suit the arrangements of civilised life, even if it could be followed without serious detriment to health. As a general rule, it may be said that it requires more than an average of constitutional vigour to enable an individual in this country and climate to do with but two meals a day, that is, to fast twelve hours at a

The consequence of too long fasting is physical exhaustion of the body generally, in which the stomach, of course, is involved; consequently, when a person has gone longer than usual without food, especially if undergoing fatigue at the same time, although the system at large requires nourishment, the stomach is so weakened, that it cannot digest a full meal. The inability to fast with impunity is increased the more rapid the changes going on in the system; thus, children and young people tolerate fasting worse than others; and for the same reason, physical exercise or fatigue, which quickens all the usual functions within the body, also renders undue fasting less easily borne, and more injurious. External circumstances, again, such as shelter, clothing, climate, all exert much influence as regards the toleration of fasting. It has been shown in more than one article in this work, that a certain proportion of the nutriment taken, is required as fuel, that is, as a chemical agent, to assist in sustaining the bodily temperature, and it is evident that the less abstraction there is of animal heat,-in other words, the better either man or animals are protected from the cold, -the less occasion have they for food within a certain limit; and as a necessary inference, fasting may be practised with less injury in a warm than in a cold climate, and such is found to be the case among civilised people. Barbarians, or uncivilised tribes, such as the Esquimaux, who feed to a repletion which would kill other persons-and thus lay in a store of nutriment -are of course exceptional. Perhaps the best instances of the power-not exactly of fasting, but of extreme abstinence, is in the runners of Northern Africa, who are said to travel immense distances and at a very rapid rate, with only the sustenance of a limited portion of gum during the journey. The Arab horses, too, have often excited the wonder of travellers from their powers of endurance on ex-

compared, at least, with what is required by | animal economy, in the building up of certain the same animal in this country. Hereditary constitution and habit, however, undoubtedly assist the influence of climate.

As a general rule, it may be taken that entire abstinence from food by persons in health in this country for more than six or eight hours, must, if habitual, be injurious, and the more so the younger and more delicate the constitution. Very many cases of stomach disease date from the practice.

The marvellous cases of long fasting, which have from time to time been brought before the public, have turned out, on strict investigation, to be impositions, although they have served to exemplify the power of sustaining life on extremely small quantities of nutri-The power of fasting, without injury, seems to be considerably increased in cases of insanity, and if it is so in one form of nervous excitement, it may be so in other excited conditions of mind.

The subject of fasting has been treated in this article in an every-day life point of view, as it applies to society generally, more especially at the present day in this country, and without any reference to Scriptural history, or to those miraculous powers which are recorded, either in the case of our Lord Himself, or of holy men of old, when for His good purposes they were imparted; the remarks are made to impress the fact that absolute fasting is injurious to the majority, the more so if habitual, and may lay the foundation of dis-

The apparently well-authenticated case of Dr. Tanner of New York, who fasted experimentally for a period of forty days, is quite exceptional, and shows the extraordinary power of water alone in sustaining the vital powers for a prolonged period. In drawing inferences from this case it ought to be kept in view, that the experimentalist had neither the tension of mind nor the sufferings which a person deprived entirely of food by shipwreck or accident would have to endure, for there can be little doubt that the knowledge, that at any moment hunger might be appeased, had a powerful effect in enabling Dr. Tanner to accomplish his quixotic enterprise.

Refer to—Animal Heat—Blood—Digestion

-Food, &c.

FAT is universally consumed, and among the hydrocarbons used for food it forms the most important heat and force-producing, its power in this respect being two and a half times greater than the carbohydrates, represented by starch and sugar. The properties of oils and fats are due to a fatty acid, and to glycerine. They are in their various combinations in food readily separated in the process of digestion, and absorbed into the circulation, after being reduced to a milky emulsion by the action of the pancreatic juice. They after-

tissues, but mostly in maintaining the animal heat. Under the name of adipose tissue, fat is deposited in greater or less amount beneath the skin, and in and about the internal organs, where it is stored up when wanted for the purposes of the animal economy. It gives roundness to the form, equalises pressure, retains internal warmth, and renders the tissues supple and elastic; but its accumulation may become so great as to amount to disease, and to produce an impediment to the performance of the duties of life, as well as a cause of its shortened duration. The following remarks from the high authority of Dr. Chambers ought to be universally diffused. After adverting to a species of "monstrous" obesity, or fatness, which dates from birth, and is generally associated with intellectual deficiency, and fortunately proves fatal before the age of puberty, he remarks:—"When the disease"—that is, obesity—"begins in childhood, or about the time of puberty, we must not be deterred by the circumstance of its being hereditary from attempting to remedy the inconvenience arising from it. We cannot truly reduce our patients entirely to the average size and weight; but we may enable them to pass life with comfort and usefulness. The later the disease commences, the more controllable it is by management, until the middle period of life is passed, and then old age impedes in some degree the benefit which we may confer; not by rendering our measures inert, but by preventing our employing them quite so actively as we should have done

"The first thing indicated, in all cases, is to cut off as far as possible the supply of material. Fat, oil, butter, should be rigorously interdicted in the diet table. But all eatables contain some portion of oleaginous matter, and especially those most convenient to advise the use of for a lengthened period; and almost all are capable of a transformation into fat, when a small quantity of this substance is previously present. It is desirable, therefore, that the mass of food should lie in the stomach as short a time as possible, in order that at least a fatty fermentation may not be set up in it. Very light meals should be taken at times most favourable to rapid digestion, and should consist of substances easy of solution and assimilation. To this end, the time of the meals should be fixed for an early hour in the day, before exertion has rendered the power of the organs of nutrition languid and weak. Breakfast should consist of dry toast, or what is still better, sea biscuit; and, if much active exercise is intended, a small piece of lean meat. Dinner at one, on meat with the fat cut off, stale bread or biscuit, and some plain boiled maccaroni, or biscuit pudding, by way of second wards perform most important offices in the meal, but half an hour after, so as not to imcourse. Liquids should be taken, not at the

FAT FEA

pede the action of the gastric juice upon the I think a trial should never be omitted. The mass. Here should end the solid feeding for the day; no second dinner or supper should follow, nor, indeed, any more meals be taken sitting down. A piece of biscuit and a glass of water can be taken standing up, if faintness is experienced; a cup of gruel, or a roast apple,

before going to bed.

"The smallest amount of nutriment consistent with the health of the individual can be found by experiment only; but we need not fear that ten ounces of solid food a day is too little. It may be remarked, by the way, that it is often advisable to add a small allowance of malt liquor at dinner, as otherwise the craving of the appetite is less easily appeased. The beers to be avoided are of course the thick sweet kinds; but that which is thoroughly fermented, at a low temperature in the Bavarian way, seems to contain very little injurious matter. I do not know that any advice concerning sleep is peculiarly applicable to obese persons, beyond what we should recommend to all classes of men. They are usually uneasy sleepers, and though lethargic, by no means averse to early rising.

"In cases where the fat is largely accumulated in the abdomen, it is very convenient for the patient to wear a band round the cavity, which may be tightened gradually. support thus given to the abdominal muscles relieves the dragging sensations in the loins which many persons, whose viscera are heavy in proportion to their strength, experience. It enables exercise to be taken with more facility, and appears also, by pressure, to afford some assistance to the absorption of fat. The above remarks will apply equally to all forms of obesity; the abstinence recommended can be borne even by the aged, and only comfort

be experienced.

"As respects exercise, however, a distinction requires to be made. The young and vigorous, whose obesity does not prevent the use of their legs, cannot employ them more usefully than in walking as long as they are able. The greater number of hours per day that can be devoted to this exercise, the quicker will be the diminution of bulk. But as riding, by the gentle shaking of the abdomen excites the secretions of the digestive organs more, it should, when practicable, be employed in addition. Where freedom of motion has once been gained, rowing, shooting-any, or all, of the forms of British gymnastics, should be adopted as regular habits. . . .

Purgatives, I have generally found not needed in the plethoric form; the bowels usually act once or twice in the day. But in the asthenic obesity of old people, where the abdominal walls are weakened by long pressure of an unnatural weight, it is necessary to

versally applicable to all cases of obesity that obscured by sobs, that it is next to impossible

chemical affinity of alkalies for fat, points them out as appropriate alteratives in this complaint, and experience proves that they are suitable to the state of the digestive organs. The most eligible one is liquor potassæ, and it may be administered in much larger quantities than any other. If given in milk and water we may safely commence with half a drachm, and raise the dose to a drachm and a drachm and a half, three times a day. The milk covers the taste of the potash better than any other vehicle. It has, truly, the advantage of saponifying a portion of the remedy, but there is no evidence to prove that its efficacy is thereby endangered; indeed, soap itself has been strongly recom-mended."

Vinegar, which is sometimes foolishly taken largely, with a view to reduce fat, can only do so by disordering the digestive organs.

Food of a fatty nature is generally difficult of digestion, and persons suffering from consumption have usually a dislike to it. As a remedy in the cure of disease, the fats of various animals, deer, vipers, &c., were formerly used in medicine. These have all given place to the oil expressed from the liver of the cod. In some cases of irritability or low inflammation of the lining membrane of the stomach, fatty food seems to be serviceable.

FEAR, the exact opposite of faith, is one of those depressing agents which always act unfavourably in cases of confirmed disease, and lay the person open to the attacks especially of contagious or epidemic maladies. Sudden fear has sometimes acted beneficially, and paralytics have been known to recover the use of their limbs in their efforts under a paroxysm of terror; more generally, however, its operation is the reverse, and many cases of epilepsy, mania, heart disease, &c., date from fright. In children, particularly of a nervous temperament, the influence of fear, either in jest or earnest, is most sedulously to be avoided. Above all things, care should be taken, that circumstances in which children may be placed accidentally, or individuals with whom they may necessarily have to come in contact, are not made sources of terror. This is too often practised, and threats of what the "doctor will do," so terrify a child, that when visited in illness, fright quickens the pulse, the tongue will not be employ them.

FEBRICULA—a slight fever.

FEBRIFUGE. - Any medicinal agent which has the power of subduing fever; but the only true febrifuge is cinchona bark and its alkaloids. The term was much more used in former times than it is now.

FECULA, or STARCH, is a principle universally diffused throughout the vegetable kingdom, nearly approaching gum in composition; it is found in various parts of plants, where it is evidently destined to be a store of nutriment for their young or newly-developed parts; thus, in seeds it nourishes the young plant; in tubers, such as the potato, the bud shoots; in the sago palm, the young leaves. Before, however, it can afford suitable nourishment, it must be converted into sugar, and this is done by the influence of Diastase, a substance already treated of. It need scarcely be said that whilst starch fulfils its peculiar office as regards the vegetable, it is a no less important provision for animal wants; it is, in short one of the chief elements of nourishment derived from the vegetable kingdom for the support of animal life. Amid other examples, arrow-root is nearly pure starch. Starch occurs in the form of granules, which vary considerably in size and shape, according to the tribe of plants from which they are obtained; of this fig. 90,  $\alpha$ , b, c, d, are instances; these represent respectively the starch granules of West India arrow-root, East India arrow-root, Tahiti arrow-root, and potato arrow-root, as seen magnified by a microscope. These granules are composed, as represented, of concentric layers. the outer of which, when exposed to a temperature of 160° in water, burst, and allow the inner layers to be dissolved, consequently starch of any kind, after exposure to the above heat, can never be restored to its original condition. It is scarcely requisite to remark, that starch is insoluble in cold water, differing in this respect

The composition of starch is simple, that is to say, it is made up of carbon and water, or of equal parts of carbon and the components of water, oxygen and hydrogen, but it contains no nitrogen, no earthy matter. From this it is evident that the nourishing power of starch, and of starchy articles of food generally, is limited, that is to say, they cannot yield what they do not possess, nitrogen and earthy salts; but as these are requisite for the full nourishment of every portion of the frame, starchy food, either alone or in too great preponderance, cannot sufficiently nourish the body, particularly during the period of growth. This will bear out remarks made under articles Arrowroot, Bread, &c., which show that animals

to arrive at an accurate judgment of the case. | or articles principally composed of starch, and that through ignorance of these facts, infants and children have been seriously injured by the improper regulation of their food. But though

starch, and such-like compounds, e.g., sugar, gum, &c., cannot build up bone and muscle, they can protect them, they can furnish respiratory aliment, or fuel, and also, when not thus required, assist largely in the formation of fat.

FERMENTATION is a process of decomposition, or of change, in the relations of the various elements of fermentable bodies. For the action of this process of decomposition or of fermentation, it is indispensable that certain "azotised" substances, named ferments, should be present. The substances all belong to the albuminous principles; bodies which in a moist condition putrefy and decompose spontaneously. Thus, a solution of pure sugar will not ferment, however long it may be kept; but but it is not the alcoholic; no gas is evoked,

men, or gluten, or yeast, be added to the solution, the change quickly commences, and goes on until fermentation is complete. Vegetable juices, such as that of the grape and others, and even a solution of brown sugar, take on the process of fermentation spontaneously, because they contain sufficient azotised principles-approaching the putrescible albuminous animal matter in composition-to act as ferments. Milk also takes on a spontaneous process of fermentation for the same reason, if a decomposing-putrefying-azotised fer- and instead of spirit, a peculiar acid, the

over, exerts much influence upon the process of fermentation, and some juices yield either alcohol or lactic acid according to whether the process is carried on under a low or high temperature. The acetous fermentation or that which results in the production of acetic acid, or vinegar, is carried on in a temperature of from 70° to 85° Fahr., and of course likewise requires the presence of a ferment. A certain amount of moisture and elevation of temperature is essential to the process of fermentation; dryness and cold alike stop the action.

constituents of blood, and of the nitrogenised sugar. Antiseptics stop the process of fermenconstituents of vegetable food, has certainly tation.

"lactic" is generated. Temperature, more- | furnished, in an unexpected manner, an explanation of the fact, that putrefying blood, white of egg, flesh, and cheese, produce the same effect in a solution of sugar as yeast or ferment.

The explanation is simply this, that ferment or yeast is nothing but a vegetable principle, resembling these animal ones, in a state of decomposition. As it is that modification of sugar only, named grape sugar, which is capable of being converted into alcohol, all fermentable substances, whether containing cane sugar, or starch, must be, and are, as the "The identity in composition of the chief first step of the process, converted into grape FER FER

"The maturation, as it is called, or sweeten- | been known and used from the earliest periods. ing of winter fruits, when stored up for their preservation in straw, is the result of a true fermentation. Unripe apples or pears contain a considerable amount of starch, which becomes converted into sugar by the nitrogenous constituent of the juice passing into a state of decomposition, and transmitting its own mutations to the particles of starch in contact with it."

The researches of chemists and physiologists in connexion with the phenomena of fermentation, have thrown much new light on the subject, especially as regards its bearing on the origin and communicability of what is now termed zymotic disease. Pasteur, the eminent French chemist, has clearly shown that correlative with the chemical changes noted above, there always occurs in the process of fermentation a continuous production and reproduction of minute organisms, which begin life and terminate it with the process. Also, that the varieties of ferments are numerous, and that each ferment possesses its own peculiarities and characters, sometimes aiding, often checking, and frequently proving detrimental to the processes when combined. Of the causes giving rise to alcoholic fermentation, the growth of the yeast plant is the best example; the wine ferment, and that occasioned in the expressed juice of fruit, although they partake much in common with yeast, differ from it materially in the size and shape of the cell globules. When fluids become sour and stale, the changes in their composition are due to the action of some particular ferment. The illustration from Pasteur (fig. 91) represents several stages in the growth of the globules and bacteric filaments, which are to be found in sour beer.

The lactic acid fermentation, which takes place in milk when it becomes sour, is traced to the presence of a small oval-shaped bacterium. The butyric acid ferment and the numerous changes allied with the decomposition of urea and other animal substances, owe their existence to living cells derived evidently from the lowest forms of plant life. In fact, all substances liable to putrefy acquire the property of fermentation, and become capable of originating the process afresh in any organic matter of a like character brought within their sphere.

Refer to-Alcohol-Antiseptic-Vinegar-

Germs of Disease—Yeast, &c.
FERMENTED LIQUORS—that is, beverages which have undergone the process of alcoholic fermentation—may almost be considered a natural product of warm climates, from the readiness with which vegetable juices take on the process in these situations. The pure juice of the grape, if left to itself in a suitable temperature, will ferment in a few hours, and the palm-juice of Africa and other tropical countries, and the "pulque" of Mexico, are instances of the same thing. Ancient records, including those of Scripture, In the present day, the principal fermented liquors in use are—1. Grape wines; 2. Domestic or home-made wines, which are for the most part rendered fermentable by the addition of sugar; 3. Liquors made from the fermented juice of the apple or pear; 4. Malt liquors from various grains, principally barley. For further information the reader is referred to the individual articles on the above subjects, also to Drinks, Food, &c.

FERN, or MALE FERN-or, as it is called in botanical language, the Aspidium filix mas. - is a common native plant, noted principally as a remedy in tape worm, but until lately too much neglected. It is one of the best vermifuges we possess. The male fern (fig. 92) grows chiefly on strong ground, in

Fig 92.

slightly-shaded situations; no description could guide an unprofessional and unbotanical person to gather it with certainty if it cannot be recognised from the illustration, but, perhaps the safest plan for any one wishing to use it, would be to have the plant either collected for him, or to have its distinctive characters pointed out by some competent person. Dr. Christison gives the following directions:—
"The root, which is the part of the plant used, should be collected between the end of May and the middle of September. It should be cleared of foreign matters, root fibres, and old or decayed tufts, but without being washed. It should then be dried quickly and thoroughly in the open air without heat, and in the shade; these tufts, as well as the parts of the root-stock, which are greenish internally, should alone be detached, and immediately reduced to powder; and the powder must be kept in well-closed bottles." It should not be trusted to when above one year old. The usual dose of the powdered root, is from one to three all tend to show that fermented liquors have ether is the best preparation, the dose eighteen drachms; but the oil extracted by means of

FER FEV

grains given at night, either in pill, emulsion, | nically called exanthems, continued, and or mixed with castor oil, and repeated again in the morning. It is better to avoid much food just before taking the dose of either powder or oil, or during their operation, and it is always requisite to follow the last dose taken with some aperient—castor oil is perhaps the best—two or three hours afterwards. The worms are discharged dead. A good way of employing the remedy is to take one drachm of the oil, ten grains of tragacanth powder and half an ounce of water, to which add an ounce and a half of new milk. The patient should be a day without food before taking the medicine, which ought to be taken in the morning, the bowels having been previously relieved by a table-spoonful of castor oil. If the draught does not purge in twelve hours, another dose of the oil should be given.

FERRUGINOUS—connected with iron. FETOR is a bad odour of any kind. In many cases it is the result of the process of

putrefactive decomposition or fermentation, and may be developed either on the external or in the internal parts of the body. The use of chlorine, charcoal, carbolic acid and other deodorants, in various ways, is the best corrective. The mercurial fetor is a peculiar odour, always acquired by the breath when the constitution is sensibly affected with mercury.

Refer to-Chlorine-Mercury, &c.

FEVER is that condition of the body in which the pulse is quickened, the skin hotter than natural, thirst present, and the functions generally disordered. This feverish state of the system may arise from, and be the concomitant of, various local and other affections, but it may also constitute a disease in itself, and it is in this light that the present article

FEVERS constitute a large class or classes of diseases which owe their origin to a specific virus, the nature of which science has not yet been able to elucidate, and which may exist in the air, or in water, or in the clothes we wear; and when it enters the body it finds there a genial soil on which it may not only live, but fructify. The poison thus introduced lies dormant for a time, during which it is said to be germinating or incubating, and after an interval certain constitutional changes take place, not affecting any special organ like the heart, brain, or lungs; but, in the first instance, manifesting themselves in the blood, by an increase of the pulse and heightened tempera-This condition, constituting the first stage of fever, does not determine what the issue may be, but after another interval, varying from three, four, seven, or eight days, and even longer, certain symptoms supervene, of such a definite type that a medical man is able to pronounce what the nature of the fever may be. The best marked forms of fever, may be divided into those attended with a rash, tech- over them. The rash is attended, as in most

periodic fevers. The first comprise small-pox, measles, and scarlet fever, to which might be added typhus and typhoid fevers, as they are each attended with a rash, though usually placed in the category of continued fevers. The remaining fevers most usually met with are febricula, relapsing, yellow, remittent, and intermittent fever or ague. The spotted fevers, and some of the others, are specially commented on under their respective headings, and the following article will mainly refer to such

fevers as are not separately noticed.

FEVER, TYPHUS .- The history of typhus is a melancholy record of famine, dirt, and overcrowding. We come across its path in old writings, where it appears under a variety of pseudonyms, connected with a kind of spontaneous origin, such as Jail fever, in cases where prisoners were too closely packed to-gether; Hospital fever, when it invaded the wards of ill-ventilated and crowded asylums for the sick; Camp fever, when it broke out among the wounded in war times; and Ship fever, when it occurred in emigrant vessels or slave ships on long voyages. It has followed the track of invading and retreating armies, as every nation in Europe has known to its cost, and in the middle of the last century it did not scruple in London to invade the courts of justice; the name of the "black assizes" becoming historical in the city annals from the fact of the Lord Mayor, two of the judges, and other eminent personages having fallen victims to the pestilence which they had contracted from the prisoners. During the present century, many wide-spread epidemics of typhus have occurred in the United Kingdom, especially in Ireland, conterminous with periods of mer-cantile depression, high prices, and great scarcity of food; and the disease being extremely contagious, it has spread rapidly among the poor, as well as amongst those who had relations with them, especially among medical men, catholic priests, and nurses.

Typhus fever sets in eight or ten days after exposure to the contagion, with intense headache, languor, and weariness, gradually passing into confusion and stupidity. It reaches its height in about fourteen days from the commencement of the symptoms, and in favourable cases a week after this or about the twenty-first day, the person as a rule is comparatively well. When the complaint is severe, delirium, coma, and utter prostration, come on, followed often by death between the twelfth and the twentieth day. Then the eruption by which typhus is distinguished from other fevers and which is said to be present in 90 cases in 100, appears often as early as the third day on the arms, on the chest, or on the abdomen, lasting generally for a week or more, as small dark red or

FEV FEV

cases of spotted fever, with a pulse ranging | from 100 beats to 150 in a minute, and with a body temperature ranging from 102° to 107° Fahr., combined with a brown furred tongue, red at the tip and edges, and with hurried respiration. These symptoms are usually well marked from the first onset of the disease, and show little inclination to diminish till the turn of the fever, the highest temperatures being most marked in such cases as are attended with a fatal termination. Suppression of urine is not an uncommon symptom of typhus, and may account for the delirium and great nervous prostration; when the suppression is complete

the disease is always fatal. Treatment.—Medical men are now pretty well agreed that the main object in treating fever is to ward off death, by sustaining life with food, and, if necessary, with stimulants, until the force of the fever has expended itself. a quick pulse and high temperature, the oxidation of the tissues proceeds at a much quicker pace than in health, and it has been ingeniously calculated that a person lying in bed in a state of high fever loses as much force, in the course of twenty-four hours, by the chemical changes taking place in his blood, as would enable a person in health to walk fifty miles in the same time with one cwt. of coals on his back. It is thus essential that the waste of tissue should be combated as far as possible; that the vital force should be restrained and husbanded, and this is best done by nourishment in a concentrated form, beef tea, milk, and stimulants; for stimulants in fever act as tonics, as well as It is often said with considerable justice, that the successful treatment of a patient suffering from fever depends as much on the nurse as upon the doctor, because the nurse has the feeding of the patient very much in her own It is well, then, that unprofessional persons should fully understand the importance of this mode of treatment, and that when typhus fever is fully established, -say, from the third to the fourth day, -nourishment should be administered every three or four hours, and should be continued throughout the course of the disease. Beef tea, mutton broth, meat juice, arrow-root, milk and light puddings, are the mainstays; while wine and spirits, though not usually required in the first week of the disease, may be necessary in the second, and if given at all, should be continued till the crisis is past. A large well-ventilated apartment is the best for a person suffering from typhus, as that implies greater safety to the attendants, as well as health and vigour to the sufferer. If a sufficient amount of fresh air can be had, less apprehension need be entertained of infection, for the contagion of typhus, like the effect of a strong drug, loses its virulence by dilution, and those are comparatively safe who remain at a considerable distance from the bedside of the patient. Although the

well that those who must be in close relation to typhus patients should avoid catching their breath, as it is mainly from the lungs that the disease is propagated. Quiet, fresh air, a free supply of iced water, milk, and beef tea are the best helpmates in typhus; but the patient requires to be well watched, and the pulse and temperature taken frequently, so as to assist in the administration of food and stimulants, and stimulants when ordered must not be taken at a gulp, but at regular intervals. The headache in typhus is often distressing, and must be treated with cold applications to the foreheadicebags are the best; it may even be necessary to apply a few leeches to the temples, but the patient requires all his strength to enable him to surmount the malady.

FEVER TYPHOID. - See ENTERIC FEVER.

FEVER-FEBRICULA-is the mildest form of all fevers. A person suffering from it may be scarcely conscious of its existence, and will probably put it down to the effects of a severe cold. It is very common in children, and mothers dread its appearance, lest it should be the precursor of some more serious complaint, as measles or scarlet fever; when, after a few days, varying from two to three, their fears are dispelled by the restoration of the child to its ordinary health. There are, however, the usual characteristics of the febrile state in febricula, the rapid pulse, the high temperature, pains in the back, great thirst, and often constipated bowels. All these symptoms subside after a little aperient medicine has been administered, or even without it, and usually on the appearance of a copious perspira-

FEVER, RELAPSING. — Although periodic in character and name, relapsing fever is always classified in the category of continued fevers. It is not endemic with us, as typhus and typhoid fevers are, but it occassionally visits some of our large towns as an epidemic, at long intervals of from fifteen to twenty years. It is by no means a deadly disease, but is spread by a contagion peculiar to itself, as has been frequently observed in hospitals appropriated for the purposes of fever, when patients recovering from typhus or typhoid fever have been seen to be attacked with relapsing fever, and the converse also holds true. From the history of the epidemics of relapsing fever in the United Kingdom, and especially in Ireland, the disease must be regarded as a kind of famine fever, attacking for the most part the starving population of the country; while from its essentially contagious character, doctors and nurses cannot enjoy an immunity from its attacks. It is a singular disease, and as the name indicates, it is attended by a repetition of the same phenomena which it had previously exhibited on the occasion of the first attack. After a week or so from the onset, all the febrile symptoms zone of contagion may be thus limited, it is disappear, and the person is not only able to

leave his bed, but feels capable of, and sometimes actually returns to, his ordinary employment, when about the fourteenth day dating from the commencement of the disease, he is seized suddenly with a relapse of all the febrile symptoms, which continue from three to eight days longer. Such is the usual course of the complaint, but in many instances, the relapse is repeated two or three or more times before the patient is entirely restored to health. In hospitals and sick asylums, where people suffering from relapsing fever are usually treated, there is often great difficulty experienced in persuading the patients to remain during the interval between the first and second attack, as they feel themselves quite able to return to their usual employment. An attack of relapsing fever is ushered in with great suddenness; shivering and chilliness, combined with a moist and white tongue, quick pulse, and high temperature, are the prominent symptoms. The temperature of the body increases towards the crisis, when it is said to rise as high as 106° Fahr., and afterwards suddenly falls to a normal state, and even below t. The complaint is readily distinguishable from all other fevers by the sudden onset and equally sudden cessation of the symptoms, by the absence of any rash on the skin, and above all, by the certain relapse which accompanies it. It is a peculiarity of the disease also, that in many of the patients, about a fourth, but varying in proportion with the type of the fever, there are marked symptoms of jaundice with nausea and vomiting, showing great derangement of the biliary secretion, the disease in some respects resembling yellow fever.

With regard to the treatment of a person suffering from relapsing fever, little need be said. Nothing will cut short the fever or prevent the relapse, but it is a wise precaution to relieve the bowels, which are apt to be constipated, from the commencement, by castor oil, or the colocynth and hyoscyamus pill of the pharmacopæia, or by some equally harmless aperient. The disease is not a deadly one, nearly all persons attacked with it recover, but severe cases do occasionally occur, the severity being in most instances due to suppression of the urine, occasioning coma and nervous prostration; very unfavourable symptoms which were noticed to accompany most cases of typhus fever. In cases of this character, the medical man endeavours by every means to promote the action of the kidneys; diureties, such as the bitartrate of potash, or compound jalap powder, or nitrate of potash, are among the safest remedies. Dr. Murchison recommended diluent drinks, such as barley-water, to which a certain quantity of nitre should be added.

FEVER, YELLOW, is a disease all but unknown in England, and although various marsh fevers, attended with yellowness of the skin, exist in hot countries all over the world, true yellow fever has its habitat mainly in the is much decaying vegetation combined with

West Indian islands and on the tropical coasts of North and South America. It has occasionally been imported by vessels into Europe, especially into France and Spain, and also into England; but it has never been known to extend beyond the ports of Plymouth and Southampton; nor has it been known to propagate beyond 48° north latitude, nor when the local temperature falls below 72° Fahr. The disease, like typhus, is spread by contagion of a virulent character, and one attack preserves an immunity from a second. It differs from most malarious fevers, in the absence of remissions and intermissions, its chief symptoms, such as yellow skin, delirium, and hæmorrhage, being continuous throughout the attack. Naval and military doctors, who have had chief experience of yellow fever, describe it as presenting three or four marked types, in keeping with some prominent symptoms, which they have named respectively the algid, or rapidly fatal form; the sthenic, or more febrile condition; the hamorrhagic, attended with effusion of blood and hæmorrhage from the bowels or stomach, sometimes called black vomit; and lastly, there is in yellow fever, as well as in many other disorders, a condition of the system to which the term typhoid is applied, and which is usually recognised by great nervous depression and stupor. There is strong reason to believe that in many cases the infection is conveyed by means of a species of mosquito; much attention therefore should be given to the destruction of mosquitoes, and to protection from them when yellow fever is prevalent.

It might reasonably be thought that, in a disease originating from infection, and pronouncing itself by a derangement of the biliary secretion, the ordinary remedies, comprising quinine and mercurials which act directly on the liver, would be found serviceable; but it does not appear from experience that their use in yellow fever has been attended with much benefit. The best authorities place more reliance on simpler remedies, such as injections of common salt and olive oil, with a pint or more of warm water, with the view of relieving the large intestine, and restoring vigour to its secreting surface. Where there is hæmorrhage from the bowels, it is usual to add a small quantity of spirits of turpentine to the enema. The most distressing symptom of the complaint, however, appears to be the excessive irritability of the stomach, for which various remedies are recommended. These are the same as have been found useful in similar conditions of the stomach unattended with yellow fever, and include hydrocyanic acid, chloroform or chloric ether, brandy, iced effervescing waters, and chlorodyne in the doses in which they are usually administered.

FEVER, INTERMITTENT. - See AGUE.

FEVER, REMITTENT. — Remittent fever is endemic in most hot climates, where there

FEV FIL

and is accompanied with a good deal of dis-turbance in the functions of the liver, which shows itself often in a yellowness of the skin, but is not nearly so marked as in yellow fever. As in ague, the essential feature of the disease is the presence of a parasite in the blood; the form the disease assumes varies very much in different countries. In Europe, on the borders of the Mediterranean, it is known as the Levantine fever, or the autumnal fever, as it usually occurs with the fall of the leaf; in India it is spoken of by our countrymen, who frequently suffer from it, as the puka, jungle, hill, or Bengal fever. On the west coast of Africa, where Europeans seldom escape an attack of it, it takes its name from the continent or the colony, namely, African or Sierra Leone fever, and on the borders of some of the American inland lakes, it is best known by the term lake fever. Besides the above places, it is endemic in Central Africa, Southern Asia, the American tropics and the West Indian Islands. In a disease so universally diffused, and presenting many local varieties, it is not easy to give a very accurate description of its features, but it is well to know that it usually affects new comers to the country, and that it is attended with a cold followed by a hot stage. The cold stage is preceded by languor, restlessness, and a certain amount of chilliness, which last for a day or two prior to the shivering fit; this is succeeded by the hot stage, which continues usually for ten or twelve hours. Throughout the fabrile attack, the pulse is full and compressible, beating from 90 to 120 in a minute, the tongue is dry and furred, and pain is felt at the pit of the stomach, and is often accompanied with vomiting. The duration and severity of the symptoms vary with the type of the disease, and the character of the attack; the hot stage or paroxysm ranging from seven or eight to forty-eight hours, when it subsides usually with full perspiration, but occasionally without any perceptible action of the skin. The interval between the first attack and the next paroxysm, may range from eight to ten, to thirty or thirty-six hours, and these periodic remissions continue for days and weeks without any well-defined course, unless the disease is checked by remedies. It is generally understood, that the second paroxysm will be more severe than the first, but serious symptoms, when they occur, do not usually appear before the third or fourth attacks; these are mostly caused by the brain and nervous system becoming involved in the constitutional disturbance.

In a disease of such tropical prevalence, it is not surprising that the remedies employed in its treatment, should have been very numerous, and comprised in the list are to be found blood-letting, cold affusion, purgatives, diaphoretics, mercury, quinine, arsenic, and opium. All these from universal experience

moisture, and is hence called malarious. It is give way to the paramount advantages of characterised by repeated remissions or relapses quinine; so much is this the case, that when our countrymen proceed to explore new countries, in distant parts of the world, they invariably take with them a quantity of the drug, not only for the treatment of remittent fever, in the event of their being attacked, but as a preventive from the fever. Our best Indian physicians laud the efficiency of quinine, and consider that in its virtues they have found a perfect antidote for the malarious poison. They recommend that before administering it, the bowels should be thoroughly evacuated, that the period of remission should be carefully watched, and that, when the first symptoms show themselves, not less than fifteen grains of quinine should be administered to an adult, and if rejected by the stomach, it should be thrown into the rectum by injection. It has also been introduced into the system by means of subcutaneous injection, which must be done repeatedly in order to get the full amount introduced. As a specific remedy for remittent and intermittent fevers, quinine occupies an almost analagous position to vaccination as a protection from small-pox.

All patients who lie long in fever, become liable to bed-sores, or ulcerations on the prominent parts of the body, which are subject to pressure as they lie; these are, especially, the back and hips, points of the shoulder blades, back of the head, tips of the ears, &c., When these ulcerations form, they not only add materially to the suffering of the patient, but may become the cause of a fatal termination to a case that might otherwise have recovered. They should, if possible, be prevented by the means recommended under the article Bed-sores.—See Bed-room—Contagion

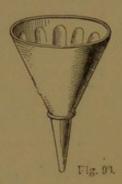

FIBRINE is that constituent of the blood which, along with the entangled globules, forms the clot. It is a composite substance found in greater quantity in arterial than in venous blood, and to a less extent in lymph and chyle. Fibrine, it was formerly thought, was identical with albumen, and constituted the fibre of flesh or muscle, but these views have undergone considerable modification of late years, blood fibrine being found to contain more oxygen than albumen, and muscle fibrine is now known by its chemical name of syntonine. In inflammatory diseases, there is usually found a larger amount of fibrine in the blood, which is apt to form into clots and plug the blood-vessels.

Refer to—Albumen — Blood — Digestion — Food, &c.

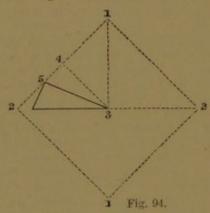

FIBULA.—The small bone of the leg. FIGS, the well-known fruit, contain a wholesome and somewhat aperient pulp, but the thick tough rind is indigestible, and should not be eaten.

opium. All these from universal experience nuts generally, and are difficult of digestion.

FILTER is an agent for separating solid impurities from fluids. Filtering papers made for the purpose, or white blotting-paper, are most usually used as medical filters, being supported by the well-known funnel or tundish, which ought to be of glass or porcelain, and ribbed inside (fig. 93). To make a paper filter,

the paper used must be square (fig. 94). By the first fold the corners 1, 1, are put together, at the next 2, 2, are put together, thus forming a triangle (1, 3, 2); 1 and 2 are next put together, making a triangle (4, 3, 2), and one

more fold (5, 3, 2) completes. The top being squared off, the filter is made, and may be opened out and placed inside the supporting tundish. In filtering through paper, it is always desirable to pass the first few ounces of the fluid through a second time, as a small amount of impurity generally escapes at first. When the solids to be separated by filtration are not in very fine powder the operation is more quickly done through linen or flannel.

There are many varieties of filters in the market, but the best known are the various kinds of loose carbon filters, the Silicon Carbon filter, and the filter of the Water-purifying Company. Filtration will remove any foul smell the water may have, arresting at the same time, particles of dirt, and other organic or inorganic matter that may be suspended in the water, and, in doing so, it also removes the atmospheric air from it, thus rendering the water less sparkling than it would otherwise be. As charcoal has little or no power of decomposing animal matter, it was reasonably thought that iron, which has that effect

to a limited extent, might be employed in the process of water filtration, and this has led to the introduction of the spongy iron filter, which promises to supersede the charcoal filter. Bischoff's spongy iron filter removes much of the organic matter from water, and it also removes any lead it may contain. Filters made in blocks of solid charcoal can have the blocks readily removed, and the outside parts scrubbed with a brush, after which a solution containing four ounces of Condy's fluid undiluted, ten drops of sulphuric acid, and half an ounce of hydrochloric acid, with two gallons of water, should be added, and the whole passed through the filter before it is again used. When an ordinary filter is unobtainable, a very good substitute for it may be improvised from a large flower pot, in which has been placed a layer of coarse pebbles covered with a few inches of charcoal. The flower pot should be raised high enough from the ground to admit of a receptacle for the filtered water being placed underneath. The above filters are useful for removing gross solid impurities, but cannot be relied on to separate or destroy noxious bacteria. The Berkefeld or Pasteur filter must be used to remove these.

Caution!- Too much faith must not be There can be but little placed in filters. doubt that domestic filters, as a rule, are worse than useless, and add to the impurity in a water rather than remove it. This arises from the fact that the apparatus is credited with some magical power which is everlasting, and the idea that no attention is required in order to maintain its efficiency. Unless a filter is periodically cleansed (and to allow of this each part should be removable), filth will collect in its pores, putrefaction will take place, and the water which passes through it, although possibly clear, will have imparted to it deleterious organic substances, the presence of which will soon become apparent by the foul smell which the water will give off on its being stored for any length of time. For this reason, then, the only domestic filter which is at all permissible is one which allows of easy cleansing, as directed above, and all fixed filters in connection with cisterns should be abolished. With this limitation, a domestic filter is a useful appliance. At the same time, if reason exists for suspecting that water may contain any specific poison, the only safe proceeding is to boil all that is used for dietetic purposes. Refer to-Water.

FIN ERS from their constant exposure, are liable to many accidents and diseases,—fractures, dislocations, whitlow, separation of the nail,—all which are treated of under their respective articles; there is, however, one mishap which does not fall under any particular head—

A ring which cannot be removed.—When this occurs, the use of cold to the finger and hand, the hand and arm being elevated at

210

the same time, may cause sufficient shrinking to permit of the removal; if this does not succeed, the following may:—A piece of fine packthread, or linen thread, is to be wrapped avenly and firmly round the finger, from the tip as far as the ring, through which its end is to be inserted, which being done, the packthread must be gradually unwound by means of the end thus placed. If this process does not succeed, the ring should be filed off. It cannot remain without risk.

Very useful shields and gloves composed of india rubber may be had at the india rubber shops. They are of great service to those who have wounds or abrasions on their fingers, or who are exposed to any sort of manual poisoning from their occupation.

FIRE .- See HEAT.

FISH, as an article of diet, generally is wholesome; it is neither so nutritive nor so heating as animal food, and on these accounts is often to be permitted when the latter is not.

Fish are classed as fresh-water, salt-water, and shell-fish. Dr. Paris remarks, "Turbot, cod, whiting, haddock, flounder, and sole, are the least heating of the more nutritive species; and the flakiness of the fish, and its opaque appearance after being cooked, may be considered as true indications of its goodness, for when the muscles remain semi-transparent and bluish, after sufficient boiling, we may reject it as inferior in value, and not in season. When fish is in high perfection, there is also a layer of white curdy matter resembling coagulated albumen, interposed between its flakes. The whiting, "the chicken of the sea," is well adapted for weak stomachs, on account of the little viscidity which it possesses; it is at the same time tender, white and delicate, and conveys sufficient nutriment, with but little stimulus to the system. The haddock is firmer in texture. Cod is not quite so digestible as the two former, but it is nutritious. Turbot is wholesome, without lobster sauce. Sole is tender, and yet sufficiently firm; it is, therefore, easy of digestion, and affords proper nutriment to delicate stomachs. Salmon is very nutritious, but, being one of the oily fishes, is less digestible than many othersvinegar in some degree corrects the fault. Eels are always indigestible." From these observations the value of fish may be appreciated, and the qualities which entitle them to selection easily understood. Firmness of texture, whiteness of muscle, and the absence of oiliness and viscidity, are the circumstances which render them acceptable to weak stomachs. The flesh of fish contains kreatine (see Kreatine). Shell-fish may, without exception, be considered as indigestible. Oysters eaten raw are undoubtedly nutritive, but by some they are not easily digested. Many persons are liable to cutaneous eruptions after the use of some descriptions of shell-fish, and some suffer from diarrhœa.

In those places, as the coast of Norway and Sweden, where a diet of fish alone is habitual, the people are very liable to chronic cutaneous disease.

The most wholesome method of cooking fish is by boiling; frying is not suitable for the invalid. It is well known that certain species of fish are poison at all times, others appear to be so only occasionally, and under peculiar circumstances. Of these, the common mussel has proved more injurious than any others. The oily fishes also, such as salmon, herring, &c., when too long kept, have given rise to symptoms of irritant poisoning.

Refer to-Poisons, &c.

FISTULA is a canal or passage formed by disease, and healing with difficulty, which opens from the surface of the body. The word fistula, alone, is generally used popularly with reference to the disease when situated at the fundament (see Rectum).

FITS.—The term is applied popularly to any form of convulsion or spasm of the voluntary muscles, such as *Epilepsy*, *Hysteria*, and *Convulsions* generally, either in adults or children. To these heads the reader is referred.

FIXED AIR-the name given by Dr.

Black to carbonic acid gas.

FLANNEL-a woollen texture, is an article of clothing which should be worn next the skin by every man, woman, and child in this kingdom, and perhaps in every other, notwithstanding its prohibition (!) by Preissnitz, amid other hydropathic regulations. Under the head of flannel, is included, of course, woollen clothing generally. Wool being a bad conductor of heat, is, in consequence, the best protection against sudden vicissitudes of temperature, such as occur in this climate, and also against chills which may supervene upon the profuse perspirations of a warmer one. Of course the thickness of the woollen material worn next the skin may and ought to be varied, but wool it ought to be, if of no stronger texture than gauze. The experience of our military and naval surgeons all tends to prove that there is no greater preservative from the dysenteric and febrile affections of hot climates than woollen clothing next the skin, and every medical man's experience in this country confirms the fact of its protective power. Notwithstanding, it is astonishing how many carelessly neglect this indispensable article of clothing. Some few persons with extremely irritable skin cannot wear flannel next it; in such cases, a dress of thin cotton should be worn, and flannel over. Flannel should be worn in summer, but of a thin texture

FLATULENCE, or the collection of gas in the stomach and bowels, is very commonly the result of indigestion; but it is often also the effect of nervous disorder. In the former case, it is probably chiefly due to the evolution of gas from the badly-digested food mass in a state of partial fermentation; in the latter, it

FLE FOM

is only possible to account for the enormous amount of flatus or wind by its formation, "secretion," in the bowels. In the course of typhoid fever and in many acute diseases of the intestinal tract, flatulent distension of the bowels, or "tympanites," as it is called, is

always an unfavourable symptom.

Persons who suffer from flatulence require sedulously to avoid most kinds of vegetables and fruits; individual experience, however, is the best guide on this head. When a severe attack of flatulence comes on, carminative (see Carminatives) and stimulating remedies are generally resorted to, and often prove useful; but in many cases, particularly in nervous individuals, with pale tongue, the mineral acids will often be of more service-either twenty to thirty drops of dilute nitric acid in a wine-glassful of infusion of orange peel, or some other warm bitter, or better still, aromatic sulphuric acid in ten-drop doses in a wine-glassful of water. A favourite remedy is the nitro-hydrochloric acid given in doses of ten or fifteen minims in water three times a day. Carbolic acid in one-grain doses twice or even thrice a day is a powerful counter-agent to flatulence. It is easily taken in a little peppermint water with glycerine, one ounce of the one to half a drachm of the other. In general flatulence of the bowels, with difficulty of expulsion, enemas of assafoetida or turpentine are most useful.

Refer to—Children—Enema—Indigestion.

FLESH.—The muscular substance of animal bodies, composed of syntonine. It is a popular error to suppose that flesh is merely present in the body "as flesh," and it is not understood that every particle of the substance is muscle, and employed as such in the movements of the living body.

Refer to—Beef—Fibrine—Mutton, &c.

FLESH-BRUSH—a brush for cleansing

and stimulating the skin. - See Skin.

FLOODING. — Hæmorrhage from the womb. — See Abortion—Child-Bed—Menstruation, &c.

FLOUR.—See GRAINS—FARINA.

FLOWERS OF SULPHUR.—Sublimed

sulphur.—See Sulphur.

FLUCTUATION—in medical language, is the movement given to fluids in cavities—either natural or diseased—by the fingers of the medical man, whilst at the same time he endeavours to make himself acquainted with the various peculiarities which characterise the collection.

Refer to-Abscess.

FLUX.—An increased discharge from any of the passages of the body, such as the bowels, lined by a mucous membrane. The term has gone out of use.

FŒTUS.—The term is applied to the infant from the early months of pregnancy till

the period of birth.

FOMENTATION is a simple and effective method of applying moist heat to any part of the body, by means of flannel wrung out of boiling water, or any other medicated hot fluid. It possesses advantages in many cases, and is to be preferred to poultices, as it is lighter and cleaner, and can be frequently repeated without much trouble. In extensive inflammations, especially of the abdomen, in erysipelas, and to allay spasms in deep-seated parts, as in cases of renal and biliary calculi, repeated fomentations are always to be preferred to poultices. When moist heat is prescribed for inflammatory disease of the joints, or as a mild derivative in rheumatic fever, to relieve the articular pain, fomentations will be found serviceable. Much depends on the way in which the fomentation is prepared. It ought to be applied as hot as the skin can bear, and, although moist, the hot water should be thoroughly squeezed out of the flannel applied to the skin. A large piece of coarse flannel folded, is employed for the purpose, and, after being soaked in boiling water, it should be enveloped in a coarse towel, and the hot water may be thus wrung out of the flannel by simply twisting the ends of the towel several times round the fomentation cloth. In hospitals where fomentations are in constant use, a very simple apparatus (fig. 95) is used to protect

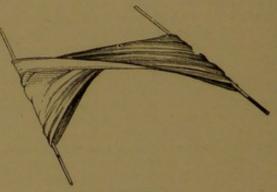

Fig. 95.

the hands of the nurse from being scalded. This consists of a wringer made from a piece of canvas, on which the fomentation flannel is laid, and by means of wooden rods fixed to each end, the canvas is twisted round by the hands until the last drop of boiling water is squeezed out of the fomentation cloth, which can then be applied to the skin of the affected part without scalding it. To retain the heat and the little moisture still remaining, it is advisable to apply a layer of dry flannel over the wet, and to envelop the whole with a piece of mackintosh cloth. If there is any danger of the fomentation slipping, a few turns of a bandage round the part will secure it. Solutions of opium, belladonna, aconite, or other narcotic substances, may be sprinkled over the fomentation flannel if it is desired to produce a soothing effect, or a few FOM FOO

drops of spirits of turpentine may be added, if | make up the greater part of the complex structhe object be to induce slight counter-irritation. A favourite fomentation is made by adding poppy heads or chamomile flowers to the hot water used, but it is doubtful whether the latter, at all events, has any medicinal effect employed in this way.

See Bran-Heat-Poultice, &c. FOMITES.—See CONTAGION.

FOOD, that by which the living body is nourished, in its widest sense comprehends both liquid and solid aliment. In the following article, the subject will be considered chiefly with reference to the principles which regulate, or ought to regulate, the food of man, and on which, as far as ascertained, the nutriment of his material frame is conducted. Much special information connected with the subject is scattered through this work in the papers which treat of the individual articles used as nourishment, and such papers as Alimentary Canal, Digestion, Dietaries, &c.,

bear directly upon it.

The food which we daily consume is absolutely necessary for the support of life, which in all warm-blooded animals has two essential requirements, the maintenance of heat, and the repair of waste tissue continually taking place in every part of the system. That we may better understand the wants of the body, it is necessary that we should have a knowledge of the elementary materials and their com-pounds, which contribute to its build. Out of the 60 or more elements which go to make up the world of nature, not less than 14 enter into the composition of the body, in the following proportions, assuming for the sake of quantitative accuracy, the weight of the body to amount to about 154 lbs. :-

			lbs.	0.00		
Ownorn				oz.	grs.	
Oxygen,			111			
Hydrogen,			15			
Carbon,			20	330	111	
Nitrogen,						
Dhamb			3	9		
Phosphorus,			1	12	190	
Sulphur,		-		2	217	
Calcium,	2.		2	-		
Fluorine,			-	***	***	
Fluorine,				2		
Chlorine,			100	2	382	
Sodium,						
Tour			***	2	116	
Iron,					100	
Potassium,					290	
Magnesium,			***			
Cili-			***		12	
Silicon,		16	200		2	
nese clamente		-10	2 4 4		- 44	

These elements are not found in their simple state in the body, but are combined with each other in various ways. Thus the two first on the list combine to form water, which constitutes rather more than two thirds of the body's weight, and is continually ebbing and flowing throughout the system. Oxygen, hydrogen, carbon, and nitrogen, are termed the organic elements, and compose the great bulk of the body. Next to water, gelatine, fat, fibrine,

tures, after which there are the various salts of soda and potash, together with iron, which gives the red colour to the blood, and silica, minute traces of which are necessary to give hardness to the enamel of the teeth.

The alimentary principles in food which have to make good the tear and wear of tissuesubstance, and support the animal temperature, are divided into the organic and the inorganic, the latter being represented by water and the salts which we take with our food, and which necessarily belong to the mineral kingdom; while the organic constituents have been classified by Liebig, Playfair, Parkes, and most modern authorities, into two sub-divisions, derived alike from animals and vegetables, one of which, because it contains nitrogen, is termed the nitrogenous, and the other because it contains no nitrogen is called non-nitrogen-

The nitrogenous group of substances, called also the albuminoids, supply the body with albumen, fibrine, and caseine, obtainable alike from the animal and vegetable kingdom, and gluten, which is found in vegetables alone. These substances, sometimes called "proteids, are the flesh-formers of the human body, and are absolutely necessary to make good the It was at one time supposed that they were also the agents of force, which was believed to be attended by an elimina-tion of the waste products of the proteids from the body, but this doctrine is no longer held.

The non-nitrogenous group of foods are variously named carbonaceous, respiratory, heat-giving, and force-producing. They consist of the three simple elements-carbon, oxygen, and hydrogen-in different proportions, which renders it necessary to classify the compounds into two well-marked subdivisions; one of which comprises sugar, starch, and gum, called carbo-hydrates, because they contain hydrogen and oxygen in exact proportion to form water; while the other includes fat, butter, and other oleaginous substances, which contain but a small proportion of oxygen, and are known by the name of hydro-carbons. All these agents supply heat, by the union of the oxygen of the air in the lungs, with the carbon floating in the blood, evolving at the same time carbonic acid and water. The fats are more important than the starchy and saccharine substances, because they aid materially in the assimilation of other foods, pass directly into the circulation, and are stored up in the tissues for future needs.

Among the inorganic agents, apart from water, sulphur and phosphorus are furnished from the flesh and bones of animals, from milk and eggs, and from those products of the vegetable kingdom which abound in gluten. The salts of lime are obtained both from animal albumen, phosphate, and carbonate of lime, and vegetable substances, while the salts of

FOO FOO

portant as any of the mineral constituents, exists in most food stuffs, and is liberally added to them in the process of cooking, as well as in eating, while iron is a constituent of the blood of the lower animals, and fluorine exists in the bones and teeth of animals. When the human body maintains a complete standard of health, the balance between the income and the outgoings should be equalised, and something like a debtor and creditor account might be established, showing not only the metamorphosis which occurs through the chemical changes that take place, but also the details of expenditure through the different outlets. Thus, in estimating the income, we allow somewhat more than 18 ounces of waterfree food, with water and oxygen in due proportion; hence, we have a daily income of:

8,000 Solid dry food, 37,650 13,000 58,650

After undergoing transformation in the body, these separate constituents are expelled as waste through the four excreting outlets, and the amount expended at each outlet may be calculated as follows:

Grains. 20,000 From the lungs, 11,750 From the skin, 24,100 From the kidneys, . 2,800 From the intestines, . 58,650

The total amount, 8 lbs. 6 oz. is eliminated in a gaseous, solid, or, mainly, in a liquid form through the organs; the nitrogenous matters, escaping chiefly through the kidneys in the form of urea, and the non-nitrogenous through the lungs and skin, as carbonic acid. When disease sets in, the appetite fails, and as happens in fever and consumption, the body wastes, the expenditure greatly exceeds the income, the balance of health is interrupted, and the abnormal condition cannot be rectified till recovery takes place.

It might reasonably be supposed that as people aiffer greatly in their appetites, effects on their constitution would be marked in proportion to the amount of food consumed; but so long as they maintain a tolerably healthy standard this is not observable. Notwithstanding this fact, rude health usually co-exists with a healthy appetite, and according to the amount of exercise mental and physical, so must the allowance of food be proportioned. A man engaged in much physical labour, requires a larger amount of food than a person at rest, and a patient in bed needs less than either. Public dietaries for prisons, workhouses, and hospitals are all arranged on these principles,

potash are derived chiefly from vegetables. as measures of ecomony, as it would be practi-Common salt, or chloride of sodium, as imcally impossible in any other way to meet the varied requirements of the inmates. As a rule more food is consumed in cold than in warm weather, and men eat more than women, unless the latter take an equivalent amount of exercise. Children and growing youths in a state of health eat more in proportion to their size than grown up people, and in old age the appetite fails, and the stores of fat which had accumulated during middle age disappear in the course of years.

It is very possible that, if more care and attention were bestowed on the selection of foods containing azotised and heat-giving properties in abundance in a concentrated form, a more economical and nutritious diet might be adopted than that in general use among both rich and poor. Such a diet is provided by the fare of the vegetarian, when he does not exclude from his menu, milk, and perhaps eggs. The poor of many countries subsist almost entirely on one or other of the grain crops which abound in starch, gluten, and fibrine, supplemented with milk, fat or other oleaginous substances. Beans and peas contain both albumen and starchy matter in abundance, and would of themselves support life, but they are liable to produce flatulence when much indulged in. The poor in Scotland, Ireland, and in the North of England, had at one time little else to subsist on than oatmeal, potatoes, and milk, and the inhabitants were ranked among the finest peasantry in the world; but now the taste for animal food has pervaded all classes alike, and though the opinion is generally entertained that a mixed diet of animal and vegetable substances is best adapted for mankind in general, there is no doubt that more harm accrues from an excess of food than from a deficiency, and the tendency of late has been rather to indulge in the former than to suffer from deprivation. Too much animal food produces plethora, and too much respiratory food induces corpulence and indigestion, and these are dis-eases from which people sometimes die. It is wiser to adopt the golden mean, and content ourselves with only a moderate amount of the good things vouchsafed to us.

It would be impossible in this article to deal separately with the various articles of food, though a few remarks on those chiefly used may not be out of place. Of vegetable productions, bread made from wheat flour is universally acknowledged as the staff of life, containing gluten, starch, and mineral matter in sufficient abundance to maintain vitality though few persons would adopt a bread and water diet from mere inclination. The other cereals, rye, barley, oats, Indian corn, and rice, though they contain in varying proportions all the essential elements of food, are not so available for bread-making as wheaten flour, and to render them equally nutritious,

FOO FOO

they should be taken with milk or fat; though oatmeal contains a considerable amount of the latter, which adds much to its strength as an Among tuberous roots the article of food. potato stands pre-eminent, and in its mealy condition is nutritious and digestible, and is always a favourite article of the diet table. Its chief alimentary constituent is starch, but it contains also salts of potash, and is one of the best antidotes to scurvy and other diseases of mal-nutrition. Other roots, such as the turnip, carrot, and beet, are made up in great bulk of water, and owe their chief nutritive value to the starch they contain. These also, as well as all green vegetables, possess antiscorbutic virtues, on account of the mineral

matters in which they largely abound.

The animal productions in most use as foods are, beef, mutton, veal, pork, eggs, and milk,which all contain the two essential elements of alimentation; lean meat representing the most purely nitrogenous, and fat pork the most carbonaceous. Mutton is generally reckoned more delicate and digestible than the flesh of most animals, then beef, lamb, veal, and last of all, pork, which is very unsuitable to the invalid. Poultry and fish are less nourishing than the meat of animals which nourish their young, though from their delicacy of flavour and easy digestion, they are very suitable for the sick-room as well as an agreeable change from the ordinary diurnal routine of beef and mutton. Boiled meat is a trifle more digestible than roast meat, and if the fluid in which the meat is boiled is partaken along with it, the juices as well as much of the mineral matter of the meat are saved; and there can be no doubt that boiling is a more economical plan of disposing of meat than roasting it, as in the process of roasting, meat loses nearly a third of its weight. Most people, and especially invalids, prefer roast meat to boiled, and it has become a question of importance in public institutions, as well as in private households, how the roasting process can be best accomplished. Cooking before an open fire, though attended with more waste, is preferable to cooking in a close oven; but much of the unwholesomeness of the latter process has been removed of late years by a better construction of oven, and the general introduction of gas in public kitchens, as a method of roasting, has almost entirely closed kitchen range. Game, especially pheasants and partridges, though somewhat less digestible, are similar in their chemical relations to poultry, and it may be assumed as a rule which generally holds good, that white meat of every kind, though somewhat less nourishing, is more delicate in flavour and easier of digestion, than red. Milk may be regarded as the type of all food, and there is no better illustration of its utility than the fact of the infant being reared upon it to the exclusion of varied only from 71 to 73.5.

digestible and palatable, it is desirable that | other food. Butter and cheese, the products of milk, represent respectively its heat-giving and flesh-forming properties, as butter is almost equivalent to fat, though of more delicate flavour, while cheese contains the nitrogenous substance caseine, combined, however, with more or less of the fatty constituents. Cheese is consequently one of the most nourishing of foods, but it is not suited for the invalid or for delicate children. Milk is sometimes used of itself as a diet in fevers, and in injuries to the head, accompanied with or without a loss of consciousness, it is now generally prescribed to the exclusion of other foods, until convalescence is established. The properties of the egg possess some analogy to milk, inasmuch as the young chick is formed from its constituent elements, which are rich in albumen and fat. Eggs, lightly boiled, are easy of digestion, and seldom pall even on the sickly appetite.

By instituting a standard for comparison, and massing together a large number of analyses, collected from the investigations of the best chemists, Professor Atwater, of Connecticut, has prepared a series of tables of much value in estimating the nutritive properties of different foods. As a basis of comparison, he has selected beef of a medium character (neither too fat nor too lean) as a standard, at a nutritive value of 100, and the following table represents in figures the nutritive properties of the following articles of ordinary consumption, meat, game, and

Anima	l food.			Nuti	itive value.
Beef (lear	1),				91.3
Beef (med					100.0
Beef (fat)					112.0
Veal (fat)					92.4
Mutton (		1),	*		86.6
Pork (fat					116.0
Smoked h					146.0
Smoked l	nam,				157.0
Venison,					88.88
Hen,			•		93.9
Duck,				200	104.0

From this table it is noticed that fat pork, so largely consumed by the poor in this country, stands highest in the nutritive scale among fresh meats, while smoked beef and ham represent a much higher value than is usually attached to them, a value attributable to the removed the objections associated with the deprivation of moisture to which they have been subjected in the process of drying and compression.

Milk and its products form a most important group of animal substances of which all classes partake, and it is interesting to notice how the cheapest of these manufactures, namely, cheese made from skimmed milk, also possesses the highest nutritive properties. The value of the egg, as an article of food, has been based on the average of several hundred analyses, which

The analyses pertaining to fish have been made from the edible parts only; thus white fish has a nutritive value calculated at 104.5, but this only means for 13.69 per cent. of the whole fish, so that as a food it would be far inferior to duck, which has the same numerical nutritive value. The percentage of edible solids in each species of fish is given in the

When we partake of food, we are scarcely aware of the existence in it of the mineral salts which are almost as necessary for nutrition as the other constituents. Apart from the four or five pints of water which a person is in the habit of consuming daily, either in the form of beverages or in the food itself, there is or ought to be fully an ounce of Water is mineral matter of various kinds. itself the most necessary of all foods, as it is concerned in every physiological change which takes place within the body, and maintains an equilibrium of temperature by continuous evaporation from the skin. It contains usually salts of lime and soda in small amounts, supplemented by the mineral matter in the food but so the question stands at present, and as

| itself ; but the chief salt, chloride of sodium, is mechanically added to the food to the extent of about half an ounce a day. It is doubtful if this addition is absolutely necessary, as almost all solid food contains salt in appreciable quantity; but its mechanical addition not only elicits flavour and assists taste, but undoubtedly

aids the process of digestion.

Existence upon vegetable food alone is much more common than that upon animal food alone, and, indeed, is the rule with many nations and people, who unquestionably maintain high strength and vigour upon it; it is, in fact, only requisite to look at the grass-eating bull to feel convinced of the possibility of the fact, and did space permit, it would be easy to cite abundant confirmatory examples; but if man lives on vegetables, he must, like the vegetable-eating animal, consume a comparatively large bulk to obtain sufficient nutriment; and so it is, the Irishman and the Hindoo must eat seven or eight pounds of potatoes, or of rice, at a meal. These, however, are extreme instances, for potatoes and rice are comparatively innutritious, in as far as building up the fabric of the body is concerned, being composed mainly of starch and water; the cereal grains and pulses, on the other hand, possess albuminous principles largely—the gluten of the former corresponding to the animal fibrine, and the caseine of the latter to the curd of milk. Those persons, therefore, whose vegetable food is composed chiefly of the above, require, of course, to consume less, and there cannot be the slightest doubt that man may lead a most active and healthy life upon a grain diet alone, and especially if it be combined with milk. But what is possible may not always be expedient, nor suited to man's circumstances, and on this hinges the argument respecting the nature of food on which man ought to live. No physiologist would dispute, with those who maintain that man ought to live on vegetables alone, the possibility of his doing so, or that many might not be as well under such a system, or better than under any other; but no physician acquainted with the requirements and constitutions of men generally, who live according to the usages-certainly, it may be allowed, too artificial-of this and other civilised countries, will allow that a vegetable diet could become the rule to the majority without serious injury. The healthy active countryman, constantly exercised in the open air, will do well on a vegetable diet, under which the city artizan or man of business, the delicate female, the pale, perhaps scrofulous, child would become dis-eased, or sink and die. Their organs of digestion and assimilation cannot extract from the vegetable mass sufficient blood nourishment, neither do they receive sufficient stimulation from it. It may be contended that the evil is an artificial one, engendered by artificial life; that may or may not be the case,

FOG FOO

man generally is circumstanced at the present | tervals of time. Most persons discover by day, he will best consult his own comfort, convenience, and usefulness, by using a mixed diet, the power to use which has been bestowed upon him by his Creator. He will, if possible, consume albuminous material, animal food in quantity sufficient to supply the waste of his bodily, especially muscular tissues; and will mingle it with such respiratory food, that is, saccharine, or starchy, and oleaginous sub-stances, as will supply the carbon and hydrogen requisite for animal temperature, without his being compelled to undergo the muscular exertion of the half-savage hunter.

To review the principles which regulate food and nourishment: We have vegetables as the first agents for taking up the elementary forms of matter, and combining and transforming them into such components as are suited to the digestive organs of the vegetable subsisting animal which consumes them, and in which they are built up into the blood-filled animal frame, of muscle, nerve, and bone, ready for the consumption of the carnivora, or flesh-eaters, and to yield sustenance suited to the wants of man. We have these nutrient principles, consisting of albuminous compounds, fitted to nourish albuminous tissues, gelatinous to nourish gelatinous, and saccharine and farinaceous to supply the matter of fuel, and to take part in all the other operations of the system, or to be stored up as fat. Lastly, we have water, the aqueous principle, as the necessary medium without which these varied operations could not be carried out.

To apply these principles to man, we find him so constituted as to be able to maintain health and life on animal food alone, or on vegetable food alone, but we also find him fitted by organisation to subsist on a mixed diet, such as is most in accordance with the habits and usages of civilised communities.

It is not easy to assign to every article of food its proportionate degree of digestibility, as this so largely depends on the methods of cooking employed, as well as on the quality of the meat and the length of time it has been preserved. Again, digestion is greatly influenced by what may be termed the idiosyncracies of the individual, which is expressed by an old saying, that "What is one man's meat is another man's poison." On this account it is scarcely legitimate to draw any definite conclusions from the well-known series of experiments, made by Dr. Beaumont of America, on a man with a hole in his stomach, through which opening Dr. Beaumont watched the process of digestion of a large number of animal and vegetable substances. It must also be borne in mind, that the act of digestion is far from being completed with the escape of the chyme from the stomach, and that the changes which the fats and starchy foods undergo in the small intestine are of the most

experience what foods best agree with them, and their knowledge in this respect is often extremely serviceable to the medical man in

prescribing for them in illness.

Owing to increased population and inability of home production to meet its wants, numerous methods of preserving food have been introduced of late years. Curing and drying as well as smoking, are old methods of preservation in use in all countries. The meat is steeped in brine, a strong solution of common salt or nitre, which hardens it and renders it less digestible, but enables it to be kept from decay for a considerable time. The drying process is chiefly had recourse to with fish, but in some hot countries strips of meat are dried by exposure to the air, and eaten afterwards in the form of soup. Meat prepared in this way loses its flavour and palatable qualities, though it may retain most of its nourishment. An attempt to introduce it from South America as a cheap substitute for the meat of this country, was abandoned after a short trial, and its place was taken by the cooked meats imported from Australia and other countries, but chiefly from Australia. This branch of food industry has attained considerable mercantile success, besides being a great boon to the poorer classes, who, however, in their individual capacity, do not appear to appreciate it as it deserves to be. To preserve it, the meat freed from bone is closely packed in tinned cases, subjected to a high temperature considerably over the boiling point for several hours, and when the air is thoroughly driven out of the vessel and the steam still escaping from an aperture in the case, the opening is soldered down and the case is thus hermetically sealed from injury from within or from without. In this state meat may be kept fresh for any length of time, and it is exceedingly convenient and handy in hot weather, and at any other times when ordinary raw meat is apt to go bad. Tinned meats are largely used in workhouses, prisons, and other public institutions, though they have not found favour

as a dietary for sick people.

The most successful method yet employed to meet the increasing demand for meat, is by preserving it in a cold temperature, as we are able in this way to draw upon the inexhaustible supplies of cattle in the United States, and probably in a short time from those in Australia and South America as well. Of late years vessels have been built specially fitted for this branch of industry, with chambers partly lined with ice, in which the dead meat is suspended in its passage across the Atlantic. After landing in this country, the meat is quickly bought up by dealers, and sold to the public, generally at a lower rate, than home produce, although in no respect inferior to it in quality. There is some reason to suppose that much of the meat exposed for sale and elaborate character, occupying varying in- bought as home-fed beef and mutton, is of

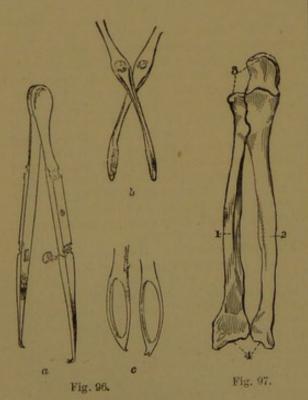

FRA FOO

experienced eye to detect the difference; but there is little doubt that had it not been for this welcome supply, the price of meat to the consumer would by this time have been greatly enhanced .- See Dietaries and special articles on various foods.

FOOT BATH.—See BATH.

FORCEPS are instruments used in medical and surgical practice as substitutes for the hands or fingers, not only for the sake of cleanliness, but as being capable of introduction into positions where the hands or fingers cannot go. A pair of the common dressing forceps would be found useful for many purposes in domestic management, if for nothing else than taking off plasters, and it would be well if responsible persons generally, who reside at a distance from medical assistance, were provided with a pair of artery spring forceps. This instrument, which differs entirely from the other in shape, is provided with a spring catch which keeps its points perfectly closed when required (fig. 96). In many cases of wounds involving the severance of an artery, an unprofessional person could not perhaps employ any means for stopping the bleeding with such probable certainty and ease.

Refer to—Hæmorrhage—Artery—Dressing.

FOREARM.—The lower arm, between the elbow and the hand. It contains two bones (fig. 97) the radius (1) and the ulna (2). These are articulated or jointed at their upper extremity (3) to the single bone of the arm; probably be requisite. If the upper extremity be the part involved, it should be well supthe wrist. The bones in the forearm are very ported by a sling in the meanwhile, and the extremity (3) to the single bone of the arm; at their lower extremities to the small bones of

American growth, and it really requires an often broken, and, of children, are often bent by accident, without fracture. - Refer to Fracture

FOWL.—See POULTRY.

FOX-GLOVE.—See DIGITALIS.

FRACTURES OF THE BONES are accidents which, from their nature, can only be treated with certain efficiency and success by the educated surgeon; but on the other hand, from their frequent occurrence, particularly in situations where no surgical assistance can be readily procured, it is highly desirable that unprofessional persons should be able to manage them in something like an intelligent manner.

The existence of fracture is, in some situations, made out with difficulty, even by the skilful; this is particularly the case in the vicinity of joints, such as the ankle, hip, shoulder, &c., but in others, as in the middle of the long bones, such as those of the leg, thigh, forearm or arm, the fact is often too obvious to be overlooked by the most careless. The general symptoms of fracture having occurred, are pain and loss of power over the injured limb, which is altered in shape or crooked, probably swollen and shortened. Its lower extremity hangs loosely, and is more movable than it ought to be, motion being generally accompanied with a sensation of grating, perceptible both to the sufferer and to the person handling the limb. The broken ends—generally the upper one—probably project against the skin, or, it may be, protrude entirely, through its continuous and the same surface of the same surface and to the same surface and the same entirely through it, constituting a compound fracture. Much of the displacement of the fractured ends of the bone is due to the contraction of some of the muscles of the limb, which are, from the nature of the injury, freed from the controlling counter-action of other muscles. This fact it is important to remember in the treatment, during which, when it can be done without sacrificing too much the other essential points, the injured limb should be placed in a position which allows the muscles generally to be in a relaxed condition. In addition to these local signs, a person who has suffered from severe fracture is generally faint and depressed for some time after.

In many cases of fractured bones, however, the symptoms are far from being so plainly

marked as described above.

The fracture of a bone is, of course, in itself, a severe injury, but it is rendered infinitely more so by the wounding and tearing of the soft parts of the limb by the, generally, ragged ends of the bone; this, therefore, it is desirable to prevent, as much as possible, both in removing the sufferer and afterwards.

It being ascertained that a fracture has occurred, if surgical assistance is not immediately at hand, the removal of the sufferer will

sufferer will find walking a much easier and | less painful mode of locomotion than any other. Much injury and suffering are often inflicted upon persons who have fractured a lower extremity, by hasty and injudicious management in the removal; the lower end of the limb is left entirely unsupported, or at best, is carried by some of those around, causing thereby great pain, increasing the wounding of the soft parts within, or, it may be, occasioning the protrusion of the bone through the skin; and thus, especially if the last should occur, diminishing greatly the chances of a good recovery. person who has fractured the leg, if he be not already lying on the ground, should be placed there till a shutter, a door, or flat board of some kind can be procured; this should be placed along side, covered of course with coats or the like, and the sufferer, gently, rather slid than lifted upon it; on this he is to be handcarried, even if the distance is considerable, as much preferable either to cart or carriage conveyance. Before lifting, however, the fractured limb should be secured from motion as much as possible, either by tying it to the sound one by means of handkerchiefs, or by straw or other material placed about it: in the meanwhile, a firm bed should be prepared for the patient; a mattress is most suitable if procurable, if not, a board of sufficient length, passed under the ordinary bed, will do; the object of this is to prevent the sinking which inevitably occurs from a person lying long in one place in bed, a circumstance which much interferes both with comfort and treatment. In most cases of fracture of the leg, relief will be given at once by bending the knee and placing the leg, lying on its outer side upon a pillow or other soft material. The object in view in the treatment of a fractured bone, is to preserve the broken ends in contact, as steadily and as exactly in their proper relative positions as possible, so that the curative and consolidating process may proceed without disturbance, and that when this is complete, the symmetry of the limb may be unaltered. In giving directions as to the management of fractured bones by unprofessional persons, the author feels how difficult the task, of conveying the information, is to himself, and how still more difficult it must be to those unaccustomed to deal with such matters, to treat them at all satisfactorily from a written description; at the same time cases do occur, in which the choice lies only between perfect ignorance and some amount of information of the methods to be adopted. For such cases this article is written; for certainly no sufferer from fracture, in his senses, would submit to, nor any unprofessional person undertake the treatment, if skilled assistance was in any way procurable. In addition, the author would strongly advise those who are likely, in their course through life, to be thrown much in out-of-the-way circumstances, and who

in some hospital the mode of putting up fractured bones. A few hours, even, of observation, would teach them more than all written descriptions, though these might afterwards refresh

the memory.

Either after or before the patient is placed in bed, the clothes must be removed, cut off it necessary, from the injured limb; of course by the seams if possible. The proper applications must meanwhile be got ready as quickly as may be. These are, splints, such as are recommended in each particular form of accident, with their cushions and bandages (see Bandage). Some surgeons delay the application of the splints for several days, till the swelling, which always occurs more or less after fracture, has subsided, and some cases may occur in which this is desirable; but the majority or practitioners put the splints on as soon as possible after the accident, and this is certainly the preferable practice. There almost always exists a tendency to spasmodic starting of a limb which has been fractured, for some time after the accident, and this constantly tends to displace the bones, and to increase the laceration and swelling of the soft parts; this may in great measure be prevented by the early steadying of the whole limb by the splint, which, however, need not be bound tightly, and may be so applied as to be loosened at once if requisite. This tendency either before or after the splints are put on, may be in a great measure obviated by pinning a handkerchief over the fractured limb on both sides, to the bed clothes, so as to keep it perfectly steady. The injection of a small dose of morphia, by means of the hypodermic needle, will also do much to relieve painful startings or spasms in a fractured limb.—See Hypodermics.

A splint is simply an agent which can be bound to a fractured limb, and which will keep it in the straight position; it may, therefore, be made of wood, iron, leather, or even straw. The variety of splints is very great, but as this article is written for use in situations where only the simplest means are supposed to be at hand, the simplest modes of management

only will be adverted to.

Moreover, fractures may be treated without splints, properly so called, as by gum and chalk, plaster of Paris, starch bandage, or the like, or by position simply. As the continued contact of hard splints would occasion pain, they are usually cushioned or padded; this may be effected by any soft material, care being taken that the padding projects everywhere beyond the edges of the splint, to which it may, if convenient, be attached by tapes (fig. 98) or common adhesive plaster.

Pasteboard, gutta percha, leather, and a manufactured material called poroplastic felt, would strongly advise those who are likely, in their course through life, to be thrown much in out-of-the-way circumstances, and who would wish to be useful, to see for themselves fracture remains to be effected. This, which

is always painful, consists in bringing the it is called, may be strong enough for ordinary broken ends into contact, as much as possible in their proper relative position. In some few cases, as in the leg, it may happen that

although there is fracture, there is no displacement; but in the majority of instances the broken ends overlap one another, being drawn by the action of the muscles; the main requisite, therefore, in the reduction of a fracture, is by gentle but steady drawing down of the lower extremity of the limb-whilst the upper is fixed—to bring the ends to a level, and, if possible, place them one against the other; in the drawing down, however, the hand should not grasp the extremity of the fractured bone, but should be applied below the joint. Thus, in setting a fractured thigh, the surgeon grasps the leg, not the lower part of the thigh, &c. After a fracture has been once set, it should never, if possible, be disturbed again. This does not mean that the appliances are not to be removed, and the progress of the case inspected; for if this be not done, and if by any chance the proper position should have been disturbed, the bones may become solidly fixed in an improper manner, and deformity result, or the skin may become ulcerated; but the appliances should not be removed if possible before the end of the first week, and if all seems going on well, not moved again for ten days at least, unless for some special purpose. If a fracture is often disturbed or pulled about during the process of consolidation, it may chance that this will only be effected imperfectly, and what is called a false joint formed, that is, the broken part, instead of being firm, moves like a joint, and the limb is useless. It had better be crooked or shortened.

Lastly, much care is always required that a limb which has been fractured is not used too soon after the accident, otherwise it may either be snapped again, or it may be bent. The first advance towards the cure of a broken bone, is the throwing out of a jelly-like matter around the ends; this gradually becomes more solid, and, at last, is converted into a thick ring of bone; but for this latter change the lapse of some months is requisite: although, accident. It may be suspected, when after therefore, the uniting material, or "callus" as injury to the spine, loss of sensation in, or of

purposes a considerable time before ossification has been effected, yet the limb will not bear

extraordinary efforts.

With respect to the general treatment of a person who has suffered from fracture, it is always advisable, that for some little time after the accident the diet should be lowered, but that when the inflammatory stage is passed, the individual should return as much as possible to his ordinary food. Care must be taken, if the person has been accustomed to much alcoholic stimulant, that it is not unduly abstracted, otherwise the powers of the constitution will be so reduced, that the reparative process cannot take place, and the fracture will remain ununited. In fractures of the lower limbs, the use of a bed-pan and urinal of some kind will be required, and attention must be given to the back, that it does not get sore. An elastic horse-shoe cushion (see India rubber) will be a great comfort in such cases.

Fractures of the skull have been already alluded to under article Brain.

Fracture of the lower jaw is generally tolerably evident. The simplest treatment when displacement exists is to apply a four-tailed bandage. This is made from a yard of calico about six inches wide and torn apart from either end, to within three inches of the centre. A slit is made in the centre of this undivided piece to receive the chin, and the two lower ends are tied over the crown of the head, and the two upper crossed behind the head, and tied over the forehead. Or two handkerchiefs may be used as represented in the accompanying figure (99). For permanent use a piece of

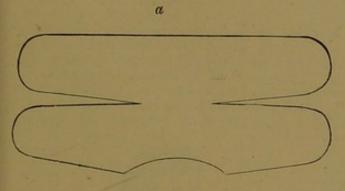

gutta percha, cut as represented (fig. 100, a and b) softened in very hot water, then moulded to the jaw and secured by a four-tailed bandage, is the most suitable; pasteboard, tin, lead or other flexible material will do as well as gutta percha, but whatever is used must be padded inside with cotton wool before being applied. The patient should rinse his mouth frequently with a weak solution of Condy's fluid or with tincture of myrrh and water.

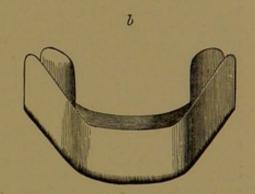

Fracture of the bones of the spine is a rare accident. It may be suspected, when after

power over the part, ensues below the site of from whatever cause arising. On this account, the accident. In such a case, nothing could be done by unprofessional persons beyond ribs should be especially careful, and for some placing the sufferer in as easy a position as little time after the accident should reduce his possible.

Fracture of the ribs is known by the pain which is felt at the injured spot in every motion of the body, even by breathing. The used over the usual bandage. When ribs on sufferer feels a grating sensation, which may be both sides of the chest are injured, this, with felt by another person laying the hand on the leeches, if requisite, should be the sole applica-The chief risk involved in fractured tion; the patient being confined to bed for at ribs is from injury to the lungs by the sharp ends of the bone, and when this occurs it is apt to give rise to inflammation, which will require the usual treatment of the affection,

on one side only are injured, less confinement | unprofessiona.. A wedge-shaped pad, of any firm is required, but the chest should be encircled, as firmly as can be borne comfortably, with a to be enveloped in the middle of a soft shawl band of stout calico, from eight to ten inches or handkerchief of suitable size. The pad is half round, and be sewn; a month will pro- side (fig. 101-1), the ends of the shawl must bably be required for the cure. When possible, it will be found better to apply broad pieces of adhesive plaster to the injured side only. These should reach from the spine to the middle line in front, and run parallel to the ribs, and should extend from three inches above the fracture to three inches below. A flannel bandage put lightly round the chest will prevent the plaster from separating.

Fracture of the collar bone is a frequent accident, usually from falls on the shoulder. It is generally easily detected. As the use of the collar bone is to keep the shoulder back,when broken, the shoulder of the injured side falls forward, pushing the broken ends over one another. The object of treatment, therefore, must be to keep back the shoulder by artificial means, until the bone has recovered its solidity. This might be done by keeping a next be crossed over the opposite shoulder (2) that the weight of the shoulder falling backwards would pull the bone into position with-out any other means being used; few persons,

wide, and double; this should go once and a then to be placed in the arm-pit of the injured

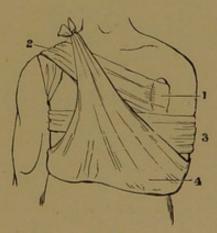

Fig. 101.

person confined to bed, and in such a position and tied in the arm-pit, as represented; folded cloth of some kind being interposed to prevent fraying of the skin. Another handkerchief or band of some kind is next to be applied (3), however, will submit to the confinement neces- so as to bind the arm down to the side in such sary, and other methods are resorted to; they are a manner that the pad in the arm-pit acts as a varied, but the following will most easily, and fulcrum, or gives such a "purchase" as allows with best prospect of success, be adopted by the the outer end of the broken collar-bone to be

side; a sling enveloping the whole forearm is next to be applied, and completes the appara tus, which should be worn for a month at least. If carefully attended to, this apparatus will prove very effectual, and the means for it can always be procured. It should be understood that the principle of the treatment is, extending the broken bone by means of the pad in the arm-pit. It is sometimes requisite to apply a bandage from the fingers upwards to prevent swelling.

Fractures and other injuries about the shoulder joint are often so obscure that no uneducated person could distinguish them. best management until surgical assistance can be procured, if it is far distant, will be perfect rest; probably much comfort may be derived from the use of the pad in the arm-pit, as recommended for broken collar bone, and also of a sling supporting the forearm, wholly or only at the wrist, as may be most easy to the patient. The confining band (fig. 101-3) must not, how-

ever, be used.

In fracture of the shaft of the arm bone it is better to put the whole limb in a sling at once, and if the person has to go to the surgeon, he will find it easier to walk than to ride in any conveyance. Confinement to bed may be requisite for some days at least, after the accident—the injured limb being laid in an easy position on a pillow, and a couple of splints of wood or

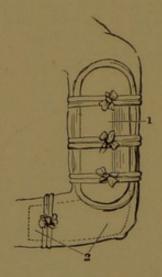

Fig. 102.

other firm material two and a half inches wide, applied one on each side the limb (fig. 102-1) and secured with just sufficient firmness to prevent movement by means of two or three-looped bandages. This bandage (fig. 103), is made by taking a doubled length, sufficient for the purpose required, of the common roller bandage; one end, or "tail," of the bandage (1) is passed through the looped extremity (2) and may then be tied to the other tail (3). This form of bandage has the great advantage of being easily and outer bandage must be well saturated with

pulled outwards, as the arm is bound to the | loosened if requisite, should swelling ensue. Temporarily the arm may be put up in any stiff material, and held in position by a handkerchief or the triangular bandage, as in figure

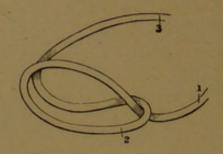

Fig. 103.

104, which represents temporary splints that might be employed in military practice, consisting of a bayonet and scabbard. After the first few days, when the swelling has subsided, the fracture of the arm may be put up more firmly and permanently. A splint of pasteboard or of gutta percha, or leather, or indeed of any

Fig. 104.

firm material, is to be put on each side of the limb (fig. 102). These ought, however, to be shaped as represented by the dotted line (2) to come along the forearm as far as the hand, and having been previously shaped on the sound arm, instead of the looped bandage, should be well fixed by means of the common roller, which may be kept from slipping by the addition of starch or paste as it is put on. Instead of the splints, however, the starch bandage alone, if the individual is not very muscular, may be used; but in this case, both the inner

or plaster of Paris, and it is well to make the addition of strips of stout paper, pasted down over the inner bandage, and covered by the outer one, to give additional firmness. In this case, it will be requisite to keep the arm very quiet till the paste has dried, or a wooden splint may be tied outside the bandages till this has taken place. This method is not to be practised by the uninitiated. A sling will be requisite to support the hand and wrist, but not the elbow, which should be allowed to hang, the weight tending to keep the bone straight. The splints should be employed for a period of not less than four weeks.

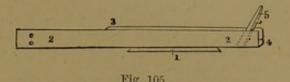

Fracture of the forearm is a very common accident. In children the bones are most frequently partly broken and partly bent; in adults both bones or one only may be broken; in the latter case, the sound bone acts as a splint to hold the other in place; and should the accident be detected, a perfectly straight splint of light wood, applied to the inside of the arm, and extending from the elbow to the tips of the fingers, fixed by a common roller, or by some looped bandages, is all that is required; and indeed, when both bones are broken, the same treatment will be sufficient, though it is better to apply a splint on each side. After the lapse of a fortnight, in adults, the splints may be taken off, and starch bandage used; but in children, who are liable to falls, it is better to give them the protection of the wood for some time longer. In fracture of the forearm, the sling ought to give support from the elbow to the ends of the fingers, and the limb must of course be kept bent at the elbow during the period of cure. The patient should begin to move the fingers in a week after the accident, especially if the injury is near the wrist, to prevent subsequent stiff-

Fracture of the fingers is treated by a narrow, straight, wood splint, or by starch bandage.

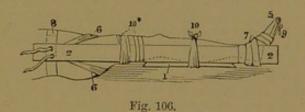

Treatment of fracture of the lower extremity by an unprofessional person must be a most unfortunate contingency; but the simpler the means used, the more likely will its management be conducted with some efficiency. Until splints are prepared, long cylindrical bags filled with sand to the extent of twothirds of their capacity should be placed on each side of the limb, and one across, above, and another below the seat of the fracture.

In a case of fracture of the thigh, the removal and preparation of the sufferer having been effected as already pointed out, the following apparatus is such as an unprofessional person might, with a little care, manage efficiently; and the materials for its construction can searcely ever fail to be procurable. Three pieces of wood, about three-eighths of an inch in thickness, will be required, and the measurement as to length should be made on

strong starch-flour paste, gum, white of egg, | be sufficiently broad to extend completely under the limb, and sufficiently long to extend from just above the middle of the thigh (fig. 105, 106 -1, 1) to below the calf of the leg, being edged

off at either end. The next piece (2, 2) to be fixed on the outer side of under one, should extend from just above the hip to a little beyond the foot, and must be pierced with two

holes at the upper end; the remaining piece (fig. 105-3) should extend from about two-thirds up the thigh, to a little beyond the foot; being fixed to the inner side of the under piece, and connected with the outer piece at the lower end (4), a slanting support for the sole of the foot, and about the same width, being fitted in, so that it will admit of the limb being extended to quite its full length; this being ascertained by measurement of the sound leg. The middle of the apparatus forms a kind of box. A soft handkerchief padded must now be placed between the thighs (fig. 106-6, 6). At this stage the limb must be set. One person should hold the body of the sufferer firmly at the hips, whilst another grasping the leg just above the ankle, by a gentle and steady pull, straightens the injured limb to the same length as the sound one; the broken ends of the bone being by this means brought into contact.

The apparatus having been previously well padded with any soft material—even chaff or dried leaves will do—the broken limb, still kept on the stretch, should be gently placed in it. The foot must then be secured to the padded foot board by means of a bandage or handkerchief (fig. 106-7), the heel being also well supported by the same or some similar application. The heel may be still further supported by means of a double tape sewed to the toe of a sock, previously put upon the foot; the tape being carried over the top of the foot board, and tied to a nail or peg, fixed to the back. The ends of the band (6, 6) passed between the thighs are to be passed through the holes in the upper part of piece No. 2, and tied with sufficient firmness to keep the limb on the stretch. This is the essential part of the treatment-the foot bound to the foot board, and the sound extremity. One of the pieces must | the band tied through the holes in the upper

keep the limb extended. The upper end of 2 must next be secured by a band (8) passed round the body, and the fixing of the apparatus is complete. It will be well, however, to fill up all the interstices between it and the limb, by means of soft material stuffed in, and when this is done, as a further means of security, to fix one or two bandages or handkerchiefs (10, 10)

round both apparatus and limb.

The above contrivance is a modification of the one most used by surgeons for the treatment of fractured thigh, but requires much less bandaging, and is, for this reason, preferable. In the usual form of long thigh splint, the entire efficiency of the arrangements depends upon the application of the bandage, and no unprofessional person is likely to put it on properly. The apparatus may be used for fractures of the upper part of the leg, as well as for the thigh. Another simple mode of treating fractures of the lower part of the thigh, or upper part of the leg, is by means of two pieces of wood similar to No. 2, fig. 105, but the leg and a large sleth much as table but shorter, and a large cloth, such as a table-cloth, in each side of which one of the pieces is to be folded up, until there is just space left to contain the limb, which being set, and placed in the space so left, the boards are to be tied up to it on each side by means of handkerchiefs, or stout tapes. This plan is represented in the following figure (107). Again,

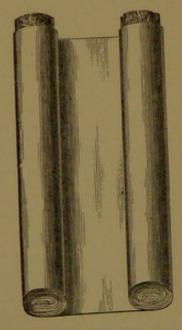

Fig. 107.

the sound limb may be made to act as a splint to the broken one. Pads of some soft material should be placed between the most prominent points of each, such as the knees, ankles, great toes, &c.; and padded bands, two or three yards long, are to be wound round the legs as they are placed together, just above the ankle and just below the knees. Or the broken from skilled assistance; and it is in such cases

part of piece 2, act against one another, and | thigh may be laid on a pillow, on its outer side, in the easiest position for the patient, and retained by sand bags.

Under the former of the two last-mentioned modes of treatment, a short splint, extending the length of the thigh, of wood, tree bark, or any other firm material, may be applied on the outer side, and will give additional support; under the last-mentioned, such a short splint

may be used on each side.

In fractures of the legs, particularly of the lower portion, a different apparatus must be used, although in many respects the mode of management as regards padding, &c., is the same. In setting the limb, however, the thigh must be grasped by one person, and the foot by the other. The easiest position for the limb will be with the knee bent (figs. 108, 109),

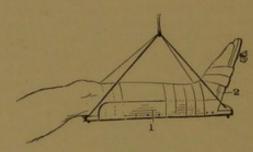

Fig. 108.

and either of the contrivances figured may be easily constructed of any common wood. upper one (fig. 108) is merely a board adapted to the size of the limb, with side pieces (1) and foot board (2) fastened to it, and slung by cords from the corners, so that it can be sus-pended, as represented, from a rafter or any other convenient support. This is a very easy kind of apparatus, especially on board ship. The other apparatus (fig. 109) is also to be constructed from boards, as represented, with side

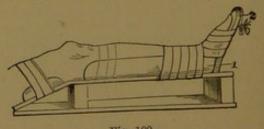

Fig. 109.

board and foot board (1 and 2). In both these, it will be an advantage to scoop out a hollow for the heel and pad well, equally with the whole contrivance, with soft materials. Should a person break his leg—that is, frac-

ture the bone between the knee and ankle-in any ordinary situation, the probability is that there would be immediate requisition for the attendance of a regular surgeon, and that the accident would be treated by him in his own mode. But limbs may be broken far away

most valuable to the sufferer, and the most easy to the unprofessional attendant. The principle of the swing splint is a semi-circular receptacle for the limb, proportioned of course to its size, which can be swung by means of bands of any sort to a cradle or framework, of which fig. 110 may be taken as a sample; α being a

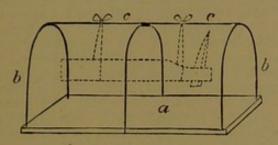

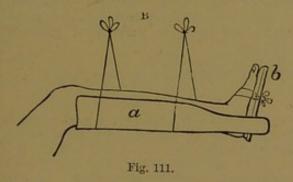

Fig. 110.

board to which are fixed the iron rods, b, across which runs the piece of iron or wood, c, this forming a support from which the splint (fig. 111), containing the leg, is hung. Of course, this framework (fig. 110), may be made of any material that may be at hand, such as green wood, or any other of which an ordinarily suggestive mind may avail itself. the splint for the limb (fig. 111, a) may be

formed of rough slats of wood tacked together, or of a piece of bark, or, indeed, of any sufficiently firm material that can be formed into the splint, and be strong enough to bear a support for the foot (b). This receptacle for the limb could be cushioned with tow, cotton wool, or any soft material, and slung in its cradle (fig. 110) with pieces of cord, if nothing better presents itself. The apparatus being ready, the fractured limb should first be arranged as straightly and comfortably as possible in its splint (fig. 111, a), and should then be slung in the cradle in the mode and position most comfortable to the patient. It is scarcely requisite to point out, even to the unprofessional person, how great must be the comfort and ease to a sufferer from fractured leg, to have the injured limb placed in an apparatus which yields to every movement like a well-springed carriage, even should the limb not be set in quite the best surgical mode. It does happen that sufferers from such accidents have to be

that the swing mode of treatment becomes the | taken long distances before they can reach In such cases the swing professional aid. splint, constructed by some intelligent person, upon the principles above enunciated, will be found of much value.

To recapitulate,—the principles of the apparatus are: a semi-circular receptacle for the limb, padded with some soft material; a support for the foot, also padded; a cradle as above described, and swing supports—cords or such like-by which the splint is swung from the cross bar of the cradle (see figs. 110, 111); a cavity formed or cut out of the splint where the heel rests. Reference to the foregoing portions of this article, especially that on fractured thigh, will sufficiently explain the

general management of these cases.

Again, the first removal of a patient who has suffered a fracture, should always be conducted with the care enjoined in the first part of the article. The bed for a patient suffering from fracture must always be a firm one. The adjustment and "putting up" of a fracture should be effected as quickly after the accident as circumstances permit, allowance being made for swelling, and if this becomes extreme, loosening of the apparatus resorted to. In setting, the bones above and below the injured one, not the injured one itself, are to be grasped; parts, such as the heel, &c., are to be relieved as much as possible from the effects of the continued pressure which they must necessarily undergo during the treatment. It must always be borne in mind, that whatever appliances are used in the treatment of fractures, they are all but different means to the one end—that of keeping the broken extremities of the bone in continued steady contact with as much ease to the patient as possible: that when this has been done for three or four weeks, lighter applications than those used at first may be employed, such as the starch bandage, &c.

In conclusion, the foregoing article will be of small benefit to those dwelling in the midst of civilisation; but its hints—and our space admits of but little more—may prove invaluable to those dwelling, or who may be destined to dwell, in a thinly-peopled country, or in such situations as on board ship, in which fractures are far from being uncommon accidents. Even if proper assistance be ultimately procurable, the intelligent management of a case for the first few days may be of the highest importance; and if it should happen, that throughout it has to be left to unprofessional management alone, even should a limb somewhat deficient in symmetry be the result, its cure is not likely to be more tardy or less painful, because those around are not in total ignorance of how it

ought to be conducted.

Compound fractures are those in which there is a wound through the skin, permitting access of the external air to the seat of the fracture. The contingency is a truly serious one to be without the assistance of a surgeon. Sometimes

the bone protrudes considerably through the | bad conducting power of fur renders it one of skin, and its end requires to be sawn off before it can be returned to its proper position. The great object is to heal the external wound as quickly as possible, and probably as good a plaster as any will be a piece of linen soaked in the blood, and when this is separated by the

discharge, the simple water dressing. FRECKLES. — The well-known spots on the skin, are most frequent upon those parts exposed to the influence of light, such as the face, neck, hands, &c., and in persons of fair complexion, especially with red hair. Water, weakly acidified with lemon juice, is sometimes useful as a wash. Sir Erasmus Wilson recommends the liniment of lime water and oil, with the addition of a little ammonia; but freckles are not to be regarded as a disfigurement to the countenance or as incompatible with health, and attempts to remove them by cosmetics are liable in the long run to prove hurtful to the

FRICTION, or rubbing a portion of the body, either with the hand or with some interposed material, is of much importance as a curative agent. Applied to the skin by means of rough towels, hair gloves, &c., it excites its nervous sensibility, and the circulation of blood through its capillary vessels. Friction with the hand in thickenings and congestion of parts beneath the skin is often of much service, and in none is its beneficial effect more obvious, than where the breasts are painfully distended with milk after child-birth. In great emaciation from chronic disease where exercise cannot be taken, friction, kneading, or shampooing of the muscles of the limbs is often of service to maintain their nutrition. The various oils, &c., used along with friction, are generally secondary to the manual effect, and are chiefly serviceable in facilitating the movement of the hand; some, however, are really beneficial, the stimulant applications by exciting, and the anodyne by soothing; moreover, some, such as cod-liver oil, turpentine, &c., appear to exert a specific effect. - See Circulation-Constipation.

FUR, as an article of dress, may be either extremely beneficial or the reverse, according to the manner in which it is used. When worn over other clothing in the open air, or as a regular fixed article of clothing in itself, the every variety in point of size, up to that of

the most efficient protectors against cold, or rather preservers of heat, we possess; but when it is used as an occasional article of dress, it is a dangerous one, and has proved so in the various forms in which it has been worn by females. When kept close to the skin—as of the neck or throat-for any length of time, it produces excited action and perspiration, which is liable to be suddenly checked the moment the fur is thrown off, and cold and sore throat are the consequences; very many cases of this kind occur, and the cause unsuspected, is repeated again and again with the same effect, laying the foundation perhaps of serious disease by the improper use of the very means employed to guard against it. Many females, liable to cold and sore throat, have been surprised how that liability has vanished with the laying aside of the use of fur round the throat. The change must, however, be made at first with caution. It is not, however, the fur which is at fault, but the uncertain mode of using it; moreover, its power of exciting the skin renders it a valuable agent when worn permanently next it, particularly on the chest in winter, by persons with delicate lungs. It not only protects from cold, but keeps up mild counter-irritation. A prepared hare or rabbit skin lined, makes as good a fur chest protector as any other. Furriers, accustomed to employ mercurial preparations in their manufacture, are liable to suffer from mercurial poisoning.

Refer to-Clothing, &c. FURUNCLE—a Boil.—See Boil.

GALBANUM, one of the gum resins, is procured from an umbelliferous plant, and is brought chiefly from Persia and India. It is stimulant and carminative, but is not much employed in medicine at present. Its best preparations are the plaster, which is stimulating, and the compound assafætida pill, which is a compound of equal parts of assafcetida, affections, flatulence, &c. GALL.—The Bile.

GALL BLADDER, the receptacle for the bile, is situated beneath the right lobe of the liver, almost exactly at the boundary line between the epigastric and right hypochondriac region (see Abdomen). It is pear-shaped (fig. 112-1); from its smaller end proceeds a duct (3) which shortly joins a similar duct from the liver (4), the two together forming the common bile duct (2), which enters the duodenum (5) in its descending portion. During its retention in the gall bladder, the bile becomes thicker from the absorption of part of its water.

GALL STONES are concretions formed

from the peculiar crystalline ingredient of the bile-the cholesterine. The concretions are of a walnut; when small, the number, either or by the mouth. If by the mouth, thirty drops passed by the patient, or found in the gall bladder after death, is often very great. These concretions may, and often do, exist in the gall bladder, without giving rise to any unpleasant symptoms; their presence only being discovered on examination after death; but should one of them, from any cause, pass into the duct, it gives rise to most violent spasmodic pain, which continues with little intermission until the stone has descended into the bowel through the ducts.

The ordinary calibre of the gall duct is about that of a goose-quill, and the stone is generally of much larger size; the passage therefore of a

gall stone is often a protracted one.

Symptoms of gall stone often supervene suddenly; the person is seized with the most agonizing pain in the region of the gall bladder; probably, there is severe shivering and vomiting, and these do not disappear till the stone has passed; there may or may not be jaundice, probably not, as long as the obstruction does

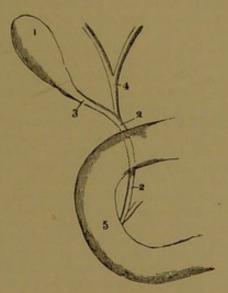

Fig. 112.

not pass into the common duct (fig. 112-2) and so stop the flow of bile from the liver. If jaundice comes on, the evacuations from the bowels become white and chalky in appearance. The fact of there being no fever present, and that the pain caused by a passing gall stone is relieved instead of aggravated by pressure, is sufficiently indicative of the absence of inflammation. After the occurrence of the above symptoms, it is always proper to examine the evacuations from the bowels, to verify the disease by finding the cause. Gall stones are easily detected in the evacuations, as they float upon water.

When an individual is suddenly seized with symptoms of gall stone, no time should be lost before applying hot applications over the seat of the pain, or getting the sufferer into a warm Opium ought to be given at once,

of laudanum may be administered at once, and failing relief, the dose may be repeated in a couple of hours. As the retching is often severe, and liquids of every kind are vomited as soon as taken, the subcutaneous injection is preferable. Persons who are liable to repeated attacks of gall stone should keep one grain opium pills beside them to take when necessary. There is generally much distressing acidity of stomach whilst a gall stone is passing, and Dr. Prout's plan of giving full and frequently repeated draughts of hot water, containing in each pint a full tea-spoonful of carbonate of soda, affords much relief, whether vomited or not. Of course laudanum may be added to the soda solution if requisite. If the stomach will not retain the remedies, the opium may be administered by enema mixed with four ounces

of liquid starch.

The suddenness of the attack of gall stone, and the agony of the pain, render it one of the diseases in which unprofessional persons may afford most valuable assistance by judicious management; and by following the above directions they will certainly give relief, perhaps from many hours of suffering, if medical assistance is distant. A person who has once suffered from gall stone ought, of course, to be examined medically, but much may be done to ward off attacks by attention and management as indicated in the articles Diet, Bile, &c., and by regular and sufficient exercise either on foot or horseback, and, in addition to these, the use of special cholagogues or liver medicines. For long, mercurials, as blue pill, calomel, and such like were chiefly used as liver regulators, but of late years we have had some most valuable vegetable substitutes, which can be regularly and freely used. Of these padophyllin has been best and longest known, but it has peculiar disadvantages, and is now being greatly superceded by euonymin and iridin, either of which may be taken in doses of two grains each in the form of pill. Their action is easy, almost insensible, and yet very effectual in regulating the liver functions.

Occasionally gall stones instead of passing into the bowel, become impacted in the common duct, giving rise to continued severe jaundice, with serious and sometimes fatal results. In such cases surgical interference may be necessary, and is often successful in removing the obstruction.

Refer to-Bile-Diet, &c.

GALLS, or GALL NUTS, are excrescences produced upon the twigs of a species of shrubby oak, by the prick of an insect for the purpose of depositing its eggs. They are brought from the shores of the Levant, and from Asia. Galls are powerfully astringent, owing to the tannin, or astringent principle they contain, which, in its separated forms, of gallic and tannic acids, is now largely used in medical practice. These acids possess the same properties, and when employed by themselves, or either by the subcutaneous injection of morphia | in the more popular form in combination with

GAR GAL

e tringent action; and by their power of precipitating albumen, they protect wounds and bleeding granulations from exposure to the air. The preparation of tannic acid, one part to four of glycerine, of the British pharmacopæia is an extremely useful one, and is employed for an infinite number of purposes. For offensive discharge from the nostrils and ear passages, to allay the intolerable itching in the common skin disease called eczema, as an application to the throat in aphthous ulceration, elongated uvula, and even in hooping cough, glycerine tannin has been found very serviceable. A mixture of glycerine tannin and glycerine of carbolic acid checks and deodorises the offensive discharge from the uterus, in cases of malignant disease of that organ. Gall ointment is a useful application in piles in persons of relaxed or enfeebled constitution, but is quite the reverse in those of full habit, in whose cases the piles are generally in a state of active inflammation. The best form of ointment is, -galls, in very fine powder, two drachms; opium, in powder, one drachm; lard, one ounce; well rubbed up together. Gallic or tannic acid is the best antidote to poisoning by tartrate of antimony, and in poisoning by strychnine or morphia, it would be given to render these agents less soluble.

GALVANISM.—See ELECTRICITY.

GAMBOGE or CAMBOGE, the wellknown pigment, is a drastic cathartic, too powerful to be used alone with safety, as a domestic remedy. In an overdose it seriously irritates the lining membrane of the stomach and bowels, causing inflammation of a dangerous or fatal character. Gamboge is said to form a constituent of some of the quack purgatives, and certainly any compound medicines containing it cannot be safely adopted for general or "universal" use, however valuable the medicine may be when administered in proper cases. When simple purgative action is required, gamboge cannot be requisite whilst we possess safer and equally effective drugs; but from its property of producing free watery evacuations from the bowels, in cases of dropsical swelling, it is very serviceable. Gamboge is most safely and advantageously given in combination, and the compound gamboge pill is a powerful cathartic adapted for those in whom confined bowels accompany a full and strong habit of body. The gamboge pill mass is composed of the following ingredients, gamboge in powder, Barbadoes aloes, and compound powder of cinnamon, of each one drachm, hard soap in powder two drachms, with a sufficiency of syrup to make a mass when beaten up. The dose is from five to ten

Refer to—Dropsy—Cathartics. GAME .- Wild animals used as food, the

glycerine, they check the secretions by their | many persons on account of the less proportion of fatty or oily substance which it contains. Of course game, like other articles of food, may be rendered hurtful by sauces and modes of dressing. - See Food.

GANGLION, in anatomy, means an aggregation of nerve substance. In surgery, it is applied to the elastic swellings which appear upon the wrist or top of the foot, generally about the size of a hazel nut. These may often be removed by bursting the small bag or cyst of which they consist, and thus effusing the contents—which resemble the white of egg—into the surrounding parts; a

bandage being applied afterwards. The case is best submitted to the surgeon.

GANGRENE .- See MORTIFICATION.

GAPING, or YAWNING, is a nervous affection, indicative of nervous exhaustion and depression of the circulation. Persons in health are, as is well known, liable to gape when tired. Like other nervous affections, it is apt to give rise to imitation in others.

Gaping is, however, a not unfrequent symptom of disease, functional or organic, particularly of the chest. Attacks of hysteria accompanied with fainting, or of spasmodic asthma with depression of the action of the heart, are often ushered in by gaping. Persons who suffer from disease of the heart are also

liable to "fits of gaping."

GARGLES are liquid applications to the back part of the throat and to the mouth, in various affections of these organs. Gargles are too often used as astringents, particularly in the first stage of inflammation of the tonsils, &c., or sore throat. In these cases, the warm water, or gruel gargle, is a much better remedy, with the addition of a small quantity of vinegar. The common domestic gargle of "sage tea and vinegar" answers very well. As a general rule, in the first stages of "sore throat," it is better to use the simple soothing gargles, nearly as warm as can be become gargles, nearly as warm as can be borne; in the latter stages, when there is often much stringy phlegm about the throat, the more stimulating and astringent gargles will be useful. For the latter, from four to five drops of hydrochloric acid in the ounce of water is as good a form as any; or the infusion of roses with ten to fifteen drops of dilute sulphuric acid to the ounce of water. Another very useful gargle in cases of relaxed sore throat is made with a drachm of alum, half an ounce of tincture of myrrh, and water sufficient to make up a pint. Perhaps one more useful still is made by adding from thirty to fifty minims of tineture of steel to half a pint of water. Cayenne pepper is also used as a gargle (see Capsicum). In cases of chronic weakness of the throat, with tendency to frequent swelling and inflammation, a gargle of oak bark decoction, or of salt water, is of much service, used every mornflesh of which is a little less digestible than ing for some time. Gargling the throat with poultry and beef and mutton, but suited to an antiseptic, such as chlorate of potash or GAR GER

the fætor from offensive ulcers of the throat. Gargling is effected by throwing the head back, and, consequently, the fluid back in the throat, and expelling the air through it from the lungs; it is thus worked, as it were, into every part of the throat. The application of medicated spray to the back part of the throat by means of Siegle's spray instrument is now much employed for the same purposes as gargles, and with equally good results.

GARLIC.—See ONION. GAS is an elastic fluid, which is permanently aëriform at all ordinary temperatures, being distinguished from vapours, which are only temporarily elastic and aëriform. The gases alluded to in the course of this work are-

Ammonia. Azote, or Nitrogen. Carbonic Acid and Carburetted Hydrogen. Chlorine. Hydrogen and Sulphuretted Hydrogen.

GAS STOVES .- See Ventilation and Warming.

GASTRIC JUICE is the acid viscid fluid secreted in the stomach when that organ is excited by the presence of food; the office of this peculiar secretion being the solution of the nutriment, or rather the reduction of its albuminous and gelatinous portions to a state in which they are fit for absorption into the system. The gastric juice owes its solvent properties, which are very powerful, to the hydrochloric acid and peptones it contains.

Refer to -Digestion - Food - Indigestion. GASTRITIS .- See STOMACH, INFLAM-MATION OF

GELATINE, or GLUE, is an azotised component of animal bodies, of simpler constitution than the azotised albuminous compounds (see Food). It may be extracted from tendons, skin, &c., by long boiling, and from bones by dissolving out their earthy matter by acids; it occurs pure in many fishes, the air bladders of which are formed of gelatine; isinglass, so well known as a jelly-making compound, being the prepared swimming or air bladders of the sturgeon, cod, ling, &c. The gelatine sold as such is generally prepared from bones. Many persons have a prejudice against this gelatine, and imagine it not so good as that extracted from calves' feet, or prepared from isinglass. The amount of nutriment in gelatine is very small, but gelatine has a remarkable facility for assimilating with other food, and with sugar and wine (the common way in which it is administered) it forms a very agreeable adjunct to the limited fare of the invalid. There is no reason to believe that the manufacture of gelatine from

Condy's fluid in solution with water, removes | is a pity that many should deprive themselves and others of so convenient an addition to cookery for the sick.—See Cookery—Food, &c.

GENERAL HEALTH .- By the term is meant the state of the body and its functions collectively, in contradistinction to the coudition of any special portion of the frame. The state of the general health is always an important consideration, with respect to local maladies, both as regards their treatment and ultimate prospects. The latter must always be more serious when the general health begins to suffer.

GENTIAN ROOT is obtained from the Gentiana lutea, or yellow gentian, which is a native of the more elevated ranges of the Alps, Pyrenees, &c. The root is brown externally, irregular, knotty, ringed, and from half an inch to an inch in diameter; it is yellow within. Like the gentians generally it is extremely bitter, and on account of this property it constitutes one of our most extensively used and most serviceable tonics and stomachics. most useful medicinal preparations of gentian are, the extract, the infusion, and the com-pound tincture. The extract is chiefly used in from five to ten grains—or more—doses, as an ingredient in tonic or aperient pills. compound tineture may be taken in one or two tea-spoonful doses, in water. Quite the best preparation, however, for general use, is the infusion prepared in a concentrated form, according to the following process: To every ounce of sliced gentian root add a quarter of an ounce of dried orange peel, and infuse thesenot boil-with successive quantities of boiling water poured over them, until their strength is entirely exhausted. The whole of the infusion thus made, being separated from the root and peel, must next be concentrated by boiling in a well-tinned or porcelain-lined saucepan, until the quantity is so far reduced that there is left half a pint of the concentrated infusion for every ounce of gentian used. To each half pint of this concentrated infusion half an ounce of alcohol is to be added. The effect of this addition of spirit is, to coagulate a quantity of jelly-looking substance, which must be separated by straining through flannel. The infusion will thus be got clear, and will keep for a great length of time, the dose being one tea-spoonful in an ounce of water. When the fresh infusion for immediate use is required, a quarter of an ounce of gentian root sliced, with the addition of a little orange peel, to the pint of water, will be a proper strength, if infused for an hour or two.

GERMS OF DISEASE. — It has long been admitted that certain forms of disease, especially such as in their epidemic form have decimated large bodies of people, were com-municated by something latent in the atmosphere, or were spread from person to person, other substances than isinglass or calves' feet by infecting particles or germs having the is otherwise than properly conducted, and it | property of reproduction to an alarming extent

under circumstances favourable to their development; but it is only within the last few years that this theory has obtained practical demonstration. Many circumstances apart from contagion tend to favour this view of the parasitic origin of disease. The analogy which exists between the process of fermentation, when associated with the growth of the yeast plant, and the febrile conditions caused by the introduction of infection, or diseased matter into the blood, naturally led observers to infer that a zymosis, or ferment similar to what takes place out of the body, had its nidus also in the interior. Hence the term "zymotic" came into common use to specialise the character of numerous diseases, originating from a virus of a specific character in an organised or live state, allied, or rather supposed to be allied, to what we know of the nature of ferments. We are greatly indebted for our knowledge of the bacteria to Pasteur, the celebrated French chemist, who, by a series of elaborate experiments, first recognised the fact (see Fermentation) that wherever there is fermentation, there must be vitality to originate, develop, and complete the process; and by the discovery of the special characteristics of numerous ferments, each capable of reproducing and multiplying its own micro-organisms, and no others, naturally led up to the understanding that each wellmarked form of disease was attributable to its own peculiar living germs. These germs or bacteria, representing the lowest forms of growth, or matter in an organised state, and bearing an analogy to the minute globules developed by yeast, are to be seen by the higher powers of the microscope in all stages of the process of putrefaction; in the progress of wounds, especially such as are of an unhealthy character, as well as in the fluids and tissues of the body in numerous diseases. It was until very lately assumed that bacteria pervaded the fluids of the body in a state of health; but this doctrine is now denied by the best and most recent authorities, and if their opinion is to be received, the ground is cleared for the more favourable investigation of the organisms of disease. Hitherto it has been chiefly among the lower animals that the specific germs of some well-known diseases have been studied, and in one well-known complaint variously named, malignant pustule, charbon, and splenic fever, which occasionally occurs in man, the micro-organism and its characteristics have been minutely investi-gated, and with manifest advantage, as proved by the success which has attended the measures for attenuating the virulence of the organisms, by a process corresponding to vaccination. In this complaint, which chiefly attacks sheep and oxen, the disease germs are well defined, are always found in myriads in the blood of the affected, and animals inoculated with the virus die in the course of a few

From the disease with which it is hours. associated, the name of "bacillus anthracis" has been given to the infecting agent, which may be separated from the blood and tissues of the body, and cultivated apart from all surroundings through successive generations of bacilli, without losing a particle of its potency. Pasteur has even shown that the remains of animals which had died from malignant pustule were still infected with the organism after the lapse of twelve years,

Fig. 113.

by reproducing the distemper in all its virulence in others. The bacilli in question are formed of translucid filaments of a more or less segmental shape; these, when examined by high microscopic power, are seen to contain spores, having the property of re-producing the organism afresh by subdivision and elongation into the rod shape represented

(fig. 113).

Malignant pustule is said to be as fatal to cattle as small-pox is to the higher animals; but since experiments on a large scale have been made in France, with the view of diluting its virulence, and by subsequent introduction of the attenuated virus into the animal's system, the ravages of the distemper have been immensely reduced. Similar investigations have been made by Pasteur on the specific character of the bacteria which are the cause of chicken cholera, and by Klein on the parasitic organisms which produce a typhoid fever peculiar to the pig; but by far the most important of these microscopic discoveries is that in which Koch, of Berlin, by pursuing a series of careful and elaborate researches, has shown those minute organisms to be intimately associated with consumption and the category of diseases allied with it, to which the name of "tuberculosis" is applied by medical men. Koch has demonstrated that in this disease there are always to be found microorganisms or bacilli of a well-defined shape and character totally distinct from other disease germs; and these, when separated from the body and their surroundings, are capable of reproducing themselves, and the disease in question and no other, among the lower animals, and doubtless in man. They are like other bacilli, of a delicate rod shape,

GIN

from a fourth to a half the diameter of a blood-corpuscle in length, and are found constantly present in the expectoration of consumptive persons. In the tubercular deposits in the lungs, and other organs of persons who have died from consumption, they are found in large colonies (especially in deposits where the growth has been active and recent), and more sparingly distributed in old tubercles where the disintegrating process has ceased.

All observations tend to show that, however much the germs of organic life pervading all nature resemble each other in their growth and characteristics, there are numerous species which have the power of conveying and reproducing, under favourable circumstances, distinct forms of disease; and although not yet clearly established, there is every reason to believe that each one of the well-marked species of infectious diseases is propagated by its own peculiar virus latent in these organisms, which, finding a genial soil in the human body, grows and fructifies therein. On the other hand, there is a limit to this vitality as there is to the life of all organic products, and the same chemical agents which we are in the habit of employing to stamp out infection, namely, heat, chlorine, sulphur, carbolic acid, &c., have the power of rendering the micro-organisms referred to, though in different degrees, comparatively innocuous. The application of this theory, if the term "theory" can any longer be applied to it, is the foundation of the system of antiseptic surgery introduced by Lister. Some of the practical results of the more exact knowledge now possessed may be gathered from the article on Disinfection, and from the remarks under the heading Enteric Fever. It is still an open question whether germs are the direct cause of the diseases with which they are associated, or whether the cause is to be attributed to the generation of poisonous materials consequent upon their existence; but this does not affect the main fact, that their presence is an essential element in the production of the diseases referred to.

Among other important results attributable to our more exact knowledge of the relation of germs to the diseases with which they are associated, may be mentioned the attention which has thus been directed to our food supply as a danger to health. For example, outbreaks of scarlet fever associated with the milk supply have more than once been fairly conclusively proved to be connected with trivial affections in cattle, which had previously been looked upon as unimportant. Again, startling evidence has been recorded which points to a connection between diphtheria and certain affections from which our domestic animals may suffer. Consumption, also, and tubercular affections generally, which have been proved to belong to the germ class of diseases, are more than likely to be produced animals suffering from tuberculosis. withstanding these facts, however, which, no doubt, as time goes on, will be more positively proved, we must not forget that by far the most important element in the propagation of infectious disease is personal communication. either direct or indirect, through the various media already indicated.—See Disinfection --Fermentation.

GESTATION .- See PREGNANCY.

GIDDINESS,— DIZZINESS,— in medical language "vertigo," is a sensation of confusion, and loss of the power of balancing the body, which is frequently momentarily experienced even by persons in good general health, and is unquestionably often attributable to stomach derangement solely. An abnormal condition of the supply of blood to the brain is a probable direct cause of giddiness, and this tendency is most palpable after persons have been confined to bed, or to the horizontal position for a short time and on first assuming the erect posture. It may result also from abnormal conditions of the eyes or ears. A mere passing giddiness is probably owing to some cause which a little attention to the state of the stomach will correct; but repeated attacks, especially if accompanied with palpitation of the heart, or pain and heat about the head, require medical examination without delay

GIN, the well-known liquor, also known as Geneva, or Hollands, contains oil of juniper, and when first introduced was used simply as a diuretic medicine; it ultimately, however, became an object of trade and of general—too general—use. It certainly often increases the

flow of urine in a marked degree.

GINGER, the well-known spice, is the creeping root of a tropical plant. That used in Britain is chiefly brought from the East and West Indies. Two kinds of ginger are met with, the dark coated, and the pale peeled ginger; the latter is the best. "The rhizomes, or root pieces, of ginger of good quality have no epidermis, or outer skin, are plump, of a whitish or faint straw colour, soft and mealy in texture, with a short fracture, exhibiting a reddish resinous zone round the circumference; the taste should be hot, biting, but aromatic. The rhizomes of ginger of inferior quality are frequently coated with epidermis, are less full and plump, often constricted and shrivelled; of darker colour, being of a brownish-yellow; of harder texture, termed flinty; and more fibrous, while the taste is inferior and less aromatic." Ginger root is chiefly adulterated by means of processes used to give the inferior quality the appearance of the best; for this purpose, whitewash, chloride of lime, sulphur fumes, &c., have been used.

As an aromatic, especially when added to medicines to correct their griping properties, ginger is peculiarly useful. For persons of rein man by milk and butcher's meat from laxed habit it is well suited as a spice, but by

the head, it should be sparingly used in diet.

GLACIAL ACETIC ACID, the strongest form of vinegar, is the best application for destroying corns and warts; a drop or less should be applied by means of a small glass rod to the excrescence, which it usually removes

after one or two applications.

GLANDERS, the malignant disease to which the horse, the ass, and the mule are subject, is also capable of being communicated to man, certainly by inoculation, perhaps by simple contact with the skin. In the above animals, the disease is manifested by a yellowish, bloody, fœtid, adhesive discharge from the nostrils, the lining membrane of which is ulcerated. Should any of this discharge come in contact with an abrasion of the skin, or even get lodged on the sound skin, as of the hands, or be snorted upon the nostrils or eyes of man, it is capable of originating this horrible disease. From two days to a week after inoculation, the attack is ushered in with fever symptoms, or by vomiting and diarrhoa; then small tumours appear which ulcerate and discharge from under the skin in various situations, and there is yellow viscid discharge from the nostrils, &c. Almost every case of this fearful disease has proved fatal. The object for mentioning it here is to impress caution upon all who may be exposed to the contingency. The immediate destruction of an affected animal should, of course, be effected, and its entire body at once buried.

GLANDS are bodies situated in various parts of the animal frame, their office being either the elaboration of some fluid, or the separation of some secretion from the blood; of the former the mesenteric glands are examples; of the latter, the liver, salivary glands,

GLUTEN is an azotised principle which exists in the grains, and corresponds to the fibrine of animal bodies; it is, therefore, highly

nutritious. - See Food-Grains, &c.

GLYCERINE is a substance which does not exist ready formed in nature, but enters into the composition of all oils and fats, whether animal or vegetable, and was discovered by the illustrious chemist Scheele, in 1779, who called it the "sweet principle of oil." It is obtained in great quantity during the manufacture of candles. Thin glycerine, and also, it may be said, English glycerine, is quite the best. It has been extensively employed in the arts as well as for a variety of medical purposes. At its first introduction the Emperor of Russia caused many little bottles of it to be distributed among the poor inhabitants of the dangerous quack carminatives frequently given

those of full habit, especially with tendency to | Caucasian mountains, who suffer so much in winter from fissures of the skin, on the hands, &c. The supply was obtained from a candle

manufactory at Odessa.

It has been used very extensively as an application to many skin diseases, both alone and as a constituent part of many ointments and soaps. It is also much used as a convenient solvent for many drugs, in the treatment of disease of the eye, throat, &c., and was fairly tried at the Brompton Hospital as a substitute for cod-liver oil, in pulmonary The results obtained were consumption. negative as to benefit, or the reverse. Those who believe in its use in consumption, will find the following a good prescription, especially if there is emaciation, loss of appetite, or profuse perspiration:—Take dilute nitric acid, two drachms; glycerine, two ounces; infusion of quassia, sixteen ounces—mix. A table-spoonful to be taken three times a day. Amongst the most useful properties possessed by glycerine may be mentioned its antiseptic power, that is to say, its capability of preserving substances immersed in it from decay. Hence it is much in use in the preparation and preservation of microscopic specimens of the animal tissues, &c. On the Continent it has been highly praised as a remedy or preventive against hospital gangrene, though surgeons in this country have not the same confidence in it.

One ounce of glycerine added to ten ounces of water, forms a lotion which can be applied so as to constitute a kind of protective varnish, which might be useful in some cases of burns,

also in cutaneous diseases.

Borax and glycerine form an excellent combination as a lotion to be applied to many cases of scaly eruptions of the skin. Take twenty or forty grains of borax, one ounce of glycerine, and seven ounces of elder flower water-mix. Apply the lotion night and morning. The following lotion is very valuable in certain cases of skin disease, with much irritation and itching: Take of glycerine, two ounces; dilute hydrocyanic acid, one drachm; bicarbonate of soda, two drachms; add water to one pint. The lotion to be applied night and Glycerine with tannin and with morning. gallic acid are two favourite methods of applying these remedies to the mouth, throat, and ear when it is necessary to produce an astringent combined with an emollient effect. parts of starch and glycerine form an excellent plasma for various affections of the skin, accompanied with harshness and dryness.

One great objection to the free use of glycerine is that it is rather expensive, at all events, for the poor, to whom it is so serviceable in cold climates. It is to be feared also, in consequence of the diminished consumption of candles, that the price will be further enhanced.

GOULARD EXTRACT is a saturated solution of sugar of lead, which, when diluted, forms goulard water.

Refer to—Lead.

GOUT is a disease of the blood. Its exact nature is disputed, but it has been positively proved by Dr. Garrod, that the blood of a gouty patient contains an undue quantity of a peculiar acid named uric acid. This acid is contained in small proportion in healthy blood, but in the disease in question, that proportion is found to be considerably increased. some, the excess of this uric acid is thought to be the effect, by others the cause, of the malady; however that may be, the fact of its presence is undoubted; moreover, the proper outlets for this acid is by the kidneys, in the urine, which, as a rule, contains it in certain proportions, but in greatly increased proportion in some peculiar conditions of the constitution, when it constitutes one form of gravel; it is even a matter of popular observation, that gravel and gout are nearly connected; they often alternate with one another in the same person, and in the same family are found affecting the various individuals of it; the gout the males, the gravel the females. There is no disease, perhaps, the hereditary tendency to which is more thoroughly established than gout. Generally it occurs in persons of full habit, especially if they consume much stimulating food and drink, and take little exercise, but it also shows itself in the weak and debilitated. The attack is generally preceded by symptoms indicative of derangement of the general health, and particularly of the digestive organs. Dr. Gairdner, one of the best authorities on the subject, enumerates dull pain in the side, headache, confined bowels, high-coloured urine, and scaly eruptions on the skin, as among the most frequent warning symptoms. The attack itself generally comes on in the night, and the sufferer is awakened by the pain in the foot, having, perhaps, previous to awaking, passed through a night-mare or "suggestive" dream (see *Dreams*) in which the scenes are connected with the uneasiness experienced. The ball of the great toe is the part most rheumatism: then give the instrument another | gout is not a common disease, for the poru-

It contains opium, and fatal twist, and you will obtain a notion of the e often the result of its admin- gant." The part attacked by the gout becomes swollen, hot, red or bluish-red, and shining; these symptoms continue with more or less intensity for some days, and then subside. Along with the local symptoms, there occurs more or less feverishness and disorder of the bowels and urine, but when the attack has passed away, the individual is left in a better state of health than before. This fact has given rise to many erroneous ideas, and much erroneous practice in connection with gout, and by those subject to it; regarding it as a salutary affection, they have rather encouraged it than otherwise-the more so that the encouragement involves indulgence, rather than selfdenial—forgetful, that although the outward manifestation of a fit of gout may end in a salutary effect, from its being the disturbance occasioned by the constitution endeavouring to free itself from morbid matter; it must be far better if no such disturbing effort is required at all, and further it is certain, that no constitution can be the subject of these repeated, violent perturbations, without its becoming permanently weakened, or wholly broken up. Let none, therefore, who have a gouty tendency, and are periodically renovated, as it were, lull themselves into security by the idea that they suffer no injury, for the constitution cannot fail to be impaired by the repeated trials. Their only security rests with themselves, in avoiding those habits and modes of life which engender that state of system and blood that winds up with a fit of the gout. Moreover, although these fits may at first be more painful than dangerous, this is far from being the case. as life advances, and the constitution suffers; then gout may, and often does, attack some more important part than the great toe; and the stomach, the heart, or brain, are apt to become its seat with fatal consequence.

The most undoubted predisposing cause of gout is hereditary tendency, and it is one very widely distributed, though not always actively developed; the other causes are, luxurious habits, the habitual consumption of a larger quantity of food-especially of animal foodthan is required by the system, and undue consumption of wine and malt liquor, especially the former. These of themselves will develop gout in the predisposed; but if their use is coupled with deficient exercise in the open air, the exciting power becomes much increased. Moreover, the same acting causes give rise to attacks of red or uric acid gravel, that is, to the excretion of this from the blood, by the kidneys in the urine. Old malt liquor has a peculiar The ball of the great toe is the part most generally attacked, though not invariably; the pain is very severe. A French author, in describing it, says, "Place your joint in a vice, and screw the vice up until you can endure it no longer; that may represent rheumatism: then give the instrument another

GOU

lation generally, whilst they do not consume | times a day, dissolved in half a tumblerful of excessive quantities of meat and malt liquor, have also the constant counter-action of plenty of fresh air and exercise. When gout is met with in the country, it is generally in those connected with inns and public houses, who consume malt liquor largely, and take little exercise.

From the above it is evident, how much any one with a liability to gout has it in his own power to prevent its occurrence; malt liquor he should never touch, wine very sparingly, or if he must have some stimulant, though he is much better as a general rule without any, a little gin or brandy and water. Meat should be eaten sparingly and only once a day; never Whole meal bread, vegetables generally, cooling fruits and milk preparations, are the safest articles of diet for those predisposed to gout; but tea, and especially coffee, should not be taken strong. Further, early rising, attention to the condition of the skin by frequent washing and regular daily exercise, are the best adjuncts to temperate diet. It is perhaps not saying too much to affirm, that persons predisposed to gout may almost wholly escape its attacks by attention to the above rules of health. In advising exercise, however, the caution must be given, that it is not violent and fitful exertion which is recommended, this being, in fact, more likely to develop the disease than to prevent it. The regularity of a sufficient amount of daily exercise is the essential: indeed, not only does violent physical exertion, especially of an unusual kind, tend to excite a fit of gout, but even strong mental emotion or violent passion has been known to do the same.

Regarding the best treatment of gout during the existence of the attack, there is considerable diversity of opinion. Little is to be done to the inflamed part; certainly cold applications, which have been recommended and used, are dangerous; but a piece of flannel, wrung out of warm water, laid lightly over the joint, and covered lightly with a piece of oiled silk will give relief, or the lotion of sugar of lead and laudanum may be used warm, perfect rest it is almost superfluous to enjoin, as the pain makes that compulsory. In some cases where the inflammation is not excessive, nothing affords so much relief as to envelop the painful part in cotton wool, and then cover this over with oiled silk, till profuse perspiration is induced. The moist wool can then be removed and dry substituted without any waterproof covering. As regards constitutional treatment, where the powers of the constitution are vigorous, a perfectly low diet should be observed; in some cases an active purgative answers well, in others, but chiefly old standing cases, it so certainly aggravates the attack, that patients from their own experience will not resort to the remedy. Ten to fifteen-grain doses of carbonate of potash may be given three | are now very much employed in the treatment

water, either simply or made effervescing by the addition of lemon juice. The remedy, however, for gout, is colchicum. A medical man may, of course, give it more boldly than an unprofessional person; but still should it so happen that the person suffering from gout is not under medical treatment, ten drops of colchicum wine may be given safely three times in the twentyfour hours. The power of colchicum, in subduing both the pain of gout and the disease itself, is often most striking. The following instance will exemplify it:—A lady suffered from repeated attacks of severe shooting pain through the region of the heart, and was treated without relief; at length one of the joints of the forefinger became suddenly affected with gouty inflammation; this gave an immediate clue; colchicum wine was prescribed in ten-drop doses twice a day and before six doses were taken, both the pain at the heart and the inflamed joint were curd; the same thing has occurred

repeatedly since in the same patient.

It is undoubtly better, safer, quicker, even in mild attacks of gout, for the case to be treated by a medical man; but patients who know what the disease is, will not always have recourse to his aid; in such cases, the perfect rest both of body and mind, the warm moist flannel, low diet, gentle regulation of the bowels, the cooling saline, and the small doses of colchicum will be the safest measures; but safer still will be attention to those preventive measures already pointed out, which any may follow by the aid of their own common sensea faculty which ought to renew the reasons for, and the reasonableness of, such a course. Many persons who have suffered from repeated attacks of gout become affected with chalkstones (see Chalk-stones), which impede greatly the usefulness of the hands; the constitution too gives way. In these cases, medical assistance ought never to be dispensed with, and there are few old sufferers from gout, in whose power it is not to procure it of the best. A much less reduction in diet will be required than in more recent cases and stronger subjects; the medicines must be of a warmer character. Fifteen grains of calcined magnesia, ten of rhubarb, and forty drops of sal volatile, in a wine-glassful of water, will form a draught which may be repeated twice a day. It may also be given with advantage with double the quantity of sal volatile, and twenty or thirty drops of laudanum in the event of gout receding to the stomach, as evidenced by pain and other signs of disorder of the organ, and by the sympathetic faintness, accompanying the attack. A glass of brandy may be substituted for the above with good effect; these stimulants, however, being given under the caution that no extreme tenderness, indicative of inflammation, exists at the pit of the stomach. The carbonate of lithia and the citrate of lithia,

of gout, the dose of the former is from three to | salts, principally phosphates of the alkalis and six grains three or four times daily, and of the latter from six to ten grains. Lithia water, an effervescing beverage, containing ten grains of the carbonate of lithia in a pint of water, is a favourite form in which the drug is taken. In addition, in an attack of "retrocedent" gout, either to the stomach, or elsewhere, the feet should be immersed in hot water with mustard, or a mustard plaster should be applied to them, with a view of attracting the disease to its more usual site. These attacks of gout shifting to internal organs are often so quick in their seizure, and so rapid in their progress, that it is highly desirable that such measures should not only be understood, but thoroughly carried out. The aged and debilitated sufferer from gout must not at any time reduce much his usual mode of living. Gout is often confounded with rheumatism and with rheumatic gout, which has features characteristic of both. The mistake is not likely to occur in the earlier attacks of gout affecting only the joint of the great toe; in later attacks more generally distributed the history of the disease distinguishes it. Gout affects the small joints, and generally but one at a time, while rheumatism affects the larger, and is usually more widely distributed over the body.

Reter to -Colchicum - Gravel - Rheumatism

Urine, &c.

GRAINS, or, as they are sometimes called, the "cereals," are the seeds of plants which belong to the order of the grasses. They constitute a large proportion of the food consumed by the human race, and likewise form no inconsiderable amount of the nutriment of vegetable feeding animals generally. are, perhaps, in one sense the most direct link between the animal and mineral kingdoms, for in them the nutrient compounds prepared by the vegetable from the mineral elements of the soil, and from the gaseous constituents of the atmosphere, are so transformed and elaborated that they are presented to the digestive organs and assimilating powers of animals in forms more fitted for affording direct nourishment to their tissues, and more direct support for their bodily functions, than any other kind of vegetable nutriment, with the exception of that yielded by the pulses, beans, peas, &c., which are not, however, so universally employed as

The grains chiefly used by man are wheat, oats, barley, rye, millet, maize or Indian corn, and rice; the nutritive powers of these, however, differ greatly. The nourishment afforded by the grains to animal bodies may be classed under three distinct heads, - the azotised nourishment, represented by the gluten, which is adapted to build up and supply the waste of the muscular, or fibrinous, and albuminous tissues; the non-azotised nourishment, repre-

earths, which supply the mineral elements to the bones, the nerves, and to the tissues generally. Upon the proportions, therefore, in which these different kinds of nourishment, represented by these different elements, are contained in the grain, depends its nourishing power. Wheat, of all the grains, contains gluten most largely in proportion to its other constituents. Oats are next to wheat in this respect. Barley and rye are inferior to both wheat and oats, and maize and rice are very far below any of the above; the former of the two not containing above five per cent. of azotised matter; the latter not above three or four per cent. In contra-distinction to the above, the starch constituents are in much larger proportion in rice and maize, than in wheat and oats. The mineral constituents of the grains vary considerably as regards proportional amount, but they consist chiefly of phosphates, with oxide of iron; they are contained most largely in the seeds of the cereals and of the pulses, and appear to be no less necessary to the perfect formation of the seed, than they are to the blood of animals, which cannot be properly nourished, unless the food from which it is formed contains these mineral constituents in certain proportion -a beautiful instance of the harmony and universal adaptation of all things which prevails throughout the works of the Creator.

The grains also contain a certain proportion of fatty or oily matter. Maize does so largely, and oats in very considerable proportion.

The grains, therefore, from their constitution, are capable of supporting, with the addition of water, the animal frame and functions. It is evident, however, from science, and experience confirms the fact, that a larger proportion of barley, and still more so of rice or maize, is required to sustain the muscular development, than of either wheat or oats, which contain a greater amount of the gluten or nitrogenised, or plastic element of nutri-tion. For further information on these points refer to—Blood—Digestion — Farina — Fecula

-Food-Gluten, &c.

The flour, or meal, prepared from grain, partakes of course of the characters of that from which it is formed, and is also modified by the mode of preparation, whether ground fine or coarse, whether entirely deprived of bran or not (see Bran-Bread-Farina, &c.). Under the microscope, the various kinds of flour, particularly their starch granules, present very different appearances; this agent therefore has become valuable as a means of detecting adulteration, which could not otherwise have been discovered with certainty. At present, owing to the abundance and cheapness of wheat and wheat flour, there is no temptation to its adulteration (see Bread)-may that sented by the starch, which goes to supply being ground into flour, some of the grains are respiratory food, and to form fat, &c.,—and the otherwise prepared artificially for food, as in temptation never be again in action! Besides

GRO GRA

the oat.—See Barley—Oat, &c.

GRANULATIONS are the small red rounded points which cover the surface of a healing sore. They are very vascular, and When the granulations are bleed easily. deficient, the sore is depressed, smooth, and glazed-looking, and is not healing well. When the granulations are excessive they constitute what is called "proud flesh." In this state they are paler than they should be, and require depressing or astringing by some caustic or astringent agent, such as lunar caustic, blue vitriol, &c. — See Caustics —

Ulcers, &c. GRAPE.—The fruit of the vine, one of, if not the most wholesome of fruits. When ripe it contains sugar abundantly, vegetable jelly and mucilage, and the characteristic tartaric acid in combination with potash; also an azotised albuminous constituent, on which depends its property of ready fermentation, in which respect the juice of grape excels all other vegetable juices, undergoing spontaneously the necessary change, and becoming converted into true wine by its own inherent power of fermentation. The juice, if kept a few hours, will spontaneously ferment. As a cooling article of diet, ripe grapes are most wholesome, and invaluable in many cases of illness; but must be forbidden when their aperient properties may prove injurious. Some years ago, what is called the "grape-cure" was introduced into Germany; the persons undergoing it living chiefly on grapes-of which they had to consume many pounds weight per day—and bread. It is probable that in some states of constitution this cooling system of diet may be useful; it has, however, at least one serious drawback: the continued application of the acid of the fruit to the teeth completely dissolves off the enamel.

GREEN-SICKNESS.—See CHLOROSIS.

GREGORY'S POWDER, or compound powder of rhubarb, is composed of two parts of rhubarb, six parts of calcined magnesia, and one part of ginger. It is taken either simply, in water, or with water along with some stimulant, such as a tea-spoonful of sal volatile; it is a good stomachic and gentle aperient; but persons sometimes get too much in the habit of taking it regularly, and injure the tone of the stomach by the undue amount of magnesia. In severe cases of colic, attended with constipation and griping, a tea-spoonful of Gregory's powder with thirty drops of sal volatile may be taken in a wine-glassful of peppermint water every three hours till relief

the case of pearl-barley and groats formed from | tion of the bowels, in consequence of irregular contraction of the muscular coat; it is in fact a minor form of colic, or spasm, and is to be relieved by the management recommended under those heads. Some medicines are more liable to gripe than others, and some individuals are more than others susceptible of these griping properties. The inconvenience is generally and successfully remedied by the addition of some carminative or aromatic, such as one of the essential oils-clove, cinnamon, &c., -or by ginger, &c. Pills which are apt to gripe are more effectually corrected by the addition of one or two grains of extract of henbane, when that medicine is admissible. Some medicines are rendered griping by faulty preparation. This is especially the case with senna. It may be pointed out, that nothing gripes more severely than the passage of morbid or acrid bile through the bowels; hence when medicines act energetically upon a torpid or disordered liver, and cause a free discharge of such bile, there is apt to be severe griping, for which the medicines get the credit, whereas it is only indirectly caused by them in their really beneficial action. The spontaneous discharge of bile in bilious disorder causes griping when no medicine has been taken. - See Senna.

GRIPPE .- The French name for the epi-

demic influenza.

GROATS are oats when deprived of the husks; "Embden groats" when they are bruised also. They are used and useful for

making gruel.

GROWTH, or increase of size of the body, as a whole, or of any part of it, is dependent, as a healthy process, first on a proper amount of nervous excitation, and second on a due supply of healthy blood. When any part, such as the arm of a workman, is regularly and vigorously exercised, the nervous power, and the flow of blood, are directed to it in increased proportion, it acquires additional substance, or grows; but should the same arm become paralysed, how quickly will it diminish in bulk. Up to a certain period of life the body grows; in animals this varies with the species; in man, the process continues, generally, up to the twentieth year, or even beyond. When growth ceases, it is not that new material ceases to be added to the body, for this is unceasingly being effected to supply the place of those constituents of the frame which are continually being used up; but the balance between the food taken and assimilated, and the waste of the body, is equalised, and after growth has ceased, this balance—with the exception of fatty deposits-is, during health, maintained with but little variation during the years of life's prime. When old age comes on, that is after the sixtieth year, the balance in clines the other way; the waste now exceeds the reparative nutriment which it is in the GRIPING is pain produced in some por- power of the system to receive and elaborate,

stature even becoming less.

Young persons require nutriment, not only to sustain the wasting processes of respiration, and of motor change or movement, but they require also sufficient to supply the growing tissues of their entire body with the various elements which go to perfect their composition; if these elements are not supplied, development is either arrested, or, the tendency to growth continuing, the bones and tissues generally lengthen, without acquiring their healthy substance. As a rule, the appetite of a healthy growing child for plain and wholesome food, ought never to be stinted .- See Children-Digestion-Food, &c.

GRUEL.—See COOKERY.

GUAIAC .- The wood and gum resin of a tree, which is a native of the West Indies. They are both used in medicine. The wood is extremely hard and tough, of a striped yellowish-green colour; the resin is a greenish-brown. Guaiac, as a medicine, acts upon the skin, and is often extremely useful in chronic rheumatism The most convenient form of and in syphilis. administration is the ammoniated tineture, which may be given in one or two tea-spoonful doses at bedtime; milk is the best vehicle for its administration; when taken in water it must be drunk as soon as mixed, otherwise the resin separates and floats on the top. The guaiac mixture of the British pharmacopœia is made with the gum resin, refined sugar and gum arabic, combined into an emulsion with einnamon water. The dose is from one ounce to an ounce and a half.

Guaiac sometimes occasions sickness, in

which case it is better abandoned.

GUARANA consists of the powdered seeds of a plant, paulinia sorbilis, a native of It has of late years been much recommended for sick headaches, and contains an alkaloid identical with that in tea and coffee. The dose of the powder is from fifteen to twenty grains taken every night, or every three

hours during an attack.

GUINEA WORM is a parasitic, long, round worm, about the thickness of a violin string, which burrows beneath the skin, chiefly of the feet and calves of the legs. is met with principally in tropical climates, particularly on the African west coast, but is sometimes brought to this country by individuals who have resided in the tropics. length of the animal varies from a few inches to five or six feet. After remaining under the skin for a longer or shorter time, the head protrudes through a small boil which forms on the skin. The only treatment is seizing the head when it presents itself, and gradually, from day to day, winding out the worm, care being taken that it is not broken, for should this happen, the portion which remains is apt to occasion severe irritation. Persons native to

and the tissues all diminish in bulk, the will always be found skilled in the mode of

extracting

GULLET - THE GULLET, OF ŒSOPHAgus, is a tube which extends from the throat or fauces to the stomach. Down, or through it, the food is propelled by the action of the muscular fibres, which form one of its coats. It is narrowest at its upper end, and it is here that choking from food most generally occurs.

Choking may occur from various causes; either the gullet may be contracted from some cause or other at a particular point, or the morsel of food may be too large, or of such a hard irregular character that it cannot pass down easily, or the cause of the impediment may be spasm, more especially of a hysterical character. Impediment to swallowing from contraction of the gullet tube, is generally a serious matter; the cause should, as soon as possible, be examined by a medical man; sometimes it follows recent injury to the lining membrane, such as scratching by sharp-pointed bone, or after poisoning by irritant agents. In a case under the author's care, it followed upon a damson stone having been swallowed some months previously, scratching the throat in its descent; the power of swallowing, which was nearly lost, in consequence, probably, of thickening of the tissues immediately beneath the lining membrane, was restored by the administration of cod-liver oil for a few weeks. When a large morsel of food gets fast in the gullet, it may occasion death by pressure upon the windpipe; at all events, it causes much distress for the time. If at all within reach of the fingers, of course they may be used for its extraction at once, if too far for this, a surgeon's assistance will be required to push the morsel beyond the upper narrow portion of the gullet into the wider; this he will effect by means of the probang (fig. 114), an instrument consisting

Fig 114.

of a piece of round whalebone about two feet long, to one end of which a portion of sponge about the size of a large marble is firmly attached, and which requires oiling or greasing before use. In passing the probang, care has to be observed that it is kept well to the back of the throat, and the patient's head well thrown back at the same time; it is then to be pushed steadily but quickly down till the obstruction is felt to pass readily before it, and away from it. Œsophagus forceps are also made to seize fish bones, pins, and sharp sub-stances which may run into the gullet, and which cannot otherwise be extricated.

These particulars are mentioned, not to induce unprofessional persons to attempt the operations when a medical man is procurable; but if he is not, an unprofessional operator and the situations where these parasites prevail, an extempore probang, made from an umbrella

GUM

a small bunch of some soft material securely fastened to one end, would be preferable to choking entirely, or partially even, for any length of time. A few smart blows on the back will, in the case of children especially, often dislodge a morsel sticking in the upper part of the gullet. Sharp pointed or irregular bodies, such as pins, fish bones or other bones, may get fixed in the throat, and it is generally in the upper part of it; the fingers may be able to remove them, if not, a piece of bread coarsely masticated and swallowed, will often, especially if followed by a draught of water, carry down the impediment. In some cases, an emetic may be useful. Frequently, after a sharppointed body has stuck in the gullet, and has scratched its lining membrane, the sensation of its still remaining may be felt for some time after it has passed away. It is well to keep this in mind, that continued, unnecessary efforts to relieve may not be persevered in. Children not unfrequently swallow coins, which may be extracted when within reach by a special instrument called a coin-catcher. If the coin has passed into the stomach, the child should have a full meal of porridge with a hard boiled egg and some dry bread, followed in a couple of hours by a dose of castor oil. If a sharp body remains fixed in the upper part of the gullet, pressure at some point or other will almost certainly cause a pricking sensation. The gullet is sometimes spasmodically affected, the food being either stopped in the passage downward, or passed with pain and difficulty; this affection falls partly under the head of rpasm and hysteria, but it is sometimes the result of too great haste in eating and swallowing. As explained under article Digestion, the food does not simply fall into the stomach down the gullet tube, but it is conveyed into the digestive organ by the regular action of the muscular fibres of the tube, which, whilst they propel forward, also close behind the morsel being swallowed. It must be evident, therefore, that if morsels follow one another in too quick succession, this action must be interfered with, and if it is, spasmodic pain at least, is produced, and not improbably choking.

Choking from things getting fixed in the gullet must not be confounded with the sensation of suffocation produced by foreign bodies getting into and irritating the upper portions of the windpipe which lies in front of the gullet (see Lungs). In the latter cases, sudden, violent, spasmodic cough ensues, and the appearance and dread of suffocation is generally much more quickly and strongly marked.

cially to Digestion-Lungs, &c.

GUM ARABIC, or GUM ACACIA, is the produce of certain species of acacia, and is brought chiefly from North Africa, Egypt, Nubia, Barbary, &c. Gum is contained in greater or less proportion in the juice of most in the same situation has also been pointed out

whalebone, a cane, or even a curved stick, with | plants, and by many it is exuded in form of round concrete drops or "tears" as they are called, such as the gums of cherry and plum trees, which are familiar to all. The gum of the acacia is, however, most generally used and esteemed as a demulcent, in affections of the throat or air passages, in irritations of the urinary organs, &c. When gum is dissolved in water the solution is named mucilage, and in this form it is one of the most convenient vehicles for other medicines, particularly those which require some degree of suspension in liquid, as, for instance, in the common chalk mixture; it is also useful for facilitating the mixture of oils, camphor, &c., in watery mixtures; but for this purpose milk is preferable. The powder of gum acacia, when genuine, is probably the best form for keeping, as it is dissolved in a few minutes, whereas gum in its ordinary form takes a considerable time, and when made into mucilage, on the other hand, is very apt to spoil. Gum is nutritive in some degree, probably in the same degree as starch or sugar, and is used as an article of diet in the countries whence it is procured. It is much more used in medical practice in France than in this country, both for its nutritive and its demulcent properties.

Gum tragacanth, another species of gum, brought chiefly from Asia Minor, Persia, &c., is procured from a tribe of plants belonging, like the acacia, to the leguminous or podbearing family. It possesses many of the properties of acacia gum, but not being so soluble, is not nearly so convenient for internal use. With hot water and prepared chalk, it forms an excellent basis for a plastic splint after fracture of the long bones. The composition is spread betwixt two layers of coarse flannel, which are wrapped round the limb and allowed to dry, after which it becomes an unyielding support of the fractured bones.

Mucilage of gum acacia may be conveniently made by dissolving ten ounces of the gum in twenty fluid ounces of water, either by gentle

heat, or by suspending the gum—tied in a muslin bag—in the water.

GUMS.—The gums, which closely invest, but do not adhere to the teeth, are composed of mucous membrane of a dense insensible character. In the investigation of disease, the gums frequently afford valuable information respecting general constitutional disorder. In sea-scurvy, the gums become spongy and swollen, extend over the teeth, and bleed easily; the symptom is always strongly corroborative of the bodily disorder. In persons who have been long subjected to the action of lead, slowly introduced into the system, either in the course of their occupation, or as sometimes occurs, from the ordinary drinking water having become impregnated with the metal from lead pipes, a blue line is often observable along the edge of the gum. A pink line

as showing itself in persons affected with pul- | and appliances are also made of this useful submonary consumption. In constitutional affection by mercury it is well known that the gums become inflamed, sore and spongy, in some cases of disease affecting the mouth the gums become dark or black in colour, and the breath is extremely fœtid.

Of course, in cases where the state of the gum is indicative of constitutional affection that must be attended to (see Scurvy, &c.), but the condition of the gums, in any case, may generally be much relieved by the use of astringent substances in the form of washes; none, perhaps, is better than the tincture of myrrh, but camphor dissolved in alcohol may also be used, or, indeed, almost any one of the astringents. A drachm of alum dissolved in a pint of water makes a very good and cheap wash.

In the case of black-looking gums, with feetid exhalation, a wash made of two drachms of hydrochloric acid to the pint of water will be found most useful, or two drachms of the solution of chlorate of soda or chlorate of potash, may be used with equally good effect. Such a case, however, must require medical attendance. The gums in the teething of children require much attention. - See Chil-

GUM-BOILS are small abscesses connected with the root of a decayed tooth, and are often caused by the fang or stump, which remains after extraction or the decay of the tooth. They give rise to great pain and local swelling. The abscess opens usually through the gum, and occasionally through the skin, and may dis-charge for a long time, indeed until the tooth is extracted. In the early stage of the affection an abscess may be warded off by holding hot water in the mouth, or better still, by applying a leech to the pained part. A free cut into the gum, with a lancet, will often relieve the uneasiness and irritation caused by an old stump. After an abscess has formed, the best method of treatment is the immediate extraction of the tooth. This precaution is more necessary, as such abscesses sometimes open and discharge under the chin, below the eye, or into the nasal cavities, and may keep discharging for months.

GUN-SHOT WOUNDS .- See WOUNDS. GUTTA PERCHA.—This substance, now familiar to all, and so extensively used in so many different ways, is obtained from a tree native to the Malay peninsula. In medical and surgical practice it has been adopted for many purposes, such as, splints for fractures. Probably, its most valuable property, in a domestic point of view, is its being waterproof, and forming a cheap and efficacious protection to bedding, in many cases in which this is apt to be spoiled by the discharges, natural or otherwise, from the sick. Gutta percha sheeting is now universally employed to cover, and to retain moisture in the different varieties of dress- the influence of the will and certain sensations

The gutta percha solution of the stance. Pharmacopæia is prepared with one ounce of gutta percha and eight ounces of chloroform, to which an ounce of carbonate of lead in fine powder is added. The mixture after being well shaken is to remain at rest in the bottle, until the insoluble matter in it has subsided, when the clear fluid can be decanted. The solution is mainly used in the preparation of mustard paper.

Refer to-Bed, &c.

GYMNASTICS are exercises regularly practised, with the object of developing the physical energies, as the mind is trained by regularly appointed studies. The one is as essential to the full enjoyment of life as the other, for bodily vigour tends to increase the mental power. The object aimed at in gymnastics is the exercise of the muscles, and this is arranged in such a manner as to bring into harmonious action all the muscles of the body. Combined movement of the various parts, and not feats of strength being the aim, all accessories in the way of gymnastic apparatus—such as dumb bells, clubs, and the like, should be of comparatively light weight, much lighter than the person can readily lift. Boys as a rule have sufficient exercise in the various games popular at school, but girls brought up in towns, and especially in London, have little or no opportunity of physical development beyond the regulation walk. For these, light gymnastic exercises once or twice a week, carried out in a loose costume, to enable the muscles to have full play, seem essential. Swimming, which is now becoming a popular amusement amongst girls of the better classes, is a good means of maintaining the health. In the case of deformities, such as contractions and stiffness of the joints, and paralysis of the limbs, no remedy is so efficient as regular exercise, since it is the voluntary attempt to work the muscles from which most benefit is to be derived. Rubbing the part is often per-severed in till the joints become hopelessly stiff, whereas in half the time regular exercise or gymnastics would have effected a cure. no one with a stiff finger or a paralysed limb despair till he has tried patiently this plan of attempting regular movements. A half-hour can be given up twice a day to train the muscles how to act, and in the case of a child, the teacher can count "one, two, three," and then tell it to perform a certain movement, illustrating the action at the same time. In this fashion the youngest child may be taught in a similar way to its being taught the alphabet, and numerous deformities may be prevented.

ings applied to wounds. Many instruments and motions in the living body, is a fact of

which every one must be conscious from personal experience; when, however, the actions resulting from these sensations and motions, are, after frequent repetition, performed without a distinct and conscious exercise of the will, they are said to be the result of habit. These habits, however, are of the body, and are distinct from habits of the mind, influences which act upon the will itself, with lesser or greater power, and impel the individual to certain acts.

It is, perhaps, needless to advert to the proverbial power which habit exercises, not only over man but animals, becoming to them a "second nature," and to their offspring a natural tendency. So powerful an agent, both mental and physical, as habit, cannot fail to be largely implicated in the consideration of the nature and treatment of disease. It is sometimes of the greatest consequence, not only to break the influence of habits of which the mind is conscious, but even of habits of disease over which the mind has generally no control. This is particularly the case with respect to periodic diseases of the nervous system, such as ague, &c., which, after a time, appear to be continued rather from the habit of the constitution than from any other cause.

Still more widely connected with the treatment of disease, is the acquisition of good habits, in the room of bad ones, which are often the causes of impaired health. Some individuals constantly eat and drink too much, from mere habit, others take little or no exer-cise "from habit," and, although conscious of these and other negligences, often require considerable exertion of the will, aided by the almost despotic commands of a medical attendant, before they can break through them. The good effects of habit in persons liable to constipation have already been pointed out in the article on that subject; in this case the habit originating in the will, becomes, after a time, partly or wholly involuntary.

There is, however, another state of disorder, and a more intractable one, in which the influence of habit may be most beneficially exercised. It is that state of hypochondriac unrest called the "troubled mind." In such a condition, nothing is more valuable than the habit of daily, at certain fixed times, forcing the mind to bend itself to some definite continuous employment, one which it will require some degree of mental exertion to carry on, and which will maintain its in-terest, perhaps an increasing one, from day to

HÆMATEMESIS.—Bleeding, or vomiting of blood, from the stomach. - See Hæmor-

HÆMATURIA. - Flow of blood from

the bladder. - See Hæmorrhage.

HÆMOPTYSIS. - Bleeding from the lungs, or "spitting of blood." See Hamorrhage.

HÆMORRHAGE, BLEEDING, is the escape of blood from its own proper vessels. but the term is usually applied to cases in which the effusion takes place in considerable quantity, and is rapidly poured out. Hæmorrhage may be either external or internal; in the former instance it is almost invariably the result of wound of some blood-vessel, either artery or vein; in the latter, the blood may also be poured out by a large vessel, but generally it is exuded through the lining membrane, or into the tissues of the part in which it occurs, from the minute vessels, so minute indeed, that after fatal cases of internal hæmorrhage, the closest examination may fail to detect any visible opening, or openings from which the blood can have escaped.

For information respecting external hæmorrhage, or such as occurs from arteries or veins, the reader is referred to the articles under

these heads.

Internal hæmorrhage, when it does occur from a large vessel, is the result of that vessel having given way, owing to disease of its coats, as in aneurism, or by ulceration. The most common situations for this accident are the brain and the large vessels near the heart. In the former, it is called apoplexy; in the latter, sudden death usually occurs, and is popularly attributed to heart disease.—See Apoplexy—

Internal hæmorrhage may be either of an active or a passive character; that is, in the former case the effusion of blood is preceded and accompanied by feverish symptoms, quickened pulse, thirst, with a sensation of fulness, and heat in the part whence the blood flows; in the latter, these symptoms are absent. The effect of active hæmorrhage is, generally, to give relief, either to the constitution at large, or to the particular part; indeed, by some, active hæmorrhage is regarded as a natural cure of what might otherwise prove an attack of inflammation. Passive hæmorrhage, on the other hand, almost invariably weakens; it is the result of weakness and relaxation, which its occurrence tends to increase.

As may be imagined, in the treatment of hæmorrhage generally, medical men have to keep these differences distinctly in mind, lest, by interfering with, too precipitately, or checking too soon an active hæmorrhage, they may thwart the natural curative effort; or by permitting passive loss of blood to continue, they allow a patient to be unnecessarily, perhaps irremediably, weakened. Moreover, it is necessary, in the treatment of hæmorrhage, to consider whether the flow may not be what is called "vicarious," that is, a substitute for some natural discharge which has been checked, or whether it may not have become a habitual safety-valve. In such cases, before actively restraining the hæmorrhage, attention should be given to improving the health and to restoring if possible the discharge which the HÆM HÆM

hæmorrhage seems to replace. Thus, where bleeding from the nose or stomach seems to take the place of menstrual discharge in women, steps must be taken to restore this flow. Habitual hæmorrhage from piles usually results from sluggish and congested circulation in the bowels; this condition should be relieved by exercise and saline purgatives before directly treating

the piles.

As regards the management of or interference with continued cases of hæmorrhage, therefore, unprofessional persons ought not, and cannot with any propriety have anything to do; but when the occurrence itself actually takes place, a knowledge of the best mode of proceeding may be of much service, for though in the case of active hæmorrhage benefit may, up to a certain point, be derived from the circumstance, the process might, possibly, especially if improperly managed, run on to an undue extent, and even affect life.

Hæmorrhagic exudation of blood is more liable to occur from some parts of the body than others, and particularly from the mucous membranes which line the nasal and air passages generally, from the alimentary canal, and genito-urinary organs. "Another important fact in respect to hæmorrhages by exhalation is, that they proceed more frequently from certain parts of these mucous membranes than others, according to differences in age. Thus, in children they are most common from the membrane that lines the nasal cavities; in youth, from the mucous membrane of the lungs and bronchi." In middle life, from the bowels

or bladder, or in the head.

When an individual is suddenly seized with bleeding or hæmorrhage from any part, as a general rule, perfect quietude of body and mind should be observed, and cold is the simplest and readiest astringent, applied in the various forms of cool air, cold water, &c. Medicinal astringents may be resorted to, such as tannic acid, perchloride of iron, diluted sulphuric acid (see Astringents), also ergot of rye, especially when the active principle, ergotine, is given hypodermically. Should the resulting depression be extreme, stimulants may be required, but their administration calls for the greatest caution, and it must be remembered, that the state of depression may be the chief security to the patient against an immediate return of the bleeding.

The causes of hæmorrhage are various. As might be expected, general plethora, or superabundance of blood is a common one; hence, persons who take but little exercise, and live freely, are liable to it more than others. Perhaps the most general cause of hæmorrhage is congestion, or accumulation of blood in any one part or organ of the body, in consequence of some impediment to the circulation; thus, disease of the heart, by damming up the blood in the lungs, or disease of the lungs themselves by impeding the flow, may, either of them, cause

seems to take women, steps w. Habitual results from the bowels; In some particular states of constitution, there appears to exist a strong tendency to effusion of blood, this is seen in scurvy, and in the disease called purpura, or, popularly, the "purples." Moreover, there is a certain constitutional tendency, or "diathesis," called the "hæmorrhagic," in which a more than usual liability to bleed from slight wounds exists. In persons subject to this complaint, to which the name Hæmatophilia has recently been given, even the extraction of a tooth may, and has proved fatal, in consequence of uncontrollable bleeding. The tendency is hereditary, and those who inherit it must be extremely cautious before submitting to even trifling operations, which involve breach of surface and effusion of the vital fluid.

Bleeding from the nose, Epistaxis, is sometimes very profuse, and either on this account, or from frequent repetition, may be the source of great weakness, in constitutions that can ill afford the drain, for its occurrence is not uncommonly associated with tendency to chest affection. Many various methods for its suppression are had recourse to, but cold applied to the forehead, spine, or other parts of the body, is the most general. Raising both arms above the head and retaining them there, stops the flow usually, or a small quantity of solution of alum, as strong as it can be made, may be thrown up with a syringe; or a piece of linen, soaked in the solution, may be stuffed up the nostril. From ten to fifteen drops of dilute sulphuric acid may be given in water at intervals, according to the nature and persistence of the attack.

Bleeding from the nose, in persons advanced in life, must be much more cautiously dealt with than in the young. In the former, it is generally preceded by symptoms indicative of congestion about the head, and, consequently, is a natural relief. It may, of course, go to an extreme extent, and require checking.

Bleeding from the lungs, or spitting of blood, is generally preceded by symptoms indicative of undue determination or congestion of blood to, or in these organs. Oppressed breathing, cough, pain in the chest and feverish symptoms usually precede the attack, and just previous to it a saltish taste is generally perceived. Bleeding from the lungs may occur in every degree, from a mere tinge of the expectoration, to the copious coughing up of fluid blood. The blood is coughed up, whereas, when it comes from the stomach, it is vomited, a distinction which appears evident enough, but which is not always readily made in prac-The management of hæmorrhage from the lungs, must be that recommended for hæmorrhage generally. Until medical assistance can be procured, perfect quiet is to be observed, cool air, especially on the chest, freely admitted, and absolute rest and silence insisted

HAI

upon. Small pieces of ice, if available, may Should the attack continue, be sucked. and medical assistance still be absent, dry cupping on the chest, or between the shoulders, might be had recourse to. Sulphuric acid may be given as recommended for bleeding from the nose; or in an extreme case, when medical aid is far distant, one grain and half of sugar of lead may be given, made into pill with crumb of bread, every two, or three, or four hours, being washed down by a draught of vinegar and water. Gallic acid or tannic acid may be also employed, in doses of four or five grains, either in the form of mixture, or pill, or lozenges (the latter contain each half a grain of tannic acid); or catechu lozenges, each containing a grain of catechu, may be freely administered. When the cough is troublesome, it will be best allayed by a few drops of laudanum

or chlorodyne.

The causes of hæmorrhage from the lungs are such as have been named above. Persons of scrofulous constitution, or who have any malformation of the chest, are most liable to suffer from it. It rarely occurs in children. The exciting causes of this form of hæmorrhage are such as call the lungs into active, strong, or continued exertion, such as violent bodily movements, much loud exercise of the voice, playing on wind instruments, &c.; these things must therefore be sedulously avoided by those who have any tendency to the disorder. Temperance and moderation, strict attention to the condition of the bowels, and to any accidental disorders of the chest, will be the best safeguards. Whilst treating of this subject, it should be mentioned that persons are often needlessly much alarmed, from thinking they are expectorating blood, whilst the fluid simply comes from the throat or gums, or, it may be, is the consequence of blood from the nose trickling down the back of the throat. perhaps is scarcely necessary to add, that the above details of management are not meant to stand in the place of competent medical advice. This should never be dispensed with in so serious a disorder as spitting of blood.

In hæmorrhage from the stomach, "Hæmatemesis," the blood is vomited, not coughed up; its causes and treatment, modified, of course, by the difference in the organ, and its site, are similar to those detailed in hæmorrhage from the lungs. Vomiting of blood in young females is not a very uncommon accompaniment of disorder of the menstrual functions, and can scarcely be considered a dangerous affection. The restoration of the proper exerction is, of

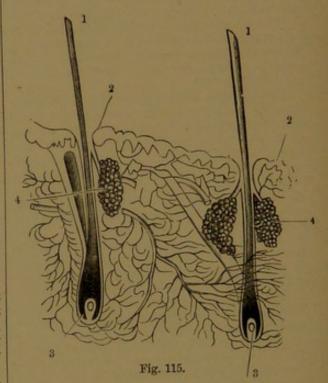

course, the most effectual remedy.

Vomiting of blood may happen in consequence of blood which has been effused from the nose having been swallowed; in this case it is generally darkened by the digestive action of the stomach. Blood from the lungs is generally much more frothy than that ejected from the much more frothy than that ejected from the Keeping it cut tolerably short is a good pre-stomach. In either case, the more florid the ventive, but of course removal of the bodily

hue, the more active or inflammatory the hæmorrhagic tendency. Profuse discharge of blood from the bowels often occurs in the course of enteric fever and dysentery, or from diseases of the abdominal organs, such as the liver, &c. Flow of blood from the bladder, -Hamaturia, -will be adverted to under article Urine.

HAIR is a development from, it might be called a prolongation from, the outer or scarf skin. Each separate hair (fig. 115-1) is con-

tained in a pit which passes into the true skin, and through it into the tissues beneath. Into this pit the outer or scarf skin (2) is folded, and at the bottom of the bulbous follicle (3), there is a small papilla of true skin, from which the hair is developed, consisting of an external or denser portion, composed of flat over-lapping scales, and under this, closely packed together, numerous horny cells, while, in some instances, a central space is left for the medulla or pith, which consists of fat cells and colouring matter. The hair follicles are usually supplied with a pair of sebaceous glands (4), whose ducts either enter the follicle or open on the surface of the skin close to the hair.

The condition of the hair is often highly symptomatic of the bodily condition; at the same time it is, of course, liable to alteration

from local influences.

The hair is apt to become split, or forked, in consequence of weak growth; this generally occurs in persons in a debilitated condition.

weakness of which the state of the hair is | bleeds but possesses feeling; the latter idea symptomatic is essential. The colour of the hair is indicative of constitution and temperament (see Temperament). Its changes in colour indicate generally the advance of years, but sometimes the premature grey speaks of continued mental toil and trouble, and it has followed at once upon violent mental emotion, a few hours sufficing for the change.

The unfortunate queens, Mary of Scotland and Marie Antoinette, are both said, among many others, to have been instances of this effect of mental emotion upon the hair; and the fact of this direct connection between the condition of the body and the colouring matter of the hair, renders it probable, that permitting the hair of children to be kept long is really subjecting them to a source of constitutional weakness.

Falling out of the hair occurs from weakness, either of the body generally or of the hair bulbs or "follicles" themselves. Various stimulant local applications are used in such cases (see Baldness). Balsam of Peru, -a drachm stirred well into an ounce of simple cerate when melted,

-is said to be a good application. Removal of the hair is a proceeding frequently called for in the treatment of disease, especially of febrile and inflammatory affections affecting the head. In these cases, it may be entirely removed, at once, without risk, and should be shaved off when the full effect of the procedure is required. Some persons, especially females, are often much vexed at the shaving of the head in fever, &c. Its necessity is, of course, or ought to be, answer sufficient; but it often happens, that if the hair has not been taken off during the course of disorder, it must, from tendency to shed afterwards, be shaved off during convalescence.

When the hair is removed in persons not suffering from acute disease, it must be done cautiously, especially if this natural clothing has been somewhat long and thick. Where it must be taken off entirely, and at once, the head should be protected by a cap of flannel, otherwise neuralgic or rheumatic attacks may be the consequence.

Frequent cutting undoubtedly strengthens the growth of the hair, and frequent brushing and washing are quite the best methods for preserving its health and cleanliness, and ought, along with the assistance of the one-sided comb, to be solely trusted to—the irritating "small tooth comb" ought to be banished from use entirely.

The hair, especially in childhood, is liable to suffer from parasitic disease, in which case it falls off, leaving bald circular patches (see

In Poland, a peculiar disease is met with, in which the hair becomes thickened, succulent as it were, and matted together by a peculiar glutinous sweat. It has been erroneously rehaving, doubtless, arisen from the irritability of the skin at its roots.

HAMMOCKS, for the transport of the sick and wounded in long journeys, are invaluable, and may be had recourse to with safety and comfort, so long as the bones are uninjured, or where the condition of the patient is such as to require his being kept flat on his back. When the stretcher becomes necessary, hammocks made of netted cord are much the most convenient and comfortable, being equally serviceable for invalids and for persons in health who may be camping out, or engaged in long voyages by sea or land. The weight of a serviceable net hammock need not exceed a couple of pounds, and it may be carried by a pedestrian over the shoulder, and used as a bed, either in the open air or in a hut or shed where the simplest means of support exist. For a person recovering from illness, the network affords a luxurious swinging couch, and may be employed with advantage out of doors, either on the lawn or suspended between a couple of trees; in the former case, it requires to be supported at either end by bamboo poles, each about four feet in length, steadied by ropes and tent pegs (fig. 116) in the manner represented

Fig. 116.

in the figure. But it is chiefly as a means of transporting invalids by rail or road that the convenience and comfort of the tent hammock is most appreciated in a medical sense. On the occasion of the Ashantee campaign, this form of ambulance was first introduced into the British army; but since then the Indian Government has furnished the Transport Military Service with net hammocks for the use of wounded or invalid soldiers, who require to undertake long journeys by rail; and the same facilities for travelling have frequently been extended to invalids in this country requiring change of air, probably to a distant coast. In either case, the hammocks are suspended from strong hooks in the roof or sides of a railway carriage, usually in the guard's or luggage van, which, in many instances, are already furnished with this means of adjusting the ropes. In the ordinary compartment of a railway carriage, children could be readily provided with a comfortable cot, by slinging a small net hammock to hooks in the roof of the compartment; and grown-up people might obtain the same luxury in a saloon carriage, provided the railway comported that the hair in this condition not only | with removable poles, about three or four feet panies did not object to having carriages fitted

HAR HAN

in height, in the centre of the floors, and hooks | is due the merit of having first introduced the at the side to which the loops or ropes of the various uses and applications of the net hamhammock could be attached. For journeys by mock to public notice. There can be little the road, any covered spring van of sufficient doubt, from its cheapness and portability, not length will answer the purpose of an ambulance hammock. The drawing (fig. 117) represents a spacious vehicle for this purpose, with the hammock in use, suggested by Messrs. Seydel and Company, of Birmingham, to which firm journeys.—See Ambulance.

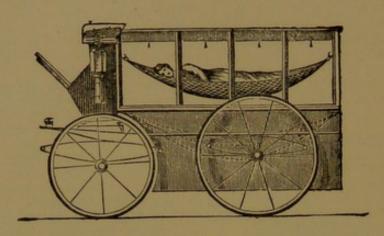

Fig. 117.

human mind is much exposed to injury. When this occurs, as it often does, at a distance trolled until the arrival of a surgeon, by means from medical aid, one principle must ever be remembered, that the preservation of as much spects, the treatment of a person hanged must of the member as possible, even of a single finger, or of part of one, is of the highest moment with reference to future usefulness. In a crush of the hand, when bleeding is not great, the best treatment will be to place it in a large warm poultice, and keep it at rest until medical aid is procured. The management of various accidents, &c., will be found under such heads as Artery, Dislocations, Wounds, &c.

HANGING-suspension of the body by the neck-may cause death in three distinct modes: by compressing the windpipe, and producing suffocation; by compressing the veins of the neck, and causing apoplexy; or more rarely by dislocating the neck. The two former modes may be combined; the latter, when it does occur, is in consequence of a "fall," such as is given at a public execution; it the roof of the mouth. The case ought to be of course causes instantaneous death. Recovery from hanging must in some degree depend upon the completeness or not of the interruption to the passage of air through the windpipe for any time; it is not likely that resuscitation will be effected if complete interruption has continued four minutes. The first thing to be done when a person is found hanging is, of course, to cut him down at once, to loosen the material around the neck, to dash cold water over him, and to bleed. In such an emergency, a person would be quite justified in cutting across the temple, where the artery beats (see Artery), with a pen-knife, and carries off the effects of intemperance in those

HAND .- This wonderful agent of the allowing blood to flow to the extent of ten or twelve ounces. The bleeding could be conpoint of view, it is important that the by-standers should observe carefully the surroundings of a body found hanging, in order to determine whether the case is one of suicide or murder, or whether the person has first been murdered, and then suspended, so as to make it appear that he committed suicide.

HARE, like other game, is extremely easy of digestion, apart from the various dressings and stuffings

HARE-LIP, or CLEFT-LIP, is a deformity with which infants are occasionally born; the lip being cleft at the furrow, to a greater or less extent. Sometimes the fissure extends through very soon submitted to the surgeon for remedy by operation.

HARROGATE.—"Dr. Hunter divides the Harrogate springs into four classes: 1. Springs impregnated with sulphuretted hydrogen gas and saline matter. 2. Saline chalybeate springs. 3. Pure chalybeate; and 4. Springs containing earthy salts, with little iron and no sulphuretted hydrogen.

"Of the skin diseases in which Harrogate water is likely to be beneficial, Dr. Hunter mentions lepra, psoriasis, porrigo, herpes, and impetigo. He says, 'It speedily and safely

HAR HAZ

who, having spent the winter and spring in | festivity, resort to Harrogate with their system loaded with impurities from the excesses of the table, and whose stomachs are debilitated by these and similar causes. Its use is acknowledged in those predisposed to apoplexy. In chlorosis it has been usual to drink the sulphur water for some time, and then to take the chalybeate.' Scrofula, scurvy, secondary syphilis, gout (regular, irregular, and atonic), hypochondriasis, jaundice, chronic rheuma-tism, stone, and gravel, are also among the diseases enumerated; and, inasmuch as they arise for the most part from the same disordered condition of the system, they are most likely to be alleviated by the use of these waters. Used in the form of bath, the water must be heated to the required temperature; and would, if employed alone, be productive of but slight medicinal effects beyond stimulation of the surface, from the sulphurous impregnation, and the salts contained in the water.

HARTSHORN.—See Ammonia.

**HASTINGS.** — This much-frequented watering place lies in a valley, enclosed towards the north, north-east, and west by hills, which shelter it from high and cold winds, and conduce to its being, perhaps, more than any other place, resorted to in winter by invalids to

whom a mild climate is applicable.

The soil, as in most parts of Sussex, is clay, with a substratum of sand, and the ground in Hastings and its neighbourhood dries soon keeps the surface continually moist, and who have at the same time suffered from some of those maladies which have their origin in, or are aggravated by a cold and humid atmowhich Hastings owes to its geological formation alone. Rarely is it necessary for the invalid, however delicate, to be confined to the house for any length of time, even in the most stormy weather.'

The south and south-westerly winds are most prevalent; the latter are at times, especially in spring, severely felt. winds, however, when not high, agree well with the majority of visitors who are not in a weak state of health. The south wind being to a certain extent impregnated from the sea, is beneficial to most persons labouring under disease of the respiratory organs; and these constitute the chief proportion of winter visitors, who are induced to seek advantage from the

climate of Hastings.

The sea bathing is good; a fine sandy beach extending for a considerable distance at low

HAY ASTHMA, or HAY FEVER, is one of the most troublesome diseases which the physician is called upon to treat; one, too, which varies extremely in its severity, present-

vated common cold, and in another, in addition to these, the disagreeable and alarming accompaniment of spasmodic asthma. It is decidedly ascertained to be caused by the pollen of certain flowering grasses which cattle will not eat; by spring grass generally, and by the fine dust of certain drugs, as ipecacuanha, the merest whiff of the powder of which causes some succeptible persons to be immediately seized with paroxysms of sneezing, so violent as to be very painful, if not alarming to witness. A sufferer from this troublesome complaint is indeed entitled to sympathy. His head aches, his eyes are suffused, he sneezes violently, and there is an acrid discharge from the nose, with harassing cough. Attacks of spasmodic asthma follow, accompanied, it may be, with great difficulty of breathing, and a sense of impending suffocation. There is nothing for it in such a case but to remove from the cause of the disorder, otherwise it may run on for a month or more. A change to the seaside is often

attended with beneficial results.

The treatment of the disease must be naturally divided into that required during an attack, and that which it is desirable to employ in order to render the system less liable to the disease. During a paroxysm, perhaps the most simple and efficacious remedy is the smoking of tobacco, which generally gives relief, if continued till slight nausea comes on. Such is the relief to the breathing in some cases, that the patient has been known to fall after rain. "Those," says Dr. Mackness, "who have resided where the character of the soil had been the previous exhaustion from the struggle for breath. The inhalation of the vapour of creasote, as recommended by Dr. Walsh, and the use of antispasmodics generally, as ether, lobelia, with the compound tincture sphere, can fully appreciate the advantage of camphor, should be used; or the vapour of camphor may be inhaled by means of Siegle's spray-producer. As the disease is generally supposed to be induced by particles of pollen from the grasses during the season of haymaking, it is suggested that those who are liable to attacks should wear a respirator composed of cotton wool or other impervious material during the period. The recently invented and specially useful form of respirator-inhaler, introduced by Dr. Coghill, may be employed for the purpose. It is made to contain either simple cotton wool, or the same with any medicated inhalation thought desirable (see Inhalations). While free from attack, the constitution of the patient should be strengthened by a liberal use of tonics, specially iron, strychnine, arsenic and quinine, either alone or in combination.—Refer to—Respiration.

HAZELINE is a clear fluid, the active principle of the witch hazel. It has powerful astringent and curative properties, and, though but recently introduced, it has been largely employed as an external application in medical which varies extremely in its severity, presenting in one person the symptoms of an aggra-viceable in checking hæmorrhages, allaying

arritation from piles and cutaneous sores, as | by sleep, overfulness is the probable cause; and well as in bruises and sprains. It is said also to be a most useful application in cases of chronic and intractable ulcers, which have

resisted other means of treatment.

It may be given, too, with much advantage internally, in doses of thirty minims thrice daily. In this way, it has been found by the writer to check, in more than one instance, a tendency to nasal and intestinal hæmorrhage that had defied treatment for years. In cases of piles, it may be injected into the bowel diluted with one or two parts of water.

HEAD .- See Brain-Giddiness-Skull

-Wounds, &c.

HEADACHE, "CEPHALALGIA," is one of the most frequent ailments, the result of a great variety of causes; consequently, many varieties of headaches are enumerated by medical writers. The consideration of all these in a work like the present would tend rather to confuse than to enlighten. The subject will probably be rendered most clear and useful to the unprofessional reader by considering it generally under the divisions of-

Headache from overfulness of blood.

Headache from deficiency of blood, or de-

Headache from excited or inflammatory

action.

Headache from sympathy; and Headache from nervous causes.

Headache is so frequent an ailment that people generally seem almost to forget its connection with so important an organ as the brain. There are, it is true, many transient slight headaches, and even severe ones in the predisposed, which do not call for much attention; but it must be remembered, that there are others which it is dangerous to neglect; and an individual who becomes subject to headache, frequently recurring, should consult a medical man on the subject. This is more imperative from the fact, that there is often considerable difficulty in determining the real nature and cause of some headaches, and that an error in this respect-in diagnosis-may, by leading to erroneous treatment, cause the most serious consequences. The most diverse line of treatment may be requisite, in two different individuals; in one, abstraction of blood may, if had recourse to, save from a fit of apoplexy; in the other, the same treatment might induce paralysis, or epileptic convulsion. The lowering measures, in fact, which cure the one, may kill the other. From these considerations, a few general remarks on the subject of headaches will probably be more safe and useful than an elaborate and detailed account.

If a person who suffers from headache is of full habit generally; if he is sleepy, dull, the vessels of the face full; if the uncomfortable sensation in the head is aggravated by stooping, by an abundant meal, by stimulants, or ally if it occurs from the use of oily or greasy

reduction of the diet, purging the bowels with calomel and colocynth, and with occasiona. doses of saline medicine, exercise, bathing the head with cold water, and, if the symptom is very severe, the application of a few leeches to the temples will be beneficial. If the urine is deficient, cream of tartar in some form may be taken with advantage. The above species of headache, the result of general overfulness of blood, may also be occasioned by whatever impedes the circulation, such as affection of the heart or liver; when the latter is the cause, the pain is frequently most severe at the back of the head. When, on the other hand, headache occurs in a person of weak constitution, when it is produced by or aggravated by exertion of mind, much talking, &c., when there is listlessness both of mind and body, rather than oppression—the face pale, the pulse weak -debility is the probable cause, although at the same time there may be overfulness of blood in the interior of the head itself; very frequently, however, in this kind of headache, the head is hot, without there being any parti-cular flushing of the countenance. This form of headache also is frequently accompanied with indigestion, and is very common in students and anxious men of business. Anything like abstraction of blood will certainly prove injurious; but cold to the head may be of service, not only as a temporary remedy, but habitually used by means of washing with cold water. Exercise, attention to the state of the bowels, without purging, some care in diet, and relaxation of mind, particularly by means of change of scene and air, will be most useful. In such cases, the whole system is weakened the brain and nervous system, the circulating system, the digestive organs-and they act and react on one another.

Headache from excitement or inflammatory causes, is such as occurs in the first stages of inflammation of the brain, and in some forms of fever, or it follows violence to the head. It of course falls to be treated under the articles

on these contingencies generally.

Sympathetic headache is very common, and is evidently connected with disorder in some organ of the body, such as the kidneys, womb, &c. Headache, sympathetic with disorder in the stomach or some part of the alimentary canal is, however, the most frequent form. The presence of bile, or of indigestible food in the stomach, almost certainly occasions dull pain in the forehead; an alkaline, or too acid condition of the contents of the organ exerts the same effect. The various symptoms of indigestion will generally point to the cause. In the first two, an emetic, or some aperient, such as the compound rhubarb pill, or a stimulant, will probably remove the disorder. A vegetable acid, such as vinegar, many persons know fron experience, will at once cure headache, especi-

food; and again, when acid eructations, heart- | squares and crescents, can give no adequate idea burn, &c., indicate the presence of super-abundant acid, a dose of soda, potash, or magnesia will correct the cause, and remove the effect. Frequently, a brisk walk for half an

hour will remove a bilious headache.

Under the head of nervous headaches, may here be classed all such as are not referable to any distinct cause. They constitute a considerable proportion of the cases of headache generally, and most frequently owe their origin to a disordered condition of the nervous system, and are named from this cause brow ague, megrim, or hemicrania. Various remedies are used for this complaint, the most simple consisting of strong tea, coffee, and guarana. Bromide of potassium, in doses of fifteen or twenty grains, often cuts short an attack of the complaint, and galvanism applied along the course of the nerve is sometimes beneficial after other remedies have failed to give relief.

It would be possible, did space permit, to extend this article to much greater length; but its intention is rather to convey some idea of the general causes of this common ailment, than to enter into the minutiæ of its symptoms, relations, or treatment. Most persons are aware of the best mode of managing their occasional headaches, but when the affection assumes a severe character, the medical man should in-

variably be consulted.

Refer to—Brain — Fever — Indigestion — Phenacetine, &c.

HEALTH. - See GENERAL HEALTH-PUBLIC HEALTH.

HEALTH RESORTS .- This term, now so common, was first used by the author, and made the title of a work on the subject, entitled Health Resorts of Great Britain; and how to profit by them, published in 1860. In this book England is divided into certain health districts, and it is sought to instruct the reader as to the advantages and disadvantages of each, as well as their adaptability for individual cases of sickness. The question of climate is largely entered into, and advice is tendered on bathing, and the use of mineral waters.

It is strongly recommended that in case of illness, an invalid, whilst following the advice of his or her trusted medical attendant, should always, on going to a health resort for health reasons, add to the advice which sent them from home, that of some medical man of reputation resident in the locality they have been sent to. None but local practitioners can be fully conversant with the requirements to be observed and the advantages to be gained, and even a single consultation may make the difference between benefit derived and time saved, or the reverse.

The standard book on British climate and health resorts has yet to be written; but this cannot be done by one man. A flying visit

or sufficient foundation for a trustworthy guide. A thorough work on the subject must be a compilation from succinct reports or short treatises furnished by one or more of the most competent practitioners of each locality; or, better still, by a committee, as in the case of the excellent publication, Harrogate and its Resources. The principal drawback to a work so compiled would undoubtedly be the natural tendency of each individual to magnify the resources and advantages of his own locality, but this would not be irremediable, and would be quite counterbalanced by the good achieved.

It is very certain that many people, from want of proper information on the subject, make a very bad choice of a health resort, and that there are many more who, to say the least, do not make the best choice, and do not reap all the advantage which they might derive from residence in a place suited to their wants. Hence before starting, each person should ask himself what is to be the object of his sojourn from home, and what it is he goes to seek. Is it merely pleasure and society, either inland, or at some of our fashionable sca-side quarters? or does he wish to avail himself of one of the sheltered places with which the southern part of our island abounds, where he may find a refuge from the cutting east wind, and all the horrors of damp and cold? Is it a place to spend the winter at, where even the most delicate may leave the house and breathe the fresh air every day, instead of being afraid to leave the fireside, or to pass from one room to another? Or, finally, is it a watering place that is desired?-in which case it is highly necessary the patient should be well-advised, not by enthusiastic friends, but by a medical man, as to the waters he is to drink or bathe in, as well as the climate he seeks.

Persons in the early stage of consumption, or those who are liable to attacks of bronchitis in the winter; persons suffering from certain forms of heart disease, with its numerous complications, from asthma, and emphysema of the lungs, as well as persons of a weak and feeble constitution generally, will often derive benefit and prolong life by passing the winter at one of our warm and sheltered health resorts, provided always that it be well selected according to medical- advice, and provided, also, that the best locality for the individual case is chosen by the advice of those to whom the place itself is well known.

Among the most favourite resorts for such cases may be mentioned Bournemouth, Hastings, Margate, Torquay, the Undercliff of the Isle of Wight, Clifton, Brighton, St. Leonard's, Ramsgate, Dover, Folkestone, and the islands

of Jersey and Guernsey.

Bournemouth is one of those places which has sprung into notoriety from absolutely from place to place, testing and tasting and nothing, owing to its semi-natural advantages, bathing in the water, or looking over the consisting of finely sheltering pine-clothed

tunately, however, now greatly destroyed by the cupidity of builders, and consequently the manifested; but it will be understood, from power of protection from bleak winds is considerably impaired. Upon the slopes of the hills are to be seen many beautiful and pic-turesque villas or cottages. The place is now firmly established as a winter residence, and has received the name of the winter garden of England. The temperature is rather lower than that of the Undercliff and Torquay, but, on the other hand, it is less relaxing and depressing to some people, and has the great advantage of fine walks and drives.

It speaks well for the healthiness of the locality, that after careful consideration this was selected as the site of the sanatorium, in connection with the far-famed Brompton Hospital for Consumption and Diseases of the Chest. Patients, who are admitted on the recommendation of governors, each pay a

small sum weekly.

There is pretty good sea-bathing to be had at Bournemouth, though it is not an agreeable summer residence, owing to the abundance of sand, which is blown about in great clouds when the wind is high. It is strongly recommended as a residence for those who, having lived in warm climates, have become morbidly susceptible to the effects of cold and damp, and for rickety and delicate children, who are said soon to recover strength and tone from the constant exercise that may be allowed, in the warm, dry, and beautiful playground

afforded by the beach.

Hastings is so well sheltered by the tall cliffs which guard the little valley in which the town lies, from the dreaded east and north winds, that it is often chosen as a refuge, especially during the months of January and February, for those to whom these winds oftentimes bring disease and death. Besides the shelter of the cliffs, which are from 300 to 600 feet in height, it has all the advantage of southern exposure, and of close proximity to the sea. Sir James Clark says of Hastings: "As might be expected from its low and sheltered situation, it affords a favourable residence generally to invalids labouring under diseases of the chest; hence, delicate persons, who require to avoid exposure to the north-east winds, may pass the cold season here with advantage. But in recommending Hastings as a residence in such cases, it will be necessary to take into consideration the full influence of the sea air; for owing to the close manner in which the place is hemmed in on the sea by steep and high cliffs, it has an atmosphere more completely marine than almost any other part of the coast, with the exception of St. Leonard's. Judging from my own experience, I should say that the climate of Hastings is unfavourable in nervous complaints, more especially in nervous headaches, connected with or entirely dependent upon derangement whilst it is comparatively cool in summer. In especially in nervous headaches, connected

hills. The pine, or rather fir-trees are, unfor- | of the digestive organs, and also in cases where what has been already stated respecting the topographical relations of Hastings, that this effect of its climate is chiefly experienced in the lower and more confined parts. Nor is such an effect peculiar to this place; it is common, I believe, to all places similarly situated. The class of persons alluded to, it induced to reside for any length of time at Hastings, should avoid the more confined situations below the cliff, and rather seek such quarters as are more open and elevated, yet in some degree protected from north and north-east winds.

> "These remarks on the climate of Hastings apply to it as a winter residence; as a summer residence, the more open and exposed situations should be sought; and for many persons, the high grounds behind Hastings would be preferable to the lower situations close to the

shore.'

Like most other watering-places of the same class, all parts of the town are not alike sheltered, and consequently medical advice should be taken as to the best situations for particular cases, and those parts which are exposed to the cold winds should be studiously shunned by the delicate in their walks. The sea-bathing is excellent, with a sandy beach; and those who visit the town find every accommodation.

Torquay.—Perhaps no town can boast of a

situation more favourable for the mildness of its climate than Torquay, which is placed between the river Dart, on the one hand, and the rivers Ex and Teign on the other. It is said to be almost entirely free from fogs, and to be remarkably dry and warm. It is particularly well sheltered from north-east and north-west winds, and, like other places, allows of considerable variety of climate at different seasons, and to different classes of visitors.

The surrounding country, varied by wooded cliff and cultivated slope, encompassing the beautiful bay, has been called the garden of Devon, and presents the most charming variety of scenery. The irregularity of the coast is such, that even within the town itself, the medical adviser is enabled to choose different situations for his patients, according to the description of atmosphere which he thinks will be most beneficial for them; and it can readily be imagined how the warmth of the lower and more sheltered parts of the town may be favourable for one class of cases, while the stimulating breezes of the higher and more exposed parts may be required for others; hence, there is no place in Great Britain which has a higher reputation for relieving the symptoms and prolonging the lives of patients suffering from consumption and chest ailments

winter, it has a mean temperature of three | -an illustration of the fact that no place or degrees above the Undercliff of the Isle of Wight, and of five degrees above Clifton and Hastings. It abounds in pleasant walks, and is in every way a most useful, interesting, and beautiful health resort.

Most persons are aware that Torquay derives its chief celebrity from the comparative warmth and mildness of its climate, as contrasted with other places in Britain; and hence its high claims to usefulness in the case of consump-tive invalids. Mild, however, as the climate is, its equability, not only as regards humidity, is perhaps a more striking and bene-ficial characteristic. Although the climate of Devonshire, generally, is a damp one, it would appear that Torquay is drier than other parts of the county, and drier, when compared with other districts of Britain, than it has generally been considered; the reason we have already given, being the attraction of the rain, by the vicinity of the rivers and of the elevation of Dartmoor. The following, copied from Mr. Vivian's tables, will best illustrate the above :-

Taking the

Average Number of Days upon which Rain falls.

At Torquay ,, Undercliff ,, Clifton ,, Hastings ,, London	it rains	Annual, 132 146 169 153 178	Winter. 35 39 45 39 48	Spring. 30 32 36 31 43	32 33 41 33	35 42 45 49
Again tak		110	10	43	44	43

The Quantity of Rain in Inches.

At Torquay there fall "Undercliff" "Clifton" "Hastings" "London"	Annual, 8 28°20 23°48 32°56 32,81 24 80	Winter 6.82 4.65 8.43 7.59 5.85	5·61 4·06 5·69 5·80	6·38 4·29 9·44 6·40	9:39 9:48 9:00 13:02
	24 00	9.80	4.80	6.67	7.43

As might be expected, even without reference to the above table, the autumn and winter months are considerably the most damp at Torquay. Moreover, as stated by Dr. Shapter, in his work on the climate of the south of Devon-"During the winter season the south wind is often accompanied by a warm thick mist, which is particularly relaxing, and, from its frequency, not inaptly styled 'Devonshire weather.' This wind, traversing the Atlantic from the warmer latitudes, reaches the coast charged with a greater degree of moisture than the air can contain, when cooled by the lower temperature of the local climate; the result is the misty appearance of a great dew deposit." Evidently, then, if Torquay is not so regularly moist in every season of the year as it has been usually considered, it is, in winter, a moist and relaxing climate, and this point requires to be taken into consideration by those persons who, either of their own accord, or in accordance with medical opinion, fix upon it for a residence. For, however beneficial the soft moist atmosphere may be in some diseases and states

climate is adapted to all constitutions and idiosyncrasies.

Since the foregoing remarks were penned, the writer has had the advantage of many years' residence in Torquay, and can well endorse what he then wrote, although, since then, the beautiful wide-spreading villa town has been greatly extended in all directions, beauties of the place, but nevertheless, a strong testimony to its continued popularity as a health resort. In 1801, the population of Torquay was 838; at the last census, it exceeded 27,000. Moreover, among other improvements has been the introduction into improvements has been the introduction into the town of a full supply of the finest and purest water, brought from the Dartmoor Hills; and equally important, there has been carried out a system of thorough main drainage, by which all impurities are carried off into deep ocean. In fact, few, if any, places of residence in the kingdom possess so fully as Torquay the conditions calculated to maintain health; and consequently, few have a lower death rate; for in spite of the invalids who come simply to prolong life, but ultimately to die, and in spite of the fact that numbers of the residents, both tradespeople and others, have come to Torquay in delicate health, the death rate average is but from 15 to 16 per 1000. It was formerly a complaint that Torquay was deficient in sources of amusement. That has been greatly done away with; for in addition to many other means of enjoyment, it now possesses an energetically managed winter garden, and as pretty and well-conducted a little theatre as can be met with out of London. It need scarcely be added, that the spiritual needs of the population are provided for by churches and chapels of nearly every denomination. Lastly, by the excellent railway arrangements, it is brought within little more than five hours' journey from London.

The Undercliff of the Isle of Wight, with Bonchurch and Ventnor, may be taken as the most favourable situations in that island for those who wish all the advantages of fine scenery with warm climate and shelter from cold winds. Sir James Clark says of it:-"The whole of the Undercliff, which presents in many places scenery of the greatest beauty, is dry and free from moist or impure exhalations, and is protected from the north, north-east, north-west, and west winds, by a range of lofty downs, or hills of chalk and sandstone, which rise boldly from its upper termination of a series of terraces composed of chalk and green sand, which have slipped down from the cliffs and hills above, and been deposited in irregular masses upon a substratum of blue marl." Thus the Underclift is only exposed to the south, south-east, and south-west winds. The beautiful scenery is of constitution, it is no less injurious in others | kind which is particularly pleasing to invalids,

presenting a combination of wooded cliffs and knolls, the trees being covered with foliage of the greatest luxuriance, and serving to add beauty as well as shelter to the many handsome and picturesque villas which adorn this charming neighbourhood. The village of St. Lawrence, beyond Ventnor, is said to be the most sheltered spot of the Undercliff district, a point to be borne in mind by those to whom such a situation has been specially recommended, for here the most delicate may enjoy many delightful days in the open air, even in the month of December.

Clifton, which is close to, or rather a continuation or suburb of Bristol, has lately become a resort for invalids suffering from consumptive tendencies, or from delicacy of chest, &c. It is said to be the mildest and driest place in the west of England, being drier and more bracing than Devonshire, so that Clifton is preferable for those whose constitutions are easily relaxed, who suffer from a want of tone, from indigestion, and debility; while such a place as Torquay, with its comparatively more humid and soothing atmosphere, is preferable for those who suffer from very irritable affections of the chest.

The locality is picturesquely wooded, the town is sheltered by rocky cliffs, and the crescentic form of the buildings in the town itself, affords a shelter in many of the terraces from

the cold northerly winds.

Brighton, in the later summer months especially, is a most delightful residence for those who are not likely to be injured by the high winds, which are, however, often a source of real danger to those who are ignorant of their intensity, and who expose themselves freely to them in their walks on the pier and on the downs. Of no place, perhaps, in Britain need it be said more than of Brighton, that it is highly necessary to choose a suitable part of the town for a residence, seeing that there is a remarkable difference of climate between one situation and another not far distant from it. Dr. Wigan gives the following sagacious advice on this point. He says:-"An invalid resorting to Brighton should be sure that he is well advised, in the first place, in going at all; in the second, that the season of the year is the proper one; and thirdly, when he gets there, that he chooses his site of residence where he is likely to derive most benefit from the climate." It must be understood that as a winter residence for invalids, Brighton is not so well sheltered and warm as Torquay, Hastings, and several other places which might be mentioned, and that from its exposure to high winds, it is not at all a desirable place of abode during the months of March, April, and May.

It stands unrivalled as a general place of amusement and resort for those who require a holiday with the pleasant adjuncts of society, fresh air, and plenty of it, with amusements

and recreations of all sorts.

Jersey.—The climate of Jersey and the Channel Islands generally, may be described as somewhat similar to that of the warmer parts of the south-west coast of England, so that in a word, while it is suitable for cases of irritable chest affection, especially during the winter, which is very mild, it is too relaxing for many invalids who suffer from indigestion, general relaxation, and want of tone of the system.

The mildness of the winter in the Channel Islands is shown by the fact that many flowers and delicate plants can be easily collected there, in the open air, which would certainly never survive the rigour of a British, or even a Con-

tinental winter.

Dover and Folkestone are scarcely to be recommended as health resorts for the invalid, though they are now a good deal frequented by those who require a modified winter climate. It is not to be supposed that Dover, with its high winds, is suitable for many cases of delicacy of chest for instance, while it will be found a pleasant resort for those who are able to enjoy rambling over its fine cliffs, and inhaling its

invigorating sea-breezes.

Having now given a short sketch of some of those places which are best adapted for consumptive invalids, or for those who are delicate, and require to choose a warm climate, more especially in winter, we proceed to indicate the best resorts for those who, suffering from disease of a peculiar kind, are directed to seek the aid of mineral waters, which are to be drunk, or bathed in, or both. It is scarcely possible to over-estimate the general value of mineral waters, it being a fact well known to physicians, that many patients can take medicines in this form, who cannot bear them in any other. Among the principal and most valuable mineral waters of England, may be mentioned the saline aperients of Leanington, Cheltenham, and Scarborough, the hot springs of Bath, Buxton, Bristol, and Matlock, the chalybeate springs of Tunbridge Wells, the chalybeate and sulphureous waters of Harrogate, Llandrindod, and Strathpeffer, and the waters containing iodine and bromine of Woodhall.

Of these, the waters of Bath, Buxton, Bristol, and Matlock are hot, while the others are cold. Perhaps the diseases for which mineral waters are most frequently sought as a remedy are indigestion in all its manifold forms, with depraved appetite, debility and nervous symptoms, gout, chronic rheumatism, paralysis, and chronic diseases of the skin. They are especially useful in those cases which prove intractable to other remedies, and in which the patient suffers from depression of spirits, or has had an excess of mental labour. With regard to indigestion, it would be impossible to recommend any one water which would be suitable for every case of this Protean malady; and indeed, it may be urged that in all cases of disease, of what kind soever, medical

advice should be resorted to before and during the acteristic sharp, acidulous taste, which, how-taking of the mineral water, and, if possible, ever, they soon lose, and become quite vapid advice from medical men on the spot, who have had experience in the action of the waters upon different diseases in different constitutions.

In gout the waters of Bath, Buxton, Leamington, and Cheltenham have a high reputation; while abroad, recourse may be had to the waters of Vichy, Carlsbad, Wiesbaden, or Aix-la-Chapelle. For the old standing and painful forms of chronic rheumatism, often not amenable to ordinary treatment, which are always tedious in their progress to recovery, and in which the symptoms consist mainly of pain, swelling and stiffness of the affected joints, great benefit has often been derived from the diligent use, both external and internal, of the waters of Harrogate, Buxton, Bath, Strathpeffer, Droitwich, and Woodhall Spa; or from the springs of Baden-Baden, Wiesbaden, Carlsbad, Marienbad, Vichy, or Aix-la-Chapelle on the Continent.

In the treatment of diseases of the skin of long standing, the sulphureous waters of Harrogate enjoy an unrivalled celebrity, and no doubt this is due in great measure to the beneficial influence exerted by these waters upon the system generally, when judiciously applied, and especially to their alterative and corrective power upon dyspepsia, in all its numerous and varied forms, arising from malassimilation of the food in its passage through the stomach and intestines, and connected with derangements of the liver, pancreas, and other

There is a very good sulphureous spring at Moffat and at Strathpeffer, in Scotland, and the most celebrated on the continent, are those of Barèges, Bagnères-de-Luchon, and Eaux Bonnes, in the Pyrenees, Aix in Savoy, Aix-la-

Chapelle, and Enghien.

Chalybeates, or mineral waters containing iron, are useful in certain cases of anæmia and debility where the features are blanched and pale, and the red particles of the blood are obviously deficient. Now, it often happens that when iron cannot be borne by the stomach, in the shape of medicine properly so called, these chalybeate mineral waters come into play, and are not only borne, but quickly restore colour and freshness to the faded cheek, and health and vigour to the system generally. In certain menstrual derangements, also, they are invaluable. The principal in this country are Tunbridge in Kent, Scarborough, Harrogate; Moffat, or rather Hartfells, and Strathpeffer, in Scotland; and abroad, we have Spa, Pyrmount, Passe, Forges, and Bussang.

Gaseous, or acidulated mineral waters, called also soda or beer springs, depend upon the carbonic acid gas which they contain for their curative or medicinal properties. They sparkle when drawn from the spring, or when poured into a glass. They have a peculiar and char-

if exposed to the air. Owing to the action of the carbonic acid gas, they are soothing and grateful to the stomach, stimulate the nervous system, increase the appetite, and hence, are of great value in cases of dyspepsia and hypochondriasis. Of course, their properties are modified by the nature of the saline ingredients which they contain. Amongst the most celebrated are those of Cheltenham and Scarborough in England, of Seltzen, Spa, Nauheim, Pyrmont, Bar, and Chateledon, and the sweet springs of Virginia.

Many of the mineral waters both of this country and of the Continent, may be had bottled, and sent to all parts of the world; but there can be doubt that in nine cases out of ten, in addition to all the advantages to be derived from change of scene and climate, it is better to drink them as they issue from the spring. Mineral water salts are also sold, as, for instance the farfamed Cheltenham salt, which is made some-times from the waters, but oftener, probably, according to some such formula as the following:-Take of common salt, sulphate of magnesia or Epsom salt, and sulphate of soda, of each, one pound; dissolve, filter, evaporate to dryness; then add half an ounce of sulphate of iron. Artificial Cheltenham water may be made of,-Epsom salts, twelve grains, iron filings, one grain; Glauber's salts, four ounces; water, four gallons, impregnated with carbonic acid gas. Harrogate salts and artificial Harrogate water are also well known.

The waters of Bath have a temperature of from 112° to 117°, of Buxton 82°, of Bristol hot well 74°. Those of Buxton are tepid, and those of Matlock and Malvern scarcely tepid. The reader is referred for further information to the author's work on the Health Resorts of

Great Britain.

HEART .- In connection with this article the reader is referred to Artery, Aorta, Chest, Circulation. The heart (fig. 118), the central organ of the circulation, is placed obliquely in the chest, the base upwards, the point, or apex, being so situated as, in the living body, to strike the side of the chest, or beat, between the fifth and sixth ribs, about two inches below the left nipple; this point, however, and indeed the position of the heart generally, is liable to alteration according to the position of the body. The size of the heart is generally computed to be a little more than that of the closed fist of the individual; the organ is contained in its own proper bag, or pericardium, which in the healthy state is lined by an extremely smooth moistened membrane; this membrane is also reflected, or carried over the surface of the heart itself; and thus during the constant motion the two surfaces glide easily, and without friction, over each other; the heart lying sufficiently loose in its bag to permit of free movement. The heart is often described

surrounded by muscular walls, and is in fact a heart are shown in their relative positions double heart; this being requisite for the performance of the double circulation-through the body and through the lungs (see Circulation). Of these four cavities, the left auricle and ventricle are dovoted to the circulation of the blood through the body, after its return in a purified state from the lungs; the right ventricle and auricle being devoted to the lungs, where, coming into conventricle and auricle being devoted to the lungs, where, coming into conventricle and lungs and their appendages, the

as a hollow muscle; it consists of four cavities, large blood-vessels communicating with the within the chest. The course of the circulation may be traced through the great veins, which ultimately terminate on the right side of the heart in the right auricle; the blood

ventricle to all parts of the body, through the medium of the large blood-vessel, the aorta. The auricle and ventricle on the right side of the heart have not, when properly formed, any communication with the corresponding cavities on the left side; but the auricle and ventricle on each side are the passage, the blood to pass freely into the vessel, but should it attempt to return, these bag-like valves instantly close the passage,—the blood itself acting as the closing agent,—and this action takes place once for every beat of the heart. If, however, from 315

any cause, one or more of these valves should | become deficient, it is evident, that each time they close, a small portion of blood will pass back, or "regurgitate," into the heart, and this actually occurs in cases of disease; and the consequence of the long-continued and constantly repeated disordered action, is to cause stretching, or "dilatation," of the cavity which receives the regurgitated blood. This example

Fig. 119.

will explain how one slight derangement in the nicely-balanced machinery of this important organ gives rise to another. From somewhat analogous causes, the blood may regurgitate into, or be dammed up in the lungs or in other parts of the body, causing hæmorrhage, dropsy, and other morbid effects.

Again, there may be impediments to the circulation; the valves above alluded to, or others in the cavities of the heart, may not yield as they should do, or there may be other causes which render it difficult for the heart to propel the blood through the body; in such a case, the heart, like any other muscle under similar circumstances, acquires increase of substance, in consequence of the continued and increased exertion demanded of it, to maintain the proper circulation; and thus we have a cause and effect, producing enlargement of the heart, an evil certainly, but a lesser evil to prevent a greater, for in this very enlargement -this strengthening, as it were, of the heart to do its extra work—the patient's safety for the time lies.

There are, of course, many other forms of heart disease, but the above instances will convey some rational idea of the nature and peculiarities of the disorders of the organ in general. It would be quite profitless in this work to enter into anything like detail respecting diseases of the heart or their treatment; disorders so varied in their nature and symptoms can only be properly investigated and managed by a medical man, conversant with the mechanism and the functions of the human frame at large, and in their relations of mutual dependence,

As might be expected, affections of the heart generally, are evidenced by pain in the chest, difficult breathing, cough, palpitation, &c.; and at other times by faintings, giddiness, irregular pulse, &c.; but there is not one is perfectly sound; none, therefore, need alarm | to his care is concerned.

themselves merely because such symptoms occur; they happen at times more or less to all, still they ought not to be neglected; if they continue to recur, a medical man should be consulted. If there is no disease the mind is set at rest, and any general disorder which may have caused the symptoms will probably be rectified. The above cautions are given, because there is no class of diseases of which people are so apt to fancy themselves the subjects as those of the heart; and the more they ponder over their feelings, the more likely are the symptoms to continue or increase, on account of the organ being so intimately associated with the emotions of the mind. Again, even if the heart be unaffected, it is by no means advisable to permit it to continue to be functionally disordered, either by mental emotion or by sympathy with other organs, for the functional disorder may end in organic disease; that it does so sometimes is evident from the fact, that there is no more fertile source of heart disease than those convulsions, either commercial or political, which occasionally agitate

If disease of the heart, either incipient or confirmed, does exist, the person should be placed under medical supervision, and the necessary precautions and regulated mode of life adopted: for with these precautions a large majority of persons who are the subjects of heart affection, may not only continue to live for years, sometimes many years, but to enjoy life. True, the knowledge to any one that he is himself the subject of heart disease may be uncomfortable, but it cannot be unprofitable; he may be aware that heart diseases are sometimes apt to have a sudden termination, and that his life may be somewhat more in jeopardy than that of an unaffected person; but surely to every right thinking man, this fact would rather be an argument why he should know his real condition. The possibility of his being called away from the affairs of this life without warning, should be a reason for his keeping them well arranged; and still more important, should it be a reason that in conducting his earthly stewardship, he should do it, not only with reference to this world, but to give account of it in another; and when the many chances and contingencies of life are considered, the consciousness of being the subject of heart disease amounts to little more than such contingencies assuming a more prominent position in the mind, and to the individual it may be a merciful dispensation. It may seem to some that in writing thus the author is assuming the character of the clerical rather than of the medical adviser; it is not so, it is but taking advantage of the privilege which falls to the lot of these symptoms, or any combination of them, which may not be developed under certain bodily conditions, although the heart of place, so far as the welfare of those entrusted of the physician, when he has in his power

numerous; as already noticed, mental disturbance and agitation is a most frequent one, also mental depression and grief, which, if long continued, appear to exert much influence over the organ, and to make the phrase "a broken heart" not altogether a poetical fiction. Violent passion strongly affects the heart-its indulgence may lay the foundation of disease, which its repetition strengthens, and may bring to a fatal termination. Rheumatism, or rather rheumatic fever, is probably another of the most fertile sources of heart affection. In this disease, inflammation of some portion of the membranes covering or lining the heart (see Carditis) is apt to occur, and to be followed by such effects as induce permanent change. Violent physical exertions, dissipation of all kinds, particularly the abuse of spirituous liquors, are all originators of the above affections. It has been said that persons with heart affections may continue to live and enjoy life, but it must be under a more regulated and restricted system of living than is imperative on persons in health. Everything which may be a cause of heart affection must also be a source of aggravation; all mental or physical excitement especially so. When these are excitement especially so. When these are guarded against, the rest may be summed up in—strict attention to the general health. Whenever an old symptom becomes aggravated, or a new one, such as swelling of the legs, &c., appears, medical advice should always be taken. The great secret in these affections consists in maintaining the balance of the various func-tions, and this can only be done by the judicious management of a medical attendant.

culation-Hysteria-Palpitation, &c.

HEART-BURN .- A burning or irritating sensation, felt either at the pit of the stomach or top of the throat, and occasioned by undue acidity, or by acrid matters, in the stomach. It is generally relieved by an alkali -potash, soda, magnesia, or chalk-which neutralises the acid. It is not, however, advisable to have too frequent recurrence to these palliative remedies, for they are only palliatives, they cannot be taken habitually without weakening, not only the stomach, but the system generally. Heart-burn cannot continue to recur without there being an error somewhere; either the diet is badly regulated, or the digestive organs require something more than simple neutralisation of the superabundant acid. This acid is a badly-formed gastric juice, and if it is neutralised, whatever digestive power it might possess is destroyed, consequently the stomach is called upon to secrete another supply before the food can be digested -a call upon its powers which cannot fail to be injurious. Moreover, persons finding how quickly a dose of alkaline medicine removes the uncomfortable sensation of heart-burn, are very apt to trust to the palliative, and con-

The causes of affections of the heart are very | tinue their indulgences, rather than to practise the self-denial requisite to effect a cure of the cause. Much benefit is derived from the use of bismuth in heart-burn. A mixture consisting of ten grains of subnitrate of bismuth with an equal amount of compound powder of tragacanth in an ounce of water for a dose, and repeated two or three times a day, is a good mode of administration. If accompanied with pain and eructations, the addition of ten minims of hydrochlorate of morphia solution, and ten grains of bicarbonate of soda, will be found to give relief. A small tea-spoonful of powdered charcoal taken at bedtime, will often allay heart-burn, if liable to occur in the night.

Some persons find Spanish liquorice a good

palliative in heart-burn.

Refer to—Indigestion, &c.

HEAT.—The agent which gives to our senses the feeling of heat, is in scientific language called caloric, to distinguish it from the term heat, used to designate the sensation. In this article, however, the one term heat is employed. It is not requisite here to enter into a consideration of the nature of heat; its best known source is the great fountain of heat, the sun; there is also the minor development of heat in the interior of the earth; that produced, or at least manifested by friction, and also by combustion, chemical change, and in the bodies of animals (see Animal Heat), and in the growth of plants.

Heat is interesting in a medical point of view; first, from its effect upon the healthy body—its physiological effect; and second, from its effects as a remedy in disease—its

therapeutical effect.

Of the first, the physiological effects of heat, much has been said under Acclimation, Animal Heat, Bile, &c., which it is unnecessary to repeat here; these articles sufficiently point out the effect of continued high temperature-from 80° to 110°-such as occurs in tropical climates,

upon the human body.

When the heat becomes very intense, particularly if there is direct exposure to the rays of the sun, more immediate and marked effects result; the brain may be affected, and sunstroke, or "coup de soleil," as it is called, be the consequence. This affection, which is not uncommon among the European residents in India, and especially among troops on march, is sometimes also witnessed in the case of harvestlabourers in this country, in very hot summer weather. The affected person falls insensible, the face flushed and swollen, and the vessels beating violently. The most efficient remedies are said to be pouring cold water on the head, and the administration of a small quantity of stimulant, ammonia or brandy.

The skin of persons exposed to extreme heat is liable to be affected with what is called "prickly heat;" an eruption of small pimples, or of minute blisters. In either case, the use of a tepid bath, with a little lead lotion, will allay

the symptoms; and it may be well to take |

some cooling saline aperient.

Although continued exposure to heat produces these effects, it is now well known that the living human body is capable of supporting, with impunity, exposure to an atmosphere of very elevated temperature, considerably above that of boiling water, provided the air be dry. The development of unusual heat at any part of, or over the whole body, is attendant on all feverish and inflammatory attacks, and gives an indication of the extent and character of the malady. The temperature of the body is taken by means of a small thermometer, placed in the arm-pit, or under the tongue, for a few minutes. The normal temperature, or the temperature of health, is 98° Fahr., that of fever may rise as high as 106° or even 108° Fahr.

The use of heat in the treatment of disease is very frequently alluded to in this work, more especially because it is not only one of the most extensively useful, but also one of the safest and most generally applicable remedial agents which can be placed in unprofessional hands. Heat may be used as a remedial agent, simply as a soother, or-if we may be allowed the expression—an anodyne. It may be used as a derivative, or as a counter-irritant. Its application in the latter form will be found alluded to under the article on the subject. In cases of severe pain, such as colic, gallstones, gravel, &c., heat properly applied seems to act as heat simply upon the nervous system, exerting an anodyne effect and relieving the spasm. For this purpose it may be used, by means of stoneware bottles or tins filled with hot water, or by hot bricks; but these solid bodies are not so useful or pleasant as other more yielding agents; and bags filled with heated grain, oats, salt, bran, or some such material are to be preferred. India rubber bags or cushions, which can be filled with hot water, are also admirable for the purpose. When a derivative (see *Derivative*) action is required, as it is in inflammation and inflammatory pain, then heat with moisture must be used, and nothing answers better than hot bran poultices or fomentations of hot water. The great effect of the heat and hot vapour when used, in these cases, is to produce perspiration from the part, and thus to combine this means of relief with the anodyne action of the elevated temperature. The use of heat, especially of moist heat, in the treatment of disease, is especially pressed upon the attention of the unprofessional reader, for it is a remedy almost always procurable, and almost always safely There are, however, a few exceptional cases, in which the use of heat is not desirable. These are such as call for astringing rather than relaxing. Bleeding from, and swelling of, various parts may be increased by heat, which must therefore be avoided.

Refer to-Animal Heat-Bran-Fomenta-

tion-Poultice, &c.

HECTIC, or HECTIC FEVER, is an intermittent form of fever which occurs in the latter stages of consumption, and also of other diseases of a slow wasting character. The par-oxysm of hectic usually comes on towards evening, the person becomes heated, perhaps thirsty, the eyes are brighter than usual, the cheeks reddened, - sometimes beautifully coloured,—and display the circumscribed "hectic flush," at the same time, an almost morbid elevation of spirits is not uncommon. Towards midnight the stage of fever is succeeded by that of perspiration, which increases as morning approaches, till towards four or five o'clock the patient is completely soaked in moisture, and is left in a state of painful exhaustion.

Refer to -Consumption, &c.

HELLEBORE.—A wine prepared from the root of the white, and a tincture made from the root of the American or green, hellebore, are admitted into the British pharmacopeia. These act powerfully as emetics and purgatives, causing great irritation of the mucous membrane of the mouth and alimentary canal. The green hellebore depresses the pulse, and has been much employed in America as a febrifuge, as well as a remedy in gout and rheumatic fever. It has not met with the same favour in this country. The dose of the tincture is from five to twenty drops.

HEMICRANIA .- Pain confined to one side of the head. It is generally of a neuralgic, or rheumatic character, and is often relieved by quinine in large doses or by galvanism .-

See Headache.

HEMIPLEGIA.—See PARALYSIS.

HEMLOCK. - CONIUM MACULATUM. -This well-known native plant belongs to the umbel-bearing tribe. Persons frequently call all plants of this tribe "hemlock," but erroneously. The true hemlock may at once be distinguished by its being the only British plant belonging to the umbelliferæ which has a smooth spotted stem. The knowledge of this fact may be useful in case of alarm, not unfrequent, from children having eaten the leaves of such plants in mistake for parsley. leaf of the hemlock is a very deep green, and, when bruised, emits an odour like that of Hemlock is used by medical men as an occasional substitute for opium. Domestically, the leaves may be used externally, as a poultice, in painful ulcerations or tumours. expressed juice of the fresh leaves, to which rectified spirit is added in the proportion of one part to three parts of the juice, is the best preparation for internal administration. It may be given in doses varying from a half to two tea-spoonfuls.

In persons poisoned by hemlock, the symptoms are giddiness and dimness of sight, convulsive twitchings, paralysis, perhaps vomiting. The same treatment as that recommended in poisoning by belladonna may be adopted until

HEM HER

medical aid can be procured. The use of the bias to the development of the disease; strong coffee or green tea will also be advisable. and it is observed, that those children which

HEMORRHAGE.—See HEMORRHAGE.
HEMP, or Indian Hemp, from which the "Haschisch" of the Arab, the Bhang and Gunjah of the East Indian is obtained, is used by Asiatics on account of its intoxicating power, and it has come into use in medical practice in this country for its anodyne and antispasmodic properties, particularly in neuralgia, asthma, tetanus, and hydrophobia.

HENBANE—HYOSCYAMUS NIGER—is a

native of Britain, and of Europe generally, peing found on the road sides and uncultivated ground, particularly in the vicinity of houses. It is, however, cultivated for medicinal use. Henbane grows from one to three feet high; its leaves are large, the edges waved,—sinuous,—pale green, and viscid, the flowers are dingy yellow, and much and darkly veined, the whole plant smells disagreeably. Henbane is one of the narcotic substitutes for opium most generally employed. It is given either in tincture, extract, or juice. The dose of the tincture and juice is from thirty minims to a tea-spoonful; of the extract from five to ten grains.

The action of henbane is, in many respects, similar, but much inferior in power to opium; it possesses, however, one great advantage over that drug; it does not confine the bowels; it is, therefore, a most admirable addition to medicines, particularly purgatives, which are apt to gripe; in many cases the addition of one-third of extract of henbane to the compound colocynth, and other aperient pills, is of much service. It sometimes occasions—in too large doses—a peculiar state of delirious hallucination. In a case of poisoning by henbane, treatment similar to that recommended under Belladonna should be adopted.

HEPATIC.—Belonging to the Liver. HEPATITIS. — Inflammation of the

Liver HEREDITARY TENDENCY. - The transmission of a tendency towards certain forms of disease from parents to children, and from ancestry generally to their descendants, has been an acknowledged fact from remote ages; a proof of the unmistakable character and frequency of the incident. Some portions of the body are more liable to be affected by transmission than others, "but no organ or texture is exempt from the chance of being the subject of hereditary disease;" and although some diseases are well known to be much more generally inherited than others, we have no means of determining how far the limitation extends, or whether indeed it does not include diseases generally within its bounds.

Although there are maladies, such as syphilis, which are so directly inherited that the off-spring is actually found to be affected with them when born; this is not the common rule, the hereditary taint acting rather by giving

the bias to the development of the disease; and it is observed, that those children which more nearly resemble the parent in physical conformation, are more likely also to resemble in liability to certain forms of hereditary affections. It is not necessary, however, for the transmission of hereditary disease that it should be developed in the parent, who, al though the connecting link between a grandparent and grandchild as regards the disease bias, may yet have been entirely free from the transmitted disorder. In other words, a hereditary tendency to disease seems often to skip over one generation.

Hereditary predisposition may be derived from a parent without special hereditary tendencies, in whom a definite disorder has been developed, from injurious habits or unhealthy environment; whatever debilitates the system, whether it be advanced life, dissipated habits, or the like, is almost certain to affect the children, and may originate a tendency to scrofula in a family previously free from it. Even a transient bodily condition seems frequently to influence the offspring, more particularly as regards the nervous system:

children; mental excitement communicates its own tendency.

Again, disease apparently hereditary may be developed in a family without its being traceable in the descent, that is, the children, many, or all of them, may be liable to certain forms of disease, towards which neither the parents or ancestors generally had displayed any marked tendency. The fact is one not

drunkenness in the parent may produce idiotic

uncommonly met with.

Scrofula and consumption, gout and rheumatism, insanity and paralysis, asthma, epilepsy, blindness, and a good many other diseases are well ascertained to be transmitted by hereditary tendency. It is not, however, necessary that the tendency should develop itself under the exact form of the disease of the parent; thus, scrofula instead of showing itself as consumption, may take the form of insanity, or gout may be substituted for gravel

The practical importance of a knowledge of these hereditary tendencies is self-evident. There are perhaps few, if any, who do not inherit some predisposition to certain forms of bodily disorder; it must, therefore, be not only to the advantage, but it must be the duty of every responsible person to consider what these predispositions are in himself, and to endea vour, as far as circumstances will permit, to avoid their being excited; still more important is it, in the contraction of marriage, to consider whether union with one having similar here-ditary tendencies will not certainly entail upon offspring an irremedial predisposition to disease thus inherited from both parents. This argument derives tenfold force if the parents happen to be nearly related by blood, for even

319

HER HIP

marriage of near relatives almost certainly leads to the production of weakened and weakly descendants.

Refer to-Marriage.

**HERNIA** means the protrusion of a portion of any organ from the cavity in which it is naturally contained; thus, there is hernia of the brain, or of the lungs; the term is, however, most generally applied to the protrusion of part of the contents of the abdomen .-See Rupture

HERPES.—A disease of the skin, characterised by the eruption of aggregations of small blisters. Shingles is a form of herpes.-

HERRING, like the other oily fishes, is

apt to disagree with weak stomachs.

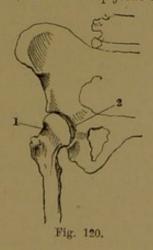

HICCUP is a spasmodic affection of the diaphragm (see Diaphragm). Generally a trivial and transient inconvenience, its occurrence in the last stages of acute disease is a grave, often a fatal, symptom, indicative of giving

way of the nervous system generally.

Continued and obstinate hiccup sometimes occurs in the persons more especially of young females of a hysterical tendency, and may continue for weeks without cessation, except during the hours of sleep, in spite of all kinds of treatment. The causes of ordinary hiccup are generally fasting, or some sudden stimulant taken into the stomach, such as highly-seasoned soup; and the affection generally subsides of its own accord. When inconvenient, nothing is so likely to remove it as some active emotion of the mind suddenly excited. The continued sipping and swallowing of cold water or sucking of ice, are frequent domestic remedies; or antispasmodics, such as sal volatile, may be useful. In the attacks of continued hiccup above-mentioned, a medical man should be consulted; but the disorder will frequently run its course in spite of his treatment.

Refer to—Hysteria

HIP-JOINT.—The hip-joint is formed on

or cavity (2), which is excavated for its recovers with a stiff joint, and a wasted use-

in healthy families the marriage and inter- reception in the bones of the pelvis, or hips, thus constituting a ball and socket joint, which, although it may suffer dislocation, can only do so from extreme violence in peculiar directions, and in peculiar positions of the limbs.

HIP-JOINT DISEASE, MORBUS COX-

ARIUS, is a disease of the joint just described, to which children of a scrofulous constitution are more peculiarly liable. It is of the highest importance as regards ultimate results that this affection should be placed under proper surgical treatment in the earliest stage in which it can be detected; but its approaches are often so insidious that in most cases it has made considerable advance before it is even suspected by parents that there is anything wrong. The following description by the late Professor Syme may perhaps put some upon their

"Hip disease prevails in cold moist climates, and attacks chiefly children between the ages of seven and fourteen, though it is not unfrequently met with both before and after this time of life. The first symptom complained time of life. The first symptom complained of, is generally pain of the knee which often exists for months before any indication can be perceived of the true seat of the disease. Sooner or later the patient is observed to walk awk-wardly and less vigorously than usual; and when the circumstances on which this difference depends are investigated, it appears that the affected limb is elongated and emaciated, -that the convexity of the hip is flattened so that the furrow between it and the thigh is less distinct and more oblique in its direction, -and that, in standing, the foot is advanced a little before the other one, with the toe slightly everted, and that the patient does not rest his weight upon it. Pain is now felt in the hip-joint itself, and though aggravated by motion, often becomes more severe from time to time without any such cause of irritation. It is most apt to do so during the night, particularly when the weather it wet and changeable. In this second stage, the disease remains generally several months, and sometime a year or two. At length the symptoms which have been mentioned, either disappear, and the limb recovers its former condition, or they are succeeded by others still more disagreeable. In the latter case, the limb becomes considerably shorter than the sound one; its mobility at the same time being much impaired or altogether destroyed, and permanent rotation either inwards or outwards also taking place. Collections of matter now generally make their appearance, most frequently on the outer side of the thigh, but occasionally in the groin and hip. In some few instances, but very rarely, the fluid of these abscesses is absorbed, but the ordinary course, which it follows, is to issue externally through openings formed, either by ulceration, or artifithe one hand by the head of the thigh bone cially by the surgeon. The patient then, after (fig. 120-1), and on the other by the deep cup, a tedious illness, becomes hectic and dies; or

HOM HOO

less limb." Great advance has been made in | lected by bees from flowers, consists almost the treatment of hip disease, since the foregoing description was written. It is now considered essential to keep the joint entirely at rest. This is best done by placing the child on a tolerably firm mattress, and keeping the limb still by means of a weight attached to the foot of the affected side. The foot is protected by a closely-fitting shoe, made of some soft material, and fastened by means of a string from the sole to a weight. For a child of five years, the weight should be about four pounds six ounces, and should be increased in proportion to age. In addition to this, a long splint reaching from the arm-pit to two inches beyond the foot, to which the entire limb is bound, and the upper end fixed by a band encircling the chest, will ensure a straight leg, should the joint become fixed. Frequently the surgeon finds it necessary to excise a portion of diseased bone from the hip, before a cure is When a large abscess forms, and the strength of the patient is being reduced by the discharge, the operation referred to is usually considered advisable.

HOME-SICKNESS, or NOSTALGIA, is a peculiar affection of the mind to which the natives of mountainous countries, especially the highlanders of Scotland and the Swiss, are liable when at a distance from, and during prolonged absence from, their homes. are seized with a vehement desire to return, and if this is not gratified, melancholy, loss of sleep and appetite, and finally, perhaps, disease of the lungs, supervene. The emotion is liable to be excited by whatever recalls forcibly to the mind the beloved scenes; national music does this most strongly; so much so, indeed, that it has been found requisite to prohibit for a time the performance of certain airs when troops have been stationed abroad.

HOMCEOPATHY is the system of treating disease founded by Hahnemann, upon the principle that diseases presenting certain sets of symptoms are cured by medicinal agents, which have the power of exciting similar symptoms in the body of a healthy person to whom they may be administered. In conjunction with this principle, practical homeopathy enjoins the administration of the above medicinal agents in inconceivably minute doses. In a work like the present, it would be futile-in the limited space which could be allotted to the subject-for the author to attempt to lay before his readers those reasons which, to his own mind, would render him loth to trust either his own life or the lives of his patients to homeopathic treatment. Of late years the majority of homeopathists have in-Oflate creased the doses of their medicines to such an extent as at times to equal, if not exceed, those given by allopathic physicians. It is somewhat difficult to reconcile this change with the

entirely of sugar, partly crystallisable, and partly not so; the first being similar to grape sugar, and capable of undergoing at once the vinous fermentation. Honey varies in degree as regards fragrance and taste, according to the flowers from which it is collected, and in some instances it is even of a poisonous nature, in consequence of being collected from poisonous plants. As an article of diet, honey is wholesome for most persons, although with some it causes acidity, and others it gripes. It is slightly aperient. For medicinal purposes, especially domestically, honey is frequently used, and answers well as a pleasant addition to cough mixtures, &c. Mixed with a little vinegar or lemon juice, it is useful in cases of sore threat and cough, with adhesive expectoration. Honey is frequently used mixed with borax in cases of thrush in children, and in sore mouths generally.

Refer to - Borax.

HOOPING or WHOOPING COUGH, or Chin Cough, may be described as a spasmodic catarrh. It is one of those diseases of which one attack confers immunity from all future liability to the affection, and as it is generally passed through in childhood, hooping cough is comparatively seldom met with in adults, although they are by no means exempt

The first symptoms of hooping cough are those of common cold, which, having continued unrelieved for ten days or a fortnight, gradually assumes the spasmodic character of the disease, that is, the cough comes on in prolonged paroxysms, which present the follow-ing symptoms. After a succession of violent expulsive coughs, a long-drawn inspiration is made, accompanied with the peculiar crowing, or "hoop," which characterises the disease, and gives it its name; this inspiratory effort is again immediately followed by the same expulsive coughs, and the alternation continues until the child is relieved by the expectoration simply of a quantity of glairy phlegm, or by vomiting, which also expedites the expectoration. Very soon after the paroxysm is over, the child resumes its ordinary condition, whatever that may be; and if the stomach has been emptied of food, generally, before long, complains of hunger.

Whilst the expulsive cough is going on, the child seems on the point of suffocation; the face becomes swollen and livid, the veins turgid, the eyes projecting; the whole frame is so shaken, that the little patient seeks to steady itself by laying hold of some fixed object, -its nurse, a table, a chair, -indeed, children who have suffered some little time from hooping cough, instinctively run to some means of support as soon as they feel a paroxysm

coming on.

The severity of hooping cough varies greatly; alleged cures effected by the infinitesimal doses.

HONEY, the well-known substance colsometimes it is so mild a disease that it is HOO HOP

existed or not, no more than one or two ought to be kept in as regular a condition as "hoops" having been heard during its course; at others, the paroxysms of hooping and cough occur many times in the twenty-four hours. At first, the expectoration is thin, and got up with difficulty; as the disease advances, especially if favourably, it becomes more consistent,

and is more readily parted with.

When hooping cough is on the decline, the paroxysms occur only at more distant intervals, and are shorter, in consequence of the greater freedom of expectoration. Bleeding at the nose is not at all an unfrequent consequence of a fit of coughing, and, in stout children, may be regarded as a relief. The duration of hooping cough may be from one month to six, according to circumstances, such as season, summer being the most favourable. When it exists alone it is not a serious disease; but when, as is too frequently the case, it becomes complicated with affections of the brain and nervous system, such as convulsions, or with inflammation of the lungs or air passages, it is transformed into a most dangerous malady, and carries off numbers of children, particularly very young children-under two or three years of age-to whom it is more fatal than to those at a more advanced stage of life, and who have passed the age of teething.

There is no question as to the contagious nature of hooping cough, and children suffering from it must be kept apart from those who have not had the complaint. The nursery

should be kept warm and comfortable.

In one respect, hooping cough is like fever; it is a disease which, as far as our present remedies are concerned, has a course to run, and one we cannot prevent; but we can guide the disease in that course, and by watching symptoms, and meeting them (should they assume a conspicuous or alarming character) by appropriate treatment, prevent the affection from those complications which constitute it a disease of danger. In many cases, if the attack of hooping cough is tolerably mild, parents never require medical attendance; but in the event of their not doing so, it is their duty to watch their children closely, and on the slightest appearance, either of inflammatory affection of the lungs, or of a tendency to convulsion, to call in proper advice, using in the interval-if there must be one-such modes of management as are recommended under these articles. As regards the actual treatment of the disease itself, it is questionable whether any system of medicine is of very great service, but much depends apon proper and judicious management. The diet of the child should be strictly attended to, and ought to consist chiefly of milk and farinaceous preparations — in short, a mild unheating diet, meat being better avoided altogether, unless the child is very delicate, in

ought to be kept in as regular a condition as possible by means of simple aperients, and the child protected from the influence of weather (see Clothing). Indeed, if hooping cough occurs in winter, the safer plan is to confine the child entirely to the house, and especially during the prevalence of the east winds in

When expectoration is difficult, it ought to be facilitated by ipecacuanha wine, which may be given in tea-spoonful doses, two or three times a day. Sometimes the paroxysms are so severe as to require the administration of a sedative or antispasmodic. A little chloroform dropped on the palm of the hand, and applied in this way to the mouth and nostrils of the child, will often mitigate a paroxysm of coughing. Belladonna, henbane, and even opium, are given by the mouth for a similar purpose. Belladonna is particularly useful in relieving the distressing spasms, and is best given in the form of tincture, of which from five to ten drops may be taken in a little water three times daily. Many other internal remedies for hooping cough are given and recommended, such as alkalies, cochineal, iron, &c., but these already mentioned are sufficient for the management of the disease. External remedies, such as embrocations, are often employed; "Roche's Embrocation" has been in much favour for the purpose; it is said to consist of olive oil two parts, oil of amber and oil of cloves, each one part; it is, therefore, stimulating, but probably any other stimulating embrocations, such as camphorated or ammoniated oil, would answer equally well. If anything can be said to cure hooping cough, it is change of air, which, in the latter stages of the affection, seems to act like a charm, and should always, when circumstances permit, be had recourse to. When the disease has passed, or is passing away, if the child, as perhaps it may be, is much reduced, strengthening remedies, tincture of steel, &c., with good diet may be required. For some time after an attack of hooping cough, more than ordinary care must be taken to guard against cold, which is very apt to bring back-in degreethe symptoms, and even the "hoop."

It is repeated, hooping cough is not in itself a disease of danger, and, especially if it occurs in summer time, may be safely and tolerably easily passed through with judicious and simple management; but should it become complicated, as mentioned in the foregoing article, it may require all the care and skill of

the physician to save life.

sion-Expectorants, &c.

HOPS, the well-known bitter agent, are the seed "catkins" of the Humulus lupulus, or hop-plant, which is native both to Europe and North America, and belongs to the nettle which case, tolerably good broth will be the tribe. The elegant twining hop is too well

HOS HOR

known to require description. agreeable aromatic bitter; it is, therefore, a stomach tonic; it possesses also narcotic properties, though not strongly marked ones; a pillow stuffed with hops is frequently used to procure sleep, and hops heated in a flannel bag are a common remedy for toothache, neuralgia, &c. The use of hops to impart bitterness to beer was commenced in this country in the reign of Henry the Eighth, and there is no question that the addition is a perfectly wholesome one when not in excess; with this view, the highly-hopped bitter India beer, or pale ale, may also be regarded as a medicinal tonic; but it must also be a matter of doubt, whether its continued use, in cold climates at least, is beneficial. Bitter tonics, generally, should not be habitually persisted in, and there seems no reason why bitter beer should be an excep-tion to the rule. The practice, therefore, of drinking it regularly cannot be recommended -as far at least as its tonic properties are concerned. The infusion of hop is a good tonic, in weak and irritable states of the stomach, either taken alone or combined with an alkali; it is made by infusing an ounce of hops in an imperial pint of water: the dose half a tea-cupful. The young shoots of the hop plant are, in some places, cooked and eaten like asparagus, for which they do not form a very bad substitute

HOREHOUND, or WHITE-HOREHOUND, botanically named Marrubium vulgare, is a tolerably common native plant; it is, too, much cultivated in gardens in the country for domestic use, horehound tea being in much

request for coughs, &c.

HORSE-RADISH, the well-known condiment, is the root of the Cochlearia armoracia, one of the scurvy grass tribe. It is powerfully stimulant. An infusion may be made in the proportion of an ounce of the scraped root to a pint of boiling water, and might be used in the absence of other stimulants; or a poultice made of the scraped root might be used instead of a mustard plaster. The infusion made into a syrup with sugar, and frequently sipped, is said to be useful in loss of voice from cold. It is well here to state the fact, that the root of the common monkshood (Aconite) has been used by mistake for horse-radish, and caused death in a very short time. The reader is re-ferred to the illustration and description of both roots given under Aconite.

HOSPITALS were institutions unknown

to heathen ages. Their origin is distinctly due to Christianity, and they have been general in Christian nations from very early times. Among ourselves, although the suppression of the monasteries in this country in the reign of Henry VIII. retarded for a period the extension of these benevolent institutions, the surrender of two of the oldest hospitals (St. Bartholomew's of two of the oldest hospitals (St. Bartholomew's and St. Thomas's) to the citizens of London in the years 1547 and 1558, kept alive the same hospitals, which admitted non-infectious maladies; and persons suffering from severe wounds, or who had undergone import-

The hop is an | public interest taken in the welfare of the sick poor. In the course of the eighteenth century the desire to extend the benefits of hospitals to the sick took a practical form, by the establishment, in nearly every town of any importance in the United Kingdom, of an hospital supported by voluntary help to which the sick or injured could be taken. Prior to the Reformation, lazar and leper houses existed in large numbers and in all parts of the country, being chiefly attached to religious houses where the patients were superintended and medically cared for by the monks. Substitutes for these, founded on a more liberal scale, and more in accordance with the wants of the community, are now universally known as hospitals or infirmaries, their growth having kept pace with the increase of population and the requirements of medical education. The accompanying table (page 324) gives the date of foundation of hospitals for the sick in Great Britain and Ireland prior to the present century, with the exception of

the two oldest already named.

During the present century an immense accession has been made to the above, while the majority of the establishments named have either been rebuilt or greatly enlarged. As medical education advanced, and the wants of the poor became better understood, the propriety of classifying and isolating various forms of disease became obvious, and special hospitals for contagious and epidemic com-plaints, as well as institutions for diseases of special organs of the body, such as the eye, the skin, or the lungs were established. In times more recent, convalescent hospitals (or homes as they are more frequently called) have been established in the country or at the sea-side, and give effectual help to the hospital system; while lastly, numerous village or cottage hospitals, each containing from six to twelve beds have been erected in various rural districts, which formerly felt the want of immediate aid in sickness and accident. Notwithstanding all this charitable help, ostensibly intended for the industrious poor, there remains still a large residuum of pauper population who cannot avail themselves, for many reasons, of the benefits of hospitals supported by voluntary charity. For these, as well as for others who choose to become paupers, the legislature has made ample provision in the numerous infirmaries attached to the unions in large towns.

Apart from their history as schools of medicine and surgery, there is nothing which brings the past and present history of hospitals into stronger relief than that which relates to the means taken from time to time to improve their sanitary condition. In the past, they acquired a bad reputation for high death rate, induced by over-crowding, especially during epidemics, when contagious complaints were drafted into

ease induced by the unhealthy atmosphere. The first step to remedy these evils was to separate the contagiously-affected from the others, and the second, to provide for each class an adequate amount of individual accommodation, combined with freedom of ventilation. In hospitals constructed in the pre-sanitary period (1840, or thereabout), it has been often found difficult, from original faults in the buildings, to remedy the latter defects, especially, as often happened, when the windows were confined to one aspect only of the building.

outbreaks of local epidemic disease which or their origin to one or other of these causes.

The entire subject of hospital construction is convertion. This condition was also complicated with engaged so much attention in connection with

ant operations, were liable to succumb to dis- another equally, if not more, inimical to a healthy atmosphere. The fact is now becoming daily more apparent that less attention was paid in those days to drainage, to the trapping of waste water and soil pipes, to cleanliness, and, in fact, to all questions relating to health, which are now considered of such vital importance for the successful treatment of the sick. The experience of almost all the older hospitals, and of many of the new, can point to partial outbreaks of local epidemic disease which owed

the faulty condition of the accommodation for at right angles to a corridor, common to all the sick and wounded soldiers, after the Crimean war, that a Royal Commission was appointed in 1857 to consider it, and the result was a report containing numerous recommendations, which have been, more or less, carried into effect in all military and most civil hospitals erected since that time. One main object sought for, and this is the key to all systems of ventilation, was to obtain abundance of light

blocks would solve the difficulty, and the first example of the system of construction in this country (for it had previously been adopted in France and Belgium) may be found in the Herbert Hospital on Woolwich Common, the plan of which is given below (figs. 121, 122).

St. Thomas's Hospital, on the river side in Lambeth, is perhaps a more familiar, and certainly a less objectionable illustration of and air, in a manner not to be incompatible with the comfort and well-being of the sick. It was believed that a hospital constructed in ridor, and the distance between the blocks is a series of oblong blocks or pavilions, running ample. Abundance of light is obtained by the

HOS HOS

block system, in consequence of the windows | help to deprive the air of the subtle impurities being situated on both sides, as well as at the far extremity, of the wards, while the beds are limited to two rows, without the intervention of a spinal wall between them. A similar mode of construction has been adopted in the new infirmary at Edinburgh, and in almost all hospitals erected by the Local Government Board in different parts of the country; but all systems of construction, however elaborate, must yield in importance, in the long run, to the improvement which has taken place in the are (1) the site and surroundings; (2) the buildsurgical treatment of the very class for whose benefit these arrangements were primarily designed. The steady employment of numerous nursing, and general arrangement. disinfecting and antiseptic agencies, which

which are prone to deteriorate the atmosphere of the best ventilated buildings, as well as a stricter attention to cleanliness in dressings and the patients' surroundings, have been prosecuted with so much success during the last few years, that there is every reason to hope that hospital disease may be ranked as an opprobrium of the past.

The points to which special attention is usually directed in connection with hospitals, ing itself, including its ventilation and warming; (3) the internal fittings, the dieting,

sick poor, it seems paradoxical to recommend that it should be placed at a distance from them, chiefly of brick work, which, in course of time, somewhere in the suburbs of a large town, away from the smoke and other abominations from public works. Still, attempts must be made to obtain as good a site as the locality stitution, for the old-fashioned brick conduit, will allow, elevated, if possible, above its of glazed earthenware pipes, securely jointed; surroundings, and situated on gravel or some but no drain, if at all possible, should be equally porous material. As important as the site, is an effective system of drainage. In all old, and in many new hospitals, the main drain, as well as the minor conduits, into which waste water as well as sewage entered, were

general hospital is to render it accessible to the | built underneath the basement, and until a

HOS HOS

every precaution must be taken against all which they could be extended at will. danger from this source, not merely by a per-fect system of interception, but also by a free communication of the pipes and drains with the external air.

2. The Building.—Although the plan of construction of a hospital has been already referred to, in connection with some remarks on the block and corridor system, it may be desirable further to consider the subject, especially as the mode of construction must in some measure depend on the extent and nature of the ground on which the hospital is to be

On account of their limitation of site and available space, nearly all the older hospitals

majority, however, adopted the rectilinear form in the first instance, though they were soon compelled to deviate from it, as the wants of the population multiplied with its growth. A common mode of extension was to add a wing or block at right angles to the rear of the primary building, thus forming a structure somewhat resembling the letter T. Another plan of extension, even more general than the last named, was to add a wing at right angles to each end of the straight-line building, after the shape of the letter [ (E without the central projection); while a third supplemented the Tshaped building with another block parallel, and in all respects similar, to the first structure, are remarkable for the absence in their original thus taking the form of the letter I. The construction of any guiding principle from faults of such additions to asylums for the sick

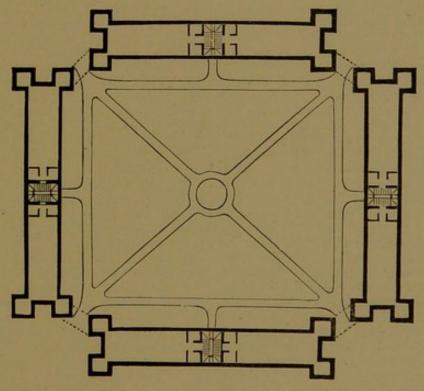

Fig. 123.

are obvious, they obstruct light and air from the | so as to form when completed four sides of an interior difficult, and isolation impossible. is admitted, however, that so long as the building retained its rectilinear form, it met (and more than met) all the objections which the block and corridor principle was originally designed to combat, and it is to be regretted that the former system has not been developed in a way that would further advance its utility. All hospitals founded and supported by voluntary or endowed charity, sooner or later undergo extension, and there is no readier means of accomplishing this than by procuring, at the construct from time to time blocks or wings (not exceeding four), isolated from each other,

outside, and render the ventilation of the open square, with a quadrangle of about an acre It in extent in the centre, to serve the double purpose of providing free ventilation for the separate wards, and an airing ground for such patients as are able to take advantage of it. The blocks should only communicate with each other directly by means of a sub-way in the basement, and the spaces between the blocks at the four corners of the quadrangle should be open and ample. Each block must have a central staircase sufficiently wide and open to permit free ventilation, communicating right and left with wards on the separate floors. outset, a sufficient area of ground, on which to design for such a building is depicted in fig. 123.

3. The Wards ought to be each capable of

beds placed alternately between the windows on both sides. Taking the bulk of hospital and fatal character than those admitted to patients, and the means now in vogue for their protection from malarious influence, there is no longer any cogent reason why the in i-vidual accommodation should exceed a thousand cubic feet of space; and a ward 90 or 100 feet in length, 24 feet in width, and 12 feet from floor to ceiling, would give this amount to twenty-six patients. Besides windows opening on each side of a ward, it is always desirable to have one or more placed at the extreme end facing the entrance, not only for light, but to be able, when necessary, with the doorway to flush the ward with fresh air, when it might be unadvisable to onen the side when it might be unadvisable to open the side windows. The requisite adjuncts to a ward comprise nurses' rooms, bath room, scullery, lavatory, and water-closets. It is clear that these should not be in too close contiguity with the patients, and there are numerous ways by which the communication can be avoided, either by adding annexes to the ward at the angles, or by a projection in the rear of the building, or by employing space near the entrance door for the purpose. The bedsteads must, of course, be made of iron with the bottom part of iron laths, or, what is better, fitted with one of the various forms of wire spring mattresses which are alike sanitary, comfortable, and durable (see Bed). If it can be afforded, no better bed can be had than a mattress of horse hair, but flock and wool make excellent beds, and possess the capability of being shaken up daily, and of being taken to pieces and cleansed without the aid of the All hospitals furnish their upholsterer. patients with small cupboards or lockers in which they can stow away necessary articles, such as mugs, spoons, knives, forks, &c., while their wearing apparel, which is often the cause of inconvenience so long as patients are confined to bed, is disposed of in numerous ways. In some hospitals, it is placed in baskets or drawers beneath the beds; in others, it is stowed away in cupboards in the wards, while in many it is preserved in a separate room, until the patient is able again to wear it. Perhaps the best plan with dirty patients is to allow the friends, if they have any, to remove their clothes from the hospital until the owners have sufficiently recovered to use them; or, if the clothes happen to be infested with vermin (as is sometimes the case), they ought in the first instance to be subjected to the powerful heat of the disinfecting oven.

4. The Patients and Internal Arrangements. -The characters of the complaints for which patients are admitted to hospitals, differ much according to locality, the facilities or otherwise of admission, the special objects for which the hospital has been instituted, and its application to the requirements of a medical school. As a rule, the diseases of patients admitted to

containing from twenty to thirty patients, in | Metropolitan hospitals, and the hospitals of large manufacturing towns, are of a more severe country hospitals, and the pressure on the accommodation of the former is infinitely greater than on the latter. The consequence of this continued pressure is felt by the necessity which exists everywhere to discharge the patients as soon as, or shortly after, they are able to leave their beds, so as to make room for others. There is less reason on this account to urge the expediency of adding to the ward accommodation already referred to, separate rooms for convalescents or for dining purposes, as has been frequently recommended of late years by writers on hospital construction. For the same reason, numerous water-closets, which at the best are always liable to become a source of nuisance, are to be avoided, since not more than ten per cent. of the inmates can probably take advantage of them. This desideratum, however, must be met by a large soil-pan or basin, placed in an airy and convenient position, into which the contents of bed-pans and chamber utensils should be thrown, and the vessels themselves cleansed and purified. The soil-pan may be made of porcelain or metal (copper is the best), and thoroughly trapped, and should be furnished with a good supply of water from a tap placed above and over it, at a sufficient height, so as to rinse out the vessels more easily.

Though modern ideas would banish cooking altogether from the hospital ward, it is difficult to see how numerous sick-room necessaries could be provided without the aid of a kitchen range and boiler, either in the ward or closely adjoining it. Beef tea and other food stuffs, warmed up and given at irregular intervals, lose half their value when prepared in the general kitchen by other hands than those of the nurse. Apart then from the open fires used for heating the apartment only, there should always be the means of obtaining boiling water for poultices or fomentations as well as for cooking delicacies. This may either be done in the ward itself, or what is better, in a well-aired recess or projection from the building, communicating directly with the ward. To economise labour, lifts are now freely made use of in hospitals as well as in most public institutions. There are usually two kinds of lifts in use, one for food, of small dimensions, and readily worked by the hands, and anoth r of larger size for coals and other weighty materials, worked by hydraulic means. The latter may also be used for raising patients, though they, as a rule, prefer being carried in a reclining chair to the apartments and beds they are intended to occupy.

The regulations regarding admission to hospital treatment, though restricted in a measure to the recommendations of subscribers to the respective charities, are usually of a very elastic character, and allow freedom of admission

HOS HOS

other persons whose complaints can be promptly remedied by treatment. Much has been said against the system of out-patient relief as now administered at most hospitals, and there can be no doubt that it is occasionally taken advantage of by persons who could afford to pay a small fee to the doctor. The medical men, however, employed in this department of hospital work, are all but unanimous in the opinion, that the abuse of the privilege is trifling in comparison with the benefits conferred. is also but fair to bear in mind, that industrious, moderately poor persons, have no other way in which they can secure the opinion of a consulting physician or surgeon, for their often protracted and frequently obscure maladies.

5. Ventilation and Warming. - In rooms, night and day occupied with sick people, next to cleanliness there is nothing so essential for the inmates, as a comparatively pure atmosphere. A perfectly pure atmosphere it is impossible to maintain, where so many causes contribute to its deterioration, but a hospital atmosphere may be kept comparatively pure by continuous renewal of the element. To obtain this desideratum has taxed the ingenuity of architects, engineers, and sanitarians at all times, and there is still much difference of opinion as to the best means of acquiring it. In the warm months of the year in this country, the difficulty is reduced to a minimum, as recourse is had at this time to open windows, which may always be planned in such a way as to prevent a down-draught on the patients, but for eight months of the year in Britain, artificial warmth combined with fresh air is equally necessary. Numerous attempts have, in consequence, been made by mechanical apparatus of various kinds to pump artificially warmed air into the wards of hospitals, and similar means have been employed to extract the atmosphere already vitiated. It is hardly necessary to state that most of these mechanical systems have proved failures, and that reliance must mainly be placed on open fires, aided by window ventilation. It is desirable that the temperature of the air inside should not fall below 60° Fahr. in cold weather during the day, and 55° Fahr. during the night; but, in such a ward as has been described, this would be found a practical impossibility with fires alone in certain conditions of the weather, during winter and spring. Recourse is had, consequently, to supplementary means of obtaining warmth, either by warming the air in the course of its admission to the building, in hot air chambers placed in the basement, or by coils of hot water or steam-pipes situated in the wards, or in the staircase and corridors, or in both. Persons suffering from chest complaints, paralysis, rheumatic affections, and some other maladies, do better in a warm atmosphere than

to all cases arising from accident, as well as to | gical cases ; hence the desirability of having separate accommodation and classification to meet both requirements. In buildings erected before these matters were much thought of, and when windows, as was often the case, were confined to but one aspect of the ward, it has been customary to aid the window ventilation, and, at times, to find a substitute for it, by admitting the air through gratings and tubes communicating directly with the outside. Such contrivances should only be introduced when found absolutely necessary, as they become in course of time harbours for dirt, and very difficult to keep clean. If employed at all, the valves or internal orifices should neither be too near the ceiling, nor too close to the floor, -six feet from the floor is usually considered the best height,—and they ought to be furnished with suitable apparatus for moderating or

shutting off the current at will.

6. Nursing.—Next to efficient medical attendance on the sick, no department of hospital work requires more care and attention than that which relates to the nursing. To secure this, much self-denial is required on the part of those who devote themselves to the work, and it is a hopeful sign of the times, that so many excellent and good women—ladies, also, of education and refinement—now freely give their labour to a task which at one time was looked upon with a species of abhorrence. But none should attempt the regular duties of a nurse, without a due sense of the responsibility which they have to encounter, and without first undergoing a season of preliminary training to test their fitness. The office is one which deserves the greatest encouragement and help from the community, and no class has more reason to appreciate its value than the medical profession, which is brought into such close relation with it. It is perhaps easier to define the duties and requirements of a nurse, than to have them in all respects satisfactorily performed, as everything depends on the moral capabilities, tact, and discernment of the individual. What are commonly considered essential to the right performance of these duties, comprise the leading virtues of order, discipline, cleanliness, method, self-control, and kindness, combined with more or less knowledge of the laws of sanitation, and the action of remedies; but it would be unreasonable to expect all these concentrated in the individual, though they all contribute more or less to the formation of the character of the efficient nurse. To enable the nurse better to attend to nursing and nursing only, it is desirable that the rough domestic work of the ward should be delegated to other hands, and this is now provided for in the best hospitals by the employment of another class of officials, designated "ward-maids." To render the night nursing in hosthose admitted with broken limbs, and the pitals equally efficient with the day service, it general mass of what are usually termed surise the rule in some hospitals to make the nurses

the greater part of their lives.

There can be no question, that to the insalubrity of the dwellings of the poorer classes especially, and often of the rich, much disease is owing. This is, undoubtedly, in great measure due to ignorance, for, spite of the many channels through which sanitary information has been attempted to be diffused of late years, it is astonishing how little real or prac-

of the nineteenth century, were satisfied in of houses depend much on the facilities of the some instances, compelled in others, to spend locality for obtaining stone, brick, concrete, or wood; but in our comparatively cold climate recourse is usually had to bricks, or stone, to protect us alike from cold or wet, and to keep in the heat. To prevent the habitation becoming a source of bodily disease, some general rules regarding its construction and site may be of service in indicating more especially what to avoid.

1. Aspect. - With respect to aspect, which is tical information is retained by people generally. always considered (and very properly so) one The materials employed in the construction of the most important features of a dwelling,

over which they have little control; still, in selecting or in building a house for occupation, there are some points which it is always useful to bear in mind. Sufficient elevation, suitable distance from high walls, hills, rivers or stagnant pools, coupled with good drainage, are, of course, the first requisites; but in addition to these, the weather features of a locality must be taken into considera-It is always desirable that the rooms most in use of a house should be free from excessive glare of the sun, and from the prevailing winds of the locality. Entrance doors should never, if possible, be made to face south-west, as the wind and rain from this quarter are often excessive. Generally speaking, a southern aspect is preferred to a northern for warmth, and an eastern to a western, so as to obtain more sun, and in the United Kingdom, especially in large towns, we are not usually insert in the different aspects:-

most people have to submit to circumstances embarrassed by too much of the latter. Much must depend on the surroundings - whether the house is sheltered by trees, or by rising ground, or other qualifying circumstances. The illustration of the aspect-compass of Professor Kerr (fig. 124), in the centre of which is a window facing the south, will explain the south, will explain the south. plain the chief guiding points to be kept in view in selecting a site for a house, provided there are no intervening obstacles to interfere with its adoption.

With the aid of the meteorological compass, Mr. Eassie, the eminent sanitary engineer, has constructed the following table, showing the length of time the sun on an average is likely to shine on the exterior of an exposed building. This is an object for comfort as well as for health, both in town and country, and may be a guide to the size, character, and number of the windows, which it would be desirable to

Window facing	Sun enters at	Is full in front at	Is lost at
East,	. 3 л.м.	6 A.M.	10.30 л.м.
South-east,	4.30 A.M. 7.50 A.M.	9 A.M. 10 A.M.	1.30 P.M. 4.30 P.M.
South-west,	10.30 A.M.	3 P.M.	7.30 P.M.
West,	1.30 р.м.	6 P.M.	Setting.

Rooms requiring a steady light should face the north, north-east, or north-west; so ought store-rooms, larders, and kitchens, on account of the character of the winds from this quarter; while a south-east exposure for the day rooms would, in the majority of cases, be found most in accordance with comfort and cheerfulness.

2. Soil.—The ground on which a house is built should, if possible, be gravel, or some other equally porous material, through which moisture may readily percolate. Nothing favours scrofula and consumption so much as a damp soil, and before fixing on a habitation, one ought to be satisfied that the superficial, as well as the sub-soil, waters may be easily carried off, either of their own accord or by

drain pipes.

3. Site.—The surroundings of the house should not interfere with the health of its inmates. It should be placed on a higher level than the stables, and other outhouses, in its immediate vicinity, to avoid the danger of sewage passing from these to the basement. For similar reasons, it is undesirable to plant a house at the foot of a hill, or on the banks of a river liable to overflow. It is a common fallacy to suppose that trees and shrubs planted near a house produce dampness, whereas they really tend to absorb moisture from the soil, besides adding beauty to the surroundings. Some species of plants possess this property in a remarkable degree, notably the sunflower and the eucalyptus. 330

4. Foundation.—The house should not be built on made ground, but the surface soil should first be removed to the extent of several feet, and a thick layer of concrete, covered with another of well-puddled clay, should be filled in, in its place, to form an impervious foundation. It is advisable to use the underground floor for cellars, but if this is not done, the space between the foundation and kitchen, and other apartments on the same floor, should admit of free ventilation, by means of perforated bricks let into the walls. What is termed a damp-proof course is often employed for this purpose. This consists of a row of perforated bricks or tiles of terra cotta, from one and a half to three inches in thickness, joined together

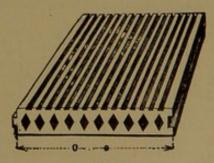

Fig. 125.

with tongue and grooved joints (fig. 125). These, as well as a great variety of stoneware articles for sanitary purposes, are manufactured by Doulton & Co., of the Lambeth Pottery Works.

 Walls and Roof.—The walls of the house | or rooms, as was formerly too much the case. should be made impervious to wet, by an open space being left between the outside and inside wall, presuming that the walls are of brick, with damp courses and bonding bricks or tiles to prevent the moisture passing into the inner wall. The illustration (fig. 126) represents the application of Jenning's improved bonding

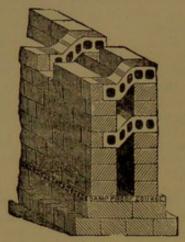

Fig. 126.

bricks for hollow walls. It will be apparent, from its shape and position, that no water can be carried through the bonding brick into the internal wall, as the former is bedded one course higher than that which takes its bear-

ing on the outer wall.

The roof should be either of slates or tiles well set, the former are most used, though the latter, when well made, possess some advantages over slates. Roofs of thatched straw were at one time common in cottages and country houses, they are warm and dry, but being of an inflammable nature, they are now

being gradually superseded by slates.

6. Drainage. - All houses should be supplied with two water-cisterns, one for drinking-water and cooking, the other for the closet supply and washing; and all soil pipes and drains should be trapped, and ventilated before reaching the main sewer. There are numerous contrivances for effecting these objects, the most generally employed being the syphon intercepting trap, fitted with an inspection as well as a ventilating pipe between the house and the spot where the soil-pipe joins the street or cesspool drain. The soil-pipe should always be placed outside, and not inside, of a house, and should be ventilated by being carried up to the roof, and the top kept open. In small houses, where the water closet is often the source of much evil, it is questionable whether it would not be more advisable to have the closet placed outside of the house.

7. Ventilation. — Every apartment, lobly scullery, staircase, &c., should communicate directly with the external air by window. Water-closets especially should always be ventilated for the fore-arm. See fig. 127.

Refer to—Fore-arm.

HUNGER.—The desire

Sleeping places should be freely supplied with light and air; the practice of employing closets and dark recesses for sleeping purposes is most objectionable.

8. Internal Arrangement. — The interior walls and ceilings are best lined with plaster or cement, so as to present a smooth surface for paint, lime-wash, or paper. If paper is employed for dwelling rooms, it should be smooth and well varnished, that it may be readily washed down; flock and other showy papers invariably harbour dirt. The floors of sitting rooms and bed-rooms ought to be made of hard and closely-fitting wooden boards, and if carpets are not used, the floor should be stained, and polished weekly, with bees-wax and turpentine. When carpets must be used, a margin of twelve or eighteen inches near the walls should be left uncovered, and treated in a similar manner. Much harm is done by excessive wet scrubbing of floors, on account of the moisture pervading a house in consequence, but it ought not to be discarded altogether, and will be found to be absolutely necessary

occasionally.
On the subject of the construction of houses, the reader is further referred to Professor de Chaumont's valuable little book entitled The Habitation in relation to Health.—See Drainage — Bed-Room — Light — Ventilation—Public

Health.

HOUSEMAID'S KNEE.—This affection has been so called on account of its frequent occurrence in servants who have to kneel much upon hard floors, or stairs, as, for instance, in scrubbing hard stone or wooden stairs, passages, &c. In fact it might, with almost equal propriety, be called "scrubber's" knee, although it is met with among others who, from the nature of their occupation, habitually exert much pressure upon the knees. The affection is usually chronic, and presents itself as a colourless, prominent, round swelling, just over the knee pan. When quite chronic, rest, and painting the part over occasionally with compound tincture of iodine, will generally suffice for a cure. When acute, red, and painful, especially if accompanied by a tendency to erysipelas, medical advice should at once be sought, as it will then probably require active treatment to subdue the inflammation. Persons employed in scrubbing should always be furnished with a cushion or pillow, on which they can rest their knees when at

HUMERUS.—The anatomical name of the arm bone (fig. 127). This bone is, at its upper end, (1) articulated or jointed at the shoulder to the shoulder-blade or "scapula"; and at the elbow, by its lower end, (2) to the two bones of the fore arm.

HUNGER .- The desire for food is an tilated from without, and never from passages | instinctive sensation, evidently connected with

HUN

HUN

not solely with the condition of the stomach. In a healthy state the appetite for food is in proportion to the waste of the body in exertion; in other words, if the transformation, or using up of tissues, goes on more quickly, as it must necessarily do when much exertion is made, the tissue must be more abundantly supplied with nutriment, and vice versa, if exertion be less. In any case, the call for nutriment is made through the medium of the stomach by the sensation of hunger. The direct cause of that sensation is doubtful; some have referred it to a distended condition of the vessels of the stomach, but, however that may be, it is certain the brain and nerves participate largely in the feeling. Dr. Alison remarks, "Whatever be the conditions under which the nerves of the stomach become the seat of these sensations, it is certain that, in the healthy state they are a true index, not only to the

Fig. 127.

state of the stomach, but to the immediate wants of the system at large." To use a simile, the brain may be likened to a great central telegraph office, to which the wiresnerves-convey the information from all parts of the body that supplies are wanted, and this information is transmitted to the stomach by its own special means of communication,or nerves, -and causes hunger. How and why this is, we cannot tell. Although, however, hunger is felt as a sensation in the stomach, in consequence of sympathy with the system at large, it is appeased by the introduction of food into that organ, long before the digestion of that food can have supplied the waste which called for it; to resume our simile, it would seem as if the stomach telegraphed back to the brain the information that the "order had been received and complied with,"—that food had been taken, -and so the sensation ceases. Moreover, the stomach may give false informa- consequence.

the requirements of the body generally, and | tion, for it is well known that the sensation of hunger may, for a time, be appeased by the swallowing of comparatively innutritious substances, which occupy the stomach, but which cannot be digested into nutriment for the system; and further, the sensation of hunger may be allayed by various medicinal substances, such as opium, tobacco, alcohol, &c., which do not nourish. Again, the information respecting the requirements of the system, conveyed to the stomach through the brain, may, so to speak, be stopped in transit; this is seen in the case of accidents; however hungry a man may be, if he should happen to sprain a joint, the appetite will disappear at once. Even mental emotions will, by their effect upon the brain, have the effect of destroying the sensation of hunger; and Shakespeare adverts to this observation, in the words addressed to Wolsey by King Henry the Eighth, along with an unpleasant communication,-

"Read o'er this; And after, this; and then to breakfast, with What appetite you may."

Intense engagement of the mind in study or upon any subject which strongly excites its interest, it is well known will often overpower completely the sensation of hunger. This frequently happens to those who are much absorbed in scientific pursuits. The anecdote of the illustrious Newton is familiar to most, -a friend calling to see him was shown into the room where Newton's dinner—a chicken was spread out; being kept waiting, he ate the dinner and replaced the covers. The philosopher coming in shortly after, and finding his dinner gone, simply remarked, "Dear me, I forgot I had dined!" It is, perhaps, unnecessary to It is, perhaps, unnecessary to remark, that such complete forgetfulness of the wants of the body is scarcely consistent with continued health, either of it or of the mind; and for it, even Newton paid the penalty.

The influence exerted by mental emotion over the sensation of hunger, may, however, tell both ways, for if it destroy real, it may excite false, hunger, and this it frequently does; very many are in the habit of eating much more largely than the wants-the wasteof the system require. This may be the result of an unhealthy excitement of the nerves of the stomach, but much more generally, it arises from epicurism, or love of excess, the mind being the cause of a false hunger, or desire for tempting and unnecessary articles of food. This is frequently the case with people who live idle and indolent lives, and who, having little else to occupy either mind or body, take refuge in the indulgences of the table. The effects of this excitement and indulgence of false hunger, this habitual consumption of excess of food beyond what the wants of the system require, may, for a time, be compensated for by the various excretory powers of the body, but, sooner or later, disease must be the

The proper and permanent appeasement of | hunger would seem, in some cases, to depend upon the fitness of the food taken for the requirements of the system generally; every one with healthy appetite feels the desire for different kinds of food in winter and summer. Sir John Richardson mentions with regard to his Arctic experience, that under exposure to intense cold, bread and such articles were not desired as food, which was always most acceptable when of as fat and oily a character as possible.

Refer to—Animal Heat—Appetite—Diges-

tion—Fasting—Food, &c.

HYDATIDS are parasites belonging to the animal kingdom, the ova of which, introduced into the stomach, are absorbed by the circulation, and become developed in different organs, more especially in the liver, the brain, and the lungs, and which are found imbedded in the tissues, particularly the glandular ones of animal bodies. The hydatid consists of a simple vesicle filled with fluid which has a tendency to increase to a considerable size, and multiplies by the development of young hydatids in its interior. When the cyst nears the surface, as sometimes happens when it is confined to the liver, the fluid may be drawn off and the hydatid with it, so as to effect a cure.

HYDRAGOGUE is a term applied to some purgative medicines which produce copious watery evacuations from the bowels.

silver. - See Mercury.

HYDROCELE, a dropsical swelling within the scrotum. It requires proper surgical treat-ment for its cure, but a patient may derive much comfort by wearing a bag truss, or some similar support, until he is relieved by opera-

HYDROCEPHALUS .- "Water in the Head."-See Brain

HYDROCYANIC ACID.—Prussic acid.

See Prussic Acid.

HYDROGEN GAS is the lightest substance known, and when pure, has neither colour, taste, nor smell; the latter, however, is very frequently present in consequence of impurity. Hydrogen gas burns with a pale yellow flame, the product of the combustion is water, this fluid being a compound of oxygen and hydrogen gases in certain definite proportions. The union of hydrogen gas with sulphur constitutes the very offensively smelling gas, sulphuretted hydrogen, which is one of the products of the decomposition of organised bodies, and also forms the characteristic feature of many of the mineral waters, such as those of Harrogate.

Refer to—Carburetted Hydrogen.

HYDROPATHY—is the system of treating disease by the use of water, both internally and externally, in the modes introduced by Priessnitz.

Of the utility of water as an agent in the treatment of certain diseases, there cannot be a question, when its employment is judiciously regulated, and combined with other methods of cure; but it is equally certain that its indiscriminate and wholesale use, as it has been practised in hydropathic establishments, is too often a most dangerous quackery-a quackery, because it is put forth with pretensions to which it has no claim, and used in an indiscriminate and ill-judged manner. There are many conditions of body-particularly that of the over-fed and the indolent-in which copious draughts of pure cold water, regulated and simple diet, exercise, and promotion of the functions of the skin, must evidently be of the greatest service, nay, are in themselves sufficient to restore health, and medical men have, perhaps, too much neglected such natural methods of cure, in their confidence in mere drugging. It is no less certain, however, that an indiscriminate and extravagant use of even these natural methods cannot fail to prove injurious in many states of the system, and so it has proved in numerous instances, and even death has been the result of the experiments. Still, it must be owned, that the practice of hydropathy has had the advantageous effect of directing the attention of medical men to its intrinsic value, and if the system itself has been mixed up with much which must be considered dangerous error, that should be no reason why the useful suggestions which may be gathered from it should not be taken advantage of; indeed, for medical men to refuse to do so, is to place themselves in the same position as the abettors of an exclusive system, or the vendors of a "panacea." Medical science can only retain its high place by liberal investigation of those new phases in medical treatment, which must ever be arising in the progress of society, when these phases offer reasonable ground for such investigation, and this, hydropathy certainly does. To refuse to investigate, or to refuse to adopt that which is good, because it has been found connected with some irregular system, is in itself quackery of the grossest kind, and is the most certain way of strengthening the hands of charlatans or of fanatics.

Refer to—Water—Baths, &c.
HYDROPHOBIA—literally "Dread of water."-This fearful and justly-dreaded disease is especially of a nervous and spasmodic character, and is produced by inoculation with the saliva of an animal labouring under the malady; fortunately it is of so comparatively rare occurrence, that very few medical men ever witness it at all. For the information in the following article, the author is indebted to the "Lectures" of Sir Thomas Watson.

After a person has been bitten by a rabid dog the wound heals in the same manner as an ordinary wound from the same cause would. "After an uncertain interval-which lies for the

HYD HYD

-the following symptoms begin to be noticeable. The patient experiences pain, or some uneasy or unnatural sensation, in the situation of the bite. If it has healed up, the scar tingles, or aches, or feels cold, or stiff, or numb; sometimes it becomes visibly red, swollen, or tivid. The pain or uneasiness extends from the sore or scar towards the central parts of the body. Very soon after this renewal of local irritation—within a few hours perhaps, but certainly within a very few days, during which the patient feels ill and uncomfortable-the specific constitutional symptoms begin; he is nurried and irritable; speaks of pain and stiffness, perhaps about his neck and throat; unexpectedly he finds himself unable to swallow fluids, and every attempt to do so brings on a paroxysm of choking and sobbing, of a very distressful kind to behold; and this continues for two or three days till the patient dies exhausted." Hydrophobia has never been cured when once the decided symptoms have shown themselves.

"Generally, the disease, when it has once set in, and shown the peculiar hydrophobic symptoms, runs a short and fierce course. The nervous irritability becomes extreme. The peculiar paroxysms of choking, spasm, and sobbing are excited, not only by attempts to swallow liquids, but by the very sight or sound of them. Even the passage of a gust of wind across his face, the waving of a polished surface, as of a mirror, before his eyes, the crawling of an insect over his skin, is often sufficient to excite great irritation, and the peculiar strangling about the fauces in a hydrophobic patient. Death occasionally takes place within twenty-four hours after the commencement of the specific symptoms. Most commonly of all, it happens on the second or third day," but may be postponed even to the seventh or eighth. In some instances, the symptoms alter before death, and the patient is able to swallow liquids.

With respect to the infection of hydrophobia, Sir T. Watson says :- "We are sure that the disease, by the inoculation of which hydrophobia may be produced in man, is common in the dog, and that it has been communicated by the fox, the wolf, the jackal, and the cat." Mr. Youatt says that the saliva of the badger, the horse, the human being, have undoubtedly produced hydrophobia, and some affirm that it has been propagated even by the hen and the duck. All animals, even fowls, are susceptible of the disorder when bitten by a rabid dog.

The late Mr. Youatt, who had seen more of the disease, probably both in man and in other animals, than any other person in this country, did not think that the saliva of a rabid animal could communicate the disorder through the unbroken cuticle: he believed that there must be some abrasions, or breach of surface.

nost part between six weeks and eighteen months | be communicated by mere contact with the mucous membranes.

Of its harmlessness on the sound integument, he offered this presumption—that his own hands had many times, with perfect impunity, been covered with the saliva of the mad dog. He records some singular instances in which the disease was transmitted by contact of the saliva with the mucous membranes. "A man endeavoured to untie with his teeth a knot that had been firmly drawn in a cord. Eight weeks afterwards he perished undeniably rabid. It was then recollected that with this cord a mad dog had been confined. A woman was attacked by a rabid dog, and escaped with the laceration of her gown. In the act of mending it, she thoughtlessly pressed down the seam with her teeth. She died. If these cases be authentic, they are conclusive of this question; unless, indeed, the lips of those who perished happened to have been chapped, or abraded. But Mr. Youatt's own opinion was, that the virus could not be received on a mucous surface

without imminent danger.
"The disease is said to have been caused by the scratch of a cat. But as we know that cats as well as dogs frequently apply their paws to their mouths, especially when the latter part is uneasy (as it clearly is in mad dogs), this fact, of the production of the disease by a scratch, if thoroughly made out, would not prove that the disease can be introduced into the system in any other way than by means of the saliva.

"It is still more interesting to inquire, whether the saliva of a human being labouring under hydrophobia be capable of inoculating another human being with the same complaint? Mr. Youatt says, yes, that the disease has undoubtedly been so produced. If this be so, the fact will teach us not to neglect or desert these unhappy patients, but to minister to their wants with certain precautions so as not to suffer their saliva to come in contact with any sore or abraded surface, nor with any mucous surface. On the other hand, all carefulness of that kind will be unnecessary if the disease cannot be propagated by the human saliva. Certainly, many experimenters have tried in vain to inoculate dogs with the spittle of hydrophobic man; but there is one authentic experiment on record, which makes it too probable that the disease, though it may not be communicated often, or easily, is yet communicable,"—enough to enforce all necessary caution upon those engaged in attending upon a hydrophobic patient.

"Is a man who has been bitten by a mad dog, and in whose case no precautions have been taken, a doomed man? Will he be sure to have the disease, and therefore to die of it? By no means. But few, upon the whole, of those who are so bitten become affected with hydrophobia. This frequent immunity from the disease in persons who have been bitten has tended to confer He held, however, that it might reputation upon many vaunted methods of

HYD HYD

prevention. persons have not failed to take advantage of They announce that they are in possession of some secret remedy which will prevent the virus from operating: they persuade the friends of those who die that the remedy was not rightly employed, or not resorted to sufficiently early: and they persuade those who escape, that they escape by virtue of the preventive remedy. If the plunder they reap from the foolish and the frightened were all, this would be of less consequence, but unfortunately the hope of security without undergoing a painful operation leads many to neglect the

only sure mode of obtaining safety.

. A still more anxious inquiry next arises. Whoever has been bitten by a rabid or suspected animal must be considered, and will generally consider himself, as being in more or less danger of hydrophobia. This dread is not entirely removed, even by the adoption of the best means of prevention. Now, how long does this state of hazard continue? When is the peril fairly over? After what period may the person who has received the injury lay aside all apprehension of the disease? To this inquiry no satisfactory reply can be given. In a vast majority of instances, indeed, the disorder has broken out within two months from the infliction of the bite. But the exceptions to this rule are too numerous to permit us to put firm trust in the immunity afforded by that interval.

. . Mr. Youatt describes cases in which there had been no symptoms of rabies observed in the dog at the time the injury was inflicted, though soon afterwards the animal became decidedly rabid. It is much to be regretted that the dog is so often destroyed. When a person has been bitten by a dog or cat suspected to be rabid, the beast ought by no means to be killed, but to be secured and kept under surveillance, and suffered, if it should so happen, to die of the disease. If he do not die, in other words, if he be really not rabid, that will soon appear, and the mind of the patient will then be relieved from a very painful state of suspense and uncertainty, which might otherwise have haunted him for months or years. Should the dog die mad, the injured person will be no worse off than if the animal had been killed in the first instance; nay, in one respect, he will be better off, inasmuch as certainty of evil is preferable to perpetual and uneasy doubt.

"There are gross errors prevalent with regard to the signs of madness in the dog. If a dog be seen in a fit in the street, some person charitably offers a conjecture that perhaps he may be mad; the next person has no doubt of it, and then woe to that dog. But Mr. Youatt assures us that the rabid dog never has fits; that the existence of epilepsy is a clear proof that there is no rabies. Again, it is a very common belief, that a rabid dog, like a hydro-

Ignorant persons and knavish | phobic man, will shun water, and if he take to a river, that is thought to be conclusive evidence that he is not mad. But the truth is, that the disease in the quadruped cannot be called hydrophobia; there is no dread of water, but an unquenchable thirst; no spasm attending the effort to swallow, but sometimes in dogs an inability to swallow from paralysis of the muscles about the jaws and throat. They will stand lap, lapping without getting any of the liquid down. They fly eagerly to the water; and Mr. Youatt states that all other quadrupeds, with perhaps an occasional exception in the horse, drink with ease.

> "There is another superstituous opinion not at all uncommon, viz., that healthy dogs recognize one that is mad, and fear him, and run away from his presence, in obedience to some mysterious and wonderful instinct, warning them of danger. This is quite unfounded. Equally mistaken are the notions, that the mad dog exhales a peculiar and offensive smell, and that he may be known by his running with his tail between his legs; except when, as Mr. Youatt says, exhausted he seeks his home."
>
> It will not be out of place to state what are

> the symptoms of rabies as observed in the dog.

"The earliest symptoms," says Mr. Youatt, "are sullenness, fidgetiness, continual shifting of posture, a steadfast gaze expressive of suspicion, an earnest licking of some part on which a scar may generally be found. If the ear be the affected part, the dog is incessantly scratching it. If it be the foot, he gnaws it

till the integuments are destroyed.

"Occasionally, vomiting and a depraved appetite are very early noticeable. The dog will pick up and swallow bits of thread or silk from the carpet, hair, straw, even dung, and frequently he will lap his own urine, and devour his own excrement. Then the animal becomes irascible, flies fiercely at strangers, is impatient of correction, seizes the whip or stick, quarrels with his own companions, eagerly hunts and worries cats, demolishes his bed, and, if chained up, makes violent efforts to escape, tearing his kennel to pieces with his teeth. If he be at large, he usually attacks only those dogs that come in his way; but if he be naturally ferocious he will diligently

and perseveringly seek his enemy."
"Very early in the disease, as it appears in the dog, the expression of the countenance is remarkably changed; the eyes glisten, and there is slight squinting. Twitchings of the face come on. About the second day a considerable discharge of saliva commences; but this does not continue more than ten or twelve hours, and is succeeded by insatiable thirst; the dog is in-

HYD HYD

frequently loses his balance and rolls over.

"A loss of power over the voluntary muscles is next observed. It begins with the lower jaw, which hangs down, and the mouth is partially open; but by a sudden effort the dog can sometimes close it, though occasionally the paralysis is complete. The tongue is affected in a less degree. The dog is able to use it in the act of lapping; but the mouth is not sufficiently closed to retain the water. There-fore, while he hangs over the fluid, eagerly lapping for several minutes, it is very little or not at all diminished. The paralysis often attacks the loins and extremities also. The animal staggers about and frequently falls. Previously to this, he is in almost incessant action." Mr. Youatt fancies that the dog is subject to illusions, for he starts up, and gazes eagerly at some real or imaginary object.

"Frequently, with his head erect, the dog utters a short and very peculiar howl; or if he barks, it is in a hoarse inward sound, altogether dissimilar from his usual tone, and generally terminating with this characteristic howl. Respiration is always affected; often the breathing is very laborious; and the inspiration is attended with a very singular grating, choking noise. On the 4th, 5th, or 6th day of the disease he dies, occasionally in slight convulsions, but oftener without a struggle."

are two forms of Rabies-certainly in animals, and possibly in man-i.e., the Furious and the Dumb; that the furious almost becomes the dumb before death, but that the dumb is

not always preceded by a furious form.

Cause.—The nature of the virus of hydro-

found that the virus occurred in greatest amount in the nervous system, as well as in the salivary glands. He further observed that the virulence could be increased or diminished by certain means. By inoculating a series of rabbits, e.g., it was found that the virulence could be exalted to a high degree, while inoculation from dogs to monkeys caused a diminution of virulence, or, as it is called, an "attenuation of the virus." Pasteur then worked out a system of treatment by which it was possible to acclimatise an individual, so that the inoculation of very virulent hydrophobic material would have no effect in producing the disease. Pasteur's system is based on the observation that by drying for certain periods the spinal cord of a rabbit which has succumbed to acute rabies, the virus becomes less and less active. The subcutaneous inoculation of an emulsion of such a spinal cord, dried for fourteen days, causes no symptoms of the disease. Following this, injections of tissues performed almost immediately.

to get rid of it; and while thus employed, he | cords dried for a shorter period are inoculated at successive intervals, and it is found that complete protection against the most powerful hydrophobic virus is obtained.

There is no doubt that such a course of treatment is effective, if carried out a short time after a person has been inoculated with rabies, and the danger of contracting rabies

from the treatment is minimal.

Strict muzzling orders, and the destruction of all vagrant curs, would probably stamp out hydrophobia in this country, if such measures were rigorously enforced for a period of at

least one year.

When an individual has been bitten by an animal respecting which the slightest suspicion of hydrophobia exists, the one certain remedy cannot be too quickly resorted to-complete excision of the bitten part. Some persons have possessed sufficient nerve to do this for themselves, few perhaps could, but it has often been effected by unprofessional persons for others; indeed, there might be more danger in waiting many hours for a surgeon, than in submitting to unprofessional operation. The method of excision most to be trusted is the insertion of a skewer of wood, made to fit into the wound caused by the tooth, and carrying the incision so far round, that the entire hollow or cone of flesh is cut out along with the piece of wood. This might be done with safety in It should be observed, however, that there the thick part of the calves of the legs, or in the back parts of the thighs or buttocks. Where excision is not resorted to, the free application of lunar caustic or, preferably, of strong nitric acid (but whichever may be most readily procured) would be advisable; or in lieu of these, a piece of iron, heated to whitephobia is unknown; but there can be little ness, may be inserted into the wound, so as toms being due to the action of the poison on parts of the nervous system.

The Pasteur Method of Treatment.—Pasteur found that the virus occurred in the symptom of the poison of the p a person who, after having been bitten, feels that due precaution has not been taken; and light indeed compared with liability to the disease itself. In the event of none of the above measures being submitted to, or available, the wound may be thoroughly washed for hours, by means of a stream of warm water poured upon it from a height; a cupping-glass being applied at intervals. These measures are of course only provisional until the attendance of a surgeon can be procured. The general treatment of developed rabies consists in the attempt to relieve the most painful symptoms by hypnotics.

As might be imagined, the preventive medicines for hydrophobia are very numerous; some have been thought highly of by medical men, but for the most part they are perfectly worthless. It is absolute folly to trust to them, to the exclusion of the only certain preventive -excision or destruction of the wounded

336

HYD HYP

When, from the peculiar symptoms (and | no medical man is at hand, the writer would taken in connection with the circumstances altogether they can scarcely be overlooked), an individual is thought to be attacked with hydrophobia, if the hope of saving life is small, much may be done to alleviate so terrible an affliction by proper medical care, which must be sought for at once; in the meantime, whilst all those sights and sounds alluded to in the first part of this article are carefully avoided as fearful aggravation to the necessary sufferer, laudanum may be given in thirty drop doses, and repeated as circumstances seem to dictate. If ice can be taken, it is said to afford relief put into the mouth in small morsels; it has also been found of service applied to the back of the neck. If, on the arrival of a medical man, he likes to try any of the various remedies which have been proposed in this disease, he of course can do so, but the above-mentioned will be sufficient for lay in-But as the disease, when fully terference. developed, is invariably fatal, the continuous administration of chloroform by inhalation is probably the best treatment that can be resorted to.

The general interest and anxiety, and the very erroneous ideas on the subject of hydrophobia which are entertained by people generally, have rendered the length of this article necessary; and in taking it almost entirely from the valuable writings of Sir Thomas Watson, the author has endeavoured to draw, from the best possible source, information which, fortunately, few medical men have an opportunity of acquiring personally.

TION HYPODERMY. - Hypodermic administration of medicinal agents, that is, their introduction into the tissues beneath the skin by means of a suitable instrument, is of comparatively recent date, at least in this country. It has scarcely been practised more than five and thurty years, and is even now not quite so extensively had recourse to as it deserves, considering its value. Although it has been proposed to use a variety of medicines by hypodermic injection, there are comparatively few employed even by medical men, and of these only one or two can safely be intrusted to non-professional hands, and then only in great necessity, and with great caution; but cases do arise, so painful in their nature, which may be quickly alleviated, that when (fig. 128) will give an idea, which more or less

not hesitate to place both instrument and drug in judicious hands, accompanied, of course, with proper instructions. Two drugs, perhaps, are all that can with propriety be so intrusted, but these are invaluable: they are morphia and ergotine. Those medical men who have had good experience of the effects of morphia administered hypodermically, must only be too thankful to have the command of a remedy upon which they can calculate with all but absolute certainty for the relief of pain, nay, of agony, especially the agony of spasm, as, for instance, that caused by the passage of a gall-stone, about as painful an occurrence as can happen to any one. The pain and starting of a broken limb, the pain of neuralgia, and

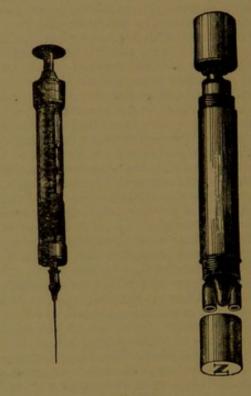

Fig. 128.

that of inflammation of the bowels, of a severe burn, nay, severe pain of all kinds, almost invariably yields to morphia, properly and carefully given under the skin, and that, not after the long waiting for relief, as when the same medicine is given by the stomach, but almost instantaneously. The clergyman in his remote parish, the emigrant—indeed, all who are likely to be far removed from efficient medical aid-would do well to have this invaluable soother of pain in their hands, having made themselves fully conversant with its powers for good or evil, and been instructed in its use.

The instruments used for hypodermic injec-

HYP HYP

comprehends them. There is a glass syringe, | ascertain that it is not blocked. It is very marked or graduated into minims, and there is a fine hollow steel needle, which has to be fitted to the syringe when in use, and through which the medicated fluid is passed, after the skin has been pierced. At one time, it was thought necessary to have gold or gilt needles, but this is not required, and such needles can never be made so fine or sharp as steel ones, which can scarcely be made too fine, so as to give as little pain as possible. Steel needles are best preserved in vaseline; and in the instrument invented by the writer, this is done perfectly in a groove provided for the purpose in the syringe case, which is made entirely of metal, and so both portable and indestructible; properties of no light value in hot climates, while at the same time the syringe piston does not become dry as in most instruments. Lastly, the needles are made to plug accurately on the syringe, instead of screwing, the screw including a washer, apt to shrivel or be lost, thus rendering the instrument useless. Indeed, for the efficient practice of hypodermy, the instrument should always be ready for instant use; it is a miserable thing to see a patient suffering agony, whilst the instrument, which has been unused for some time, is being got into working order, the piston shrunk, or the needles rusted or blocked. The instrument alluded to above, by the writer, he believes provides greatly against these contingencies. It is made by Mr. Hawkesley of Oxford Street.

Given the instrument, how is the morphia best used, when it has probably to be employed at a distance from either doctor or chemist? The best plan is to carry along with the syringe hypodermic tabloids of morphia of various strengths in tubes carefully labelled. Those are now obtainable from all druggists. Presuming a case occurs in which the practice is called for, a first or trial dose should be given, and this in unprofessional hands should never exceed the twelfth of a grain; this may not give full relief at first, but it is safest. To get the above dose, a quarter grain tabloid is to be dissolved in thirty minims of pure warm water, and of this ten minims will be the dose. solution may be made in a teaspoon, carefully throwing the residue away at once after use, but the best thing is a two-drachm widemouthed white glass bottle, that will admit the syringe. In this the morphia is put, the water measured upon it by the syringe, and by holding the bottle in warm water, solution is quickly effected. The dose required may then be drawn up with the syringe, and the needle fixed on. To draw the fluid up through the needle almost always involves the fine point touching the glass, and being turned. One caution has here to be given. A charge of warm water should always be passed through

unpleasant, both for patient and operator, to find that after the skin has been pierced, the needle is impervious. The fine wire sent with the needles, if passed in immediately after use, will do much to prevent blocking. The dose in the syringe, and the needle fixed, the operation of injecting the solution is the next step. At one time it was thought necessary to inject as near the seat of pain as possible; it is now considered of no consequence, a safe place being much more essential, and for all purposes the outsides of the limbs, arms or thighs, present abundant space for safe hypodermy. As to the mode of passing the needle, five minutes instruction will do more for anyone than pages of print, and the writer would counsel all who may be called upon to use the instrument to get that instruction. In emergency, however, the needle may be safely passed quite under the true skin (a fold of which is pinched up) in the localities above indicated, and when passed, the fluid in the syringe is injected through it, and the needle gently withdrawn, keeping the finger for a few seconds upon the place to prevent the fluid exuding. stain of blood should follow the use of a fine steel needle properly used. Immediately after use, both syringe and needle should be carefully cleansed by warm water being passed through them. The finer the needles, the more are they apt to block. So much for the little operation which, comparatively painless and simple, has perhaps relieved more suffering than all our remedies combined. There are a few people who cannot bear morphia, in any form or dose, however administered, and to such it should not be given, but many will bear it hypodermically who cannot take it otherwise. The dose indicated, one-twelfth of a grain, is a safe one to begin with, and from its effects some judgment may be formed as to what can be given safely, consistent with relieving pain. One-sixth of a grain is perhaps as large a dose as any unprofessional person should venture on without professional sanction.

The writer is well aware that a strong prejudice exists with many against the hypodermic use of morphia, one argument being that once begun it is never left off. This is a complete fallacy; after a very large experience, the writer never knew of but one instance, and then it was a substitute for brandy, in which morphia so given was continued viciously. Certainly, in some exceptional cases, the use of morphia hypodermically might prove extremely prejudicial. A great blessing, it is capable of being converted into a curse. To some, opium in any form is as seductive as alcohol is to others, and, strange though it may seem, the use of it in the form of morphia, hypodermically, is specially so. The writer of this article would indeed regret, if, in giving directions for the legitimate use of this powerthe needle, before the morphia is used, to ful drug, he should lead any to use it as an

HYP HYS

tions of health, mental and bodily, and even of life itself. But the abuse of a remedy must not blind us to its real, God-given use and value. In cases of incurable and painful disease, such as cancer and the like, it has been a most merciful boon, for which both patient and physician might thank God. This paper will not remove the prejudices of many, but that would be no reason for not placing the instructions in proper hands, and thus giving the means of saving hours, perhaps days, of agony

to suffering fellow creatures.

Ergot of rye, or rather its active principle Ergotine, was named as the only other medicinal agent to be used by unprofessional hands, but this too might do so much to save, not pain, but life, that its use ought to be known. In bleedings generally, it is most efficacious; but in bleeding from the lungs, bowels, or womb, perhaps no remedy is equal to it. The chief difficulty is to get ergotine pure, and to keep it, but an excellent preparation is now made by Mr. Hugget, of Liverpool. Of this ten minims contain three grains of ergotine, the proper dose to be injected by the needle in case of any severe bleedings occurring as indicated above. The rules for injecting ergotine are the same as those for morphia, only both syringe and needle require more careful washing out. (S. T.)

HYPOGASTRIUM.—See ABDOMEN.

HYSTERIA is a disease more particularly manifested through the nervous system, and is, almost without exception, peculiar to females between the age of puberty and the fiftieth year of life.
"Hysteria" is from the Greek word for

the womb; it was supposed that the disease arose from disorders of that organ; but it quite as often arises from irritation of other organs, such as the stomach and bowels; in a person predisposed to it probably any uncomfortable

sensation may initiate an attack.

Hysteria may manifest itself particularly in three different modes. First, either as a pure nervous and spasmodic affection; second, as a simulator of other and more directly definable disease; and third, as a modifier of other diseases really existing. The varied forms of hysteria, and the way in which it modifies and masks, or closely simulates other more important affections, is apt to render it at times one of the most puzzling disorders with which the physician has to deal; it is one, moreover, especially liable to mislead the young or inexperienced practitioner.

A fit of hysteria may assume different forms, but, generally, the female becomes, apparently of a sudden, partially insensible, it may be, falls down, but more generally has sufficient warning to seat herself on a chair; the eyes are closed, the lids tremulous, the limbs are stretched out, and spasmodically and suddenly contracted at intervals, or there is violent tend to develop the hysteric tendency; and,

indulgence, a vice that would sap the founda-|struggling; the chest heaves, the heart and vessels of the neck beat violently, the face is more or less flushed; frequently, the patient puts the hand to the throat and neck, as if to dispel some uneasiness, and not uncommonly gives utterance to incoherent or disconnected sentences, generally in a peevish or distressed tone of voice. In most cases the power of supporting the body when seated remains, unless it is worked off the chair in the struggles. At length, the attack, having lasted for a longer or shorter period, from a few minutes to some hours, terminates, probably with a fit of sobbing and crying; the patient recovers consciousness, but is left exhausted and fatigued with the efforts and struggles, and, perhaps, falls into disturbed or heavy snoring sleep. When a fit has terminated, or even during its progress if continued, the kidneys act very freely, and large quantities of urine, almost resembling pure water, are voided.

Such are the leading features of a "fit" of hysteria, but they may be greatly varied; the struggles, especially, being so violent as to require the assistance of two or three strong men to restrain a comparatively feeble female, and to prevent her injuring herself, and some-times, though not commonly, those around

Such are the outward manifestations of a fit of hysteria; but before it comes on, many patients complain of a sense of general oppression or uneasiness, with coldness or numbness of the limbs. Just previous to the accession, the characteristic hysteric "globus," or ball in the throat, is probably felt; it seems as if a ball commenced rolling upwards in the bowels, generally from the lower left side, and as if it kept gradually ascending towards the throat, which it seems entirely to fill up, causing those sensations which induce hysteric patients so often to carry the hand to, and pull at the fore-

part of the neck or throat.

It would serve no good purpose here to follow the history of hysteria into the minutiæ of its various phases. It might be said, that there is scarcely a disease to which the human body is liable, which it may not simulate so closely as to call for all the tact and discrimination of the physician to detect the difference between the two. Continued, incessant, hard cough, loss of voice, delirium of various kinds, paralysis, contractions of the limb, obstinate vomiting or constipation, nay, even pregnancy, may be enumerated amid the various simulated conditions. Neither would it be profitable, in the present work, to enter into an investigation of the way in which the hysteric tendency will modify the various diseases to which the body is liable; this can only be conducted by the modified and the conducted by the conducted be conducted by the medical practitioner; but it is a matter of importance, that not only parents, but that the individuals themselves should be aware of those habits, &c., which

HYS HYS

further, that the best mode of managing a circumstances, it is not to be wondered at if hysterical individual during the fit, and in the absence of a medical man, should be under-

During the continuance of a fit of hysteria, little either need or should be done, beyond preventing the patient hurting herself during the struggling. Cold water dashed upon the face may be useful, or it may be poured in a stream upon the head for a few minutes at a time, from a ewer or large jug; literally putting the patient under the pump is the best remedy. If there is much flatulence, a teaspoonful or two of sal volatile in water will give it relief. It must be remembered, that in most cases of hysteria, the patient is sensible of what is going on around, and may, in the excited state of the nervous system, be painfully alive to any unguarded or unfavourable opinions uttered by those in attendance; for this reason, it is not to be recommended that, as sometimes is done, severe and violent remedies should be proposed within hearing of the patient with the view of frightening her out of the fit; such a course has had the opposite effect, causing an aggravation of the symptoms. This is a different thing from threatening severe remedies whilst the patients are comparatively well; such a plan of treatment, it is well known, has often succeeded in putting a stop to the spread of hysteria—by imitation through schools, or similar gatherings of young females.

The exciting causes of hysteria are, remotely, whatever tends to exalt the influence of the nervous system. Among the moderately-fed and hard-working population in the country, hysteria is comparatively rare, but it is not unfrequent in servants who remove from the poor living of their own homes to the stimulating diet of a rich man's house. Most generally, hysteria, although in some degree the result of constitutional tendency, is connected with debility, and irregularity of the usual conditions of female health, all these being aggravated by emotions of the mind, particularly those which are connected with the affections; these, too, when in direct excitement, as well as inordinate physical exertion, which produce exhaustion of the nervous system, must be ranked as among the most general directly originating causes of the hysterical fit itself. If, however, mental influences either of excitement or of depression, connected with the affections, are apt to occasion hysteria, excitement of another kind has been found to be one of the best counter-agents of the morbid tendency. It has been remarked, that amid states of great public agitation, such as revolutions, hysterical affections have decreased in frequency; and instances often occur, of women subject to frequent attacks of hysteria as long as easy circumstances permitted self-indulgent habits, losing the tendency when reverse of fortune or some other cause has forced them into active exertion. Under these

marriage, with its new cares and duties and

interests, often cures hysteria.

The prevention of a disease, or of the tend-ency to it, must ever be the most important consideration connected with it, particularly when, as in the case of hysteria, prevention is very possible. Experience testifies to the much greater frequency of hysteria among those classes whose mode of life is comparatively indolent and luxurious, being, in fact, that best calculated to develop those hysterical tendencies, of which the foundation is too often laid in the absurd education of the girl. This subject has been sufficiently entered into under the head of education, and requires no further amplification here; suffice it to say, that those who would not have their daughters grow up subject to the miseries of "nervous-ness," should use the rational means of developing their physical health, and give them those habits of healthful exertion, both of body and mind, which, carried up into womanhood, will be the best preventives of hysteria, with its long train of exaggerated ideas and exaggerated ailments, which are too apt to render single life useless and a burden, and, if long continued, to make weak mothers and nurses, if marriage is entered into.

As regards the treatment of the hysterical tendency, it is needed to say but little in a work like this, beyond the enforcement of those general means of health which are laid down in the various articles. As regards medicinal treatment, it requires to be so varied according to each particular case, that it can only be rightly conducted under the care of a medical man, and in a disease like hysteria, long continued, and also a concomitant of artificial life, medical assistance always can and should be

procured.

Lastly, although hysteria may be dependent on physical derangements, it must be considered as a disease to a considerable extent under the control of the will, and this fact should be strongly urged upon the subjects of it, even when they are sufficiently sensible, as they most generally are, during the existence of a fit of the disease. is a disease which lives and grows on superabundant sympathy and attention, and whilst all kindness and consideration is shown, it is wonderful how much good may be derived from a little wholesome neglect. recommending that the medical treatment of the hysteric tendency should be committed to the medical man, it is right to caution, that there is always much tendency to a confined, and, consequently, loaded state of the bowels, which it is highly necessary should be obviated. The compound colocynth or compound rhubarb pills, compound decoction of aloes, infusion of senna, or enemata, will be found the best adapted aperient remedies.

Refer to-Imitation.

IDI ICE

the action of cold, or more correctly by the abstraction of heat, is often an agent of the greatest value in the treatment of disease-one, indeed, for which there is at times no substitute. As an external application, when cold is desirable for the purpose of reducing the heat of any particular part, such as the head, ice manifestly offers the most efficient means; it may either be permitted to dissolve in the water in which the clothes are dipped, or, better, it may be pounded and placed on the part in bladders, or in ice-bags made of India rubber, which are manufactured for the purpose (see India Rubber). As an internal remedy in inflammatory affections of the stomach, in obstinate vomitings, in fevers and in hysteria, small fragments of ice swallowed frequently, or allowed to dissolve in the mouth, are, often, not only of the most essential service, but the remedy is one most agreeable to the feelings of the patient. Under the article Hydrophobia, it was stated that ice used in this way had afforded comfort, at least, to a Of late, the action of the extreme cold produced by the admixture of pounded ice and salt, has been introduced as a local anæsthetic, and as an external remedial application in neuralgic and other similar affections. The treatment consists in partially freezing the affected part, and is often successful; it is, of course, not adapted for unprofessional use. In inflammatory affections of the throat and upper part of the windpipe, either the result of cold, or of accident, such as that which so often occurs to children in consequence of their swallowing boiling water from the spout of a kettle, ice given in small frequently-repeated morsels will be found at once one of the safest, best, and most agreeable remedies. Ice taken internally should be obtained from a pure water. Refer to-Cold.

ICED DRINKS, or ICES, as articles of luxury, if taken moderately, cautiously, and slowly, and when the stomach is not full of food, are not injurious to healthy persons. It was found, however, in Dr. Beaumont's experiments, that cold fluids and the like produced a reduction in the temperature of the interior of the stomach some 20° or 30° Fahr., and that the organ did not recover its proper heat for some time. As, however, the natural temperature of the stomach-about 98° Fahr.-is necessary for healthy digestion, it is evident that the custom of eating ice after dinner, or after any full meal, must materially interfere with the disposal of that meal. It is right that people should be aware that draughts of fully iced milk may, and have, proved fatal-the lump of iced curd which forms in the stomach acting, probably, as a profound depressant upon the sympathetic nervous system.

Refer to—Indigestion.

ICELAND MOSS, which belongs to the class of lichens, in some degree resembles the happened to be placed, but their mental condi-

ICE .- Water solidified or crystallised by | lichen which grows upon the trunks and branches of trees; it is, however, more of an olive-green colour. Iceland moss is found abundantly in the country whence it derives its name, but also in Northern Europe generally, and in Britain. It has been long noted as a nutritive remedy in cases of debility, and, when prepared for food, is frequently first soaked in water, to deprive it of its bitter principle; it is a question, however, whether this proceeding does not materially interfere with the tonic properties of the remedy. Iceland moss may be prepared in a similar way to Carrageen, moss (see Cookers). The Saxon Carrageen moss (see Cookery). The Saxon government published a report upon the nutritive value of the lichen a few years ago; in which we are informed, that six pounds eleven ounces of lichen meal, boiled with fourteen times its quantity of water, and baked in this state with 39½ pounds of flour, produced 111½ pounds of good household bread. Without this addition the flour world with out this addition, the flour would not have produced more than 784 pounds of bread, consequently the addition of six pounds eleven ounces of lichen meal, occasioned an increase of above thirty-two pounds of good bread, this increase, however, being owing, of course, to additional water. A demulcent decoction of Iceland moss may be prepared by boiling an ounce of the moss in thirty ounces of water, until it is reduced down to twenty ounces; a wine-glassful to be taken occasionally.

ICHOR is a thin, acrid, often brown or

bloody-looking discharge from wounds or ulcers.
ICTHYOSIS.—A disease in which the skin

becomes covered with thick hard scales, which make it, in some degree, resemble the skin of a fish. The disease is often hereditary and usually congenital, and is peculiar to certain districts. It is of a very intractable nature .--

IDIOCY and IMBECILITY may be regarded as degrees of deficient mental manifestation, consequent upon a similar disordered or defective state of the brain. Some have defined the difference, that idiocy is congenital, and imbecility acquired; but, generally, imbecility is regarded as a minor degree of idiocy.

An idiot has been defined as one "who knows nothing, wishes nothing, and can do nothing," whose instincts scarce prompt him to seek food under the pressure of hunger; from this lowest condition of all, up to the weak mind or judgment, every shade of idiocy, weak intellect, imbecility or silliness, is met with, and all perhaps are, more or less, capable of im provement, by means of attention to the physical health, and by education of the faculties.

Till within the last few years, the general idea has been, that idiocy was incurable; the unfortunate beings, whether in the families of the rich or of the poor, were allowed to grow up, their physical wants attended to in accordance with the circumstances in which they

nately the error has been exposed, and institutions, both in this kingdom and on the Continent, are now in successful operation, for the end of elevating these unfortunate beings from their debased position. The fact, that idiocy has been regarded too much as a fault of the mind alone, independent of physical influences, has tended in some degree to interfere with the efforts for its amelioration. Attention to the physical health is a matter of paramount necessity. In the case of the cretins of Switzerland, this fact is peculiarly manifest.

Enough has been said to give hope to those who number among their families an idiot, that something may be done to ameliorate the calamity, and to induce them, as soon as the condition of the idiot child becomes manifest, to place it, or, if possible, to get it placed, under judicious management at an early age. Dr. Forbes Winslow remarks with regard to the causes of idiocy: "The great mass of idiots are said to spring from an unhealthy stock, and have either been the children of idiotic parents, or of those of vitiated organisations, of scrofulous diathesis, or of intemperate habits. Three hundred idiots were ascertained to have been the children of drunkards." Dr. Winslow also refers to the effects of intermarriages of near relatives, and to the influence of the mind of the mother, as well as that of the father, upon the condition of their offspring.

IDIOPATHIC is a term applied to disease

in which the cause is not apparent.

IDIOSYNCRASY is a peculiar state, either mental or physical, which renders an individual more than usually susceptible to certain influences, which do not affect the generality of persons. Thus, some cannot take the smallest dose of any mercurial without suffering from it constitutionally,-that is, being salivated, -owing, as it is expressed, to their peculiar idiosyncrasy: another cannot eat the pip of an apple, a bit of almond, or indeed any of the seeds belonging to the same family-which contain prussic acid-without suffering from cutaneous eruption. These, and numerous others which might be cited, are instances of peculiar idiosyncrasy, and probably every one is subject to such influences in some way or other; every one, probably, has his idiosyncrasy, whether he is aware of it or not. Mental idiosyncrasies are not less common than physical, and neither for one or other is it possible to fix on any assignable cause. It is, however, a matter of considerable importance, when any peculiar idiosyncrasy exists, more especially with regard to medicines, that whenever a medical man is consulted for the first time, he should be informed of it. As there is no traceable cause for idiosyncrasy, it cannot become known to a medical adviser, except by experience respecting his patient's constitution, or by information given him. The

tion left without attempt at cultivation. Fortu- | latter should always be given at a first visit. It is a very annoying circumstance for an invalid, to find that he has unwittingly taken a medicine which invariably disagrees, and equally annoying is it for a practitioner, having every reason to expect benefit as the result of his prescription, to find that the case has, perhaps, to say the least, been unrelieved, simply because he was not warned that calomel invariably caused vomiting, that colchicum produced distressing nervous depression, or that senna griped most unmercifully.

ILIAC PASSION .- See Colic.

IMITATION.—The tendency to imitate, by which all, perhaps, but especially children, are more or less influenced, is, of course, an important consideration in the education of the latter, particularly with respect to the imitation of involuntary movements or peculiarities, such as stammering, squinting, &c., which young persons are very apt to acquire, if much associated with those who are the subjects of them. The power of the tendency to imitate in causing the diffusion of disease of the nervous system, such as hysteria, epilepsy, &c., is well known. Persons of susceptible nervous system, by exposure to the influence, that is, by witnessing the occurrence of the disease in another, may themselves become, involuntarily, imitators; in some cases, doubtless, quite involuntarily, without power of control, but in others only partially so. That in many cases the power of the will may prevent the manifestation or development of disease from imitation, has often been proved. The anecdote related of Boerhaave is known to most. This celebrated physician was consulted respecting the girls of a school, who, daily, one after the other, became the subjects of fits of hysteria, simply from imitation. Boerhaave had it made known that his mode of treatment must be to apply actual cautery, that is a red hot iron, to the spine. Not another case of hysteria occurred.

pervious qualities of this most useful substance, both in its natural condition, and in its numerous preparations, have been abundantly taken advantage of, in the formation of various sick-room appliances, instrumental and otherwise, of which the water or air-bed and cushion, the enema syringe, catheters, pessaries, and water-proof sheeting, are among the most familiar examples. Mr. Hooper of Pall Mall, who was among the first to introduce these useful appliances, continues to adapt the pure rubber to a variety of purposes, apart from the water bed and cushion, having ingeniously contrived to make it available for bed-pans, bed slippers, ice bags, urinals, and other portable apparatus in common use. Fig. 129, A, B,

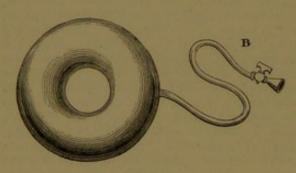

Fig. 129.

represents the horse-shoe, and round forms of the ordinary water cushion, as they may be employed to relieve pressure and prevent sores on parts liable to suffer from long-continued confinement in bed from chronic disease. India rubber hot-water bottle, of which an illustration is also given (fig. 130) is a most valuable invention, which is coming gradually into general use, as a ready means of applying a dry fomentation to any pained part of the body, and also as a convenient foot warmer. It is all the better for being encased in a woollen cover expressly made for it, or in a roll of Ice bags for the continuous application of cold are frequently referred to in the course of this work; the accompanying illustration (fig. 131) will convey an idea of the apparatus, which has now taken the place of the bladder, formerly employed with the same object. The ice bag is fitted with a cork of large size, is triangular in shape, and the bottom is made

wide and loose, to adapt itself to the irregular surfaces of the body, especially of the forehead and scalp, to which parts it is often ordered to be applied. In most cases, in consequence of the restlessness of the patient, it is necessary to attach the ice bag, by strings or bandage, to the parts affected, and it is absolutely essential

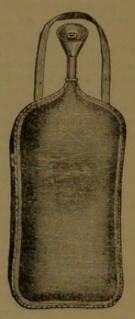

Fig 130.

that the supply of ice fragments should be kept up continuously to render it efficient. The India rubber sheeting employed as a protective to the bed clothes (often called "Mackintosh" from the original inventor), is a cloth covered either on one, or on both sides,

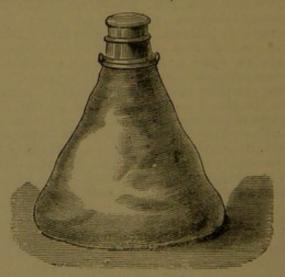

Fig. 131.

with India rubber, and is now universally employed for sick-room purposes. One of the most useful applications of India rubber may be found in the air pad, employed sometimes in trusses, and for a variety of surgical purposes, where it is desirable to sustain an equable pressure on any part of the body. The air

IND IND

will, of any size likely to be wanted, and may be applied to any part, where they exert a gentle pressure, without causing the inconvenience or discomfort, which are occasionally produced by pads stuffed with less elastic material. The illustration (fig. 132) shows how fracture of the collar-bone may be treated by a pad of this

kind, placed in the arm-pit of the injured side, and supported by three of Esmarch's bandages (see Bandage), in the manner recommended by Dr. Eddowes.

Lastly, the India rubber bandages, elastic belts and stockings, are among the most valuable resources of modern surgery, and are especially useful in supporting and aiding the vinous circulation, where there is a tendency to a varicose condition and to ulceration.

INDIGESTION, or DYSPEPSIA.—Under the article Digestion, to which the reader is referred, those conditions which are requisite for the healthy performance of this important function were pointed out. It was shown that the due mastication of the food by the teeth, and its admixture, particularly when of a farinaceous character, with the saliva, were essential to its perfect digestion in the stomach by means of the gastric juice, and in the alimentary canal generally, by means of the various secretions which become mingled with the food mass during its progress through that tube. It was further pointed out, that not only is a healthy condition of the organs of digestion themselves requisite for the proper performance of their functions, but that the food must, in some measure at least, bear a relation to the natural

pads are usually made so as to be inflated at | at large influences considerably the exertion and progress of the digestive powers; that is, to ensure the vigorous putting forth of those powers, the system must stand in need of the supply of nutriment which the stomach is called upon to elaborate; and partially at least, and for a longer or shorter period, its efforts must be devoted, in efficient co-operation with those of the stomach, to the preparation of the nutriment for its own requirements-plastic material for its tissues, respiratory elements for its animal heat.

When it is considered how much the stomach is under man's regulation and control-how dependent its management is upon his external relations, his habits and caprices, whether these affect it directly or indirectly—it can scarce be a matter of surprise, that in the present condition of mankind, indigestion is universally admitted to be the most common of all disorders. The savage, with his long periods of fasting, terminated by a gluttonous meal of perhaps indigestible, or, if cooked at all, badly-cooked food, suffers from it; the pampered, the luxurious, and the indolent suffer from it; the over-wrought in body, and the over-taxed in mind, are all liable to dyspepsia in one or other of its varied forms. It is, in fact, one of those maladies most closely and evidently connected with man in a state of disorder, or of vice; or of ignorant or wilful disregard of all the conditions of health, either by the individual sufferer himself, or by those from whom he is descended.

Many varieties of indigestion are enumerated; in the present work, it will serve every practical purpose to consider the disorder in the first place, as dependent upon causes directly connected with the digestive organs themselves; and in the second, as indirectly dependent upon causes which, although manifested through the digestive organs, are traceable to certain disordered conditions of the system in general, or of some of its organs not specially devoted to the preparation of

It is unquestionable that there exists great difference in the natural digestive power of different individuals; even in childhood this is evident; and when weakness is evinced thus early, it must be considered as a tendency congenital in or natural to the constitution, which will probably continue with it during life. Persons thus constituted, even as children, cannot eat the food-either of the same quality, or in the same quantity—that their stronger companions do; and if they occasionally do so, or, as too often happens, are forced to do so, sickness and vomiting frequently follow. Such individuals, their whole life through, are liable to dyspepsia; with all their care they cannot always escape its visitations, even under the most favourable circumstances; and constitution and assimilative powers of these organs; and, lastly, that the state of the system shops, counting-houses, and the like, they are

IND IND

except when their stomachs are empty, and not always then. It is very common to hear such persons say: "If I could live without eating I should be perfectly well." They are always conscious of sensations in the stomach, it is generally most comfortable when free from food, but even in its state of rest is apt to be the seat of pain, or of craving or gnawing uneasiness. After a meal has been taken, instead of the satisfied feeling of health, the stomach and bowels generally feel distended; perhaps there is tolerably acute pain; windy, and acid, very acid, eructations quickly follow; there is heart-burn, perhaps headache, sometimes, though not often, vomiting, and these symptoms continue, with more or less severity, till the food has passed off the stomach in some condition or other. After this there is a state of comparative comfort. Along with these periodical dyspeptic symptoms, the tongue is at all times more or less furred, especially at the back part; on first waking in the morning this furring is notably increased, and the mouth is almost invariably dry; the bowels are costive; the hands and feet are almost always cold, and the face is very liable to be the seat of pimply eruptions. Notwithstanding all these symptoms, the appetite often remains good, too good in fact for the

digestive powers.

With such persons, the slightest indiscretion or excess in diet, is liable to bring on protracted fits of aggravated dyspepsia: a little additional anxiety of mind, a little extra fatigue, is almost sure to put them wrong. But yet these species of indigestion, which belong to the atonic or weak form of disorder, seldom tend materially to shorten existence; many pass on from year to year, throughout a tolerably long life, without being a single day quite free from its visitations. It may be that the care they are compelled to take saves them from many of the sources of disease to which those who do not know they have stomachs, and who can take any liberty with them, wilfully expose themselves; but so it is. Medicine (that is, drugs) does but little good in this form of indigestion, except in its occasional aggravation, and aperient remedies, habitually and frequently taken, materially increase the natural weakness of the digestive powers. The best remedies are, strict attention to the laws which regulate health, and to the means of invigorating the constitution. When a young person shows the tendency, the fact ought to influence the choice of the employment for life: if possible, all such as involve close confinement at desks, or work which calls for much wear and tear of brain, should be avoided; agricultural and similar pursuits, which require regular exertion in the open air, should be chosen. A man had better earn his daily bread by the—literal—sweat of his brow—earn as Abernethy used to stimulus, and no sooner does it get it, than it

perfect martyrs to the disease-are never happy | say, a shilling a day, and live upon it, than be a miserable hypochondriac, dyspeptic, valetudinarian, in the more dignified study or office. In the form of indigestion we are considering, particular regulation of the diet is worse than useless; and especially the confinement, once so fashionable, to two or three articles of food —to wit, mutton chops, brown bread, &c.—considered more than usually wholesome. The healthy, strong stomach craves for and requires change, still more the weak one. There are, it is true, certain general rules of diet, such as the avoidance of pastry, cheese, and such-like well-known indigestible articles, to be observed; but this is different from the minute considering, nay, almost the weighing and measuring of food. Nothing is so liable to aggravate and perpetuate a tendency to dyspepsia, as the constant attention to the actions and capabilities of the digestive organs, which minute dietetic regulation involves. It is a welldietetic regulation involves. known fact, that organs, such as the heart, not usually under the influence of the will, may in the course of time come to be affected thereby, if the attention be frequently directed to the organ, which, as a consequence, becomes disordered in action. This is well exemplified in the act of breathing; this function, though generally performed involuntarily, may nevertheless be sensibly affected by the will, and if any one tries to regulate his breathing by his own will, it quickly becomes most fatiguing and necessarily embarrassed; so it is with the stomach, there is no surer way of disordering its functions than by keeping the mind continually attending to its operations. A dyspeptic is more likely to get quit of his complaint by casting aside restraints of diet, if he at the same time untrammels his mind, than by the constant minute dieting, and reference to tables of the digestibility of whatever he eats; within certain limits, a latitude and variety is absolutely necessary. The dyspeptic who, instead of trusting to attention to the general laws of health, trusts to limiting his food to such things as he finds, or thinks he finds, his stomach capable of digesting comfortably, will shortly get himself driven into a corner by the enemy; water-gruel and sago pudding will succeed the mutton chop and bread; and at last, the stomach, so long allowed its choice of work, refuses it altogether, and reduces its possessor to despair. author has known such cases, and the very despair has worked its own cure; the dyspeptic has made a rush at some long-dreaded or forbidden viands; a beef steak and a tumbler of porter are perhaps taken, with some floating idea of its being a suicidal act, and, much to the surprise of the despairing invalid, they seem to take up their quarters, and to be most

may be that it will not continue thus after a few repetitions to respond to the stimulus so vigorously; but if reasonable judgment and moderation are exercised as regards food, if the person trusting to the unexpected power does not run into excess, the reverse of his former abstemiousness, and if he attends to the general health and strength, especially, if possible, by means of change of air and scene, he may to a great degree get the better of his former miserable condition. The above case is put to demonstrate that ultra-dietetic regulation is not only useless, but worse than useless in cases of atonic dyspepsia generally, and a large proportion of the cases of the disorder met with in medical practice are of this class; not, it is true, of hereditary or congenital origin, or of life-long continuance, but still, long-continued cases, the effects of the various debilitating and depressing influences which affect the citizens of large towns; the deficient supply of fresh air, and the contamination of this vital element by noxious emanations, the contamination of water, the close confinement and anxiety of business, and the hurried meal, all tend to produce the form of atonic dyspepsia. Such cases may perhaps be relieved temporarily by medicine and regulation; but they have but little hope of cure, without removal from the causes which originated them; they are the cases which confer celebrity upon watering places, and would confer celebrity on any place which happened to become their resort, provided it offered plenty of fresh pure air, and relaxation from care and anxiety. It matters but little-water cure, in moderation, grape cure, sulphurous or chalybeate springs, sea bathing, or shampooing, even homeopathy, will suffice-the atonic dyspeptic will get well under the influence of the natural stimuli of fresh air and cheerful exercise.

Persons who suffer from the above form of dyspepsia, if they have been accustomed to the use of alcoholic stimuli, cannot leave them off, at least when following out their usual mode of life, without risk of having their ailments much aggravated, and suffering much both from mental and physical depression. They must, moreover, carefully avoid whatever tends to exhaust the powers of the system, long fasting, long fatiguing walks, especially before breakfast, active exertion or severe study soon after a meal, are all injurious to them. Their digestive organs are so comparatively feeble, that for the first stages of their operation they call upon the whole nervous energies of the system for assistance, and if these energies are called off for other purposes, the func-tion of digestion necessarily suffers. It matters little whether the nervous exhaustion or derivation takes place immediately before or after the meal, the effect is the same. Persons who

rouses to the proper exercise of its powers. It | in consequence of the nervous power going to the stomach instead of to the muscular system.

The next form of indigestion to be considered, partakes more of strength than weakness; it occurs in persons of naturally good constitutional powers and digestion. It may be brought on by indolence and close confinement, but is more generally induced by excess in eating and drinking, and is, in most cases, connected with more or less biliary disorder. The appetite fails, the tongue is much furred, there is often sickness and vomiting of bile, the bowels are rather irregular than confined, the urine is high-coloured and deposits red or pink sediments, there is heart-burn and acidity, and generally headache, often pain between the shoulders extending to the back of the head; the condition, in fact, is in great degree similar to that which precedes an attack of British or bilious cholera, and often ends in a "sick headache," or "bilious attack." In this form of dyspepsia, abstinence and exercise may effect a cure, but it is much facilitated by proper medicine; it is in such cases, that the calomel, or blue pill and black draught method, are most useful, if properly employed; the system at large, and the whole of the digestive organs, are oppressed and over-loaded, and one or more doses of the above medicines clear them in a way that nothing else will, bringing away large quantities of acrid, dark bile, with immediate relief. After this remedy has been repeated, the bowels ought to be kept lax by means of the blue pill and compound rhubarb, or blue pill and compound colocynth pill at bed-time. If the tongue remains furred, and the appetite deficient, two or three doses during the day, of effervescing mixture, with the addition of a tea-spoonful of tincture of calumba, or of tincture of gentian, to each, will be of service; or a mixture composed of a drachm of carbonate of potash, half an ounce of nitrous ether, and twelve ounces of infusion of calumba or of gentian may be used, a wine-glassful being taken twice a day. In this form of dyspepsia also, the infusion of dandelion, either alone or combined with one of the bitters, is very serviceable. This form of dyspepsia does not call for change of air and scene as the first-mentioned does, although unquestionably - especially if the attack has been a severe one-these remedies are of service, if taken advantage of after the organs have been relieved, and the functions regulated by medical treatment.

A very necessary caution is requisite with respect to the management of this form of indigestion. The immediate and striking relief which follows the clearance of the liver and digestive organs, by the use of the mercurial and purgative, is very apt to induce people to trust to this means of cure, or rather of relief, and to disregard all those methods of selfmanagement and self-restraint which would suffer from this form of dyspepsia, almost in-variably experience languor after a full meal, tute, nothing which will so completely, at the

IND IND

outset of the treatment of a case of this form | as bicarbonate of soda in ten-grain doses, two of dyspepsia, clear away the causes of its symptoms, and leave a good foundation for after treatment and management; but to trust to this mode of relief alone, and from time to time to persevere in those habits of self-indulgence and of excess in which the disorder originates, is most dangerous, and must, sooner or later, lay the foundation of disease, or at least substitute for the dyspepsia of a strong stomach that of a weak one, and with it of a weak system generally.

The form of dyspepsia of which we now treat is, in so great a majority of instances, the result of excess in eating or drinking, and of inattention to proper exercise, &c., rather than of any real weakness of digestive function, that there are few who suffer from it, who might not enjoy, under proper restriction, the best

possible health.

The two forms of indigestion above treated of, that which results from weakness, and that which does not, may be taken as the types of dyspeptic ailments generally, and all incline, more or less, to one or other of these divisions. To enter into the varied phases which cases of indigestion assume, and to detail the varied symptoms they present, would demand a volume of itself. Although, therefore, in this article, less is said than in most others respecting application to a medical man, it is not because it is not highly desirable in all cases of continued or aggravated indigestion; there are often so many anomalous symptoms, and the disorder is frequently dependent upon so many causes which skill and experience only can detect, that it is the safer and wiser plan to take advantage of these guides whenever pro-

One of the most general features of dyspeptic disorder is the mental depression, often amounting to Hypochondriasis, or even Monomania, which accompanies it. In sufferers from the atonic and continued condition, this is more apt to take the form of constant dwelling upon symptoms and feelings, and magnifying their importance; in fact, such persons' whole time and attention seems to be occupied in registering the various sensations they experience in the course of the day; and, if attended by a medical man, they do not failif allowed-to trace the turning and winding of every pain and ache, how much and what they ate for the last week, and so on. In the form of indigestion less connected with constitution, the spirits are apt to be more regularly depressed, and more decidedly hypochondriacal, or even, in some, suicidal emotions are felt. In many cases of indigestion the urine becomes loaded with gravel (uric acid), and sometimes crystals of oxalate of lime are found in it. This condition is most commonly found amongst those who live well, and indulge largely in fermented liquors, and is best provided against by abstinence and alkalies, such graver character must at least be watched for.

or three times a day.

Headache, which is so frequent an accom-paniment of indigestion, arises from very various and very opposite causes. The most general headache, is a dull persistent pain over the eyes, which comes on from half an hour to two hours after food, and seems to be connected, so to speak, with a negative or inactive condition of the stomach, on which the food remains with but little change. This kind of dyspeptic headache is accompanied with dulness of the mental powers, and incapability of their exertion. It is best relieved by whateve stimulates the stomach: a cup of hot tea, a glass of wine, an effervescing draught, and often a spoonful of vinegar will relieve it, the acid seeming to alter the activity of the nerves, for whatever may be the cause on which the symptom depends, even acid generated in the stomach itself will cause its disappearance, and persons who suffer from this headache, are often aware that it will probably subside as soon as heartburn begins. The same description of headache may be produced in persons of weak stomach by a dose of soda or magnesia, or by any article of food which does not stimulate sufficiently the stomach and its nerves. A headache, exactly the reverse of the foregoing, is caused by the presence of superabundant acid, and is, of course, relieved by the alkaline remedies - carbonates of ammonia, soda, or potash, which neutralise the acid. Persons liable to indigestion often suffer also from various forms of nervous headache, from giddiness, dimness of sight, &c. The chest comes in for its share of disorder when indigestion exists. A peculiarly irritable "stomach cough" is not unusual; palpitation of the heart is almost a constant attendant upon the condition, and shortness of breathing often results from pressure exerted upon the chest by the stomach distended with gas. Indeed, there is scarcely a symptom which may not, some time or other, be met with, traceable to disorder of the digestive powers. The sympathetic connections of the stomach, and its office as preparer of the nutriment which is to supply the body, necessarily make its derelictions felt throughout the system; and gout, gravel, rheumatism, cutaneous affections, scrofula, and indeed most other disorders, may at times be distinctly traced back to faulty digestion. Moreover, the abundant sympathetic connections of the stomach make it liable to be affected by the state of, as well as to affect, distant organs; and it not unfrequently happens, that obstinate cases of indigestion turn out to be not so much the consequence of disorder of the stomach itself, as of its sympathy with disease going on else-where—in the heart, the kidneys, or womb; when, therefore, indigestion, in spite of all proper regulation and treatment, continues to harass a patient, something of a deeper-seated and

IND INF

Nervous pain at the stomach, also called | difficulty in determining the treatment and gastrodynia, is one of the most painful forms of indigestion, sometimes coming on when the stomach is empty, sometimes after eating. The disorder ought to be treated by a medical man. If there is much tenderness, a few leeches, followed by blister or mustard-plaster, may be applied to the pit of the stomach. Bismuth, in five-grain doses, twice or thrice a day, will sometimes relieve; the author has found the oxide of silver, in one-third of a grain dose, as recommended by Sir James Eyre, of considerable service in some cases. In this affection of the stomach, as well as in other forms of dyspepsia, the rhubarb and magnesia mixture, with or without the addition of sal volatile, is often very useful. When the pain is present, and very acute, a cup of hot water, swallowed as hot as possible, is often of service, with the addition, if there is acid on the stomach, of fifteen or twenty grains of carbonate of soda, or as a possible addition, four or five drops of laudanum, or chlorodyne. A mixture containing ten grains of the subnitrate of bismuth, the same amount of carbonate of soda, and ten drops of the solution of morphia for a dose, may be given three times a day. In many forms of indigestion, and especially when, as is often the case, the disease is a distressing accompaniment of consumption, benefit is derived from the use of pepsin, either in the form of powder, of which five grains may be taken three times a day, between thin slices of bread and butter, or as pepsine wine in doses from a tea-spoonful to a table-spoonful three times a day. In some cases the maltine preparations combined with peptones give much relief. When the pain amounts to spasm, it must be dealt with as recommended in the article on the subject.

The principal features connected with indigestion have now been enumerated; a short general recapitulation of the subject will probably make it more clear to the mind of the unprofessional reader. The first form of indigestion noticed, was that dependent on weakness: in this it may be taken as an axiom, that it is better to bring the stomach up to its reasonable work, than to reduce the work to suit the enfeebled powers of the stomach. doing the former, the whole system must be attended to and strengthened, and the stomach made to participate in and to give its proper aid to the strengthening process; in attempting to do the latter, not only do the powers of the stomach become less and less, shrink away as it were from their work, but the whole system partakes of the enfeeblement.

In the second form of indigestion adverted to, that accompanied by strength, or at least not dependent on weakness, it was shown that medicines and abstemiousness offered the proper means of relief. Lastly, the varied forms, systems, and connections of dyspepsia, were

true nature of the case, and to impress the unprofessional reader, that when suffering from anything more than transient indigestionunless indeed his be one of the cases of consti tutionally feeble digestion-the safest, best, and perhaps most economical plan, will be to put himself under proper medical care. Above all things, those who suffer from the form of indigestion dependent on weakness, must beware of purgatives; nothing so completely debili-tates whatever digestive powers they may possess. The bowels perhaps (probably) may be regularly costive, but they must be, as a rule, regulated by injections or by small doses of castor oil.

INFANTS .- See CHILDREN.

INFECTION.—See CONTAGION — DISIN-

FECTANTS, &C.

INFLAMMATION is an action set up in the living body, which is characterised by redness and swelling of the portion affected, and also by an increase of temperature and When these phenomena occur on a pain. visible part, they are recognisable by all, but when they occur internally, their presence must be judged of by concomitant symptoms. Few diseases are unaccompanied by inflammation in a greater or less degree in some part of their course, and many seem to owe their characters and influence chiefly to its presence.

Nevertheless, inflammation is not solely a process of disease tending to disease, it must accompany the reparative action of the wound or fracture; in other words, the means of reparation are the consequences of inflammation and one of its "terminations." When inflammation of a part occurs, the chief effect is, determination of blood to it, the stream being quickened in some parts, and in others impeded, whence arise the characteristic redness and swelling, heat and pain, the latter, especially, being the result of pressure on the nerves by the distended tissues. After the process has continued for some time, it may subside, the parts resuming the same appearance and action which they possessed before it arose. This termination of inflammation is named "resolution"; it is of course the most desirable of all, and to bring it about, the efforts of the medical man are directed. In the event of inflammation not terminating by "resolution," it may give rise to effusion of serum, that is, of the watery portion of the blood; this effect is familiar in the case of scald or blister; internally, it happens in pleurisy, in water on the brain, &c.

This effect of inflammation is, undoubtedly, in many instances, productive of serious consequences (see Pleurisy). A third most important termination of inflammation is the effusion of what is called "lymph," pointed out, to show how often there must be that is, of an adhesive-at first liquid, after-

wards solid-matter, which becomes a perma- | mation in some of its forms is going on within nent medium of connection between two parts (see Adhesion). As, however, this exudation of adhesive matter takes place as a necessary consequence of inflammation, in many cases irrespective of circumstances, it must happen that it is sometimes as much a source of injury, as it is at others of benefit; thus, in the case of inflammation within the abdomen, it may glue the bowels together; in the chest, it may fix the lungs to the side, or the heart to its containing bag. Nevertheless, even internally, it is often beneficial; it may seal parts together in such a way as to prevent the escape of matters, as for instance, from the bowels into the abdomen, which must otherwise have proved

But inflammation may terminate in none of the ways above-mentioned; it may go on to the formation of pus or matter, as in the case of abscess (see Abscess). Or ulceration may take place (see Ulcer), or, lastly, the vitality of the inflamed part being completely destroyed, mortification occurs, and the tissues slough or break down into one putrefying mass. These various effects of inflammation, are in some degree dependent upon the violence of the action in the first instance, but they are modified by the nature of the affected tissue. What has now been said, however, will demonstrate how closely this important process is connected with the whole science and practice of medicine, and how greatly all treatment must have reference to it, and, especially, to induce its termination in "resolution," which leaves the affected part uninjured in structure and func-

The means used to procure resolution of inflammation are bleeding, either general from the arm, or local by means of leeches, cupping, and counter-irritation, which relieve the overloaded and obstructed vessels; further, fomentations and poultices, that is, heat and moisture, which relax, and also relieve the inflammatory condition by their derivative action; also medicines, such as diuretics, diaphoretics, purgatives, &c. In some cases, when inflammation is seated on the surface, it is treated successfully by the direct application of astringents to the Thus, inflammation of the covering membrane of the eye is cured by an astringent wash, along with the more directly medical treatment; the diet in most cases of active inflammation requires great reduction.

In addition to the local symptoms of inflammation, there are those of the constitution, which always accompany the process, except in its most trivial forms. These are fever, in its most trivial forms. inflammatory, hectic, or typhoid, according to the nature and extent of the local affection, the part involved, or the constitution of the The first occurs, generally, in the active stage of inflammation; the second, should matter be formed; the third, if mortification or sloughing take place. When inflam- inflammatory affections are those of the brain,

the body, the blood acquires the peculiar property of becoming buffed, after it has been drawn from a vein, that is, instead of the clot formed by coagulation presenting a red surface, it is covered on the top by a tough yellow coat

of greater or less thickness.

Although redness, swelling, heat and pain, when combined, certainly indicate inflam-mation, they do not do so separately; the redness of blushing is no inflammation, and pain may result from spasm; swelling may be caused by simple effusion; heat by exercise. The above characteristic symptoms, moreover, are greatly modified by the site and nature of the inflamed part; the severity of the pain, especially, being by no means commensurate with the importance of the affected organ. Some parts, such as bone, which in their healthy state possess but slight sensation, become when inflamed most acutely sensitive. Further, in some respects, pain in inflammation is a deceitful guide; sometimes it is altogether absent when its presence might have been fully anticipated; and again, if felt, it is not perhaps at the affected part, but at some distance from As a general rule, inflammatory pain is increased by pressure, and is in this way distinguished from the pain of spasm. In some forms of inflammation, such as those of gout, rheumatism, &c., what is called "Metastasis" occurs, that is, the action seems to be transferred from one portion of the body to another (see Rheumatism). This tendency of inflammation may of course be exerted either for good or evil. Its good the physician tries to imitate, when, by blisters and other means (see Counter-Irritation-Derivative), he endeavours to produce inflammation artificially upon the skin, with the view of drawing it off from some more directly vital, and less accessible, organ. The causes of inflammation are very numerous; whatever irritates locally, as familiarly instanced by dust in the eye, will cause it; but it may also originate from causes affecting the constitution, such as cold, or it may arise in the course of constitutional diseases, such as fever.

Such are the principal general points connected with the subject of inflammation, with which it is expedient unprofessional readers should be acquainted; a clear understanding of them will tend greatly to assist the formation of rational and common-sense ideas respecting the nature and progress of disease, and will throw light upon some, at least, of the ques tions bearing on its rational treatment.

The inflammations which affect the body may

be classed as external and internal.

The external inflammatory affections, properly so called, are the various skin diseases, particularly erysipelas, which is, essentially inflammation of the skin; inflammation of the eye, ear, inside of the mouth, &c. The internal

croup, which affect the windpipe; and bronchitis, which is situated in the air tubes; also pneumonia and pleurisy, carditis and pericarditis, or inflammation of the heart and its

investing membrane.

Of the abdomen, the most important inflammatory diseases are those of the stomach and bowels generally, and of the other viscera, such as the liver and kidneys, and womb. In addition to the above, there are inflammations of the blood-vessels, especially of the veins, inflammation affecting the bones, joints, &c. All these are entered into sufficiently under their separate articles, with exception of inflammation of the lungs-pneumonia and pleurisyand inflammation of the bowels or alimentary canal, to which reference will now be made.

INFLAMMATION OF THE LUNGS.—The important organs of the lungs and bronchi (see Lungs) are liable to three distinct forms of inflammation-bronchitis, or inflammation of the bronchi, or air tubes; pneumonia, or inflammation of the tissue or substance of the lungs; and pleurisy, or inflammation of the pleural, or covering membrane of the lungs (see Chest). The subject of bronchitis has been fully entered into in its proper place. Although three distinct inflammations of the lungs are mentioned, it is not to be supposed that they are always distinctly separated practically; frequently they are, but they often coexist. Bronchitis merges into pneumonia, and often accompanies the latter disease, while, on the other hand, pneumonia is often connected with

pleurisy.

As might be expected, the inflammatory affections of the lungs have certain symptoms in common. They are all characterised by general symptoms of fever, heat, thirst, and quick pulse, by more or less embarrassment of breathing, and by tendency to cough. In pneumonia and pleurisy there is generally pain in the side, or under the breast more or less severe, but sometimes this symptom is entirely absent. The distinctive characters of bronchitis have been pointed out in the article on the subject. Those of pneumonia are marked by a greater amount of fever, and especially a higher temperature than in the other forms; generally the pain is less acute, but there is more cough than in pleurisy. It is, however, in the expectoration of pneumonia that one marked distinction is found. Shortly after the attack commences, the mucus coughed up, becomes of a remarkably glairy adhesive character, so tenacious as to adhere firmly to the bottom of the spitoon, at first uncoloured, but soon acquiring a yellow tinge, and at length is streaked throughout with blood, which gives it a peculiar rusty or plum juice hue. When, then, in an inflammatory chest affection, the expectoration is characterised as above, and goes through these changes, it may be considered that pneumonia is present.

of the chest and lungs, including laryngitis and | severe, of a peculiar, sharp, cutting character (compared often to a stitch), which is aggravated at every respiration, and prevents the proper expansion of the chest; it is, too, aggravated by all attempts to lie on the affected side, and

by the cough, which is short and dry.

An attack of pneumonia, or of inflammation of the substance of the lungs, tends to terminate either in the return of the lung to its ordinary healthy condition, in its becoming solidified, or or as medical men call it "hepatised," that is, converted into a mass as solid as a piece of liver, or in the formation of abscess in the lung. In either of the latter cases, the result is, of course, impairment of the functions of a vital organ, which is felt by the whole constitution, and which occasions more or less distress, locally, according to the amount of lung damaged. The condition, moreover, often lays the foundation of future disease. More rarely pneumonia terminates in mortification. An attack of pleurisy tends to terminate in return to health; in the effusion of water or of matter into the cavity of the chest, and in the formation of adhesions between the smooth surfaces of the lungs and those of the chest with which they lie in contact. If the water or matter formed in the chest is of large amount, as it must find room somewhere, it compresses the spongy substance of the lung to so great a degree that no air can possibly enter it, and thus, as may be imagined, causes great distress in breathing. When this occurs, the sharp cutting pain, which was partly the result of the inflamed surfaces rubbing against each other, subsides, for the surfaces are now separated, and the patient, instead of lying on the back, or on the other side, now inclines to the one affected, as, by doing so, he throws the weight of the fluid off the sound lung.

The inflammatory affections of the lungs occur, of course, in every degree of severity, and frequently prove fatal. They are generally the result of cold, but also at times arise from violence or other causes. They are, moreover, diseases which often occur suddenly, and with much severity, in situations at a distance from medical aid. When such is the case, much assistance may be given by the well-directed efforts of the unprofessional. Confinement to bed, low diet, a plentiful supply of diluent drinks to quench the urgent thirst, and hot poultices of bran or other material to the affected side, are the first necessary measures. If the bowels are confined, they should be acted upon moderately, but no good can be derived by strong purging in the diseases in question, and by it the strength of the patient will only be unnecessarily depressed. The propriety of bleeding from the arm in inflammations of the lungs is becoming much questioned, and, except by medical sanction, the operation will be better let alone in unprofessional hands, In pleurisy, the pain in the side is frequently chiefly to be relied upon are tartar emetic, and

calomel, and opium. In pneumonia, the former | like that of other inflammatory diseases, is should be given in from a fourth to an eighth of a grain doses, every three or four hours; and of the latter, a pill containing a grain and half of calomel and a quarter of a grain of opium should be given every six hours, and continued till either the disease is removed, or till the gums become sore. The antimony may be gone on with till the disease is subdued, unless it acts violently upon the bowels, or unless there is much depression. Should the latter occur, the treatment with ammonia as re-commended in article *Bronchitis*, ought to be adopted, and the strength supported by nourishing broths, beef tea, &c. In some cases of inflammation of the lungs, when the pain is severe and the symptoms urgent, leeches, from six to twelve, according to the strength of the patient, may be applied, or cupping practised; but in most cases the hot bran poultice, assiduously used, will obviate the necessity. The mistake of applying moderate sized blisters in the early stages of inflammation is frequently committed, it should never be done; in the latter stages of the attack, however, they are useful. In pleurisy, the chief modification of the above treatment ought to be, the substitution, for the tartar emetic, of moderate doses of some saline, such as nitrate of potash, in ten-grain doses, every four or five hours, and the calomel and opium may be given at rather shorter intervals. It is seldom that an attack of inflammation of the lungs will run its entire course without being visited by a medical man; but should it of necessity do so, under unprofessional care, the best procedure will be, when the disease subsides, to do as little as possible in the way of medicine, beyond attending to the action of the bowels, and, if requisite, of the kidneys by some safe diuretic; if cough is troublesome, it may be allayed by a few drops of laudanum, or by paregoric, in some demulcent, such as barley-water. The patient should be nursed gently and cautiously into health. - See Bronchitis.

INFLAMMATION OF THE BOWELS OR ALIMEN-TARY CANAL. - Inflammation of the bowels, or alimentary canal, may affect any portion of it—the stomach, the large and small bowels, or it may attack its covering membrane, the "peritoneum," or its lining mucous membrane. Inflammation of the peritoneal covering of the bowels (Peritonatis-see Alimentary Canal) is one of the most formidable and often one of the most painful of the acute diseases; it may be confined to a small portion of the abdomen (see Abdomen), or be spread over, not only the peritoneum, which covers the alimentary canal, but that which covers the other contents of the cavity, such as the liver, hence medical men distinguish general and partial peritonitis, the latter being named according to the part

affected.

The accession of peritonitis, or inflammation of the covering membrane of the bowels, as characteristic of peritoneal inflammation,

attended with the usual symptoms of fever, languor, depression, shivering, and is followed by heat, thirst, and quick pulse. Either simultaneous with these symptoms, or shortly after, there is usually intense cutting or burning pain in the abdomen, general, or confined to one spot, according to circumstances. This pain is much increased by pressure, so much so, indeed, that even the weight of the bed-clothes cannot be borne, and the patient lies on the back with the knees drawn up—an attitude very characteristic of this disease-in order to keep off the weight of the clothes. At this time, the pulse, which is very quick, is usually of a peculiarly hard and wiry character. The symptoms of peritoneal inflammation of the bowels are usually so well marked as to be distinguishable even by an unprofessional person; when they do occur, especially under circumstances to be hereafter pointed out, as likely to occasion them, it need scarcely be said here, that a medical man should be called with the shortest possible delay. The disease is most serious and dangerous, often very rapid in its course, and cannot too soon be submitted to the active treatment which skill and experience alone can venture upon. In the meanwhile, the provisional remedies to be adopted must be, in some degree, regulated by circumstances. If many hours must elapse before medical assistance can be obtained, and if the affected person is of strong full habit, leeches may be freely applied over the seat of the pain; a warm bath for half an hour will be useful, and hot fomentations assiduously used for a long time will give much relief, being preferable to the hot poultice, the weight of which, probably, could not be borne, unless made very light. The bowels should be prevented from acting for some days, and then gently relaxed by means of castor oil. If the stomach is unable to retain food, injections of beef tea or nourishing soups, plain or peptonised, repeated from time to time, not only keep the bowels clear, but act as an internal fomentation; they should not amount to more than four ounces at a time, and if the pain is severe, twenty to thirty drops of laudanum may be added. best medicine is opium, to relieve pain and subdue inflammation. It should be given in doses of one grain every three or four hours until the doctor arrives. The diet must of course be reduced, and nothing but diluents, such as thin gruel, barley and toast water, allowed. In following out the above directions, an unprofessional person, at a distance from medical aid, would be doing the utmost possible to keep the disease in check; the means may, of course, require varying in some degree, but in this, as, indeed, in all such matters, something must be left to the judgment of an intelligent person.

Whenever, with the symptoms enumerated

may be strongly suspected, sufficiently so, at least, should more active measures not be adopted, to forbid all administration of stimulants, such as is had recourse to in colic and spasmodic pain. Indeed, should the attack turn out to be the latter, all the remedies recommended for peritonitis, except the bloodletting, would be serviceable, especially the warm bath and fomentation. The causes of inflammation of the bowels, apart from surgical operations within the abdomen, are chiefly cold, the abuse of stimuli, or of strong purgative medicines, mechanical violence, constipation, a loaded state of the alimentary canal, and child-birth. The most severe and rapidly fatal case of inflammation of the peritoneal covering of the bowels the author ever witnessed, was traceable solely to the individual rising from a warm bed and standing for some time on a stone floor barefoot. For information respecting inflammation after child-birth, the reader is referred to the article on that subject. It is, however, right in this place to warn that, under this circumstance, a spurious or imitative inflammation is apt to occur, in which bleeding will do the greatest possible mischief; in such cases, therefore, its employment will be most prudently left to the judgment of the medical man. Inflammation of the lining or mucous membrane of the bowels, is generally associated with diarrhoa or dysenteric affection, and to these articles the reader is referred.

Refer to-Abdomen-Alimentary Canal-

INFLUENZA .- This disease was cited under the article Epidemic, as the best specimen of an epidemic disease. It is a peculiar feverish attack, accompanied with catarrhal affection of the air-tubes of the lungs, and great prostration of strength. It is not uncommon to call various forms of cold and catarrh, influenza; but the true influenza is a very distinct disease, and seldom occurs but as an epidemic, attacking large numbers at once.

The symptoms of influenza are those of general fever; coming on suddenly, there is shivering, loss of appetite, perhaps vomiting, heat and thirst, with cough, frontal headache, and generally great depression and languor. The feverish symptoms may last from one day to ten, but their general duration is from three to five, or seven days, the cough usually remaining a variable time, after the acute symptoms are gone, according to exposure and circumstances, such as a predisposition to cough, &c.

To the strong and healthy, influenza is but a trifling disease; it certainly prostrates them for a few days, and this is perhaps its most distinctive feature, and leaves them afterwards weak, but it is in almost all cases perfectly devoid of danger-with ordinary care-and requires little or no medicine. A few days in bed, according to the severity of the case, with

there is tenderness on pressure, inflammation | low diet, a gentle aperient, and diluents, putting the feet in hot water, being all that is required. If the catarrhal symptoms are severe, treatment similar to what is recommended for catarrh or cold may be had recourse to.

To the weakly and the aged, influenza is, on the other hand, a comparatively fatal disease, and from the almost universal nature of its attack, carries off more, perhaps, of these classes, than many more apparently severe and more dreaded disorders. The attack of influenza in the description of persons above mentioned, should be the signal for medical attendance, as bronchitis or pneumonia is very apt to supervene. Lowering means especially must not be resorted to; confinement to bed, and the use of diaphoretic remedies, as recommended under articles Cold and Catarrh, will be required; broth, strong or weak, must be allowed, according to circumstances, and if the strength is deficient, wine may be requisite, and stimulant expectorant medicines, especially in the aged, if the expectoration is abundant, viscid, and difficult to be got up. In such cases the following will be found useful: Take of carbonate of ammonia, thirty te forty grains; tincture of squill one drachm; wine of ipecacuanha forty drops; water or camphor water, sufficient to make an eightounce mixture, of which two table-spoonfuls, or one-eighth part, may be given every few hours. If the cough is very irritating and troublesome, two drachms of paregoric may be added to the above, but the opium rather tends to check the free expectoration, which is so desirable. Demulcent drinks, such as barleywater, should not be neglected, and repeated mustard plasters to the chest will do good. In severe forms of the disease, with difficult breathing, if the strength is much reduced and the appetite bad, two doses of decoction of bark may be given during the day.

Persons who generally suffer from delicacy of chest, should beware of allowing the effects of influenza to hang about them; the debility and cough are very apt, if predisposition exists, to lay the foundation of consumption. The strong and healthy may trust to the domestic management of influenza, the weak and aged ought to have proper medical advice, if it is

within reach.

The history of the various epidemics of influenza which have visited Europe, and, indeed, the world, at intervals, is a subject of much interest. It has been remarked, that the invasion of the epidemic has been preceded by dense, dark, and in some places, it is said, offensive fogs.

Different epidemics of influenza vary very much in their character. In one epidemic lung affections may be the prominent feature, in another high fever, while in a third the diges-

tive organs may chiefly suffer.

Refer to-Cold-Catarrh-Diaphoretics, &c. INFUSION is the submission of sub-

INH INF

stances to the action of water, hot or cold, for the purpose of extracting from them certain portions soluble in the fluid. The most familiar instance of an infusion is common tea. For the purpose of infusion, a jug, of the form of fig. 133, is the most useful, with both cover and spout with strainer, but, of course, a common jug, with a saucer or plate placed on the of hot water and of medicated sprays, is intop of it, or an earthenware teapot, will and generally does make a good substitute. object of an infusion is to extract volatile and other substances, which would either be dissipated or injured by exposure to higher heat, such as decoction or boiling; indeed, some infusions, such as that from senna, &c., as noticed in their articles, are better made without heat at all.

The commonest method of forming a hot infusion is, to pour the water boiling upon the substance, cover, and allow the whole to stand near the fire for some time before it is permitted to become cold. If the substance to be infused is thick or tenacious, it ought, of course, either

Fig. 133,

to be cut up, or well bruised before being submitted to the action of water. The chief inconvenience connected with infusions, is their great tendency to spoil; some, such as calumba and dandelion, becoming unfit for use calumba and dandelion, becoming unit for use in twenty-four hours in summer. It is said that if the infusion be poured boiling hot into a bottle, filled up to the top, and the bottle immediately well corked, it will keep be beneficial, it is still more certain that the presence of others in the atmosphere breathed is most inimical to health. This subject, however, is sufficiently bottle immediately well corked, it will keep good a long time. Concentrated infusions are now made by chemists, but many of them contain so much spirit, that they are almost tinetures, and in some cases, therefore, are inadmissible; otherwise they are good preparations. The most useful infusions are:

Infusion of Bark.

Broom. Calumba. Chamomile. Dandelion. Hop. Gentian. Linseed. 29 Quassia. 22 Rhubarb. 23 Rose-leaf. 23

Senna.

INHALATION is the act of inhaling or inspiring vapour into the throat or lungs as a means of medical treatment. The inhalation of ether, chloroform, and nitrous oxide gas for the prevention of pain in surgical operations, is the best-known application of the principle of inspiration, while the inhalation of the vapour tended mainly for complaints of the surface of the throat and windpipe.

The steam from water may often be used as a safe domestic inhalation, in cases which require the local application of heat and moisture; indeed, in sore throat, steaming is very commonly had recourse to. It may also be employed with advantage in cases where the breathing is difficult, with tenacious expectoration, especially in old people. In chest affections, such as consumption, with spasmodic cough, the vapour of boiling water, into which has been put a few drops of sulphuric or chloric ether, or ten or a dozen drops of laudanum, will frequently afford much temporary relief. Medicated inhalations, such as those from chlorine, if used at all, must be so under direct medical superintendence. It is probable that the slow, imperceptible, but continual breathing of an atmosphere, impregnated with such medicinal agents as chlorine, iodine, &c., is more likely to be of service than their temporary use in more powerful doses. It has been observed in manufactories in which a chlorine atmosphere prevails, in consequence of the operations, such as bleaching, carried on within them, that men who have entered the works with weak chests or consumptive tendencies, have, in the course of time, become much improved in health. It is, too, not improbable, that part of the benefit, at least, derived from sea-side residence, may be due to the constant imperceptible inhalation of chlorine salts, and other vaporised substances. If, however, the constant inhalation entered into in other articles, such as Air-

Atmosphere—Ventilation, &c.

Various methods of inhaling steam are employed: simply holding the mouth over a jug of hot water will answer, but if the throat be the part affected, the vapour is most directly conducted to it by means of a tube of some kind, and by such apparatus as are described in the next article.

INHALERS.—The method of administering remedies of different kinds by means of inhalation, for the cure and, in many cases, for the relief of disease, is now so general that it seems well to give some idea of the way in which this is effected by the instruments used, called inhalers.

These latter are now so numerous that it would be quite endless to describe them all.

INH INH

The following is a sectional illustration of Dr. Nelson's improved earthenware inhaler, an apparatus for the inhalation of the vapour of hot water, either alone, or impregnated

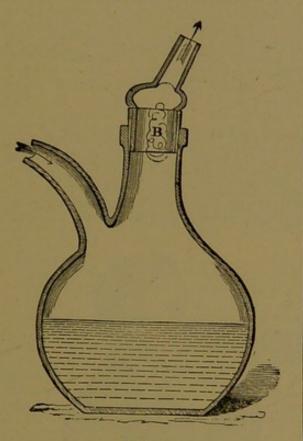

Fig. 134.

with ether, choloroform, henbane, or other medicinal preparations, in affections of the throat and bronchial tubes, asthma, consumptions, &c. (fig. 134).

Directions for use: - Remove the corked stopper, and fill the vessel half full of hot water, then pour the remedy to be employed upon the sponge, contained in the hollow tube at B; and, having replaced the latter, inhale the vapour through the mouth-piece, the exhaled breath passing freely through the tube. For the inhalation of the vapour of hot water only, or hot water medicated, the sponge

in the tube need not be displaced.

To obtain the same object, a cheap apparatus called the "poor man's inhaler" has been brought out by Mr. Martindale, and is a good deal used. In this case the inhaler is composed of tin, and is in two parts, the upper chamber being furnished with an earthenware mouth-piece. In the illustration (fig. 135), the inhaler is denuded of a woollen covering which invests it when in use, and which is intended for the double purpose of retaining the heat and preventing the metal from burning the fingers. When required for use, the lower chamber (f), which can be readily disconnected from the upper (d), is filled with water at a temperature of 140° or 150° Fahr. until the holes c,c, establishing communication between the interior and outside channel are about a quarter of an inch below the surface of the The apparatus is supplied with a thermometer (a), to regulate the temperature of the water, which passes through an aperture (g) specially made for it.

Instruments may also now be obtained for subdividing fluids into the finest vapour, or spray, either in a hot or cold state, by which means they may be easily brought in contact with the mucous membrane of the throat, nostrils, windpipe, &c., and in this way many valuable and important remedies can be used that were formerly inapplicable to such cases.

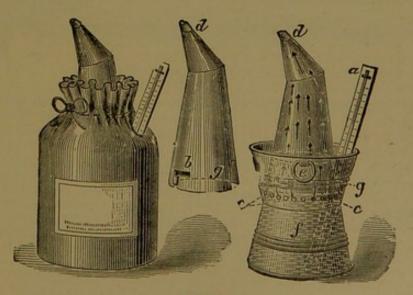

Fig. 135.

Dr. Richardson's ether spray-producer for producing local anæsthesia, figured under article Cold, is equally well adapted for inhalation. It will be evident to any one that liquid substances can in this way be brought in contact with parts of the throat and air passages, and

INH INH

nostrils. Gargling is a very imperfect and unsatisfactory method of applying such remedies, as it is only possible to reach a very small portion of the throat in that way, but when the above-mentioned instrument is used, the vapour penetrates to all parts in the neighbourhood of the throat, and is equally diffused over them.

The following inhalation will be found useful in cases of foul breath from ulceration at the back of the palate, nostrils, gullet, &c. : Take of carbolic acid one drachm, boiling water, a pint, mix, and inhale the vapour.

Turpentine is sometimes useful, when inhaled, in checking excessive expectoration, especially when there is old standing bronchitis with dilatation of the bronchial tubes. The following formula is recommended: Take of the face, which is held in the hand at a slight

of the gullet and posterior openings of the | oil of turpentine two ounces, lukewarm water half a pint, mix, and inhale the vapour.

The annexed engraving (fig. 136) represents the action of Siegle's inhaler, frequently referred to in other parts of the present work, as affording an excellent means of inhaling atomised vapours in a condition combining the efficacy of a gargle with that of a fomentation to the internal parts of the throat and air passages. The apparatus consists of a small boiler heated by a spirit lamp; the steam from the boiler, which has also a safety valve attached to it, passes through a minute orifice of a glass tube, at a right angle with a separate tube in the centre of a bottle containing a medicated fluid, which is gradually absorbed by the steam. In using the inhaler, it is customary to employ a funnel either of glass or cardboard to protect

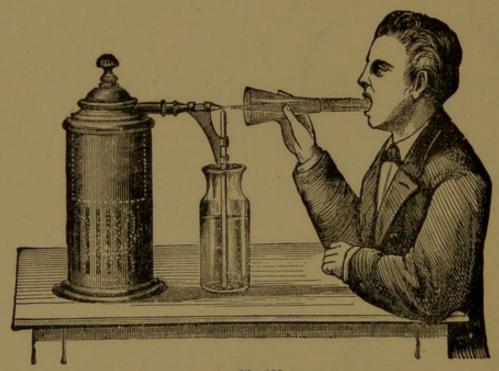

Fig. 136.

in the engraving.

On account of the delicate and fragile character of the glass connexions in Siegle's instrument, it is very liable to injury, or to get out of order, and to avoid this inconvenience, the steam draft inhaler of Dr. Lee, composed entirely of metal, is now coming into use.

The following represent the more useful drugs employed with steam inhalers generally. Alum, tannin, and hazeline, in varying proportions from one to twenty grains to the ounce of water, in ulceration of the fauces and apper part of the throat, and in hæmorrhage from the lungs and air passages. Carbolic acid, chlorinated soda or eucalyptus oil, in the proportion of a drachm to the ounce, in cases of offensive expectoration or sloughing of the mental in others; and again, cold spray is in

distance from the mouth, in the manner shown | back parts of the mouth and throat. Opium in the form of tincture or liquid extract, or acetate of morphia, spirits of camphor, tinctures of henbane, hyoscyamus, or belladonna, are all employed in greater or less proportions to allay irritation; and iodine, in the proportions from five to fifteen drops of the tincture to the ounce of water, has been found serviceable in numerous instances in phthisis and chronic bronchitis, but in this, as well as in the other agents mentioned, it is advisable to act under professional advice.

There is, however, one disadvantage connected with the use of many inhalers, and that is, the necessity for steam or spray being inhaled at a comparatively high temperature. This, useful in some cases, is sometimes detri-

invented inhaler-respirator of Dr. Coghill, of Ventuor, presents many advantages. By its means a great variety of medicated inhalations may be inhaled without fuss or fatigue, and the inhalation continued without difficulty for hours together -an immense gain when it is an object to act with gentle but certain effect upon the air passages, including, if need be, the nostrils.

Refer to-Respirator.

INJECTION .- See ENEMA.

**INOCULATION** is the introduction of a poison into the system by means of a wound. Any poison which will thus affect the part in which it is placed, or the system generally, may be said to be introduced by inoculation. The term is most generally used with reference to the poison of small-pox, to the article on which the reader is referred.

Refer to-Poisons.

INQUEST .- The inquiry into the cause of death from violence, or in an unusual, or in an unexpected manner, is of Saxon origin, and ought to be one of those safeguards to human life in this country, which every one should uphold and promote, instead of, as is too often done, throwing impediments in the way of the operation of the law. For this purpose, in cases of unexpected death (see Death-Drowning), those who chance first to be at the scene should note carefully whatever may be of service in the inquiry of the coroner and jury. It is a very common opinion that inquests are only called for when there is a strong suspicion of crime; if they are to be confined to such cases, they might almost be superseded entirely; their great use is to investigate unexpected death, whether suspicion exists or not. In this way only can they be an effectual and dreaded check upon crime. Moreover, the full efficiency of the coroner's office is very greatly impaired, by the anomalous proceeding of generally placing what ought to be a medical inquiry in the hands of a legal functionary. The law of inquest is, or ought to be, in some degree at least, a fixed principle or rule of action; the medical questions which are involved in the majority of inquests are so varied, that they cannot possibly be fully judged of by a non-medical inquirer. Medical men alone are, or ought to be, competent to seize hold of and follow up many clues of inquiry that must and do fail to attract the notice of those whose knowledge-if possessed at all-is necessarily limited on subjects of medical science. While inquests are held, and very properly so, under circumstances of just suspicion, they are far more frequently held and sometimes at great length when the cause of death is as clear as noonday, causing thereby much distress and annoyance to surviving relatives. In cases of sudden death from natural and inevitable causes, a post-mortem examination of the deceased by a competent

some cases injurious. As a medium, the newly | medical man ought to obviate the necessity of a coroner's inquest.

Refer to — Death — Drowning — Hanging —

INSANITY, LUNAOY, MENTAL ALIENA-TION, UNSOUNDNESS OF MIND, are all terms for a disorder, of which it has puzzled the most acute to give an accurate, and, at the same time, sufficiently comprehensive definition, although all are aware of the general sense of the terms used to indicate the malady. It is sufficient for our purpose here to mention, that the most general division of the subject is into mania, that is insanity, along with more or less violence in demeanour and action; monomania, in which either the understanding or the will is perverted on one particular point; and dementia, or incoherent thought, verging on imbecility; amentia, or idiocy, has been already adverted to.

The main character of insanity, in a legal point of view, is said to be the existence of delusion, that is, that a person should believe something to exist which does not exist, and that he should act upon this belief. Many persons may labour under harmless delusions, and still be fitted for their social duties; but should these delusions be such as to lead them to injure themselves or others in person or property, then the case is considered to require

legal interference, -otherwise not.

The approaches of insanity are variously characterised; sometimes, to all appearance, it comes on without warning, a sudden outbreak of violent mania being the first intimation of the disease; even in these cases, however, investigation will generally discover, that there has been some amount of preceding disorder, some sleeplessness, some unusual irritability, or mental excitement, perhaps concealed or controlled by the individual. In other cases, the mental oddities, irritabilities, fluctuations of spirits, &c., have been evident, but too slight to excite apprehension. At the last, the acute attack may be induced by some severe or prolonged mental emotion, or by some physical depression. The onset of the attack itself is frequently preceded by or accompanied with feverish symptoms, which particularly affect the head. In this case, the insanity is, probably at its first onset, accompanied with acute affection of the brain or its membranes, and partakes of the character of delirium properly so called. Where the circumstances, such as hereditary predisposition, or previous warning symptoms, give rise to the suspicion of impending insanity, medical advice must at once be sought, preparatory to the one essential and most merciful step—removal of the patient to an asylum. In the meanwhile, the most perfect quiet, both of body and mind, and the treatment meanwhile and produce the head of treatment recommended under the head of Delirium, will be the most advisable mode of proceeding.

The definition of insanity, as has been

INS INS

said, is very difficult, and frequently gives | certain cases of mental aberration in which rise to much legal controversy. Broadly, it may be viewed as a mental condition which unfits a person for the ordinary business and duties of life. The malady may arise from a congenital deficiency of intellect, as in idiocy and imbecility, or in a perverted condition of the intellect expressed by certain delusions of the understanding; or the intellect may remain intact while the sentiments become depraved. To this latter condition, the term moral insanity is sometimes applied, and it comprises the well-known form of the disease called melancholia, as well as various aberrations of the moral faculties in which the passions and emotions manifest themselves, sometimes in an exalted, and at other times in an impulsive and incontrollable manner. As often as not, both conditions are combined, and it is barely possible in most cases to draw a rigid line between them; still, for the purpose of classification and analysis, the College of Physicians have recognised in their nomenclature the following classes of mental disorders; (1) mania; (2) melancholia; (3) dementia; (4) paralysis of the insane; (5) idiocy; (6) imbecility.

Mania may be either acute or chronic, and is characterised at first by emotional peculiarities, and afterwards by disordered intellect. The symptoms are ushered in by gloom and despondency, sleeplessness, impatience, and irritability, and often combined with these, the natural functions are disturbed; the skin is hot and dry, the bowels are confined, and there is much aversion to food. The patient, hitherto reasonable and methodical, becomes moody and morose; kindhearted and affectionate, he takes a deep-rooted antipathy to those he was wont to love, or some special form of the malady is manifested by an inordinate craving or exalted propensity. A desire on the part of the patient to take away his own life or the life of another, to which the terms "suicidal" and "homicidal" mania are applied, is not uncommon. Then there is "kleptomania," a desire to appropriate anything belonging to another, "pyromania," a disposition to commit the crime of arson, and "dipsomania," an unconquerable longing for intoxicating liquors. Puerperal mania is that form of insanity which sometimes takes place a few days after child-birth, and is attended at the outset with much fever and delirium. Epileptic mania results from continuous attacks of epilepsy, by which, at length, the mind becomes hopelessly impaired and the memory of past events is lost. The term "climacteric" is affixed to a form of mania which occasionally occurs with women when the menses cease to When the acute stages of these various phases of mental disorders pass away, the victim is very liable to repeated relapses, and chronic mania, which by slow degrees enfeebles all the faculties of the mind, is the sequel.

grief and despondency predominate, where life becomes a burden to its possessor, who is too often prompted by a desire to get rid of it. Like mania, it has many phases, sometimes assuming a religious garb, in which most grotesque notions regarding religious doctrines are predominant, or the dread of everlasting punishment is ever before the patient. Sometimes it takes the character of an aggravated form of hypochondriasis, a disease akin to hysteria in the female, and sometimes, especially with emigrants from rural and mountainous districts, it is expressed by a sad longing to return to the home of their birth.

Dementia signifies a more aggravated form of madness than mania or melancholia, although it is often the sequel of both. It is characterised by failure of thought and memory, and may range in its symptoms from a feeble mental condition, simply, to complete fatuity of intellect. In its advanced state persons suffering from the malady often become paralytic, their utterance is affected, and they become perfectly helpless both in body and mind.

What is termed "general paralysis" of the insane is perhaps the most serious malady of all. The commencement of the complaint is generally very gradual, and is marked by symptoms common to other forms of paralysis, but after a time these are combined with delusions of a very exalted character, in which a sense of the patient's own importance is a distinguishing feature. He asserts his dignity as a prophet or king, and lays down laws for the million in the most incoherent and ridiculous manner. As the disease advances, the paralysis becomes worse, frequently affecting the act of swallowing, while the mind lapses into a condition of complete dementia. The disease is attended with short convulsive attacks of a mixed epi-leptic and apoplectic character, after one of which death often ensues.

When a person is shown to be insane, there can be little doubt that a lunatic house or asylum is the place best suited for his reception, as the moral management of the insane cannot be satisfactorily carried out so long as they are surrounded by home influences. On the other hand, it is very important that the State should provide safeguards to protect sane persons from the risk of being isolated from interested motives on the part of others. The laws relating to the custody of lunatics are consequently very stringent, and apart from the formalities necessary to be taken before a person can be lodged in a lunatic asylum, the house itself, whether public or private, undergoes periodical inspection by the Commissioners in Lunacy. With regard to their admission, a wide distinction is made between pauper patients, and such as are able to pay for their maintenance in a private asylum. In the former case, all that is needed is to take the The term melancholia is largely applied to lunatic before a magistrate, who, aided by a

INS INS

person to the county lunatic asylum. Should there be any doubt in the matter, the patient may be retained under observation in the workhouse, until the union medical officer is satisfied of his insanity, when the same formality may be gone through. In private cases, the lunacy commissioners require the certificate of two medical men who have visited the patient at separate times, the certificate being drawn up in a medico-legal form, and counter-signed by a magistrate or Justice of the Peace. Among other less important details, the certificate must refer to facts indicative of insanity, observed by the signer at the time of examination, who must make the examination apart from the other certifying medical man, and in addition, the certifier must refer to facts conveyed to him by others, and must also state whether the person is "a lunatic, idiot, or of unsound mind," and a proper person to be taken charge of, and detained under care and treatment. With the medical certificate, a request for the reception of the patient must be sent by the nearest friend or relative, together with a statement, on a separate form, containing answers to a variety of questions bearing on the antecedents of the lunatic, such as the duration of the present attack, the supposed cause, whether the patient is dangerous to others, and similar matters of detail.

Insanity is a disease, which, when once developed, ought never to be kept under domestic management, or rather mismanagement; the only reasonable hope of cure rests with speedy removal to proper care, and to a state of external circumstances especially adapted to promote recovery. Asylums for the insane are not what they were, and the most attached and affectionate relative need not fear to place the afflicted under the protection of a well-managed establishment.

A very erroneous idea exists, particularly among the ignorant, that if a person be insane, he cannot act or look like a rational being at all, but must be constantly doing things in an insane manner. Consequently, if the individual be simply lunatic or monomaniac, without being actually under the influence of maniacal excitement, or even should he have a "lucid interval," that is, a temporary cessation of mania, and temporary return, either wholly or partly, to his rational condition, those around are apt to be lulled into a false security, the vigilance or attendance is relaxed, and a momentary return of the delusion is attended, perhaps, with the most serious consequences, rendering nugatory hours and days of anxious

In addition to the various causes predisposing to, and directly exciting insanity, such as hereditary tendency, political or commercial excitement, grief and disappointment, false or erroneous religious excitement, &c., no fact is more clearly ascertained than the vast amount | vantage :-

medical opinion, has the power to send the of insanity caused by drunkenness. The temperson to the county lunatic asylum. Should porary insanity of intoxication cannot be indulged in with impunity; it may be frequently repeated, but at length the mind permanently gives way, and the individual becomes a confirmed lunatic. On this point, an experienced writer remarks: "Intemperance and insanity, the two greatest curses of civilisation, are in their very nature so intimately connected, that any examination of the one would be necessarily incomplete without the other; for both exhibit, as their essential phenomena, perversion or disorder of those mental powers which impart to man his vast superiority over the rest of the creation. Since, then, a single dose of intoxicating substance possesses the power of temporarily disordering the intellect, perverting the moral sentiments, and even wholly suppressing the operations of the mind, it is not wonderful that the continued use of such agents should frequently induce permanent mental derangement." In a table drawn up from the returns of twenty-five asylums in England and Wales, it was found that one-fourth of the cases of insanity admitted were due to intemperance alone, and to it, in conjunction with vice and sensuality, nearly

INSPIRATION .- The act of drawing air into the lungs, and the opposite of expiration, which consists of its expulsion; the two together constituting respiration.

INSTRUMENTS .- But few of these mechanical agents used by the surgeon in the treatment of disease can ever be of legitimate use to unprofessional persons living within reach of a medical man; and those who are likely to be placed in circumstances where such assistance is not available, who may wish to be prepared for emergencies, should get themselves practically instructed in the use of the few they may venture to take in hand. The instruments required in such operations as bleeding, cupping, tooth-drawing, &c., are sufficiently described under the articles devoted to the subjects. In addition to them, the dweller (such as a clergyman) in a remote parish, even in this country, might find the following useful:-

A lancet. A silver probe.

A pair of scissors with blunt points.

A caustic holder.

A gum scarificator (see Childhood).

A pair of plain forceps. (See Forceps A pair of spring forceps. (and Dressing.) A vaccinating lancet (see Vaccination).

To these the emigrant might add with ad-

A tenaculum (see Tenaculum). A tourniquet (see Tourniquet). A shut-up bistoury, or knife. Two pairs of tooth forceps.

It is perhaps superfluous to add, that these should be got at some respectable surgical cutler's; and it is well to add, that all who provide themselves with them, should endeavour, if possible, to get a little practical instruction in their employment.

INTEMPERANCE.—See STIMULANTS. INTER-MARRIAGE.—See MARRIAGE. INTERMENT.—See Burial.—Death,

INTERMITTENT,—a term applied to diseases which, like ague and neuralgia, come on in paroxysms, between which there is an interval of comparative freedom from the symptoms of the disease. The term is also applied to the pulse, when some of its beats are, as it were, omitted.

INTESTINES .- The intestines (see accompanying illustration, fig. 137) occupy the greater part of the abdominal cavity, and comprise that portion of the alimentary canal which, commencing at the pyloric or distal end of the stomach, terminates in the rectum, the last or terminal division of the large intestine. From their relative size, the intestines are divided into small and large; the former (though of less calibre than the latter) are more than three times the length, and are the main channels through which the chyle is conveyed into the circulation. For convenience of description, the small intestine is divided by anatomists into three parts, the Duodenum, the Jejunum, and the Ileum.

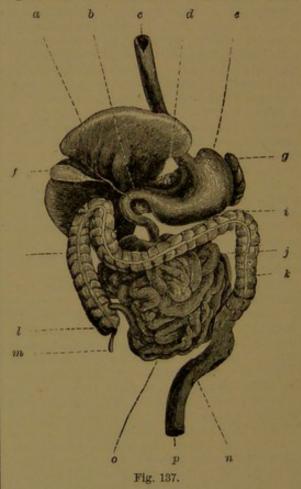

The duodenum is from eight to ten inches in length, and is continuous with the pyloric orifice of the stomach; it forms a horse-shoe curve between the liver and the pancreas, and about its middle receives the bile and pancreatic juice by a duct common to both organs. It is in this portion of the alimentary tube that the chyle begins to be formed and also absorbed by the lymphatic vessels of the intes-

tines. Continuous with the duodenum is the jejunum, so named from the fact of its being usually found empty after death; in other respects it presents characters very similar to those of the first part of the intestine.

The jejunum is continued in the ileum, which forms the third and last part of the small intestine; its calibre is somewhat narrower than the others, and its coils and convolutions are more numerous. The entire length of the small intestine is about twenty feet; its inner surface or mucous membrane is liberally supplied with glands, follicles, and villi, by which the nutritive matters of the food are readily absorbed into the circulation. The ileum terminates in the large intestine or colon in a species of valve or opening called ileo-colic, sphincter muscle or valve, to guard against t which opens into the side of the large intestine too ready passage of the intestinal contents.

about three inches above its termination, which forms a pouch or cul-de-sac called the cacum. Attached to the cacum is a worm-like appendage or tube, about the thickness of a goose quill, and four to six inches in length, called the appendix vermiformis, the object and uses of which in the animal economy have not been ascertained.

Commencing at the cæcum, the colon ascends upwards on the right side of the abdominal cavity, until it reaches the liver, when it crosses horizontally to the left side, thus forming the second or transverse division; it after-

lity, as shown in their continuous peristaltic action, are retained in their position by their serous covering, the peritoneum, which lines the abdominal walls, and especially by that portion of it called the mesentery, which invests the small intestines, and, collecting them into folds, attaches them to the spinal column behind.

The intestines are subject to numerous diseases, the most familiar of which are the two opposite conditions of constipation and diarrhœa, they are also liable to serious obstruction from stricture, tumours, hernia or rupture, and from numerous other causes, likewise to hæmorrhage from ulceration of the internal lining, as in dysentery, enteric fevers, &c. The diseases of the intestines are referred to in separate articles. - See Abdomen - Alimentary Canal -Constipation—Diarrhwa—Digestion—Villi, &c.

INTOXICATION means literally what it really is, a condition of poisoning, either by alcohol or by other narcotic agents: the former however being the most frequent cause in this country. Intoxication from the use of opium, Indian hemp, &c., is adverted to in the articles upon these agents. The phenomena of alcoholic intoxication are thus described by an esteemed writer: "The effects which follow the introduction of a large quantity of moderately diluted alcohol into the stomach, are, first, the local excitement of this organ indicated by the sensation of heat in it: this impression is next conveyed to the brain, spinal marrow, and entire nervous system; ideas of unusual brilliancy pass through the mind. As the power of the stimulus increases, all control of the will is suspended; the ideas are then irregular, and instead of being combined in such a manner as to produce even agreeable conceptions, they arise in the most incongruous order; the extent of the excitement becomes apparent in the unusual vivacity of the eye, the swelling of the veins of the neck, and the beating of the arteries: but new symptoms quickly follow, namely, pain in the frontal region, the head drops on the chest, the eyes lose their expression and are halfclosed, the physiognomy is altered and vacant, the voluntary muscles cease to act, the arms are pendent, or their movements are irregular, the legs cross one another in the effort to walk, giddiness supervenes, and delirium follows. The exhausting influence of such a state is too great to continue: in a short time collapse, and sleep, resembling that of apoplexy, follow." Probably the influence of alcohol upon the brain, in the first place at least, is partly effected through the nerves of the stomach; but it is very quickly absorbed into the blood, and speedily reaches and acts di-rectly upon the brain itself: this has been proved by experiment and examination after alcohol has been swallowed, and there has been applied to the pit of the stomach, or between found in the brain after death a considerable the shoulders. It ought to be remembered,

The intestines, though capable of great mobi- | quantity of fluid distinctly impregnated with

spirit, to such an extent, even, as to burn.

The cases of sudden death—too frequently recorded in the newspapers-from the rapid drinking of a large quantity of spirit, may be quite accounted for by the shock communicated directly to the brain itself, or indirectly by a shock given to the stomach and its nervous connections, with an effect similar to that which ensues from drinking largely of very cold water when the body is over-heated and exhausted, or from a blow on the stomach. Death in the latter stages of intense intoxication is similar to that from some forms of apoplexy. Some indication of the amount of danger to life, existing in a person in a state of intense intoxication, may be gathered from the condition of the pupil (see Eye). If this retains its power of contraction, the person will generally recover; if, on the contrary, it remains in a state of extreme dilatation and immobility when a strong light is directed upon it, only a feeble hope of recovery can be entertained. The ordinary duration of fatal cases of intoxication is said to be from twelve to eighteen hours, but on this head there is considerable variation. When death is threatened from the absorption of alcoholic fluid into the system, the individual, after the usual symptoms of intoxication, becomes insensible; the face is flushed and the vessels of the head distended; the pupils are contracted and the skin hot; or, contrasting with violent throbbing action of the heart and arteries, the face is deadly pale, lips blue, pupils dilated, surface cold and covered with clammy sweat; the natural contraction of the muscles is suspended so that the jaw drops; in short, there is every appearance of death, which, indeed, may speedily take place: even from this apparently hopeless state, nevertheless, a patient may be roused by appropriate measures.

The first proceeding which naturally presents itself in the treatment of such cases is to procure the evacuation of any alcoholic fluid which may remain on the stomach. medical man is at hand he will probably effect this by the stomach pump, if not, sickness may be excited by the first procurable emeticexcept antimony-or by a feather in the throat. After the stomach has been emptied by vomiting, a little sal volatile in water, or hartshorn in water, or vinegar and water should be given; cold water should be used freely to the head: it is most effectual if poured upon it in a regular continued stream for some minutes. If the extremities are cold, heat should be applied to them. Galvanism and electricity frequently rouse the drunkard when other methods fail. The author has found a stimulant injection of an ounce of turpentine in half a pint of gruel, of much service in rousing the depressed system. Mustard plasters may be

IPE INU

however, that sensibility may be restored, and | the most serious symptoms apparently dispelled, and yet, if the stomach has not been entirely emptied, they may again return and prove fatal, unless the patient is closely watched.

Refer to—Stimulants.

INUNCTION.—The rubbing of an ointment upon the skin, for the purpose of promoting the absorption into the system of any medicinal substance contained in the ointment. Ointments which contain mercury or iodine

are principally used with this intent.

INVERSION.—The turning inside out of an organ, such as the womb. It is a serious accident, which sometimes occurs under peculiar circumstances, as after labour. The assistance of a medical man is always imperatively called

IODINE is a body at present considered as elementary; it is principally obtained from the burnt ash of sea-weed, but is also found in some mineral waters, and in some plants, such as common water-cress. Iodine exists in the form of dark metallic-looking scales; it possesses a strong pungent odour, and stains whatever it may come in contact with of a deep yellow or brown colour. When heated in a flask, iodine rises in the form of a beautiful violet-coloured vapour, and condenses unchanged on the side of the glass. Iodine and its preparations are much used by medical men, but can scarcely fall within the sphere of domestic remedies; the ointment of the combination of iodine with potash is used in bronchocele, or swollen neck (see Bronchocele). When combined with iron, potassium, mercury, lead, and sulphur, in what are termed the iodides of these substances, iodine is a remedy of much value in many diseases, especially gout, rheumatism, and scrofula; it is, however, a medicine that should never be taken without medical sanction.

IPECACUANHA-at once one of the most valuable medicines of the practitioner, and one of the safest remedies which can be used domestically—is the root of a pretty little South American plant. It is brought to this country in pieces about the thickness of a goose quill (fig. 138), and about six inches long, brown, wrinkled, and knotty; but its most characteristic feature, and that which serves to distinguish it from spurious roots often attempted to be substituted for it, is its ringed appearance; it seems as if made up of a number of separate pieces, or rings, strung, as it were,

upon one central stem.

Ipecacuanha is best known as an emetic, and it is perhaps the most certain, safest, and best of the class we possess. No family medicine chest in the country should be without it. is also a valuable expectorant and diaphoretic remedy, and facilitates greatly the action of aperients. The powder and the wine of ipecatounha are the most general forms in which it is improved by combination with an alkali is used; as an emetic, it should always be given such as soda. Four grains of powder of ipeca-in powder if possible; a great error is often cuanha and one drachm of carbonate of soda,

committed in giving children the wine to act emetically, for frequently it fails in action altogether, or so much is required, as to make the amount of wine given a consideration; in cases of febrile disease especially. As an emetic, the dose of ipecacuanha powder is from twenty to thirty grains for an adult, half that to a child of ten years old. For young children, especially when, as in chest affections, the constitutional and expectorant influence of ipecacuanha is as much wanted as its emetic effect, the author prefers giving it in smaller divided doses; for this purpose, from twelve grains to a scruple of ipecacuanha powder may be rubbed up with an ounce and a half of sugar and water, and of this a tea-spoonful is to be given at intervals, according to the effect desired or produced. Quarter-grain doses of ipecacuanha, combined with any of the common aperient pills, seem to facilitate their action, and to

Fig. 138.

leave the bowels with a better tendency to relaxation than before.

When ipecacuanha fails in exerting its emetic influence; and indeed, sometimes when it does cause vomiting, it acts upon the bowels, producing diarrhoea. Its emetic action is slower than that of sulphate of zinc, and the latter is therefore more generally used in cases of poisoning, provided it is at hand. Ipecacuanha enters into the composition of Dover's powder (see Opium). Lozenges each containing a grain of ipecacuanha, and others combining morphia along with it, are admitted to the British pharmacopæia. The latter are much

IRR IRI

with half a pint of water, form an excellent is a very cheap and good preparation, in doses expectorant mixture, to which may be added from half a drachm to a drachm of spirits of chloroform to improve the taste. From twenty to thirty minims of laudanum may be also added to subdue cough; or one or two drachms of tincture of squills, to aid expectoration.

Dose two table-spoonfuls.

Ipecacuanha may be kept in the form of powder; but, perhaps, for those who may not be able to renew their stock frequently, it will be preferable to have it in the form of the entire root, as it will thus longer preserve its activity: moreover, the purchaser may then assure himself that he gets the genuine article, which it is impossible for him to do when he buys the drug in powder. The labour of powdering is not very great, and the wine may be made by steeping half an ounce of the wellbruised root in half a pint of sherry for two or three weeks, and then filtering.
